4:30PM C35.00011 Flux-quantum-discretized dynamics of intermediate state flux structures in current-driven type-I superconductors , G.R. BERDIYOROV, Departement Fysica, Universiteit Antwerpen; Department of Physics, Loughborough University, A.D. HERNANDEZ-NIEVES, Centro Atomico Bariloche, Argentina, M.V. MILOSEVIC, F.M. PEETERS, Departement Fysica, Universiteit Antwerpen, Belgium, D. DOMINGUEZ, Centro Atomico Bariloche, Argentina — Nonlinear flux dynamics in a current-carrying type-I superconductor is studied using Ginzburg-Landau theory. The current induces the intermediate state, where nucleation of flux domains is *discretized to a single fluxoid at a time*, while their final shape (tubular or laminar) and size depend on applied current. The current induces opposite flux domains on opposite edges, and subsequently drives them to annihilation—which is *also discretized*, as a sequence of vortex-antivortex pairs. In the presence of pinning centers, both pinning and depinning processes occur in a single flux-discretized form regardless of the shape and size of the flux configurations. Repulsive centers (i.e., obstacles) can results in splitting of tubular domains and branching of laminar structures or transformation of them into tubular patterns. The discretization of nucleation and annihilation, as well as pinning/depinning processes leaves measurable traces in the voltage across the sample and in locally probed magnetization. The reported dynamic phenomena thus provide an unambiguous proof of a flux quantum being the smallest building block of the intermediate state in type-I superconductors.

4:42PM C35.00012 Comparison of local electrodynamic responses of superconducting materials–from bulk Nb to MgB_2 and Nb thin films[1] , TAMIN TAI, BEHNOOD GHAMSARI, University of Maryland-College Park, TENG TAN, XIAOXING XI, Temple University, STEVEN ANLAGE, University of Maryland-College Park — A near-field magnetic field microwave microscope that enables mapping of the local electrodynamic response in the GHz frequency regime at liquid helium cryogenic temperatures was successful built using the combination of a magnetic writer and a near field-microwave microscope [1]. Many superconducting materials, especially the candidate materials for superconducting RF cavities, were tested at a fixed location to analyze the local electromagnetic response, including both the intrinsic and extrinsic nonlinearities. The bulk Nb materials only show extrinsic nonlinearity, consistent with vortex generation and annihilation in the material. The measurements on Nb and MgB_2 thin film materials shows not only the extrinsic nonlinearity due to the vortex mechanism, but also intrinsic nonlinearity. The intrinsic nonlinearity comes from the modulation of the superconducting order parameter near T_c, but behaves differently for single band gap (Nb) and two-gap (MgB_2) superconductors. Quantitatively analyzing the nonlinear mechanisms will enable the microscope to extract many material parameters and image the superconducting properties by raster scanning.

4:54PM C35.00013 Lower critical magnetic field for a 2-D superconductor in a non-uniform field[1] , JOHN DRASKOVIC, THOMAS LEMBERGER, The Ohio State University — Our exploration of nonlinear effects in two-coil measurements of superfluid density in thin superconducting films led us to calculate the lower critical field of infinite-radius, thin superconducting films in the non-uniform field of a nearby coil powered by an external current supply. We obtain an expression for the Helmholtz free-energy of vortices and antivortices added to the vortex-free Meissner state, and for the work done by the current supply when vortices appear. From these quantities we construct the appropriate "Gibbs" free energy ΔG to minimize. We find that ΔG of a vortex-bearing state dips below that of the Meissner state when the applied magnetic field exceeds: $B_0^* \approx \frac{8\sqrt{2}\Lambda}{R} B_{c1}^{2D}$ where the intrinsic 2D lower critical field is defined as: $B_{c1}^{2D} \equiv \frac{\Phi_0}{4\pi\Lambda^2} ln\left(\frac{\Lambda}{\xi}\right)$. Here, Λ is the 2-D penetration depth, $2\lambda^2/t$, and t is film thickness. We show that in amorphous MoGe films, this theoretical field is much smaller than the experimental field where vortices become evident in the data. Experimentally, the onset of vortex physics is close to the point where the Meissner screening supercurrent density approaches its theoretical maximum value.

5:06PM C35.00014 Nature of the Cuprate Pseudogap State in the Presence of High Magnetic Fields , PETER SCHERPELZ, DAN WULIN, KATHRYN LEVIN, James Franck Institute and Department of Physics, University of Chicago, ATTIPAT RAJAGOPAL, Inspire Institute and Harish-Chandra Research Institute — We address the important question of how to characterize the pseudogap state of superconductors under the influence of magnetic fields strong enough to lead to vortex lattices in the condensate. Here we adopt a preformed pair interpretation of the pseudogap in which non-condensed pairs (arising from a stronger-than-BCS attraction) are present above and below T_c. We use a simple extension of Gor'kov theory to arrive at a formalism for treating BCS-to-BEC crossover physics. We thereby demonstrate how these pairs organize above the transition T_c into precursors of a vortex configuration via small distortions of the superconducting vortex state. We believe this provides a possible scenario for a normal state "pseudo"-vortex state which has been the object of discussion in the literature. Because their dispersion is no longer effectively one-dimensional, this precursor vortex configuration appears to enable otherwise problematic "Bose condensation" in a field.

5:18PM C35.00015 ABSTRACT WITHDRAWN –

Monday, March 18, 2013 2:30PM - 5:30PM –

Session C36 DCMP: HTSC: Optical Probe of Competing Orders 344 - Xiao-Jia Chen, Carnegie Institution of Washington

2:30PM C36.00001 Pump-probe reflectivity study of competing orders in the electron doped cuprate superconductor $Nd_{2-x}Ce_xCuO_{4+?}$[1] , J.P. HINTON, UC Berkeley, LBNL, J.D. KORALEK, LBNL, G. YU, University of Minnesota, E.M. MOTOYAMA, Stanford University, Y.M. LU, A. VISHWANATH, UC Berkeley, LBNL, M. GREVEN, University of Minnesota, J. ORENSTEIN, UC Berkeley, LBNL — We study the electron doped cuprate superconductor $Nd_{2-x}Ce_xCuO_{4+?}$ using optical pump-probe spectroscopy over a range of dopings including both superconducting and underdoped antiferromagnetic samples. We focus on the pseudogap (PG) response, which is observed over the entire doping range, and its interaction with superconductivity (SC). The PG response onsets below values of T^* consistent with other probes, and its time dependence exhibits scaling consistent with critical fluctuations in samples near optimal doping. Furthermore, we observe laser fluence-dependent interaction between the PG and SC responses below T_c, indicative of a repulsive interaction between superconductivity and another fluctuating order.

2:42PM C36.00002 Fluctuating charge density waves in a cuprate superconductor , FAHAD MAHMOOD, DARIUS TORCHINSKY, Massachusetts Institute of Technology, ANTHONY BOLLINGER, IVAN BOZOVIC, Brookhaven National Laboratory, NUH GEDIK, Massachusetts Institute of Technology — Cuprate compounds that host high-temperature superconductivity also exhibit various forms of charge and/or spin ordering whose role in the complex cuprate phase diagram is not fully understood. Static charge-density wave (CDW) ordering has been detected so far by diffraction probes only for special doping or in an applied external field. However, dynamic (fluctuating) CDWs may also be present more broadly while being difficult to detect by conventional techniques. To observe and characterize fluctuating CDWs in cuprates, and determine whether they favor or compete with HTS, is thus an important open problem. Here, we present a new method, based on ultrafast spectroscopy, to detect the presence and measure the lifetime of CDW fluctuations in cuprates. In an underdoped $La_{1.9}Sr_{0.1}CuO_4$ film (Tc = 26 K), we observe collective excitations of CDW that persist up to 100 K. This CDW is dynamic; it fluctuates with a characteristic lifetime of 2 ps at T = 5 K which decreases to 0.5 ps at T = 100 K. In contrast, in an optimally doped $La_{1.84}Sr_{0.16}CuO_4$ film (Tc = 38.5 K), we see no signatures of fluctuating CDW at any temperature, favoring the competition scenario. This work opens a path towards a broad study of fluctuating order parameters in various superconductors and other materials.

2:54PM C36.00003 Modified electron-boson coupling in $Bi_2Sr_2CaCu_2O_{8+\delta}$ nanocrystals , LUKE SANDILANDS, University of Toronto, Canada, ZHIJUN XU, ALINA YANG, GENDA GU, Brookhaven National Lab, USA, TOR PEDERSEN, FERENC BORONDICS, Canadian Light Source, Canada, KENNETH BURCH, University of Toronto, Canada — The coupling between electrons and bosons is thought to underlie a variety of unusual behavior in the cuprates. Here we present optical evidence that the electron-boson coupling is strongly modified in mechanically-exfoliated $Bi_2Sr_2CaCu_2O_{8+\delta}$ nanocrystals. Through an extended Drude analysis of the mid-infrared optical conductivity, we demonstrate that the electron-boson spectral function is blue-shifted and enhanced in thin $Bi_2Sr_2CaCu_2O_{8+\delta}$ nanocrystals. Taken together with complementary Raman and Laue diffraction data, our results provide further evidence that the bosons relevant to the electrodynamics of the normal state are magnetic.

3:06PM C36.00004 Effect of out-of-plane disorder on electronic Raman spectra of Bi2212 single crystals , TAKAHIKO MASUI, NAOKI MURAI, Department of Physics, Graduate School of Science, Osaka University, MOTOYUKI ISHIKADO, Japan Atomic Energy Agency, SHIGEYUKI ISHIDA, Department of Physics, University of Tokyo, HIROSHI EISAKI, National Institute of Advanced Industrial Science and Technology (AIST), SHIN-ICHI UCHIDA, Department of Physics, University of Tokyo, SETSUKO TAJIMA, Department of Physics, Graduate School of Science, Osaka University — Out-of plane disorder in cuprate superconductor is known to suppress Tc without serious increase of residual scattering of conduction carriers. This is quite advantageous for spectroscopic measurements. In this study we have measured electronic Raman spectra of optimally-doped Bi2212 single crystals with different degree of out-of plane disorders. In the superconducting state, the B1g electronic Raman spectra, which detect maximum of d-wave superconducting gap, show coherence peaks. Interestingly, the peak energies are independent of Tc for lower Tc samples. On the other hand, the peak position for a higher Tc sample shifts to higher energy. This is clear contrast with the B2g electronic Raman spectra, which detect nodal region of the superconducting gap. The strange polarization dependence of superconducting Raman spectra could be a clue to understand the doping dependence of the superconducting Raman responses in cuprates.

3:18PM C36.00005 Optical scattering rate and effective mass throughout the phase diagram of $Bi_2Sr_{2-x}La_xCuO_6$, R.P.S.M. LOBO, Y.M. DAI, LPEM, ESPCI, CNRS, Paris, France, H.H. WEN, Nanjing University, Nanjing, China, P. CHENG, H.Q. LUO, B. XU, X.G. QIU, Institute of Physics, Chinese Academy of Sciences, Beijing, China — We determined the optical conductivity of $Bi_2Sr_{2-x}La_xCuO_6$ at dopings covering the phase diagram from the underdoped to the overdoped regimes. The frequency dependent scattering rate shows a pseudogap extending into the overdoped regime. We found that the effective mass enhancement calculated from the optical conductivity is constant throughout the phase diagram. Conversely, the effective optical charge density varies almost linearly with doping. Our results suggest that the low frequency electrodynamics of $Bi_2Sr_{2-x}La_xCuO_6$ is not strongly affected by the long range Mott transition. [Y.M. Dai *et al.*, Phys. Rev. B **85**, 092504 (2012)].

3:30PM C36.00006 Microwave conductivity survey of $YBa_2Cu_3O_{6+x}$: from underdoped to overdoped , JORDAN BAGLO, JAMES DAY, PINDER DOSANJH, RUIXING LIANG, WALTER HARDY, DOUG BONN, University of British Columbia — Recent experimental results and theoretical proposals suggest significant changes in the electronic structure of the high-T_c cuprate superconductors as one approaches optimal doping, including Fermi surface reconstruction associated with proposed electronic ordering transitions. As sensitive probes of the low-energy electrodynamics, microwave surface resistance and penetration depth measurements - from which the real and imaginary parts of the microwave conductivity may be extracted - are well-suited for investigating such changes in the electronic structure of the cuprates across their phase diagram. Here we present preliminary results of a detailed and systematic doping dependence study of the microwave conductivity of the cuprate superconductor $YBa_2Cu_3O_{6+x}$ from the underdoped to the overdoped regime. The implications of these results for various proposed scenarios will be discussed.

3:42PM C36.00007 Disentangling the in- and out-of-plane components of the microwave surface resistance in Tl-2201[1] , S. MAHYAD AGHIGH, JAMES DAY, JORDAN BAGLO, Department of Physics & Astronomy, University of British Columbia, Vancouver, V6T 1Z1, Canada, DARREN PEETS, Max Planck Institute Festkorperforsch, D-70569 Stuttgart, Germany, LUDIVINE CHAUVIERE, PINDER DOSANJH, RUIXING LIANG, WALTER HARDY, DOUG BONN, Department of Physics & Astronomy, University of British Columbia, Vancouver, V6T 1Z1, Canada, UBC SUPERCONDUCTIVITY GROUP (MICROWAVE MEASUREMENT) TEAM, UBC SUPERCONDUCTIVITY GROUP (MATERIAL DEVELOPMENT) TEAM — Investigation of $Tl_2Ba_2Cu_1O_x$ (Tl-2201) properties is important as it provides access to the overdoped side of the superconducting dome. We are measuring the surface resistance of Tl-2201, $R_s(\omega,T)$, using a bolometric technique well established by our group. Experimentally separating the in- and out-of-plane components of R_s for Tl-2201, however, is challenging due to demagnetization effects. To account for this complication, we are measuring R_s of an isotropic replica sample of NbZr in two specific orientations where the field is parallel and perpendicular to the crystal plane. In this talk I will describe the modified bolometric technique, share the technical difficulties encountered in preparing the replica, and present the most up-to-date results.

[1]This project has been supported by Natural Sciences and Engineering Research Council of Canada (NSERC).

3:54PM C36.00008 Ion-size effects in HTS cuprates - superfluid density and energy gaps , BENJAMIN MALLETT, MacDiarmid Institute, Victoria University of Wellington, CHRISTIAN BERNHARD, University of Fribourg, THOMAS WOLF, Karlsruhe Institute of Technology, EDI GILIOLI, Istituto dei Materiali per l' Elettronica ed il Magnetismo (IMEM), JEFF TALLON, MacDiarmid Institute, Industrial Research Limited — The demonstrated central role that ion size plays in determining T_c in the HTS cuprates needs to be further explored in order to determine whether the demonstrated systematic behaviour plays out in other superconducting properties. After all, T_c can be diminished simply by disorder effects. What is the effect of systematic ion-size variation on the superfluid density and superconducting energy gap? And can these effects be used to infer details concerning the pairing mechanism? To address these issues we report the effect of changing ion size on muon spin relaxation measurements of the superfluid density and Raman measurements of the superconducting gap in the model system $RA_2Cu_3O_y$ (where R = La,..., Lu and A=$Ba_{2-x}Sr_x$). The electronic density of states is determined from the effect of Zn substitution in this system and we are able to discount disorder scattering as the source of the systematic changes in superconducting properties. Our results confirm a picture where the polarizability of the charge-reservoir layer plays a key role in setting the energy scale for pairing in this system.

4:06PM C36.00009 New insights into the phase diagram of the copper oxide superconductors from electronic Raman scattering , ALAIN SACUTO, SIHAM BENHABIB, YANN GALLAIS, MAXIMILIEN CAZAYOUS, MARIE-AUDE MEASSON, SEBASTIEN BLANC, Universite Paris Diderot, Laboratoire Materiaux et Phénomènes Quantiques, Paris, France, GENDA GU, Brookhaven National Laboratory, Condensed Matter Physics & Materials Science Department, NY 11973, DOROTHEE COLSON, Service de Physique de l'Etat Condensé, CEA-Saclay, 91191 Gif-sur-Yvette, France — We explore the cuprate phase diagram by electronic Raman spectroscopy and shed light on the superconducting state in hole doped cuprates. Namely, how superconductivity is impacted by the pseudogap.

4:18PM C36.00010 Ion-size effects in HTS cuprates – dielectric versus magnetic pairing , JEFFERY TALLON, MacDiarmid Institute, Industrial Research Ltd, BEN MALLETT, MacDiarmid Institute, Victoria University, NEIL ASHCROFT, LASSP, Cornell University — We have been exploring the systematic effects of changing ion size on superconducting and normal-state properties of the HTS cuprates. In the model system $RA_2Cu_3O_y$ (where R = La,..., Lu and A=$Ba_{2-x}Sr_x$) the maximum T_c in the dome-shaped phase curve can be shifted from 70 to 110 K in the model system. Surprisingly T_c correlates with the dielectric properties and not the magnetic properties. This highlights the fundamental importance of charge fluctuation and dielectric screening in the cuprates and may signal a novel pairing mechanism having its origin with quantized waves of electronic polarization.

4:30PM C36.00011 Berry phase mechanism for polarization rotation in chiral metals[1] , JOSEPH ORENSTEIN, JOEL MOORE, UC Berkeley and LBNL — There is currently considerable interest in inversion symmetry breaking in unconventional metals, particularly in chiral stacking of atomic layers with stripe-like charge density modulation in systems such as TiSe2 and the cuprate superconductor LBCO. A signature of broken chiral symmetry is optical gyrotropy, that is, different indices of refraction for left and right circular polarized light. In this talk we show that intraband gyrotropic response is a consequence of the anomalous velocity associated with the non-zero Berry curvature and we derive its strength for a model band structure as a function of the chiral order parameter. This work demonstrates that optical gyrotropy in chiral metals is the linear response counterpart to the anomalous Hall effect in time-reversal breaking metals.

4:42PM C36.00012 Faraday and Kerr Effect Measurements of Cuprates in THz Regime , Y. LUBASHEVSKY, LIDONG PAN, Department of Physics and Astronomy, The Johns Hopkins University, Baltimore, MD 21218 USA, T. KIRZHNER, G. KOREN, Physics Department, Technion - Israel Institute of Technology Haifa, 32000, Israel, N.P. ARMITAGE, Department of Physics and Astronomy, The Johns Hopkins University, Baltimore, MD 21218 USA — Recent results using a laser-based zero-area loop Sagnac interferometer have found a small but significant spontaneous Kerr rotation [1] suggesting an emergent chiral or time-reversal broken character to the pseudogap regime in the cuprate superconductors. In this work, we have performed high resolution THz polarimetry to measure the low frequency Faraday and Kerr rotation in these compounds. The THz range gives an advantage for these studies as it presumably corresponds more closely to frequency scales relevant for the pseudogap (1 THz - 48 K). We have found that low frequencies enhances the signal into the tens of milli-radians range. Moreover, time-domain THz spectroscopy reveals more information about this phenomena as frequency dependent and birefringent effects among others can be measured. Results from YBCO and LBCO will be presented.

[1] J. Xia etal, Phys. Rev. Lett. 100, 127002 (2008).

4:54PM C36.00013 Elastic moduli across the superconducting and pseudogap phase boundaries in four cuprate compounds , BRAD RAMSHAW, ARKADY SHEKHTER, JON BETTS, ALBERT MIGLIORI, Pulsed Field Facility, NHMFL, Los Alamos National Laboratory — A detailed understanding of the physics of the cuprate superconductors relies on an experimental determination of the thermodynamic phase diagram. Resonant ultrasound spectroscopy (RUS) is a unique thermodynamic probe, capable of measuring part per million changes in elastic moduli, and has access to symmetry information. Here we present a symmetry analysis of changes in the elastic moduli across the superconducting and psedogap phase boundaries in several classes of cuprates: YBCO, LSCO, Hg-1201, and Tl-2201.

5:06PM C36.00014 Quantum Fluctuations of Superconductivity in Critically Underdoped $La_{2-x}Sr_xCuO_4$, N.P. ARMITAGE, Y. LUBASHEVSKY, L.S. BILBRO, R.V. AGUILAR, Department of Physics and Astronomy, The Johns Hopkins University, G. LOGVENOV, I. BOZOVIC, Brookhaven National Laboratory — In the underdoped pseudogap regime of the high-temperature superconductors, one expects that due to low superfluid densities and short correlation lengths, superconducting fluctuations will be very significant for transport and thermodynamic properties. We have used THz time-domain spectroscopy (TTDS) to probe the fluctuations of superconductivity in extremely underdoped $La_{2-x}Sr_xCuO_4$ films close to and beyond the superconducting quantum critical point. On the approach to the transition from above, we find a significant range of quantum superconducting fluctuations that we quantify through a comparison of the low and high frequency phase stiffnesses. An explicit measure of these fluctuations through the quantity we propose as a "quantum Debye-Waller factor" shows that these fluctuations diverge and drive the transition.

5:18PM C36.00015 Feedback effect on high-energy magnetic excitations in the model high-temperature superconductor $HgBa_2CuO_{4+\delta}$, YUAN LI, International Center for Quantum Materials, Peking University, China, M. LE TACON, M. BAKR, D. TERRADE, D. MANSKE, Max Planck Institute for Solid State Research, Germany, R. HACKL, Walther Meissner Institute, Bavarian Academy of Sciences and Humanities, Germany, L. JI, M.K. CHAN, N. BARISIC, X. ZHAO, M. GREVEN, School of Physics and Astronomy, University of Minnesota, USA, B. KEIMER, Max Planck Institute for Solid State Research, Germany — Magnetic excitations might play an important role in the superconducting mechanism in the cuprates. Their contribution below $\sim$60 meV is manifested by the generic neutron "resonance" feature, which signifies a feedback effect of pairing on the magnetic excitations. However, the spectral weight of the resonance is insufficient to explain the high superconducting temperature (T_c). Recent research has demonstrated that intense magnetic excitations exist above 100 meV up to high doping, but it remains unknown whether and how these excitations participate in the pairing mechanism. Here we present a systematic electronic Raman scattering study of the model cuprate superconductor $HgBa_2CuO_{4+\delta}$. In an overdoped sample upon cooling below T_c, we observe a pronounced enhancement of a high-energy peak related to two-magnon excitations in insulating cuprates, which is accompanied by the opening of the superconducting gap and can be understood as a high-energy feedback effect that implies a direct involvement of high-energy magnetic excitations in the Cooper pairing. The effect occurs already above T_c in two underdoped samples, demonstrating a related feedback mechanism associated with the pseudogap.

Monday, March 18, 2013 2:30PM - 5:30PM –

Session C37 DMP DCOMP: Focus Session: Fe-based Superconductors: DFT and DMFT

345/346 - Wei Ku, Brookhaven National Laboratory

2:30PM C37.00001 First principles investigation of Sr and P doping of $CaFe_2As_2$, HARALD O. JESCHKE, MILAN TOMIC, ROSER VALENTI, Institut für Theoretische Physik, Goethe-Universität Frankfurt, Max-von-Laue-Str. 1, 60438 Frankfurt, Germany — The doping-temperature-pressure phase diagrams of the 122 family of superconductors have been discussed intensively due to electronic nematicity above the structural and superconducting transition and the complex coupling between electronic and lattice degrees of freedom. We employ density functional theory to determine the structure of supercells of $Ca_{1-x}Sr_xFe_2As_2$ and $CaFe_2(As_{1-x}P_x)_2$. We then predict structural transitions of the doped compounds under pressure and compare to the parent compound. We carefully analyze the changes in the electronic structure caused by doping and stress.

2:42PM C37.00002 Effect of uniaxial stress on structural and electronic properties of $BaFe_2As_2$ and $CaFe_2As_2$, MILAN TOMIC, HARALD O. JESCHKE, ROSER VALENTI, Institut für Theoretische Physik, Goethe-Universität Frankfurt, Max-von-Laue-Strasse 1, 60438 Frankfurt/Main , Germany — We investigate the effects of the uniaxial tensile and compressive stresses applied along $\mathbf{a}$, $\mathbf{b}$ and $\mathbf{a}+\mathbf{b}$ directions in $BaFe_2As_2$ and $CaFe_2As_2$ in the framework of ab initio density functional theory calculations. While the systems remain in the orthorhombic phase at moderate pressures, we observe an inversion of magnetism at a critical strain happening when the $\mathbf{a}$ and $\mathbf{b}$ axes approach the tetragonal condition. We discuss our results in view of recent reports of modified magnetic and structural transitions in $BaFe_2As_2$ under externally applied uniaxial strain and make a connection to phenomenological models proposed for these transitions.

2:54PM C37.00003 Electronic band structure of $BaCo_2As_2$: a fully-doped ferropnictide with reduced electronic correlations , PIERRE RICHARD, N. XU, Institute of Physics, Chinese Academy of Sciences, A. VAN ROEKEGHEM, Institute of Physics, Chinese Academy of Sciences, and Ecole Polytechnique (France), P. ZHANG, H. MIAO, W.-L. ZHANG, T. QIAN, Institute of Physics, Chinese Academy of Sciences, M. FERRERO, Ecole Polytechnique (France), A. S. SEFAT, Oak Ridge National Laboratory, S. BIERMANN, Ecole Polytechnique (France), H. DING, Institute of Physics, Chinese Academy of Sciences — We report an angle-resolved photoemission spectroscopy investigation of the Fermi surface and electronic band structure of $BaCo_2As_2$. Although its quasi-nesting-free Fermi surface differs drastically from that of its Fe-pnictide cousins, we show that the $BaCo_2As_2$ system can be used as an approximation to the bare unoccupied band structure of the related $BaFe_{2-x}Co_xAs_2$ and $Ba_{1-x}K_xFe_2As_2$ compounds. However, our experimental results, in agreement with dynamical mean field theory calculations, indicate that electronic correlations are much less important in $BaCo_2As_2$ than in the ferropnictides. Our findings suggest that this effect is due to the increased filling of the electronic $3d$ shell in the presence of significant Hund's exchange coupling.

3:06PM C37.00004 First-principle studies of electronic structure and magnetic excitations in FeSe monolayer[1] , TIMUR BAZHIROV, MARVIN L. COHEN, University of California, Berkeley — Recent experimental advances made it possible to study single-layered superconducting systems of iron-based compounds. The results show evidence of significant enhancement of superconducting properties compared to the bulk case. We use first-principle pseudopotential density functional theory techniques and the local spin-density approximation to study the electronic properties of an FeSe monolayer in different spin configurations. The results show that the experimental shape of the Fermi surface is best described by a checkerboard antiferromagnetic (AFM) spin arrangement. To explore the underlying pairing mechanism, we study the evolution of the non-magnetic to the AFM-ordered structures under constrained magnetization, and we estimate the electronic coupling to magnetic excitations involving transfer and increase of iron magnetic moments and compare it to the electron-phonon coupling. Finally, we simulate the substrate-induced interaction by using uniform charge doping and show that the latter can lead to an increase in the density of states at the Fermi level and possibly produce higher superconducting transition temperatures.

[1]This work was supported by NSF grant No. DMR10-1006184 and U.S. DOE under Contract No. DE-AC02-05CH11231. Computational resources have been provided by DOE at Lawrence Berkeley National Laboratory's NERSC facility

3:18PM C37.00005 Glide symmetry of iron-based superconductors: Electronic structure and superconductivity , CHUNG-PIN CHOU, CHIA-HUI LIN, WEI KU, Brookhaven Natl Lab — The alternating positioning of As/Se atoms above and below the Fe plane is known to alter the in-plane translational symmetry of Fe-based high-temperature superconductors, into a glide symmetry: translation followed by z-inversion. The proper descriptions of this symmetry and its consequences on the electronic structure and superconductivity have become a focus of recent intense theoretical studies [1-3]. In this talk, we will explicitly incorporate the glide symmetry in our first-principles studies of electronic structure, and discuss its consequence in superconductivity and other correlation in this class of materials. [1] Chia-Hui Lin, et al., Phys. Rev. Lett. 107, 257001 (2011). [2] Jiangping Hu and Ningning Hao, Phys. Rev. X 2, 021009 (2012). [3] M. Khodas and A. V. Chubukov, Phys. Rev. Lett. 108, 247003 (2012).

3:30PM C37.00006 Density functional study on anisotropic magnetic exchange couplings in iron-based superconductors , HYUNGJU OH, HYOUNG JOON CHOI, Department of Physics and IPAP, Yonsei University — Iron-based superconductors exhibit many different antiferromagnetically ordered ground states. An understanding of the magnetic exchange couplings and ground-state Hamiltonian in the parent compounds of these materials is important because such an information could be the basis to unveil the mechanism of unconventional superconductivity. By performing first-principles calculations of the electronic and magnetic properties with non-collinear spin configurations, we study the anisotropic magnetic exchange couplings in iron-based superconductors. We obtain magnetic excitations using the anisotropic magnetic exchange couplings, and compare the results with published inelastic neutron scattering data. This work was supported by the NRF of Korea (Grant No. 2011-0018306). Computational resources have been provided by KISTI Supercomputing Center (Project No. KSC-2012-C2-14).

3:42PM C37.00007 Impact of Hund's rule on the physics of the Fe-based superconductors , ZHIPING YIN, Department of Physics, Rutgers University — The Hund's rule coupling J_H, as opposed to the Coulomb interaction (Hubbard) U, plays a dominating role in the Fe-based superconductors. The strong Hund's rule coupling combined with the multi-orbital nature and special valence of the Fe $3d$ shell, as well as the small crystal fields from the surroundings of an Fe atom, lead to many experimental consequences. In this talk, I will discuss the insights from first-principles calculations based on a combination of density functional theory and dynamical mean field theory. I will demonstrate the observable effects of *Hundsness* on transport, optical conductivity, X-ray spectroscopy, angle-resolved photoemission spectroscopy, spin/magnetic excitations, and so on.

4:18PM C37.00008 Many-body effects in iron pnictides and chalcogenides – non-local vs dynamic origin of effective masses , JAN M. TOMCZAK, Department of Physics and Astronomy, Rutgers University, Piscataway, New Jersey 08854, USA, MARK VAN SCHILFGAARDE, Department of Physics, Kings College London, Strand, London WC2R 2LS, UK, GABRIEL KOTLIAR, Department of Physics and Astronomy, Rutgers University, Piscataway, New Jersey 08854, USA — We apply the quasi-particle self-consistent GW (QSGW) approximation to some of the iron pnictide and chalcogenide superconductors. We compute Fermi surfaces and density of states, and find excellent agreement with experiment, substantially improving over standard band-structure methods. Analyzing the QSGW self-energy we discuss non-local and dynamic contributions to effective masses. We present evidence that these two contributions are mostly separable. Indeed the quasi-particle weight is found to be essentially independent of momentum. The main effect of non-locality is captured by the static but non-local QSGW effective potential. Moreover, these non-local self-energy corrections, absent in e.g. dynamical mean field theory (DMFT), can be relatively large. We show, on the other hand, that QSGW only partially accounts for dynamic renormalizations at low energies. These findings suggest that QSGW combined with DMFT will capture most of the many-body physics in the iron pnictides and chalcogenides.

4:30PM C37.00009 Effect of Pressure on the Electronic Structure and Optical Properties of FeSe: A DFT+DMFT Study[1] , SUBHASISH MANDAL, R.E. COHEN, Geophysical Laboratory, Carnegie Institution of Washington, K. HAULE, Department of Physics and Astronomy, Rutgers University — Superconductivity in the iron-chalcogenide superconductors is extremely sensitive to pressure; T_c increases from 8 K to 37 K upon applying pressure[1]. In order to better understand the sensitivity of T_c to pressure in FeSe we have performed fully self-consistent Density Functional Theory - Dynamical Mean Field Theory (DMFT) (DFT-DMFT) computations with a continuous quantum Monte Carlo impurity solver as a function of compression and temperature. Using analytic continuation, we have computed spectral functions, Fermi surfaces, and the optical properties for comparison with experiments. Our preliminary results, obtained at room temperature show a $\sim$ 43% reduction of the dc conductivity upon increasing the pressure from 0 to 2.6 GPa.

4:42PM C37.00010 Fermi surface topology of LaFePO, LiFeP and LiFeAs , ROSER VALENTI, JOHANNES FERBER, HARALD O. JESCHKE, Institut für Theoretische Physik, Goethe-Universität Frankfurt, Max-von-Laue-Strasse 1, 60438 Frankfurt/Main, Germany — We performed charge self-consistent LDA+DMFT (density functional theory combined with dynamical mean field theory) calculations to study correlation effects on the Fermi surfaces of the iron pnictide superconductors LaFePO, LiFeP an LiFeAs. We find a distinctive change in the topology of the Fermi surface in LaFePO and LiFeP where a hole pocket with Fe dz^2 orbital character changes its geometry from a closed shape in LDA to an open shape upon inclusion of correlations. In LiFeAs correlations influence mostly the shape of the hole pockets. We discuss our results in the context of angle-resolved photoemission spectroscopy and de Haas van Alphen observations.

4:54PM C37.00011 Development of a two-particle self-consistent method for multi-orbital systems and its application to unconventional superconductors , HIDEYUKI MIYAHARA, RYOTARO ARITA, Department of Applied Physics, University of Tokyo, HIROAKI IKEDA, Department of Physics, Kyoto University — We extend the two-particle self-consistent method proposed by Vilk and Tremblay [1] to multi-orbital systems. Starting with the sum rules for the spin and charge susceptibilities, we derive self-consistent equations to determine the renormalized effective interactions. We apply this method to LaFeAsO. In the former, we study the two-orbital model for the $La_{2-x}(Sr/Ba)_xCuO_4$ system. FLEX underestimated the pairing instability for it.[2] We show that, in our TPSC, the inter-orbital scattering enhances the d-wave instability. In the latter, we investigate a five-orbital d-model for LaFeAsO. This model has been extensively studied by RPA [3]. There, it has been shown that strong spin fluctuation mediates the s_{+-} superconductivity. On the other hand, it has been pointed out that vertex corrections can enhance orbital fluctuations, which mediate s_{++} superconductivity [4]. Finally, we show that orbital fluctuations can be enhanced in TPSC, while the dominant pairing symmetry is still s_{+-} superconductivity when the system resides.

5:06PM C37.00012 Impact of Dynamic Orbital Correlations on Magnetic Excitations in the Normal State of Iron-Based Superconductors[1] , WEI-CHENG LEE, University of Illinois at Urbana-Champaign, WEICHENG LV, University of Tennessee at Knoxville, JOHN TRANQUADA, Brookhaven National Lab, PHILIP PHILLIPS, University of Illinois at Urbana-Champaign — We show here that orbital degrees of freedom produce a distinct signature in the magnetic excitation spectrum of iron-based superconductors above the magnetic ordering temperature. Because d_{xz} and d_{yz} orbitals are strongly connected with Fermi surface topology, the nature of magnetic excitations can be modified significantly due to the presence of either static or fluctuating orbital correlations. Within a five-orbital itinerant model, we show that static orbital order generally leads to an enhancement of commensurate magnetic excitations even when the original Fermi surface lacks nesting at commensurate wavevectors. When long-range orbital order is absent, Gaussian fluctuations beyond the standard random-phase approximation capture the effects of fluctuating orbital correlations on the magnetic excitations. We find that commensurate magnetic excitations can also be enhanced if the orbital correlations are strong. We propose that this unusual incommensurate-to-commensurate transformation is an important signature to distinguish orbital from spin physics in the normal state of iron-based superconductors.

5:18PM C37.00013 Orbital differentiation and the role of orbital ordering in the magnetic state of Fe superconductors , ELENA BASCONES, BELEN VALENZUELA, MARIA J. CALDERON, Instituto de Ciencia de Materiales de Madrid, Consejo Superior de Investigaciones Científicas, ICMM-CSIC (Spain) — There is increasing evidence for orbital differentiation and a possible coexistence of itinerant and localized electrons in Fe superconductors. In order to shed light on the role of the different orbitals on the magnetic state of these superconductors we analyze the metallic $(\pi, 0)$ antiferromagnetic state as a function of the interactions treated within mean field. We find that with increasing interactions the system does not evolve trivially from the pure itinerant to the pure localized regime. Instead we find a region with a strong orbital differentiation between xy and yz, which are half-filled gapped states at the Fermi level, and itinerant zx, $3z^2 - r^2$ and $x^2 - y^2$. We argue that orbital ordering between the yz and zx orbitals arises as a consequence of the interplay of the exchange energy in the antiferromagnetic x direction and the kinetic energy gained by the itinerant orbitals along the ferromagnetic y direction with an overall dominance of the kinetic energy gain. We indicate that iron superconductors may be close to the boundary between the itinerant and the orbital differentiated regimes and that it could be possible to cross this boundary with doping [arXiv: 1208.1917. Phys. Rev. B, November 2012].

Monday, March 18, 2013 2:30PM - 5:30PM –

Session C38 FEd: Undergraduate Physics Education 347 - Mel Sabella, Chicago State University

2:30PM C38.00001 Parallel Performance Analysis between Free Response Environments and the Force Concept Inventory in Introductory Mechanics Courses , NICOLE BOBBITT, AARON WADE, CHANDRA PRAYAGA, University of West Florida — This paper reports our attempts to: 1) create a problem solving situation that folds in both kinematics and force discussions 2) find a way to model and predict common thought processes that cause typical misconceptions identified by the Force Concept Inventory (FCI). Two pen and paper test questions were designed with these goals in mind, both broken into specific elements to arrive at a quantifiable fragmentation of the necessary thought processes required to solve the problem. These results were compared to pre- and post-FCI data to analyze the common misconceptions as defined by FCI. The data was analysed using factor analysis to group performance across the two environments. Two styles of grading were used to highlight the effectiveness of this method. Ultimately this, and any future questions, would become a tool in the classroom to pinpoint the critical ideas with which a typical student struggles during an introductory mechanics course.

2:42PM C38.00002 Using a flipped classroom in an algebra-based physics course , LEIGH SMITH, University of Cincinati — The algebra-based physics course is taken by Biology students, Pre-Pharmacy, Pre-Medical, and other health related majors such as medical imaging, physical therapy, and so on. Nearly 500 students take the course each Semester. Student learning is adversely impacted by poor math backgrounds as well as extensive work schedules outside of the classroom. We have been researching the use of an intensive flipped-classroom approach where students spend one to two hours each week preparing for class by reading the book, completing a series of conceptual problems, and viewing videos which describe the material. In class, the new response system Learning Catalytics is used which allows much richer problems to be posed in class and includes sketching figures, numerical or symbolic entries, short answers, highlighting text, etc in addition to the standard multiple choice questions. We make direct comparison of student learning for 1200 sudents who have taken the same tests, 25% of which used the flipped classroom approach, and 75% who took a more standard lecture. There is significant evidence of improvements in student learning for students taking the flipped classroom approach over standard lectures. These benefits appear to impact students at all math backgrounds.

2:54PM C38.00003 The Use of Research-Based Instructional Strategies in Introductory Physics: Where do Faculty Leave the Innovation-Decision Process?[1] , CHARLES HENDERSON, Western Michigan University, MELISSA DANCY, University of Colorado Boulder, MAGDALENA NIEWIADOMSKA-BUGAJ, Western Michigan University — During the Fall of 2008 a web survey was completed by a representative sample of 722 United States physics faculty. In this talk we will briefly present summary statistics to describe faculty knowledge about and use of 24 specific research-based instructional strategies (RBIS). We will then analyze the results based on a four stage model of the innovation-decision process: knowledge, trial, continuation, and high use. The largest losses occur at the continuation stage, with approximately 1/3 of faculty discontinuing use of all RBIS after trying one or more of these strategies. These results suggest that common dissemination strategies are good at creating knowledge about RBIS and motivation to try a RBIS, but more work is needed to support faculty during implementation and continued use of RBIS. Based on a logistic regression analysis, only nine of the 20 potential predictor variables measured were statistically significant when controlling for other variables. Faculty age, institutional type, and percentage of job related to teaching were not found to be correlated with knowledge or use at any stage. High research productivity and large class sizes were not found to be barriers to use of at least some RBIS.

3:06PM C38.00004 Wikispaces (Wikis) and Group Problem Solving (GPS) sessions in Physics classes , HASHINI MOHOTTALA, University of Hartford — We report the combine use of Wikispaces (Wikis) and Group Problem Solving (GPS) sessions conducted in the introductory level and upper level physics classes. This method gradually evolved from the combine use of Wikis and Just in Time Teaching (JiTT) practiced over the past years. As a part of this new teaching method, some essay type problems, parallel to the chapter in discussion, were posted on the Wikis at the beginning of each week and students were encouraged to visit the pages and do the work without providing numerical final answers but the steps. At the end of each week students were evaluated on the problem solving skills opening up more opportunity for peer interaction by putting them into small groups and letting them solve one selected problem. A class of 30 students is divided into 6 groups and as a whole four lengthy essay problems are discussed - each group is given to solve one problem. The problem numbers are drawn in a raffle and the groups are excited to find out what they get each week. The required skills to solve a problem are gained from the weekly given Wiki exercises. Wiki provides a user-friendly platform to make this effort a success. GPS sessions help the professor identify the failing students earlier and help them before it's too late.

3:18PM C38.00005 Computer-based, Jeopardy^{TM}-like game in general chemistry for engineering majors[1] , S.S. LING, F. SAFFRE, M. KADADHA, D.L. GATER, A.F. ISAKOVIC, KUSTAR - Khalifa University — We report on the design of Jeopardy^{TM}-like computer game for enhancement of learning of general chemistry for engineering majors. While we examine several parameters of student achievement and attitude, our primary concern is addressing the motivation of students, which tends to be low in a traditionally run chemistry lectures. The effect of the game-playing is tested by comparing paper-based game quiz, which constitutes a control group, and computer-based game quiz, constituting a treatment group. Computer-based game quizzes are Java^{TM}-based applications that students run once a week in the second part of the last lecture of the week. Overall effectiveness of the semester-long program is measured through pretest-postest conceptual testing of general chemistry. The objective of this research is to determine to what extent this "gamification" of the course delivery and course evaluation processes may be beneficial to the undergraduates' learning of science in general, and chemistry in particular. We present data addressing gender-specific difference in performance, as well as background (pre-college) level of general science and chemistry preparation. We outline the plan how to extend such approach to general physics courses and to modern science driven electives, and we offer live, in-lectures examples of our computer gaming experience.

3:30PM C38.00006 The Physics Learning Center at the University of Wisconsin-Madison , S.M. NOSSAL, L.E. WATSON, E. HOOPER, A. HUESMANN, B. SCHENKER, P. TIMBIE, M. RZCHOWSKI, Physics Department, University of Wisconsin-Madison — The Physics Learning Center at the University of Wisconsin-Madison provides academic support and small-group supplemental instruction to students studying introductory algebra-based and calculus-based physics. These classes are gateway courses for majors in the biological and physical sciences, pre-health fields, engineering, and secondary science education. The Physics Learning Center offers supplemental instruction groups twice weekly where students can discuss concepts and practice with problem-solving techniques. The Center also provides students with access on-line resources that stress conceptual understanding, and to exam review sessions. Participants in our program include returning adults, people from historically underrepresented racial/ethnic groups, students from families in lower-income circumstances, students in the first generation of their family to attend college, transfer students, veterans, and people with disabilities, all of whom might feel isolated in their large introductory course and thus have a more difficult time finding study partners. We also work with students potentially at-risk for having academic difficulty (due to factors academic probation, weak math background, low first exam score, or no high school physics). A second mission of the Physics Learning Center is to provide teacher training and leadership experience for undergraduate Peer Mentor Tutors. These Peer Tutors lead the majority of the weekly group sessions in close supervision by PLC staff members. We will describe our work to support students in the Physics Learning Center, including our teacher-training program for our undergraduate Peer Mentor Tutors

3:42PM C38.00007 Re-Envisioning the Introductory Physics Sequence at Georgia Gwinnett College (GGC) , SCOTT J. THOMPSON, KENNETH B. SALES, Georgia Gwinnett College — GGC is a new, 4-year, open-access institution located in the northeast of Atlanta. As an open access college, many of the students who take the introductory physics sequence do not have a strong mathematical background. A large percentage of the students have significant work or family obligations in addition to being full-time students. To better serve these students, the first semester of the trig-based introductory physics sequence was modified in a manner that focuses and structures the material to be completed by the students both outside and inside of class such that the time spent outside of class can be reduced. Specifically, focused notes were provided to the students with an online assignment prior to class in place of reading from a textbook. Class time was then focused on a deeper understanding of the concepts to be covered instead of an initial (or secondary) introduction to the material. Data was collected for specific exam questions and compared with the results from previous classes taught by the same instructors. An overview of the results and observations of the instructors using this method will be discussed.

3:54PM C38.00008 On "Global Warming/Climate Change" — A Critical-Thinking Approach to Analyzing some of the Science while Teaching the Scientific Method , LAURENCE I. GOULD, University of Hartford — Undergraduates tend to learn and enjoy physics through its well-established corpus (mechanics, electricity and magnetism, quantum theory, etc.). However, there is a relatively new opportunity to enhance the learning of physics through critical thinking in a non-traditional area. Such thinking can be fostered through an analysis of both the science and methodology involved in the area commonly known as "global warming/climate change" (AGW). This opportunity arises because of an increasing number of scientists from around the world who have been examining and challenging[1] the apparently dominant claim that dangerous AGW is caused primarily by human-produced carbon dioxide. This talk will go over how such critical thinking works through: (1) two independent-study courses I have done with some physics majors, and (2) a college-wide freshman seminar about AGW (which may encourage students to consider taking more physics courses or even take physics as a Minor or Major).

4:06PM C38.00009 ABSTRACT WITHDRAWN –

4:18PM C38.00010 Sensory illusions: Common mistakes in physics regarding sound, light and radio waves

, T.M. BRILES[1], A.E. TABOR-MORRIS[2], Georgian Court University — Optical illusions are well known as effects that we see that are not representative of reality. Sensory illusions are similar but can involve other senses than sight, such as hearing or touch. One mistake commonly noted among instructors is that students often mis-identify radio signals as sound waves and not as part of the electromagnetic spectrum. A survey of physics students from multiple high schools highlights the frequency of this common misconception, as well as other nuances on this misunderstanding. Many students appear to conclude that, since they experience radio broadcasts as sound, then sound waves are the actual transmission of radio signals and not, as is actually true, a representation of those waves as produced by the translator box, the radio. Steps to help students identify and correct sensory illusion misconceptions are discussed.

4:30PM C38.00011 Introducing New Experiments to the Contemporary Physics Lab: Emphasis on Quantum Mechanics Foundations and New Physics Frontiers

, KHALID EID, JAN YARRISON-RICE, HERBERT JAEGER, Miami University — We remodeled our sophomore curriculum extensively both in the laboratories and the lectures. Our Experimental Contemporary Physics laboratory (PHY293) was almost completely re-built both in curriculum and pedagogy. Among the new experiments that we introduced are Nanoparticle plasmon resonance, Saturated absorption and fluorescence in iodine molecules, Quantized conductance in atomic-scale constrictions, and Water droplets behavior and manipulation on metal surfaces. This presentation will focus on the last two experiments. Quantized conductance in a constriction in a gold wire being pulled slowly is a unique direct application of the one-dimensional potential wells. Unlike most experiments on quantum mechanics that use optics, this experiment is transport-based, conceptually simple, and robust in addition to being low-cost. The transport properties of the wire span multiple transport regimes while being pulled. It is quite valuable for students (a significant fraction of whom are biological physics and engineering physics majors) to understand the behavior of water droplets on different surfaces. Water is the medium in which biological activities occur and is important in many other applications like air conditioning and refrigeration. We design simple gradients in the hydrophobic/hydrophilic properties of metal surfaces in order to move water droplets in a controlled way, even against gravity. Students explore the effects of surface tension and metal roughness on droplets.

4:42PM C38.00012 On the Electron Gas Heat Capacity in Undergraduate Solid State

, JAVIER HASBUN, University of West Georgia — In undergraduate solid state physics the electronic energy, U_{el}, is calculated through the Fermi distribution function while the energy is weighted with the density of states. The electronic heat capacity is the derivative of the electronic energy with respect to temperature. Through this process, it is possible [1] to obtain a low temperature approximation for the heat capacity, C_{el} that's proportional to the temperature. It is of interest to do a numerical calculation of U_{el} from which the numerical C_{el} is extracted. However, the result obtained, while agreeing with the low temperature approximation, has a slope that's substantially different. The disagreement appears large as the temperature is increased from zero K. Here we show that the reason has to do with the constancy of the Fermi level. By including the self consistent behavior of the chemical potential, the deviation from zero Kelvin is much improved and the result seems to make better sense. The lesson learned is significant enough to be of great pedagogical importance as regards the heat capacity calculation and the behavior of the chemical potential with temperature.

4:54PM C38.00013 Design and operation of an inexpensive far-field laser scanning microscope suitable for use in an undergraduate laboratory course

, ARTHUR PALLONE, Norwich University, ERIC HAWK, None — Scanning microscope applications span the science disciplines yet their costs limit their use at educational institutions. The basic concepts of scanning microscopy are simple. The microscope probe - whether it produces a photon, electron or ion beam - moves relative to the surface of the sample object. The beam interacts with the sample to produce a detected signal that depends on the desired property to be measured at the probe location on the sample. The microscope transforms the signal for output in a form desired by the user. Undergraduate students can easily construct a far-field laser scanning microscope that illustrates each of these principles from parts available at local electronics and hardware stores and use the microscope to explore properties of devices such as light dependent resistors and biological samples such as leaves. Students can record, analyze and interpret results using a computer and free software.

5:06PM C38.00014 Simulation and Visualization of Chaos in a Driven Nonlinear Pendulum – An Aid to Introducing Chaotic Systems in Physics

, GODFREY AKPOJOTOR, Theoretical and Computational Condensed Matter Physics, Physics Department, Delta State University, Abraka, Nigeria, LOUIS EHWERHEMUEPHA, Computational Science, Chapman University, Orange, California, USA, OGHENERIOBORORUE AMROMANOH, Department of Biosystems Engineering School, University of Manitoba, Manitoba, Canada — The presence of physical systems whose characteristics change in a seemingly erratic manner gives rise to the study of chaotic systems. The characteristics of these systems are due to their hypersensitivity to changes in initial conditions. In order to understand chaotic systems, some sort of simulation and visualization is pertinent. Consequently, in this work, we have simulated and graphically visualized chaos in a driven nonlinear pendulum as a means of introducing chaotic systems. The results obtained which highlight the hypersensitivity of the pendulum are used to discuss the effectiveness of teaching and learning the physics of chaotic system using Python. This study is one of the many studies under the African Computational Science and Engineering Tour Project (PASET) which is using Python to model, simulate and visualize concepts, laws and phenomena in Science and Engineering to compliment the teaching/learning of theory and experiment.

5:18PM C38.00015 Incorporating Ideas from Detector Physics into the Physics Curriculum: from HS to College[1]

, MISO KOMAROV, BERNARD BOSTON, RODNEY CARMONA, ELY LEON, MEL SABELLA, EDMUNDO GARCIA-SOLIS, Chicago State University — The goal of this project is to improve student understanding of modern physics in the undergraduate curriculum by building stronger content knowledge, reasoning and laboratory skills. This project is centered on the development of lab modules that help students move beyond theory and develop an appreciation of modern experimental physics. These modules allow students to build knowledge of subatomic particles by experimenting with detectors made of scintillator plastic, phototubes and read-out electronics. These instructional modules we are developing will permeate throughout the undergraduate curriculum forming a coherent conceptual thread. As students progress through the materials the content will become more challenging as the level of scaffolding decreases. As students complete the conceptual thread they will become versed in nuclear physics experimental techniques. In this talk we introduce the project, the detectors and the lab modules. Module one relates the kinetic energy we study in introductory mechanics to the kinetic energy of sub-atomic particles. Module two relates the principles of electromagnetism and charge from the interaction of magnets and coils to that of a sub-atomic particle moving through a detector.

Monday, March 18, 2013 2:30PM - 5:30PM –

Session C39 DMP GERA FIAP DCOMP: Focus Session: Materials for Electrochemical Energy Storage I 348 - Apparao Rao, Clemson University

2:30PM C39.00001 Enhanced electrochemical performance of graphene modified $LiFePO_4$ as a cathode material for lithium ion batteries , KULWINDER SINGH DHINDSA, BALAJI PRASAD MANDAL, MING-WEI LIN, MARYAM NAZRI, GHOLAM ABBAS NAZRI, Wayne State University, Detroit, Michigan, USA, VAMAN M. NAIK, University of Michigan, Dearborn, Michigan, USA, PREM VAISHNAVA, Kettering University, Flint, Michigan, RATNA NAIK, ZHIXIAN ZHOU, Wayne State University, Detroit, Michigan, USA — We synthesized $LiFePO_4$/graphene nano-composites using a sol-gel method by adding water dispersed graphene oxide to the $LiFePO_4$ precursors during the synthesis. The graphene oxide was subsequently reduced to graphene by annealing the composite which was confirmed by Raman spectroscopy and X-ray Photoelectron spectroscopy. The electronic conductivity of the composite was found to be six orders of magnitude higher than that of pure $LiFePO_4$ Scanning Electron microscopy and Transmission electron microscopy images show $LiFePO_4$ particles are wrapped in uniformly distributed graphene sheets throughout the material forming a three dimensional conducting network. At low currents, (C/3), the capacity of the composite cathode reaches 160 mAh/g, which is very close to the theoretical limit. More significantly, the graphene wrapped $LiFePO_4$ shows a dramatically improved rate capability up to 27C, and excellent charge-discharge cycle stability over 500 stable cycles as compared to the pure $LiFePO_4$.

2:42PM C39.00002 Multilayer Graphynes for Lithium Ion Battery Anode , HOONKYUNG LEE, Konkuk University — Graphynes, two-dimensional layers of *sp*- and sp^2-bonded carbon atoms, have recently received considerable attention because of their potential as new Dirac materials. Here, focusing on their large surface area, we explore the applicability of graphynes as lithium ion battery anodes through the first-principles density functional calculations. We have found that Li potential energies are in the range suitable to be used as anodes. Furthermore, the maximum composite of Li-intercalated multilayer α- and γ-graphynes is found to be C_6Li_3, which corresponds to a specific capacity of 1117 mAh g^{-1}, twice as large as the previous theoretical prediction for graphynes. The volumetric capacity of Li-intercalated multilayer α- and γ-graphynes is 1364 and 1589 mAh cm^{-3}, respectively. Both specific and volumetric capacities of Li-intercalated graphynes are significantly larger than the corresponding value of graphite, from which we conclude that multilayer graphynes can serve as high-capacity lithium ion battery anodes.

2:54PM C39.00003 Evaluating and enhancing quantum capacitance in graphene-based electrodes from first principles[1] , TADASHI OGITSU, Lawrence Livermore National Laboratory, MINORU OTANI, AIST, JONATHAN LEE, MICHAEL BAGGE-HANSEN, JUERGEN BIENER, BRANDON WOOD, Lawrence Livermore National Laboratory — Graphene derivatives are attractive as supercapacitor electrodes because they are lightweight, chemically inert, have high surface area and conductivity, and are stable in electrolyte solutions. Nevertheless, devising reliable strategies for improving energy density relies on an understanding of the specific factors that control electrode performance. We use density-functional theory calculations of pristine and defective graphene to extract quantum capacitance, as well as to identify specific limiting factors. The effect of structural point defects and strain-related morphological changes on the density of states is also evaluated. The results are combined with predicted and measured *in situ* X-ray absorption spectra in order to give insight into the structural and chemical features present in synthesized carbon aerogel samples.

[1]Performed under the auspices of the U.S. DOE by LLNL under Contract DE-AC52-07NA27344.

3:06PM C39.00004 Architectures for Nanostructured Batteries[1] , GARY RUBLOFF, University of Maryland — Heterogeneous nanostructures offer profound opportunities for advancement in electrochemical energy storage, particularly with regard to power. However, their design and integration must balance ion transport, electron transport, and stability under charge/discharge cycling, involving fundamental physical, chemical and electrochemical mechanisms at nano length scales and across disparate time scales. In our group and in our DOE Energy Frontier Research Center (www.efrc.umd.edu) we have investigated single nanostructures and regular nanostructure arrays as batteries, electrochemical capacitors, and electrostatic capacitors to understand limiting mechanisms, using a variety of synthesis and characterization strategies. Primary lithiation pathways in heterogeneous nanostructures have been observed to include surface, interface, and both isotropic and anisotropic diffusion, depending on materials. Integrating current collection layers at the nano scale with active ion storage layers enhances power and can improve stability during cycling. For densely packed nanostructures as required for storage applications, we investigate both "regular" and "random" architectures consistent with transport requirements for spatial connectivity. Such configurations raise further important questions at the meso scale, such as dynamic ion and electron transport in narrow and tortuous channels, and the role of defect structures and their evolution during charge cycling.

3:42PM C39.00005 Electrochemistry of ion inserted vanadium oxide nanosheets[1] , MARC POMEROY, SHAOLA REN, QIFAN YUAN, VICTORIA SOGHOMONIAN, Virginia Tech — Electrochemical energy storage is becoming increasingly important for its high specific power and quick charge and discharge rates. We investigate the electrical properties of hydrothermally synthesized vanadium oxide nanosheets as potential anode component of an electrochemical capacitor. The room temperature resistivity of the as-synthesized and pristine vanadium oxide nanosheets is around 10^7 ohm-cm, and variable temperature measurements indicate the semiconducting behavior of the material. Electrodes are fabricated from the nanosheets, and inserted into appropriate chloride solutions of Li, Na and ammonium. Room temperature voltammetry in the solutions are recorded and provide a measure of stored energy relative to each cation. Scanning electron micrographs obtained before and after various cyclic voltammograms provides a visual measure of nanosheet stability and a correlation to its electrochemical activity. Micrographs show that the material is robust towards Li insertion, but after several cycles of ammonium insertion, degradation occurs. Degradation upon Na insertion is minimal. These comparative studies shed light on the interactions between ions and metal oxide nanosheets.

3:54PM C39.00006 Redox electrodes comprised of polymer-modified carbon nanomaterials , MARK ROBERTS, ROBERT EMMETT, Department of Chemical and Biomolecular Engg., Clemson University, Clemson, SC 29634, MEHMET KARAKAYA, RAMAKRISHNA PODILA, APPARAO RAO, Department of Physics, Clemson University, Clemson, SC 29634, CLEMSON PHYSICS TEAM, CLEMSON CHEMICAL ENGINEERING TEAM — A shift in how we generate and use electricity requires new energy storage materials and systems compatible with hybrid electric transportation and the integration of renewable energy sources. Supercapacitors provide a solution to these needs by combining the high power, rapid switching, and exceptional cycle life of a capacitor with the high energy density of a battery. Our research brings together nanotechnology and materials chemistry to address the limitations of electrode materials. Paper electrodes fabricated with various forms of carbon nanomaterials, such as nanotubes, are modified with redox-polymers to increase the electrode's energy density while maintaining rapid discharge rates. In these systems, the carbon nanomaterials provide the high surface area, electrical conductivity, nanoscale and porosity, while the redox polymers provide a mechanism for charge storage through Faradaic charge transfer. The design of redox polymers and their incorporation into nanomaterial electrodes will be discussed with a focus on enabling high power and high energy density electrodes.

4:06PM C39.00007 Thin films with transvers concentration gradient as a model system to study core-shell cathodes for lithium ion batteries , SHINTARO YASUI, ZHI-PENG LI, JOYSURYA BASU, DMITRY RUZMETOV, LEONID BENDERSKY, National Institute of Standards and Technology, ICHIRO TAKEUCHI, University of Maryland, ALEC TALIN, Sandia National Laboratries, FILM GROWTH AND CHARACTERIZATION TEAM, FILM GROWTH COLLABORATION, CHARACTERIZATION TEAM — Recently it has been reported that heterogeneous structures of cathode materials for high-energy, high-power lithium-ion batteries have improved electrochemical properties, especially thermal stability. As an example, the spherical core-shell (or concentration-gradient) cathode particles with a Ni-rich core and a Mn-rich shell of $Li(Ni_{0.8}Co_{0.1}Mn_{0.1})O_2$ have better retention of capacity in comparison to uniform materials1. In this work the $Li(Ni,Mn)O_2$ thin films with transverse compositional gradients were used as a model system to investigate and understand the reported improvements. Preparation of the films by multi-target pulse lased deposition (PLD) on single-crystal conductive $Nb:SrTiO_3$ substrates allowed great compositional control and ability to deposit different compositional profiles, ranging from continuous to discreet variations of the Mn/Ni ratio. The film structures were studied by XRD and analytical TEM to correlate the structural and compositional variations. The films were tested for their electrochemical cycling performance and for the effect of cycling on structural degradations. [1] Chen, Z., Lee, D.-J., Sun, Y.-K. and Amine, K., MRS Bull. 36, 498–505 (2011).

4:18PM C39.00008 Real time measurement of Al anode degradation in thin film batteries , MARINA LEITE, DMITRY RUZMETOV, Center for Nanoscale Science and Technology - NIST, and Maryland NanoCenter, University of Maryland., ZHIPENG LI, LEONID BENDERSKY, Material Measurement Laboratory, NIST, A. ALEC TALIN, Center for Nanoscale Science and Technology, NIST, and Sandia National Laboratories — Li-ion battery (LIB) anodes that alloy with Li, including Si, Ge, Sn, and Al have specific capacities that significantly exceed that of carbon-based intercalation anodes. However, the large volume expansion and contraction that accompany charging and discharging processes lead to large mechanical stresses that ultimately lead to loss of capacity and failure of the anodes. To better understand the failure mechanism, we cycle a thin film LIB with an Al anode in a scanning electron microscope to measure in real time the nucleation and growth of a highly strained (-44%) Al-Li alloy. We use galvanostatic charging and discharging to control the rate of Li diffusion into the Al anode, and by collecting a series of SEM images in small time intervals we are able to directly correlate the nucleation events of Li-Al with specific peaks in the measured voltage. Based on these observations and ex situ transmission electron microscopy we develop a semi-quantitative description for the mechanism of Al anode degradation that could be extended to other alloy anode materials.

4:30PM C39.00009 Carbon Nanotube-templated Polymer Single Crystals Serve as Controllable Spacers to Form Novel Battery Architectures[1] , ERIC D. LAIRD, CHRISTOPHER Y. LI, Drexel University — One of the many challenges in battery cathode architectures lies in creating a porous structure with tunable features on the 10-100 nm length scale. Stable features of this size are desirable for engineered surface topology as well as charge storage applications. Few materials exist that can satisfy this requirement. Fewer still have high enough electron conductivity to be of use without adding an additional conducting phase. The "nanohybrid shish kebab" (NHSK) structure may be a solution to this obstacle. This physical functionalization technique for carbon nanotubes uses polymer single crystals grown from solution to produce a controllable spacer. In our previous work, it was shown that NHSKs can be controllably tuned to have average diameters ranging from 18 to 94 nm for single-walled carbon nanotubes. Films of these materials can easily be made free-standing and are highly flexible. Recent work in extending the functionality of these materials through the formation of ternary composites for battery applications will be presented. Pulsed electrodeposition of MnO2 onto the surfaces of these films forms an electrochemically active layer for lithium cells. High specific cathodic capacity has been observed in a rechargeable battery based on these materials.

4:42PM C39.00010 Graphitic electrodes modified with boron and nitrogen for electrochemical energy storage enhancement[1] , GUOPING XIONG, RAJIB PAUL, RON REIFENBERGER, TIMOTHY FISHER, Purdue University — Electrodes based on carbon nanomaterials (carbon nanotubes or graphitic nanopetals) have been modified with boron (B) and nitrogen (N) through a facile microwave heating cycle. During the microwave heating, the electrodes are immersed in a precursor solution consisting of urea and boric acid dissolved in either water or methanol. After microwave heating and overnight vacuum drying, the electrodes are again heated in nitrogen to remove unreacted chemicals and to form C_xBN. Hydrogen plasma was then used to remove any residual boron oxide from the surface of the electrodes. Carbon nanotubes modified with B and N exhibited higher lithium storage capacity as compared to pure carbon nanotube electrodes. We note that the modification appears to produce a highly unexpected and substantial cycle-to-cycle improvement in battery capacity as the electrode cycles through hundreds of charge-discharge iterations. This process can be applied to other carbon-based electrodes, which themselves are recognized for their high performance, to add further improvements.

4:54PM C39.00011 Rapid Synthesis of Few Layer Graphene Films and Their Electrochemical Behavior as Li-ion Battery Anode , LAMUEL DAVID, GURPREET SINGH, Kansas State University — We study the process of graphene growth on Cu and Ni substrates subjected to rapid heating (approx. 8 °C/sec) and cooling cycles (approx. 10 °C/sec) in a modified atmospheric pressure chemical vapor deposition furnace. Electron microscopy followed by Raman spectroscopy demonstrated successful synthesis of large area few-layer graphene (FLG) films on both Cu and Ni substrates. The overall synthesis time was less than one hour. Further, the as-synthesized films were utilized as anode material and their electrochemical behavior was studied in a lithium half-cell configuration. FLG on Cu (Cu-G) showed reduced lithium-alloying capacity when compared with SLG, BLG and Bare-Cu suggesting its substrate protective nature (barrier to Li-ions). While FLG on Ni (Ni-G) showed better Li-cycling ability similar to that of other carbons suggesting that the presence of graphene edge planes (typical of Ni-G) is important in effective uptake and release of Li-ions in these materials.

5:06PM C39.00012 A multi-physics study of Li-ion battery material $Li_{1+x}Ti_2O_4$, TONGHU JIANG, MICHAEL FALK, Johns Hopkins University, KRISHNA SIVA SHANKAR RUDRARAJU, KRISHNA GARIKIPATI, ANTON VAN DER VEN, University of Michigan — Recently, lithium ion batteries have been subject to intense scientific study due to growing demand arising from their utilization in portable electronics, electric vehicles and other applications. Most cathode materials in lithium ion batteries involve a two-phase process during charging and discharging, and the rate of these processes is typically limited by the slow interface mobility. We have undertaken modeling regarding how lithium diffusion in the interface region affects the motion of the phase boundary. We have developed a multi-physics computational method suitable for predicting time evolution of the driven interface. In this method, we calculate formation energies and migration energy barriers by ab initio methods, which are then approximated by cluster expansions. Monte Carlo calculation is further employed to obtain thermodynamic and kinetic information, e.g., anisotropic interfacial energies, and mobilities, which are used to parameterize continuum modeling of the charging and discharging processes. We test this methodology on spinel $Li_{1+x}Ti_2O_4$. Elastic effects are incorporated into the calculations to determine the effect of variations in modulus and strain on stress concentrations and failure modes within the material. We acknowledge support by the National Science Foundation Cyber Discovery and Innovation Program under Award No. 1027765.

5:18PM C39.00013 Novel Quinone-Based Couples for Flow Batteries , BRIAN HUSKINSON, Harvard School of Engineering and Applied Sciences, SARAF NAWAR, Harvard College, MICHAEL AZIZ, Harvard School of Engineering and Applied Sciences — Flow batteries are of interest for low-cost grid-scale electrical energy storage in the face of rising electricity production from intermittent renewables like wind and solar. We will report on investigations of redox couples based on the reversible protonation of small organic molecules called quinones. We will report half-cell measurements of current density vs. potential for aqueous solutions of various quinones and hydroquinones in sulfuric acid, facilitated by a variety of electrocatalysts. For a subset of these we will report full fuel cell measurements as well.

Session C40 DMP: Focus Session: Control of Ultrathin Film Morphology 349 - Shirley Chang, University of California Davis

2:30PM C40.00001 Quantitative model of heterogeneous nucleation and growth of SiGe quantum dot molecules[1] , HAO HU, FENG LIU, Department of Materials Science and Engineering, University of Utah, FENG LIU TEAM — We develop a quantitative theoretical model for heterogeneous nucleation and the growth of a quantum dot molecule — a few islands "strain bonded" by a pit in heteroepitaxy of thin films, in contrast to homogeneous nucleation and growth of isolated strain islands on the surface. We use a multiscale approach combining continuum model with first-principles calculation, and show that the critical size and energy barrier for island nucleation next to a pit is substantially reduced with the increasing pit size, but the reduction approaches an upper bound of ∼85% and ∼72% for the size and barrier, respectively. Our model also predicts a self-limiting effect on island growth, resulting from an intriguing interplay between island-pit attraction and island-island repulsion, that drives the island size to increase linearly with the pit size, which explains a long-standing puzzle of experimental observation.

[1]The work was supported by DOE-BES (Grant # DE-FG02-04ER46148).

2:42PM C40.00002 Influence of Surface Reconstruction on Droplet Epitaxy of InAs/GaAs Quantum Dots for Photovoltaics[1] , SIMON HUANG, LARRY AAGESEN, JINYOUNG HWANG, ALAN TERAN, JAMIE PHILLIPS, ROY CLARKE, KATSUYO THORNTON, RACHEL GOLDMAN, University of Michigan, Ann Arbor — Quantum dot (QD) superlattices have been proposed for improving solar cell efficiency by providing intermediate energy bands to allow sub-bandgap photon absorption. Although photocurrent enhancement from QD solar cells has been demonstrated, QD cells exhibit lower open-circuit voltages and efficiencies than the GaAs reference cells, presumably due to the high electron capture rates induced by the elliptically shaped Stranski-Krastanov QDs. To improve the QD aspect ratio, thereby reducing the electron capture rate, we are exploring an alternative QD fabrication approach, droplet epitaxy (DE). To date, we have explored the influence of buffer surface reconstructions on the In exposure dependence of DE QD densities and size distributions. The GaAs (1x1) surfaces lead to higher density of smaller QDs with broad log-normal size distributions, suggesting coalescence dominated QD growth with inhibited In atomic surface diffusion. The c(4x4) surfaces enable the formation of larger QDs with lower density and narrow Gaussian size distributions, suggesting Ostwald ripening dominated growth with enhanced In atomic surface diffusion. Furthermore, we will discuss correlations between the formation, interface structure, and photovoltaic properties of DE QDs.

2:54PM C40.00003 Formation and coalescence of surface domains introduced by metal deposition on a stepped Si(111) surface[1] , F.K. MEN, A.L. CHIN, C.P. CHANG, Department of Physics, National Chung Cheng University, Chia-Yi 621, Taiwan, ROC — By depositing sub-monolayer Au atoms onto a stepped Si(111)-(7×7) surface at 600°C, stripes of (5×2) domain form on the upper step edges of most terraces. Upon continued annealing at a higher temperature, most of the terraces transform into either Au-free (7×7) terraces or fully reconstructed (5×2) terraces. After analyzing the distance distribution between neighboring (5×2) terraces we detect the presence of an optimal distance separating (5×2) terraces. This optimal distance, controllable via the Au coverage, can be explained by the minimization of long-range strain relaxation energy of a system consisted of alternating domains. The ability of tuning surface domain structure through metal deposition provides a new way of manipulating surface morphology in the nanometer-scale range.

3:06PM C40.00004 Probing phase transitions at surfaces with ultrafast electron diffraction , MICHAEL HORN VON HOEGEN, Department of Physics, University Duisburg-Essen — The multitude of possible processes that can occur at surfaces cover many orders of magnitude in the time domain. While large scale growth and structure formation happens on a timescale of minutes and seconds, diffusion is already much faster, but can still be observed by electron microscopy. Many other processes as chemical reactions, phonon dynamics, or phase transitions, however, take place on the femto- and picosecond timescale and are yet way to fast for imaging techniques. In order to study such ultrafast processes at surfaces we have combined modern surface science techniques with fs laser pulses in a pump probe scheme. We use a RHEED setup with grazing incident electrons of 7 - 30 keV to ensure surface sensitivity. In order to overcome the velocity mismatch between light and electrons a tilted pulse front scheme is used to achieve a time resolution of less than 2 ps. The sample is excited with 800 nm photons with a pulse energy of 0.5 mJ at 5 kHz repetition rate. The huge potential of this technique for the study of transient surface phenomena is demonstrated with the non-equilibrium dynamics of the In induced c(8x2) reconstruction on Si(111). This surface exhibits a Peierls-like phase transition at 100 K from a c(8x2) groundstate, which is accompanied by the formation of a charge density wave (CDW), to (4x1) excited state. Upon excitation by the fs-laser pulse this structural phase transition is driven into the excited (4x1) state at a sample temperature of 20 K. The surface is only excited electronically, the CDW is lifted by photo doping and the surface remains up to 500 ps in a super cooled excited (4x1) state. Relaxation into the c(8x2) groundstate happens delayed through the nucleation of the c(8x2) at defects which triggers a 1-dim. recrystallisation front which propagates with the velocity of sound. Utilizing the Debye Waller effect, the excitation, conversion and relaxation of vibrational excitations in monolayer adsorbate systems like the Pb induced HIC ($\sqrt{3}$x$\sqrt{3}$) phase on Si(111) was studied. Initially only a high frequency optical mode with an amplitude parallel to the surface is excited. Subsequently, this mode decays into low frequency acoustic modes with an amplitude vertical to the surface which, however, do not couple to the phonons of the Si substrate and survive for many nanoseconds.

3:42PM C40.00005 Conversion among Co adsorption states on Si(111)-(7×7) by atomic manipulation , QIN LIU, KEDONG WANG, GUOHUA ZHONG, FANGFEI MING, XUDONG XIAO[1], Department of Physics, The Chinese University of Hong Kong, Shatin, New Territory, Hong Kong, China — Eight types of adsorption structure of single Co atom have been identified by comparing scanning tunneling microscopy (STM) images of Si(111)-(7×7) surface before and after in situ Co deposition at room temperature. The adsorption of single Co atom causes silicon adatoms appearing dimmer or brighter than their symmetry equivalents. Density functional theory calculations are performed to find the possible adsorption sites of Co atom and the magnetic moments of each type of adsorption structure, showing that the magnetic moments of the eight structures are different. Furthermore, atomic manipulation method has been used to realize conversions among the various Co adsorption structures. We have demonstrated that the single Co atom in eight different structure on Si(111)-(7×7) surface can be converted to each other directly or indirectly. Therefore, it makes this single Co/Si(111)-(7×7) become a promising system for building practical atomic magnetic structures for quantum computing since that each kind of single Co atom structure represents different magnetic states.

3:54PM C40.00006 Iridium-silicide nanowires on Si(001) surface[1] , DYLAN NICHOLLS, NURI ONCEL, University of North Dakota — Iridium (Ir) modified Silicon (Si) (001) surface is studied with low energy electron diffraction (LEED) and scanning tunneling microscopy (STM). The surface exhibits $p(2 \times 2)$ domains on LEED intensity images. The STM images show that the basis of the crystal lattice is consists of an Ir atom and a Si dimer and similar to Si(001) dimer rows, they are aligned parallel to the [110] orthogonal directions.

4:06PM C40.00007 On the Connection between Kinetic Monte Carlo and the Burton-Cabrera-Frank Theory[1] , PAUL PATRONE, University of Maryland, College Park and CNST at NIST Gaithersburg, DIONISIOS MARGETIS, T.L. EINSTEIN, University of Maryland, College Park — In the many years since it was first proposed, the Burton- Cabrera-Frank (BCF) model of step-flow has been experimentally established as one of the cornerstones of surface physics. However, many questions remain regarding the underlying physical processes and theoretical assumptions that give rise to the BCF theory. In this work, we formally derive the BCF theory from an atomistic, kinetic Monte Carlo model of the surface in 1+1 dimensions with one step. Our analysis (i) shows how the BCF theory describes a surface with a low density of adsorbed atoms, and (ii) establishes a set of near-equilibrium conditions ensuring that the theory remains valid for all times.

[1]Support for PP was provided by the NIST-ARRA Fellowship Award No. 70NANB10H026 through UMD. Support for TLE and PP was also provided by the CMTC at UMD, with ancillary support from the UMD MRSEC. Support for DM was provided by NSF DMS0847587 at UMD.

4:18PM C40.00008 Capture Zone Distributions and Island Morphologies in Organic Epitaxy and Graphene Formation , ALBERTO PIMPINELLI, Rice Quantum Institute, Rice Univ. & Univ. of Maryland, College Park (UMD), T.L. EINSTEIN[1], Physics & CMTC, UMD — Stating that island nucleation is an essential step in the formation of an epitaxial or supported layer may appear trivially obvious. However, less trivial is the observation that the size of the critical nucleus plays a crucial role in that it determines both the island density (and therefore the size of domains) and the evolution of the island morphology. In this talk we will describe recent developments in the analysis of capture zone distributions (CZD) specifically tailored for application to organic materials. We will also describe specific features of organic and graphene island morphologies, and discuss how they are related to the nucleation process and to the size of the critical nucleus.

[1]Work at UMD supported by NSF-MRSEC, Grant DMR 05-20471 and NSF CHE 07-49949

4:30PM C40.00009 Electromigration-driven dynamics of single-layer epitaxial islands on substrates , DWAIPAYAN DASGUPTA, GEORGIOS I. SFYRIS, DIMITRIOS MAROUDAS, University of Massachusetts, Amherst — Electromigration-driven dynamics of single-layer epitaxial islands on substrates can lead to surface pattern formation that may have significant impact on nanofabrication. We develop a fully nonlinear model for the driven morphological evolution of single-layer homoepitaxial islands and coherently strained heteroepitaxial islands on crystalline elastic substrates with diffusional mass transport limited to the island periphery. We carry out dynamical simulations of the driven dynamics of such islands and validate the model by comparisons of the simulation results for individual islands with published experimental results. We find that the island migration speed varies linearly with 1/R, where R is the island size, up to a critical size that marks the onset of island morphological transition; further increase in R triggers other morphological or dynamical transitions. We also find an exponential dependence of the island mobility on the misfit strain. We also study the driven dynamics of island pairs with the island sizes and the island center-to-center line misalignment with respect to the electric-field direction being the key parameters. This parametric study identifies several classes of pattern forming dynamical phenomena mediated by island coalescence and break-up.

4:42PM C40.00010 Electromigration- and thermomigration-driven surface morphological stabilization of coherently strained thin films on elastically deformable substrates , GEORGIOS I. SFYRIS, DWAIPAYAN DASGUPTA, DIMITRIOS MAROUDAS, University of Massachusetts, Amherst — We study the surface morphological stability of a coherently strained thin film grown epitaxially on a substrate and subjected to an external electric field and temperature gradient. Due to its lattice mismatch with the substrate the film may undergo a Stranski-Krastanow (SK) instability, resulting in formation of islands on its surface. We consider various types of substrates placing emphasis on compliant substrates that partly accommodate elastically the lattice-mismatch strain in the epitaxial film. To examine the morphological stability of the film's planar surface state, we conduct a linear stability analysis based on a three-dimensional model of driven film surface morphological evolution. We find that the simultaneous action of properly applied and sufficiently strong external fields is necessary to stabilize the planar film surface morphology; in such cases, surface electromigration and thermomigration can inhibit SK-type instabilities and control the onset of island formation on the film surface. We derive the conditions for synergy and competition of the two external fields for surface stabilization and demonstrate the beneficial effects of the thermal field on reducing the critical electric-field strength required to stabilize the planar film surface morphology.

4:54PM C40.00011 Strain and Shape-Driven Self-Organization of Atomically Abrupt Junctions on Patterned Ge (001) Surfaces , BORIS LUKANOV, KEVIN GARRITY, FRED WALKER, SOHRAB ISMAIL-BEIGI, ERIC ALTMAN, Yale University — We employ STM, electron diffraction, and other experimental techniques, complemented by density functional theory, in order to explore the interaction of alkaline-earth metals with the Si and Ge (001) surfaces on the atomic scale. Our results reveal a complex series of phase transitions as the alkaline-earth coverage is varied. Each phase transition is accompanied by significant changes in the surface morphology that can only be explained by mass transfer induced by the formation of alloy surfaces. Through comparison of bias-dependent atomic-resolution STM images with first-principle calculations, we develop atomic structural models of the surface alloy phases. Incorporation of the larger alkaline earth atoms into the Ge surface creates anisotropic strain that is ultimately relieved by the formation of remarkably well-ordered arrays of islands and trenches. With applications in mind, we investigate deposition onto a Ge substrate lithographically patterned with shapes, designed to direct the self-organization of the alkaline-earth induced surface structures. Sr deposition onto a Ge substrate patterned with cross-shaped nano-templates results in phase segregation within the template boundaries and the formation of atomically abrupt junctions between the different surface alloys.

5:06PM C40.00012 Exploring the Role of Steps: A Collection of Case Studies of Vicinal Metal Surfaces using Density Functional Theory , JAMES WESTOVER, ABDELKADER KARA, University of Central Florida — We will present results from multiple case studies done using DFT. We have explored the contribution made by step edges when metal surfaces are in contact with organic molecules, specifically, the cases involving pentacene ($C_{22}H_{14}$). The cases of vicinal surfaces with terrace geometries of 100 and 111 will be compared and contrasted. The question of terrace width is also addressed by results presented for situations involving diminishing step width. Because of the abundance of experimental data for copper it has been chosen as one metal surface to be considered. Additionally, copper's lattice constant is commensurate with the ring width in the benzene chain that forms pentacene. To contrast copper results for another noble metal, silver, will also be presented. We will present results for both structural and electronic changes in both the substrate and molecule.

5:18PM C40.00013 Large-scale Molecular Dynamics Simulations of Glancing Angle Deposition[1] , BRADLEY HUBARTT, XUEJING LIU, JACQUES AMAR, University of Toledo — While a variety of methods have been developed to carry out atomistic simulations of thin-film growth at small deposition angles with respect to the substrate normal, due to the complex morphology as well as the existence of multiple scattering of depositing atoms by the growing thin-film, realistically modeling the deposition process for large deposition angles can be quite challenging. Accordingly, we have developed a computationally efficient method based on the use of a single graphical processing unit (GPU) to carry out molecular dynamics (MD) simulations of the deposition and growth of thin-films via glancing angle deposition. Using this method we have carried out large-scale MD simulations, based on an embedded-atom-method potential, of Cu/Cu(100) growth up to 20 monolayers for deposition angles ranging from 50° to 85° and for both random and fixed azimuthal angles. Our results for the thin-film porosity, roughness, lateral correlation length, and density vs height will be presented and compared with experiments. Results for the dependence of the microstructure, grain-size distribution, surface texture, and defect concentration on deposition angle will also be presented.

5:30PM C40.00014 First-principles study of tilted binding and precession motion of diatomic NO adsorbed to Co-porphyrin on Au(111) , YUNHEE CHANG, Graduate School of Nanoscience and Technology, KAIST, HOWON KIM, SE-JONG KAHNG, Department of Physics, Korea University, YONG-HYUN KIM, Graduate School of Nanoscience and Technology, KAIST — To understand the bright square ring structures observed in scanning tunneling microscopy (STM) experiments of NO adsorption to CoTPP on Au(111), we performed first-principles calculations within the spin-polarized DFT formulation and DFT-D method; which includes the van der Waals interaction between CoTPP and Au(111). With the correction, the calculated electronic structrues of NO adsorbed CoTPP/Au(111) are well consistent with STM and scanning tunneling spectroscopy (STS) results. Upon NO exposure, three-lobed structures of CoTPP were transformed to bright square ring shapes on Au(111). The adsorbed NO molecule is tilted away from the axial direction. Due to the symmetry of the CoTPP, the adsorbed NO molecule have a precession motion with the energy barrier of 33 meV. This energy barrier is small enough to allow a fast precession motion of the NO molecule even in cryogenic temperatures as low as 80 K. We will discuss details about NO adsorption mechanisms and electronic structures.

Monday, March 18, 2013 2:30PM - 5:30PM –

Session C41 DAMOP: Quantum Simulation with Cold Atoms and Molecules 350 -

2:30PM C41.00001 ABSTRACT WITHDRAWN –

2:42PM C41.00002 Towards Strongly Interacting Quantum Mixtures of Light Fermions and Heavy Bosons[1] , COLIN PARKER, SHIH-KUANG TUNG, JACOB JOHANSEN, CHENG CHIN, University of Chicago, YUJUN WANG, PAUL JULIENNE, Joint Quantum Institute and University of Maryland — Cold atomic gases have attracted interest as many body quantum simulators due to the tunable nature of the basic parameters, such as lattice depth, particle density, and interaction. However, for single species alkali atoms, simulations are limited by the nature of the interactions between atoms, which is necessarily short-range. Heteronuclear mixtures offer the potential for more exotic interactions, either by formation of cold molecules with a permanent electric dipole moment, or by allowing one species to mediate interactions between the other. With the addition of an optical lattice, an analog of electron-phonon interactions should be possible, with heavy bosons playing the role of material ions. In all of these scenarios, ^{6}Li and ^{133}Cs are a compelling choice, as they maximize the mass ratio within the stable alkali family. Furthermore, either species by itself offers significant tunability. Recently, we have discovered a family of interspecies Feshbach resonances between 800 and 900 G in the ^{6}Li-^{133}Cs system. These resonances are in a favorable position for the production of dual degenerate quantum gases. The implications for universal few-body states and strategies for sympathetic evaporation to dual degeneracy will be discussed.

[1]We acknowledge support from the NSF-MRSEC program, NSF Award No. PHY-0747907 and AFOSR-MURI cold molecules grant.

2:54PM C41.00003 Making Dipolar Chain Liquid and Crystal[1] , DAW-WEI WANG, JHIH-SHIH YOU, Department of Physics, National Tsing-Hua University, Hsinchu, Taiwan 300 — Recent experimental progress on ultra-cold polar molecules opens new realms to explore intriguing quantum phase with dipolar interaction. One of possible phenomena is self assembled chain liquid in a stack of strongly confined pancake traps. It is, however, not easy for polar molecules to form a spontaneous chain liquid due to lack of binding mechanism. Here, we propose an adiabatic process and calculate the entropy and resulting temperature for the formation of dipolar chain liquis after adiabatically switching on the electric field and then followed by reducing the optical lattice field. We further investigate the elementary excitations of the dipolar chain crystal and derived the finite temperature KTNHY transition as well as compressibility of such many-body system. We also discuss how such interesting large-composite object can be experimentally measured even above the quantum degenerate temperature.

[1]We acknowledge support from National Center for Theoretical Sciences and National Science Concil, Taiwan

3:06PM C41.00004 Pomeranchuk Cooling in Frustrated Magnets – a Route to Spin Liquids in Cold Atoms , DAVID MROSS, Massachusetts Institute of Technology — Fermions hopping on a two-dimensional triangular lattice at half filling with moderate repulsive interactions are expected to form an exotic Mott insulating state. This Mott insulator, also known as a quantum spin liquid (QSL), does not order magnetically, nor break any other symmetry. It hosts many gapless excitations which give rise to a parametrically larger low-temperature entropy than in magnetically ordered states. We show that adiabatically tuning the strength of the interaction from the metallic into the QSL state leads to a significant reduction in temperature. This makes such a system a good candidate for accessing novel quantum phases in cold atom experiments.

3:18PM C41.00005 Symmetry-protected topological phases of alkaline-earth cold fermionic atoms in one dimension , SYLVAIN CAPPONI, Toulouse University, HELOISE NONNE, Technion, Haifa, MARION MOLINER, PHILIPPE LECHEMINANT, Université de Cergy-Pontoise, KEISUKE TOTSUKA, Kyoto University — We investigate the existence of symmetry-protected topological phases in one-dimensional alkaline-earth cold fermionic atoms with general half-integer nuclear spin I at half filling. Using complementary techniques, we show that SU(2) topological phases are stabilized where the SU(2) symmetry stems from the existence of a metastable excited state in alkaline-earth atoms. On top of these phases, we find the emergence of topological phases with enlarged SU(2I+1) symmetry which depend only on the nuclear spins degrees of freedom. The main physical properties of the latter phases are further studied using a matrix-product state approach. We find that these phases are symmetry-protected topological phases, with respect to inversion symmetry, when I=1/2,5/2,9/2..., which is directly relevant to ytterbium and strontium cold fermions.

3:30PM C41.00006 Quantum Monte Carlo simulation of the power-law correlated SU(6) quantum magnets with ^{132}Yb fermions , DA WANG, Department of Physics, University of California, San Diego, CA92093, ZI CAI, Department of Physics and Arnold Sommerfeld Center for Theoretical Physics, Ludwig-Maximilians-Universität München, D-80333 München, Germany, CONGJUN WU, Department of Physics, University of California, San Diego, CA92093 — We systematically investigate the half-filled SU(2N) Hubbard model on the two dimensional square lattice, using the projector quantum Monte-Carlo method which is free of sign problem. We find that the ground state changes from the long-range Neel order in the SU(2) case to a paramagnetic state in the large N limit, in which no long-range order was observed. Employing Maximum entropy method to analytically continue imaginary-time data, we obtain both one-particle and two-particle spectral functions in the whole Brillouin zone. As N increases, the charge gap is quickly suppressed and the spin-wave feature with linear dispersion around (π,π) is finally destroyed. The related physics is discussed as well as some applications to the experiments.

3:42PM C41.00007 Thermodynamics for reaching SU(N) quantum magnetism in ultracold alkaline earth atoms , KADEN HAZZARD, JILA, NIST, CU-Boulder, LARS BONNES, Institute for Theoretical Physics, University of Innsbruck, SALVATORE MANMANA, Institute for Theoretical Physics, University of Göettingen, VICTOR GURARIE, MICHAEL HERMELE, Dept. of Physics, CU-Boulder, STEFAN WESSEL, Institute for Theoretical Solid State Physics, Aachen University, ANA MARIA REY, JILA, NIST, CU-Boulder — Motivated by the prediction that SU(N) Hubbard models in a large-N limit possess a chiral spin liquid ground state, we investigate how to exploit the large number of degrees of freedom to cool alkaline earth atoms in optical lattices, which are described by the SU(N) Hubbard model with N as large as 10. Combining analytic high temperature expansions and sophisticated quantum Monte Carlo calculations, we show that the entropy increases with N for $T > t^2/U$ independent of dimension and lattice geometry, and down to temperatures $T = 0.1t^2/U$ in one dimensional chains. As a consequence, when one loads these atoms into optical lattices, the final temperatures can be orders of magnitude colder for $N = 10$ than for the usual $N = 2$ case. The use of alkaline earths with large N is thus particularly exciting for cold atoms experiments, where achieving low entropy states displaying quantum magnetism remains an outstanding challenge. This finding explains the dramatic cooling seen in recent Yb ($N = 6$) experiments [Y. Tanaka et al., Nature Physics 8, 800 (2012)].

3:54PM C41.00008 Superfluid state of repulsively interacting three-component fermionic atoms in optical lattices[1] , SEI-ICHIRO SUGA, University of Hyogo, KENSUKE INABA, NTT BRL, CREST — We investigate the superfluid state of repulsively interacting three-component (color) fermionic atoms in optical lattices using Feynman diagrammatic approaches and the dynamical mean field theory [1]. When the anisotropy of the three repulsive interactions is strong, atoms of two of the three colors form Cooper pairs and atoms of the third color remain a Fermi liquid. This superfluid emerges close to half filling at which the Mott insulating state characteristic of the three-component repulsive fermions appears [2]. An effective attractive interaction is induced by density fluctuations of the third-color atoms. The superfluid state is stable against the phase separation that occurs in the strongly repulsive region. We determine the phase diagrams in terms of temperature, filling, and the anisotropy of the repulsive interactions.

4:06PM C41.00009 Short-Range Correlations and Cooling of Ultracold Fermions in the Honeycomb Lattice , BAOMING TANG, Georgetown University, THEREZA PAIVA, Universidade Federal do Rio de Janeiro, EHSAN KHATAMI, MARCOS RIGOL, Georgetown University — We study experimentally relevant thermodynamic properties and spin correlations of the Hubbard model in the honeycomb lattice by using determinantal quantum Monte Carlo simulations and numerical linked-cluster expansions. We find that the honeycomb lattice exhibits a more pronounced anomalous region in the double occupancy that leads to stronger adiabatic cooling than in the square lattice. We also find that, at half filling and finite temperature, nearest-neighbor spin correlations can be stronger in the honeycomb lattice than in the square lattice, even in regimes where the ground state in the former is a semimetal or a spin liquid while it is an antriferromagnetic Mott insulator in the latter. The implications of these findings for optical experiments are also discussed.

4:18PM C41.00010 From Topological Insulator to Topological Superfluid[1] , XIONG-JUN LIU, Institute of Advanced Study and Department of Physics, Hong Kong University of Science and Technology, Clear Water Bay, Hong Kong, K.T. LAW, T.K. NG, Department of Physics, Hong Kong University of Science and Technology, Clear Water Bay, Hong Kong — Majorana zero bound state exists in the vortex core of a chiral p+ip superconductor (SC), which can be driven from an s-wave SC by spin-orbit (SO) coupling. In cold atoms, an s-wave superfluid (SF) can be obtained by Feshbach resonance. Together with the Rashba SO interaction and Zeeman field, the s-wave SF gives rise to a chiral topological SF. However, a Rashba-type SO interaction is not experimentally realistic for cold atom gas. We propose here a novel scheme to study exotic topological phases in an optical lattice, where we can observe both the topological insulating phase and chiral topological SF under different parameter regimes. We examine in detail our prediction with realistic experimental platforms, and show its great feasibility in the experimental realization.

4:30PM C41.00011 Direct Measurement of the Zak phase in Topological Bloch Bands , MARCOS ATALA, MONIKA AIDELSBURGER, Ludwig-Maximilians Universitat, JULIO BARREIRO, Ludwig-Maximilians Universitat and Max-Planck Institute of Quantum Optics, DMITRY ABANIN, TAKUYA KITAGAWA, EUGENE DEMLER, Harvard University, IMMANUEL BLOCH, Ludwig-Maximilians Universitat and Max-Planck Institute of Quantum Optics — Geometric phases that characterize the topological properties of Bloch bands play a fundamental role in the modern band theory of solids. Here we report on the direct measurement of the geometric phase acquired by cold atoms moving in one-dimensional optical lattices. Using a combination of Bloch oscillations and Ramsey interferometry, we extract the Zak phase – the Berry phase acquired during an adiabatic motion of a particle across the Brillouin zone – which can be viewed as an invariant characterizing the topological properties of the band. For a dimerized optical lattice, which models polyacetylene, we measure a difference of the Zak phase equal to π for the two possible polyacetylene phases with different dimerization. This indicates that the two dimerized phases belong to different topological classes, such that for a filled band, domain walls have fractional quantum numbers. Our work establishes a new general approach for probing the topological structure of Bloch bands in optical lattices.

4:42PM C41.00012 Ground-state properties of spin-imbalanced fermions on square lattices , SIMONE CHIESA, JIE XU, SHIWEI ZHANG, College of William and Mary — Atoms in optical lattices offer the opportunity to probe exotic pairing states experimentally. We consider spin-imbalanced fermions on a square lattice. Using Bogoliubov-de Gennes theory and fully self-consistent numerical calculations reaching the thermodynamic limit, we make several predictions of the physics of the ground state and the Fulde-Ferrell-Larkin-Ovchinnikov (FFLO) order. We show, in particular, that the experimentally accessible momentum distribution can be used to identify the hidden Fermi surface of the condensate and the presence of Fermi arcs. There exists a regime of density (away from half-filling) and interactions where the system can support a supersolid order. Finally, we address the crystallography of the inhomogeneous state by determining the leading wave vector as a function of U, density and polarization.

4:54PM C41.00013 ABSTRACT WITHDRAWN –

5:06PM C41.00014 Enhancing the thermal stability of entanglement between Majorana fermions with dipoles in optical lattices[1] , VITO SCAROLA, FEI LIN, Virginia Tech — Pairing between spinless fermions can generate Majorana fermion excitations. Such excitations may exhibit intriguing properties arising from non-local entanglement, including anyonic braid statistics and enough stability to encode quantum information. But simple models indicate that non-local entanglement between Majorana fermions becomes unstable at non-zero temperatures. We discuss this issue and show that anisotropic interactions between dipolar fermions in optical lattices can be used to form domains that significantly enhance thermal stability. We construct a model of oriented dipolar fermions in a square optical lattice. We explicitly compute the correlation functions defining entanglement. We find that domains established by strong interactions exhibit enhanced entanglement between Majorana fermions over large distances and long times even at finite temperatures.

5:18PM C41.00015 Structures forming out of quantum seeds in Bose condensates with time-dependent tunnel coupling , FLORIAN MARQUARDT, CLEMENS NEUENHAHN, University of Erlangen-Nuremberg, Germany, ANATOLI POLKOVNIKOV, Boston University — Quantum fluctuations can be amplified into macroscopic structures in the course of time. This can happen in quench scenarious, where some parameter is time-dependent, and it has wide-ranging implications, from condensed matter physics to cosmology. Here, we investigate the behaviour of a model system of two 1D clouds of bosonic atoms. Specifically, we track the time-evolution of the quantum field that describes the relative phase between the quasi-condensates as a function of position. When suddenly switching on the tunnel-coupling, the subsequent dynamics is first governed by parametric amplification of the initial quantum fluctuations. At a later stage, nonlinear dynamics takes over, and localized phase structures form. These structures, which we term 'quasi-breathers', then stochastically form and decay, and we characterize their features using numerical simulations of the underlying sine-Gordon equation based on the truncated Wigner approximation. We then turn to a scenario where the tunnel coupling is changed smoothly over time. It turns out this can be mapped to the evolution of the quantum sine-Gordon field in an expanding 1+1 dimensional toy universe, giving insight into nonlinear structure formation in cosmology.

Monday, March 18, 2013 2:30PM - 5:42PM –

Session C42 FIAP: Quantum Hall Effect: Materials, Geometries, & nu = 2 Hilton Baltimore Holiday Ballroom 3 - Michael Zudov, University of Minnesota

2:30PM C42.00001 Very Narrow Intersubband Excitations in High Mobility 2DESs[1] , URSULA WURSTBAUER, ARON PINCZUK, Columbia University, JOHN WATSON, SUMIT MONDAL, MICHAEL J. MANFRA, Purdue University, KEN W. WEST, LOREN N. PFEIFFER, Princeton University — We report the observation of very narrow collective intersubband excitations (ISBE) of 2D electron systems (2DESs) with ultra-high mobility ($\mu \geq$15x10^6 cm^2/Vs) in high quality GaAs quantum structures. These findings from resonant inelastic light scattering (RILS) experiments are used as tools for exploration of links between transport mobility and collective electron behavior in 2DES of high perfection. We find that the line-widths of collective ISB modes can be as low as 80μeV. Comparison of ISBE measurements from several samples exhibits a variation in line-width of more than a factor of two. There is, however, a surprising lack of direct correlation between ISBE line-width with mobility in the range 15$\geq \mu \geq$24x10^6 cm^2/Vs. Measurements of ISBE by RILS will be evaluated as a method to explore the interplay of quality (as indicated by mobility) and fundamental interactions in the fractional quantum Hall effect.

2:42PM C42.00002 Growth of high mobility, in-situ back-gated two-dimensional electron gases in GaAs/AlGaAs quantum wells , JOHN WATSON, SUMIT MONDAL, Department of Physics and Birck Nanotechnology Center, Purdue University, MICHAEL MANFRA, Department of Physics, Birck Nanotechnology Center, Schools of Electrical and Computer and Materials Engineering, Purdue University — Investigations of the energy scales of many-body phenomena in high mobility two-dimensional electron gases (2DEGs) often require the ability to tune the electron density in a single device. Electrostatic gating is often the method of choice, but traditional device designs are less than ideal. The 2DEG density in top-gated devices is often hysteretic and/or unstable over time due to intervening doping layers, and traditional back-gates applied to mechanically thinned substrates typically require large gate voltages ($\sim$ 100 V) to achieve significant modulation of the electron density due to the large gate-channel separation ($\sim$ 150 μm). We report on the growth of a series of high mobility 2DEGs in 30 nm GaAs/AlGaAs quantum wells in which the density is modulated by an in-situ grown back-gate. Such in-situ gates can be grown close to the 2DEG ($\sim$ 1 μm) and without doping layers between the 2DEG and gate. We discuss heterostructure design parameters and device processing conditions leading to low gate leakage currents, low ohmic contact resistances, and high electron mobilities (10^7 cm^2/Vs) at low temperature (T = 300 mK).

2:54PM C42.00003 Anisotropic Fermi Contour of (001) GaAs Holes in Parallel Magnetic Fields[1] , DOBROMIR KAMBUROV, MANSOUR SHAYEGAN, LOREN PFEIFFER, KENNETH WEST, KIRK BALDWIN, Princeton University, ROLAND WINKLER, Northern Illinois University — We demonstrate tuning the dispersion anisotropy in a high-mobility (001) GaAs two-dimensional hole system through the application of an in-plane magnetic field. We employ surface-strain-induced commensurability oscillations to probe directly the anisotropy and the size of the Fermi contours. The experimental data are in semi-quantitative agreement with the results of a parameter-free energy band model. We find a severe spin-dependent anisotropy of the 2D hole Fermi contours stemming from the combined effect of the strong coupling of the parallel field to the orbital motion, the large spin-orbit interaction in the GaAs valence band, and heavy hole-light-hole coupling.

[1]We acknowledge support through the NSF (ECCS-1001719 and MRSEC DMR-0819860) for sample fabrication and characterization, and the DOE BES (DE-FG0200-ER45841) for measurements.

3:06PM C42.00004 Anisotropic Fermi Contour of Composite Fermions in Tilted Magnetic Fields[1] , MANSOUR SHAYEGAN, DOBROMIR KAMBUROV, YANG LIU, M.A. MUEED, SUKRET HASDEMIR, LOREN PFEIFFER, KENNETH WEST, KIRK BALDWIN, Princeton University — We employ surface-strain-induced commensurability oscillations of hole-flux composite fermions to study the effect of parallel magnetic field on their Fermi contours in high-quality C-doped (001) GaAs hole quantum wells. Our measurements reveal that the composite fermion Fermi contours are significantly distorted in the presence of parallel field. Along the direction of the parallel field, the Fermi wave vectors shrink while in the perpendicular direction they grow, and at 25 T parallel field, the relative distortion reaches 50%.

[1]We acknowledge support through the NSF (ECCS-1001719 and MRSEC DMR-0819860) for sample fabrication and characterization, and the DOE BES (DE-FG0200-ER45841) for measurements.

3:18PM C42.00005 Unconventional Quantum Hall Effect and Tunable Spin Hall Effect in monolayer MoS_2 , XIAO LI, Department of Physics, The University of Texas at Austin, FAN ZHANG, Department of Physics and Astronomy, University of Pennsylvania, QIAN NIU, Department of Physics, The University of Texas at Austin — We analyze the Landau level (LL) structure in a monolayer MoS_2 and find a field-dependent unconventional quantum Hall plateau sequence $\nu = \cdots -2M-6$, $-2M-4$, $-2M-2$, $-2M-1$, $\cdots$, -5, -3, -1, 0, 2, 4 $\cdots$. Due to orbital asymmetry, the low-energy Dirac fermions become heavily massive and the LL energies grow linearly with B, rather than with $\sqrt{B}$. Spin-orbital couplings break spin and valley degenerate LL's into two distinct groups, and LL crossing effects appear in the valence bands only. In a p-n junction, spin-resolved fractionally quantized conductance appears in two-terminal measurements with a controllable spin-polarized current that can be probed at the interface. We also show that the zero-field spin Hall conductivity has some interesting tunability. For more information, please refer to arXiv: 1207.1205.

3:30PM C42.00006 Landau level crossing and enhanced g-factor of a 2-dimentional hole gas in Ge/SiGe quantum well , RAI MORIYA, IIS, University of Tokyo, YUSUKE HOSHI, ARL, Tokyo City University, YOSHIHISA INOUE, SATORU MASUBUCHI, IIS, University of Tokyo, KENTARO SAWANO, YASUHIRO SHIRAKI, ARL, Tokyo City University, NORITAKA USAMI, IMR, Tohoku University, TOMOKI MACHIDA, IIS, University of Tokyo — Strained Ge has been received much attention due to its small effective mass and large hole mobility. Moreover, two-dimetional hole gas (2DHG) provide additional band-structure effects such as mixing and non-parabolicity, thus makes this system fascinating for studying quantum transport. On the other hand, the detail study on the quantum Hall effect (QHE) on this system is still missing. We measured angular dependence of QHE in the single layer (SL) and bi-layer (BL) 2DHG in the strained Ge/SiGe quantum well (QW). Clear Landau level (LL) crossing and anti-crossing have been observed in BL 2DHG system. We extracted hole g-factor g$\sim$38 almost independent of Landau filling factor. This g-factor is largest among all the reported value for Ge. Interestingly, observed behavior is distinct form SL 2DHG. LL crossing is not observed on SL QW in our measurement, and estimated g-factor for the single layer 2DHG is g$\sim$1, order of magnitude smaller than BL sample. We think this giant enhancement of effective g-factor in BL 2DHG attribute to the interlayer interaction between the two layers. Our finding reveals the possibility of large g-factor modulation by tuning interlayer coupling in bi-layer 2DHG system.

3:42PM C42.00007 The Integer and Fractional Quantum Hall Effect in the Lowest Landau Level of Valley Degenerate 2D Electrons on Hydrogen Terminated Si(111) , TOMASZ M. KOTT, BINHUI HU, S.H. BROWN, B.E. KANE, University of Maryland, College Park — We report low temperature magnetotransport measurements on a high mobility ($\mu = 325\,000\,\mathrm{cm}^2/\mathrm{V\,sec}$) 2D electron system on a H-terminated Si(111) surface. In Si(111), there are six degenerate, anisotropic valleys which can affect the magnetotransport in unexpected ways. While low magnetic field data indeed show a six-fold valley degenerate system, we observe the integral quantum Hall effect at all filling factors $\nu \leq 6$, indicating a magnetic-field-induced breaking of the valley degeneracy. Additionally, we find that $\nu = 2$ develops in an unusually narrow temperature range, which might indicate the existence of a novel broken-symmetry valley phase. Finally, we observe an extended, exclusively even numerator, fractional quantum Hall hierarchy surrounding $\nu = 3/2$ with denominators up to 15. This hierarchy is consistent with two-fold valley-degenerate composite fermions. We determine activation energies and provide the first estimate the composite fermion mass in a multi-valley system.

3:54PM C42.00008 Heat equation approach to geometric changes of the torus Laughlin-state[1] , ZHENYU ZHOU, ZOHAR NUSSINOV, ALEXANDER SEIDEL, Washington University in St. Louis — We study the second quantized -or guiding center- description of the torus Laughlin state. Our main focus is the change of the guiding center degrees of freedom with the torus geometry, which we show to be generated by a two-body operator. We demonstrate that this operator can be used to evolve the full torus Laughlin state at given modular parameter τ from its simple (Slater-determinant) thin torus limit, thus giving rise to a new presentation of the torus Laughlin state in terms of its "root partition" and an exponential of a two-body operator. This operator therefore generates in particular the adiabatic evolution between Laughlin states on regular tori and the quasi-one-dimensional thin torus limit. We make contact with the recently introduced notion of a "Hall viscosity" for fractional quantum Hall states, to which our two-body operator is naturally related, and which serves as a demonstration of our method to generate the Laughlin state on the torus.

[1]Supported by the National Science Foundation under NSF Grant No. DMR-1206781 (ZZ and AS), and NSF Grant No. DMR-1106293 (ZN). AS would like to thank N. Read, K. Yang, I. Gruzberg, T.H. Hansson, and G. Möller for insightful comments.

4:06PM C42.00009 Fractional Quantum Hall states on an infinite cylinder: topological properties and edge exponents using the iDMRG , MICHAEL ZALETEL, UC Berkeley, ROGER MONG, California Institute of Technology, JOEL MOORE, UC Berkeley, FRANK POLLMANN, Max Planck Institute for the Physics of Complex Systems — Exact diagonalization has been a tremendously successful approach to quantum Hall numerics, but is limited for certain applications due to finite size effects. We show how the infinite density matrix renormalization group (iDMRG) can be adapted to study microscopic quantum Hall Hamiltonians on a cylinder of infinite length. Using iDMRG to obtain the set of topologically degenerate ground states in their matrix product state form allows us to determine the energy, charge, quantum dimension and topological spin of the quasi-particles. When a trapping potential around the cylinder is introduced the fluid collapses into an infinitely long strip, an ideal geometry for extracting the central charge and edge exponents without the usual finite size effects.

4:18PM C42.00010 Coherent State Wave-Functions on a Torus with a Constant Magnetic Field , MIKAEL FREMLING, Stockholm University — We study two alternative definitions of localized states in the lowest Landau level (LLL) on a torus. The first is to project a delta function onto the LLL, while the other is to put all the N zeros of the wave function at the same point, thus localizing the function at the vicinity of the antipodal point. These two families of localized states both have many properties in common with the coherent states on the plane and on the sphere, viz. a simple resolution of unity and a self-reproducing kernel. However, only the projected delta function gives maximally localized states. We also show how to project expressions containing holomorphic derivatives and nonholomorphic coordinates onto the LLL, and briefly discuss the importance of this for constructing hierarchical QH wave functions.

4:30PM C42.00011 Exactly solvable 1D lattice model for the Laughlin states on torus geometries , ZHENG-YUAN WANG, MASAAKI NAKAMURA, Department of Physics, Tokyo Institute of Technology — We study the fractional quantum Hall (FQH) states on a thin torus where the 2D continuum system in a magnetic field can be reduced into a 1D lattice model with short-range interaction. We introduce a minimal model with exact ground states in Laughlin series (flling factors of the lowest Landau level $\nu = 1/q$).The model has the same degrees of freedom as that of the pseudo-potential for the Laughlin wave function, and it naturally derives general properties of the Laughlin wave function such as the Z_2 properties (the FQH effect is limited only odd q for fermions). The obtained exact ground states have high overlaps with the Laughlin states and well describe their properties, the incompressibility and the fractional charge excitations. The physical quantities such as the correlation functions are calculated analytically by using matrix product method. We also compute the entanglement spectrum and show the diamond structure of the FQH states on torus geometries. Thus, our model gives a simple reference model to describe the Laughlin states. (arXiv:1206.3071)

4:42PM C42.00012 Advantages of studying the fractional quantum Hall effect in a cylindrical geometry[1] , SONIKA JOHRI, Z. PAPIC, Department of Electrical Engineering, Princeton University, Princeton, New Jersey 08544, USA, ZI-XIANG HU, Department of Physics, Chongqing University, Chongqing 400044, China, R.N. BHATT, Department of Electrical Engineering, Princeton University, Princeton, New Jersey 08544, USA, PETER SCHMITTECKERT, Institut für Nanotechnologie, Forschungszentrum Karlsruhe, D-76021 Karlsruhe, Germany — We report results of numerical studies of the fractional quantum Hall effect in the cylindrical geometry using exact diagonalization as well as density-matrix renormalization group techniques. We provide convergence benchmarks that illustrate the advantage of the cylinder over the sphere, based on the number of sweeps and basis elements that need to be kept in order to achieve the desired accuracy for the ground state at $\nu = 5/2$ filling [1]. Further, we address several issues of interest that can be studied more directly using the cylindrical geometry. These include (i) transitions between the hierarchy of fractional quantum Hall states as a function of the confining potential; (ii) quasiparticle tunneling between the two edges of the cylinder; and (iii) generalized off-diagonal long-range order as a probe of the local geometry fluctuations in fractional quantum Hall liquids due to confinement potential or mass anisotropy.

4:54PM C42.00013 Shot Noise Signatures of Charge Fractionalization in the $\nu = 2$ Quantum Hall edge , MIRCO MILLETARI', BERND ROSENOW, Leipzig University — We investigate the effect of non-equilibrium and interactions on shot noise in $\nu = 2$ quantum Hall edges, where interactions between the two co-propagating edge modes are expected to give rise to charge fractionalization. We consider a setup consisting of a Hall bar pinched by two Quantum point contacts (QPCs). The first QPC selectively drives out of equilibrium the outer edge mode only, which then interacts with the unbiased inner one over the distance between the two QPCs. We describe the edge modes by two coupled chiral Luttinger liquids, and employ the method of non-equilibrium bosonization to study the relaxation dynamics of the inner one. We find that even asymptotically the edge distribution function does not thermalize, but instead depends in a sensitive way on the interaction strength between the two edge modes. We compute shot noise and Fano factor from the asymptotic distribution function of the inner edge mode at the second QPC, and from comparison with a reference model of fractionalized excitations we find that the Fano factor can be close to the value of the fractionalized charge.

5:06PM C42.00014 Anomalous Energy Gaps of the Odd Denominator Fractional Quantum Hall States in Different Spin Branches of the Second Landau Level , ETHAN KLEINBAUM, Purdue University, ASHWANI KUMAR, Monmouth College, MICHAEL MANFRA, Purdue University, LOREN PFEIFFER, KEN WEST, Princeton University, GABOR CSATHY, Purdue University — The nature of the fractional quantum Hall states forming in the second Landau level, including those with odd denominator Landau level filling factors, remain unknown. Conjectures of nonconventional origins have lead to the investigation of several odd denominator states in the lower spin branch of the second Landau level, such as the ones at ν=2+1/3 and 2+2/3. We report first measurements of the energy gaps in the upper spin branch of the second Landau level at ν=3+1/3, 3+2/3, 3+1/5 and 3+4/5. A comparison of the energy gaps of these states to those of their counterparts in the lower spin branch reveals a surprising reversal in the relative magnitudes of the states at partial filling factors 1/3 and 1/5. We explore possible explanations of this unusual observation. The work at Purdue was supported by the DOE BES contract no. DE-SC0006671. K.K. West and L.N. Pfeiffer acknowledge the support of the Princeton NSF-MRSEC and the Moore Foundation.

5:18PM C42.00015 Ground states at the filling factors $\nu = 7/3$ and $8/3$ in the second Landau level , TORU ITO, NAOKAZU SHIBATA, Department of Physics, Tohoku University, KENTARO NOMURA, Institute for Material Research, Tohoku University, DEPARTMENT OF PHYSICS, TOHOKU UNIVERSITY TEAM — The Laughlin state successfully describe the fractional quantum Hall state at $\nu = 1/3$ in the lowest Landau level. However, it is known that the Laughlin wavefunction has little overlap with the ground state wavefunction at $\nu = 7/3$ in the second Landau level. The ground states at $\nu = 7/3$ and $8/3$ are still unknown.To determine the ground states at these fillings, we use the exact diagonalization method and density-matrix renormalization group (DMRG) method. We calculate overlaps between the ground state and the trial wavefunctions, the ground state energies, and the ground-state pair-correlation functions. We find that the ground state wavefunction at $\nu = 8/3$ have very high overlap between the parafermion state, and the ground state energy of the parafermion state is lower than that of the Laughlin state. Further, the short-range structures of pair-correlation functions are significantly different from that of the Lauglin state.From these results, we consider that the parafermion state is a strong candidate of the ground state at $\nu = 7/3$ and $\nu = 8/3$.

5:30PM C42.00016 7/3 fractional quantum Hall effect: topology, trion excitations and edge states , AJIT C. BALRAM, YING-HAI WU, Pennsylvania State University, G.J. SREEJITH, NORDITA, ARKADIUSZ WÓJS, Wrocław University of Technology, J.K. JAIN, Pennsylvania State University — Exact diagonalization studies on finite systems show that the quasihole and quasiparticle excitations in the 7/3 fractional quantum Hall (FQH) state are qualitatively distinct from those of the 1/3 state, suggesting the possibility of different topological origins for the two states. We perform composite-fermion diagonalization on larger systems and also evaluate the entanglement spectrum, which shows that in spite of these strong finite size deviations, the 7/3 and 1/3 FQH states have the same topological structure in the thermodynamic limit. Nonetheless, there are substantial non-topological differences between the two, arising from the stronger residual interaction between composite fermions at 7/3. In particular, we show that the lowest energy charged excitations of the 7/3 state are complex trions of composite fermions, which have a much larger size than the charged excitations at 1/3. We discuss many observable consequences of our results.

Monday, March 18, 2013 2:30PM - 5:30PM –

Session C43 DCP: Focus Session: Plyler, Broida, Langmuir, and Research in an Undergraduate Institution prizes Hilton Baltimore Holiday Ballroom 2 - James Skinner, University of Wisconsin

2:30PM C43.00001 Earle K. Plyler Prize for Molecular Spectroscopy & Dynamics Lecture: Broadband Rotational Spectroscopy for Chemical Kinetics, Molecular Structure, and Analytical Chemistry[1] , BROOKS PATE, University of Virginia — Advances in high-speed digital electronics have enabled a new generation of molecular rotational spectroscopy techniques that provide instantaneous broadband spectral coverage. These techniques use a chirped excitation pulse to coherently excite the molecular sample over a spectral bandwidth of 10 GHz or larger through rapid passage. The subsequent time-domain emission is recorded using high-speed digitizers (up to 100 Gigasample/s) and the frequency domain spectrum is produced by fast Fourier transformation. The chirped-pulse Fourier transform (CP-FT) method has been implemented in the microwave frequency range (2-40 GHz) for studies of cold samples in pulsed jet sources and in the mm-wave/terahertz (THz) frequency range for studies of samples at room-temperature. The method has opened new applications for molecular rotational spectroscopy in the area of chemical kinetics where dynamic rotational spectroscopy is used to measure the rates of unimolecular isomerization reactions in highly excited molecules prepared by pulsed infrared laser excitation. In these applications, the isomerization rate is obtained from an analysis of the overall line shapes which are modified by chemical exchange leading to coalescence behavior similar to the effect in NMR spectroscopy. The sensitivity of the method and the ability to extend it to low frequency (2-8 GHz) have significantly increased the size range of molecules and molecular clusters for structure determination using isotopic substitution to build up the 3D molecular structures atom-by-atom. Application to the structure of water clusters with up to 15 water molecules will be presented. When coupled with advances in solid-state mm-wave/THz devices, this method provides a direct digital technique for analytical chemistry of room-temperature gases based on molecular rotational spectroscopy. These high-throughput methods can analyze complex sample mixtures with unmatched chemical selectivity and short analysis times.

3:06PM C43.00002 Herbert P. Broida Prize Lecture: Probing chemical dynamics with negative ion photodetachment , DANIEL NEUMARK, University of Calfornia, Berkeley — Photoelectron spectroscopy and its variants have been used in our laboratory to study diverse phenomena in chemical dynamics, including transition state spectroscopy, the electronic and vibrational spectroscopy of clusters, the photodissociation of reactive free radicals, hydrated electron dynamics in clusters and liquid jets, and the ultrafast dynamics of helium nanodroplets. This talk will focus on two examples of this type of work: slow electron velocity map imaging (SEVI) of trapped and cooled negative ions, and time-resolved photoelectron spectroscopy (TRPES) of negative ions. SEVI of cold ions represents a powerful means of performing high resolution photoelectron spectroscopy on complex species. Time-resolved radiation chemistry in nucleobases will be carried out with TRPES. In this work, starting with iodide-nucleobase complexes, we inject electrons into low-lying unoccupied orbitals of the nucleobase and follow the ensuing dynamics.

3:42PM C43.00003 Irving Langmuir Prize in Chemical Physics Lecture: The Inner Machinery of Single Molecules: resolving the unresolved with the STM , WILSON HO, University of California, Irvine — The scanning tunneling microscope (STM) is a unique instrument that can probe and induce changes in a molecule with atomic scale resolution. Its operation is based on the current that flows between the tip and the substrate with the molecule sandwiched in between. Therefore, the STM can be used to understand the coupling of electrons to the different states and excitations in the molecule and to investigate the influence on them by its environment. From the spatial and energy dependences of the coupling to the charge, spin, and nuclear motions in the molecule, verification of and new insights into the quantum mechanical properties of molecules can be obtained, including the discovery of new conduction and energy transfer mechanisms. This understanding of electron-molecule interactions with the STM enables rational ways to control chemistry and the exploration of novel physical technologies based on molecules.

4:18PM C43.00004 Prize for a Faculty Member for Research in an Undergraduate Institution Lecture: Studies of the Structure and Properties of Oxide Glasses with Applications[1] , MARIO AFFATIGATO, Coe College — This presentation will summarize the research work carried out by Prof. Affatigato and his undergraduate students over the past eighteen years. It will focus on some highlighted projects, namely: the determination of glass structure using laser ionization time of flight mass spectrometry; studies of glass modification by laser irradiation; bactericidal glass; and, most recently, glass manufacturing by aerolevitation and glasses for particle detection. The work on mass spectrometry will cover a broad range of oxide glass systems, including the borates, borosilicates, germanate, and gallate families. It has provided novel insights into the structure of glasses at intermediate length scales, measurements that are hard to obtain by any other techniques. The studies of glass structure modification will primarily center on vanadate glasses, which also form the basis for more recent electronic conductivity work at the heart of new particle calorimeter detectors. This project shows the power of serendipity and the strong capabilities of undergraduate students involved in advanced work and state of the art instrumentation. Bactericidal glass illustrates a nice collaborative project that involved simple borate glasses and helped pioneer their use in the human body—work that has led to significant medical developments by other colleagues and researchers. Finally, the aerolevitation project gives new insight into the crystallization and property behavior of glasses and melts at very high temperatures (from 2000 °C to 3000 °C).

[1]The work by Prof. Affatigato and his students has been supported by grants from the Research Corporation, the Petroleum Research Fund, and, primarily, by the U.S. National Science Foundation.

4:54PM C43.00005 Presentation of 2013 DCP APS Fellows , DONALD TRUHLAR, University of Minnesota — The new APS Fellows in the Division of Chemical Physics will be introduced.

Monday, March 18, 2013 2:30PM - 5:30PM –

Session C44 DBIO GSNP: Focus Session: Population and Evolutionary Dynamics III Hilton Baltimore Holiday Ballroom 1 -

2:30PM C44.00001 The physics of evolution and biodiversity: Old answers to new questions, and more...

, YANEER BAR-YAM, New England Complex Systems Institute — In recent years there has been a contentious battle among prominent biologists about the validity of Kin versus Group Selection as models of evolutionary biology. I will show that the controversy is widely misunderstood and is rooted in the mean field basis of RA Fisher's statistical treatment of population biology, which is the origin of the "gene centered view"–kin selection and inclusive fitness–but is also often used in analysis of group selection. As in statistical physics, symmetry breaking and pattern formation, and their spatial realizations, result in breakdown of the mean field approximation and the widely believed mathematical 'proofs' of the universality of the gene centered view. Our simulation and analysis (http://necsi.edu/research/evoeco/) of the role of this breakdown in spatial ecology, biodiversity, speciation and altruism, suggest there is an entire field of new opportunities to explore in the implications for evolutionary theory. The difference between biodiversity of wildtype populations and narrowly homogeneous laboratory types manifest the self-consistency of theoretical assumptions and laboratory experiments performed under conditions in which the mean field approximation applies. In contrast, the highly diverse natural populations manifest the role of boundaries between types (hybrid zones), speciation by spontaneous clustering, and spatio-temporal dynamics in predator prey systems. Altruism arises in evolving populations due to the spontaneous dynamic group formation and the heritability of environmental conditions created by parents and experienced by offspring (niche construction with symmetry breaking), so that altruists are better able to survive over the long term than selfish variants. Many versions of the mean field approximation that are traditionally used eliminate these spatio-temporal processes, leading to false analytic conclusions about their impossibility. The traditional view of altruism influenced views also of individuals in their relationship to society. In addition to the basic reframing of the origin of altruism, the role of space in evolution has important implications for understanding global dangers today, including pandemics driven by evolution of virulent pathogens that escape death through long-range transportation, and economic or environmental overexploitation when globalization enables exploiters to escape the consequences of their actions. 3:06PM C44.00002 Universality in a Neutral Evolution Model[1]

, DAWN KING, ADAM SCOTT, NEVENA MARIC, SONYA BAHAR, University of Missouri at Saint Louis — Agent-based models are ideal for investigating the complex problems of biodiversity and speciation because they allow for complex interactions between individuals and between individuals and the environment. Presented here is a "null" model that investigates three mating types – assortative, bacterial, and random – in phenotype space, as a function of the percentage of random death δ. Previous work has shown phase transition behavior in an assortative mating model with variable fitness landscapes as the maximum mutation size (μ) was varied (Dees and Bahar, 2010). Similarly, this behavior was recently presented in the work of Scott et al. (submitted), on a completely neutral landscape, for bacterial-like fission as well as for assortative mating. Here, in order to achieve an appropriate "null" hypothesis, the random death process was changed so each individual, in each generation, has the same probability of death. Results show a continuous nonequilibrium phase transition for the order parameters of the population size and the number of clusters (analogue of species) as δ is varied for three different mutation sizes of the system. The system shows increasing robustness as μ increases. Universality classes and percolation properties of this system are also explored.

3:18PM C44.00003 Characterizing Phase Transitions in a Model of Neutral Evolutionary Dynamics[1]

, ADAM SCOTT, DAWN KING, SONYA BAHAR, Department of Physics and Astronomy - University of Missouri at St. Louis — An evolutionary model was recently introduced for sympatric, phenotypic evolution over a variable fitness landscape with assortative mating (Dees & Bahar 2010). Organisms in the model are described by coordinates in a two-dimensional phenotype space, born at random coordinates with limited variation from their parents as determined by a mutation parameter, mutability. The model has been extended to include both neutral evolution and asexual reproduction in Scott et al (submitted). It has been demonstrated that a second order, non-equilibrium phase transition occurs for the temporal dynamics as the mutability is varied, for both the original model and for neutral conditions. This transition likely belongs to the directed percolation universality class. In contrast, the spatial dynamics of the model shows characteristics of an ordinary percolation phase transition. Here, we characterize the phase transitions exhibited by this model by determining critical exponents for the relaxation times, characteristic lengths, and cluster (species) mass distributions.

3:30PM C44.00004 Theory for the Emergence of Modularity in Complex Systems

, MICHAEL DEEM, JEONG-MAN PARK, Rice University — Biological systems are modular, and this modularity evolves over time and in different environments. A number of observations have been made of increased modularity in biological systems under increased environmental pressure. We here develop a theory for the dynamics of modularity in these systems. We find a principle of least action for the evolved modularity at long times. In addition, we find a fluctuation dissipation relation for the rate of change of modularity at short times. We discuss a number of biological and social systems that can be understood with this framework. The modularity of the protein-protein interaction network increases when yeast are exposed to heat shock, and the modularity of the protein-protein networks in both yeast and E. coli appears to have increased over evolutionary time. Food webs in low-energy, stressful environments are more modular than those in plentiful environments, arid ecologies are more modular during droughts, and foraging of sea otters is more modular when food is limiting. The modularity of social networks changes over time: stock brokers instant messaging networks are more modular under stressful market conditions, criminal networks are more modular under increased police pressure, and world trade network modularity has decreased

3:42PM C44.00005 The Evolution of Biological Complexity in Digital Organisms

, CHARLES OFRIA, Michigan State University — When Darwin first proposed his theory of evolution by natural selection, he realized that it had a problem explaining the origins of traits of "extreme perfection and complication" such as the vertebrate eye. Critics of Darwin's theory have latched onto this perceived flaw as a proof that Darwinian evolution is impossible. In anticipation of this issue, Darwin described the perfect data needed to understand this process, but lamented that such data are "scarcely ever possible" to obtain. In this talk, I will discuss research where we use populations of digital organisms (self-replicating and evolving computer programs) to elucidate the genetic and evolutionary processes by which new, highly-complex traits arise, drawing inspiration directly from Darwin's wistful thinking and hypotheses. During the process of evolution in these fully-transparent computational environments we can measure the incorporation of new information into the genome, a process akin to a natural Maxwell's Demon, and identify the original source of any such information. We show that, as Darwin predicted, much of the information used to encode a complex trait was already in the genome as part of simpler evolved traits, and that many routes must be possible for a new complex trait to have a high probability of successfully evolving. In even more extreme examples of the evolution of complexity, we are now using these same principles to examine the evolutionary dynamics the drive major transitions in evolution; that is transitions to higher-levels of organization, which are some of the most complex evolutionary events to occur in nature. Finally, I will explore some of the implications of this research to other aspects of evolutionary biology and as well as ways that these evolutionary principles can be applied toward solving computational and engineering problems.

4:18PM C44.00006 Intervention-Based Stochastic Disease Eradication[1] , LORA BILLINGS, Montclair State University, LUIS MIER-Y-TERAN-ROMERO, Johns Hopkins Bloomberg School of Public Health, BRANDON LINDLEY, IRA SCHWARTZ, US Naval Research Laboratory — Disease control is of paramount importance in public health with infectious disease extinction as the ultimate goal. Intervention controls, such as vaccination of susceptible individuals and/or treatment of infectives, are typically based on a deterministic schedule, such as periodically vaccinating susceptible children based on school calendars. In reality, however, such policies are administered as a random process, while still possessing a mean period. Here, we consider the effect of randomly distributed intervention as disease control on large finite populations. We show explicitly how intervention control, based on mean period and treatment fraction, modulates the average extinction times as a function of population size and the speed of infection. In particular, our results show an exponential improvement in extinction times even though the controls are implemented using a random Poisson distribution. Finally, we discover those parameter regimes where random treatment yields an exponential improvement in extinction times over the application of strictly periodic intervention. The implication of our results is discussed in light of the availability of limited resources for control.

4:30PM C44.00007 Effect of disease-induced mortality on structural network properties , LAZAROS GALLOS, NINA FEFFERMAN, Department of Ecology, Rutgers University — We study epidemic processes on complex networks, where infected nodes are either removed permanently or they can potentially recover. The process influences the localization of the infection by creating buffered zones, which in turn isolate large parts of the network. We show that there is an interesting interplay between the percentage and location of the removed population with the network structural integrity, even before reaching the critical point of total network disruption. The model can be used to determine the impact of disease-induced mortality to extinction of organisms, where destruction of the social structure can lead to loss of the species ability to recover.

4:42PM C44.00008 Contagion dynamics in time-varying metapopulation networks , ANDREA BARONCHELLI, SUYU LIU, NICOLA PERRA, MoBS Lab - Northeastern University — The metapopulation framework is adopted in a wide array of disciplines to describe systems of well separated yet connected subpopulations. The subgroups/patches are often represented as nodes in a network whose links represent the migration routes among them. The connections are usually considered as static, an approximation that is appropriate for the description of many systems, such as cities connected by human mobility, but it is obviously inadequate in those real systems where links evolve in time on a faster timescale. In the case of farmed animals, for example, the connections between each farm/node vary in time according to the different stages of production. Here we address this case by investigating simple contagion processes on temporal metapopulation networks. We focus on the SIR process, and we determine the mobility threshold for the onset of an epidemic spreading in the framework of activity-driven network models. Remarkably, we find profound differences from the case of static networks, determined by the crucial role played by the dynamical parameters defining the average number of instantaneously migrating individuals. Our results confirm the importance of addressing the time-varying properties of complex networks pointed out by the recent literature.

4:54PM C44.00009 Controlling Contagion Processes in Time Varying Networks , SUYU LIU, NICOLA PERRA, MARTON KARSAI, ALESSANDRO VESPIGNANI, Laboratory for the Modeling of Biological and Socio-Technical Systems,Northeastern University — The vast majority of strategies aimed at controlling contagion and spreading processes on networks consider the connectivity pattern of the system as quenched. In this paper, we consider the class of activity driven networks to analytically evaluate how different control strategies perform in time-varying networks. We consider the limit in which the evolution of the structure of the network and the spreading process are simultaneous yet independent. We analyze three control strategies based on node's activity patterns to decide the removal/immunization of nodes. We find that targeted strategies aimed at the removal of active nodes outperform by orders of magnitude the widely used random strategies. In time-varying networks however any finite time observation of the network dynamics provides only incomplete information on the nodes' activity and does not allow the precise ranking of the most active nodes as needed to implement targeted strategies. Here we develop a control strategy that focuses on targeting the egocentric time-aggregated network of a small control group of nodes.The presented strategy allows the control of spreading processes by removing a fraction of nodes much smaller than the random strategy while at the same time limiting the observation time on the system.

5:06PM C44.00010 Global and local threshold in a metapopulational SEIR model with quarantine[1] , MARCELO F.C. GOMES[2], LUCA ROSSI, ANA PASTORE Y PIONTTI, ALESSANDRO VESPIGNANI, Department of Physics, College of Computer and Information Sciences, Bouve' College of Health Sciences, Northeastern University — Diseases which have the possibility of transmission before the onset of symptoms pose a challenging threat to healthcare since it is hard to track spreaders and implement quarantine measures. More precisely, one main concerns regarding pandemic spreading of diseases is the prediction–and eventually control–of local outbreaks that will trigger a global invasion of a particular disease. We present a metapopulation disease spreading model with transmission from both symptomatic and asymptomatic agents and analyze the role of quarantine measures and mobility processes between subpopulations. We show that, depending on the disease parameters, it is possible to separate in the parameter space the local and global thresholds and study the system behavior as a function of the fraction of asymptomatic transmissions. This means that it is possible to have a range of parameters values where although we do not achieve local control of the outbreak it is possible to control the global spread of the disease. We validate the analytic picture in data-driven model that integrates commuting, air traffic flow and detailed information about population size and structure worldwide.

5:18PM C44.00011 Epidemic dynamics on a risk-based evolving social network , SHADRACK ANTWI, LEAH SHAW, College of William and Mary — Social network models have been used to study how behavior affects the dynamics of an infection in a population. Motivated by HIV, we consider how a trade-off between benefits and risks of sexual connections determine network structure and disease prevalence. We define a stochastic network model with formation and breaking of links as changes in sexual contacts. Each node has an intrinsic benefit its neighbors derive from connecting to it. Nodes' infection status is not apparent to others, but nodes with more connections (higher degree) are assumed more likely to be infected. The probability to form and break links is determined by a payoff computed from the benefit and degree-dependent risk. The disease is represented by a SI (susceptible-infected) model. We study network and epidemic evolution via Monte Carlo simulation and analytically predict the behavior with a heterogeneous mean field approach. The dependence of network connectivity and infection threshold on parameters is determined, and steady state degree distribution and epidemic levels are obtained. We also study a situation where system-wide infection levels alter perception of risk and cause nodes to adjust their behavior. This is a case of an adaptive network, where node status feeds back to change network geometry.

Session C45 DBIO DMP: Focus Session: Physics of Biomineralization Hilton Baltimore Holiday Ballroom 4 - Pupa Gilbert, University of Wisconsin at Madison

2:30PM C45.00001 Gradual ordering in mollusk shell nacre: theoretical modeling and experimental results[1]

, SUSAN N. COPPERSMITH, Department of Physics, University of Wisconsin-Madison — Biominerals have attracted the attention of materials scientists, biologists, and mineralogists as well as physicists because of their remarkable mechanical properties and incompletely elucidated formation mechanisms. Nacre, or mother-of-pearl, is a layered biomineral composite that is widely studied because of its self-assembled, efficient and accurately ordered architecture results in remarkable resistance to fracture. New experimental tools enable us to obtain new information about the organization and structure of the mineral tablets in nacre. Our experimental and theoretical investigations yield strong evidence that orientational ordering of these tablets is the result of dynamical self-organization.

3:06PM C45.00002 Structural and Optical Analysis of the Bio-mineralized Photonic Structures in the Shell of the Blue- Rayed Limpet *Ansates Pellucida*[1]

, MATHIAS KOLLE, Harvard University, LING LI, Massachusetts Institute of Technology, STEFAN KOLLE, JAMES WEAVER, Harvard University, CHRISTINE ORTIZ, Massachusetts Institute of Technology, JOANNA AIZENBERG, Harvard University — Many terrestrial biological organisms have evolved a variety of micro- and nanostructures that provide unique optical signatures including distinctive, dynamic coloration, high reflectivity or superior whiteness. Recently, photonic structures have also been found in the shells or spines of marine animals. Life under water imposes very distinct constraints on organisms relying on visual communication and on the designs and the materials involved in aquatic photonic structures. Here, we present a bio-mineralized calcium carbonate - based crystalline photonic system buried in the shell of the blue-rayed limpet *Ansates pellucida*. The structure consists of a layered stack of calcite lamellae with uniform thickness and inter-lamella spacing. This arrangement lies at the origin of the blue-green iridescence of the organism's characteristic stripes, which is caused by multilayer interference. The multilayer is supported by a disordered array of spherical particles with an average diameter of 300nm, likely serving to enhance the contrast of the blue stripes. We present a full structural and optical characterization of this bio-mineralised marine photonic system, supported by optical FDTD modeling.

3:18PM C45.00003 Time-resolved evolution of short- and long-range order during the transformation of amorphous calcium carbonate to calcite in the sea urchin embryo

, CHANTEL TESTER, CHING-HSUAN WU, MINNA KREJCI, LAURA MUELLER, ALEX PARK, Northwestern University, BARRY LAI, SI CHEN, CHENGJUN SUN, MAHALING BALASUBRAMANIAN, Argonne National Laboratory, DERK JOESTER, Northwestern University — The biological use of amorphous mineral precursors is thought to be directly related to the ability to create single crystalline, yet composite materials with complex shapes that are beyond our synthetic capabilities. Despite considerable effort in recent years, it has not been possible to capture the mechanistic detail of the disorder-to-order transformation that is a key element of this process. This is largely due to lack of sensitivity, lack of temporal and spatial resolution, and artifacts of sample preparation. To overcome these challenges we use strontium as a probe for X-ray absorption spectroscopy (XAS). In pulse-chase experiments, sea urchin embryos incorporate Sr2+ from Sr-enriched seawater into small volumes of the developing endoskeleton. During the chase, the transformation of the newly deposited amorphous mineral is characterized by Sr-Kα XAS of cryo-frozen whole embryos. We find that the initial mineral has short-range order resembling hydrated amorphous calcium carbonate. Within 3h, the short-range order of calcite is adopted, with long-range order developing over the next 20h. Pulse-chase experiments combined with heavy element labeling can be used in numerous mineralizing systems to study phase transformations during biological crystal growth.

3:30PM C45.00004 Reaction-diffusion controlled growth of complex structures[1]

, WILLEM NOORDUIN, Harvard University, School of Engineering and Applied Sciences, L. MAHADEVAN, Harvard University, School of Engineering and Applied Sciences, Wyss Institute for Biologically Inspired Engineering, JOANNA AIZENBERG, Harvard University, School of Engineering and Applied Sciences, Wyss Institute for Biologically Inspired Engineering, Department of Chemistry — Understanding how the emergence of complex forms and shapes in biominerals came about is both of fundamental and practical interest. Although biomineralization processes and organization strategies to give higher order architectures have been studied extensively, synthetic approaches to mimic these self-assembled structures are highly complex and have been difficult to emulate, let alone replicate. The emergence of solution patterns has been found in reaction-diffusion systems such as Turing patterns and the BZ reaction. Intrigued by this spontaneous formation of complexity we explored if similar processes can lead to patterns in the solid state. We here identify a reaction-diffusion system in which the shape of the solidified products is a direct readout of the environmental conditions. Based on insights in the underlying mechanism, we developed a toolbox of engineering strategies to deterministically sculpt patterns and shapes, and combine different morphologies to create a landscape of hierarchical multi scale-complex tectonic architectures with unprecedented levels of complexity. These findings may hold profound implications for understanding, mimicking and ultimately expanding upon nature's morphogenesis strategies, allowing the synthesis of advanced highly complex microscale materials and devices.

3:42PM C45.00005 Biomimetic control over size, shape and aggregation in magnetic nanoparticles

, NICO SOMMERDIJK, Eindhoven University of Technology — Magnetite (Fe_3O_4) is a widespread magnetic iron oxide encountered in both geological and biomineralizing systems, which also has many technological applications, e.g. in ferrofluids, inks, magnetic data storage materials and as contrast agents in magnetic resonance imaging. As its magnetic properties depend largely on the size and shape of the crystals, control over crystal morphology is an important aspect in the application of magnetite nanoparticles, both in biology and synthetic systems. Indeed, in nature organisms such as magnetotactic bacteria demonstrate a precise control over the magnetite crystal morphology, resulting in uniform and monodisperse nanoparticles. The magnetite formation in these bacteria is believed to occur through the co-precipitation of Fe(II) and Fe(III) ions, which is also the most widely applied synthetic route in industry. Synthetic strategies to magnetite with controlled size and shape exist, but involve high temperatures and rather harsh chemical conditions. However, synthesis via co-precipitation generally yields poor control over the morphology and therefore over the magnetic properties of the obtained crystals. Here we demonstrate that by tuning the reaction kinetics we can achieve biomimetic control over the size and shape of magnetite crystals but also over their organization in solution as well as their magnetic properties. We employ amino acids-based polymers to direct the formation of magnetite in aqueous media at room temperature via both the co-precipitation and the partial oxidation method. By using 2D and 3D (cryo)TEM it is shown that acidic amino acid monomers are most effective in affecting the magnetite particle morphology. By changing the composition of the polymers we can tune the morphology, the dispersibility as well as the magnetic properties of these nanoparticles.

4:18PM C45.00006 Understanding the biological stabilization of ferrihydrite and its transformation to magnetite , LYLE GORDON, DERK JOESTER, Northwestern University — The biosynthesis of magnetite in the chiton tooth begins with the formation of ferrihydrite, which is transformed into magnetite. This strategy, which employs crystallization of a precursor into the desired polymorph, is generalized across a range of organisms. However, the specific biological factors that control the transformation are not known. Our results employing atom probe tomography of chiton tooth magnetite revealed the presence of acidic proteins binding sodium and magnesium ions associated with chitin nanofibers. Using a model system we are investigating the influence of organic and inorganic additives on the stabilization of ferrihydrite and the transformation to magnetite. I will discuss the influence of a range of organic and inorganic additives on the formation and transformation of ferrihydrite within the gel. We have found that acidic polymers stabilize ferrihydrite and prevent the formation of the crystalline polymorphs. Transformation of the ferrihydrite to magnetite upon addition of ferrous iron is observed as early as 30 minutes. Taken together, the contribution of these factors to magnetite biomineralization in the presence of an organic matrix will help to elucidate biological mechanisms for nucleation, stabilization, and transformation of iron oxides.

4:30PM C45.00007 Probing physical and chemical changes in cortical bone due to osteoporosis and type 2 diabetes by solid-state NMR[1] , DONGHUA ZHOU, AMANDA TAYLOR, Department of Physics, Oklahoma State University, BETH RENDINA, BRENDA SMITH, Department of Nutritional Sciences, Oklahoma State University, DEPARTMENT OF PHYSICS COLLABORATION, DEPARTMENT OF NUTRITIONAL SCIENCES COLLABORATION — Approximately 1.5 million fractures occur each year in the U.S. due to osteoporosis, which is characterized by decreased bone mineral density and deterioration of bone micro-architecture. On the other hand, type 2 diabetes also significantly increases fracture risks, despite having a normal or even higher bone mineral density. Solid-state NMR has been applied to bone tissues from normal and disease-inflicted mouse models to study structural and chemical dynamics as the disease progresses. Proton relaxation experiments were performed to measure water populations in the bone matrix and pores. Collagen-bound water has strong influence on bone resilience, while water content in the pores reveals amount and size of pores from micro- to millimeter range. Other biochemical and atomic-scale structural alterations in the mineral and organic phases and their interface were investigated by proton, phosphorus, and carbon NMR spectroscopy. Experiments were designed to individually detect different types of phosphorus environments: near the mineral surface, similar to hydroxyapatite, and deficient of hydrogens due to substitution of the hydroxyl group by other ions. A new method was also developed for accurate quantification of each phosphorus species.

[1]The authors appreciate financial support for this project from the College of Human Sciences and the College of Arts and Sciences, Oklahoma State University.

Session C46 SPS: SPS Undergraduate III Hilton Baltimore Holiday Ballroom 5 - Melissa Hoffman, Drew University

2:30PM C46.00001 X-ray Magnetic Circular Dichroism Study of $La_{(1-x)}Sr_xMnO_3$ Thin Films[1] , XILEI KUANG, ZHUYUN XIAO, Bryn Mawr College, EUN JU MOON, STEVEN MAY, Drexel University, DAVID KEAVNEY, YAOHUA LIU, Argonne National Laboratory, X.M. CHENG, Bryn Mawr College — The perovskite manganite $La_{(1-x)}Sr_xMnO_3$ (LSMO) has attracted great attention recently due to its fundamental physics and potential applications in spintronics and data storage. In this work, we report a temperature-dependent x-ray magnetic circular dichroism (XMCD) study of epitaxial LSMO thin films deposited on orthorhombic $NdGaO_3$ (NGO) substrates grown by the molecular beam epitaxy (MBE) method. Small angle x-ray reflectivity and atomic force microscopy (AFM) results confirmed good epitaxial quality. XMCD measurements were performed at beamline 4-ID-C of the Advanced Photon Source at Argonne National Laboratory. XMCD spectra were taken in a 0.5 tesla field at temperatures ranging from 5 K to 180 K after the 0.5 tesla field cool. The total electron yield absorption spectra showed the oxide state characteristics of Mn, and the shapes of the Mn and O dichroism spectra change with temperature.

2:42PM C46.00002 Synthesis of Ag_2O Films using RF Magnetron Sputtering , ERIC KAISER, JOHN BONINI, Department of Physics and Astronomy, Rowan University, WILLIAM FORDHAM, Department of Chemical Engineering, Rowan University, MATTHEW LONG, Department of Physics and Astronomy, Rowan University, JOSEPH NATALE, SEAN REDMOND, ADAM WESTERLAND, Department of Electrical and Computer Engineering, Rowan University, MICHAEL YANAKAS, XIAO HU, SAMUEL LOFLAND, Department of Physics and Astronomy, Rowan University, ROBERT KRCHNAVEK, Department of Electrical and Computer Engineering, Rowan University, JEFFREY HETTINGER, Department of Physics and Astronomy, Rowan University — Silver oxide (Ag_2O) thin films were successfully grown using reactive RF magnetron sputtering onto SiO_2 and Al_2O_3 substrates at room temperature. Synthesis of these films was achieved in a gaseous mixture of oxygen and argon which was 40% oxygen. X-Ray diffraction tests yielded numerous peak intensities at angles correlating directly to Ag_2O. Deposition rates were shown to be a significantly greater on Al_2O_3 in comparison to SiO_2. Understanding this difference is a point of future investigations. ASTM D3359 adhesion tests as well as four terminal conductivity tests were also performed on the films and will be reported.

2:54PM C46.00003 Properties of Ti_8C_5 thin films created at different temperatures using magnetron sputtering , CHRISTOPHER ROTELLA, JEFFREY HETTINGER, EMMA CORTES, SAMUEL LOFLAND, Rowan University Department of Physics and Astronomy, MIN HEON, Drexel University Department of Materials Science, CARL LUNK, Rowan University Department of Physics and Astronomy — We were able to create thin films of Ti_8C_5 on c-axis oriented single crystal Al_2O_3 using both co-deposition magnetron sputtering and reactive magnetron sputtering. While TiC is generally used as a precursor film when making "on-chip" super capacitors, Ti_8C_5 is of similar composition and may have some advantages when making super capacitors. The Ti_8C_5 is more porous and demonstrates slightly different properties than TiC. Film deposition was optimized using elemental composition data obtained by WDXRF and characterized using XRD. It was found that composition and phase of Ti_8C_5 greatly depended on the temperatures at which the samples were grown. We outline the different parameters at which Ti_8C_5 grows best by outlining features of the Ti-C phase diagram.

3:06PM C46.00004 Field Directed Ordering in Magnetic Nanocrystal Structures , STUART LAWSON, ROBERT MEULENBERG, University of Maine — Iron oxide nanocrystals (NCs) have been the focus of intense research owing to the observation of tunable magnetic properties which could lead to advances in many fields including magnetic storage devices and medicine. We have been targeting the use of iron oxide NCs as magnetoresistance (MR) based sensors using ordered NC arrays. In this work, we will present our efforts toward using external magnetic fields to induce intraparticle ordering in iron oxide NC drop cast films. We use x-ray diffraction to analyze effects of the external fields on the NC array structure, while using SQUID magnetometry to probe the effects of NC interactions on the magnetic properties of iron oxide NCs ranging from 5 - 20 nm in diameter. MR measurements suggest large changes in the MR ratio can be achieved using the directed ordering approach for NC arrays. Our work could provide new avenues towards the fabrication of new magnetic devices.

3:18PM C46.00005 Photocatalysis of Thin Films of TiO_2 on Al_2O_3 Substrates[1] , DAVID TURBAY, Brown University, TIMOTHY LUTTRELL, MATTHIAS BATZILL, University of South Florida — Titanium dioxide (TiO_2) has grown to be one of the most promising photocatalysts in recent years because of extensive applications in renewable and clean energy. The rise in demand for these new energies has driven an increase in research on metal oxides and their properties. Our interest in growing the rutile structure of TiO_2 stems from its lower excitation energy (3.0 eV) when compared to anatase (3.2 eV), which indicates it has better activity in the visible portion of the spectrum. It has been shown that sapphire (Al_2O_3) substrates are conducive to epitaxial rutile growth. In this study, we measured the photocatalytic activity of thin films of TiO_2 on r-Al_2O_3 (1 -1 0 2) substrates. We used PLD and MBE to grow the films, which were characterized using XPS and AFM. Photoactivity was measured via the decomposition of methyl orange on the film's surface using a UV/VIS spectrophotometer. The decomposition of this organic compound is driven by oxidation-reduction reactions on the surface of the TiO_2 film. From this, we calculated the charge carrier diffusion length and compared it to that of anatase.

3:30PM C46.00006 Synthesis and Characterization of Ni-NiO Nanocomposites for Optoelectronic Applications , G. BEAVER, A. LAUDARI, K. GHOSH, Missouri State University — LEDs and solar cells are becoming increasingly ubiquitous in modern society as they offer low energy consumption in a world where energy concerns are becoming increasingly prominent. Nonetheless, these devices have to overcome several shortfalls before they will be able to effectively replace traditional devices. In particular, these devices are fabricated using diodes, which depend on p-n junctions. While n-type oxide semiconductors are relatively plentiful, p-types are harder to produce. This research attempts to create a p-type oxide semiconductor with long lifespan and low resistivity. Using pulse laser deposition, NiO thin films with Ni nanoparticles were fabricated on quartz and Al_2O_3 substrates. Detailed structures of the thin films were studied by X-Ray diffraction, scanning electron microscopy, and Raman spectroscopy techniques. Physical parameters such as magnetic moment of nickel, carrier concentration, and bandgap have been estimated using ultra violet-visible spectroscopy, photoluminescence, Hall effect, and magnetization data. Detailed results will be discussed in the presentation. This work is supported by NSF (Award Number DMR-0907037).

3:42PM C46.00007 ABSTRACT WITHDRAWN –

3:54PM C46.00008 Experimental and analytical study of ionic self-assembly of silica and titania nanoparticles , BRIAN SIMPSON, WILL BANKS, VINCENT KIM, ANDREW SEREDINSKI, KATY WILSON, IRINA MAZILU, DAN MAZILU, Washington and Lee University — Using the ionically self-assembled monolayers (ISAM) technique we investigate the time dependence of the surface coverage of thin films that consist of alternating layers of silica or titania nanoparticles deposited on polymer substrates. We conduct experiments in order to investigate the significant observable factors that affected the quality of the coatings including the dipping time, pH, and the molarity of the silica, titania, and PDDA solutions. Using SEM micrographs, we analyzed the surface coverage and compared it to analytical results obtained using a cooperative sequential adsorption model.

4:06PM C46.00009 Nanoscale Thermal Analysis of Organic Solar Cells , KYLE KELLEY, EITAN LEES, CORTNEY BOUGHER, TONYA COFFEY, BRAD CONRAD, Appalachian State University, PATRICK HEAPHY, CHRIS COLLISON, SUSAN SPENCER, JEREMY CODY, Rochester Institute of Technology — Our research uses atomic force microscopy (AFM) and a Nanoscale Thermal Analysis (NanoTA) system from Anasys Instruments to correlate the morphology of local structures with the thermal material properties of organic solar cells. The NanoTA system uses AFM probes that can be heated up to 350°C over a 50 nm region to quantify the melting transition temperatures of nanoscale regions. We show results for two materials: $D_iPSQ[OH]_2$ and PCBM, for both pure and systematically blended thin-films. We have characterized the morphology and melting points of the blend films with increasing anneal time, and differences in melting points of blended as compared to pure samples.

4:18PM C46.00010 Characterization of organic solar cell morphology , EITAN LEES, KYLE KELLY, CORTNEY BOUGHER, Appalachian State University, SUSAN SPENCER, PATRICK HEAPHY, JEREMY CODY, CHRISTOPHER COLLISON, Rochester Institute of Technology, TONYA COFFEY, BRAD CONRAD, Appalachian State University — The morphology of organic solar cell bulk heterojunctions were characterized using atomic force microscopy (AFM). The RMS roughness of solar cells composed of 1,3-bis[4-(N,N-diisopentylamino)-2,6-dihydroxyphenyl]squaraine [$DiPSQ(OH)_2$] and phenyl[C_{61}]-butyric acid methyl ester [PCBM] through spin casting were measured. Solar cells of various blend concentrations, anneal times, and cooling methods were characterized. Through RMS roughness analysis we can study the crystallization process in solar cell fabrication. Morphology will be related to device characterization.

4:30PM C46.00011 Computational study of a class of cooperative sequential adsorption models on Cayley trees and two- dimensional lattices , WILL BANKS, ANDREW SEREDINSKI, BRIAN SIMPSON, VINCENT KIM, IRINA MAZILU, DAN MAZILU, Washington and Lee University — We present a Monte Carlo simulation study of a class of cooperative sequential adsorption models with constant and variable attachment rates and their possible applications for ionic self-assembly of thin films, drug encapsulation of nanoparticles and susceptible-infected-recovered epidemic models. We do a comparison study of these models on a Cayley tree and a two - dimensional lattice and discuss the cases for which four-branch Cayley trees are good approximations for two -dimensional lattices.

4:42PM C46.00012 Characterization of Ion Movement in Light-Emitting Electrochemical Cells via ToF-SIMS , TYKO SHOJI, Department of Physics and Astronomy, Western Washington University, Bellingham, WA, USA, ZIHUA ZHU, Environmental Molecular Sciences Laboratory, Pacific Northwest National Laboratory, Richland, WA, USA, ANTON ILKEVICH, Department of Chemistry, Western Washington University, Bellingham, WA, USA, JANELLE LEGER, Department of Physics and Astronomy, Western Washington University, Bellingham, WA, United States — An emerging advantage of organic semiconductors is their ability to conduct ions in applications such as light-emitting electrochemical cells (LECs), photovoltaic devices, and electrochromic devices. This ability of organic materials to conduct both ionic and electronic currents in the solid state sets these materials apart from their inorganic counterparts. However the fundamental electrochemical processes are not well characterized. Evidence suggests that the profiles of ions and electrochemical doping in the polymer film during operation significantly impact the performance and stability of the device. Here, we present our findings from direct profiling of ion distributions in LECs following application of voltage, via time-of-flight secondary ion mass spectrometry. Ion distributions were characterized with regard to film thickness, salt concentration, applied voltage, and relaxation over time. Results provide insight into correlation between ion profiles and device performance and potential approaches to tuning electrochemical doping processes in LECs.

4:54PM C46.00013 Asymmetric laser sideband generation with a tapered semiconductor amplifier[1] , MICHAEL YANAKAS, MICHAEL LIM, Department of Physics and Astronomy, Rowan University — We have constructed a free-space, frequency-shifted feedback amplifier using a tapered semiconductor gain element. The general layout of the system is similar to that described in Littler, et al., *Opt. Comm.* **88**, 523 (1992). Traveling-wave feedback is demonstrated with the $m = -1$ order of several different acousto-optic modulators driven at variable frequency. Asymmetric sideband production is observed in the rf spectrum of a fast photodiode and in the transmission of a scanning Fabry-Perot interferometer. The number of asymmetric modes is controlled with the AOM rf drive power and the seed laser optical power.

[1]Supported by NSF PHY-0613659

5:06PM C46.00014 Synchronization in a network of phase-coupled oscillators: the role of learning and time delay , LIAM TIMMS, LARS ENGLISH, Dickinson College — We investigate numerically the interplay of network "learning" and finite signal speed in one and two-dimensional arrays of coupled Kuramoto oscillators. The finite signal speed is introduced into the dynamical system via a time-delay in the coupling. The network structures we examine include various one and two-dimensional arrays with both long and short-range connectivity; the structure of these arrays is imposed via a time delay and a connection matrix. The learning is governed by the Hebbian learning rule which allows the coupling strengths between pairs of oscillators to vary dynamically. It corresponds to a neurological type of learning in which the synapses between neural oscillators increase in strength when they fire action potentials together. We explore the coherent spatio-temporal patterns that can emerge as a function of model parameters such as learning rate and signal speed.

Monday, March 18, 2013 2:30PM - 5:30PM –

Session C47 GSNP: Invited Session: Statistical Physics for Systemic Risk and Infrastructural Interdependencies Hilton Baltimore Holiday Ballroom 6 - Antonia Scala, CNR-ISC Institute for Complex Systems

2:30PM C47.00001 Self-consistency in Capital Markets , HAMID BENBRAHIM, TD Ameritrade — Capital Markets are considered, at least in theory, information engines whereby traders contribute to price formation with their diverse perspectives. Regardless whether one believes in efficient market theory on not, actions by individual traders influence prices of securities, which in turn influence actions by other traders. This influence is exerted through a number of mechanisms including portfolio balancing, margin maintenance, trend following, and sentiment. As a result market behaviors emerge from a number of mechanisms ranging from self-consistency due to wisdom of the crowds and self-fulfilling prophecies, to more chaotic behavior resulting from dynamics similar to the three body system, namely the interplay between equities, options, and futures. This talk will address questions and findings regarding the search for self-consistency in capital markets.

3:06PM C47.00002 DebtRank: Distress Cascades and Financial Immunization , STEFANO BATTISTON, ETH Zurich — Systemic risk, here meant as the risk of default of a large portion of the financial system, depends on the network of financial exposures among institutions. However, there is no widely accepted methodology to determine the systemically important nodes in a network. To fill this gap, we introduce, DebtRank, a novel measure of systemic impact that overcomes the limitations of the current state of the art. DebtRank is inspired by feedback-centrality in complex networks but delivers an estimation of systemic impact in monetary terms of the impact of distress on individuals and groups of institutions. We illustrate various applications of DebtRank to real world financial networks.

3:42PM C47.00003 Interdependent complex systems and critical infrastructures , RAISSA D'SOUZA, University of California, Davis — Collections of networks are at the core of modern society, spanning technological, biological and social systems. Understanding the network structure of individual systems has lead to tremendous advances in the past decade. Yet, in reality, none of these individual networks lives in isolation and the consequences of interdependence can be surprising. Here we present results from random graph models of interacting networks. First, from a structural perspective, we show that interactions between different types of networks can enhance or delay the onset of large scale connectivity. Second, we consider a dynamical process on coupled networks. We use the classic Bak-Tang-Wiesenfeld sandpile model as an abstraction for cascades of load shedding and show that their can exist optimal levels of interconnectivity between networks that provide stabilizing effects with respect to cascades. We will also discuss recent advances in understanding interdependent social and technological networks which rely on coupling game theory to statistical physics and spatial models of random graphs that attempt to capture interdependencies in critical infrastructure systems.

4:18PM C47.00004 The Fragility of Interdependency: Coupled Networks Switching Phenomena[1] , H. EUGENE STANLEY, Center for Polymer Studies at Boston University — Recent disasters ranging from abrupt financial "flash crashes" and large-scale power outages to sudden death among the elderly dramatically exemplify the fact that the most dangerous vulnerability is hiding in the many interdependencies among different networks. In the past year, we have quantified failures in model of interconnected networks, and demonstrated the need to consider mutually dependent network properties in designing resilient systems. Specifically, we have uncovered new laws governing the nature of switching phenomena in coupled networks, and found that phenomena that are continuous "second order" phase transitions in isolated networks become discontinuous abrupt "first order" transitions in interdependent networks [S. V. Buldyrev, R. Parshani, G. Paul, H. E. Stanley, and S. Havlin, "Catastrophic Cascade of Failures in Interdependent Networks," Nature 464, 1025 (2010); J. Gao, S. V. Buldyrev, H. E. Stanley, and S. Havlin, "Novel Behavior of Networks Formed from Interdependent Networks," Nature Physics 8, 40 (2012). We conclude by discussing the network basis for understanding sudden death in the elderly, and the possibility that financial "flash crashes" are not unlike the catastrophic first-order failure incidents occurring in coupled networks. Specifically, we study the coupled networks that are responsible for financial fluctuations. It appears that "trend switching phenomena" that we uncover are remarkably independent of the scale over which they are analyzed. For example, we find that the same laws governing the formation and bursting of the largest financial bubbles also govern the tiniest finance bubbles, over a factor of 1,000,000,000 in time scale [T. Preis, J. Schneider, and H. E. Stanley, "Switching Processes in Financial Markets," Proc. Natl. Acad. Sci. USA 108, 7674 (2011); T. Preis and H. E. Stanley, "Bubble Trouble: Can a Law Describe Bubbles and Crashes in Financial Markets?" Physics World 24, No. 5, 29 (May 2011)].

[1]This work was carried out in collaboration with a number of colleagues, including T. Preis, J. J. Schneider, S. Havlin, R. Parshani, S. V. Buldyrev, J. Gao, and G. Paul–see "When Networks Network," Science News, 22 Sept. 2012.

4:54PM C47.00005 Information and disease diffusion in dynamic social environments , ALESSANDRO VESPIGNANI, Northeastern University — In recent years the increasing availability of computer power and informatics tools has enabled the gathering of reliable data quantifying the complexity of socio-technical systems. Data-driven computational models have emerged as appropriate tools to tackle the study of contagion and diffusion processes as diverse as epidemic outbreaks, information spreading and Internet packet routing. These models aim at providing a rationale for understanding the emerging tipping points and nonlinear properties that often underpin the most interesting characteristics of socio-technical systems. Here I review some of the recent progress in modeling contagion and epidemic processes that integrates the complex features and heterogeneities of real-world systems.

Monday, March 18, 2013 5:45PM - 6:45PM –

Session E11 APS: Special Outreach Session: Meso-Physics 310 - Laura H. Greene, University of Illinois at Urbana-Champaign

7:30PM E11.00001 Meso Scale Science: Challenges and Opportunities , HARRIET KUNG, Basic Energy Sciences, Department of Energy, Office of Science — The Director of DOE's Office of Science issued a charge to the Basic Energy Sciences Advisory Committee (BESAC) in 2011 to define the research agenda for mesoscale science, the regime where classical, quantum, and nanoscale science meet. The charge builds on over a decade's strategic planning BESAC has undertaken that establishes the importance of nanoscale science – atomic and molecular scale understanding of how nature works and how this relates to advancing the frontiers of science and innovation. Beyond a new level of science, the opportunity for new, cheaper and more efficient technology and solutions to societal problems is significant and timely. This presentation will discuss the impact of the report and how it has shaped and will continue to inform future research programs in DOE Office of Science.

7:50PM E11.00002 From Quanta to the Continuum: Opportunities for Mesoscale Science , GEORGE CRABTREE[1], Materials Science Division, Argonne National Laboratory; Depts of Physics, Electrical and Mechanical Engineering University of Illinois at Chicago — Mesoscale science embraces the regime where atomic granularity and quantization of energy yield to continuous matter and energy, collective behavior reaches its full potential, defects, fluctuations and statistical variation emerge, interacting degrees of freedom create new phenomena, and homogeneous behavior gives way to heterogeneous structure and dynamics. Mesoscale architectures form a hierarchy extending from atoms and molecules through polymers, supramolecular assemblies, periodic lattices, multilayers, nanocrystal arrays and multiphase materials. Mesoscale science builds on the foundation of nanoscale knowledge and tools that the community has developed over the last decade and continues to develop. Mesoscale phenomena offer a new scientific opportunity: designing architectures and interactions among nanoscale units to create new macroscopic behavior and functionality. Examples of mesoscale successes, challenges and opportunities will be described.

A more complete discussion of mesoscale science can be found in the BESAC report, *From Quanta to the Continuum: Opportunities for Mesoscale Science*, http://science.energy.gov/bes/news-and-resources/reports/basic-research-needs/

Innovative community input on opportunities for mesoscale science can be found on the *Mesoscopic Materials and Chemistry* website, http://www.meso2012.com/

Tuesday, March 19, 2013 8:00AM - 11:00AM –

Session F1 DCMP GSNP: Invited Session: Physics from the Laboratory to the Universe: Davisson-Germer/Heineman/Onsager/Lilienfeld Prizes Ballroom I - Barbara Jones, International Business Machines

8:00AM F1.00001 Davisson-Germer Prize in Atomic or Surface Physics Lecture: Line 'Em All Up: Macromolecular Assembly at Liquid Interfaces , GERALDINE RICHMOND, Department of Chemistry, University of Oregon — Advances in our molecular level understanding of the ubiquitous fluid interface comprised of a hydrophobic fluid medium, and an aqueous solution of soluble ions and solutes has been slow until recently. This more recent upsurge in interest and progress comes from advances in both experimental and computational techniques as well as the increasingly important role that this interface is playing in such areas as green chemistry, nanoparticle synthesis, improved oil and mineral recovery and water purification. The presentation will focus on our most recent efforts in understanding (1) the molecular structure of the interface between two immiscible liquids, (2) the penetration of aqueous phase ions into the interfacial region and their effect on its properties, and (3) the structure and dynamics of the adsorption of surfactants, polymers and nanoparticles at this interface. To gain insights into these processes we use a combination of vibrational sum frequency spectroscopy, surface tension measurements using the pendant drop method, and molecular dynamics simulations. The results demonstrate that weak interactions between interfacial oil and water molecules create an interface that exhibits a high degree of molecular structuring and ordering, and with properties quite different than what is observed at the air-water interface. As a consequence of these interfacial oil-water interactions, the interface provides a unique environment for the adsorption and assembly of ions, polymers and nanoparticles that are drawn to its inner-most regions. Examples of our studies that provide new insights into the unique nature of adsorption, adsorption dynamics and macromolecular assembly at this interface will be provided.

8:36AM F1.00002 Lars Onsager Prize Lecture: Statistical Dynamics of Disordered Systems , DANIEL S. FISHER, Stanford University — The properties of many systems are strongly affected by quenched disorder that arose from their past history but is frozen on the time scales of interest. Although equilibrium phases and phase transitions in disordered materials can be very different from their counterparts in pure systems, the most striking phenomena involve non-equilibrium dynamics. The state of understanding of some of these will be reviewed including approach to equilibrium in spin glasses and the onset of motion in driven systems such as vortices in superconductors or earthquakes on geological faults. The potential for developing understanding of short-term evolutionary dynamics of microbial populations by taking advantage of the randomness of their past histories and the biological complexities will be discussed briefly.

9:12AM F1.00003 Dannie Heineman Prize for Mathematical Physics Prize Lecture: Correlation Functions in Integrable Models: Ising Model and Monodromy Preserving Deformation , TETSUJI MIWA, Kyoto University — Studies on integrable models in statistical mechanics and quantum field theory originated in the works of Bethe on the one-dimensional quantum spin chain and the work of Onsager on the two-dimensional Ising model. I will talk on the discovery in 1977 of the link between quantum field theory in the scaling limit of the two-dimensional Ising model and the theory of monodromy preserving linear ordinary differential equations. This work was the staring point of our journey with Michio Jimbo in integrable models, the journey which finally led us to the exact results on the correlation functions of quantum spin chains in 1992.

9:48AM F1.00004 Dannie Heineman Prize for Mathematical Physics Prize Lecture: Correlation Functions in Integrable Models II: The Role of Quantum Affine Symmetry , MICHIO JIMBO, Rikkyo University — Since the beginning of 1980s, hidden infinite dimensional symmetries have emerged as the origin of integrability: first in soliton theory and then in conformal field theory. Quest for symmetries in quantum integrable models has led to the discovery of quantum groups. On one hand this opened up rapid mathematical developments in representation theory, combinatorics and other fields. On the other hand it has advanced understanding of correlation functions of lattice models, leading to multiple integral formulas in integrable spin chains. We shall review these developments which continue up to the present time.

10:24AM F1.00005 Julius Edgar Lilienfeld Prize Lecture: Mapping the Universe: Physics Writ Large , MARGARET GELLER, Harvard-Smithsonian Center fro Astrophysics — The age of mapping the universe began in earnest in the late twentieth century. I will describe the enormous strides we have made in mapping the galaxy distribution and in understanding its nature and history. I will show how techniques for measuring the (primarily dark) matter distribuion in massive systems of galaxies are an astrophysical route to tests of fundamental physics.

Tuesday, March 19, 2013 8:00AM - 11:00AM –

Session F2 DCMP: Invited Session: Low Energy Excitations in Iridates Ballroom II - Paolo Radaelli, University of Oxford

8:00AM F2.00001 Correlated phases and excitations in the iridates[1] , LEON BALENTS, Kavli Institute of Theoretical Physics, UCSB — The iridium oxides form an intriguing set of materials controlled by a delicate balance of kinetic, spin-orbit, and Coulomb interaction energies. Many possible exotic phases and phenomena have been suggested for them in the literature. I will review the theoretical context for these compounds, emphasizing effects arising from the combination of strong spin-orbit coupling and electron-electron correlations. Finally, I will discuss our group's on-going efforts to understand the excitations and magnetic phases in these materials.

[1]I acknowledge support from the DOE BES grant DE-FG02-08ER46524, and the NSF MRSEC program, grant DMR1121053

8:36AM F2.00002 RIXS Studies of Magnetic Excitations in Layered Iridates , B.J. KIM, Materials Science Division, Argonne National Laboratory — $5d$ Transition metal oxides lie at the intersection of strong spin-orbit coupling and electron correlation, and open a new playground for novel electronic phases with unconventional magnetic, superconducting, magneto-electric, and band-topological properties. In particular, a rich variety of magnetic phases are predicted from the magnetic interactions that take various forms ranging from Heisenberg to bond-directional dipolar-like couplings in the strong spin-orbit coupling limit. In this talk, I will review on these novel aspects of magnetism in iridates studied using resonant x-ray scattering techniques. Specifically, following topics will be discussed: (i) Heisenberg-like nature of magnetic coupling in Sr_2IrO_4 that sharply contrast with the unusually large spin-wave gap in $Sr_3Ir_2O_7$, (ii) the origin of strong Ising anisotropy in $Sr_3Ir_2O_7$, and (iii) the contrasting dynamics of "spin-orbit exciton" modes in the Heisenberg and Ising magnets.

9:12AM F2.00003 Interplay of spin-orbit coupling, correlations, and crystal anisotropy in 5d oxides , LIVIU HOZOI, Institute for Theoretical Solid State Physics, IFW Dresden, Germany — We investigate the correlated d-level electronic structure of $5d$ Ir and Os oxide compounds by fully *ab initio* quantum-chemical many-body calculations on finite embedded clusters. The wave-function quantum-chemical methods provide a promising alternative to density-functional-based approaches to the electronic structure of solids. The computed d-d excitations in square-lattice, honeycomb, pyrochlore, and chain-like iridates compare well with recent RIXS (resonant inelastic x-ray scattering) data. We also perform a detailed analysis of the relativistic spin-orbit wave functions and compute observables such as the $\langle \mathbf{L}\cdot\mathbf{S}\rangle$ ground-state expectation value of the spin-orbit operator. The latter is in principle accessible from x-ray absorption and provides information on the role of t_{2g}–e_g couplings in the ground-state wave function and on the strength of non-cubic fields that lift the degeneracy of the t_{2g} levels. As concerns the departure from cubic symmetry, interesting effects are found in $A_2Ir_2O_7$ pyrochlores, where the highly anisotropic, hexagonal configuration of the adjacent A-site ions breaks cubic symmetry even in the absence of O-ligand trigonal distortions and moreover competes with the latter. Our findings open new perspectives in pyrochlore oxides. In 227 iridates, the outcome of this competition is decisive for the actual realization of any type of non-trivial topological ground state. In 227 spin systems with $S>1/2$, e.g., $Cd_2Os_2O_7$, this interplay decides the sign of the single-ion anisotropy and the degree of magnetic frustration.

9:48AM F2.00004 Low energy excitations in iridates studied with Resonant Inelastic X-ray Scattering[1] , XUERONG LIU[2], 1) Brookhaven National Laboratory; 2) Institute of Physics, Chinese Academy of Sciences — In the iridium oxides, the strong spin-orbit coupling (SOC) of the 5d iridium electrons entangles the orbital and spin degrees of freedom, providing opportunities for exotic magnetic states with highly anisotropic exchange interactions. At the same time, the spatially extended 5d electrons are expected to have much stronger hybridization with the oxygen 2p orbitals, comparing with that in 3d transition element compounds. Both factors make crystal symmetry and local environment crucial in determining the electronic and magnetic properties of the iridates. We present here our resonant inelastic X-ray scattering (RIXS) studies of a number of octahedrally coordinated iridates with special structures, exploring these effects. In particular, for the 1-D spin 1/2 chain compound, Sr_3CuIrO_6, the wavefunction of the hole in the t2g manifold was reconstructed based on the RIXS spectra. Our results show that it is significantly modified from the isotropic shape expected for $J_{eff} = 1/2$ states in the strong SOC limit, due to the distortion of the oxygen octahedral cage. This distortion is comparable to, or smaller than, that present in most iridates and thus this work emphasizes the importance of local symmetry for the iridate families. Further, the magnetic excitations of this material were also measured. A large gap of ~30 meV, was found, comparable to the magnetic dispersion bandwidth. This is in contrast to the gapless dispersion expected for linear chain with isotropic Heisenberg exchange interaction. We also studied $Na_4Ir_3O_8$ which has a hyperkagome lattice, and is a candidate quantum spin liquid. Here, a low energy continuum is observed below the d-d excitations. Optical conductivity measurements performed on the same sample and polarization dependence of the RIXS signal suggest that these excitations are magnetic in origin, agreeing with the spin-liquid state prediction.

10:24AM F2.00005 Spin Dynamics in Na2IrO3 Probed by Inelastic Neutron Scattering: Implications for Kitaev Physics[1] , RADU COLDEA, University of Oxford — We explore the spin dynamics in the layered antiferromagnet Na_2IrO_3, a candidate for the Kitaev spin model on the honeycomb lattice [1]. Using powder inelastic neutron scattering with an optimised setup to minimise neutron absorption by Ir we observed evidence for dispersive spin wave excitations of the Ir moments below a zone-boundary energy of 5 meV [2]. Results are compared quantitatively with predictions of a Kitaev-Heisenberg model, as well as a Heisenberg model with further neighbour couplings, both with a magnetic ground state of zig-zag ferromagnetic chains ordered antiferromagnetically. By combining single-crystal xray diffraction and ab initio calculations we propose a revised crystal structure model with significant departures from the ideal case of regular IrO6 octahedra and 90° Ir-O-Ir bonds required for large Kitaev exchanges.

Session F3 GQI DAMOP: Invited Session: Quantum Computing in AMO Ballroom III - Ivan Deutsch, University of New Mexico

8:00AM F3.00001 Quantum Computation with Trapped Rydberg Atoms[1] , MARK SAFFMAN, University of Wisconsin — Highly excited atomic Rydberg states provide strong, long range dipolar interactions which can be used to create entanglement between atoms, between atoms and optical photons, and between atoms and microwave photons. I will review recent progress in this rapidly developing area including optical trapping of Rydberg atoms, experiments with a 2D array of qubits, and progress towards a coherent quantum interface between neutral atom and superconducting qubits.

[1]Work supported by NSF, DARPA, IARPA

8:36AM F3.00002 Quantum computation with atomic ensembles , KLAUS MOELMER, University of Aarhus — No abstract available.

9:12AM F3.00003 Hybrid quantum information processing , AKIRA FURUSAWA, The University of Tokyo — There are two types of schemes for quantum information processing (QIP). One is based on qubits, and the other is based on continuous variables (CVs), where the computational basis for qubit QIP is $\{|0\rangle, |1\rangle\}$ and that for CV QIP is $\{|x\rangle\}$ $(-\infty < x < \infty)$. A universal gate set for qubit QIP is {'bit flip'σ_x, 'phase flip'σ_z, 'Hadamard gate'H, '$\pi/8$ gate', 'controlled NOT (CNOT) gate'}. Similarly, a universal gate set for CV QIP is {'x-displacement'$\hat{D}(x)$, 'p-displacement'$\hat{D}(ip)$, 'Fourier gate'$\hat{F}$, 'cubic phase gate'$e^{ik\hat{x}^3}$, 'quantum non-demolition (QND) gate'}. There is one-to-one correspondence between them. CV version of 'bit flip'σ_x is 'x-displacement'$\hat{D}(x)$, which changes the value of the computational basis. Similarly, CV version of 'phase flip'σ_z is 'p-displacement'$\hat{D}(ip)$, where 'phase flip'σ_z switches the "value" of 'conjugate basis' of qubit $\{|+\rangle, |-\rangle\}$ $(|\pm\rangle = (|0\rangle \pm |1\rangle)/\sqrt{2})$ and 'p-displacement'$\hat{D}(ip)$ changes the value of CV conjugate basis $\{|p\rangle\}$. 'Hadamard' and 'Fourier' gates transform computational bases to respective conjugate bases. CV version of '$\pi/8$ gate' is a 'cubic phase gate'$e^{ik\hat{x}^3}$, and CV version of CNOT gate is a QND gate. However, the origin of nonlinearity for QIP is totally different, here the very basic nonlinear operation is calculation of multiplication and of course it is the heart of information processing. The nonlinearity of qubit QIP comes from a CNOT gate, while that of CV QIP comes from a cubic phase gate. Since nonlinear operations are harder to realize compared to linear operations, the most difficult operation for qubit is a CNOT gate, while the counter part, a QND gate, is not so difficult. CNOT and QND gates are both entangling gates, it follows that creating entanglement is easier for CV QIP compared to qubit QIP. Here, creating entanglement is the heart of QIP. So, it is a big advantage of CV QIP. On the other hand, the fidelity of CV QIP is not so high because perfect fidelity needs infinite energy, which comes from the infinite dimensionality of CV QIP. To overcome the difficulty, "hybrid" approach is proposed. In this approach, qubits are used as inputs for CV QIP. It is possible because qubits can be regarded as a special case of CVs. So, we can circumvent the infinite dimensionality problem of CV QIP by using qubits as the inputs. The basic example is qubit teleportation with a CV teleporter, where the qubit is a so-called "dual-rail" qubit with a single photon; $c_0|1,0\rangle + c_1|0,1\rangle$. We recently succeeded in creating time-bin qubits with single photons, and now we are working on the teleportation experiment with the technology developed for teleportation of highly nonclassical wave packets of light.

9:48AM F3.00004 Photonic quantum technologies , JEREMY O'BRIEN, University of Bristol — Of the approaches to quantum computing [1], photons are appealing for their low-noise properties and ease of manipulation [2], and relevance to other quantum technologies [3], including communication, metrology [4] and measurement [5]. We report an integrated waveguide approach to photonic quantum circuits for high performance, miniaturization and scalability [6–10]. We address the challenges of scaling up quantum circuits using new insights into how controlled operations can be efficiently realised [11], demonstrating Shor's algorithm with consecutive CNOT gates [12] and the iterative phase estimation algorithm [13]. We have shown how quantum circuits can be reconfigured, using thermo-optic phase shifters to realise a highly reconfigurable quantum circuit [14], and electro-optic phase shifters in lithium niobate to rapidly manipulate the path and polarisation of telecomm wavelength single photons [15]. We have addressed miniaturisation using multimode interference architectures to directly implement NxN Hadamard operations [16], and by using high refractive index contrast materials such as SiO_xN_y, in which we have implemented quantum walks of correlated photons [17], and Si, in which we have demonstrated generation of orbital angular momentum states of light [18]. We have incorporated microfluidic channels for the delivery of samples to measure the concentration of a blood protein with entangled states of light [19]. We have begun to address the integration of superconducting single photon detectors [20] and diamond [21,22] and non-linear [23,24] single photon sources. Finally, we give an overview of recent work on fundamental aspects of quantum measurement, including a quantum version of Wheeler's delayed choice experiment [25].

10:24AM F3.00005 Quantum information processing with trapped ions[1] , JOHN GAEBLER, National Institute for Standards and Technologies — Trapped ions are one promising architecture for scalable quantum information processing. Ion qubits are held in multizone traps created from segmented arrays of electrodes and transported between trap zones using time varying electric potentials applied to the electrodes. Quantum information is stored in the ions' internal hyperfine states and quantum gates to manipulate the internal states and create entanglement are performed with laser beams and microwaves. Recently we have made progress in speeding up the ion transport and cooling processes that were the limiting tasks for the operation speed in previous experiments. We are also exploring improved two-qubit gates and new methods for creating ion entanglement.

Session F4 FIAP: Industrial Physics Forum: Frontiers in Biophysics Ballroom IV - James Hollenhorst, Agilent Technologies

8:00AM F4.00001 Biophysical Variables Which Are Available from Single-Molecule Optical Studies[1] , W.E. MOERNER, Stanford University — Since the first optical detection and spectroscopy of a single molecule in a condensed phase host in 1989, a wealth of new information has been obtained from time-dependent measurements and single-molecule probability distributions. When single-molecule imaging is combined with active control of the emitter concentration, enhanced spatial resolution well beyond the optical diffraction limit can be obtained for a wide array of biophysical structures in cells. Single-molecule emitters also provide precise and accurate 3D position as well as dipole moment orientation when combined with Fourier plane processing. Examples here include the implementation of a double-helix point spread function for 3D position information (Backlund, Lew et al. PNAS (2012)), and the creation of a quadrated pupil response to sense emission dipole orientations (Backer et al. submitted 2012). If high-resolution spatial information is not needed, a machine called the Anti-Brownian ELectrokinetic (ABEL) trap provides real-time suppression of Brownian motion for single molecules in solution for extended analysis of dynamical state changes (Wang et al. Acc. Chem. Res. (2012)). With proper design of reporter fluorophore, individual electron transfer events to a single Cu atom in a redox enzyme may be sensed under turnover conditions (Goldsmith et al. PNAS (2011)). Optical counting of fluorescent ATP nucleotides on a multisubunit enzyme provides measurement of ATP number distributions, which can be used to generate a new window into enzyme cooperativity devoid of ensemble averaging (Jiang et al PNAS (2011)). With advanced control system design of feedback to enable optimal trapping performance, the ABEL trap also allows direct, simultaneous measurement of three variables: brightness, excited state lifetime, and emission spectrum, for objects as small as individual ∼1-2 nm sized fluorophores in solution (Wang et al. JPCB (in press 2013)). These examples illustrate some of the wide variety of physical variables which may now be measured for single molecules in a various condensed phase environments ranging from aqueous solutions to living cells.

8:36AM F4.00002 Accounting for conformational flexibility when targeting proteins , SARA NICHOLS, University of California San Diego — Molecular simulation techniques are well-established tools for understanding protein motion and complementing experimental observations. Molecular conformations from such simulations provide insight into receptor flexibility, particularly with respect to the binding of activity-modulating molecules, such as drugs. With the ultimate goal of predicting and designing these favorable interactions, incorporating information about flexibility can enhance structure-based drug design. While modeling all receptor degrees of freedom can be challenging due to conformational space sampling restrictions, advances in computing technology, hybrid and hierarchical protocol, as well as enhanced sampling algorithms are making an impact now, and will continue to do so in the future. An overview of these topics and applications to specific therapeutic targets will be presented.

9:12AM F4.00003 Changing Chasses and Inventing Elements: Developing a Combined Systems Biology and Engineering Approach to Designing Complex Function in Cells , ADAM ARKIN, Department of Bioengineering University of California, Berkeley and Physical Biosciences Division, E.O. Lawrence Berkeley National Laboratory — To meet the goal of creating reliable, predictable, efficient, and transparent methods to harness cellular capabilities for human benefit, it is necessary both to have standard libraries of elements from which useful pathways can be constructed and an understanding of the how host physiology and the environment impacts the functioning of these heterologous circuits. We show how variations in cellular and environmental context affect the operation of the basic central dogma functions underlying gene expression. Then we describe progress on creating a complete, scalable, and relatively homogeneous and designable sets of part families that can control central dogma function predictably in the face of varying configurations, genetic contexts, and environments. We show the challenges that arise in attempting this in applications such as a tumor destroying bacteria.

9:48AM F4.00004 Frontiers of Biophysics: Single Molecule and Single Cell Sensing with Nanomechanical Systems , MICHAEL ROUKES, California Institute of Technology — Nanoelectromechanical systems (NEMS) resonators can detect inertial mass with exceptional sensitivity. We have used NEMS devices to realize a new method for single-molecule mass spectrometry. In our first-generation approach, mass spectra from several hundred adsorption events were assembled into mass spectra using statistical analysis. Our second-generation approach now enables NEMS-based mass spectrometry (MS) in real time: as each molecule in the sample adsorbs upon the NEMS resonator, its mass and position-of-adsorption are determined by continuously tracking two driven vibrational modes of the device. We demonstrate the potential of this method by analyzing individual IgM antibody complexes and other biological analytes in real-time. NEMS-MS is a unique and promising new form of mass spectrometry: it can resolve neutral species, provides resolving power that increases markedly for very large masses, is readily scalable to millions of channels, and is and producible *en masse* by methods from the semiconductor industry for very-large-scale integration.

10:24AM F4.00005 Cytometry and Atomic Mass Spectrometry Converge in Single Cell Deep Profiling of the Human Immune System , SCOTT TANNER, Department of Chemistry, University of Toronto, Canada — Mass cytometry addresses the challenges of polychromatic flow cytometry by capitalizing on the analytical benefits of atomic mass spectrometry. Fluorescence flow cytometry has helped to define the cell subsets of the immune system. The addition of intracellular staining facilitated examination of signaling networks and, recently stratification of patients correlated with clinical outcome. However, the potential for further advances has been stymied by the physical and spectral limitations of fluorophores. This technical barrier has been broached by replacing fluorophores with heavy metal isotopes, and optical detection with atomic mass spectrometry. Antibodies raised against phenotypic and functional proteins are tagged with polymers that are labeled with the transition metal isotopes. More than 30 lanthanide isotopes, complemented by noble metals, permit the immunological recognition of more than 40 (and conceptually up to 100) proteins in single cells simultaneously. Individual cells are injected at nearly 1 kHz into an Inductively Coupled Plasma where the cells are vaporized, atomized and ionized. The reporting ions within the vaporization cloud of each cell are extracted, separated and counted by a time-of-flight mass spectrometer. The data output is a massively multivariate signature of each cell. Already the technology has offered dramatic new insights into the operation and function of the human hematopoietic hierarchy, shown novel application for the screening and mechanistic understanding of drug candidates, and foresees improved prognostic and diagnostic application in the clinic. We will report on our work, and the work of others, in profiling the signaling and functional responses of the suite of cell populations in human bone marrow, the revealing of unappreciated levels of organization in virus-specific memory T cell compartments, and massively multiplexed single-cell kinase inhibitor profiling.

Tuesday, March 19, 2013 8:00AM - 11:00AM –

Session F5 DMP DCOMP: Focus Session: Computational Discovery and Design of New Two-dimensional Materials beyond Graphene 301 - Richard Hennig, Cornell University

8:00AM F5.00001 Electronic and magnetic properties of 2D BCN nanostructures[1] , HYOUNGKI PARK, The Ohio State University — Recent developments of two-dimensional (2D) nanomaterials hold great promises for future electronics, optics and spintronics. Since the isolation and electronic characterization of graphene, other layered 2D crystals also have been synthesized. In particular, carbon can be combined with its neighboring atoms in the periodic table, boron and nitrogen as hexagonal BN (h-BN), to obtain hybrid BCN configurations. These BCN 2D nanostructures show a rich variety of physical properties, distinct from parent materials. Their electronic properties can in principle be tuned by varying the concentration of each of the three elements. We study electronic structures of a variety of 2D BCN nanostructures using hybrid functional HSE in density functional theory (DFT). We show that their electronic properties can be gradually tuned by composition and the atomic configuration of three elements. We demonstrate that the substitution-induced impurity states, associated with carbon atoms, and their interactions dictate the electronic structure and properties of C-doped h-BN. Stacking of localized impurity states in small C clusters embedded in h-BN forms a set of discrete energy levels in the wide gap of h-BN, leading to electronic structures of quantum dots made of carbon nano-domains for applications in optics and opto-electronics. We also show that half-metallic electron transport can be achieved by low concentration substitutional doping of only one sublattice of graphene by nitrogen or boron atoms. The delocalized spin-densities induced by the unpaired electrons at substitutional sites permeate only through the sublattice where the nitrogen (boron) atoms belong. For interacting nitrogen (boron) atoms located along the "zigzag" direction and in the same sublattice the ferro-magnetic spin-ordering is energetically favored, and substitution-induced impurity states selectively disturb the spin-polarized π-orbital of that same sublattice.

[1]Supported by DOE-Basic Energy Science DOE-BES-DMS (DEFG02-99ER45795). Computing resources are provided by NERSC and OSC.

8:36AM F5.00002 Electronic Structures of Single-Layer Boron Pnictides , HOULONG L. ZHUANG, RICHARD G. HENNIG, Department of Materials Science and Engineering, Cornell University — Single layered materials such as graphene and boron nitride promise alternative routes to electronic devices. We use density-functional calculations to identify potential novel 2D materials in the boron pnictide family and determine their stability and electronic properties.[1]Hybrid density functional calculations show that BN, BP, BAs and BSb in this family exhibit a direct bandgap of 6.1, 1.4, 1.2 and 0.6 eV, respectively, that originates from the energy difference of the p_z orbitals of the species and is tunable by strain. The bandgap linearly decreases with strain for BN, while it increases non-linearly for BP, BAs, and BSb. The calculated natural band offsets between the various boron pnictides are all of type I. We expect that these results will provide valuable guidance in designing electronic devices based on single-layer boron pnictides.

8:48AM F5.00003 Impurity induced states in monolayer hexagonal BN[1] , SUSUMU SAITO, YOSHITAKA FUJIMOTO, TAKASHI KORETSUNE, Department of Physics, Tokyo Insitute of Technology — Ever since the experimental production of graphene, it has attracted much attention as a future device material with monoatomic-layer thickness although the material has metallic electronic transport properties. In this respect, a monoatomic layer of hexagonal boron nitride (hBN) can be even more interesting device material to be used in the future since it possesses semiconducting electronic properties with the fundamental energy gap. We study the electronic properties of the hBN monolayer in the framework of the density-functional theory and the many-body theory with Hedin's GW approximation. Both donor and acceptor-type states induced by the substitutional C impurity atom at B and N sites respectively are studied in detail. In addition, we also study the impurity states induced by the substitution of the cluster of atoms in hBN by the graphene flake. These impurity states are found to be generally rather deep, and therefore we discuss the possible methods to change the ionization energies of these impurity-induced states [1].

[1] Y. Fujimoto, T. Koretsune, and S. Saito, to be published.

9:00AM F5.00004 Ab initio study of the buckling on silicene and germanene , EDGAR MARTINEZ-GUERRA, KARLA HERNÁNDEZ, Universidad Autónoma de Nuevo León, EDUARDO CIFUENTES-QUINTAL, ROMEO DE COSS, CINVESTAV-MERIDA — Recently, a new graphene-like silicon structure was discovered: silicene. Since its discovery, silicene has been more exciting than graphene because this is a semiconductor and it should be compatible with silicon-based electronic. Silicon and germanium atoms have similar electronic configurations as those of carbon and this the reason that the bandstructure of silicene and germacene exhibits the Dirac cones at K point, with a very similar linear dispersion around it, like in graphene. The disvintage is that sp^2 bonded Si is much less stable than for carbon resulting that to be stable in the planar layer their atoms must buckle. In this work, we calculated the sp character on silicene and germacene to correlate its hibridization with the velocity of electrons and holes at Dirac cones. The calculations were performed using the pseudopotential LCAO method with GGA for the exchange-correlation energy functional. The buckling of silicene and germacene layer was 0.50 and 0.69 Å, respectively. In addition, the sp- character of silicene and germacene buckled was 2.33 and 2.64, respectively. Thus, a detailed analysis on the electronic band structure of these system show that as sp character goes from sp2 to sp3 it is correlated with a decrease of velocity of electrons and holes at Dirac cones. This study is primarly important and it could address a new future to modulate carrier velocities on bidimensional systems. This research was supported by Conacyt under Grant No. 133022.

9:12AM F5.00005 Properties of silicene on graphene , LOK LEW YAN VOON, The Citadel, RUIPING ZHOU, YAN ZHUANG, Wright State University, CITADEL-WSU COLLABORATION — Silicene, the silicon analog of graphene, was first shown by one of the authors in 2007 to have similar properties to graphene. Three groups have reported the fabrication of silicene on metal in Phys. Rev. Lett. in 2012. In this talk, we will present results on the structure and properties of silicene on graphene obtained from ab initio calculations. A new structure of bilayer silicene on graphene is obtained. The band structure reveals a phenomenon of self-doping. Finally, the application of a transverse electric field and I-V characteristics will be presented.

9:24AM F5.00006 Gated Silicene as a tunable source of nearly 100% spin-polarized electrons , WEI-FENG TSAI, CHENG-YI HUANG, National Sun Yat-sen Unversity, Taiwan, TAY-RONG CHANG, National Tsing Hua University, Taiwan, HSIN LIN, Northeastern University, HORNG-TAY JENG, National Tsing Hua University, Taiwan, ARUN BANSIL, Northeastern University — We demonstrate, via first-principles calculations, that gated silicene with a low-buckled honeycomb structure posseses two gapped Dirac cones with nearly full spin-polarization at the corners of the Brillouin zone. By using this key finding, we further propose a design of a silicene-based spin-filter to switch the output spin current simply by gating without the need to switch magnetic domains. Quantum transport calculations indicate that such designs will be highly efficient (nearly 100% spin-polarized) and robust against weak disorder and edge imperfections. We also propose a Y-shaped spin/valley separator that produces spin-polarized current at two output terminals with opposite spins.

9:36AM F5.00007 Density functional investigation of epitaxial silicene on semiconducting substrates , G.P. DAS, A. BHATTACHARYA, S. BHATTACHARYA, Indian Association for the Cultivation of Science, Kolkata-700032, India — In spite of the uniqueness of carbon to form pristine fullerene, nanotube and graphene, there have been attempts to replicate these nanostructures with silicon. Most recently, the free-standing quasi-2D honeycomb structure of silicene has been predicted to be stable with linear band dispersion and Dirac cone feature similar to graphene. Epitaxial silicene on Ag(110) and on ZrB_2(0001) substrates have already been reported [1,2]. We have carried out first principles density functional investigation of the structural and electronic properties of silicene monolayer on various wurzite structured III-V and II-VI semiconducting substrates, with metal terminated (MT) as well as non-metal terminated (NMT) top surface [3]. The binding energies of silicene on MT semiconductors are in the range 0.5 - 0.7 eV/atom and their behavior can be metallic, semi-metallic or even magnetic, depending on the choice of substrates. The silicene overlayer undergoes n-/p-type doping on MT/NMT semiconductor surface, depending upon the direction of the charge transfer. [1] P. Vogt, et al, Phys. Rev. Lett. **108** (2012) 155501. [2] A. Fleurence et al, Phys. Rev. Lett. **108** (2012) 245501 [3] A. Bhattacharya et al,, to be published.

9:48AM F5.00008 Physisorption of nucleobases on silicene and applications for DNA sequencing , RODRIGO AMORIM, RALPH SCHEICHER, Uppsala University — We have used density functional theory including van der Waals corrections combined with the non-equilibrium Green's function (NEGF) method to study the adsorption of individual nucleobases on top of a 2-D allotrope of silicon, known as silicene, which was experimentally discovered to exist in a hexagonal buckled form. Our study focused on the stability, electronic properties and transverse electronic transport, i.e., changes in the transmission and the conductance caused by each base (A, C, G, T) in silicene compared to its pristine form. Intriguingly, despite the weak interaction between nucleobases and silicene, considerable changes in the transmittance at zero bias are predicted by us. This opens up the possibility to utilize silicene as an integrated-circuit biosensor as part of a lab-on-a-chip device.

10:00AM F5.00009 Normal Compressive Strain Induced Metallic Transition of Semiconducting Bilayer Transition Metal Dichalcogenides , ABHISHEK SINGH, SWASTIBRATA BHATTACHARYYA, Materials Research Centre, Indian Institute of Science Bangalore 560012 INDIA — First principle density functional theory based calculation was carried out to investigate the effect of strain on the band gap of bilayer semiconducting transition metal dichalcogenides (TMDs). The band gap of these materials was observed to decrease smoothly with the application of normal compressive strain. Most importantly, the materials exhibit semiconductor to metal (S-M) transition after a critical pressure (inter-layer distance) is reached. This critical pressure varies with the type and stacking pattern of the material. The S-M transition is attributed to lifting of degeneracy of the bands at the fermi level caused by inter-layer interactions via charge transfer from metal to chalcogens. The GGA result was validated by incorporating the band gap corrections using hybrid functionals and GW method. The tuning of band gap of TMDs by applying normal compressive strain opens a possibility to use these materials in various applications of nanoelectronics such as electromechanical sensors, switches etc.

10:12AM F5.00010 First-principles study of electric field effect on GaN bi- and trilayers , DONGWEI XU, HAIYING HE, RAVINDRA PANDEY, Michigan Technological University, SHASHI P. KARNA, US Army Research Laboratory, Weapons and Materials Research Directorate, ATTN: RDRL-WM — First-principles calculations based on density functional theory (DFT) are performed to study bilayers and trilayers of GaN. The calculated results suggest that the bi- and trilayer systems both prefer planar graphene-like configurations rather than buckled bulk-like configurations in their ground states. The most stable configurations are predicted to be the so-called AA′ stacking for the bilayer and the AA′A stacking for the trilayer at the GGA-DFT level of theory. By appling an external perpendicular electric field to the AB-stacked bilayer, its band gap increases monotonically. However, this is not case for the symmetric AA′ stacked bilayer, ABA or AA′A stacked trilayer where the applied electric field reduces the band gap. Furthermore, a semiconductor-metal transition is predicted for the ABA stacked GaN trilayer at about 0.4 V/ Å.

10:24AM F5.00011 Interfaces between buckling phases in Silicene , MATHEUS P. LIMA, ANTÔNIO J.R. DA SILVA, ADALBERTO FAZZIO, University of São Paulo — Silicene has a honeycomb buckled lattice, with two energetically degenerate geometric phases (α and β). The α phase has one atom shifted up, and its neighbors shifted down, whereas the β phase the shifts are reversed. Some consequences of this buckling pattern are: i) the increase of spin-orbit coupling, thus enhancing the Quantum Spin Hall Effect; ii) potential to tune several properties with the application of an external electric field. Therefore, the understanding of the effects caused by this buckling is crucial to fully explore the potential of this material. In this work we performed simulations based on Density Functional Theory to investigate the co-existence of the α and β phases in the same sample. We show that: i) This phase inversion is stable in the zigzag and armchair directions, and can make curves, allowing the formation of islands; ii) The formation energy per unit length is approximately $0.02\ eV$/Ang; iii) The modifications caused in the Density of States (DOS) are small, and appear $0.5\ eV$ below the Fermi energy. Finely, we show how these linear defect will appear in Scanning Tunneling Microscopy (STM) experiments.

10:36AM F5.00012 Electron-Phonon Coupling in Two-Dimensional Germanene , RYAN STEIN, DAVID SCHAEFER, JIA-AN YAN, Department of Physics, Astronomy and Geosciences, Towson University 8000 York Road, Towson, MD 21252-0001, USA — The phonon properties of the two-dimensional honeycomb allotrope of germanium, germanene, were studied by first-principles calculations. We found that the highest optical branches on the phonon dispersions at Γ and K symmetry points of the first Brillouin zone exhibit similar behavior as in graphene and graphite, indicating possible Kohn anomalies in germanene. Electron-Phonon coupling for the high symmetric modes will be discussed.

10:48AM F5.00013 Optical signatures of valley-spin coupling in graphene-like materials: silicene and germanene[1] , E.J. NICOL, C.J. TABERT, University of Guelph, L. STILLE, University of Toronto — With the success of graphene and the development of the field of two-dimensional crystals, other graphene-like materials are now of interest, such as, monolayers of silicon (silicene) and germanium (germanene). The interplay of spin orbit coupling, due to the buckled structure of these materials, and a perpendicular electric field is predicted to give rise to a rich variety of phases via an electrically tunable band gap [1,2]. These span a topological or quantum spin Hall insulator, a valley-spin-polarized metal and a band insulator [2]. We have calculated the dynamical conductivity [3] and show that it should reveal signatures of these different phases which would allow for their identification along with the determination of parameters such as the spin orbit energy gap. Furthermore, the effect of spin-valley coupling can be seen in the response to circularly polarized light as a function of frequency. Using right- and left-handed circular polarization it is possible to select a particular combination of spin and valley index. The frequency for this effect can be varied by tuning the band gap.

Session F6 DMP: Focus Session: Van der Waals Bonding in Advanced Materials - Functional Materials 302 - Per Hyldgaard, Chalmers University of Technology

8:00AM F6.00001 Active Pharmaceutical Ingredients: Prediction of Physical-Chemical Properties from First Principles , LOREDANA VALENZANO, Michigan Technological University — Polymorphism in active pharmaceutical ingredients (APIs) plays a crucial role both for medical and intellectual property concerns but despite ongoing efforts, experimental and computational investigations of the existence and the physical-chemical properties of the same compound in different forms is still an open question.While comparison between computed and experimental values for properties derived from differences between states is often promising (such as bulk modulus), results are disappointing for absolute values (such as density). Quantum mechanical computational methods describe the systems at 0K, experimentally properties are often evaluated at room temperature. Therefore it is not surprising that results determined from first principles dramatically differ from those obtained experimentally. By applying a quantum mechanical periodic approach that takes into account long range London dispersion forces fitted for solid materials, and by imposing different cell volumes corresponding to different thermodynamic conditions, we show how results from calculations at 0K (structures, vibrational spectra, elastic constants) may be compared to experimental values at higher temperatures, helping to foster a stronger linkage between computational and experimental work on systems such as APIs. Where experimental results are not available, our work represents an innovative approach in addressing the properties of APIs. Our results can also serve as foundation for the developing of new force fields to be adopted within a multi-scale computational approach.

8:12AM F6.00002 Many-Body van der Waals Effects in Advanced Materials , ALEXANDRE TKATCHENKO, Fritz-Haber-Institut der MPG, ANATOLE VON LILIENFELD, Argonne National Laboratory, ROBERT A. DISTASIO JR., Princeton University — Van der Waals (vdW) interactions are ubiquitous in molecules and condensed matter. These interactions are inherently quantum mechanical phenomena that arise from concerted correlations between many electrons within a given molecular system. Despite this fact, the vast majority of theoretical calculations include long-range vdW interactions based on a simple effective interatomic pairwise model. We introduce an efficient method that accurately describes the full long-range many-body vdW energy [1,2], and demonstrate that many-body contributions can significantly exceed the highly coveted "chemical accuracy". Cases studied include intermolecular binding energies, the conformational hierarchy of DNA structures [2], the geometry and stability of molecular crystals [1], and supramolecular host–guest complexes [3]. Our findings suggest that inclusion of the many-body vdW energy is essential for achieving chemical accuracy and therefore must be accounted for when studying advanced materials. [1] Tkatchenko, DiStasio, Car, Scheffler, PRL (2012), [2] DiStasio, von Lilienfeld, Tkatchenko, PNAS (2012), [3] Tkatchenko, Alfe, Kim, JCTC (2012).

8:24AM F6.00003 First-Principles Calculations of the Role of PVP in the Controlled Synthesis of Au Nanostructures[1] , SHIH-HSIEN LIU, Penn State University, WISSAM AL-SAIDI, University of Pittsburgh, KRISTEN FICHTHORN, Penn State University — Structure-directing agents such as PVP play an important role in determining the shape of metal nanostructures in solution-phase syntheses. It is usually hypothesized that structure-directing molecules bind more strongly to certain crystal facets, which grow at the expense of facets on which they are less strongly bound. In this study, we use dispersion-corrected density functional theory to resolve the role of PVP in the shape-selective synthesis of Au nanostructures. We calculate binding energies for the 2-pyrrolidone ring of PVP on Au(111), (5×1) Au(100)-hex, and Au(100) slabs in vacuum. The results show that there is no significant difference between the binding of 2-pyrrolidone to Au(111) and Au(100)-hex, while 2-pyrrolidone binds more strongly to Au(111) than to Au(100). We discuss the origins of these trends. Our results are consistent with experiments, in which (111)-faceted Au nanostructures are formed with the assistance of PVP.

8:36AM F6.00004 van der Waals Density Functional Studies of Gas Binding and Transport in Zeolitic Imidazolate Frameworks[1] , KEITH RAY, Department of Physics, University of California, Berkeley, DAVID OLMSTED, Department of Materials Science and Engineering, University of California, Berkeley, NING HE, Department of Chemistry, University of Kansas, YAO HOUNDONOUGBO, Department of Chemistry and biochemistry, Eastern Washington University, BRIAN LAIRD, Department of Chemistry, University of Kansas, MARK ASTA, Department of Materials Science and Engineering, University of California, Berkeley — Gas adsorption selectivity and transport barriers in a series of Zeolitic Imidazolate Frameworks (ZIFs) are calculated with the van der Waals density functional [1]. In these microporous materials, promising for natural gas upgrading applications, CO2 molecules are found to preferentially adsorb [2] when compared with CH4 depending on the ZIF chemical functionalization. The role of the interaction between the CO2 quadrupole and the host framework, as well as the significant dispersion contribution to both CO2 and CH4 binding are discussed. Diffusion barriers are calculated with the nudged elastic band method (NEB) and results are found to depend on the inclusion of the van der Waals energy.

8:48AM F6.00005 Self-assembly of functionalized anthradithiophene on Au(111) , BRAD CONRAD, SHAWN HUSTON, Appalachian State University, JIUYANG WANG, North Carolina State University, MARSHA LOTH, JOHN ANTHONY, University of Kentucky, DANIEL DOUGHERTY, North Carolina State University — We utilize scanning tunneling microscopy (STM) to characterize the initial growth and crystallization of the high-performance, small organic molecule 2,8-difluoro-5,11-triethylsilylethynyl (diF TESADT) on Au(111). Two ordered structures are observed with diF TESADT backbone planes parallel to the substrate. Submolecular resolution imaging of the first monolayer ordered film regions realizes structures with close approach of fluorine-sulfur and fluorine-fluorine atoms of alternating molecules. These measurements provide evidence for the importance of non-covalent F-S and F-F interactions in driving 2D self-assembly. Scanning Tunneling Spectroscopy indicates a 2.4 eV transport gap which is insensitive to the local domain. Structures and growth are put in context of bulk measurements and device performance measurements.

9:00AM F6.00006 Using NMR to study small molecule adsorption in metal organic frameworks , M.G. LOPEZ, P. CANEPA, T. THONHAUSER, Wake Forest University — We calculate the carbon nuclear magnetic resonance (NMR) chemical shift for the CO_2 molecule and the hydrogen shift for both H_2 and H_2O inside the metal organic framework structure Mg-MOF74 using *ab initio* calculations at the density functional theory level[1,2] with the van der Waals density functional (vdW-DF).[3] These shifts are obtained while placing the small molecules throughout the structure, including the calculated adsorption site for various loading scenarios. Our binding energy results agree well with previous experiments and calculation, and the NMR calculations show that it is reasonable to expect an experimentally observable change in the chemical shift depending on adsorbant, position, and loading. By providing this mapping of chemical shift to position and loading for these adsorbants, we argue that NMR probes could be used to provide information about the position at which these small molecules bind within the MOF and provide information about the loading of the adsorbed molecule.

9:12AM F6.00007 Spectroscopic studies of van der Waals bonding and interactions in microporous materials[1] , YVES CHABAL, The University of Texas at Dallas — Van der Waals interactions govern the interaction of gas phase molecules in microporous materials. New theoretical approaches, such as DF-vdW methods, have brought great insight into the results of vdW forces on the adsorption and diffusion properties of molecular guests. In this talk, we highlight the role of vibrational spectroscopies (infrared and Raman) in providing information that can directly test such theoretical approaches. Typically, vdW interactions lead to measurable shifts in molecular internal modes, which can be calculated. We also show that vdW interactions often lead to minor structural alteration or reconfiguration of the microporous hosts, which can clearly be observed by IR or Raman spectroscopy. Examples will be taken from molecular hydrogen storage and gas phase separation in Metal Organic Framework materials, which represent a versatile class of porous materials. For example, the origin of interesting "gate opening" phenomena in flexible MOFs, leading to highly selective adsorption, will be described.

9:48AM F6.00008 Van der Waals density functional study of water binding in metal-organic frameworks , KYUHO LEE, UC Berkeley; Molecular Foundry, LBNL, BEREND SMIT, UC Berkeley; LBNL, JEFFREY B. NEATON, Molecular Foundry, LBNL — Metal-organic frameworks (MOFs) are promising candidate materials for gas storage, gas separation and catalysis. However, MOFs are vulnerable to humid air and effective surface area drops dramatically on an exposure to water [1]. In this theoretical study, we investigate the interaction of single water molecule with MOF-74 on different binding sites by using van der Waals density functionals. We also explore how different type of metal cations affect the interaction.

[1] S. S. Kaye, A. Daily, O. M. Yaghi and J. R. Long, J. Am. Chem. Soc. **129**, 14176 (2007).

10:00AM F6.00009 Understanding CO_2/N_2 Selectivity and Binding in MOFs Using Dispersion-Corrected DFT[1] , JOSHUA HOWE, KYUHO LEE, UC Berkeley Department of Chemical and Biomolecular Engineering; Molecular Foundry, LBNL, BEREND SMIT, UC Berkeley Department of Chemical and Biomolecular Engineering, JEFFREY NEATON, Molecular Foundry, LBNL — Metal-organic frameworks (MOFs) are a class of highly ordered, highly customizable nanoporous materials that are attractive for use in energy-relevant gas separations. MOF-253 (AlOH)(bpydc) can be post-synthetically modified by introduction of metal cations and charge-stabilizing anions [1]. Post-synthetically modified MOF-253 samples have been shown to exhibit enhanced CO_2/N_2 selectivity over the unmodified framework [1]. Here we focus on the following series of post-synthetic modifications: $CoCl_2$, $CuCl_2$, $FeCl_2$, $NiCl_2$, $PdCl_2$. We use the vdW-DF, vdW-DF2, and DFT-D2 dispersion-corrected density functional theory (DFT) methods to study CO_2 and N_2 binding trends in this series of modified frameworks. Particular focus is paid to examining the predictive power of our calculations on both the modified framework and modified bipyridine clusters as a proxy for the full framework. Additionally, we examine the suitability of an approximate Henry coefficient model to predict measured gas selectivity trends [1].

10:12AM F6.00010 The Role of Many-Body Dispersion Interactions in Molecular Crystals , NOA MAROM, The University of Texas at Austin — The structure, energetics, and electronic properties of molecular crystals are studied using density functional theory (DFT) with the recently developed many-body dispersion (MBD) method [Tkatchenko et al. Phys. Rev. Lett. 108, 236402 (2012)]. It is shown that accounting for the long-range electrostatic screening in extended systems is essential for obtaining the correct dielectric constants and ensuing optical properties of molecular crystals [Schatschneider et al., arXiv:1211.1683]. Furthermore, accounting for the non-additive many-center dispersion interactions is crucial for obtaining a highly accurate description of the energetics of molecular crystals. This includes lattice energies, sublimation enthalpies [Reilly et al., to be published], and relative stabilities of polymorphs [Marom et al. arXiv: 1210.5636]

In collaboration with Leslie Leiserowitz, Weizmann Institute of Science, Israel; Bohdan Schatschneider, The Pennsylvania State University, Fayette; Robert DiStasio, Princeton University; Anthony Reilly and Guo-Xu Zhang, Fritz Haber Institute of the Max Planck Society, Berlin; James Chelikowsky, The University of Texas at Austin; and Alexandre Tkatchenko, Fritz Haber Institute of the Max Planck Society, Berlin.

10:48AM F6.00011 Stiffness of Diphenylalanine-Based Molecular Solids from First Principles Calculations , IDO AZURI, Weizmann Institute of Science, Israel, ODED HOD, EHUD GAZIT, Tel Aviv University, Israel, LEEOR KRONIK, Weizmann Institute of Science, Israel — Diphenylalanine-based peptide nanotubes were found to be unexpectedly stiff, with a Young modulus of 19 GPa. Here, we calculate the Young modulus from first principles, using density functional theory with dispersive corrections. This allows us to show that at least half of the stiffness of the material comes from dispersive interactions and to identify the nature of the interactions that contribute most to the stiffness. This presents a general strategy for the analysis of bioinspired functional materials.

11:00AM F6.00012 Molecular Transport in Metal Organic Framework Ma- terials , P. CANEPA, Wake Forest University, N. NIJEM, Y.J. CHABAL, University of Texas at Dallas, T. THONHAUSER, Wake Forest University — Metal organic frameworks (MOF) materials are a class of porous materials well suited for hydrogen storage and gas separation. While current work on MOFs focuses mostly on the adsorption properties of small molecules, their diffusion is still poorly understood. To elucidate the diffusion process, we study the diffusion of H_2, CO_2, and H_2O in the nano-pores of MOF-74-Mg by combining *ab initio* simulations with infrared (IR) spectroscopy. We present computed adsorption energies and changes in the IR frequencies upon adsorption. We also discuss several diffusion mechanisms and their calculated barriers. We further verify the existence of the debated secondary binding sites for guest molecules and we discuss the role played by H_2O. We find that H_2O is much more likely to adsorb in the MOF than H_2 and CO_2, leading to a significant reduction of the adsorption capabilities of the MOF towards these target molecules, and hence resulting in limitations for practical applications. Overall, our computational findings are in very good agreement with experiment and they provide a fundamental understanding of the diffusion processes of small molecules in these nano-porous materials, with implication for the usability of MOFs in gas separation and storage applications.

Tuesday, March 19, 2013 8:00AM - 11:00AM –

Session F7 DMP: Focus Session: Graphene Devices IV 303 - Cory Dean, City College of New York

8:00AM F7.00001 Multi-state current switching by the interference between standing electronic waves in two misoriented crossed graphene nanoribbons[1] , K.M. MASUM HABIB, ROGER LAKE, Dept of Electrical Engineering, University of California, Riverside — In semi-infinite armchair graphene nanoribbon (aGNR), the electronic wavefunctions are standing waves with energy dependent wavelengths. The wavelength of the electrons can be controlled by an external electric field. These standing electronic waves show some unique transport phenomena in crossed graphene nanoribbon (xGNR) consisting of two semi-infinite aGNRs with one placed on top of the other and a relative rotation of 90 degrees in between. At any given energy, the matrix element between a bottom aGNR state and a top aGNR state depends on the phases of the standing waves at that energy. The matrix element and hence the inter-aGNR transmission is strongly suppressed when a zero of the standing wave of either the top or the bottom aGNR falls inside the overlap region. An external bias applied between the aGNRs can control the wavelengths and hence the phases of the standing waves which in turn modulates the inter-aGNR transmission and current. Calculations show that the inter-aGNR current is an oscillatory function of the bias voltage with multiple negative differential resistance (NDR) regions and that the period of the oscillation is controlled by the length of the finite ends of the xGNR.

8:12AM F7.00002 Vertical Transport through Twisted Graphene/h-BN Heterostructure[1] , XINGYUAN PAN, SHAYAN HEMATIYAN, JAIRO SINOVA, Texas A&M University, MARCO POLINI, NEST, Istituto Nanoscienze-CNR and Scuola Normale Superiore, ALLAN MACDONALD, University of Texas at Austin — Graphene and its heterostructues are promising candidates for high-frequency electronics. Vertical heterostructures created by stacking graphene layers and hexagonal boron nitride layers together display orientational disorder, due to rotational stacking faults. In this work we report our theoretical study of vertical charge transport through a rotated graphene/h-BN heterostructure. Our theoretical model combines the microscopic tight-binding method with the Landauer formalism for electrical transport. Electrical conductances are calculated for a variety of system configurations and system sizes. We found that the electrical conductance has a maximum value when the rotation angle is commensurate. Away from commensurate angles transport is suppressed but cannot be completely ignored. We show that the distance dependence of the transfer integrals between two atoms is crucial in modeling the rotation-angle dependence of the vertical transport.

[1]The authors would like to acknowledge support from ONR and SWAN

8:24AM F7.00003 Vertical Transport Properties of Graphene/h-BN Hetrostructures[1] , SHAYAN HEMMATIYAN, XINGYUAN PAN, Department of Physics, Texas A&M University, College Station, Texas 77843-4242, USA, MARCO POLINI, NEST-CNR-INFM and Scuola Normale Superiore, I-56126 Pisa, Italy, ALLAN MACDONALD, Department of Physics, University of Texas at Austin, Austin, Texas 78712, USA, JAIRO SINOVA, Department of Physics, Texas A&M University, College Station, Texas 77843-4242, USA — We present results of extensive first principles, studying the scaling behaviour of inter-layer tight-binding hopping parameters in vertical graphene/h-BN heterostructures. We focus, in particular, on the dependence of these parameters on orientational disorder and inter-layer distances. We will report relevant inputs for numerical studies of the vertical transport in graphene/h-BN heterostructures.

[1]SWAN, ONR

8:36AM F7.00004 Superconducting Graphene Nanodevices in Ballistic Transport Regime , YUAN CHEN, JOEL I-JAN WANG, Massachusetts Institute of Technology, KENJI WATANABE[1], TAKASHI TANIGUCHI[2], National Institute for Materials Science, PABLO JARILLO-HERRERO, Massachusetts Institute of Technology, PABLO JARILLO-HERRERO'S GROUP TEAM — Superconductivity carried by Dirac fermions can be realized through induced superconductivity in grapheme. Observation of novel phenomena anticipated by theories requires graphene devices with low disorder whereas the carrier transport is ballistic. Current fabrication procedures to make graphene devices with low disorder like suspension or ultra-flat substrates all call for certain kinds of annealing to remove organic residues derived from the fabrication process. Applying these methods to superconducting devices can be challenging since the transparency at the graphene/superconductor interface will be destroyed. Here we present a method to do dry transfer of patterned hexagonal Boron Nitride (hBN) flakes onto graphene. The ultra flatness and lack of dangling bond in the boron nitride substrate reduces the disorder in graphene, and the top layer hBN can protect the graphene from contamination in the nanofabrication procedures and yield the geometry desired for different experimental exploration.

8:48AM F7.00005 Exploring graphene properties in a periodic electrostatic potential , NIKOLAI N. KLIMOV, Maryland NanoCenter, UMD, MD / PML, NIST, MD, DAVID B. NEWELL, PML, NIST, MD — Graphene, a unique two-dimensional honeycomb lattice of carbon atoms, exhibits rich new physics and great promise for applications in electronics. It was been predicted that a slowly varying nanoscale external periodic electrostatic potential applied to a graphene modifies its lectronic structure in a very unique way and leads to novel phenomena and possible applications [1-4]. In particular, a one-dimensional electrostatic potential applied to graphene may result in strong anisotropy of the group velocity of Dirac fermions, appearance of new zero-energy states at the Fermi energy, unusual Landau levels and quantum Hall effects. Both the anisotropy of the group velocity and the number of zero-energy modes can be altered by varying parameters of the superlattice potential. Although graphene in periodic potentials has been intensively studied theoretically, a thorough experimental investigation is still missing due to difficulties of fabricating of graphene devices, in which an external periodic potential can be applied with nanoscale periodicity. In this talk we present our results on the fabrication of graphene devices with nanoscale periodic local gates. The devices will be used to investigate graphene electronic properties in a one-dimensional periodic electrostatic potential using both magnetotransport and scanning probe microscopy measurement techniques. 9:00AM F7.00006 Effect of non-uniform magnetic field on Dirac fermions in graphene , FEN GUAN, NAOMI MIZUNO, BENT NIELSEN, XU DU, Department of Physics and Astronomy, Stony Brook University — It has been theoretically proposed that non-uniform magnetic field can trigger bound, quasi-bound and scattering states in graphene, while electrostatic barriers cannot serve this purpose due to Klein tunneling. To observe this tuning effect on the transport properties of graphene experimentally, we need high quality graphene and microscopically inhomogeneous magnetic field. Here we report building of the inhomogeneous magnetic field through magnetic vortices in type II superconductor and study the effect of this magnetic field on the transport properties of the Dirac electrons in graphene. We present the fabrication and measurements of suspended graphene over Nb thin films which generate superconducting vortices.

9:12AM F7.00007 ABSTRACT WITHDRAWN –

9:24AM F7.00008 Alternative polymer scaffolds for clean transfer of CVD-grown graphene , JOSHUA WOOD, GREGORY DOIDGE, BASIL ARUIN, HEFEI DONG, JUSTIN KOEPKE, ENRIQUE CARRION, ISHA DATYE, KAMALIKA CHATTERJEE, JEFFREY MOORE, ERIC POP, JOSEPH LYDING, University of Illinois at Urbana-Champaign — We investigate and benchmark polymer scaffolds used to support large-area chemical vapor deposition (CVD) grown graphene on Cu during transfer. CVD graphene must be transferred off of Cu to be used in various applications. PMMA transfers introduce hard-to-remove residues, and thermal release tape transfers have removable residue but give holey graphene films. Films transferred by poly(bisphenol A carbonate) (PC) are atomically clean after room-temperature polymer dissolution, and we confirm this by atomic force microscopy, Raman spectroscopy, device transport, and scanning tunneling microscopy. Compared to PC-, PMMA-transferred films have fewer wrinkles but higher RMS roughness. When we use a PC/PMMA bilayer, we find lower graphene wrinkle density but higher RMS roughness from polymer co-mixing. We also transfer graphene with other industrially relevant scaffolds like polylactic acid (PLA) and chemically modified photoresists. PLA-transferred films, after polymer dissolution, have sub-nm RMS roughness, and this improves upon PLA gasification above 180 °C. Graphene transfer polymers that require low thermal budgets will open possibilities for temperature-sensitive substrates or graphene encapsulation of biological specimens (e.g. viruses, bacteria).

9:36AM F7.00009 Effect of sample preparation on charged impurities in graphene substrates[1] , K.M. BURSON, Center for Nanophysics and Advanced Materials, University of Maryland, College Park, MD 20742-4111, USA, C.R. DEAN, Columbia University, New York, New York, 10027, USA, K. WATANABE, T. TANIGUCHI, Advanced Materials Laboratory, National Institute for Materials Science, 1-1 Namiki, Tsukuba, 305-0044, Japan, J. HONE, P. KIM, Columbia University, New York, New York, 10027, USA, W.G. CULLEN, M.S. FUHRER, Center for Nanophysics and Advanced Materials, University of Maryland, College Park, MD 20742-4111, USA — The mobility of graphene as fabricated on SiO_2 has been found to vary widely depending on sample preparation conditions. Additionally, graphene mobility on SiO_2 appears to be limited to $\sim$20,000 cm^2/Vs, likely due to charged impurities in the substrate. Here we present a study of the effect of fabrication procedures on substrate charged impurity density (n_{imp}) utilizing ultrahigh-vacuum Kelvin probe force microscopy. We conclude that even minimal SEM exposure, as from e-beam lithography, induces an increased impurity density, while heating reduces the number of charges for sample substrates which already exhibit a higher impurity density. We measure both SiO_2 and h-BN and find that all n_{imp} values observed for SiO_2 are higher than those observed for h-BN; this is consistent with the observed improvement in mobility for graphene devices fabricated on h-BN over those fabricated on SiO_2 substrates.

9:48AM F7.00010 Graphene / Boron Nitride Heterostructures , ROMAN GORBACHEV, University of Manchester — The talk is dedicated to multilayer boron nitride/graphene heterostructures. It will review several aspects of microfabrication of such structures as well as the transport experiments. Graphene placed on boron nitride and exhibiting nanometer-scale moiré patterns showing strong anomalies in the density of states which can be associated with new Dirac cones formed high up in graphene's original spectrum. We describe quantum transport in specially aligned graphene-on-hBN devices such that the DoS anomalies reproducibly appear within the Fermi energy range achievable in transport measurements. We report a strongly reconstructed graphene spectrum with new sharp neutrality points and extra sets of Landau levels and quantum Hall states. Different experiments done on multilayer structures containing two interacting graphene layers will be discussed.

10:24AM F7.00011 Characterization Of Graphene-Ferroelectric Superlattice Hybrid Devices[1] , MOHAMMED YUSUF, XU DU, MATTHEW DAWBER, Dept of Physics and Astronomy, Stony Brook University — Ferroelectric materials possess a spontaneous electrical polarization, which can be controlled by an electric field. A good interface between ferroelectric surface and graphene sheets can introduce a new generation of multifunctional devices, in which the ferroelectric material can be used to control the properties of graphene. In our approach, problems encountered in previous efforts to combine ferroelectric/carbon systems are overcome by the use of artificially layered superlattice materials grown in the form of epitaxial thin films. In these materials the phase transition temperature and dielectric response of the material can be tailored, allowing us to avoid polarization screening by surface absorbates, whilst maintaining an atomically smooth surface and optimal charge doping properties. Using ferroelectric $PbTiO_3/SrTiO_3$ superlattices, we have shown ultra-low-voltage operation of graphene field effect devices within $\pm$ 1 V at room temperature. The switching of the graphene field effect transistors is characterized by pronounced resistance hysteresis, suitable for ultra-fast non-volatile electronics. Low temperature characterization confirmed that the coercive field required for the ferroelectric domain switching increases significantly with decreasing temperatures.

10:36AM F7.00012 Transport properties of graphene devices transferred to STO substrates[1] , RAYMOND SACHS, PATRICK ODENTHAL, ROLAND KAWAKAMI, JING SHI, University of California, Riverside — The effect of substrate on graphene transport properties can help us understand the scattering mechanisms relevant to its carrier mobility. Single-layer graphene is easily located on the surface of Silicon with 300nm SiO_2 using optical microscopy. We have developed a technique for wet-etching the SiO_2, peeling the device with metallic leads from the surface, and transferring it to any substrate. This technique eliminates the need to locate the graphene flake on the target substrate for aligning and patterning. A direct comparison can be made between the transport properties of graphene on SiO_2 and the target substrate. A device has been transferred to 500um and 200um thick Strontium Titanate (STO) substrates as well as 250nm thick layer of STO that has been grown epitaxially on Nb-doped STO via Pulsed Laser Deposition. The STO layer, with a higher dielectric constant than SiO_2, has a higher capacitance and produces a more effective graphene FET. A higher mobility is expected for a device on the surface of a material with a higher dielectric constant if charged impurity scattering is a primary limiting factor. The devices transferred to STO display a gate voltage dependent hysteresis in both the longitudinal and Hall resistances. However, the mobility obtained from these measurements remains the same as that of the device on SiO_2. Possible reasons for the absence of the high dielectric substrate effect on graphene carrier mobility and hysteretic behavior will be discussed.

[1]Research was supported in part by NSF/NEB and DOE.

10:48AM F7.00013 Impact of atomic hydrogen on graphene on hexagonal boron nitride , MASA ISHIGAMI, JYOTI KATOCH, Department of Physics, University of Central Florida — We have measured the transport property of graphene on hexagonal boron nitride as a function of density of adsorbed atomic hydrogen. Atomic hydrogen is reversibly chemisorbed and has a large carrier scattering cross section. The impact was previously found to be radically different on graphene on silicon oxide where atomic hydrogen is mostly physisorbed and the saturation coverage of hydrogen was found to correspond to the number of native scatterers. Our results can directly test the theoretical results on the resonant impurities and suggest the nature of the native scatterers in graphene on hexagonal boron nitride. These finding will be outlined in this talk.

Tuesday, March 19, 2013 8:00AM - 11:00AM –

Session F8 DCMP: Functionalization and Decoration of Graphene 307 - Jun Zhu, Pennsylvania State University

8:00AM F8.00001 Hydroxyl-decorated Graphene Systems: Organic metal-free Ferroelectrics, Multiferroics, and Proton battery Cathode Materials , MENGHAO WU, Department of Physics, Virginia Commonwealth University, Richmond, VA 23284, J.D. BURTON, EVGENY TSYMBAL, Department of Physics, University of Nebraska, Lincoln, NE 68588, XIAO CHENG ZENG, Department of Chemistry, University of Nebraska, Lincoln,NE 68588 , PURU JENA, Department of Physics, Virginia Commonwealth University, Richmond, VA 23284, PROF.JENA'S GROUP TEAM, PROF.BURTON'S GROUP TEAM, PROF.TSYMBAL'S GROUP TEAM, PROF.ZENG'S GROUP TEAM — Through density-functional-theory calculations we show that hydroxylized graphene systems are ideal candidates for light-weight organic ferroelectric materials with giant polarizations. For example, the polarization of semi-hydroxylized graphane and graphone as well as fully hydroxylized graphane are, respectively, 41.1, 43.7, 67.7 μC/cm^2, much higher than any organic ferroelectric materials known to date. In addition, hydroxylized graphone is multiferroic due to the coexistence of ferroeletricity and ferromagnetism. Zigzag graphene nanoribbons decorated by hydroxyl groups also exhibit ferroelectric properties with a large polarization of 27.0 μC/cm^2. Moreover, proton vacancies at the end of ribbons can induce large dipole moments that can be reversed by both hopping of protons and rotation of O-H bonds under an electric field. These materials have the potential as high-capacity cathode materials with specific capacity six times larger than lead-acid batteries and five times that of lithium-ion batteries.

8:12AM F8.00002 Quantum Sticking of Atomic Hydrogen to Graphene[1] , YANTING ZHANG, IBM Microelectronics, ADAM DOHERTY, University of Vermont, ANDREW GERAGOTELIS, Siena College, DENNIS CLOUGHERTY, University of Vermont — We consider the low-energy behavior of the sticking probability of atomic hydrogen to suspended graphene. For energy transfer through the flexural modes of graphene, we find that the inelastic coupling falls in the subOhmic regime. Thus the effects of low-frequency fluctuations of the graphene sheet are crucially important for quantum sticking. We analytically solve for the low-energy asymptotic behavior of the sticking coefficient using a variational mean-field method [D.P. Clougherty and Y. Zhang, Phys. Rev. Lett. 109, 120401 (2012)]. We find that as a result of strong coupling to the low-frequency flexural modes of graphene, a new scaling law results. For suspended graphene at finite temperature, we find that at a critical incident energy, the sticking probability drops discontinuously; below this critical energy, the sticking probability is suppressed by the orthogonality catastrophe. We compare our nonperturbative variational results to those obtained by using Fermi's golden rule.

8:24AM F8.00003 Electronic structure of oxygen functionalized graphene nanoribbons[1] , ADAM SIMBECK, DEYANG GU, Rensselaer Polytechnic Institute, NEERAV KHARCHE, Brookhaven National Laboratory, SAROJ NAYAK, Rensselaer Polytechnic Institute — We investigate the electronic and magnetic properties of armchair graphene nanoribbons whose edges are passivated by oxygen. Using a first-principles density functional approach and the many-body GW method we find that oxygen-passivation results in a rich geometrical environment which in turn determines the electronic and magnetic properties of the ribbon. For planar systems we report magnetic ground states whose electronic structure depends upon the magnetic coupling between edges. For non-planar ribbons we report a nonmagnetic ground state with a band gap that decreases as a function of increasing ribbon width. Our results will be discussed in light of previous experimental and computational studies.

8:36AM F8.00004 Optical properties of functionalized monolayer and bilayer graphene , JINLUO CHENG, CUAUHTÉMOC SALAZAR, JOHN E. SIPE, Department of Physics and Institute for Optical Sciences, University of Toronto, 60 St. George Street, Toronto, Ontario, Canada M5S 1A7 — We use *ab initio* calculations to investigate the structures, band structures, and optical properties of functionalized monolayer and bilayer graphene, where a hydrogen atom is attached to only one carbon atom site periodically every few unit cells. The hydrogen atom distorts the carbon atoms vertically, but the inplane structure is approximately unchanged. The ground state acquires a bandgap due to adsorption depending on the supercell size, and shows magnetic order, which is in agreement with a recent experiment [1]. The calculated optical absorption spectra displays detailed structures at lower photon frequencies than that of the pristine graphene.

J. Hong *et al.*, Sci. Rep. **2**, 624 (2012).

8:48AM F8.00005 Ferromagnetism in hydrogenated epitaxial graphene on 6H-SiC , A.J.M. GIESBERS, Eindhoven University of Technology, K. UHLIROVA, Leiden Institute of Physics, M. KONECNY, Eindhoven University of Technology, J. AARTS, Leiden Institute of Physics, C.F.J. FLIPSE, Eindhoven University of Technology — Graphene remains a material of interest in both fundamental and applied physics due to its unique combination of properties [1] such as its mechanical strength, surface sensitivity, relativistic bandstructure and large spin relaxation length. Functionalizing graphene leads to a whole new range of properties [2] varying from photoluminescence in graphene oxide [3] to ferromagnetism in hydrogenated graphene [4]. Here we will show a detailed investigation of the (ferro-)magnetic properties of hydrogenated epitaxial graphene on SiC (HeG). The magnetization of the of the HeG shows a clear hysteresis loop, which remains visible up to room temperature with a saturation magnetization of 0.5 μ_B/hexagon. The saturation magnetization depends on the hydrogen coverage and shows a strong anisotropy to the sample orientation with respect to the magnetic field. [1] N. M. R. Peres, Rev. Mod. Phys. 82, 2673 (2010) [2] W. Wei and X. Qu, Small 8, 2138 (2012). [3] Z. Luo et al., Appl. Phys. Lett. 94, 111909 (2009). [4] L. Xie et al., Appl. Phys. Lett. 98, 193113 (2011).

9:00AM F8.00006 Electronic structures and magnetism of hydrogenated and fluorinated graphene with vacancies[1] , BI-RU WU, Center for General Education, Chang Gung University, Kueishan, Taiwan, CHIH-KAI YANG, Graduate Institute of Applied Physics, National Chengchi University, Taipei 11605, Taiwan — Graphene is a gapless semiconductor. As graphene is covered with one layer of hydrogen or fluorine, it becomes a wide band gap insulator. However, vacancies are easily found during the hydrogenated or fluorinated processes. We investigate the electronic structure and magnetism of the hydrogenated and fluorinated graphene with a variety of configuration of vacancies. We found that a continuous zigzag chain distribution of vacancies will result linear energy dispersion both in the hydrogenated and fluorinated graphene. This finding should be very useful for the design of graphene based electronic devices.

9:12AM F8.00007 First-principles study of the spin-orbit interaction in graphene induced by hydrogen adatoms[1] , MARTIN GMITRA, DENIS KOCHAN, JAROSLAV FABIAN, University of Regensburg — We have performed first principles calculations of the spin-orbit coupling effects in hydrogenated graphene structures, for varying hydrogen coverage densities, using the linearized augmented plane wave method as implemented in the FLEUR code. The covalent bonding between the hydrogen and carbon atoms leads to a local structural puckering of graphene sheets, giving rise to an overlap between the Dirac and sigma electrons and a giant enhancement (from roughly 0.01 to 1 meV) of the local spin-orbit interaction. The calculated effects on the band structure and the emerging spin patterns of the electronic states can be well explained by effective Hamiltonian models derived from group theoretical principles.

9:24AM F8.00008 A Model for the Origin of Spin half Para-magnetism in Fluorinated Graphene

, PIALI ADITYA, ALEJANDRO SUAREZ, Pennsylvania State University, TYLER MAUNU, School of Physics & Astronomy, University of Minnesota, DIEGO B. CARRASCO, Engineering Physics Department, Universidad Iberoamericana A.C, JORGE SOFO, Pennsylvania State University — It came as a surprise when the Manchester group reported a paramagnetic response in fluorinated graphene [*Nair et al., Nature Physics 8, 199-202 (2012)*]. The response is characteristic of non-interacting spin 1/2 with a concentration that is almost zero up to 60% fluorination and peaks at 80% fluorination. The density is never larger than a few spins per 1000 carbon atoms. Prior DFT calculations show an absence of magnetism for dilute fluorinated graphene samples [*Sofo et al., Phys. Rev. B Rapid Comm. 83, 081411 (2011)*]. We propose that the magnetic response originates from regions with a small number of non-fluorinated carbon atoms surrounded by fluorinated ones. In support of this model we combine the exact response of the non-fluorinated regions with a stochastic model to account for the fluorination process. Our calculation reproduces the magnetic response of the samples and tracks the origin of this magnetic phenomenon to the grain boundary between fluorinated patches. If our model is correct, the number of spins in this sample is not an intrinsic quantity but is determined by the fluorination process.

9:36AM F8.00009 Analytic Local and Total Density of States for Hydrogen Adatoms on Graphene[1]

, NICHOLAS PIKE, DAVID STROUD, The Ohio State University — Spin transport through graphene is strongly influenced by the presence of adatoms with unpaired spins, such as hydrogen adatoms. In this work, we calculate the local density of states (LDOS) for a simple model of hydrogen on graphene using a tight binding model. The model includes nearest neighbor hopping between carbon atoms, the value of the hydrogen energy level, hopping between the carbon and hydrogen atoms, and a Hubbard U-term to account for the on-site Coulomb interaction. When U = 0, we develop an exact analytic equation for the LDOS on the adatom site, and for the total density of states (DOS). When U $\neq$ 0, we carry out the same calculation but treat the Hubbard term using mean-field theory. We find that the hydrogen adatom has a net non-integer spin polarization, and that some of the electronic density is transferred from the hydrogen adatom to the graphene host. Possible implications of these results for spin transport through graphene will be discussed.

[1]This work was supported by the Center of Emerging Materials at The Ohio State University, an NSF MRSEC (Grant No. DMR0820414).

9:48AM F8.00010 Electrical detection of phase changes in adsorbed neutral dipolar molecules on graphene

, YILIN WANG, Materials Research Science and Engineering Center (MRSEC), University of Maryland, College Park, WENZHONG BAO, SHUDONG XIAO, Department of Physics, University of Maryland, College Park, MICHAEL FUHRER, JANICE REUTT-ROBEY, Materials Research Science and Engineering Center (MRSEC), University of Maryland, College Park, MRSEC TEAM — Graphene is a very promising material for sensing application because its transport properties are highly sensitive to adsorbates on its surface. Here, we study the carrier-density-dependent resistance of bilayer graphene to neutral dipolar adsorbates under ultra-high vacuum condition. Halocarbon molecules with known dipole moment are deposited on graphene at $\sim$ 20 K. After deposition of a few monolayers of molecules, the resistance of graphene near the Dirac point is measured as a function of carrier density (tuned by gate voltage) and temperature, from 20 K to room temperature. We observe negligible shifts of the gate voltage of maximum resistance, indicating negligible charge transfer from adsorbate to graphene. In the temperature-dependent-resistance curve, a sharp step-like increase and decrease in resistance occur at $\sim$ 45 K and $\sim$ 65 K, respectively. We relate these abrupt changes in resistance to phase transitions in the adsorbate overlayer. The same molecules adsorbed on graphite are known to exhibit a complex temperature - coverage phase diagram. We will discuss the relationship between graphene resistance and the phases of molecules on graphite. This work was supported by the NSF-MRSEC at the University of Maryland, DMR 0520471

10:00AM F8.00011 Optical properties of hydrogenated graphene from first principles[1]

, SEBASTIAN PUTZ, MARTIN GMITRA, JAROSLAV FABIAN, University of Regensburg — We investigate the effect of hydrogen coverage on the optical properties of single-side hydrogenated graphene from first principles. To account for different degrees of uniform hydrogen coverage we calculate the complex dielectric function for graphene supercells of various size, each containing a single additional H atom. We use the Linearized Augmented Planewave (LAPW) method, as implemented in WIEN2k, to show that the hydrogen coverage strongly influences the complex dielectric function and thus the optical properties of hydrogenated graphene. The absorption coefficient in the visible range, for example, has different characteristic features depending on the hydrogen coverage. This opens up new possibilities of determining the hydrogen coverage of hydrogenated graphene samples in the experiment by contact-free optical absorption measurements.

10:12AM F8.00012 A Theoretical Analysis of the Effect of the Hydrogenation of Graphene to Graphane on Its Mechanical Properties[1]

, Q. PENG, CHAO LIANG, WEI JI, SUVRANU DE, Rensselaer Polytechnic Institute — We investigated the mechanical properties of graphene and graphane using first-principles calculations based on density-functional theory. A conventional unitcell containing a hexagonal ring made of carbon atoms was chosen to capture the finite wave vector "soft modes", which affect the the fourth and fifth elastic constants considerably. Graphane has about 2/3 ultimate strengths in all three tested deformation modes – *armchair*, *zigzag*, and *biaxial*– compared to graphene. However, graphane has larger ultimate strains in *zigzag* deformation, and smaller in *armchair* deformation. We obtained the second, third, fourth, and fifth order elastic constants for a rigorous continuum description of the elastic response. Graphane has a relatively low in-plane stiffness of 240 N/m which is about 2/3 of that of graphene, and a very small Poisson ratio of 0.078, 44% of that of graphene. The pressure dependence of the second order elastic constants were predicted from the third order elastic constants. The Poisson's ratio monotonically decreases with increasing pressure.

10:24AM F8.00013 Fluorination of CVD graphene: the role of wrinkles, folds, multi-layer islands and grain boundaries

, BEI WANG, JUNJIE WANG, J. ZHU, Department of Physics, Penn State University — Chemical functionalization, such as fluorination, can modify the gapless band structure of graphene and turn it into an insulator. Fluorinated graphene (FG) can potentially be integrated into graphene electronics and serve as ultrathin gate dielectrics or tunnel barriers. Here we present our effort in synthesizing and understanding the properties of FG. Graphene sheets synthesized by chemical vapor deposition (CVD) are fluorinated using CF_4 plasma under varying conditions. The resulting FG is systematically examined using a wide range of spectroscopic and microscopic tools including XPS, Raman, FTIR, electrical transport and conductive AFM. We obtain high F:C ratio of 0.1-1. Our results show that 1. Morphological features of CVD graphene (wrinkles, folds, multi-layer islands) are less fluorinated and charge transport in FG occurs through the conductive network formed by these features. 2. Lattice defects and grain boundaries play a significant role in the chemical reactivity of CVD graphene. XPS studies indicate the formation and evolution of CF_x (x=1,2,3) bonds, as well as oxygen-passivated defect sites in FG. These studies highlight current challenges in realizing electronics-grade FG and point to the possible pathways forward.

10:36AM F8.00014 Theory of the hydrogen adatoms induced spin-orbit coupling in graphene[1] , DENIS KOCHAN, MARTIN GMITRA, JAROSLAV FABIAN, University Regensburg — We have analyzed the first-principles data of the electronic structure of hydrogenation in graphene by means of group theory derived effective Hamiltonians. We propose effective models for semihydrogenated graphene as well as for graphene with a single hydrogen adatom. The chemisorption of hydrogen modifies the structural symmetry of the plane graphene in two essential ways—it breaks the pseudospin (sublattice) symmetry and induces rippling. We show that in addition to the Rashba spin-orbit interaction there emerges another spin-orbit field which is induced by the pseudospin inversion asymmetry due to the adatoms. Our realistic effective Hamiltonians should be useful for spin transport and spin relaxation investigations.

10:48AM F8.00015 Adsorption Configurations of Carbon Monoxide on Gold Monolayer Supported by Graphene or Hexagonal Boron Nitride Film: A First-Principles Study , LU WANG, WAI-NING MEI, Department of Physics, University of Nebraska at Omaha, Omaha, NE 68182, JIAXIN ZHENG, JING LU, State Key Laboratory for Mesoscopic Physics and Department of Physics, Peking University, Beijing 100871, P. R. China, PETER DOWBEN, Department of Physics and Astronomy, University of Nebraska-Lincoln, Lincoln, NE 68588 — Using density functional theory with a semiempirical van der Waals approach proposed by Grimme, the adsorption behavior of carbon monoxide on a gold monolayer supported by graphene or monolayer hexagonal boron nitride has been investigated. Based on the changes in the Dirac cone of graphene and a Bader charge analysis, we observe that the Au(111) monolayer gains a small electron charge from graphene and monolayer h-BN. The adsorbed CO molecule adopts similar adsorption configurations on Au(111)/graphene and Au(111)/h-BN with Au-C distance 2.17−2.50 Å and Au-C-O angle of $123.9° - 139.6°$. Moreover, we found that for low CO coverages, bonding to the gold surface is surprisingly energy-favorable. Yet the CO adsorption binding energy diminishes at high coverage due to the repulsive van der Waals interactions between CO molecules.

Tuesday, March 19, 2013 8:00AM - 10:24AM –

Session F9 FPS GERA: Invited Session: The Impact of Hydraulic Fracturing 308 - Richard Wiener, Research Corporation for Scientific Advancement

8:00AM F9.00001 The EPA's Study on the Potential Impacts of Hydraulic Fracturing on Drinking Water Resources , SUSAN SHARKEY, US Environmental Protection Agency — Natural gas plays a key role in our nation's clean energy future. The United States has vast reserves of natural gas that are commercially viable as a result of advances in horizontal drilling and hydraulic fracturing technologies, which enable greater access to gas in rock formations deep underground. These advances have spurred a significant increase in the production of both natural gas and oil across the country. However, as the use of hydraulic fracturing has increased, so have concerns about its potential human health and environmental impacts, especially for drinking water. In response to public concern, the US Congress requested that the US Environmental Protection Agency (EPA) conduct scientific research to examine the relationship between hydraulic fracturing and drinking water resources. In 2011, the EPA began research to assess the potential impacts of hydraulic fracturing on drinking water resources, if any, and to identify the driving factors that may affect the severity and frequency of such impacts. The study is organized around the five stages of the hydraulic fracturing water cycle, from water acquisition through the mixing of chemicals and the injection of fracturing fluid to post-fracturing treatment and/or disposal of wastewater. EPA scientists are using a transdisciplinary research approach involving laboratory studies, computer modeling, toxicity assessments, and case studies to answer research questions associated with each stage of the water cycle. This talk will provide an overview of the EPA's study, including a description of the hydraulic fracturing water cycle and a summary of the ongoing research projects.

8:36AM F9.00002 Induced Seismicity Potential of Energy Technologies , MURRAY HITZMAN, Colorado School of Mines — Earthquakes attributable to human activities–"induced seismic events"–have received heightened public attention in the United States over the past several years. Upon request from the U.S. Congress and the Department of Energy, the National Research Council was asked to assemble a committee of experts to examine the scale, scope, and consequences of seismicity induced during fluid injection and withdrawal associated with geothermal energy development, oil and gas development, and carbon capture and storage (CCS). The committee's report, publicly released in June 2012, indicates that induced seismicity associated with fluid injection or withdrawal is caused in most cases by change in pore fluid pressure and/or change in stress in the subsurface in the presence of faults with specific properties and orientations and a critical state of stress in the rocks. The factor that appears to have the most direct consequence in regard to induced seismicity is the net fluid balance (total balance of fluid introduced into or removed from the subsurface). Energy technology projects that are designed to maintain a balance between the amount of fluid being injected and withdrawn, such as most oil and gas development projects, appear to produce fewer seismic events than projects that do not maintain fluid balance. Major findings from the study include: (1) as presently implemented, the process of hydraulic fracturing for shale gas recovery does not pose a high risk for inducing felt seismic events; (2) injection for disposal of waste water derived from energy technologies does pose some risk for induced seismicity, but very few events have been documented over the past several decades relative to the large number of disposal wells in operation; and (3) CCS, due to the large net volumes of injected fluids suggested for future large-scale carbon storage projects, may have potential for inducing larger seismic events.

9:12AM F9.00003 Environmental Dimensions of Shale Gas Extraction and Stray Gas Migration , ROBERT JACKSON, Nicholas School of the Environment, Duke University — Shale gas extraction is growing rapidly in the United States and elsewhere, developed in part through advances in technologies such as horizontal drilling and hydraulic fracturing. Concerns over potential environmental impacts have accompanied the boom in natural gas extraction. For several years we have studied drinking water quality, asking the question, "Is water quality different for homeowners living near natural gas wells?" We have sampled shallow groundwater systems of $>$ 300 homeowners, the majority of them in the Marcellus formation of Pennsylvania and New York, for brines, dissolved gases, and other attributes. We have also examined how much methane reaches the atmosphere during the extraction and distribution of natural gas. In a study published in May of 2011 (Osborn et al. 2011, PNAS 108:8172-8176), we found no evidence of increase salt concentrations or fracturing fluids with distance to gas wells for 68 sampled homes. However, dissolved methane concentrations were 17 times higher on average for water wells found within 1km distance of them. A subset of homeowners also had groundwater that indicated the presence of natural hydraulic connections to deeper formations, suggesting specific structural and hydrodynamic regimes where shallow drinking water resources might be at greater risk of contamination with fugitive gases during drilling and hydraulic fracturing of shale gas (Warner et al. 2012, PNAS 109:11961-11966). This presentation will discuss new results from shale gas sampling in 2011 and 2012.

9:48AM F9.00004 The natural gas revolution – Scale, cost and uncertainty , FRANCIS O'SULLIVAN, Massachusetts Institute of Technology — Over the past decade, the natural gas industry landscape in North America has undergone tremendous change. The focus of exploration and production has shifted from "conventional" to "unconventional" resources, and in particular to shale formations. The fact that some shale formations contain significant volumes of gas-in-place has been known for as long as gas production has taken place – these rocks have always been viewed as the source rock for conventional gas resources. What changed over the past decade is that it became possible to recover this gas directly from the source rock at economically attractive production rates. Horizontal drilling and hydraulic fracturing technologies were key to these developments. This presentation will describe how the unlocking of shale gas through horizontal drilling and fracturing has changed perspectives regarding the scale of the overall recoverable natural gas resource in the United States. The potential impact of shale gas on the global gas resource will also be described. The results of volumetric assessments of recoverable shale gas will be presented and the critical issue of uncertainty surrounding these estimates will be highlighted. The economics of shale gas relative to conventional resources in the United States will be described, and this will be compared with the economics of gas elsewhere in the world. In discussing the economics of shale gas, the very important issue of intra and inter-play well-to-well performance variability will be highlighted. The presentation will also describe some of the major environmental concerns that surround that shale gas production. The issue of water intensity in hydraulic fracturing operations will be examined, as will the concerns regarding surface and subsurface water contamination. The debate regarding the GHG footprint of hydraulic fracturing operations will be described and an assessment of "potential" and "actual" fugitive methane emissions from hydraulic fracturing operations in the major U.S. shale plays will be presented.

Tuesday, March 19, 2013 8:00AM - 11:00AM –

Session F10 GMAG: Invited Session: Spin-Orbit Transfer Torques in Magnetic Bilayers 309 - Kyung-Jin Lee, Korea University

8:00AM F10.00001 The spin Hall effect in transition metal-ferromagnetic material bilayer devices , CHI-FENG PAI, Cornell University — The strong spin-orbit interaction from certain heavy metal/ferromagnetic material bilayer systems has been shown to be intense enough to drive the magnetization into steady dynamics and/or magnetic switching via spin transfer torque mechanism. The spin Hall effect, which describes the generation of a transverse spin current from a longitudinal charge current, plays an important role in these bilayer devices that typically contain a heavy transition metal underlayer. Here we demonstrate that the spin Hall effect induced spin transfer torque (SHE-STT) from Ta and W based systems can be utilized to control the magnetization direction in magnetic tunnel junctions through a three-terminal device architecture. We also demonstrate DC current induced dynamics in the magnetic layer due to the SHE-STT in these three-terminal devices.

8:36AM F10.00002 Interfacial current induced torques in Pt—Co—GdOx , GEOFFREY S. D. BEACH, Massechusetts Insititue for Technology — No abstract available.

9:12AM F10.00003 Rashba spin-orbit coupling and orbital chirality in magnetic bilayers[1] , HYUN-WOO LEE, Department of Physics, Pohang University of Science and Technology, Pohang, Kyungbuk 790-784, Korea — The phenomenon of the Rashba spin-orbit coupling is examined theoretically for an ultrathin magnetic layer in contact with a non-magnetic heavy metal layer. From first-principles calculation, large Rashba parameter of order 1 eV·Å is obtained, which is strong enough to generate large spin transfer torque of spin-orbit coupling origin. Large Rashba parameter is attributed to the orbital mixing of $3d$ magnetic atoms and non-magnetic heavy elements with significant atomic spin-orbit coupling. Interestingly the magnitude and sign of the parameter vary from energy bands to bands, which we attribute to band-specific chiral ordering of orbital angular momentum. Through a simple tight-binding model analysis, we demonstrate that d-orbital hybridization allowed by the breaking of structural inversion symmetry generates band-specific chiral ordering of orbital angular momentum, which combines with atomic spin-orbit coupling to give rise to band-specific Rashba parameter. The band-dependence of the Rashba parameter is discussed in connection with recent experiments and we argue that the dependence may be utilized to enhance device application potentials.

[1]This work is supported by NRF grant (2010-0008529, 2011-0015631, 2010-0014109, 2011-0030789).

9:48AM F10.00004 Vector measurements of the current induced effective fields in Ta/CoFeB/MgO heterostructures , MASAMITSU HAYASHI, National Institute for Materials Science — Ultrathin magnetic heterostructures exhibit a variety of rich physics owing to the strong effects from the interfaces. Power efficient current induced magnetization switching and domain nucleation, fast current driven domain wall motion have been observed in ultrathin Co or CoFeB layer sandwiched between a heavy metal (Pt, Ta) and an oxide. Most of the current (or voltage) induced effects in these systems can be represented by the "effective magnetic fields", which illustrate the strength and direction of the torque exerted on the magnetic moments. A comprehensive understanding of the effective fields is key to the development of magnetic nano-devices aimed for memory and logic applications. We have studied the current induced effective field vector in Ta|CoFeB|MgO heterostructure to reveal the underlying physics of the interaction between the magnetic moments and current in such structure. A low current lock-in detection scheme is used to evaluate the effective field vector. The CoFeB layer is perpendicularly magnetized owing to the interface magnetic anisotropy of CoFeB|MgO. We find that the effective field is very sensitive to the thickness of the Ta and CoFeB layers. The effective field even changes its direction when the Ta layer thickness is varied, indicating that there are competing effects that contribute to the effective field generation. We discuss our results in light of the spin Hall effect and an effect due to Rashba-like Hamiltonian. (Acknowledgment: FIRST program)

10:24AM F10.00005 Giant spin Hall effect in CuBi alloys , YOSHICHIKA OTANI, ISSP University of Tokyo — Spintronic devices manipulating pure spin currents, flows of spin angular momentum without net charge current, should play an important role in low energy consumption electronics for next generation. This explains the current interest for the spin Hall effect (SHE) which provides a purely electrical way to create spin currents without ferromagnets and magnetic fields. In this work, we have studied extrinsic SHEs in Cu-based alloys [1]. Copper itself does not show any SHE, but by adding impurities with strong spin-orbit interactions such as Ir and Bi, the extrinsic SHEs can be generated and one can tune the SH angle which represents the maximum yield of conversion of charge to spin current density. The SH resistance was measured by means of spin absorption method using a lateral spin valve structure with an inserted wire of SHE material [1]. We found that $Cu_{99.5}Bi_{0.5}$ exhibited a very large negative SH resistance whereas Pt and a $Cu_{99}Ir_1$ alloy had positive SH resistances. From nonlocal spin valve measurements with the SHE materials, we can obtain the spin absorption rates as well as the spin diffusion lengths of the SHE materials. The spin Hall angle was determined by fitting experimental data to two theoretical models, i.e., a purely 1D model [2] and a 3D spin transport model based on an extension to 3D of the Valet-Fert formalism [3]. For Pt and CuIr alloys, the spin diffusion lengths are smaller than their thickness (20 nm), and the SH angles obtained from the 1D and 3D analyses are similar to each other (about 2% for both Pt and CuIr). For CuBi alloys, however, the analysis in the 3D model gave much larger SH angle of about - 24% than the 1D of about -12%. More interestingly the fact that Bi impurities generated much larger SH angle than Pt and Ir, was consistent with a recent ab-initio theoretical calculation [4].

Tuesday, March 19, 2013 8:00AM - 11:00AM –

Session F11 DPOLY: Invited Session: Polymer Physics Prize Session 310 - John Torkelson, Northwestern University

8:00AM F11.00001 Polymer Physics Prize Lecture: Self-assemblies of Giant Molecular Shape Amphiphiles as a New Platform for Engineering Structures with Sub-Nanometer Feature Sizes , STEPHEN Z.D. CHENG, University of Akron — Utilizing nano-building blocks rather than atoms to construct and engineer new structures is a fresh approach to design and develop functional materials for the purpose of transferring and amplifying microscopic functionality to macroscopic materials' property. As one of the important elements of these nano-building blocks, giant molecular shape amphiphiles (GMSAs) provide a latest platform for generating self-assembled ordered structures at nanometer scale, which are stabilized by collective physical bonds (such as collective hydrogen bonding). In this talk, two topics will be focused on. First, composed of functionalized hydrophilic molecular nanoparticles as the heads with rigid shape and fixed volume, and tethered polymer chains as the tails (such as giant molecular surfactants and lipids and other topologies), these GMSAs of various architectures can self-assemble into highly diversified, thermodynamically stable microstructures at sub-10 nm length scale in the bulk, thin film and solution states. Second, GMSAs could also be constructed solely from nanoparticles interconnected via different numbers of the rigid linkages in specific symmetry, simulating the overall shapes of small molecules but with sizes that are one-order of magnitude larger in length and three-order of magnitude larger in volume. Giant crystal structures can then be obtained from this class of "giant molecules" via supramolecular crystallization. These findings are not only scientifically intriguing in understanding the physical principles underlying their self-assembly, but also technologically relevant in industrial applications.

8:36AM F11.00002 Polymer Spheulites , BERNARD LOTZ, Institut Charles Sadron (CNRS and ULP) — The growth and/or structural features that determine lamellar shape in polymer spherulites and therefore their structure and properties have been debated for many years. The spectacular twisting of lamellae in optically banded spherulites has been explained by the existence of unbalanced stresses in opposite fold surfaces of the lamellae. This mechanical origin implying the folds explains also the demonstrated absence of correlation between lamellar twist sense and molecular chirality of chiral polymers. Unbalanced surface stresses may also generate spherulites made of scrolled lamellae, with the scroll axis radial. This original morphology was first observed in spherulites of poly(vinylidene fluoride) in its γ phase. It arises from a chemical disparity of folds formed on opposite fold surfaces, the volumes of which differ by 10Å*3. Similar chemical disparities have been suggested to explain the formation of highly unusual scrolled single crystals of polyamide 66 obtained from solution under specific annealing and crystallization conditions. Related thermal histories lead to the formation, in the bulk, of unusual optically negative spherulites of polyamide 66 that were first observed in the 1940s. These still poorly understood negative spherulites may well display a similar scrolled lamellar morphology. The analysis of unbalanced surface stresses requires to evaluate the interplay and mutual impact of crystal and fold structures. The stresses associated with different fold structures are locally small perturbations but are cumulative and are exerted on thin, flexible lamellae. The latter non-planar morphologies reveal these stresses and help reach sub-moleculr insights on the fold structures.

9:12AM F11.00003 Cellulose as Sustainable Materials for Separation Membranes[1] , BENJAMIN CHU, Stony Brook University — Polysaccharides, while complex, form one of the most abundant sustainable resources on earth. We want to take advantage of fundamental advances in materials understanding across length and time scales to investigate the interrelationships between structure, morphology, processing, properties, performance, and cost to meet the specific challenges arising from separation membranes for water purification. Non-woven fiber mats have unique properties, such as interconnected pores, a very large surface-to-volume ratio, and a high capacity for surface modifications. The breakthrough concept of combining fibrous mats composed of different fiber diameters for fabricating scaffolds as a unique platform for water purification is presented. Further, we take advantage of recent advances in chemical modifications, structural studies using synchrotron X-rays, and physical scale-up transformations to drastically improve filtration membrane development.

[1]Support of this work by the NSF, ONR, NIH and Stony Brook Univ. is gratefully acknowledged. The Chu/Hsiao group on water purification includes Profs. B.S.Hsiao and C.Burger, Drs. H-Y.Ma, D-F.Fang, R.Wang, and grad students: X.Wang, Z. Wang, Y.Su, R. Yang

9:48AM F11.00004 Computational Modeling Studies of Peptides and Proteins on Inorganic Surfaces , BARRY FARMER, Air Force Research Laboratory Materials & Manufacturing Directorate — Biological moieties offer exquisite sensitivity and selectivity in their interactions with small molecules, offering considerable potential in applications as chemical sensors. To detect binding events between the peptide and the intended molecule, a transduction mechanism is needed. This often involves an association of the peptide with an inorganic surface, such as a metal nanoparticle, a carbon nanotube, or graphene. Understanding the nature of the association of the peptide with the surface and its effect on the conformational (and thus, binding) properties of the peptide are key to optimizing the sensing mechanism. We utilized computational approaches ranging from *ab initio* to molecular dynamics to bond-fluctuation Monte Carlo methods to study the adsorption of peptides and proteins on inorganic surfaces to develop an understanding of the role that composition and substrate character plays in the adsorption process, and in turn, the effects on the binding events with the molecules of interest.

10:24AM F11.00005 Periodic Polymers , EDWIN THOMAS, Mechanical Engineering and Materials Science Rice University — Periodic polymers can be made by self assembly, directed self assembly and by photolithography. Such materials provide a versatile platform for 1, 2 and 3D periodic nano-micro scale composites with either dielectric or impedance contrast or both, and these can serve for example, as photonic and or phononic crystals for electromagnetic and elastic waves as well as mechanical frames/trusses. Compared to electromagnetic waves, elastic waves are both less complex (longitudinal modes in fluids) and more complex (longitudinal, transverse in-plane and transverse out-of-plane modes in solids). Engineering of the dispersion relation between wave frequency w and wave vector, k enables the opening of band gaps in the density of modes and detailed shaping of w(k). Band gaps can be opened by Bragg scattering, anti-crossing of bands and discrete shape resonances. Current interest is in our group focuses using design - modeling, fabrication and measurement of polymer-based periodic materials for applications as tunable optics and control of phonon flow. Several examples will be described including the design of structures for multispectral band gaps for elastic waves to alter the phonon density of states, the creation of block polymer and bicontinuous metal-carbon nanoframes for structures that are robust against ballistic projectiles and quasi-crystalline solid/fluid structures that can steer shock waves.

Session F12 DMP: Focus Session: Complex Oxide Interfaces - Polar interfaces II 314 - Jeremy Levy, University of Pittsburgh

8:00AM F12.00001 Mott p-n junctions in layered materials[1] , MAXIME CHARLEBOIS, Universite de Sherbrooke, Québec, Canada, SYED HASSAN, RAJESH KARAN, The Institute of Mathematical Sciences C.I.T., Chennai, India, DAVID SENECHAL, Universite de Sherbrooke, Québec, Canada, A.-M.S. TREMBLAY, Universite de Sherbrooke, Québec, Canada and CIFAR, Canada — Correlated electron heterostructure became a possible alternative when thin film deposition techniques achieved structures with a sharp interface transition [1]. We study here the electronic reconstruction of doped Mott insulator p-n junctions based on a Cluster Dynamical Mean Field Theory (CDMFT) calculation of the Hubbard model in the limit where electrostatic energy dominates over the kinetic energy associated with transport across layers. The grand potential of individual layers is first computed within CDMFT and then the electrostatic potential energy is taken into account in the Hartree approximation. The charge reconstruction in an ensemble of stacked planes of different nature can lead to a distribution of electron charge [2], density of states, and optical properties that are unique to doped-Mott insulators.

8:12AM F12.00002 Strong electron correlation enhancement to capacitance via frustrated phase separation[1] , JAMES FREERICKS, SIMON HALE, Department of Physics, Georgetown University — Recent experiments on strongly correlated capacitors from Mannhart's group have shown that the capacitance can be enhanced by about 50% over the geometric capacitance when the metallic leads are gated to be nearly depleted of electrons. More recently, direct measurements of the electron compressibility in those leads show that they become phase separated in this regime. It has long been known that proximity to phase separation, or equivalently negative electron compressibility, should lead to an enhancement of capacitance. In this work, we show that this phenomenon is quite general. By employing a microscopic model of a strongly correlated capacitor composed of multilayers of electronic leads and a Mott insulating dielectric, we show that by tuning the barrier to lie in the regime where it is phase separated in the bulk, it exhibits a type of frustrated phase separation in the multilayer, which gives rise to an enhancement in the capacitance with capacitance curves versus gate voltage resembling quite close to those of experiment. In the calculations, the enhancement effect is lower (on the order of 10%), and the mechanism is different, because here the phase separation is in the dielectric instead of the metallic plates. Nevertheless, this behavior seems to be ubiquitous.

8:24AM F12.00003 Theory of optical response and ellipsometry spectra of $LaAlO_3/SrTiO_3$ heterostructures[1] , SE YOUNG PARK, ANDREW MILLIS, Columbia University — We present a theory of the optical and ellipsometric properties of the electron gas at the $LaAlO_3/SrTiO_3$ (LAO/STO) interface. The reflectivity and ellipsometry angles are obtained by calculating the random phase approximation (RPA) dielectric constant including the optical phonon of STO and the charge response of the electron gas. We find a dip in the ellipsometry angle at the plasma edge of STO phonon that is related with in-plane Drude response and a peak in high energy from the plasmon excitation of yz and xz electrons and show how these may be related to subband occupancy and scattering rates. Comparison of the theory to published data indicates that about 80% of electrons in xy band are inert to optical transition, possibly explaining the discrepancy in charge density between transport measurements and polar catastrophe scenario.

8:36AM F12.00004 Optical conductivity of $SrTiO_3$ based interfaces , MING XIE, GURU KHALSA, ALLAN MACDONALD, The University of Texas at Austin — Since the discovery of a high mobility two-dimensional electron gas at the interface of $LaAlO_3/SrTiO_3$, there has been a large scientific effort to understand the properties of perovskite interfaces. Naturally, this effort has focused on magneto-transport and photoemission studies. Here we use the Kubo formalism to study the optical conductivity of $SrTiO_3$ based interfaces and discuss its implications on the underlying physical properties of these systems. In particular, the response to light polarized in- and out-of-plane will be contrasted.

8:48AM F12.00005 Oxygen vacancies and magnetism at titanate interfaces[1] , NATALIA PAVLENKO, Institute of Physics, University of Augsburg — Breaking the translation or inversion symmetry at surfaces and interfaces may lead to the formation of new charge, spin and orbital electronic states which are different than the bulk states. The emergence of these states is particularly relevant for oxides where the balance of competing interactions and the resulting stable electronic phase crucially depend on the local oxidation state near the interface. A prominent example is the interface of $LaAlO_3/SrTiO_3$ (LAO/STO), which exhibits a two-dimensional electron liquid state in the structures with $LaAlO_3$-layers more than 4uc thick, and undergoes a transition into a superconducting state below 0.2 K. Depending on growth conditions LAO/STO has also been found to display pronounced magnetotransport effects indicating the existence of local moments. Recently, even a coexistence of ferromagnetism and superconductivity has been reported, possibly due to an electronic phase separation within the interface. We analyze the magnetic state at the LAO/STO interface within density functional theory and provide evidence that it is caused by the spin polarization of Ti 3d interface electrons. The magnetic state depends strongly on the oxidation state of the interfaces. We show that oxygen vacancies at titanate interfaces induce a complex multiorbital reconstruction which involves a lowering of the local symmetry and an inversion of t_{2g} and e_g orbitals resulting in the occupation of the e_g orbitals of Ti atoms neighboring the O vacancy. In contrast to stoichiometric nonmagnetic interfaces of $LaAlO_3$ and $SrTiO_3$, the vacancy-induced orbital reconstruction at LAO/STO interfaces generates a two-dimensional interface magnetic state not observed in bulk $SrTiO_3$. We demonstrate that oxygen vacancies in the TiO_2 interface layer enhance the tendency for ferromagetism considerably. This allows for the notion that areas with increased density of oxygen vacancies produce ferromagnetic puddles and account for the previous observation of a superparamagnetic behavior in the superconducting state. Using generalized gradient approximation (LSDA) with intra-atomic Coulomb repulsion (GGA+U), we find that this magnetic state is common for titanate surfaces and interfaces.

9:24AM F12.00006 Local Moment Formation and Magnetism at $LaAlO_3/SrTiO_3$ Interfaces[1] , ONUR ERTEN, SUMILAN BANERJEE, MOHIT RANDERIA, The Ohio State University — One of the most exciting observations at oxide interfaces relate to the observation of magnetism at the $LaAlO_3/SrTiO_3$ (LAO/STO) interface, since neither material is magnetic in the bulk even with doping. Experiments [1,2] give incontrovertible evidence for local moments at the LAO/STO interface, consistent with an areal density close to 0.5 per interfacial Ti atom. The particular splitting of the t_{2g} orbitals at the interface, leads to a quarter-filled d_{xy} band on the top band. Using a slave-rotor approach for the on-site Coulomb interaction U and Hartree-Fock for nearest neighbor V, we show that local moments form in a checkerboard charge-ordered insulating (COI) state, even for a very modest values of U. Phonons further stabilize the COI state as the breathing mode couples cooperatively to the charge order. To understand the magnetic interactions between moments, we examine both the small superexchange and the dominant kinetic exchange mediated by conduction electrons. We show that this leads to a ferromagnetic double exchange model with some very interesting twists arising from the Rashba SOC of the conduction electron due to broken inversion at the interface. 9:36AM F12.00007 Theory for magnetic exchange and anisotropy at the $LaAlO_3/SrTiO_3$ interface[1] , SUMILAN BANERJEE, ONUR ERTEN, MOHIT RANDERIA, Department of Physics, The Ohio State University, Columbus, Ohio, 43210 — The $LaAlO_3/SrTiO_3$ interface exhibits unusual magnetic properties with a large density of local moments seen by both torque and scanning SQUID experiments. We develop a model where local moments are formed on a 2D checkerboard lattice due to correlation-driven charge ordered insulator. We focus on the double exchange interaction of these moments via conduction electrons with a large Rashba spin-orbit coupling (SOC) due to broken inversion at the interface. We derive an effective Hamiltonian for the local moments that has an unusual double square-root ferromagnetic exchange, previously seen in a different context [1]. Two new features arise from SOC, direction-dependent anisotropic exchanges and Dzyaloshinskii-Moriya type terms, which can be tuned by gating. We show that SOC accounts for the the unusually large easy-plane magnetic anisotropy seen in experiment. We will explore the phase diagram, as a function of the strength of Rashba SOC, to see what unusual magnetic states might be stabilized. We will comment on the possibility of reconciling the apparently different conclusions reached by torque and scanning SQUID measurements regarding the magnetic ordering and ordered moment.

9:48AM F12.00008 ABSTRACT WITHDRAWN –

10:00AM F12.00009 Intrinsic spin Hall effect at oxide interfaces: a simple model[1] , LORIEN HAYDEN, University of Missouri-Columbia, ROBERTO RAIMONDI, Universita' di Roma Tre, MICHAEL FLATTE', University of Iowa, GIOVANNI VIGNALE, University of Missouri-Columbia — An asymmetric triangular potential well provides one of the simplest model for the confinement of mobile electrons at the interface between two insulating oxides, such as $LaAlO_3$ and $SrTiO_3$ (LAO/STO). In this paper we study the intrinsic spin Hall effect due to Rashba coupling in an asymmetric triangular potential well. Besides splitting each subband into two branches of opposite chirality, the spin-orbit interaction causes the wave function in the direction perpendicular to the plane of the quantum well (i.e., the growth direction) to depend on the in plane wave vector kv. In contrast to the extreme asymmetric case, i.e., the wedge-shaped quantum well, for which the intrinsic spin Hall effect is known to vanish due to vertex corrections, we find that the asymmetric well supports a non-vanishing intrinsic spin Hall conductivity, proportional to the square of the spin-orbit coupling constant. Its origin lies in the non-vanishing matrix elements of the spin current between subbands corresponding to different states of quantized motion perpendicular to the plane of the well. Vertex corrections are carefully considered, both for the intra-band and the inter-band contributions to the spin Hall conductivity.

10:12AM F12.00010 Theory of spin-orbit effects in the t_{2g} band of pseudo-cubic perovskites , GURU KHALSA, The University of Texas at Austin, BYOUNGHAK LEE, Texas State University, ALLAN MACDONALD, The University of Texas at Austin — Epitaxial interfaces of perovskite systems have recently been the focus of an enormous amount of research due to their novel properties and potential for integration with silicon based technologies. Although the role of spin-orbit effects has been discussed in the literature, a first principles study of their influence on electronic structure has been lacking. We have conducted a study of spin-orbit effects in pseudo-cubic t_{2g} perovskite systems in which inversion symmetry has been broken by the presence of an external electric field. In this talk, we discuss our results and compare with available magneto transport studies on LAO/STO and related systems.

10:24AM F12.00011 Theory of spin-orbit coupling at LaAlO3/SrTiO3 interfaces and SrTiO3 surfaces , ZHICHENG ZHONG, ANNA TOTH, KARSTEN HELD, Vienna University of Technology — A full theoretical understanding of the spin-orbit coupling (SOC) effects at $LaAlO_3/SrTiO_3$ interfaces and $SrTiO_3$ surfaces is still needed. We perform first-principles density-functional-theory calculations and derive from these a simple tight-binding Hamiltonian, through a Wannier function projection and group theoretical analysis. We find striking differences to the standard Rashba theory for spin-orbit coupling in semiconductor heterostructures, because the relevant t_{2g} orbitals are very different from nearly free electrons. The key ingredients to the spin splitting are the atomic SOC and the interface asymmetry, which enters via asymmetric t_{2g} orbital lobes. ArXiv:1209.4705 by Zhicheng Zhong, Anna Toth, Karsten Held

10:36AM F12.00012 Transport through oxide interfaces - The case of $SrTiO_3$ based heterostructures[1] , M. BEN SHALOM, E. FLEKSER, Y. DAGAN, Raymond and Beverly Sackler School of Physics and Astronomy, Tel-Aviv University, Israel, M. KIM, C. BELL, Y. HIKITA, H.Y. HWANG, Stanford Institute for Materials and Energy Sciences, SLAC National Accelerator Laboratory, Menlo Park, California 94025, USA — Sharp interfaces can host phenomena that are absent in their constituting materials. By depositing a thin layer of $LaAlO_3$ on top of $SrTiO_3$, the interface between these two band-insulator is highly conducting. Conductivity emerges only for TiO_2 termination and above a critical $LaAlO_3$ thickness of 4 unit cells, pointing to the importance of the polar structure. The transition, from insulating to high mobility electron gas, can be controlled continuously by gate voltage, thus enabling a careful study of the dependence of system properties on charge density. Carrier-controlled two-dimensional superconductivity, and magnetic hysteresis were observed between the two non-magnetic oxides. We have found anisotropic magnetoresistance (AMR) in our samples, an outcome of magnetic scattering, which affect the transport through the spin orbit (SO) interaction, and coexists with superconductivity. Gate bias enables tuning the SO energy, which dominates the magnetotransport properties. The exceptionally large amplitude and sign of the AMR suggests a Rashba-type SO coupling. The different AMR characteristics for Nb doped $SrTiO_3$, a symmetric non-polar with similar resistivity and carrier density, demonstrates the significant role of interface polarity for its magnetic properties.

Session F13 DCMP: Topological Insulators: Theory I 315 - Pouyan Ghaemi, University of Illinois

8:00AM F13.00001 Homological Order in Three and Four dimensions: Wilson Algebra, Entanglement Entropy and Twist Defects[1] , ABHISHEK ROY, XIAO CHEN, JEFFREY TEO, University of Illinois at Urbana-Champaign — We investigate homological orders in two, three and four dimensions by studying Z_k toric code models on simplicial, cellular or in general differential complexes. The ground state degeneracy is obtained from Wilson loop and surface operators, and the homological intersection form. We compute these for a series of closed 3 and 4 dimensional manifolds and study the projective representations of mapping class groups (modular transformations). Braiding statistics between point and string excitations in (3+1)-dimensions or between dual string excitations in (4+1)-dimensions are topologically determined by the higher dimensional linking number, and can be understood by an effective topological field theory. An algorithm for calculating entanglemnent entropy of any bipartition of closed manifolds is presented, and its topological signature is completely characterized homologically. Extrinsic twist defects (or disclinations) are studied in 2,3 and 4 dimensions and are shown to carry exotic fusion and braiding properties.

8:12AM F13.00002 Weyl points and line nodes in gapless gyroid photonic crystals , LING LU, LIANG FU, JOHN JOANNOPOULOS, MARIN SOLJACIC, Department of Physics, Massachusetts Institute of Technology, MIT TEAM — Weyl points and line nodes are three-dimensional linear point- and line-degeneracies between two bands. In contrast to Dirac points, which are their two-dimensional analogues, Weyl points are stable in the momentum space and the associated surface states are predicted to be topologically non-trivial. However, Weyl points are yet to be discovered in nature. Here, we report photonic crystals, based on the double-gyroid structures, exhibiting frequency-isolated Weyl points with complete phase diagrams by breaking the parity and time-reversal symmetries. The surface states associated with the non-zero Chern numbers are demonstrated. Line nodes are also found in similar geometries; the associated surface states are shown to be at bands. Our results are based on realistic "numerical experiments" with true predictive power and should be readily experimentally realizable at both microwave and optical frequencies.

8:24AM F13.00003 The optical conductivity of quasicrystals: evidence of a Weyl semimetal with 3D Dirac spectrum , THOMAS TIMUSK, JULES CARBOTTE, McMaster University, CHRISTOPHER HOMES, Brookhaven National Laboratory, DIMITRI BASOV, University of California, San Diego, SERGEI SHARAPOV, Bogolyubov Institute for Theoretical Physics, Kiev — The optical conductivity of quasicrystals is characterized by an absence of the Drude peak and a conductivity that rises linearly over a wide range of frequencies. The absence of the Drude peak has been attributed to a pseudogap at the Fermi surface but a detailed explanation of the linear behavior has not been found. This unusual behavior is seen in all icosahedral quasicrystal families and their periodic approximants. A simple model that assumes that the entire Fermi surface is gapped, with the exception at a finite set of Dirac points, fits the data. There is no evidence of a semiconducting gap in any of the materials suggesting that the massless Dirac spectrum is protected by topology leading to a Weyl semimetal. The model gives rise to a linear conductivity with only one parameter, the Fermi velocity. In accord with this picture decagonal quasicrystals should have a frequency independent conductivity, without a Drude peak. This is in accord with the experimental data as well.

8:36AM F13.00004 Chiral magnetic effect in Weyl semimentals and insulators , MOHAMMAD VAZIFEH, MARCEL FRANZ, University of British Columbia — It has been proposed recently, on the basis of field-theoretical considerations, that the effective electromagnetic action of Weyl semimetals (as well as the closely related Weyl insulators) contains an axion term with the θ-angle dependent on time t or spatial position $\mathbf{r}$. If correct this would lead to a number of novel observable phenomena, such as the chiral magnetic effect, whereby an applied uniform magnetic field induces a dissipationless bulk current $\mathbf{j} \propto \mathbf{B}$. In this work we construct a simple lattice model for a Weyl semimental (insulator) and use it to explicitly test for the chiral magnetic effect by means of numerical techniques combined with analytical calculations. We discuss possible ways to engineer a suitable material in layered nanostructures and comment on the physical observability of the effect.

8:48AM F13.00005 Axion field theory, chiral anomaly and anomalous non-dissipative transport properties of (3+1)-dimensional Weyl semi-metals and superconductors[1] , PALLAB GOSWAMI, National High Magnetic Field Laboratory and Florida State University, SUMANTA TEWARI, Department of Physics and Astronomy, Clemson University — From a direct calculation of the anomalous Hall conductivity and an effective electromagnetic action obtained via Fujikawa's chiral rotation technique, we conclude that an axionic field theory with a non-quantized coefficient describes the electromagnetic response of the (3+1)-dimensional Weyl semi-metal. The coefficient is proportional to the momentum space separation of the Weyl nodes. Akin to the Chern-Simons field theory of quantum Hall effect, the axion field theory violates gauge invariance in the presence of the boundary, which is cured by the chiral anomaly of the surface states via the Callan-Harvey mechanism. A direct linear response calculation also establishes an anomalous thermal Hall effect and a Wiedemann-Franz law. But, thermal Hall conductivity does not directly follow from the well known formula for the (3+1)-dimensional gravitational chiral anomaly. By calculating the gravitational chiral anomaly at finite temperature we show the existence of a new term, which correctly accounts for the thermal Hall effect in (3+1)-dimensional Weyl materials, topological insulators and topological superconductors.

9:00AM F13.00006 ABSTRACT WITHDRAWN –

9:12AM F13.00007 Friedel oscillations due to Fermi arcs in Weyl semimetals , PAVAN HOSUR[1], Department of Physics, University of California at Berkeley — Weyl semimetals harbor unusual surface states known as Fermi arcs, which are essentially disjoint segments of a two-dimensional Fermi surface. We describe a prescription for obtaining Fermi arcs of arbitrary shape and connectivity by stacking alternate two-dimensional electron and hole Fermi surfaces and adding suitable interlayer coupling. Using this prescription, we compute the local density of states–a quantity directly relevant to scanning tunneling microscopy–on a Weyl semimetal surface in the presence of a point scatterer and present results for a particular model that is expected to apply to pyrochlore iridate Weyl semimetals. For thin samples, Fermi arcs on opposite surfaces conspire to allow nested backscattering, resulting in strong Friedel oscillations on the surface. These oscillations die out as the sample thickness is increased and Fermi arcs from the opposite surface retreat and weak oscillations, due to scattering between the top surface Fermi arcs alone, survive. The surface spectral function, accessible to photoemission experiments, is also computed. In the thermodynamic limit, this calculation can be done analytically and separate contributions from the Fermi arcs and the bulk states can be seen.

[1]My present affiliation is Department of Physics, Stanford University

9:24AM F13.00008 Topological Phases of Point Group Symmetric Weyl Superconductors , VASUDHA SHIVAMOGGI, University of Illinois. Urbana-Champaign, CHEN FANG, Princeton University, TAYLOR HUGHES, MATTHEW GILBERT, University of Illinois. Urbana-Champaign — We study superconductivity in a Weyl semimetal with broken time-reversal symmetry and stabilized by a point-group symmetry. The resulting superconducting phase is characterized by topologically protected bulk nodes and surface states with Fermi arcs. We derive a phase diagram of possible superconducting phases which are distinguished by the number of bulk nodes and discuss novel properties of the corresponding surface states. We show how the topological behavior may be understood in terms of the properties of the parent Weyl semimetal at high-symmetry momenta.

9:36AM F13.00009 Excitonic Phases of Weyl Semi-Metals with Coulomb Interaction , HUAZHOU WEI, UC Riverside, SUNG-PO CHAO, National Tsing Hua University, VIVEK AJI, UC Riverside — Weyl semi-metals have an even number of nodes which are perfectly nested in the absence of a chiral chemical potential. For repulsive interactions these are susceptible to excitonic instabilities. The vanishing density of states requires that the coupling be larger than a critical value for the states to be realized. There are eight possible states in the particle-hole channel, only two of which gap out the weyl nodes for long range Coulomb interactions. The lowest energy state is the Charge Density Wave state, which is more stable than the ferromagnetic insulator that arises in the context of short range repulsion. The defects of the state, i.e. dislocations, have been shown in the literature, to carry gapless chiral modes.

9:48AM F13.00010 Excitonic Phases from Weyl Semi-Metals with short range interaction[1] , SUNG-PO CHAO, National Tsing Hua University, HUAZHOU WEI, VIVEK AJI, UC Riverside — Weyl semimetal, possibly realized in Pyrochlore irridates or supperlatice of 3D topological-normal insulators system, has strong spin orbit interactions leading to effective low energy described by massless linearly dispersing fermions. In the absence of interactions chirality is a conserved quantum number, protecting the semi-metallic physics against perturbations that are translationally invariant. We show that the interplay between short range repulsive interaction and topology yields a novel chiral excitonic insulator. The state is characterized by a complex vectorial order parameter leading to a gapping out of the Weyl nodes. An interesting feature is that it is ferromagnetic, with the phase of the order parameter determining the direction of the induced magnetic moment. The case of Coulomb interaction will be discussed by Huazhou Wei in his report.

[1]The authors acknowledge the financial support by University of California at Riverside through the initial complement.

10:00AM F13.00011 Probing the Chiral Anomaly via Nonlocal Transport in Weyl Semimetals[1] , SIDDHARTH PARAMESWARAN, UC Berkeley, TARUN GROVER, Kavli Institute for Theoretical Physics, UC Santa Barbara, ASHVIN VISHWANATH, UC Berkeley — Weyl semimetals are three-dimensional analogs of graphene in which a pair of bands touch at points in momentum space, known as Weyl nodes. Electrons originating from a single Weyl node possess a definite topological charge, the chirality. Consequently, they exhibit the Adler-Jackiw-Bell anomaly, which in this condensed matter realization implies that application of parallel electric ($\mathbf{E}$) and magnetic fields ($\mathbf{B}$) pumps electrons between nodes of opposite chirality at a rate proportional to $\mathbf{E} \cdot \mathbf{B}$. We argue that this pumping is measurable via transport experiments, in the limit of weak internode scattering. Specifically, we show that injecting a current in a Weyl semimetal subject to an $\mathbf{E} \cdot \mathbf{B}$ term leads to nonlocal features in transport.

10:12AM F13.00012 Effective field theories for topological insulators by functional bosonization , PAK ON CHAN, TAYLOR L. HUGHES, SHINSEI RYU, EDUARDO FRADKIN, Department of Physics, University of Illinois at Urbana-Champaign — Effective field theories that describe the dynamics of electric current for topological insulators in general dimension D = d+1 are discussed using the functional bosonization. For non-interacting topological insulators with a conserved U(1) charge and characterized by an integer topological invariant, we derive the BF-type topological field theories supplemented with the Chern-Simons (when D is odd) or the Axion term (when D is even). For topological insulators characterized by a Z2 topological invariant, their topological field theories are obtained by dimensional reduction. Building on this effective field theory description for non-interacting topological phases, we also discuss, following the spirit of the parton construction of the fractional quantum Hall effect, the putative "fractional" topological insulators and their possible effective field theories.

10:24AM F13.00013 Physics of three dimensional bosonic topological insulators I , ASHVIN VISHWANATH, UC Berkeley, TODADRI SENTHIL, MIT — We discuss physical properties of "integer" topological phases of bosons in D=3+1 dimensions, protected by internal symmetries like time reversal and/or charge conservation. These phases invoke interactions in a fundamental way but do not possess topological order and are bosonic analogs of free fermion topological insulators and superconductors. Here we develop a field theoretic description of several of these states and show that they possess unusual surface states, which if gapped, must either break the underlying symmetry, or develop topological order. In certain cases the topological phases are characterized by a quantized magneto-electric response θ, which, somewhat surprisingly, is an odd multiple of 2π. A surface theory in which vortices transform under a projective representation of the symmetry group is shown to capture these properties. A bulk field theory of these states is also identified, which furthermore predicts phases characterized by the thermal analog of the magneto-electric effect, that lie beyond the current cohomology description.

10:36AM F13.00014 Physics of three dimensional bosonic topological insulators II , S. TODADRI, Massachusetts Institute of Technology, ASHVIN VISHWANATH, University of California Berkeley — We discuss physical properties of interacting boson/spin analogs of free fermion topological insulators and superconductors. We discuss general constraints on the surface theories of these phases, and their field theoretic descriptions. We illustrate some of the results in the context of quantum paramagnetic phases of spin systems. For the 3d states we describe the 2d surface either spontaneously breaks symmetry or is in a spin liquid phase. In the latter case the symmetry is realized in the surface spin liquid in a way that is forbidden in strictly two dimensional quantum magnets.

10:48AM F13.00015 Wilson-loop Classification of Inversion-Symmetric Topological Insulators and the $\mathbf{Z}_2$ Crystalline Topological Insulator , A. ALEXANDRADINATA, Department of Physics, Princeton University, XI DAI, Beijing National Laboratory for Condensed Matter Physics and Institute of Physics, Chinese Academy of Sciences, B. ANDREI BERNEVIG, Department of Physics, Princeton University — In the context of translationally-invariant insulators, Wilson loops describe the adiabatic evolution of the ground state around a closed circuit in the Brillouin zone. We propose that the Wilson-loop eigenspectrum provides a complete characterization of (a) the inversion-symmetric topological insulator, and (b) the $\mathbf{Z}_2$ crystalline topological insulator: time-reversal symmetric insulators with either C_4 or C_6 rotational symmetry, but with no spin-orbit coupling. For the 1D inversion-symmetric insulator, we formulate a $\mathbf{Z}$ Wilson-loop index, which is identifiable with the number of protected boundary modes in the entanglement spectrum. For the 2D inversion-symmetric insulator, we identify a $\mathbf{Z}$ relative-winding number, which is the inversion-analog of the first Chern class (for charge-conserving insulators). For the $\mathbf{Z}_2$ crystalline topological insulator, we show how the $\mathbf{Z}_2$ invariant can be extracted from the Wilson-loop eigenspectrum; this aids the identification of materials that realize this phase.

Session F14 DMP FIAP GMAG: Focus Session: Material Properties Important for Spin-torque Dynamics 316 - Ting Yong Chen, Arizona State University

8:00AM F14.00001 Quantifying spin torque effects using a current-driven magnetic vortex[1] , KRISTEN BUCHANAN, Department of Physics, Colorado State University — Spin transfer torques offer great potential for the development of spin-based devices for processing and storing information but there is still debate surrounding the relative contributions of the adiabatic and non-adiabatic spin torque effects. Magnetic vortices in patterned magnetic films provide a model system that can be used to quantify these effects. Micromagnetic calculations of the current-driven motion of a magnetic vortex in a patterned Permalloy element show that the two spin torque effects have distinguishable influences on the trajectories of the vortex core and, furthermore, that the effect of the current-generated magnetic fields (Oersted) that are often non-negligible when current flows through magnetic nanostructures can also be separated out. An analysis of a series of experimental images of vortex trajectories obtained using a recently developed dynamic Lorentz transmission electron microscopy technique provides a measure of the non-adiabatic spin torque parameter with greatly improved precision [1]. The work described here was carried out in collaboration with Shawn Pollard, L. Huang, Dario Arena, and Yimei Zhu (Brookhaven).

8:36AM F14.00002 Anisotropy of spin relaxation in metals and ultrathin metallic films[1] , NGUYEN H. LONG, PHIVOS MAVROPOULOS, BERND ZIMMERMANN, SWANTJE HEERS, STEFAN BLUGEL, YURIY MOKROUSOV, Peter Gruenberg Institut and Institute for Advanced Simulation, Forschungszentrum Juelich and JARA, 52425 Juelich, Germany — We predict a hitherto overlooked anisotropy of the spin relaxation time T_1 in non-magnetic metallic systems with respect to the orientation of the spin porlarization $\hat{s}$ of the injected electrons relative to the crystallographic directions. In the Elliott-Yafet mechanism, the spin relaxation time is related to the Elliott-Yafet parameter b^2 that quantifies the degree of spin-mixing of Bloch states due to spin-orbit interaction. It can be demonstrated that b^2 depends on $\hat{s}$ due to the directional dependence of the spin-orbit matrix-elements between Bloch states comprising directional orbitals. The directional dependence becomes very pronounced in the case of degeneracies or near-degeneracies leading to *spin-flip hot spots* or even extended *hot areas* on the Fermi surface. The calculated anisotropy can reach values as large as 830% for hcp Hf or 87% in W(110) 10-layer-films, as we find from first-principles calculations employing the Kohn-Korringa-Rostoker Green function method. The anisotropy offers interesting new functionalities in spintronics applications such as GMR, spin Hall effect as well as spin dynamics. [1] B. Zimmermann, P. Mavropoulos, S. Heers, N. H. Long, S. Blugel, and Y. Mokrousov, Phys. Rev. Lett., in press (arXiv:1210.1801).

8:48AM F14.00003 Extraction of spin-transport parameters from ferromagnetic resonance measurements of spin-pumping in metallic multilayers , CARL BOONE, HANS NEMBACH, JUSTIN SHAW, THOMAS SILVA, National Institute of Standards and Technology — We use ferromagnetic resonance to measure damping due to spin-pumping in symmetric multilayers of Ta(3)/Ni(x)/Pd(y)/CoFe(2)/Pd(y)/Ni(x)/Ta(3) (thicknesses in nm, $0 \leq x \leq 2$nm, $0 \leq y \leq 10$nm). The stack's symmetry ensures that spin-pumping on both sides of the ferromagnet is identical and allows us to unambiguously characterize the multilayer spin-transport properties. When $x = 0$ (no Ni), the Pd-Ta interface is found to be strongly spin-impedant, due to the low spin conductivity of Ta, leading to greatly reduced damping for thin Pd. As the Pd thickness approaches the spin diffusion length, the damping increases. By inserting Ni, a strong spin absorber, at the Pd/Ta interface, the damping for thin Pd is maximized. Varying the thickness of the Ni layer can be used to tune the inter-layer spin current flow in the Pd/Ni/Ta heterostructure. Comparison of the data with the conventional model for diffusive spin-polarized transport in normal metals permits quantitative determination of the spin-diffusion length in the normal metals. The results have implications for the detection of spin-currents in lateral spin valves via the inverse spin Hall effect in high-resistivity materials such as Ta.

9:00AM F14.00004 Controlling the Gilbert damping using spin pumping and magnetic impurities , TIM VERHAGEN, HOLLY TINKEY, JAN VAN RUITENBEEK, JAN AARTS, Leiden University — The ability to control the magnetic damping parameter of thin magnetic films is an important issue when designing for example giant magnetoresistance (GMR) devices. A well-known way to influence the damping of the ferromagnetic (F) layer is by using the spin pumping effect in which a spin current is emitted into an adjacent normal (N) layer by bringing the F-layer into ferromagnetic resonance (FMR). As N layer, we used the well studied strongly spin sinking material Pt and the bad spin sink Cu, but also a Cu layer with Co impurities. We find that by adding a small amount of Co impurities, the Cu layer becomes as effective in damping as a Pt layer. In the latter case, the damping is caused by the strong spin orbit coupling. Using magnetic impurities, we rather make use of the inelastic spin scattering. This opens up new ways to control the damping of a ferromagnetic thin layer, for example in current-in-plane (CIP) GMR sensors, where the extra damping can suppress the spin transfer torque which becomes dominant with the further decrease of the size of the sensor.

9:12AM F14.00005 Gilbert damping parameter characterization in perpendicular magnetized Co_2FeAl films[1] , YISHEN CUI, JIWEI LU, University of Virginia, BEHROUZ KHODADADI, SEBASTIAN SCHÄFER, TIM MEWES, University of Alabama, STUART WOLF, University of Virginia — Materials with perpendicular magnetic anisotropy(PMA) have gotten extensive recent attention because of their potential application in spintronic devices such as spin transfer torque random access memory (STT-RAM). It was shown that a much lower switching current density(J_C) is required to write STT-RAM tunnel junctions with perpendicular magnetic anisotropy ferromagnetic electrodes (p-MTJ). Additionally Heusler alloy Co_2FeAl is expected to further reduce J_C due to its ultra low Gilbert damping parameter. In our study, Heusler alloy Co_2FeAl films were prepared using a Biased Target Ion Beam Deposition (BTIBD) technique. We demonstrated a low Gilbert damping parameter achieved in thick B2-Co_2FeAl films. Besides, we achieved an interfacial PMA in ultra thin Co_2FeAl films by rapid thermal annealing (RTA) with no external field presented. Annealing conditions were carefully adjusted to maximize the interfacial PMA. However it was noticed that a higher annealing temperature was required for a low damping parameter which to some extent sacrificed the interfacial PMA. We also deposited ultra thin CoFeB films and characterized their damping parameters for comparison.

[1]We acknowledge the financial support from DARPA.

9:24AM F14.00006 Bonding, magnetic properties and stability of the half-Heusler alloys LiMnZ (Z=N, P, Si)[1] , LIAM DAMEWOOD, BRIAN BUSEMEYER, C.Y. FONG, University of California, Davis, MICHAEL SHAUGHNESSY, Sandia National Laboratories at Livermore — We examined the bonding and magnetic properties, as well as the stability, of three magnetic half-Heusler alloys, namely LiMnZ, with Z=N, P or Si, in the three different atomic ordering of the $C1_b$ crystal structure (i.e. α, β, and γ phases). Using LiMnP as a prototype, we examined the bonding properties of the three phases and found, at the optimized lattice constant, each phase is a ferromagnetic metal. Assuming a proper matching substrate could be found, we found that α-LiMnN, LiMnSi in the β and γ phases, and LiMnP in the α and β phases can be ferromagnetic half-metals at lattice constants larger than the optimized values. Volume stability studies showed that the β phase is the most stable for these materials. In our search for more half-metals, we found that β-$Li_{0.75}$MnSi, β-$Li_{0.75}$MnP and γ-$Li_{0.75}$MnN can be half-metals at the respective LiMnSi half-metallic lattice constants. By comparing β-LiMnP to the metastable zinc blende phase of MnP, the role of Li in the structure, with respect to the elastic stability, electronic properties, and magnetic properties, was studied. Finally we examined the possibility of a compensated half-metallic phase in these materials.

9:36AM F14.00007 Dirac Half-Metal in a Triangular Ferrimagnet , HIROAKI ISHIZUKA, YUKITOSHI MOTOME, Dept. of Appl. Phys., Univ. of Tokyo — Massless Dirac fermions show substantially different nature from ordinary electrons due to the peculiar cone-like dispersion with the point node. While it was originally introduced in the relativistic quantum theory, recent discovery of graphene, a single layer sheet of graphite, has carved out a new direction of their study in condensed matter systems. From the viewpoint of potential application to electronics, it is of great interest to control the electronic spin degree of freedom. However, there is not so much flexibility in graphene, as the relativistic spin-orbit interaction is very weak. Here, we present an alternative idea for realizing massless Dirac fermions in itinerant electrons coupled to a well-known ferrimagnet on a triangular lattice [1]. The Dirac fermions are spin-polarized, and stable in a wide range of the spin-charge coupling including typical values in solids. We demonstrate that, by an unbiased Monte Carlo simulation, such Dirac half-metal with ferrimagnetic order spontaneously emerges in a minimal Kondo-lattice type model. The realization will be beneficial for spintronics as a candidate for spin-current generator.

9:48AM F14.00008 GMAG PhD Dissertation Research Award Talk: Experimental characterization of non-isochronous properties of spin torque nano-oscillators , MICHAEL QUINSAT, CEA Leti / Spintec — Spin Torque Oscillators (STO) are nano-sized auto- oscillators whose frequency can be tuned in a wide range. This tuning originates from the nonlinear properties of the underlying magnetization dynamics that is induced by spin transfer torque (STT) in magnetic nanostructures. Being highly tunable in frequency has the inconvenience of being very sensitive to noise. As a result the spectral purity of STOs is below the one required for applications. The magnetization dynamics induced by STT has been described theoretically in the frame of a non-isochronous auto-oscillator model [1]. Within this model the important information on the excitation mode is contained within two phenomenological parameters which are, the amplitude-phase coupling ν, and the amplitude relaxation rate Γ_{p}. They completely determine the non-autonomous oscillator response and their experimental determination is thus an important issue. This presentation describes several experimental methods to extract these parameters. The first involves time domain noise spectroscopy which permits the power spectral density of phase and amplitude noise to be extracted [2]. The analysis of such noise in light of theoretical models allows not only direct extraction of the nonlinear parameters, but also to quantify the phase noise - the characteristics important for applications. This is demonstrated for magnetic tunnel junction devices. A second method involves the analysis of higher harmonic linewidths $\Delta \mathrm{f_n}$ [3], where it is shown that due to the non-isochronous property of STOs, the relationship between $\Delta \mathrm{f_n}$ and $\Delta \mathrm{f_1}$ is nontrivial and allows one to extract ν and Γ_{p}. We then apply the information gathered on the autonomous dynamics of STOs to understand their non-autonomous dynamics that are a prerequisite for the use of STOs in more complex devices (field sensors, frequency synthesizers, etc). It is shown experimentally how the nonlinear parameters ν and Γ_{p} determine this non-autonomous behavior of the STO.

10:24AM F14.00009 Correlation effects in disordered conductors with spin accumulation , ALEXANDER ZYUZIN, University of Basel — We consider the effect of electron-electron interaction on the density of states of disordered thin film paramagnetic conductor in the presence of spin accumulation and magnetic field. We assume a mechanism of electrical spin injection from a ferromagnet into a paramagnet as a particular realization of the spin accumulation. We show that interaction correction to the electron density of states of the paramagnet exhibits singularities at energies corresponding to the difference between chemical potentials of electrons with opposite spins. The correction to the conductivity of the paramagnet in the metallic region as well as in the hopping region in the presence of spin accumulation is calculated.

10:36AM F14.00010 Spin transport in the Neel and collinear antiferromagnetic phase of the two dimensional spatial and spin anisotropic Heisenberg model on a square lattice[1] , TRINANJAN DATTA, Augusta State University, ZEWEI CHEN, DAO-XIN YAO, State Key Lab of Optoelectronic Materials and Technologies, School of Physics and Engineering, Sun Yat-sen University — We analyze and compare the effect of spatial and spin anisotropy on spin conductivity in a two dimensional S=1/2 Heisenberg quantum magnet on a square lattice. We explore the model in both the Neel antiferromagnetic (AF) phase and the collinear antiferromagnetic (CAF) phase. We find that in contrast to the effects of spin anisotropy in the Heisenberg model, spatial anisotropy in the AF phase does not suppress the zero temperature regular part of the spin conductivity in the zero frequency limit - rather it enhances it. In the CAF phase (within the non-interacting approximation) the zero frequency spin conductivity has a finite value which is suppressed as the spatial anisotropy parameter is increased. Furthermore, the CAF phase displays a spike in the spin conductivity not seen in the AF phase. We also explore the finite temperature effects on the Drude weight in the AF phase (within the collision less approximation). We find that enhancing spatial anisotropy increases the Drude weight value and increasing spin anisotropy decreases the Drude weight value. Based on these studies we conclude that antiferromagnets with spatial anisotropy are better spin conductors than those with spin anisotropy at both zero and finite temperatures.

10:48AM F14.00011 Study of the Switching Current Density Reduction in Spin Transfer Torque Magnetic Tunneling Junction by Using Micromagnetic Simulations , CHUN-YEOL YOU, Department of Physics, Inha University, Korea, MYUNG-HWA JUNG, Department of Physics, Sogang University, Korea — We investigate the reduction of switching current density of the spin transfer torque magnetic tunneling junction (STT-MTJ) with micromagnetic simulations for the various parameters and structures. We introduce a non-collinear magnetization polarizer layer and find noticeable switching current density reduction. The physical origin of the reduction ascribe to the enhanced coherent spin rotation due to the asymmetry breaking. Furthermore, when we cut the one edge of the MTJ ellipse structure, conspicuous reduction of switching current density is also found. In contrast to the normal MTJ structure where the switching process is accompanied with non-coherent spin dynamics, enhanced coherent spin rotations play an important role in both new structures. In addition, we find that the switching current density is sensitively varied with the exchange stiffness and junction size due to the weakly quantized spin wave vector. Based on our micromagnetic simulations, we open new path to reduce the switching current density with new MTJ structures.

Session F15 GMAG DMP: Focus Session: New Frustrated Quantum States: Theory & Materials 317 - Piers Coleman, Rutgers University

8:00AM F15.00001 Lattices of Magnetic Vortices in a Frustrated Mott Insulator , CRISTIAN BATISTA[1], Los Alamos National Laboratory — Chiral spin textures with different length scales emerge in some itinerant magnets and are attracting increasing interest in the study of magneto-transport and possible applications to magnetic data storage and spin-electronic devices. It is natural to ask if similar topological textures can emerge in Mott insulators and also lead to magneto-electric effects. In this talk I will show that this is indeed possible when the exchange interactions are geometrically frustrated. For this purpose, I will consider a frustrated S=1/2 XXZ Hamiltonian that is a low-energy effective model for Ba_3Mn2O_8, a novel layered spin-dimer compound, comprising magnetic dimers of Mn^{5+} ions arranged on triangular planes. Successive layers are stacked following an ABC sequence, such that the dimer units on adjacent planes are positioned in the center of the triangular plaquettes of the layers above and below. The effective exchange anisotropy of the low-energy model results from frustration between exchange interactions connecting the same pair of dimmers. The competition between intra and inter-layer exchange interactions leads to a triplon dispersion with six-fold degenerate minima at the incommensurate wave vectors $\pm Q_n$ ($1 \leq n \leq 3$). This degeneracy leads to a very rich quantum phase diagram near the magnetic field induced quantum critical point, that is constructed by adding ladder diagrams and minimizing the resulting energy functional. The phase diagram includes different multi-Q magnetic orderings, which combine up to the six degenerate incommensurate lowest-energy modes $\pm Q_n$ ($1 \leq n \leq 3$). In particular, it includes a six-Q state that consists of a lattice of magnetic vortices and other complex spin textures associated with different multi-Q ordered states.

[1]Work done in collaboration with Yoshitomo Kamiya

8:36AM F15.00002 Unconventional quantum critical points in the generalized quantum dimer models , ZI-XIANG LI, Institute for Advanced Study, Tsinghua University, Beijing, FAN YANG, School of Physics, Beijing Institute of Technology, Beijing, HONG YAO, Institute for Advanced Study, Tsinghua University, Beijing — We study a class of generalized quantum dimer models with both NN and NNN dimers on the square lattice, whose exact ground state wave function can be constructed. By varying the weight of NNN dimers and the interactions between dimers, we obtain a rich quantum phase diagram which hosts quantum spin liquid phases and various valence bond solids. We then investigate the quantum critical behavior of the transitions between spin liquids and valence bond solids by analytically studying its effective field theory and numerically doing variational Monte Carlo simulations. We discuss unconventional quantum critical points in this system.

8:48AM F15.00003 Supersolids and Anomalous Hysteresis in Frustrated Spin-Dimer Systems , DAISUKE YAMAMOTO, RIKEN, IPPEI DANSHITA, YITP — We study the ground-state properties of weakly coupled spin dimers on a triangular lattice. The competition of the two (direct and crossed) interdimer interactions and the geometry of the triangular lattice lead to a strong frustration. By using a large-size cluster mean-field method and the cluster-size scaling, we determine the quantitative magnetic phase diagram of the system under the presence of a magnetic field. The strong intradimer interaction provides a gapped spin-singlet ground state. If the magnetic field exceeds a certain critical value, the system undergoes a phase transition to a magnetically ordered state, which is known as a Bose-Einstein condensation (BEC) of spin-triplet excitations called "triplons." We find that for strong magnetic fields, the magnetization curve shows plateaus at 1/3 and 2/3 of the total magnetization, in which the local singlet and triplet states form a superlattice pattern. This state can be regarded as a solid of triplons. We also find that if increasing (decreasing) the magnetic field from the 1/3 (2/3) plateau, the BEC of triplons occurs on the superlattice background, leading to the transition into "magnon supersolid" phase. The region of supersolid phase in the phase diagram is reasonably large compared to the square-lattice case.

9:00AM F15.00004 Quantum spin-ordered states for the frustrated XY model on the honeycomb lattice , ANDREA DI CIOLO, Joint Quantum Institute, University of Maryland and Georgetown University, JUAN CARRASQUILLA, Georgetown University and Pennsylvania State University , FEDERICO BECCA, International School for Advanced Studies and CNR-Istituto Officina dei Materiali (Trieste) , VICTOR GALITSKI, Joint Quantum Institute, University of Maryland , MARCOS RIGOL, Georgetown University and Pennsylvania State University — We consider the frustrated XY model on the honeycomb lattice and determine the stability of several classical spin states supplemented with a long-range Jastrow factor that introduces quantum fluctuations. In particular, we focus on the competition between antiferromagnetic, collinear, and generic spiral order upon increase of frustration. Our investigation is based on Variational Monte Carlo calculations.

9:12AM F15.00005 Evidence of valence bond condensation in the frustrated cluster magnet $LiZn_2Mo_3O_8$, JOHN SHECKELTON, JAMES NEILSON, DANIEL SOLTAN, TYREL MCQUEEN, Johns Hopkins University — The reduced molybdenum oxide $LiZn_2Mo_3O_8$ is a Mott insulating material built of two dimensional layers of magnetic Mo_3O_{13} triangular clusters, arranged on a triangular lattice. Between these magnetic layers are disordered non-magnetic $LiZn_2$ layers. The formal oxidation state and calculations show each molybdenum cluster collectively produces a S=1/2 moment. The "triangle of triangles" arrangement of magnetic clusters gives rise to exciting frustrated magnetic physics while also preventing Jahn-teller instabilities and site disorder seen in single ion frustrated systems. In addition, the structure allows for facile electronic doping of the magnetic layers. Structural and measured physical properties and ongoing research will be discussed. The evidence discussed indicates the formation of an exotic condensed valence bond state, reminiscent of the long-sought resonating valence bond state.

9:24AM F15.00006 $LiZn_2Mo_3O_8$: honeycomb spin liquid in a triangular lattice material? , REBECCA FLINT, PATRICK LEE, MIT — $LiZn_2Mo_3O_8$ is a S=1/2 triangular lattice material in which two-thirds of the spins vanish at 100K, while the remaining spins remain free down to the lowest temperatures. There is no thermodynamic phase transition, and does not appear to be any magnetic order. The experimental proposal is that the triangular lattice decouples into a honeycomb lattice with free spins in the center of each hexagon, however, it is not immediately clear what favors this decompostion. We argue that a set of alternating octahedral rotations can strengthen the bonds of the honeycomb lattice while weakening those to the central spin. Furthermore, if the honeycomb lattice forms a Z_2 spin liquid, as proposed for the $J_1 - J_2$ Heisenberg model, instead of a Néel or valence bond solid state, the central spin can delocalize over the hexagon, further favoring this decomposition, and also stabilizing the spin liquid phase over the Néel and VBS phases. Experimentally, this proposal can be tested by searching for signatures of the octahedral rotations, which may be short range or dynamic, but should result in a $q = 0$ soft phonon mode. The spinon spectrum of the gapped Z_2 spin liquid should also have signatures in inelastic neutron scattering. We also discuss possible 3D analogues.

9:36AM F15.00007 ABSTRACT WITHDRAWN –

9:48AM F15.00008 Improved cluster-effective-field study on frustrated quantum spin systems in 2D , YOSHIHIKO NONOMURA, Computational Materials Science Unit, National Institute for Materials Science, Tsukuba 277-0062, Japan — Although frustrated quantum spin systems in two dimensions are fascinating playground of novel quantum states, systematic numerical study with the quantum Monte Carlo method is difficult in such systems owing to the negative sign problem. Then, cluster-effective-field approach may be useful as an alternative numerical tool. Crucial points of formulation are to use periodic boundary clusters and to compare two different clusters. As an example, the J_1-J_2 model, where $S = 1/2$ Heisenberg spins are located on a square lattice with the nearest-neighbor and next-nearest-neighbor antiferromagnetic couplings J_1 and J_2. Classical Néel or sublattice Néel orders become unstable in the vicinity of $J_2/J_1 = 0.5$, where novel quantum states are expected to be stable. When the 16- and 20-spin clusters are used and the columnar or staggered dimer orders are taken as order parameters, we have coexisting regions of magnetic and dimer orders and first-order phase transitions between the columnar and staggered dimer orders. Further results based on larger clusters and improved formulations including multi-body effective fields are also discussed in the presentation.

10:00AM F15.00009 Theory of inelastic neutron scattering in a quantum spin nematic , NIC SHANNON, ANDREW SMERALD, Okinawa Institute of Science and Technology — The idea that a quantum magnet could act like a liquid crystal, breaking spin-rotation symmetry without breaking time-reversal symmetry, holds an abiding fascination. However, despite being a viable form of magnetic order, None the less, experimental evidence for "spin nematic" states in magnetic insulators remains scarce. And the very fact that spin nematic states do not break time-reversal symmetry renders them "invisible" to the most common probes of magnetism — they do not exhibit magnetic Bragg peaks, a static splitting of lines in NMR spectra, or oscillations in μSR. However, as a consequence of breaking spin-rotation symmetry, spin-nematic states do posses a characteristic spectrum of dispersing excitations which could be observed in inelastic neutron scattering. With this in mind, we develop a symmetry-based description of long-wavelength excitations in a broad class of spin-nematic states, based on an SU(3) generalisation of the quantum non-linear sigma model. We use this field theory to make explicit predictions for inelastic neutron scattering, and argue that the wave-like excitations it predicts could be used to identify the symmetries broken by the unseen spin-nematic order.

10:12AM F15.00010 Gapless spin liquid phase in the J1-J2 Heisenberg model , WENJUN HU, FEDERICO BECCA, SANDRO SORELLA, Democritos Simulation Center CNR-IOM Istituto Officina dei Materiali and International School for Advanced Studies (SISSA) — We study the stability of a Z2 spin liquid in the highly frustrated regime of the J1-J2 Heisenberg model in the square lattice, namely with nearest and next nearest antiferromagnetic superexchange interactions. We use state of the art quantum Monte Carlo methods[S. Sorella $et\ al.$, prl **88**, 117002 (2002)] and show that, by means of few Lanczos steps acting over our initial wave function, we can achieve basically exact energies for the ground state and the low lying spin excitations, whenever our results can be compared with exact diagonalization reference data. For large clusters we show evidence that our calculations remain very accurate because we can estimate exact eigenvalues by extrapolating our results to the exact zero variance limit. By taking into account these important corrections, our final phase diagram seems to be inconsistent with an opening of a sizable spin gap in the spin liquid region, as recently found by a DMRG study [H.-C. Jiang $et\ al.$, prl **86**, 024424 (2012)].

10:24AM F15.00011 Symmetric and nematic Z_2 quantum spin liquids: applications to the J_1-J_2 Heisenberg model , YIFAN JIANG, Institute for Advanced Study, Tsinghua University, Beijing, FAN YANG, School of Physics, Beijing Institute of Technology, HONG YAO, Institute for Advanced Study, Tsinghua University, Beijing — We classify symmetric and nematic Z_2 quantum spin liquid states on the square lattice by analyzing bosonic PSG. We then compute the energies of various symmetric and nematic Z_2 spin liquid states for the J_1-J_2 square Heisenberg model by doing variational Monte Carlo simulations. The connections of our variational Monte Carlo studies with the recent DMRG results on the same model will also be discussed.

10:36AM F15.00012 Deconfined Criticality in a $J-Q$ model on Honeycomb lattice , SUMIRAN PUJARI, FABIEN ALET, LPT, IRSAMC, Université Paul Sabatier, Toulouse, France, KEDAR DAMLE, TIFR, Mumbai, India — The Deconfined Criticality scenario[1] describes in the context of quantum magnets a generic non-Landau second-order transition between two orders that break different symmetries - antiferromagnetic order that breaks $SU(2)$ symmetry and Valence bond (VB) order breaking lattice translational symmetry. We investigate this physics in the context of a $J-Q$ model[2] on the honeycomb lattice using both $T=0$ Projector Quantum Monte Carlo (QMC) and finite-T Stochastic Series Expansion QMC techniques. We find evidence for a continuous transition from different measurements including scaling of Néel and VB order parameters, Binder ratios of staggered magnetization, stiffness and uniform susceptibility. We have indications that this critical point belongs to the same universality class as the one observed on square lattice $J-Q$ model. Our results also suggest that this critical fixed point controlling deconfined critical behaviour remains essentially unchanged even on the honeycomb lattice which allows three-fold hedgehog defects in the Néel order to be present in the continuum description of the critical point.

[1]T. Senthil $at\ al$, Science 303, 1490 (2004).
[2]A. W. Sandvik, Phys. Rev. Lett. 98, 227202 (2007).

10:48AM F15.00013 Monte Carlo studies of spinon deconfinement in two dimensions[1] , YING TANG, ANDERS SANDVIK, Boston University — We have used a recently proposed quantum Monte Carlo algorithm [1] to study spinons (emergent $S=1/2$ excitations) in 2D Resonating-Valence-Bond (RVB) spin liquids and in a J-Q model hosting a Néel–VBS phase transition at zero temperature. We found that spinons are well defined quasi-particles with finite intrinsic size in the RVB spin liquid. The distance distribution between two spinons show signatures of deconfinement. However, at the Néel–VBS transition, we found that the spinon size itself is comparable to the confinement length (the size of the bound state), even showing a shrinkage of the bound state (triplon) relative to the single spinon. Both the spinon size and the confinement length diverge as the critical point is approached. We attempt to extract the corresponding exponent. [1] Y. Tang and A. W. Sandvik, Phys. Rev. Lett. **107**, 157201 (2011).

Tuesday, March 19, 2013 8:00AM - 11:00AM –

Session F16 GMAG DMP: Focus Session: High Magnetic Anisotropy Materials 318 - Randy Dumas, Gothenburg University, Sweden

8:00AM F16.00001 Growth, structure and magnetism of self-organized epitaxial nano-alloys on a metallic substrate , S. ROUSSET, N. MOREAU, V. REPAIN, C. CHACON, Y. GIRARD, J. KLEIN, J. LAGOUTE, MPQ, University Paris-Diderot Paris 7, UMR CNRS 7162, H. BULOU, F. SCHEURER, C. GOYHENEX, IPCMS, University of Strasbourg UMR CNRS 7504, PH. OHRESSER, SOLEIL, Saint-Aubin, France — The CoPt alloy is one of the most studied bimetallic compounds, due to its potential application for magnetic recording. We report here on Co_xPt_{1-x} nano-alloys deposited on the well-known Au(111) reconstructed surface since it has been recognized as a powerful substrate in order to investigate the magnetic properties of metallic nano-clusters [1,2]. The growth of Co_xPt_{1-x} clusters on the Au(111) surface observed by STM revealed a morphological transition from single layer to bilayer islands with the Co concentration x. Using molecular dynamics calculations, we show that this transition is driven by the local strain due to Co atoms. These results are interpreted by a competition between the interface energy, the mixing energy and the elastic energy. Using X-ray Magnetic Circular Dichroism, we have studied the magnetic properties of these nano-alloys. The out-of-plane anisotropy of pure Co clusters strongly decreases, until it goes in-plane for 40% of Pt. This spin reorientation transition is interpreted by a phenomenological pair model for magnetic anisotropy. **References** [1] N. Weiss et al., Phys. Rev. Lett. 95, 157204 (2005) [2] S. Rohart et al., Phys. Rev Lett. 104, 104, 137202 (2010).

8:12AM F16.00002 Tailoring anisotropy in (001) oriented $(Fe_{1-x}Cu_x)_{55}Pt_{45}$ films , DUSTIN GILBERT, Physics Department, University of California, Davis, CA 95616 USA, LIANG-WEI WANG, Department of Materials Science and Engineering, National Tsing Hua University, Hsinchu, Taiwan, TIMOTHY KLEMMER, JAN-ULRICH THIELE, Seagate Technology, Fremont, CA 94538 USA, CHIH-HUANG LAI, Department of Materials Science and Engineering, National Tsing Hua University, Hsinchu, Taiwan, KAI LIU, Physics Department, University of California, Davis, CA 95616 USA — High anisotropy magnetic materials are central to future spintronic and recording technologies. Binary alloy FePt in its fct-$L1_0$ phase offers ideal magnetic properties, but usually requires high temperature annealing. Alloying with Cu has been suggested to lower the annealing temperature. However, it has been difficult to grow oriented films and prior studies have often focused on non-ideal compositions. In this work we investigate $(Fe_{1-x}Cu_x)_{55}Pt_{45}$ films – an ideal ratio for the $L1_0$ phase. Fully ordered films with a strong (001) texture were grown by an atomic-scale multilayer sputtering method and rapid thermal annealing at 400 °C. The room-temperature deposition, low annealing temperature, and lack of a seed layer shows the strength of this technique. An increase in the tetragonal lattice distortion and fragmentation of the microstructure [while retaining the (001) texture] were observed with added Cu. Magnetic properties were evaluated and show a strong perpendicular anisotropy. The Cu inclusion is demonstrated to decrease T_C without hefty sacrifices to M_S and K_U, making such films ideal for heat-assisted magnetic recording.

8:24AM F16.00003 Direct Chemical synthesis of $L1_0$ FePt Nanoparticles with High Coercivity[1] , XIAOCAO HU, RYAN GALLAGHER, GEORGE HADJIPANAYIS, University of Delaware — FePt particles with tetragonal $L1_0$ structure have been of great interest as one of the most promising candidate for ultra-high density recording media. Chemical synthesis is one of the two major methods to fabricate FePt nanoparticles because it can lead to high uniformity and patterned assembly. However, traditional approaches require post annealing above 500° to transform the FePt nanoparticles from the disordered face-centered cubic (fcc) to the ordered $L1_0$ phase which introduces undesirable agglomeration and sintering. In this study, we have fabricated ordered $L1_0$ FePt nanoparticles using one-step chemical synthesis without post annealing. The traditional synthesis method of reduction of $Pt(acac)_2$ and $Fe(CO)_5$ was used at higher temperatures in the range of 300 to 400° . Monodispersed Au nanoparticles with average size of 10 nm were used as catalysts. X-ray diffraction (XRD) spectra and selected area electron diffraction (SAED) patterns revealed that the FePt nanoparticles are in $L1_0$ phase. The highest coercivity obtained was 8 kOe at room temperature and 11 kOe at 50 K and is achieved at the reaction temperature of 400°. Transmission electron microscopy (TEM) images showed that FePt nanoparticles are partially agglomerated which needs further improvement.

8:36AM F16.00004 Structure and Magnetic Properties of Sm-Co Particles Synthesized From Nanostructured Precursor Oxides[1] , BRIAN KELLY, KARL UNRUH, University of Delaware — Sm-Co particles have been synthesized by a calciothermic reduction/diffusion reaction from a Sm-Co-O precursor. The precursor oxide was prepared by an autocombustion reaction and was subsequently milled with CaO, which served as a grain-growth inhibitor and thermal ballast. The effects of varying the amount of Ca metal between 2 and 6 times the amount needed for complete reduction of the available Sm-Co-O precursor, the reaction temperature between 850 and 1000 C, and reaction time between 15 minutes and 24 hours were studied. The structural and magnetic properties of the Sm-Co reaction products were studied by x-ray diffraction, scanning electron microscopy, and vibrating sample magnetometry measurements. The results of these measurements indicated that magnetically hard $SmCo_5$ was preferentially formed in samples synthesized with high Ca amounts and short diffusion times, or low Ca amounts and long diffusion times. Particle sizes were also observed to increase with both increasing diffusion time and increasing Ca amount. The influence of changes in both reaction temperature and size of the CaO additive on the final product were also studied.

8:48AM F16.00005 Magnon softening in exchange-coupled hard-soft nanocomposites , ALEXANDER BELEMUK, SIU TAT CHUI, University of Delaware — We study spin excitations of the fully aligned state for three-dimensional nanocomposites of exchange coupled hard (SmFeN) and soft (FeCo) phases. When the amount of soft phase is increased the energy of low-lying spin excitation is considerably softened and contains a contribution proportional to the anisotropy constant of the soft phase. The dipolar interaction further lowers the magnon energy and controls the spin wave gap at $\mathbf{k} = 0$, which closes when the amount of soft phase exceeds a critical value. With the addition of soft phase or increasing the temperature the system moves to another ground state characterized by a magnetization mismatch between spins of hard and soft phases.

9:00AM F16.00006 ABSTRACT WITHDRAWN –

9:12AM F16.00007 Atomic structure of high-coercivity cobalt-carbide nanoparticles ensembles , D.A. ARENA, G. STERBINSKY, NSLS / BNL, P.W. STEPHENS, Physics Dept, SUNY-Stonybrook, K.J. CARROLL, H. YOON, S. MENG, Dept. Nano-Engineering, UC San Diego, Z. HUBA, E.E. CARPENTER, Chemistry Dept, Virginia Commonwealth Univ. — Permanent magnets are increasingly important in numerous applications, including the quickly expanding area of green technologies ($e.g.$ high efficiency electric car motors and wind turbine power systems). We present studies of novel permanent magnet materials based on cobalt carbide nanoparticles (NPs), where the energy product (BH_{max}) exceeds 20 kJ / m^3 [1]. The NPs are synthesized via a polyol process, which offers a flexible approach to modify the Co-carbide phase (Co_2C and Co_3C), and NP morphology, size and size dispersion. The Co_2C and Co_3C phases have unique magnetic properties, and the combination exhibits the high BH_{max}. We present a detailed assessment of the structure of mixtures of Co_2C and Co_3 NPs, measured by high-resolution, synchrotron based powder x-ray diffraction (p-XRD). Both the Co_2C and Co_3 phases exhibit an orthorhombic structure (Pnnm and Pnma space groups, respectively). The high-resolution p-XRD facilitates identification of mixed phase samples, enabling detailed comparisons of the atomic structure with the magnetic properties, measured by both lab-based magnetometry and x-ray spectroscopy (soft x-ray XAS & XMCD).

9:24AM F16.00008 Magnetic and electronic structure of high-coercivity cobalt-carbide nanoparticles for permanent magnet applications , GEORGE STERBINSKY, National Synchrotron Light Source, Brookhaven National Laboratory, KYLER CARROLL, HYOJUNG YOON, SHIRLEY MENG, Department of NanoEngineering, University of California San Diego, ZACHARY HUBA, EVERETT CARPENTER, Department of Chemistry, Virginia Commonwealth University, DARIO ARENA, National Synchrotron Light Source, Brookhaven National Laboratory — Permanent magnets are important in numerous technological applications. However, those with the largest energy product (BH_{max}) contain rare earth elements, which increase costs and introduce volatility into the supply chain. Recently, rare-earth free Co_2C and Co_3C nanoparticles (NPs) with large magnetic coercivity and BH_{max} have been synthesized using a polyol process [1]. Optimal $BH_{max}$is found in a mixture of the two phases. In this system, the nature of the magnetic interparticle interactions and the origins of intrinsic magnetic properties of the Co-carbide phases are not fully understood. We have investigated the origins of the magnetic properties of Co_2C and Co_3C NPs using x-ray absorption spectroscopy (XAS) and x-ray magnetic circular dichroism (XMCD) measurements at the Co L-edge and C K-edge. From differences in the electronic structures of the two Co-carbide phases, as determined by XAS, the nature of their unique magnetic properties can be deduced. Furthermore, the role of the spin and orbital moments in determining magnetic anisotropy and BH_{max} in these materials is examined with XMCD. [1] V. G. Harris et al. J. Phys. D: Appl. Phys. **43**, 165003 (2010).

9:36AM F16.00009 Brilliant CoC nanomagnets: highly magnetocrystalline anistropy for potential applications , AHMED EL-GENDY, TURKI ALMUGAITEEB, EVERETT CARPENTER, None — No doubt that the development of novel materials and their understanding on a smaller size scale is still a challenging issue at the basis of progress in many areas of materials science. This is almost entirely true in the development of new magnetic materials for a various types of vital applications. Recently the focus has moved from the microcrystalline to the nanocrystalline magnetic regime. The most common amorphous and nanocrystalline magnetic materials are classified to be one of either magnetically hard (a quite larger coercivity) or soft (a material with a very smaller coercivity) materials. In the work at hand we are concerning the hard magnetic CoC nanopareticles. This material shows a mono-dispersed, stable against air environment and larger magnetocrystalline anisotropy as well as larger coercivty. In addition, the mono-dispersed and small particle size led to getting a Curie temperature much smaller than the related bulk materials. Based on the relation between the Curie temperature and the number of atoms, the shape of the particles can be determined. Therefore, the CoC nanomagnes with impressive magnetic properties open the root for various essential applications such as permanent magnets, magnetic sensors and contrast agent for MRI diagnostic tools.

9:48AM F16.00010 Structural stability of $HfCo_7$ and Zr_2Co_{11} magnetic nanoclusters[1] , BALAMURUGAN BALASUBRAMANIAN, BHASKAR DAS, RALPH SKOMSKI, DAVID SELLMYER, Department of Physics and Astronomy and Nebraska Center for Materials and Nanoscience, University of Nebraska — The gas-aggregation-type cluster deposition has emerged as an attractive method to create uniaxially aligned nanoparticle building-blocks of metastable and new permanent-magnet materials such as $HfCo_7$ and Zr_2Co_{11} with appreciable coercivities ($H_c \approx 5.0$ kOe), magnetocrystalline anisotropies ($K_1 \approx 10$ Mergs/cm^3), and magnetic polarization ($J_s \approx 10$ kG) at 300 K. In comparison, bulk $HfCo_7$ and Zr_2Co_{11} alloys form only at ideal stoichiometries and high temperatures above 1000 °C at thermal equiliburium conditions. We have investigated the structural stability of $HfCo_7$ and Zr_2Co_{11} phases on varying their stoichiometries from ideal values in $HfCo_{7\pm\delta}$ and $Zr_2Co_{11\pm\delta}$ nanoclusters ($0\leq \delta \leq 1$), respectively and compared these results with the corresponding bulk phase diagrams. This study provides new insights to understand the underlying crystal structure and magnetic properties of the nanoclusters and to explore them for significant applications.

10:00AM F16.00011 Growth and Properties of Mn_xGa Magnetic Nanostructures[1] , MICHELLE JAMER, BADIH A. ASSAF, Physics Department, Northeastern University, MARIUS EICH, MIT Francis Bitter Magnet Lab, JAGADEESH S. MOODERA, MIT Francis Bitter Magnet Lab, Physics Department, MIT, DON HEIMAN, Physics Department, Northeastern University — Rare-Earth (RE) magnets are becoming more expensive and less available for current applications in technology. Mn_xGa (x=2-3) has previously shown coercivity of $>$ 2.5 T, close to that of RE magnets.[2] In this project, the vapor-liquid-solid (VLS) method was used to grow nanoparticles of Mn_xGa (x=1-3) with MBE. The goal was to study the magnetic properties as a function of reduced dimensionality. The samples were prepared by depositing a 3-6 nm layer of Au on Si, GaAs, and glass. It was found that the miscibility of Ga and Au is high, but for Mn and Au it is much lower. Therefore, during the growth process Ga was deposited on the gold catalyst followed by Mn deposition. The samples were then annealed at temperatures 100-500 °C. Nanostructures, including regions of nanowires, were found using scanning electron microscopy on all samples. The magnetic properties of the nanostructured samples were studied with SQUID magnetometry and found to have a magnetization of 200 emu/cm^3.

[2]T.J. Nummy, S.P Bennett, T. Cardinal, and D. Heiman, *Large Coercivity in Nanostructured Rare-earth-free Mn_xGa Films*, Appl. Phys. Lett. **99**, 252506 (2011).

10:12AM F16.00012 Magnetism of MnGa-based nanostructures[1] , PARASHU KHAREL, Nebraska Center for Materials and Nanoscience(NCMN) and Department of Physics and Astronomy, University of Nebraska, Lincoln, NE, 68588, YUNG HUH, NCMN and Department of Physics, South Dakota State University, Brookings, SD, 57007, VALLOPPILLY SHAH, NCMN,University of Nebraska, Lincoln, NE, 68588, RALPH SKOMSKI, DAVID SELLMYER, NCMN and Department of Physics and Astronomy University of Nebraska, Lincoln, NE, 68588 — Materials with high magnetic anisotropy and Curie temperature well above room temperature have potential for a range of applications including high-density recording, nonvolatile memory and permanent-magnet materials. Mn_yGa ($1 \leq y \leq 2$) is one such compounds that can be synthesized in the tetragonal $L1_0$ or $D0_{22}$ structures based on the value of y in Mn_yGa. Our experimental investigation of the rapidly quenched nanostructured ribbons shows that the material with y =1.2, 1.4 and 1.6 prefers the $L1_0$ structure and that with y =1.9 and 2.1 prefers $D0_{22}$ structure. We have found a maximum saturation magnetization of 88 emu/g in $Mn_{1.2}Ga$ which decreases monotonically to 50 emu/g as y reaches 2.1. Although both the $L1_0$ and $D0_{22}Mn_yGa$ samples show a high Curie temperature (T_c) well above room temperature, the value of T_c decreases almost linearly from 740 K for $Mn_{2.1}Ga$ to 550 K for $Mn_{1.2}Ga$. We will also discuss the effect of boron doping on the structural and magnetic properties of this material.

[1]This research is supported by DOE (DMR-0820521) (DJS, RS), NSF MRSEC (NSF-DMR-0820521) (PK, YH), and NCMN (VRS).

10:24AM F16.00013 MnBi: a better magnet via computational design , NIKOLAI A. ZARKEVICH, LIN-LIN WANG, Ames Laboratory, ICHIRO TAKEUCHI, University of Maryland, College Park, MATTHEW J. KRAMER , DUANE D. JOHNSON, Ames Laboratory — Using DFT-based methods, we study the magnetic properties of MnBi in the technologically important low-temperature phase. We identify the origin and behavior of the magnetoanisotropy and magnetism versus structure and doping. We perform high-throughput screening for dopants that improve magnetoanisotropy (larger, c-axis only – no reorientations) and magnetization, and chemical and structural stability. We also assess the best-in-class materials for exchange-spring coupled magnet, without the use of rare-earth elements. Experimental assessment of the predictions is also provided. Work was supported by the U.S. Department of Energy, ARPA-E under REACT (0472-1526), using methods develop under support by the Office of Basic Energy Science, Division of Materials Science and Engineering (DE-FG02-03ER46026 and DE-AC02-07CH11358). Ames Laboratory is operated for the U.S. DOE by Iowa State University under contract DE-AC02-07CH11358.

10:36AM F16.00014 DFT high-throughput screening of transition metal dopant in MnBi for better magnetic properties[1] , LIN-LIN WANG, NIKOLAI A. ZARKEVICH, Ames Laboratory, ICHIRO TAKEUCHI, University of Maryland, College Park, YIYING YE, VLADIMIR ANTROPOV, MATTHEW J. KRAMER, DUANE D. JOHNSON, Ames Laboratory — To improve the magnetic properties of MnBi, especially magnetic energy product, we use density functional theory (DFT) calculations to study alloying effects on MnBi properties with transition metals (TMs), both as dopant and soft phase in an exchange-spring magnet composite. We have considered various defects in the NiAs-type structure with interstitial and substitutional sites. Via high-throughput screening for dopants from groups 3-16, we have DFT trends in impurity formation energy, magnetization, structural parameters, magnetoanisotropy, etc. Early and late TMs prefer to occupy the Mn sites, while mid-TMs are not stable. Early and late TMs are antiferromagnetically coupled, while mid-TMs are ferromagnetically coupled to MnBi. For $3d$ mid-TMs, there is no increase in magnetization. However, energetically favorable mid-late-TM substitutes at Mn sites can improve the magnetic anisotropy. To investigate improving the magnetic energy product of a composite alloy system, we also detail the coupling between MnBi thin films with soft magnetic materials having a high magnetization.

[1]Work was supported by the U.S. Department of Energy (DOE), ARPA-E REACT Project (0472-1526). Ames Laboratory is operated for DOE by Iowa State University under contract DE-AC02-07CH11358.

10:48AM F16.00015 First Principles Studies of the Magnetic Properties of Alnico Permanent Magnet Materials[1]

, BALAZS UJFALUSSY, Research Institute for Solid State Physics & Optics, Budapest, GERMAN SAMOLYUK, KHORGOLKHUU ODBADRAKH, G. MALCOLM STOCKS, Oak Ridge National Laboratory, Oak Ridge, TN 37831 — Until the advent of rare earth based magnets Alnico was one of the highest energy product hard magnets available. Recently, interest in this system has been rekindled as system whose properties and utility may be further enhanced but does not contain rare earth elements. Recent experiments on Alnico alloy suggest that there is no sharp interface between the disordered bcc FeCo magnetic phase and the ordered B2 NiAl non-magnetic phase; thereby undermining our understanding of the large coercivity of this material. By utilizing several electronic structure methods we first study the issue of the effect of substitutions of additional elements into B2 NiAl phase. We also calculate the magnetic moment distribution across the interface and examine the magnetic ground state. These calculations suggest that the magnetic structure of the B2-phase as well as the interface in much more complex than previously thought.

Session F17 DMP GMAG: Focus Session: Magnetic Spinel and Perovskite Heterostructures

319 - Anand Bhattacharya, Argonne National Lab

8:00AM F17.00001 Growth and Properties of Magnetic Spinel Ferrite Thin Films and Heterostructures[1]

, ARUNAVA GUPTA, University of Alabama — There is considerable interest in the growth of single crystal spinel ferrites films because of their numerous technological applications in areas such as microwave integrated devices, magnetoelectric coupling heterostructures, and potentially as an active barrier material in an emerging class of spintronic devices called spin filters. Unlike perovskites, the study of spinel ferrite films is quite limited in part due to the complex crystal structure with a large unit cell consisting of many interstitial sites and that the transition metal cations can adopt various oxidation states. We have grown high-quality, atomically smooth epitaxial ferrite ($NiFe_2O_4$, $CoFe_2O_4$ and $LiFe_5O_8$) films using chemical vapor deposition and pulsed laser deposition techniques and carried out detailed studies of their structural, magnetic and optical properties. Of particular interest are systematic studies on the formation of antiphase boundaries in epitaxial $NiFe_2O_4$ films grown on different substrates and the accurate determination of the band gap of this material using optical spectroscopy and first principles calculations. Additionally, we have grown ferrite films on piezoelectric substrates and observed large shifts in the ferromagnetic resonance profile due to magnetoelectric coupling resulting from electrostatic field-induced changes in the magnetic anisotropy field. Work done in collaboration with N. Z. Bao, W. H. Butler, R. Datta, B. S. Holinsworth, M. Iliev, S. Kanuri, S. V. Karthik, G. Kim, T. M. Klein, N. Li, M. Liu, P. R. LeClair, J. X. Ma, D. Mazumdar, T. Mewes, D. V. B. Murthy, J. L. Musfeldt, K. R. O'Neal, N. Pachauri, V. M. Petrov, H. Sato, S. Schäfer, L. Shen, H. Sims, G. Srinivasan, N. X. Sun, Q. -C. Sun, and Z. Zhou.

8:36AM F17.00002 Temperature-dependent time-domain THz spectroscopic study of spinel $NiCo_2O_4$ thin films

, PUNAM SILWAL, TIANQI SHAN, DAEHO KIM, DIYAR TALBAYEV, Tulane University — The unique combination of electrical conductivity, infrared transparency, electro catalytic activity, and ferrimagnetic order makes the spinel $NiCo_2O_4$ an attractive material for various technological applications. Our previous study showed that high quality epitaxial spinel $NiCo_2O_4$ films on $MgAl_2O_4$ (001) substrate exhibit metallic behavior accompanied by ferrimagnetic order. The electrical properties of these films can be tuned from metallic to insulating by changing the growth temperature. The comprehensive understanding of the microscopic details of carrier transport in these films requires the study of frequency-dependent optical properties. Terahertz time-domain spectroscopy (THz TDS) can determine the frequency dependent complex dielectric constant, refractive index, and optical conductivity. We used THz TDS to measure the optical properties of $NiCo_2O_4$ in the 0.2 – 2.7 THz spectral region. The complex conductivities display a Drude-type frequency response. The extrapolated DC conductivity is consistent with our previous work. The temperature- and growth-condition dependent Drude parameters provide further insight in the metal-insulator transition in these materials.

8:48AM F17.00003 Theory of the magnetic and metal-insulator transitions in RNiO3 bulk and layered[1]

, BAYO LAU, ANDREW J. MILLIS, Department of Physics, Columbia University — A slave rotor-Hartree Fock formalism is presented for studying the properties of the p-d model describing perovskite transition metal oxides, and a flexible and efficient numerical formalism is developed for its solution. The methodology is shown to yield, within an unified formulation, the significant aspects of the rare earth nickelate phase diagram, including the paramagnetic metal state observed for the $LaNiO_3$ and the correct ground-state magnetic order of insulating compounds. It is then used to elucidate ground state changes occurring as morphology is varied from bulk to strained and un-strained thin-film form. For ultrathin films, epitaxial strain and charge-transfer to the apical out-of-plane oxygen sites are shown to have significant impact on the phase diagram.

[1]This effort is supported by US National Science Foundation under grant NSF-DMR-1006282

9:00AM F17.00004 Perovskite $BaCrO_3$: completing a materials system with an anomalous Mott transition[1]

, Z.H. ZHU, F.J. RUECKERT, J.I. BUDNICK, W.A. HINES, M. JAIN, H. ZHANG, B.O. WELLS, University of Connecticut — Perovskite $BaCrO_3$ cannot be stabilized in bulk but we have synthesized this compound as a film. $BaCrO_3$ films have a substantially larger lattice constant than other chromates, are insulating, and exhibit weak ferromagnetism likely associated with canted antiferromagnetism. Comparison with the sister compounds $CaCrO_3$ and $SrCrO_3$ suggests an anomalous Mott transition caused by lattice expansion where magnetism is independent of whether the compound is metallic or insulating.

[1]Supported by the NSF through grant DMR-0907197.

9:12AM F17.00005 Above room temperature ferroelectricity and weak ferromagnetism in $LaFeO_3/LnFeO_3$ digital superlattices

, SAURABH GHOSH, CRAIG J. FENNIE, Scholl of Applied and Engineering Physics, Cornell University — We have studied from first principles the structural, ferroelectric, and magnetic properties of the $(LaFeO_3)_1/$ $(LnFeO_3)_1$ digital superlattices, with Ln = lanthanide (or Y). We show that in this class of artificial materials constructed from Pnma perovskites, which are highly amenable to advanced oxide thin film growth techniques, octahedral rotations induce a spontaneous electrical polarization (consistent with the recently developed rules of Rondinelli and Fennie). Furthermore, this rotation pattern is shown to induce linear magnetoelectricity and weak-ferromagnetism, much like the recently discussed '327' manganite Ruddlesden-Popper. In these ferrite superlattices, however, it is clear that both the ferroelectric and magnetic ordering temperatures should occur above room temperature. Finally we discuss how the 'La/Ln' cation radius mismatch controls the magnitudes of the induced polarization and magnetization, as well as the barrier to switch the polarization.

9:24AM F17.00006 Polarization in epitaxial $LaFeO_3/SrFeO_3$ superlattice thin films[1] , ROHAN MISHRA, SOKRATES PANTELIDES, Vanderbilt Univ. Oak Ridge National Lab., YOUNG-MIN KIM, Oak Ridge National Lab. Korea Basic Science Institute, ALBINA BORISEVICH, STEPHEN PENNYCOOK, Oak Ridge National Lab., SEONGKEUN KIM, SEOHYOUNG CHANG, ANAND BHATTACHARYA, JEFFREY EASTMAN, DILLON FONG, Argonne National Lab. — Controlling ferroelectricity in perovskite thin-films requires an understanding of the many factors that are known to affect their polar behavior, such as octahedral rotations, cation ordering, oxygen vacancies, and the surface and interface terminations. Here, we report a study using a combination of aberration-corrected scanning transmission electron microscopy, electron-energy loss spectroscopy (EELS), and density functional calculations (DFT) to demonstrate how these factors work in concert to give rise to polarization in $LaFeO_3/SrFeO_3$ superlattices grown on $SrTiO_3$ substrates. Although both $LaFeO_3$ and $SrFeO_3$ are non-polar in the bulk, microscopy results show Fe-displacements in the superlattices indicating a dipole-like electric field. The magnitude of the observed displacements peaks in the interior of the films and goes to zero towards the substrate and the surface. O K EELS results show variation in intensities within the films, suggesting that oxygen vacancies may play a role. DFT results explaining the origin of the observed polar displacements within the superlattices and the effect of the abovementioned factors will be presented.

[1]Research sponsored by the U.S. DOE, Office of BES, MSE Division and ORNL's ShaRE.

9:36AM F17.00007 Tuning the electronic structure of $(SrTiO_3)_n/(SrFeO_{3-x})_m$ superlattices[1] , ROBERT BERGER, Lawrence Berkeley National Laboratory, DANIEL BROBERG, University of Texas, CAROLINA ADAMO, Stanford University, SHAWN SALLIS, NICHOLAS QUACKENBUSH, LOUIS PIPER, Binghamton University, CRAIG FENNIE, DARRELL SCHLOM, Cornell University, JEFFREY NEATON, Lawrence Berkeley National Laboratory — $SrTiO_3$ and other d^0 perovskite-derived compounds are of interest as possible solar water-splitting catalysts, due to their band-edge energies and stability in water. To optimize their ability to absorb and convert solar energy, it is desirable to understand how to tune the electronic structure and band gap of these compounds. One controllable way to experimentally tune the crystal structure, and consequently the electronic structure, of these compounds is through the growth of epitaxially layered superlattices. Past computational work has studied the interleaving of $SrTiO_3$ and $SrFeO_3$, in which the d^4 Fe^{4+} atoms result in metallic electronic structure. However, the synthesis of related compounds suggests that oxygen vacancies in these superlattices would likely reduce some or all of the Fe^{4+} to Fe^{3+} (d^5), which could once again open a tunable band gap. We use density functional theory and beyond to study the energetics of oxygen vacancy patterns in $(SrTiO_3)_n/(SrFeO_{3-x})_m$, and the possibility of favorably tuning the electronic structure and band gap of these superlattices via changes in layering, oxygen vacancy concentration, and biaxial strain. Our results are thoroughly discussed in the context of recent experiments.

[1]This work is supported by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences, at the Molecular Foundry (DE-AC02-05CH11231) and as part of the Energy Materials Center at Cornell (DE-SC0001086).

9:48AM F17.00008 Electronic and Magnetic Reconstruction at Manganite Interfaces[1] , KALPATARU PRADHAN, ARNO P. KAMPF, University of Augsburg, Germany — We investigate interfaces between ferromagnetic metallic (FM) and antiferromagnetic insulating (AFI) manganites using a two-orbital double-exchange model including superexchange interactions, Jahn-Teller lattice distortions, and long range Coulomb interactions. In FM/AFI heterostructures the magnetic and the transport properties critically depend on the thickness of the AFI layers. We focus on superlattices where the constituent parent FM and AFI manganites have the same electron density n. For n=0.6, the induced ferromagnetic moment in the AFI layers sandwiched between FM manganites decreases monotonically with increasing layer width. For n=0.5 instead, the induced ferromagnetic moment varies non-monotonously with the layer width. These differences for n=0.6 and n=0.5 originate from different charge-transfer profiles and magnetic reconstructions at the FM/AFI interfaces. The width of the AFI layers furthermore controls the magnitude of the magnetoresistance and the metal to insulator transition of the FM/AFI heterostructure. These results are discussed in the context of recent experiments on LSMO/PCMO [1] and LCMO/PCMO superlattices [2].

10:00AM F17.00009 DFT investigation of structural effects on perovskites exhibiting metal-insulator phase transitions , JOSEPH SCHICK, Villanova University, LAI JIANG, DIOMEDES SALDANA-GRECO, ANDREW RAPPE, University of Pennsylvania — The rich variety of electronic, magnetic, etc. properties available in perovskite materials are closely linked to octahedral tilting and other details of the arrangements of atoms within these materials. Furthermore, it has been demonstrated that the tilts and structural details are altered by the growth of films of these materials on substrates that provide strain and changed by the creation of new layered or superlattice structures from these materials. We employ density functional methods to investigate the relationship between tilting and charge ordering in a variety of strained-layered perovskite materials. We present these DFT results along with model calculations that aid in interpreting the complex connections between atomic structure and electronic properties, *e.g.* structural control of metal-insulator phase transitions.

10:12AM F17.00010 The effect of interfacial octahedral behavior on magnetic properties in ultrathin manganite films[1] , EUN JU MOON, Dep. of Materials Science and Engineering, Drexel Univ., X.M. CHENG, Dep. of Physics, Bryn Mawr College, D.J. KEAVNEY, Advanced Photon Source, Argonne National Lab., S.J. MAY, Dep. of Materials Science and Engineering, Drexel Univ. — In ABO_3 perovskites, the rotation and distortions of BO_6 octahedra lead to crystal symmetric variants of the basic perovskite structure. The rotation angles play a role in magnetic exchange with previous work demonstrating a clear relationship between bond angles and ordering temperatures. Recent work has shown that heteroepitaxial oxide films can be stabilized with non-equilibrium crystal structures due to structural coupling of octahedral behavior across the substrate/film interface. However, it is not yet apparent how the crystal symmetry across a heteroepitaxial oxide interface contributes to magnetic properties. Here, we report on the effect of crystal symmetry in $La_{0.67}Sr_{0.33}MnO_3$ (LSMO), a canonical magnetic oxide, grown using molecular beam epitaxy on different symmetric substrates with similar lattice parameters. For this study, we have used x-ray magnetic circular dichroism, transport, and magnetoresistance measurements to explore the magnetic properties of ultrathin LSMO films for a direct comparison of magnetic behavior in isocompositional perovskites with different octahedral behavior.

10:24AM F17.00011 Electronic and Magnetic Tunability of Sr_2CrReO_6 Thin Films by Growth-mediated Oxygen Modulation and Template Variation , JEREMY LUCY, The Ohio State University — Highly ordered epitaxial films of ferrimagnetic semiconductor Sr_2CrReO_6 have been fabricated by off-axis magnetron sputtering, and characterized as a function of the oxygen partial pressure at optimal growth conditions. In this letter, we report 18,000% modulation in electrical resistivity at T= 7K (60% at room temperature) from a 1% modulation in the oxygen partial pressure during film growth. The growth window was chosen to center around the condition for peak saturation magnetization, which drops due to both increasing and decreasing oxygen growth pressure. The results suggest that n-type doping from oxygen vacancies in the film likely play the dominant role in the electrical properties and modulation of Sr_2CrReO_6 thin films. We also explore the effects of substrate templates on the structural, electrical, and magnetic properties of Sr_2CrReO_6. Sr_2CrReO_6 films fabricated on double perovskite substrates or buffer layers exhibit increased resistivities at low temperatures.

10:36AM F17.00012 High-resolution terahertz spectroscopy of Sr_2CrReO_6 at cryogenic temperatures and high magnetic fields , D.R. DAUGHTON, R. HIGGINS, S. YANO, Lake Shore Cryotronics, C.H. DU, A.J. HAUSER, R. ADUR, J.M. LUCY, H.L. WANG, D.V. PELEKHOV, E. JOHNSTON-HALPERIN, F.Y. YANG, P.C. HAMMEL, The Ohio State University — Temperature and magnetic field dependent terahertz spectroscopies have proven useful in elucidating the interplay between structure charge, and magnetism in complex oxide systems. To this end, we are developing a turn-key, continuous-wave (CW) terahertz transmission spectrometer operating from 6 K to 300 K and in fields up to 9 T. Fiber-coupled photoconductive switches operate from 200 GHz to 1.8 THz in the cryogenic and high-field sample environment – eliminating the need to align a THz beam through multiple cryostat windows. In this work we compare CW-THz measurements on epitaxial thins films of Sr_2CrReO_6, a double-perovskite ferrimagnet, with conventional THz time-domain spectroscopy.

10:48AM F17.00013 Indications of spin-polarized transport in thin film double perovskites Sr2FeMoO6 and Ba2FeMoO6 , SIMON GRANVILLE, Industrial Research Ltd., IAN FARRELL, University of Canterbury, ADAM HYNDMAN, DUNCAN MCCANN, Industrial Research Ltd., GRANT WILLIAMS, Victoria University of Wellington — Double perovskite oxides Sr2FeMoO6 and Ba2FeMoO6 have attracted attention for spintronic device development due to their predicted highly spin-polarized transport characteristics. However, most published experimental results are from bulk material, not thin films that are more relevant for realistic device development. We will present our results of the growth as well as structural, magnetic and transport properties of thin films of double perovskites Sr2FeMoO6 and Ba2FeMoO6 produced by pulsed laser deposition. We have produced highly crystalline, near-epitaxial thin films of each material. We will survey the magnetic and magnetotransport properties, including the magnetoresistance, planar and anomalous Hall effects, which provide evidence for the presence of spin-polarized charge carriers well above room temperature and the potential for developing high sensitivity magnetic sensors.

Tuesday, March 19, 2013 8:00AM - 11:00AM –

Session F18 DCMP: Two Dimensional Topological Insulators I 320 - Yong Chen, Purdue University

8:00AM F18.00001 Imaging currents in HgTe quantum wells in the quantum spin Hall regime , KATJA NOWACK, ERIC SPANTON, MATTHIAS BAENNINGER, MARKUS KÖNIG, JOHN KIRTLEY, Stanford University, BEENA KALISKY, Stanford University; Bar-Ilan University, CHRISTOPHER AMES, PHILIPP LEUBNER, CHRISTOPH BRÜNE, HARTMUT BUHMANN, LAURENS MOLENKAMP, Wuerzburg University, DAVID GOLDHABER-GORDON, KATHRYN MOLER, Stanford University — Dissipationless edge channels are a key feature of the quantum spin Hall (QSH) state, which was predicted and experimentally demonstrated to exist in HgTe quantum wells. The existence of the edge channels has been inferred from local and non-local transport measurements. Here we image the current in Hall bars made from HgTe quantum wells by probing the magnetic field generated by the current using a scanning superconducting quantum interference device. We observe that the current flows mainly along the edge of the device in the QSH regime, and furthermore that an identifiable edge channel exists even in the presence of disorder and considerable bulk conduction as the device is gated and its temperature is raised. Our results represent a versatile method for the characterization of new quantum spin Hall materials systems.

8:12AM F18.00002 Electronic properties of HgTe/CdTe heterostructure under perturbations preserving time reversal symmetry[1] , TOME SCHMIDT, Universidade Federal de Uberlândia, JONAS ANVERSA, PAULO PIQUINI, Universidade Federal de Santa Maria, ADALBERTO FAZZIO, Universidade de São Paulo — Using first principles calculations, the Dirac cone of HgTe/CdTe heterostructure is identified at the interface, inside the valence band. The spin texture of the 2D Dirac states is totally in-plane for all interface directions, different from the 3D topological insulators, where there is always some out-of-plane spin components. The masless Dirac states are strongly affected by applying positive or negative biaxial pressure. While negative pressure turns the system metallic, suppressing the Dirac states, positive pressure maintains the protected topological states, but dislocates the Dirac cone upward in energy. The protected Dirac states are kept up to a contraction of 3% in the lattice parameter. Larger compressive pressures leads to suppression of the protected metallic states.

[1]FAPESP, FAPEMIG, CNPq, CAPES

8:24AM F18.00003 Quantized Conductance in InAs/GaSb Quantum Wells[1] , LINGJIE DU, IVAN KNEZ, RUI-RUI DU, Department of Physics and Astronomy, Rice University, Houston, Texas 77251-1892, USA, GERALD SULLIVAN, Teledyne Scientific and Imaging, Thousand Oaks, California 91630, USA — We have studied electrical transport in inverted InAs/GaAs quantum wells (QWs) made by molecular beam epitaxy, in which the evidences for helical edge modes were observed in messoscopic samples with either normal or superconductor contacts. Here we report on measurements of QWs that are doped with Si at the InAs/GaSb interface, where Si is a donor in InAs and an acceptor in GaSb. The influences of induced disorder in the quantum Spin Hall effect as well as outside this regime are systematically studied and results will be presented.

[1]The work is supported by NSF DMR-0706634 and DMR-1207562.

8:36AM F18.00004 Scanning SQUID measurements of current flow in InAs/GaSb Quantum Wells , ERIC SPANTON, Stanford Institute for Materials and Energy Sciences, LINGJIE DU, Rice University, KATJA NOWACK, Stanford Institute for Materials and Energy Sciences, GERRY SULLIVAN, Teledyne Scientific, RUI-RUI DU, Rice University, KATHRYN MOLER, Stanford Institute for Materials and Energy Sciences — InAs/GaSb quantum wells have been predicted theoretically to exhibit the quantum spin hall phase in the inverted regime. In this phase, spin-polarized helical edge modes are expected to exist. Previous published results on length and width dependence of InAs/GaSb 4-terminal devices suggests these helical edge states coexist with a residual bulk conductivity when the device is tuned into the minigap. We probe the spatial distribution of currents in devices using a scanning SQUID to measure the resulting magnetic fields. Specifically, we find that when the device is tuned into the gap with a front gate, current flows along the edge and coexists with bulk current. We also look at dependence on back gate voltage and temperature dependence.

8:48AM F18.00005 Quantum Transport near the Charge Neutrality Point in Inverted Type-II InAs/GaSb Field-Effect Transistors , W. PAN, J.F. KLEM, J.K. KIM, M. THALAKULAM, M.J. CICH, Sandia National Labs, S.K. LYO, University of California, Irvine — We present here our recent quantum transport results around the charge neutrality point (CNP) in a type-II InAs/GaSb field-effect transistor. At zero magnetic field, a conductance minimum close to $4e^2/h$ develops at the CNP and it follows semi-logarithmic temperature dependence. In quantized magnetic (B) fields and at low temperatures, well developed integer quantum Hall states are observed in the electron as well as hole regimes. Electron transport shows noisy behavior around the CNP at extremely high B fields. When the diagonal conductivity σ_{xx} is plotted against the Hall conductivity σ_{xy}, a conductivity circle law is discovered, suggesting a chaotic quantum transport behavior. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

9:00AM F18.00006 Quantum Anomalous Hall Effect in 2D Organic Topological Insulators[1] , ZHENGFEI WANG, ZHENG LIU, FENG LIU, Department of Materials Science and Engineering, University of Utah — Quantum anomalous Hall effect (QAHE) is a fundamental transport phenomenon in the field of condensed-matter physics. Without external magnetic field, spontaneous magnetization combined with spin-orbit coupling give rise to a quantized Hall conductivity. So far, a number of theoretical proposals have been made to realize the QAHE, but all based on inorganic materials. Here, using first-principles calculations, we predict a family of 2D organic topological insulators (OTIs) for realizing the QAHE. Designed by assembling molecular building blocks of triphenyl-transition-metal compounds into a hexagonal lattice, this new classes of organic materials are shown to have a nonzero Chern number and exhibit a gapless chiral edge state within the Dirac gap.

[1]This work was supported by US DOE-BES (Grant No. DE-FG02-04ER46027).

9:12AM F18.00007 Quantum anomalous Hall effect with in-plane magnetization in HgMnTe , HSIU-CHUAN HSU, XIN LIU, CHAO-XING LIU, Department of Physics, Pennsylvania State University — A quantum anomalous Hall (QAH) insulator carries quantized Hall conductance which is similar to Quantum Hall (QH) effect. However, it originates from the exchange coupling of magnetization instead of Landau levels. It was proposed that QAH effect can be realized in HgTe quantum wells doped with Mn (**Phy. Rev. Lett. 101, 146802 (2008)**) and evidenced by recent experiments. However, Mn is paramagnetic and an external magnetic field, which also leads to Landau levels, is required to obtain Mn polarization. Thus, it is essential to find an experimentally feasible way to distinguish between the two effects. In this study, we propose to distinguish QH effect and QAH effect by inducing the in-plane magnetization of Mn with an in-plane magnetic field. The in-plane magnetic field reduces the QAH effect by tilting the magnetization of Mn into the quantum well plane and reducing the out-of-plane magnetization. In contrast, the in-plane magnetic field has little influence on the conventional QH effect which only depends on the out-of-plane magnetic field. The phase diagram is identified based on the band structure calculation and Landau level calculation with the realistic material parameters of HgMnTe quantum wells, which can serve as the guidance for the future transport experiment.

9:24AM F18.00008 Engineering quantum anomalous Hall phases with orbital and spin , HONGBIN ZHANG, FRANK FREIMUTH, GUSTAV BIHLMAYER, STEFAN BLÜGEL, YURIY MOKROUSOV, Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich and JARA — Combining tight-binding models and first principles calculations, we demonstrate that under external exchange fields, non-zero Chern numbers and nontrivial QAH effect could be induced by on-site spin-orbit coupling (SOC) in buckled honeycomb lattices with sp orbitals. In the Haldane model [1], the occurrence of QAH effect is attributed to complex next nearest neighbor hopping. Detailed analysis of a generic tight-binding models reveals that there exist different mechanisms giving rise to complex hoppings, utilizing both orbital and spin degrees of freedom of electrons on a lattice. Furthermore, it is shown that in Bi/Sb(111) bilayers [2], different topological phases exist as function of the magnitude of SOC and external exchange fields. These phases are characterized using Chern and spin Chern numbers [3] together with transverse charge and spin conductivities. At last, we show that introducing ferromagnetic dopants provides a practical way to induce nontrivial topological phases, whereas the physics is modified due to incompletely filled d states around the Fermi energy.

9:36AM F18.00009 Effective field theory of nematic QAH for interacting fermions , YIZHI YOU, EDUARDO FRADKIN, University of Illinois at Urbana-Champaign — We consider 2D fermionic lattice models with quadratic band touching. By turning on a marginal relevant interaction of this system, the system condenses into a state that spontaneously breaks time reversal and/or rotation (point-group) symmetry. When both symmetries are broken the state is a nematic quantum anomalous Hall (QAH) phase. We derive an effective field theory which describes the quantum phase transition into this state from a spontaneous QAH state. The effective field theory has the form of Maxwell-Chern-Simons action for the hydrodynamic degrees of freedom of the spontaneous QAH state with a coupling to the nematic order-parameter field that induces a spatial anisotropy. The fluctuations of the nematic field modify the local spatial geometry and couples to the Maxwell term as the spatial components of a metric tensor. We will discuss the behavior at quantum criticality and the relation with recent theories that associate transitions of this type with quantum Lifshitz criticality [1]. We will also discuss extensions of our theory to nematic fractional QAH state. [1] M. Mulligan, C. Nayak, and S. Kachru, Phys. Rev. B 82, 085102 (2010); Phys. Rev. B 84,195124 (2011) This work was supported in part by the NSF grant DMR-1064319 at the University of Illinois.

9:48AM F18.00010 Symmetry protected Spin Quantum Hall phases , ZHENG-XIN LIU, Tsinghua university, Beijing, XIAO-GANG WEN, MIT, Perimeter institute — Symmetry protected topological (SPT) states are short-range entangled states with symmetry. Nontrivial SPT states have symmetry protected gapless edge excitations. Topological insulators are examples of nontrivial SPT phases. We study Bosonic SPT phases protected by $SU(2)$ or $SO(3)$ symmetry in 2D. There are infinite number of such phases, which can be described by $SU(2)/SO(3)$ nonlinear-sigma models with a quantized topological θ-term. At open boundary, the θ-term becomes the Wess-Zumino-Witten term and consequently the boundary excitations are decoupled gapless left movers and right movers. Only the left movers (if $\theta > 0$) carry the $SU(2)/SO(3)$ quantum numbers. As a result, the $SU(2)$ SPT phases have a half-integer quantized spin Hall conductance and the $SO(3)$ SPT phases have an even-integer quantized spin Hall conductance. Both the $SU(2)/SO(3)$ SPT phases are symmetric under their $U(1)$ subgroup and can be viewed as $U(1)$ SPT phases with even-integer quantized Hall conductance.

10:00AM F18.00011 Bloch Model Wavefunctions and Pseudopotentials for All Fractional Chern Insulators , YANG-LE WU, Princeton University, N. REGNAULT, Princeton University, Ecole Normale Superieure and CNRS, B. ANDREI BERNEVIG, Princeton University — We introduce a Bloch-like basis in a C-component lowest Landau level fractional quantum Hall effect (FQH), which entangles the real and internal degrees of freedom and preserves an $N_x \times N_y$ full lattice translational symmetry. We implement the Haldane pseudopotential Hamiltonians in this new basis. Their ground states are the model FQH wavefunctions, and our Bloch basis allows for a mutatis mutandis transcription of these model wave functions to the fractional Chern insulator (FCI) of arbitrary Chern number C, obtaining wavefunctions different from all previous proposals. For $C > 1$, our wavefunctions are related to color-dependent magnetic-flux inserted versions of Halperin and non-Abelian color-singlet states. We then provide large-size numerical results for both the $C = 1$ and $C = 3$ cases. This new approach leads to improved overlaps compared to previous proposals. We also discuss the adiabatic continuation from the FCI to the FQH in our Bloch basis, both from the energy and the entanglement spectrum perspectives.

10:12AM F18.00012 First-principles study on quantum valley Hall effects in silicene , YOUNGKUK KIM, Department of Physics and Astronomy, Seoul National University, Seoul 151-747, Republic of Korea, HOSUB JIN, Department of Physics and Astronomy, Northwestern University, Evanston, Illinois 60208, USA, KEUNSU CHOI, JISOON IHM, Department of Physics and Astronomy, Seoul National University, Seoul 151-747, Republic of Korea — Silicene is a two-dimensional honeycomb lattice of silicon atoms, similar to graphene. Based on first-principles calculations, we suggest that silicene is an ideal host for realization of quantum valley Hall effects. We show that the intrinsic buckled structure allows the formation of topological domain walls in silicene under a uniform applied electric field and valley-polarized kink states emerge on the domain walls. Peculiar behaviors of the kink states under various applied electric fields are demonstrated, and simulated scanning tunneling microscopy images are presented to show that they can be used to identify the topological domain walls as well as valley-polarized kink states. Our findings suggest that the one-dimensional domain wall may be used as an electrical wire through which valley-polarized current can flow, and silicene can be used as a valley polarizer.

10:24AM F18.00013 Quantum Topological Hall Effect in Kagome Ice , YUKITOSHI MOTOME, HIROAKI ISHIZUKA, Dept. of Appl. Phys., Univ. of Tokyo — The quantum Hall state was originally discovered in two-dimensional electron systems associated with the formation of quantized Landau levels in external magnetic field. Later, a quantum anomalous Hall effect without Landau levels was proposed, and the idea has been generalized to topological insulators in the presence of the spin-orbit coupling. Besides, a noncoplanar magnetic order was shown to give rise to the quantum anomalous Hall effect through the Berry phase mechanism. Here, we present yet another example of the quantum anomalous Hall state which emerges in the absence of Landau levels, spin-orbit coupling, and magnetic ordering. The new state is realized in itinerant electrons coupled with local spin textures subject to geometrical frustration of lattice structure. Considering the double-exchange model with spin-ice type Ising spins on a kagome lattice, we numerically show that a local spin correlation called kagome-ice opens a charge gap, resulting in quantization of the Hall conductivity in the absence of magnetic ordering. By Monte Carlo simulation, we discuss the stability of the anomalous Hall insulating region in the magnetic phase diagram.

10:36AM F18.00014 Critical behavior of the transport coefficients at the Chern-to-normal insulator transition[1] , YU XUE, EMIL PRODAN, Yeshiva University, New York, NY — Using the non-commutative Kubo formula for disordered lattice systems, we mapped the conductivity tensor $\sigma_{xx}(E_F,T)$ and $\sigma_{xy}(E_F,T)$ as function of Fermi level E_F and temperature T, for a model of a Chern insulator in the presence of strong disorder. In line with previous studies, σ_{xy} displays a quantized non-trivial value near the half-filling, value that changes rapidly to a trivial value as E_F crosses a critical value E_F^c. As expected, the T-dependence of σ_{xx} display the typical signature of the insulating behavior, except at E_F^c. Examining the resistivity tensor $\hat{\rho} = \hat{\sigma}^{-1}$, we found that the data looks extremely similar to the experimental data for the plateau-insulator transition in the Integer Quantum Hall Effect: 1)$\rho_{xx}(E_F,T)$ vs E_F plots for various temperatures intersect each other at precisely one point; 2) At this E_F^c, $\rho_{xx} \approx 1$ and $\sigma_{xy} \approx 0.5$; 3) The plots near E_F^c for different temperatures collapse into one curve when rescaled with an exponent that is consistent with the universally accepted value.

10:48AM F18.00015 Topological protection of localization against the hybridization[1] , BOHM-JUNG YANG, MOHAMMAD SAEED BAHRAMY, RIKEN, ASI, NAOTO NAGAOSA, Department of Applied Physics, University of Tokyo — Localization of electronic wave functions is governed by their topological nature as well as the symmetry and dimensionality of the system. Two prominent examples are the presence of the extended states in two-dimensional quantum Hall systems and the absence of localization for the surface states of three dimensional topological insulators. In these cases, the extended states are protected by topological invariants. Here, we show that the two-dimensional quantum Hall system put on the three dimensional trivial insulator manifests a new class of localization phenomena of topological origin, where the two dimensional states remain localized along the surface normal direction in spite of the hybridization with the continuum extended states. The one-dimensional edge channel is also localized along the same direction as long as its energy is within the band gap. This finding demonstrates that the localized states are protected by the topological invariants against the hybridization with the continuum.

[1]We are grateful for support from the Japan Society for the Promotion of Science (JSPS) through the 'Funding Program for World-Leading Innovative R&D on Science and Technology (FIRST Program).

Tuesday, March 19, 2013 8:00AM - 10:48AM –

Session F19 DCMP: Heavy Fermions and Quantum Criticality in 115's 321 - Johnpierre Paglione, University of Maryland

8:00AM F19.00001 The electronic structure of Ce-based 115's , FILIP RONNING, Los Alamos National Lab, YUSUKE NOMURA, RYOTARO ARITA, University of Tokyo, HIROAKI IKEDA, University of Kyoto, ANTON KOZHEVNIKOV, ETH, JIANXIN ZHU, Los Alamos National Lab — The Ce and Pu-based 115's embody the notion that reduced dimensionality and increased spin fluctuation energy scales are good for unconventional superconductivity. Often these materials are considered to be quasi two-dimensional systems similar in spirit to the high temperature cuprate superconductors. However, in reality the systems are rather three dimensional. Consequently, we construct an accurate down-folded Hamiltonian from ab-initio electronic structure calculations for the Ce-based 115 materials. We subsequently perform a constrained RPA calculation to obtain effective Coulomb parameters as a starting point to further investigate the magnetic, superconducting, and heavy fermion phenomena which these materials possess.

8:12AM F19.00002 Stability of the Kondo Lattice and Field-tuned Antiferromagnetic Structures in the $Ce_{1-x}Yb_xRhIn_5$ System[1] , SOOYOUNG JANG, BENJAMIN WHITE, MARC JANOSCHEK, BRIAN MAPLE, University of California, San Diego — We have investigated the series $Ce_{1-x}Yb_xRhIn_5$ ($0 \leq x \leq 0.8$) by means of x-ray diffraction, energy dispersive x-ray spectroscopy, electrical resistivity (ρ), specific heat (C), and magnetic susceptibility measurements. The coherence temperature T_{coh} inferred from $\rho(T)$ remains nearly constant over a wide range of Yb concentrations $0 \leq x \leq 0.8$. Measurements of $C(T)$ were made in various magnetic fields up to 9 tesla on the $Ce_{1-x}Yb_xRhIn_5$ samples. In $CeRhIn_5$, the peak in $C(T)$ associated with the incommensurate antiferromagnetic (AFM) transition is accompanied by another peak that is associated with the commensurate AFM transition that emerges in an applied magnetic fields. Measurements on $Ce_{1-x}Yb_xRhIn_5$ samples (x = 0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.8) reveal that the field induced commensurate AFM peak shifts relative to the incommensurate peak with Yb substitution. The results indicate that Yb substitution stabilizes the electronic state and tunes the AFM structures in $Ce_{1-x}Yb_xRhIn_5$.

[1]Sample synthesis was funded by the US DOE (Grant No. DE-FG02-04-ER46105), and physical properties measurements were supported by the NSF (Grant No. DMR-08024478)

8:24AM F19.00003 London penetration depth in $Ce_{1-x}Yb_xCoIn_5$ $(0 \leq x \leq 0.4)$, HYUNSOO KIM, MAKARIY A. TANATAR, RUSLAN PROZOROV, The Ames Laboratory, Ames, IA, BENJAMIN D. WHITE, IVY K. LUM, M. BRIAN MAPLE, Department of Physics, University of California, San Diego, CA — The London penetration depth was measured in single crystals of superconducting $Ce_{1-x}Yb_xCoIn_5$ $(0 \leq x \leq 0.4)$ by means of a tunnel diode resonator technique operating at 15 MHz in a dilution refrigerator down to 100 mK. Judging from the suppression of the superconducting transition temperature, the superconductivity in $CeCoIn_5$ is relatively robust to Yb - substitution on Ce site unlike the substitution with other rare earth elements. On the other hand, the Yb substitution induces a drastic change of the Fermi surface near $x = 0.2$, from which one may expect a significant change in properties of superconducting pairing upon doping. Possible evolution of superconducting order parameter in $Ce_{1-x}Yb_xCoIn_5$ with increasing x will be discussed based on the results from penetration depth measurements.
Work in Ames was supported by the Department of Energy Office of Science, Basic Energy Sciences under Contract No. DE-AC02-O7CH11358. Work in San Diego was supported by the Department of Energy Office of Science (Grant DE-FG02-04-ER46105).

8:36AM F19.00004 Non-Fermi liquid behavior with and without quantum criticality in $Ce_{1-x}Yb_xCoIn_5$[1] , Y.P. SINGH, T. HU, Kent State University, L. SHU, M. JANOSCHEK, University of California, San Diego, M. DZERO, Kent State University, M.B. MAPLE, University of California, San Diego, C.C. ALMASAN, Kent State University — In a growing number of f-electron systems the non-Fermi liquid (NFL) behavior occurs in the absence of an obvious quantum phase transition (QPT), which takes place at a quantum critical point (QCP). An intriguing candidate is $Ce_{1-x}Yb_xCoIn_5$ that exhibits an unconventional T – x phase diagram without an apparent QCP. Therefore, it is important to elucidate the nature of the NFL behavior and to search for possible QCPs in this system Here we reveal a field induced QCP (H_{QCP}) through normal state magneto-resistivity measurements and find its evolution with x. The full suppression of H_{QCP} for $x > 0.2$ has surprisingly little effect on the Kondo lattice coherence. At low Yb concentrations, resistivity consists of two contributions with linear and sub-linear temperature dependences, while at higher concentrations only the sub-linear term is present. These results imply that the NFL behavior could be a new state of matter in its own right rather than a consequence of the underlying QPT.

[1]This work was supported by NSF (DMR-1006606 and DMR- 0844115), ICAM Branches Cost Sharing Fund from Institute for Complex Adaptive Matter, and Ohio Board of Regents (Grant OBR-RIP-220573) at KSU, and DOE (DE-FG02-04ER46105) at UCSD.

8:48AM F19.00005 Superfluid density in heavy fermion superconductor $Ce_{1-x}Yb_xCoIn_5$[1] , LEI SHU, Fudan University, China, D.E. MACLAUGHLIN, University of California, Riverside, USA, O.O. BERNAL, California State University, Los Angeles, USA, X.P. SHEN, Fudan University, China, S. PHAM, California State University, Los Angeles, USA, I. LUM, M.B. MAPLE, University of California, San Diego, USA — Recent x-ray diffraction, electrical resistivity, magnetic susceptibility, and specific heat measurements on the superconducting heavy fermion system $Ce_{1-x}Yb_xCoIn_5$ reveal that the correlated electron state is stabilized throughout the range $0 < x < 0.8$, apparently due to cooperative behavior of Ce and Yb ions involving their unstable valences. Phase separation occurs for $x > 0.8$. Interestingly, the superconducting critical temperature decreases linearly with x from 2.3 K at $x = 0$ towards 0 K at $x = 1$. Transverse-field muon spin rotation experiments have been performed on $Ce_{1-x}Yb_xCoIn_5$ alloys. Based on these measurements, we report the absolute value of magnetic penetration depth as a function of x and discuss whether T_c is controlled by the superfluid density of superconducting carriers. The results are compared to a recently proposed theory for the superconductivity in $Ce_{1-x}Yb_xCoIn_5$

[1]This work was supported by Chinese NSF, grant 11204041, NSF of Shanghai, grant 12ZR1401200, the U.S. NSF, grants DMR-0801407 (Riverside), DMR-1105380 (Los Angeles), and the U.S. DOE, contract DE-FG-02-04ER46105 (San Diego).

9:00AM F19.00006 Anomalous upper critical field in $CeCoIn_5/YbCoIn_5$ superlattices with a Rashba-type heavy fermion interface , MASAAKI SHIMOZAWA, Department of Physics, Kyoto University, S.K. GOH, Cavendish Laboratory, University of Cambridge, Y. MIZUKAMI, H. SHISHIDO, D. WATANABE, S. YASUMOTO, M. YAMASHITA, Department of Physics, Kyoto University, T. TERASHIMA, Research Center for Low Temperature and Materials Science, Kyoto University, Y. YANASE, T. SHIBAUCH, Department of Physics, Kyoto University, A.I. BUZDIN, Universite Bordeaux I, LOMA, Y. MATSUDA, Department of Physics, Kyoto University — We report the precise angular dependence of the upper critical field (H_{c2}) in the epitaxial superlattices $CeCoIn_5(n)/YbCoIn_5(5)$, formed by alternating layers of n and 5 unit-cells thick $CeCoIn_5$ with a strong Pauli effect and normal metal $YbCoIn_5$, respectively [1]. For the $n = 3$ superlattice, $H_{c2}(\theta)$ changes smoothly as a function of the field angle θ. However, near the superconducting transition temperature,$H_{c2}(\theta)$ shows a cusp near the angle parallel to the plane of the superlattice. This cusp behavior disappears for $n = 4$ and 5. This sudden disappearance suggests the relative dominance of the orbital depairing effect in the $n = 3$ superlattice, which may be due to the suppression of the Pauli effect in a system with local inversion symmetry breaking [2].

9:12AM F19.00007 Strong pressure dependence of the magnetic penetration depth in single crystals of the heavy fermion system $CeCoIn_5$ studied by muon spin rotation , LUDOVIC HOWALD, ALEXANDER MAISURADZE, University of Zurich, Switzerland, PIERRE DALMAS DE RÉOTIER, ALAIN YAOUANC, CEA Grenoble, France, CHRISTOPHER BAINES, Paul Scherrer Institut, Switzerland, GERARD LAPERTOT, KARINE MONY, JEAN-PASCAL BRISON, CEA Grenoble, France, HUGO KELLER, University of Zurich, Switzerland — The pressure dependence ($0 - 1$ GPa) of the in-plane magnetic penetration depth (λ_a), the penetration depth anisotropy ($\gamma = \lambda_c/\lambda_a$) and the temperature dependence of $1/\lambda_i^2$ $(i = a, c)$ were studied in single crystals of the heavy fermion system $CeCoIn_5$ by means of muon spin rotation. A strong decrease of λ_a with pressure was observed, while γ and $\lambda_i^2(0)/\lambda_i^2(T)$ are pressure independent. A linear relationship between $1/\lambda_a^2$(270 mK) and Tc was also found. The large decrease of λ_a with pressure is the signature of an increase of the number of superconducting quasiparticles by a factor of about 2.

9:24AM F19.00008 STM Spectroscopic Mapping of Quasiparticle States in the Superconducting State of $CeCoIn_5$, SHASHANK MISRA, BRIAN ZHOU, EDUARDO H. DA SILVA NETO, PEGOR AYNAJIAN, Princeton University, RYAN BAUMBACH, J.D. THOMPSON, ERIC BAUER, Los Alamos National Laboratory, ALI YAZDANI, Princeton University — The heavy fermion compounds provide an interesting playground to study strongly correlated physics, as a variety of unusual low-temperature states emerge in relatively close proximity to one another in their phase diagrams. However, to date, very little spectroscopic information about these low-temperature phases, including unconventional superconductivity, is known. Recently, at comparatively high temperatures, Aynajian and coworkers[1] used scanning tunneling microscopy (STM) to visualize the formation of heavy quasiparticles in one of the prototype 115 compounds, $CeCoIn_5$. Here, we use a new home-built STM to extend the spatial mapping of the electronic states of $CeCoIn_5$ down to its superconducting state at mK temperatures. This work was supported by the DOE and NSF.

9:36AM F19.00009 STM Spectroscopic Mapping of Quasi-Particle States in the Vortex State of $CeCoIn_5$[1] , BRIAN ZHOU, SHASHANK MISRA, PEGOR AYNAJIAN, EDUARDO DA SILVA NETO, Princeton University, RYAN BAUMBACH, J.D. THOMPSON, ERIC BAUER, Los Alamos National Laboratory, ALI YAZDANI, Princeton University — The superconducting properties of the heavy-fermion $CeCoIn_5$ emerge from a remarkable backdrop of strong electron correlation and magnetic criticality. Fittingly, this superconducting phase is itself remarkable, displaying signatures of unconventional pairing with (d-wave) line nodes in the order parameter and a Pauli-limited upper critical field below 700 mK [1]. Through scanning tunneling microscopy at milli-kelvin temperatures, we present, for the first time, atomically-resolved spectroscopy of $CeCoIn_5$ as the application of a magnetic field weakens and eventually destroys superconductivity.

9:48AM F19.00010 Long range order and two-fluid behavior in heavy electron materials , NICHOLAS CURRO, ABIGAIL SHOCKLEY, KENT SHIRER, ADAM DIOGUARDI, NICHOLAS ABROBERTS-WARREN, JOHN CROCKER, CHING LIN, DAVID NISSON, University of California at Davis — The heavy electron Kondo liquid is an emergent state of condensed matter that displays universal behavior independent of material details. Properties of the heavy electron liquid are best probed by NMR Knight shift measurements, which provide a direct measure of the behavior of the heavy electron liquid that emerges below the Kondo lattice coherence temperature as the lattice of local moments hybridizes with the background conduction electrons. Because the transfer of spectral weight between the localized and itinerant electronic degrees of freedom is gradual, the Kondo liquid typically coexists with the local moment component until the material orders at low temperatures. The two-fluid formula captures this behavior in a broad range of materials in the paramagnetic state. In order to investigate two-fluid behavior and the onset and physical origin of different long range ordered ground states in heavy electron materials, we have extended Knight shift measurements to URu_2Si_2, $CeIrIn_5$ and $CeRhIn_5$. Our results indicate that the ordered state can emerge from either the Kondo liquid or heavy electron component, and imply that the nature of the ground state is strongly coupled with the hybridization in the Kondo lattice.

10:00AM F19.00011 Study of the Kondo lattice on La doped $CeCoIn_5$, G. KOUTROULAKIS, H. YASUOKA, Los Alamos National Laboratory, T. ZHOU, S. E. BROWN, UCLA, E. D. BAUER, J. D. THOMPSON, Los Alamos National Laboratory — The effect of non-magnetic impurities on the properties of the Kondo lattice was investigated through nuclear magnetic/quadrupolar resonance (NMR/NQR) experiments on $Ce_{1-x}La_xCoIn_5$. Specifically, comprehensive ^{115}In, ^{139}La NQR and NMR measurements were carried out on single crystals of various La concentration levels (x=0, 2, 3, and 5%) for temperatures 1.5K-80K and applied magnetic field values 0T-7T. Our results indicate that the ramifications of the Kondo-ion substitution extend well-beyond the vicinity of the particular site, readily affecting the heavy-fermion forming hybridization. It is suggested that the spin polarization around La impurities is modulated on a much larger length scale than that of charge oscillations.

10:12AM F19.00012 High Field Knight Shift studies in $CeIrIn5$[1] , ABIGAIL SHOCKLEY, NICHOLAS APROBERTS-WARREN, DAVID NISSON, University of California, Davis, PHIL KUHNS, ARNEIL REYES, National High Magnetic Field Lab, PETER KLAVINS, NICHOLAS CURRO, University of California, Davis — All heavy fermion compounds that have been measured with NMR exhibit a Knight shift anomaly, in which the Knight shift does not scale with the bulk susceptibility below a characteristic temperature, T*. Typically this temperature corresponds with the Kondo lattice coherence temperature as measured by other probes. In order to investigate the microscopic origin of this anomaly, we have conducted high field measurements of the In-115 Knight shift in CeIrIn5 up to 30 T. We find that although the onset temperature T* is field independent, the overall low temperature shift below T* is suppressed. In the context of the two-fluid model, these results suggest that that the dominant change is in the local moment channel.

[1]National High Magnetic Field Lab

10:24AM F19.00013 Probing the hybridization gap in heavy fermions by temperature dependent ARPES[1] , CRIS ADRIANO, University of Illinois at Chicago, FANNY RODOLAKIS, Argonne National Laboratory, PRISCILA ROSA, University of Campinas, FRANCISCO RESTREPO, DIMITAR TENEV, University of Illinois at Chicago, MUCIO CONTINENTINO, Centro Brasileiro de Pesquisas Físicas, ZACHARY FISK, University of California at Irvine, JUAN CARLOS CAMPUZANO, University of Illinois at Chicago, PASCOAL PAGLIUSO, University of Campinas — We report temperature dependent angle-resolved photoemission spectroscopy (ARPES) for pure and Cd-doped Ce_2RhIn_8 heavy fermion compounds. Our results reveal that for Ce_2RhIn_8 at T = 100 K once the $f-$ conduction electrons magnetic scattering becomes larger than the phonon scattering, even states of different parities can hybridize, forming many-body quasiparticles with heavy masses. We further show that at a temperature of 20 K, where the hybridization of conduction electrons and $f$states is stronger, a spectral gap is observable in the ARPES spectra. Interestingly, when replacing In by Cd to tune the local density of conduction electrons states at the Ce^{3+} site, we find a strong reduction of the f - conduction electrons hybridization strength, and the suppression of the hybridization gap at low temperatures. We also observe that the $f$states near the chemical potential hybridize mostly with out-of-plane p states (presumably from In). These findings have important consequences for the understanding of the different antiferromagnetic and exotic superconducting ground states that occur in these families of materials.

10:36AM F19.00014 Fermi Surface evolution as a function of temperature in heavy fermion Ce_2RhIn_8 probed by ARPES , FANNY RODOLAKIS, Argonne National Laboratory, CRIS ADRIANO, FRANCISCO RESTREPO, DIMITAR TENEV, University of Illinois at Chicago, PASCOAL PAGLIUSO, University of Campinas, JUAN CARLOS CAMPUZANO, University of Illinois at Chicago — The crossover of $4f$ localized magnetic moments at high temperatures into itinerant states of heavy mass at low temperatures in Cerium-based heavy fermion materials is a fundamental problem in condensed matter physics, involving a temperature-dependent hybridization between the f levels immersed in a sea of conduction electrons (ce). Due to the Luttinger theorem, this hybridization leads to a Fermi surface (FS) enlargement at low temperature: as the f electrons become itinerant, their contribution to E_F increases. We have studied the evolution of the heavy fermion FS in Ce2RhIn8 as a function of temperature using angle resolved photoemission. We observed topological changes that emerge at a temperature scale much higher than the onset of the coherence character of the f electrons. This behavior can be related to the evolution of the electrical resistivity as a function of temperature: as typically found for Kondo lattice materials, it first decreases when temperature is lowered, but increases below $\sim$ 150K as the magnetic scattering of the ce by the localized f electrons becomes larger than the phonon scattering. It reaches a maximum and then drops when the magnetic scattering becomes coherent for $T^* \sim$ 5K. This multiple scale behavior of the f electrons is in good agreement with a recent theoretical study performed in the parent compound $CeRhIn_5$ [1].

Session F20 DMP: Focus Session: Mesoscopics - Optics and Plasmonics

8:00AM F20.00001 Electron Microscopy: an Analytical Tool for Solid State Physicists , GUSTAAF VAN TENDELOO, EMAT, University of Antwerp, Belgium — For too long the electron microscope has been considered as "a big magnifying glass." Modern electron microscopy however has evolved into an analytical technique, able to provide *quantitative* data on structure, composition, chemical bonding and magnetic properties. Using lens corrected instruments it is now possible to determine atom shifts at interfaces with a precision of a few picometer; chemical diffusion at these interfaces can be imaged down to atomic scale. The chemical nature of the surface atoms can be visualized and even the bonding state of the elements (e.g. Mn^{2+} versus Mn^{3+}) can be detected on an atomic scale. Electron microscopy is by principle a projection technique, but the final dream is to obtain atomic info of materials in three dimensions. We will show that this is no longer a dream, but that it is possible using advanced microscopy. We will show evidence of determining the valence change Ce4+ versus Ce^{3+} at the surface of a CeO^2 nanocrystal; the atomic shifts at the interface between $LaAlO^3$ and $SrTiO^3$ and the 3D relaxation of a Au nanocrystal.

8:36AM F20.00002 Spatial mapping of surface plasmons in nanoscale Ag islands on graphite using Scanning Probe Energy Loss Spectroscopy , KARL BAUER, SHANE MURPHY, LIN TANG, RICHARD PALMER, Nanophysics Research Laboratory, University of Birmingham — A scanning STM tip operated at high voltage can be used to obtain localized spectroscopic information about surfaces via energy loss measurements [1]. In this technique, known as Scanning Probe Energy Loss Spectroscopy (SPELS), the STM tip is used as a localized source of field-emitted electrons, which, upon backscattering from a surface, are analyzed by an energy-dispersive detector to obtain localized energy loss spectra. Characteristic surface excitations such as plasmons and excitons (as well as secondary electrons) can be probed with a spatial resolution below 50 nm and an energy resolution approaching 0.3 eV [2]. We report the development of a new generation SPELS instrument utilizing a 400-Channel detector, allowing sufficiently fast sampling of the energy loss spectra to allow us to obtain 2D spatially-resolved maps of energy loss features in a reasonable timeframe. We demonstrate the new instrument by mapping plasmons in (thermally evaporated) Ag nano-islands on the surface of graphite and illustrate the various mechanisms give rise to the contrast obtained in the energy-resolved maps. 8:48AM F20.00003 Ultrafine and Smooth Full Metal Nanostructures for Plasmonics , XINLI ZHU, JASENG ZHANG, JUN XU, ZHIMIN LIAO, XIAOSONG WU, DAPENG YU, School of physics, Peking University, Beijing, China — Surface plasmon polaritons (SPPs), which are coupled excitations of electrons bound to a metal-dielectric interface, show great potential for application in future nanoscale photonic systems due to the strong field confinement at the nanoscale, intensive local field enhancement, and interplay between strongly localized and propagating SPPs. The fabrication of sufficiently smooth metal surface with nanoscale feature size is crucial for SPPs to have practical applications. A template stripping (ST) method combined with PMMA as a template was successfully developed to create extraordinarily smooth metal nanostructures with a desirable feature size and morphology for plasmonics and metamaterials. The advantages of this method, including the high resolution, precipitous top-to bottom profile with a high aspect ratio, and three-dimensional characteristics, make it very suitable for the fabrication of plasmonic structures. By using this ST method, boxing ring-shaped nanocavities have been fabricated and the confined modes of surface plasmon polaritons in these nanocavities have been investigated and imaged by using cathodoluminescence spectroscopy. The mode of the out-of-plane field components of surface plasmon polaritons dominates the experimental mode patterns, indicating that the electron beam locally excites the out-of-plane field component of surface plasmon polaritons, and quality factors can be directly acquired. Numerous applications, such as plasmonic filter, nanolaser, and efficient light-emitting devices, can be expected to arise from these developments.

9:00AM F20.00004 Low Loss Plasmonic Oxide Nanocrystals with Controlled Morphology[1] , THOMAS GORDON, TAEJONG PAIK, DAHLIA KLEIN, MATTEO CARGNELLO, CHRISTOPHER MURRAY, University of Pennsylvania — Localized surface plasmon resonance (LSPR) is a observed in metallic particles and results from the resonant oscillation of free electrons on the particle surface. One can manipulate the resonant frequencies through adjustment of the shape and size of the metal. A series of recent papers report LSPR at NIR and IR frequencies resulting from doped semiconductor nanocrystals. Free carriers in semiconductor particles result from atomic vacancies or through doping with aliovalent cations. While the plasma frequency (ω_p) is considered an intrinsic property of metals, through adjustment of dopant concentrations, ω_p can be tuned in plasmonic semiconductors, opening the possibility of producing tunable, low-loss plasmonic nanocrystals to substitute for Au and Ag. We report the size and shape controlled synthesis of plasmonic oxide nanocrystals with highly uniform morphology and shape dependent optical properties. The size, shape, and doping concentration are independently controlled by modifying the synthetic parameters, allowing for precise modulation of optical response. These nanocrystals may be assembled to form superlattices, which function as plasmonic metamaterials, or used as precursors to produce bulk like films with tunable plasma frequencies.

[1]Funded by Office of Naval Research Multidisciplinary University Research Initiative on Optical Metamaterials through award N00014-10-1-0942.

9:12AM F20.00005 Aluminum Plasmonic Nanoantennas[1] , HENRY EVERITT, Army Aviation & Missile RD&E Center, and Dept. of Physics, Duke University, MARK KNIGHT, Dept. of Electrical and Computer Engineering, Rice University, LIFEI LIU, Dept. of Physics & Astronomy, Rice University, YUMIN YANG, Dept. of Electrical and Computer Engineering, Rice University, LISA BROWN, SHAUNAK MUKHERJEE, Dept. of Chemistry, Rice University, NICHOLAS KING, Dept. of Physics & Astronomy, Rice University, PETER NORDLANDER, NAOMI HALAS, Dept. of Electrical and Computer Engineering, Rice University — We have explored the plasmonic properties of individual Al nanorod antennas fabricated by planar lithography on lightly doped n-type silicon. Energy-resolved cathodoluminescence was used to image the local density of optical states with a spatial resolution of ~ 20 nm and thereby identify the radiative modes of these nanostructures. Al nanoantenna emission exhibited highly tunable plasmonic resonances from the deep UV through the visible region of the spectrum. The dependence of the radiative dipolar and quadrupolar plasmon modes on antenna length and photon energy agreed well with finite difference time domain-based analysis of these nanostructures. The results herald nano-structured aluminum as a practical and highly promising material system for the design and implementation of UV and visible frequency plasmonics, broadening the range of potential applications of plasmonics into areas where complementary metal−oxide−semiconductor (CMOS) compatibility or low-cost, mass producibility are desired.

9:24AM F20.00006 Plasmon coupling between distance-controlled gold nanoparticles[1] , HOLGER LANGE, Deptartment of Physics, Columbia University, BEATRIZ HERNANDEZ JUAREZ, IMDEA Nanoscience, Madrid, CHRISTIAN THOMSEN, Institut fuer Festkoerperphysik, TU Berlin, TONY F. HEINZ, Deptartment of Physics, Columbia University — For small enough distances of noble metal nanoparticles in a matrix an additional plasmon-coupled mode is known to appear as a collective excitation between the nanoparticles. We show an approach of combining gold nanoparticles that allows to obtain coupled plasmons that can be dynamically changed, allowing systematic studies of the coupling. Poly-(N-isopropylacrylamide) pNIPAM is a polymer that can be used to produce thermo responsive gels, which have a volume phase transition at around 32°C. A ligand exchange on Au nanoparticles allows the attachment of the nanoparticles to pNIPAM spheres. The combined hybrid Au-pNIPAM system shows a plasmon-coupled mode above the pNIPAM's phase transition, additionally to the well-known shift and broadening of the fundamental plasmon peak. This plasmon mode can be switched on and off and modified simply by changing the temperature. We present discrete dipole approximation (DDA) calculations that characterize this resonance as a quadrupole Au plasmon mode, which results from close-to-contact-particles within the statistically distributed nanoparticles in the pNIPAM matrix. The presented approach is generalizable and allows to investigate the interaction between different kinds of metal nanostructures.

[1]DFG individual grant, Max Kade Foundation

9:36AM F20.00007 Energy concentration of periodic nanoparticle array using Green function formalism , KING CHUN LAI, SZE FUNG LEE, KIN WAH YU, The Chinese University of Hong Kong — We have studied a periodic array of nanoparticle wires by using the Green function formalism (GFF). When light is incident on the wire, a collective oscillation of the free electrons is excited on the surface of the wires, which is called the coupled surface plasmon. The excitation of coupled surface plasmon can cause an enhancement of the local energy density. By tuning the separation relative to the radius of the wires, an energy concentration can be controlled. When the separation of the wires is small, multipolar effect becomes significant. Dealing with tight-binding model by Park and Stroud (2004) would involve interaction term which appears to be non-existent and the resolution of FDTD is insufficient to resolve the multipole interaction as the multipole field can vary rapidly. We applied GFF to this problem which expresses all interaction in a Greenian within one unit cell. The system was studied under spectral representation and the relation between different resonance modes and the outcoming energy concentration was examined. The energy concentration is largest several hot spots which depend on the incident directions.

9:48AM F20.00008 Tunable optical excitations in transition-metal doped arrays of noble-metal chains[1] , NEHA NAYYAR, VOLODYMYR TURKOWSKI, TALAT S. RAHMAN, Department of Physics and NanoScience Technology Center, University of Central Florida, Orlando, FL — We apply time-dependent density-functional theory to study the absorption spectrum of arrays of nano-scale pure noble and transition metal (TM) chains. We find that as the number of chains in the noble atom array increases the plasmon peak shifts to higher energies and appears in the visible range for an array of three gold chains, each consisting of more than 10 atoms. We also find collective excitations (plasmons) in arrays of TM chains: a behavior distinct from bulk TM systems. Doping noble metal chains with TM atoms leads to additional plasmon peaks close in energy to the main one for the undoped case. We compare the calculated optical absorption spectrum of the doped chains for several different types of TM atoms at different positions in the chains, and provide rationale for the trends. In the multi-chain case, the response is very sensitive to the position of the doped atoms. We argue that the origin of the additional modes is charge oscillations around the impurity atoms. Finally, we analyze the effect of interaction of excitonic modes created in infinite chains with plasmons in neighboring nanochains, including the possibility of resonance excitations and their trapping by the TM impurity atoms.

10:00AM F20.00009 Hollow Shells Of Dipoles: A Group Theoretical Approach[1] , CHRISTOPHER DEVULDER, SLAVA ROTKIN, Lehigh University — We investigate the plasmonic properties of hollow cylindrical lattices whose constituent elements are modeled as point dipoles. The symmetry of the lattice is described within the framework of group theory, which enables us to obtain the eigenmodes and eigenvalues of the entire polarization field by diagonalizing the dipole interaction part of the Hamiltonian. An incoming plane wave electric field that couples resonantly with the dipole lattice is expanded in terms of cylindrical harmonics, allowing us to precisely determine the contribution of various modes in its response function. The latter can then be obtained analytically for an arbitrary plane wave excitation. This work facilitates the study of cylindrical plasmonic shells with various geometry, as in the case of gold nanoparticles surrounding carbon nanotubes.

10:12AM F20.00010 ABSTRACT WITHDRAWN –

10:24AM F20.00011 Band edge excitons and trions in CdSe/CdS core/shell nanocrystals , ANDREW SHABAEV, George Mason University, USA, ANNA RODINA, Ioffe Physical-Technical Institute, Russia, ALEXANDER EFROS, Naval Research Laboratory, USA — We have developed a theory of positevly and negatively charged excitons (trions) in "giant" CdSe/CdS core-shell nanocrystals. The theory describes the energy structure of excitons and trions. We present the results of calculations for the fine structure of the the positively charged trion, the binding energy of the negatively charged trion, and the radiative decay time for excitons and trions. The theoretical results are compared with available experimental data.

10:36AM F20.00012 Controlling orientational order of multivalent prisms in superlattice assemblies , KEVIN L. KOHLSTEDT, MONICA OLVERA DE LA CRUZ, GEORGE C. SCHATZ, Northwestern University — Multivalent nanostructures are an increasingly important player in the self-assembly of optically responsive superlattices. Understanding the role nanostructure coordination plays in the ordering of superlattice assemblies is crucial for the plasmonic response of the material. We developed a simple design rule for the assembly of multivalent DNA-Au triangular nanoprisms into 1D ordered superlattices based on both the length of the valent DNA and the size of the prism. Using MD simulations, we describe an order parameter that captures the short-range order of the mesoscale assembly controlled by the design rule. The order parameter shows that even short chains of prisms have a high-degree of orientational order when 1D superlattices are formed. Unlike isotropic polyvalent nanostructures, we find the highly oriented prism superlattices lose orientational order in a multistage fashion through loss of coordination during melting.

10:48AM F20.00013 Quantum Size Effects in α-Pu (020) Layers[1] , SARAH C. HERNANDEZ, ASOK K. RAY, Physics Department, University of Texas at Arlington, Arlington, Texas 76019, CHRISTOPHER D. TAYLOR, Materials Science and Technology Division, Los Alamos National Laboratory, Los Alamos, NM 87545 — First principles calculations using the projector-augmented wave method and a plane wave basis set as implemented in the Vienna *Ab Initio* Simulation Package (VASP) have been performed for the α-Pu (020) layers. Because of severe demands on computational resources, scalar-relativistic computations were performed at the experimental geometry. The surface was assumed to be anti-ferromagnetic (AFM) since previous theoretical studies indicate the ground state of bulk α-Pu to be AFM. Up to ten layers have been considered in this study. Work functions and surface energies appear to converge as the number of layers increase. We predict the work function to be around 3.4eV, with the surface energy being approximately 1.6eV. While no experimental results are available for α-Pu, experimental results for δ-Pu indicate a work function of approximately 3.2eV and a surface energy of 2.0eV. We will also present results on the magnetic moments and density of states of the layers. Results will be compared with results using the full-potential linearized-augmented-plane-wave method as implemented in the WIEN2k suite of software.

Session F21 DMP: Focus Session: Multiferroics and Magnetoelectrics 323 - Hans Christen, Oak Ridge National Laboratory

8:00AM F21.00001 Magnetoelectricity in Spinel $FeCr_2S_4$[1] , LIN LIN, DAN LIU, ZHENGYIN ZHAO, Laboratory of Solid State Microstructures, Nanjing University, Nanjing 210093, China, JIAJIA WEN, Department of Physics and Astronomy, The Johns Hopkins University, Baltimore, MD 21218, USA, ZHIBO YAN, Laboratory of Solid State Microstructures, Nanjing University, Nanjing 210093, China, SHUAI DONG, Department of Physics, Southeast University, Nanjing 210008, China, JUNMING LIU, Laboratory of Solid State Microstructures, Nanjing University, Nanjing 210093, China — We report on ferroelectricity, magnetic susceptibility, dielectric property, and specific heat capacity of the polycrystalline spinel $FeCr_2S_4$. We provide clear evidence of a ferroelectric transition at $\sim$ 8.5K, which accompanies an orbital-ordering transition and a dielectric anomaly. The polarization increases with decreasing temperature, and reaches 3.6μC/m^2 at 2 K. We also carry out detailed multiferroic measurements, and a remarkable magnetoelectric coupling is observed. A very small magnetic filed $H \sim$ 500Oe enhances the polarization to 8.13.6μC/m^2 at 2 K, with a magnetoelectric coupling coefficient $\alpha \sim$ 120%. However, the polarization rapidly decreases for fields beyond $H \sim$ 1T. The multiferroic behavior of $FeCr_2S_4$ is proposed to arise from competition between the spin-orbital coupling and the Jahn-Teller effect for the Fe ion.

8:12AM F21.00002 The internal and external magnetoelectric effect in $LiFeP_2O_7$, K.-C. LIANG, TCSUH and Department of Physics, University of Houston, Houston, TX 77204, USA, W. ZHANG, TCSUH and Department of Chemistry, University of Houston, Houston, TX 77204, USA, B. LORENZ, Y.Y. SUN, TCSUH and Department of Physics, University of Houston, Houston, TX 77204, USA, P.S. HALASYAMANI, TCSUH and Department of Chemistry, University of Houston, Houston, TX 77204, USA, C.W. CHU, TCSUH and Department of Physics, University of Houston, Houston, TX 77204, USA — We study the internal and external magnetoelectric (ME) effect of the single-crystalline $LiFeP_2O_7$ by magnetic, thermodynamic, and magnetoelectric measurements. The Fe^{3+} spins form a canted antiferromagnetic (AFM) order below $T_N \sim$ 27K with weak ferromagnetic components along the b-axis. A sharp peak found in the pyroelectric current at 27K indicates the strong internal ME interaction resulting in a sizeable polarization decrease. With external magnetic field applied, the ME polarization shows a combination of a linear and a quadratic field dependence below T_N, but it only shows the quadratic ME response above then. A large uniaxial magnetoelastic response in the thermal expansion data indicates strong spin-lattice coupling. A qualitative explanation regarding to the ME interaction between electric polarization and magnetic order parameters will be proposed and discussed.

8:24AM F21.00003 Epitaxial Strain Induced Robust Multiferroicity in $BiMnO_3$, XUEZENG LU, XINGAO GONG, HONGJUN XIANG, Fudan University, COMPUTATIONAL CONDENSED MATTER GROUP TEAM — By performing first principles calculations, we investigate the effects of the epitaxial strain on the properties of $BiMnO_3$ films grown along the pseudocubic [001] direction. Unlike the ground state with the centrosymmetric $C2/c$ space group in bulk, two previously unreported phases, namely, paraelectric *Pnma* and ferroelectric *Cc* phases, are stabilized by epitaxial strain. Several surprising and interesting phenomena are revealed. In particular, we find a metal-insulator transition between the ferromagnetic metallic state and antiferromagnetic insulating ferroelectric state under compressive epitaxial strain. On the other hand, the tensile epitaxial strain stabilizes the ferromagnetic and ferroelectric *Cc* state with the large polarization ($P >$80 μC/cm^2) and high Curie temperature (estimated $T_c \sim$ 395 K). Moreover, there is a novel intrinsic magnetoelectric coupling in the multiferroic *Cc* state with the easy magnetization axis tunable by the external electric field.

8:36AM F21.00004 Chemistry and synthesis of new polar perovskites with small tolerance factors[1] , ALEXEI BELIK, International Center for Materials Nanoarchitectnics (WPI-MANA), National Institute for Materials Science — "Usual" perovskite-type compounds with the general formula ABO3, where A is La-Lu and Y and B is V, Cr, Mn, Fe, Co, Ni, and Cu have been attracting a lot of attention for decades. "Exotic" perovskites are also highly interesting because new phenomena may emerge in them. The term "exotic" may include compounds with unusual oxidation states, unusual ion distribution, and unusual ions at the A site and B site. Perovskites with A = Sc and In have small tolerance factors, and they can be prepared only at high pressure. We will discuss "exotic" perovskites with A = Sc and In. A limited number of compounds can be prepared at 6 GPa. Results on (A1-yMy)MnO3 (A = Sc and In, M = Mn, Mg, Co, and Ni), InCrO3, ScCrO3, InRhO3, ScRhO3, InNi0.5Mn0.5O3, and ScNi0.5Mn0.5O3 will be presented. We will also describe a new class of multiferroic polar materials: In-based perovskites. We show that (In1-yMy)MO3 with y = 0.112-0.176 and M = Fe0.5Mn0.5 is isostructural with BiFeO3 (space group R3c) and has a high ferroelectric Curie temperature; (In1-yMy)MO3 is a canted antiferromagnet with the Néel temperature close to RT. Our results give a significant contribution to the development of RT multiferroics and also show new ways for the preparation of perovskite-type materials.

9:12AM F21.00005 The search for new multiferroic ABF_4 fluorides via first-principles structure maps , BRIAN ABBETT, ADITI KRISHNAPRIYAN[1], CRAIG J. FENNIE, Cornell University — Transition metal ABF_4 fluorides are observed in a wide variety of different structure types. One, the $BaMnF_4$ structure, is an interesting family of polar (possibly ferroelectric) materials that display canted-antiferromagnetism, which has been predicted (Ederer and Spaldin) to reverse when the polarization reverses. This strong coupling between magnetism and polarization has motivated us to explore additional ABF_4 structure types. In this talk we will discuss our search for new multiferroic ABF_4 fluorides by creating structure maps from first principles. As a first step we categorize the ABF_4 compounds found in the ICSD. We focus on structures for which the B-site is octahedrally coordinated; these can be fitted into one of four categories: $BaMF_4$, Dion-Jacobson, and the so-called slip (100) or slip (110) structures. These four categories represent high symmetry structures which allow distortions to lower symmetry structures. Note that most of the known multiferroic ABF_4 compounds form in the $BaMF_4$ structure. We elucidate a simple descriptor that helps to build the chemical and physical intuition as to why a compound forms in this structure type needed for the rational design of new multiferroic ABF_4 fluorides.

9:24AM F21.00006 Magnetic field enhanced structural instability in $EuTiO_3$, ZURAB GUGUCHIA, HUGO KELLER, Physik-Institut der Universität Zürich, JÜRGEN KÖHLER, ANNETTE BUSSMANN-HOLDER, Max-Planck-Institut für Festkörperforschung — $EuTiO_3$ undergoes a structural phase transition from cubic to tetragonal at $T_S = 282$ K which is not accompanied by any long range magnetic order. However, it is related to the oxygen ocathedra rotation driven by a zone boundary acoustic mode softening. Here we show that this displacive second order structural phase transition can be shifted to higher temperatures by the application of an external magnetic field ($\Delta T_S \simeq 4$ K for $\mu_0 H = 9$ T). This observed field dependence is in agreement with theoretical predictions based on a coupled spin-anharmonic-phonon interaction model.

9:36AM F21.00007 Spin-Lattice Coupling and Third Neighbor Magnetic Interactions in $EuTiO_3$, TURAN BIROL, CRAIG J. FENNIE, School of Applied and Engineering Physics, Cornell University — An ongoing challenge in materials physics is to identify materials that display a strong coupling between the electrical polarization and magnetism. $EuTiO_3$ is one such material that has been of much recent interest. This novel material is antiferromagnetic and paraelectric in bulk but becomes simultaneously ferromagnetic and ferroelectric under biaxial strain due to a rather large spin-lattice (phonon) coupling. In this talk we will present the results of our first-principles study on the effect of ferroelectric distortions and octahedral rotations on the magnetic exchange interactions in $EuTiO_3$. We elucidate the evolution of the octahedral rotation pattern with strain and show how they influence the properties of the multiferroic phase. Going beyond the proposed cation-mediated exchange for $EuTiO_3$, which has been linked to the large spin-lattice coupling in this material, we uncover the importance of third-neighbor magnetic interactions and illustrate how it is responsible for the "giant" cross-field magnetoelectric effect recently demonstrated.

9:48AM F21.00008 Magneto-orbital helices: a novel coupling mechanism between magnetism and ferroelectricity in multiferroic $CaMn_7O_{12}$[1] , PAOLO G. RADAELLI, NATASHA PERKS, ROGER D. JOHNSON, Clarendon Laboratory, Department of Physics, University of Oxford, Oxford, OX1 3PU, UK, CHRISTINE MARTIN, Laboratoire CRISMAT, ENSICAEN, UMR F-6508 CNRS, 6 Boulevard du Marechal Juin, F-14050 Caen, France, LAURENT CHAPON, Institut Laue-Langevin, BP 156X, 38042 Grenoble, France — The trigonal quadruple perovskite $CaMn_7O_{12}$ displays one of the largest magnetically induced ferroelectric polarisations measured to date (2870 μC m^{-2}). Ferroelectricity appears below 90 K, together with an incommensurate helical magnetic modulation, and cannot be explained within the framework developed for cycloidal magnets [2]. We report an unprecedented magneto-orbital texture in multiferroic $CaMn_7O_{12}$, which is directly connected to ferroelectricity[3]. X-ray and neutron diffraction characterisation of the structural and magnetic modulations in these "magneto-orbital helices", and analysis of magnetic exchange shows that orbital order is crucial in stabilising a chiral magnetic structure. Additionally, the presence of a global structural rotation enables the magnetic helicity to couple with the lattice, giving rise to electric polarisation. These novel principles open up the possibility of discovering new multiferroics with even larger polarization and higher transition temperatures. [1] G. Zhang, *et al.*, Phys. Rev. 10:00AM F21.00009 Magneto-Electric Coupling in Single Crystal Cu_2OSeO_3 Studied by a Novel Electron Spin Resonance Technique , ALEXANDER MAISURADZE, Physics Institute, University of Zurich, Zurich, Switzerland, ALEXANDER SHENGELAYA, Department of Physics, Tbilisi State University, Tbilisi, Georgia, HELMUTH BERGER, DEJAN DJOKIĆ, Institute of Condensed Matter Physics, EPFL, Lausanne, Switzerland, HUGO KELLER, Physics Institute, University of Zurich, Zurich, Switzerland — The magneto-electric (ME) coupling on spin-wave resonances in single-crystal Cu_2OSeO_3 was studied by a novel technique using electron spin resonance combined with electric field modulation. An external electric field $\mathbf{E}$ induces a magnetic field component $\mu_0 H^i = \gamma E$ along the applied magnetic field $\mathbf{H}$ with $\gamma = 0.7(1)$ μT/(V/mm) at 10 K. The ME coupling strength γ is found to be temperature dependent and highly anisotropic. $\gamma(T)$ nearly follows that of the spin susceptibility $J^M(T)$ and rapidly decreases above the Curie temperature T_c. The ratio γ/J^M monotonically decreases with increasing temperature without an anomaly at T_c.

10:12AM F21.00010 Strong Dzyaloshinskii-Moriya Interaction and Origin of Ferroelectricity in Cu_2OSeO_3[1] , JI-HUI YANG, ZHENG-LU LI, XUEZENG LU, X.G. GONG, HONGJUN XIANG, Key Laboratory of Computational Physical Sciences (MOE), State Key Laboratory of Surface Physics, and Dept of Physics, Fudan University, Shanghai, M.-H. WHANGBO, Department of Chemistry, North Carolina State University, Raleigh, North Carolina 27695-8204, USA, SU-HUAI WEI, National Renewable Energy Laboratory, Golden, Colorado 80401, USA — In this work, we try to understand the skyrmions recently observed experimentally in Cu2OSeO3 system, as well as its origin of ferroelectricity. Based on the spin Hamiltonian, we developed four-state-energy-mapping method to derive these spin interaction parameters. For this system, we found a very large ratio between the DM term and the symmetric exchange interaction. Besides, the spin arrangements in the ground state are found degenerate and the spin energy is independent of the propagation vector q. Taking these two factors into account, we explained the experimental observation of skyrmions to some extent. Then we built a model to describe the polarization of this system. By the symmetry analysis, the ferroelectricity is supposed to result from the spin single-site term, as is confirmed by direct calculations of our model. Using this model, we analyzed its ferroelectricity dependence of the spin arrangement and find the largest polarization happens when the spins are along <111> direction, in excellent agreement with the experimental results.

Session F22 DCMP: Strongly Correlated Electron Theory I 324 - Steve Hellberg, Naval Research Laboratory

8:00AM F22.00001 Spin flip in spin-orbit split quantum wires in magnetic field[1] , OLEG A. TRETIAKOV, Tohoku University and Texas A&M University, K. S. TIKHONOV, V. L. POKROVSKY, Texas A&M University and Landau Institute for Theoretical Physics — We study spin-flip processes induced by ac electromagnetic field in quantum wires with strong spin-orbit coupling in the presence of an external magnetic field. The dc magnetic field is essential to enable the electric dipolar excitation of the spin-flip processes. We consider the electron spin-flip resonance in the framework of Luttinger liquid theory. The electron-electron interaction is strong in quantum wires and changes the shape of the spin-flip resonance curve at the spin wave frequency and produces an additional cusp at the frequency of collective charge excitation. We discuss how this spin flip is affected by the dissipation processes and the dispersion curvature.

[1]This work has been supported by the DOE under the grant DE-FG02-06ER46278, by NSF under Grants No. DMR-0757992, ONR-N000141110780, and by NHARP.

8:12AM F22.00002 Theoretical study of a one-dimensional chain of alternating spin-1 and electron sites with spin-mediated hopping , WING-HO KO, HONG-CHEN JIANG, Kavli Institute for Theoretical Physics, University of California, Santa Barbara, Santa Barbara, California 93106, USA, JEFFREY RAU, Department of Physics, University of Toronto, Toronto, Ontario M5S 1A7, Canada, LEON BALENTS, Kavli Institute for Theoretical Physics, University of California, Santa Barbara, Santa Barbara, California 93106, USA — Motivated by the nickel valance controversy in the perovskite nickelate $RNiO_3$, we consider a one-dimensional chain consisting of alternating spin-1 ("nickel") and electron ("oxygen") sites, which in addition to the usual electron hopping and spin-spin interaction between the spin-1 and the electron also contains a spin-1 mediated electron hopping term. Using density-matrix renormalization group (DMRG), we obtain the phase diagram of such model, as well as various correlation functions in each phase. Importantly, for certain range of parameters the model exhibits a quasi-long-range spiral (QS) order. To understand the DMRG results, we construct a mean-field theory based on Schwinger fermion decomposition of the spin-1 spins, from which we argue that the QS phase corresponds to a phase in proximity to the spin Bose metal state proposed by Sheng, Motrunich, and Fisher [Phys. Rev. B, 79, 205112 (2009)].

8:24AM F22.00003 Magnetic Phase Transition Induced by the Hubbard and Spin-orbit Interactions in a Nanoribbon Geometry , HYEONG JUN LEE, MOO YOUNG CHOI, Department of Physics and Astronomy and Center for Theoretical Physics, Seoul National University, Seoul 151-747, Korea, GUN SANG JEON, Department of Physics, Ewha Womans University, Seoul 120-750, Korea — The local repulsive Coulomb interaction between the electrons tends to cause a Mott transition into a magnetically ordered phase. In a honeycomb lattice, particularly, the magnetic order is known to emerge on the edges of graphene, which is attributed to the electron interactions. Meanwhile, the introduction of the spin-orbit interaction gives rise to metallic boundary states, which is a prominent characteristic of the topologically nontrivial materials. We study the effect of the spin-orbit interaction on the edge states as well as the bulk properties of the electron system on the honeycomb lattice. By employing a Hartree-Fock approximation, we compute the local magnetization in the half-filled nanoribbon system at zero temperature. We pay particular attention to the decaying behavior of the local magnetization from the edge toward the center. It is found that the characteristic length associated with the decay is divergent on the phase boundaries. Such slow decay is found to be algebraic in the thermodynamic limit. We discuss the relation between the bulk phase transitions and the decay of magnetization at the edges.

8:36AM F22.00004 Nonequilibrium thermal transport and its relation to linear response , CHRISTOPH KARRASCH, RONI ILAN, JOEL MOORE, UC Berkeley — We study the real-time dynamics of spin chains driven out of thermal equilibrium by an initial temperature gradient $T_L \neq T_R$. We demonstrate that the nonequilibrium energy current saturates fast to a finite value if the linear-response thermal conductivity is infinite, i.e. if the Drude weight D is nonzero. Our data suggests that a nonintegrable dimerized chain might support such dissipationless transport ($D > 0$). We show that the steady-state value of the current for arbitrary $T_L \neq T_R$ is completely determined by the linear conductance. Inhomogeneous systems exhibiting different bulk parameters as well as Luttinger liquid boundary physics induced by single impurities are discussed shortly.

8:48AM F22.00005 Quantum Monte-Carlo simulation of spin-one antiferromagnets with single-ion anisotropy[1] , YASUYUKI KATO, Theoretical division, T-4 and CNLS, Los Alamos National Laboratory, KEOLA WIERSCHEM, School of Physical and Mathematical Sciences, Nanyang Technological University, 21 Nanyang Link, Singapore 637371, YUSUKE NISHIDA, Theoretical division, T-2, Los Alamos National Laboratory, CRISTIAN BATISTA, Theoretical division, T-4 and CNLS, Los Alamos National Laboratory, PINAKI SENGUPTA, School of Physical and Mathematical Sciences, Nanyang Technological University, 21 Nanyang Link, Singapore 637371 — We study a spin-one Heisenberg model with uniaxial single-ion anisotropy, D, and Zeeman coupling to a magnetic field, B, parallel to the symmetry axis. We compute the $(D/J, B/J)$ quantum phase diagram for square and simple cubic lattices by combining analytical and Quantum Monte Carlo approaches, and find a transition between XY-antiferromagnetic and ferronematic phases that spontaneously break the U(1) symmetry of the model. In the language of bosonic gases, this is a transition between a Bose-Einstein condensate (BEC) of single bosons and a BEC of pairs. For the efficient simulation of ferronematic phase, we developed and implemented a new multi-discontinuity algorithm based on the directed-loop algorithm. The ordinary quantum Monte-Carlo methods fall into freezing problems when we apply them to this system at large D/J and finite $B/J \sim 1$. The new method does not suffer from the freezing problems.

[1]This research used resources of the NERSCC (DOE Contract No. DE-AC02-05CH11231). Work at LANL was performed under the auspices of a J. Robert Oppenheimer Fellowship and the U.S. DOE contract No. DE-AC52-06NA25396 through the LDRD program.

9:00AM F22.00006 Majorana dimerised order in magnetic systems , EDMUND BENNETT, University of St Andrews — We consider the analysis of quantum critical points (QCPs) using a Majorana fermion[1] representation of spin. Majorana fermions are a useful spin representation as they obey Wick's theorem and automatically provide the correct $S^2_{\text{tot.}} = 3/4$ for stationary spin-1/2 lattice spins. We consider an Ising model in various dimensions in an applied transverse field, a model which exhibits a QCP and has an exact solution in 1D. In the Majorana fermion representation, the interaction vertex may be decoupled into either a "Majorana dimerisation (MD)" decoupling or an Ising magnetic decoupling. A mean-field analysis of the MD decoupling (which involves two Majorana fermions of the same flavour on adjacent lattice sites) suggests an ordered phase in the region above the QCP extant in the model, which extends through to high magnetic fields. Full RPA corrections to this mean-field theory are also presented, which give insight into the stability of this ordered phase to quantum perturbations.

[1]W. Mao, P. Coleman, C. Hooley & D. Langreth; PRL, 91, 20, p. 2072031-2072034; 2003

9:12AM F22.00007 Spin Orbit Magnetism and Unconventional Superconductivity , YI ZHANG, KEVIN BEDELL, Boston College — We find an exotic spin excitation in a magnetically ordered system with spin orbit magnetism in 2D, where the order parameter has a net spin current and no net magnetization. Starting from a Fermi liquid theory, similar to that for a weak ferromagnet, we show that this excitation emerges from an exotic magnetic Fermi liquid (EMFL) state that is protected by a generalized Pomeranchuck condition. We derive the propagating mode using the Landau kinetic equation, and find that the dispersion of the mode has a $q^{1/2}$ behavior in leading order in 2D. We find an instability toward superconductivity induced by this exotic mode, and a further analysis based on the forward scattering sum rule strongly suggests that this superconductivity has p-wave pairing symmetry. We perform similar studies in the 3D case, with a slightly different magnetic system and find that the mode leads to a Lifshitz-like instability most likely toward an inhomogeneous magnetic state in one of the phases.

9:24AM F22.00008 Magnetic properties of $d-$atomic systems with unquenched orbital moments , VICTOR ANTONOV, (1). Ames Laboratory USDOE, Ames, IA 50011 (2). Institute for Metal Physics, 36 Vernadsky blrd., Kiev, Ukraine, 03680, LIQIN KE, ANTON JESCHE, VLADIMIR ANTROPOV, Ames Laboratory USDOE, Ames, IA 50011 — Many systems of d-atoms with unquenched orbital moments demonstrate unusually large values of atomic magnetic moments, high magnetic anisotropy and small magnetic ordering temperatures. Using electronic structure analysis, we study a mechanism of the formation of strong on-site electronic correlations that lead to a strong orbital polarization, and in turn, generate a highly orbitally polarized hybridization with non-magnetic host atoms. In this case, even a small spin orbital coupling of $3d$-atoms can create a significant effect. We introduce a consistent model of the formation of large orbital moments and magnetic anisotropy both in the metallic and insulating cases, and apply it to several realistic systems. Detailed calculations of magnetic properties, including magneto-optical studies of the Kerr angle rotation, are performed for several nitrometalates of Mn, Fe and Co where a rather large (3-5 degrees) Kerr angle rotation is predicted for the first time. We further discuss the nature of critical temperature in magnetic phase transition in such systems and the opportunity to increase it.

9:36AM F22.00009 ABSTRACT WITHDRAWN –

9:48AM F22.00010 Fractional Chern insulator on the triangular lattice , STEFANOS KOURTIS, JÖRN VENDERBOS, JEROEN VAN DEN BRINK, MARIA DAGHOFER, Leibniz Institute for Solid-State and Materials Research — The opportunity for the formation of fractional quantum-Hall (FQH) states in 3-orbital Hubbard and Kondo lattice models on the triangular lattice without an external magnetic field has been recently demonstrated [1,2]. With this as motivation, an effective interacting spinless-fermion model, which is designed to capture the essential relevant physics, has been extensively studied. Its numerically obtained ground states at several fillings exhibit features which suggest that the former are spontaneously occurring FQH states on a lattice, i.e. fractional Chern insulator (FCI) states. The most unequivocal feature of such states is arguably their fractionally quantized Hall conductivity. This effect, as seen in numerical calculations for finite clusters, will be presented and discussed. Having thus identified FCI states, further signatures of their nature are highlighted, e.g. fractional quasihole statistics.

10:00AM F22.00011 ABSTRACT WITHDRAWN –

10:12AM F22.00012 Magnetic phase transitions in the chiral helimagnet $Cr_{1/3}NbS_2$[1] , NIRMAL GHIMIRE, The University of Tennessee/Oak Ridge National Laboratory, MICHAEL MCGUIRE, BRIAN SALES, LISA DEBEER-SCHMITT, HUIBO CAO, BRYAN CHAKOUMAKOS, ADAM ACZEL, BALAZS SIPOS, Oak Ridge National Laboratory, SIWEI TANG, YUEN YIU, JIAQIANG YAN, The University of Tennessee, STEPHEN NAGLER, Oak Ridge National Laboratory/The University of Tennessee, DAVID MANDRUS, The University of Tennessee/Oak Ridge National Laboratory — $Cr_{1/3}NbS_2$ is a long period chiral helimagnet crystallizing in the noncentrosymmetric, hexagonal space group $P6_322$. Helimagnetic ordering along the c-axis is attributed to the competition between the symmetric exchange interaction, favoring parallel moments, and the anti-symmetric Dzyaloshinsky-Moriya interaction, favoring perpendicular moments. Recently, the ground state helical ordering is found to be destabilized by a magnetic field applied perpendicular to c, forming a chiral soliton lattice phase, and, above a critical field, a commensurate ferromagnetic state. Thermal and transport properties also show interesting behaviors in the vicinity of the transition temperature. Here we present magnetic, thermal and transport properties of $Cr_{1/3}NbS_2$ measured on single crystals, along with recent results from neutron scattering experiments conducted on the four circle single crystal diffractometer and general purpose SANS at the High Flux Isotope Reactor, ORNL.

10:24AM F22.00013 ABSTRACT WITHDRAWN –

10:36AM F22.00014 Possible non-coplanar spin structure and large Hall effect in Na_xCoO_2 , J.W. KIM, E.D. MUN, R.D. MCDONALD, V. ZAPF, NHMFL/MPA-CMMS, LANL, J.D. THOMPSON, MPA-CMMS, LANL, L. BALICAS, NHMFL, I. MARTING, T4/CNLS,LANL, D. ARGYRIOU, Hahn-Meitner-Institut — We present magnetotransport studies of Na_xCoO_2 (x =0.46) and its relation to possible non-coplanar spin texture. This compound exhibits a unique insulating state below temperature (T) of 53 K related to charge-order which is different from other composition with metallic behavior. It also has frustrated local spin texture owing to its hexagonal structure. Previous works report a very large Hall signal for composition x =0.5 (M. Foo *et al.*, Phys. Rev. Lett. 92, 247001 (2004)) at low magnetic field (B) and prior high-field studies (L. Balicas *et al.*, Phys. Rev. Lett. 94, 236402 (2005)) have found the existence of a small Fermi surface in the system and a two-fold angular magnetoresistance. Using pulse and hybrid magnets at NHMFL, we mapped out a detailed T-B phase diagram up to 65 T which is strong enough to suppress the charge-order. When B is applied along the c-axis, the charge-ordered state is suppressed at $B \sim$ 41 T with highly non-monotonic shape in ρ_{xy}. We found that this Hall signal reaches a maximum around $T \sim$ 30 K and $B \sim$ 27 T and on further cooling the absolute change of ρ_{xy} decreases significantly. Interestingly, we found no significant changes in field-dependent magnetization which suggests that this behavior does not come from the ordinary anomalous Hall effect. We discuss the origin of this unique Hall signal by existence of a non-coplanar spin structure that may exist in this compound (I. Martin, C. D. Batista, Phys. Rev. Lett. 101, 156402 (2008)).

10:48AM F22.00015 Combined Transport, Magnetization and Neutron Studies of Structural and Magnetic Behavior in Ca3Ir4Sn13 , ZHENSONG REN, MANI POKHAREL, TOM HOGAN, Boston College, ATHENA SEFAT, CLARINA DE LA CRUZ, HUIBO CAO, Oak Ridge National Laboratory, BO LI, CYRIL OPEIL, STEPHEN WILSON, Boston College — Ca3Ir4Sn13, synthesized by Espinosa and his coworkers almost 30 years ago, was recently suggested to possess an unconventional superconducting ground state in the presence of a background of strong spin fluctuations. This signature for this claim stemmed from charge transport and magnetization anomalies near 45K, yet, later a detailed single crystal XRD investigation revealed that the anomaly is produced by a second order superlattice transition and that this transition can be tuned to zero temperature—suggesting a structural quantum critical point. Here in an attempt to characterize this phase further, we present a picture of the evolution of the structural and magnetic behavior in Ca3Ir4(Sn1-xSbx)13 via a combined transport, magnetization and neutron scattering study.

Tuesday, March 19, 2013 8:00AM - 11:00AM –

Session F23 DMP: Focus Session: Dopants and Defects in Semiconductors IV 325 - Beall Fowler, Lehigh University

8:00AM F23.00001 The electronic structure of Group V dopants in silicon – The requirements for a realistic DFT model[1]

VERONIKA BRAZDOVA, DAVID R. BOWLER, ANDREW J. FISHER, University College London — Typical concentrations of Group V donors in Si wafers used in experiment are up to 10^{18} cm^{-3}. In contrast, the simulation cell in a typical atomistic simulation would contain a few hundred Si atoms and one or two dopants. That is equivalent to concentrations on the order of at least 10^{20} cm^{-3}. We investigate the effect of donor concentration on the electronic structure of doped bulk silicon in density functional simulations (DFT) using the linear scaling DFT code Conquest on very large cells, and the cell sizes required to model the metal-semiconductor transition correctly.

8:12AM F23.00002 Charged defect in GaSb by selective occupation in density functional theory[1]

JIANWEI WANG, YONG ZHANG, Department of Electrical and Computer Engineering, UNC Charlotte — In a density functional theory (DFT) approach, the transition energy of an acceptor-like defect is typically calculated by the total energy difference between E(N+1) and E(N), where N is the total number of the valence electrons of the defected system. Effectively, in this scheme, the hole in the valence band is simulated by a uniform positive background charge or a plane wave. A scheme closer to the reality would be to move one electron from the valence band maximum (VBM) to the defect level, because the VBM state usually is quite different from a plane wave. We apply this selective occupation scheme to a defect problem, an antisite defect of Ga on Sb in GaSb, and compare the results of two schemes with varying supercell size, using a pseudopotential DFT theory.

8:36AM F23.00004 Small polaron characteristics of the OH center in TiO_2[1]

W. BEALL FOWLER, Department of Physics and Sherman Fairchild Laboratory, Lehigh University, Bethlehem, PA 18015 — Most insulating crystals have nearly-free-electron conduction bands and corresponding conduction properties, with the effective mass increased slightly by large-polaron effects. In TiO_2, the lowest conduction bands contain considerable admixture of Ti 3d states. In this case the conduction electrons become localized, or self-trapped, into small-polaron states [1], and their conduction properties differ considerably from the usual case. EPR experiments by Halliburton *et al.* [2] have shown that this self-trapping is also present in association with point defects, namely substitutional F and interstitial H (which forms a bond with a lattice O). In each case the spin of the unpaired electron is localized on a nearest neighbor Ti. Infrared absorption experiments as a function of temperature on the OH center by Bekisli *et al.* [3] have resolved apparent inconsistencies in the model used to fit earlier IR data. Through detailed analysis they have interpreted their results in terms of a small polaron model which involves several configurations corresponding to the localization of the OH electron on different Ti sites, each of which yields an IR line of slightly different frequency. These conclusions are supported by theoretical results in the literature and by our calculations using the CRYSTAL06 code [4] with a hybridized DFT Hamiltonian.

9:12AM F23.00005 H and D centers in In_2O_3 studied by IR spectroscopy[1]

WEIKAI YIN, Lehigh University, KIRBY SMITHE, University of Tulsa, MICHAEL STAVOLA, W. BEALL FOWLER, Lehigh University, L.A. BOATNER, Oak Ridge National Lab — Hydrogen has been predicted to be an important source of n-type conductivity in transparent conducting oxides (TCO's) [1]. We have used IR spectroscopy to investigate the properties of H (and D) in single crystals of the prototypical TCO, In_2O_3, and to test the predictions of recent theory [2]. H (or D) introduces several O-H (or O-D) stretching lines and also the broad absorption arising from free carriers. We have used the vibrational properties of H- (and D-) containing centers as a probe of microscopic structure and as a strategy to monitor H-related reactions that occur upon annealing. [1] M. McCluskey *et al.*, J. Mater. Res. **27**, 2190 (2012) [2] S. Limpijumnong *et al.*, Phys. Rev. B **80**, 193202 (2009).

9:24AM F23.00006 Controlled introduction of defects in GaMnAs and GaBeAs thin films by ion-beam irradiation[1]

MARCELO SANT'ANNA, ELIS SINNECKER, TATIANA RAPPOPORT, MAURICIO PIRES, GERMANO PENELLO, DAVID SOUZA, SERGIO MELLO, JOAQUIM MENDES, Universidade Federal do Rio de Janeiro, JACEK FURDYNA, XINYU LIU, University of Notre Dame — The existence of interstitial Mn atoms, and other point defects, significantly modify magnetic and transport properties of $Ga_{1-x}Mn_xAs$. This opens a door to manipulate these properties in a controlled way by ion-beam irradiation of thin films. We study how the simultaneous lowering of hole concentration and increasing of disorder, introduced by ion-beam irradiation, affects the magnetization and conductivity of $Ga_{1-x}Mn_xAs$ samples [1,2]. Highly doped $Ga_{1-x}Be_xAs$ is a material that can be produced with similar doping levels but that shows no ferromagnetism, acting as an interesting experimental standard for comparison of transport properties of $Ga_{1-x}Mn_xAs$. We irradiate $Ga_{1-x}Mn_xAs$ and $Ga_{1-x}Be_xAs$ thin films with 2 MeV oxygen ion beams. Samples were grown by molecular beam epitaxy. Sheet resistance of the thin films was measured in situ in the irradiation chamber as a function of the incident dose.

9:36AM F23.00007 The role of d levels of substitutional magnetic impurities at the (110) GaAs surface , M.R. MAHANI, ANNA PERTSOVA, FHOKRUL ISLAM, C.M. CANALI, Linnaeus University, Kalmar, Sweden — The study of the spin of individual transition-metal dopants in a semiconductor host is an emergent field known as magnetic solotronics, bearing exciting prospects for novel spintronics devices at the atomic scale. Advances in different STM based techniques allowed experimentalists to investigate substitutional dopants at a semiconductor surface with unprecedented accuracy and degree of details [1]. Theoretical studies based both on microscopic tight-binding (TB) models and DFT techniques have contributed in elucidating the experimental findings. In particular, for the case of Mn dopants on the (110) GaAs surface, TB models [2] have provided a quantitative description of the properties of the associated acceptor states. Most of these TB calculations ignore dealing explicitly with the Mn d-levels and treat the associated magnetic moment as a classical vector. However recent STM experiments [3] involving other TM impurities, such as Fe, reveal topographic features that might be related to electronic transitions within the d-level shell of the dopant. In this work we have included explicitly the d levels in the Hamiltonian. The parameters of the model have been extracted from DFT calculations. We have investigated the role that d levels play on the properties of the acceptor states of the doped GaAs(110) surface, and analyzed their implications for STM spectroscopy. 9:48AM F23.00008 Optical measurements of trap state density and minority carrier lifetime in GaAs heterostructures grown at varying rates , CHELSEA HAUGHN, KENNETH SCHMIEDER, JOSHUA ZIDE, University of Delaware, ALLEN BARNETT, Univeristy of New South Wales, CHRIS EBERT, Veeco MOCVD, ROBERT OPILA, MATTHEW DOTY, University of Delaware — Semiconductor growth rates are a critical factor for production costs and can have a significant impact on electrical properties. We use time resolved photoluminescence (TRPL) to characterize the effective lifetime of carriers in gallium arsenide - indium gallium phosphide (GaAs/InGaP) double heterostructures grown at varying rates. We measure the PL decay time as a function of laser fluence and extract an approximate trap state density by fitting this data with the Shockely-Read-Hall model of carrier recombination. Using the approximate trap densities, we then calculate minority carrier lifetimes for a range of doping conditions. The results suggest that the increased density of trap states associated with a two-fold increase in growth rate are less limiting to carrier lifetime than doping at the levels required for devices. The techniques and analysis developed here can be applied for rapid, non-destructive quantification of trap state densities in materials grown under varying conditions.

10:00AM F23.00009 First-principles study on scattering potentials of defects on Ge(001) surfaces , TOMOYA ONO, Osaka University — As new techniques for the nanoscale manipulation and modification of materials progress, the electron scattering properties of nanostructures are the focus of attention both experimentally and theoretically. The spatial maps of the local density of states obtained by scanning tunneling spectroscopy can give us the images of standing waves, which provide important information about the dispersion relation of the electron scattering process at the potential barrier. I examined the scattering potential of the Ge-Si and Ge-Sn dimers on Ge(001) surfaces using a first-principles calculation. By calculating the scattering wave functions, the standing waves in the spatial map of the local density of states are examined; the waves correspond to the image of the differential conductance obtained by scanning tunneling spectroscopy. The period of the standing wave and its phase shift agree with those obtained by the experiment. I found that the scattering potential acts as a barrier when the electronegativity of the upper atom of the dimer is larger than that of the lower atom, while it becomes a well in the opposite case. The scattering potential is related to the stabilization of the ? bands of the Ge(001) surface due to the difference in electronegativity between Ge and the impurity.

10:12AM F23.00010 Why Cu diffuses fast in semiconductors? , JIE MA, SU-HUAI WEI, national renewable energy lab — It is well-known that experimentally Cu diffuses fast in semiconductors and the fast diffusion plays an important role in many applications. However, the theoretical reason for the fast diffusion is still unclear. Using first-principles calculations, we compare the diffusion behavior between Cu and group-IA atoms in CdTe, and find that the fast diffusion of Cu can be explained by the existence of the symmetry-induced strong s-d coupling in the system, which lowers the energy significantly at the site usually consists the barrier for group-IA system. Due to this s-d coupling, the most stable doping site, diffusion pathway, and diffusion energy curve of Cu are different from those of group-IA atoms, and the diffusion barrier for Cu+ is usually larger than that for neutral Cu. The mechanism is expected to be general for all tetrahedral semiconductors.

10:24AM F23.00011 Density functional study of the properties of Tl6SeI4 for radiation detection applications , KOUSHIK BISWAS, Arkansas State University, MAO-HUA DU, DAVID SINGH, Oak Ridge National Laboratory — The extra compositional freedom available in ternary compounds allow flexibility to tune their electronic and structural properties compared to the binary counterparts. Indeed, the Tl-based ternary semiconductor Tl6SeI4 is a promising candidate for radiation detectors. It has a band gap (1.86 eV) that is intermediate between those of Tl2Se (0.6 eV) and TlI (2.75 eV) and suitable for room temperature detectors. However, the flexibility in ternary semiconductors may come at the expense of more channels for defect formation and more complex defect chemistry, which need to be studied in details. To better understand the properties of Tl6SeI4 in relation to the radiation detection, we performed first-principles study of electronic structure, phase diagram, and dielectric, optical, and defect properties in Tl_6SeI_4.[1] We will discuss the properties of defects and their diffusion barriers in the context of resistivity and polarization phenomenon in Tl6SeI4. [1] K. Biswas, M.-H. Du, and D. J. Singh, Phys. Rev. B **86**, 144108 (2012).

10:36AM F23.00012 Electronic Structure Engineering of Elpasolites for Brighter and Faster Scintillators , MAO-HUA DU, Oak Ridge National Lab, KOUSHIK BISWAS, Department of Chemistry and Physics, Arkansas State University — Utilization of scintillator materials is one of the primary methods for radiation detection. Elpasolites are a large family of quaternary halides that have attracted considerable interest for their potential applications as γ-ray and neutron scintillators. However, many elpasolite scintillator materials currently under development suffer from low light yield and long scintillation decay time. The low light yield is partially due to a large band gap while the long scintillation decay time is a result of slow carrier transport to Ce dopants, where electrons and holes recombine to emit photons. We suggest that these problems may be mitigated by optimizing the band gap and carrier mobility by selecting constituent elements of proper electronegativity. For example, cations with lower electronegativity may lower the conduction band and increase the conduction band dispersion simultaneously, resulting in higher light yield and faster scintillation. First-principles calculations of electronic structure, small polarons, and Ce dopants in Cs_2LiYCl_6 and Cs_2AgYCl_6 compounds show that the strategy of manipulating electronegativity can lead to brighter and faster elpasolite-based scintillators. This work was supported by the U.S. DOE Office of Nonproliferation Research and Development NA22.

10:48AM F23.00013 Hydrogen configurations at a high-angle grain boundary in yttria-stabilized zirconia[1] , APOSTOLOS MARINOPOULOS, CEMDRX and Physics Department, University of Coimbra — Hydrogen is a common impurity in many technologically-relevant semiconductors and oxides. Being mobile and reactive it can form defect complexes with native defects or other extrinsic point defects. Ab initio calculations based on density-functional theory (DFT) have so far been instrumental in elucidating the tendency of hydrogen to form stable complexes with oxygen vacancies and acceptor dopants. The interaction of hydrogen with internal extended defects, such as grain boundaries, needs also to be addressed given the fact that metal oxides are commonly used in polycrystalline or nanocrystalline forms. The present DFT study aims to determine the type of hydrogen configurations that can exist at the core of a high-angle tilt grain boundary in yttria-stabilized zirconia (YSZ). The core is characterized by strong distortions for both anion and cation sublattices and lower ionic density and coordination numbers that lead to larger interstitial spaces at the interface with respect to the bulk. Formation energies and charge transition levels are determined and compared to those in the bulk YSZ where hydrogen was found to incorporate either at hydroxide-bond configurations or at interstitial sites with strong atomic character.

Session F24 DCOMP: Focus Session: Computational Studies of Interactions between Electromagnetic Fields and Materials I 326 - Carsten Ullrich, University of Missouri

8:00AM F24.00001 Coherent phonon generation in time-dependent density functional theory[1]

, GEORGE BERTSCH, University of Washington — We apply the time-dependent density functional theory (TDDFT) to the generation of coherent optical phonons in Si and Sb crystals. The computations are carried out by real-time evolution of the orbital wave functions on a coordinate-space mesh. The theory reproduces the main phenomena observed experimentally: dependence on polarization, strong growth at the direct band gap, and the change in phase from below to above the band gap. Comparing with more phenomenological models, we find that the TDDFT supports the impulsively stimulated Raman mechanism at low frequencies and the qualitative aspects of the displacive mechanism at higher frequencies. We also compare with the more detailed model of displacive excitation by Stevens, Kuhl, and Merlin.

8:36AM F24.00002 Spectral Representation analysis of dielectric screening in solids and molecules[1]

, AMANDEEP KAUR, ERIK YLVISAKER, University of California, Davis, CA, DEYU LU, Center for Functional Nanomaterials, Brookhaven National Laboratory, NY, TUAN ANH PHAM, GIULIA GALLI, WARREN PICKETT, University of California, Davis, CA — We propose a new approach to identify and rationalize the contribution of core electron polarization to dielectric screening, based on ab initio calculations of the dielectric matrix in its eigenpotential basis. We also present calculations of phonon frequencies, dielectric constants for alkali hydrides and quasiparticle energies of several sp bonded molecules, and we discuss the quantitative effect of including core polarization. We find that inclusion of semi-core (SC) electrons leads to new eigenmodes in the dielectric matrix with respect to those with valence electron only. These eigenmodes are highly localized in real space. Polarization arising from SC orbitals may contribute 4-6% to the computed dielectric constants in alkali hydrides, and to differences in QP energies of $\sim$100 meV for sp bonded molecules. Our findings illustrate efficient ways of approximating the spectral decomposition of dielectric matrices used, e.g. in many body perturbation theory and dielectric constant calculations, with substantial computational gains for large systems composed of heavy atoms.

8:48AM F24.00003 Real Time Dynamical Core-hole Effects in X-ray Spectra[1]

, A.J. LEE, F.D. VILA, J.J. KAS, J.J. REHR, University of Washington, Seattle — We present an extension of the real-time x-ray spectroscopy code RTXS[2] to introduce dynamic effects due to the sudden creation of a core hole in x-ray absorption (XAS) and emission (XES) spectra. RTXS is based on a local, time-correlation function approach using a real-time extension of the SIESTA code with a Crank-Nicolson time-evolution operator, and projector augmented wave (PAW) transition matrix elements. Originally RTXS used a statically screened core hole, an approximation equivalent to the final state rule as in ΔSCF approaches. To introduce dynamic effects, we now start with the system in the ground state, suddenly introduce the core-hole, and then propagate the system in real time, again with the Crank-Nicolson approach. This implementation yields a generally applicable code that builds in full-potential electronic structure and dynamic core-hole screening. Illustrative examples are presented and compared with initial and final state rule approximations.

9:00AM F24.00004 New method for calculating the optical absorption spectrum for solids using the transcorrelated method

, MASAYUKI OCHI, Department of Physics, The University of Tokyo, SHINJI TSUNEYUKI, Department of Physics, The University of Tokyo, ISSP, The University of Tokyo — *Ab initio* calculation of an accurate optical absorption spectrum for solids is a challenging problem, and various methods are proposed for this purpose, such as TDDFT using new functionals and GW+BSE. In this study, we propose a new method for calculating the optical spectra, using the transcorrelated (TC) method[1-6], which is one of the promising wave-function theories. In the TC method, the total wave function is approximated as the Jastrow-Slater-type wave function, and the many-body Hamiltonian is similarity-transformed by the Jastrow factor. Then we solve an SCF equation and optimize one-body orbitals in the Slater determinant with a relatively low computational cost.[6] For excited-state calculations, we use configuration interaction singles (CIS) for the TC method, and will present an optical absorption spectrum of LiF calculated with this method. 9:12AM F24.00005 Computationally efficient dielectric calculations of molecular crystals

, KATHLEEN SCHWARZ, Cornell University Department of Chemistry and Chemical Biology, T.A. ARIAS, Cornell University Department of Physics — The dielectric response is a key quantity for electronic materials such as organic semiconductors. Calculations of the dielectric response for molecular crystals are currently either expensive, or rely on extreme simplifications such as multipole expansions. We present an alternate approach using an analogue of the Clausius-Mossotti equation, which constructs the crystal's dielectric response from an eigenvalue decomposition of the molecular dielectric response. This method can be used to examine the effects of defects and surfaces on the dielectric properties of molecular crystals.

9:24AM F24.00006 Exciton and trions binding energies in single-layer MoS_2: applications of the density-matrix time dependent density[1]

, ALFREDO RAMÍREZ-TORRES, VOLODYMYR TURKOWSKI, TALAT S. RAHMAN, Department of Physics, University of Central Florida, Orlando, Florida 32816, USA — Exciton and trion binding energies of a single layer of MoS_2 are studied using a time- dependent density-functional theory formalism. Kohn-Sham orbitals of the initial state were obtained using ab initio electronic structure calculations based on density functional theory. Several types of exchange-correlation (XC) kernels are implemented in our code to compare their performance. As expected our results depend crucially on the XC kernels used. In particular, the exchange-only adiabatic local density approximation kernel results in the binding energy about 0.1 eV, which is smaller than those obtained using the GW theory approximation ($\sim$ 0.9 eV) [1]. We have generalized the approach on the case of trion excitations, which gives the trion binding energy $\sim$ 0.3eV when one used the LDA approximation. On the other hand, we demonstrate that the results for the experimental binding energies can be reproduced by using phenomenological local and long-range XC kernels. [1] T. Cheiwchanchamnangij and W. R. L. Lambrecht, Phys. Rev. B **85**, 205302 (2012).

9:36AM F24.00007 Landau-Zener Tunneling in 1-d periodic potential , JIAJUN LI, JONG HAN, SUNY at Buffalo — Landau-Zener tunneling can be used to model the transition between energy bands of a particle in 1-d periodic potential [1-2]. It is pointed out that a specific model could be utilized to explain the transition driven by a uniform external force, between energy bands in a periodic lattice [3]. Here we examine the transition driven by an external force, in a sinusoidal periodic potential, by solving Schrödinger equation numerically. As an exact solution, all bands and transitions between them are included. By considering arbitrary crystal potential of any supercell size, we can approximate random potential scattering and examine how random elastic scattering modifies the inter-band transition and eventually the electron transport. Non-exponential decays and other patterns for different ranges of parameters will be presented. We will also make a connection between the numerical results and conventional Landau-Zener transition model, and show how a time-dependent periodic potential will change the nature of transition. Supported by NSF.

9:48AM F24.00008 Efficient Numerical Modeling of Nonequilibrium Fluctuation Phenomena , M. T. HOMER REID, Massachusetts Institute of Technology, ALEJANDRO RODRIGUEZ, Harvard University; Massachusetts Institute of Technology, STEVEN JOHNSON, Massachusetts Institute of Technology — We present efficient numerical methods for computing non-equilibrium Casimir forces and radiative heat transfer between bodies of complex shapes and realistic material properties. Our methods borrow techniques from computational electromagnetism (specifically, surface integral equations and boundary-element methods) to describe fluctuations in *fields* in terms of fluctuating *sources* on the surfaces of material bodies. We obtain concise formulas expressing forces and heat-transfer rates in terms of traces of matrix products, where the elements of the matrices describe the interactions of tangential currents flowing on the surfaces of the interacting material bodies. Using our methods, we obtain new predictions of nonequilibrium phenomena in geometries that would be difficult or impossible to treat using other methods for modeling nonequilibrium fluctuations.

10:00AM F24.00009 Solution of electric-field-driven tight-binding lattice in contact with fermion reservoirs[1] , JONG HAN, SUNY at Buffalo — Electrons in tight-binding lattice driven by DC uniform force field dissipate their energy through on-site fermionic thermostats. Due to the translational invariance in the transport direction, the problem can be block-diagonalized. We solve this time-dependent quadratic problem and demonstrate that the problem has an oscillatory steady-state. The steady-state occupation number shows that the Fermi surface disappears for any damping from the thermostats and any finite electric field. Despite the lack of momentum scattering, the conductivity takes the same form as the semi-classical Ohmic expression from the relaxation-time approximation. Despite the similarity of the Ohm's law with the Boltzmann transport, this solution does not support gradual shift of Fermi surface by drift velocity and, therefore, when used for many-body steady-state calculations, may lead to pathological effects. We discuss extensions of this model for more realistic dissipation mechanisms.

10:12AM F24.00010 Investigation of quantum-confined Stark effect on exciton binding energy and electron-hole recombination in GaAs qdots , CHRISTOPHER BLANTON, ARINDAM CHAKRABORTY, Dept. of Chemistry, Syracuse University, Syracuse, NY — We present the field-dependent explicitly correlated full configuration interaction (XCFCI) method for calculating highly accurate electron-hole wavefunction in presence of external electric field. The XCFCI is a variational method which is based on performing FCI calculation using explicitly correlated reference wavefunction. Field-dependent basis functions were used and were constructed using a variational field-dependent coordinate transformation. A discussion between this method and the variational polaron transformation for spin-boson system will be presented. The exciton energy, exciton binding energy (EB), and electron-hole recombination probability (eh-RP) were computed using XCFCI and the analysis of the scaling laws will be presented. One of the key results is that EB and eh-RP follow very different scaling with respect to the field strength. It was found that for a 500 kV/cm change in the field reduces the EB and eh-RP by a factor of 2.6 and 166, respectively. The explicitly correlated term was found to be crucial for accurate computation of eh-RP and was also responsible for improving convergence of the XCFCI energy with respect to basis size. The field dependent basis functions were found to very important and comparison with field independent basis will be presented

10:24AM F24.00011 ABSTRACT WITHDRAWN –

10:36AM F24.00012 A Computational Framework for Cavity Mediated Energy Transfer in Nanostructures , ANDREW BACZEWSKI, NICHOLAS MILLER, DANIEL DAULT, CARLO PIERMAROCCHI, BALASUBRAMANIAM SHANKER, Michigan State University — Cavity mediated energy transfer is vital to numerous technologies, such as systems that harvest/generate light, quantum information, and platforms for studying strongly coupled cavity QED. In these processes, the density of photonic states through which a donor and acceptor complex exchange energy is dramatically modified by a resonant structure such as a photonic crystal or a distributed Bragg reflector. The design and optimization of new systems of this nature is greatly facilitated by the development of high fidelity numerical methods for resolving the fields in structures not amenable to analytical methods. This is increasingly relevant at the nanoscale, wherein optically dense geometric features exist at or below the scale of the free space wavelength. To this end, we have implemented a nodal Discontinuous Galerkin discretization of the curl-curl Maxwell eigenproblem for the resolution of the spectrum of photonic modes in nanostructures. This framework delivers a high accuracy representation of light-matter coupling constants and optical eigenfrequencies that can be fed into quantum mechanical models of energy transfer. Details of our framework, implementation/validation, and applications germane to energy transfer between cavity-confined quantum dots will be presented.

10:48AM F24.00013 Real-Time TDDFT simulation for coherent phonon generation in crystalline solids , YASUSHI SHINOHARA, SHUNSUKE A. SATO, KAZUHIRO YABANA, University of Tsukuba, TOMOHITO OTOBE, Japan Atomic Energy Agency, JUN-ICHI IWATA, University of Tokyo, GEORGE F. BERTSCH, University of Washington — We have been developing a theoretical framework to describe electron dynamics in a crystalline solid under an ultrashort laser pulse. We rely upon the time-dependent density functional theory, solving the time-dependent Kohn-Sham equation in real-time and real-space. Using our method, it is possible to describe both linear and nonlinear light-matter interactions in a unified way. In my presentation, I will focus on the application to coherent phonon generation, a coherent atomic oscillation over a macroscopic volume. I will show applications to two material, semiconductor Si and semimetal Sb. For Si, we have found that the TDDFT is capable of describe two distinct mechanisms of the coherent phonon generation. When the laser frequency is below the direct bandgap, virtual electronic excitation induces impulsive force to atoms. When the laser frequency is above the gap, real electronic excitation causes the atomic motion. For Sb, we study the frequency dependence of the coherent phonon generation and compare our results with phenomenological theories.

Session F25 GQI: Superconducting Qubits: Read-out, Feedback and Stabilization 327 - Will Oliver, Massachusetts Institute of Technology

8:00AM F25.00001 Non-linear processes in thin titanium nitride transmission lines for parametric amplification , MICHAEL VISSERS, JIANSONG GAO, SUPTARSHI CHAUDHURI, CLINT BOCKSTIEGEL, MARTIN SANDBERG, DAVID P. PAPPAS, National Institute of Standards and Technology - Boulder — Nitride superconductors, such as titanium nitride and niobium titanium nitride, are a non-linear, low dissipation medium at microwave frequencies. The lossless nonlinearity may be probed and utilized. Important applications include generation of higher harmonics , e.g. 3f, and a microwave version of the optical paramagnetic amplifier, i.e. the degenerate-pump case of four-photon mixing (FPM). An amplifier based on these principles should allow for very wide bandwidth, low noise (quantum limited) and high dynamic range devices. These measurements are performed via a single layer, 3 meter long TiN spiral and measured at temperatures below 100 mK. Initial results of the design, fabrication, testing, and impedance optimization of a titanium nitride based parametric amplifier are presented.

8:12AM F25.00002 Efficiency of a microwave photon detector based on a current-biased Josephson junction[1] , AMRIT POUDEL, CANRAN XU, MAXIM VAVILOV, Department of Physics, University of Wisconsin-Madison — In this talk we discuss the efficiency of a microwave photon detector based on a current-biased Josephson junction driven by a classical microwave source. We consider the evolution of the junction in the presence of the environment and tunneling events to the voltage state. We calculate the switching time distribution to the voltage state and evaluate the efficiency of the photon detector as a function of input power and the junction parameters. We present conditions for the optimal power matching between the detector and the microwave source.

8:24AM F25.00003 Optimization of single shot readout of a transmon qubit using a SLUG microwave amplifier[1] , YANBING LIU, SRIKANTH SRINIVASAN, Princeton University, DAVID HOVER, ROBERT MCDERMOTT, University of Wisconsin, Madison, ANDREW HOUCK, Princeton University — We report on measurement of a superconducting transmon qubit using a number of optimization techniques and a low noise amplifier. Optimization is performed over power and frequency, and a genetic algorithm is employed to optimize the readout fidelity as a function of the measurement pulse shape. In addition, a superconducting low-inductance undulatory galvanometer (SLUG), a SQUID-based microwave amplifier, is used to reduce system noise. The SLUG amplifier has very high dynamic range and low noise over a relatively wide frequency range. Both the SLUG amplifier and genetic algorithm lead to improved readout fidelity over analytic pulse shaping and HEMT amplification.

8:36AM F25.00004 Large gain quantum-limited qubit state measurement using a two mode nonlinear cavity , SAEED KHAN, AASHISH CLERK, McGill University, Dept. of Physics — A single nonlinear cavity dispersively coupled to a qubit functions as a large gain detector near a bifurcation, but also has an unavoidable large backaction that prevents QND measurement at weak couplings [1]. We show theoretically that a modified setup involving two cavities (one linear, one nonlinear) and a dispersively coupled qubit allows for a far more optimal measurement. In particular, operating near a point of bifurcation, one is able to both achieve a large gain as well as a near quantum-limited backaction. We present analytic results for the gain and noise of this detector and a heuristic understanding of the physics, thus presenting a complete description of this new way of performing weak qubit state measurements. The setup we describe can easily be realised in experiments with superconducting circuits involving Josephson junctions [2,3].

8:48AM F25.00005 A >10 GHz JPC with Trans-Gain for Qubit Readout[1] , K. SLIWA, A. NARLA, M. HATRIDGE, F. SCHACKERT, B. ABDO, S. SHANKAR, L. FRUNZIO, M.H. DEVORET, Applied Physics Department, Yale University — For multi-qubit circuit QED experiments, it is desirable to work with cavities at frequencies >10 GHz to allow for design flexibility. However, performance of following electronics can be best optimized at low frequencies (3-5 GHz). These seemingly contradictory requirements can be naturally reconciled using the Josephson Parametric Converter (JPC). The JPC is a quantum limited amplifier comprised of two non-degenerate resonators coupled via a ring of Josephson junctions. It can bridge frequency ranges separated by more than an octave via its trans-gain, a process in which a signal incident on one port is frequency converted and transmitted with gain on the other port. Here we present data on the trans-gain of a JPC with one resonator at 11.5 GHz and the other at 4.5 GHz which could be used in such a readout scheme without any significant compromise on gain, dynamic range, or bandwidth.

9:00AM F25.00006 Characterization of a Multi-Layer Parametric Amplifier with On-Chip Bias Line , T. WHITE, R. BARENDS, J. BOCHMANN, B. CAMPBELL, Y. CHEN, B. CHIARO, E. JEFFREY, J. KELLY, M. MARIANTONI, A. MEGRANT, J. MUTUS, C. NEILL, P. O'MALLEY, S. OHYA, P. ROUSHAN, D. SANK, A. VAINSENCHER, J. WENNER, A.N. CLELAND, J.M. MARTINIS, UC Santa Barbara — Single shot dispersive readout of superconducting qubits requires a near quantum limited microwave amplifier. Based on the parametric amplifier design from UC Berkeley, we have developed a parametric amplifier using the UCSB multilayer fabrication with a single ended input and an on-chip flux bias line. These changes enable us to use a smaller and simpler chip mount with separate signal and flux ports. The high bandwidth of the flux port allows us to flux pump the amplifier and should allow dynamic frequency tuning on ns timescales. Flux pumping also requires fewer components in the measurement line, reducing signal loss. With this design we have achieved parametric amplification using two kinds of input pumping and three kinds of flux pumping; for each mode we have characterized gain bandwidth product, saturation power, and noise temperature.

9:12AM F25.00007 Increasing dynamic range in microwave parametric amplifiers , J. MUTUS, R. BARENDS, J. BOCHMANN, B. CAMPBELL, Y. CHEN, B. CHIARO, E. JEFFREY, J. KELLY, M. MARIANTONI, A. MEGRANT, C. NEILL, P. O'MALLEY, S. OHYA, P. ROUSHAN, D. SANK, A. VAINSENCHER, J. WENNER, T. WHITE, A.N. CLELAND, J.M. MARTINIS, UC Santa Barbara — Parametric amplifiers have long been of interest in quantum information due to their high gain and near quantum limited performance. In collaboration with UC Berkeley, we are improving upon their proven parametric amplifier design, which consists of a lumped element LC resonator, with a SQUID providing a tunable nonlinear inductance. In order to improve the dynamic range of these amplifiers, multiple SQUIDs are used in series in order to distribute the non-linearity across many junctions. We report on the design of a single-ended amplifier using our 7-layer fabrication process, combining photo and electron beam lithography. We explore the experimental optimization of such a design, specifically the impact of adding additional SQUIDs on overall device performance.

9:24AM F25.00008 Improved JPC performance via a low inductance, lumped element design[1]

, A. NARLA, K. SLIWA, M. HATRIDGE, S. SHANKAR, F. SCHACKERT, B. ABDO, L. FRUNZIO, R.J. SCHOELKOPF, M.H. DEVORET, Applied Physics Department, Yale University — The Josephson Parametric Converter (JPC), a linear, non-degenerate, nearly quantum-limited amplifier, is a promising tool for quantum information applications. We propose a new JPC design characterized by the use of multi-pF parallel-plate capacitors. By decreasing the geometric inductance of the system, higher critical-current Josephson junctions can be used. Both the bandwidth and dynamic range can thus be increased by a factor of two relative to existing microstrip devices. When integrated with a shunted ring of Josephson junctions [1], these devices should also be tunable over more than a GHz. We present simulations of the circuit behavior and preliminary measurements of a proof-of-concept device.

9:36AM F25.00009 Optimizing bandwidth and dynamic range of lumped Josephson parametric amplifiers[1]

, A. EDDINS, R. VIJAY, C. MACKLIN, QNL, UC Berkeley, Z. MINEV, Yale University, I. SIDDIQI, QNL, UC Berkeley — Superconducting parametric amplifiers have revolutionized the field of quantum measurement by providing high gain, ultra-low noise amplification. They have been used successfully for high-fidelity qubit state measurements, probing nano-mechanical resonators, quantum feedback, and for microwave quantum optics experiments. Though several designs exist, a simple and robust architecture is the Lumped Josephson Parametric Amplifier (LJPA). This device consists of a capacitively shunted SQUID directly coupled to a transmission line to form a low quality factor (Q) nonlinear resonator. We discuss amplifiers which can be tuned over the full 4-8 GHz band with 20-25 dB of gain and 10 - 50 MHz of signal bandwidth. However, similar to other parametric amplifiers employing a resonant circuit, the LJPA suffers from low dynamic range and has a -1 dB gain compression point of order -130 dBm. We explore new designs comprised of an array of SQUIDs to improve the dynamic range. We will present the results of numerical simulations and preliminary experiments. We will also briefly discuss improvements obtained from different biasing methods and packaging.

9:48AM F25.00010 Real-time digital processing of qubit readout and feedback control[1]

, Y. LIU, N. OFEK, K. GEERLINGS, M. HATRIDGE, R.J. SCHOELKOPF, M.H. DEVORET, Applied Physics Department, Yale University — Rapid progress in high fidelity readout of superconducting qubits paves the way for measurement-based feedback control of quantum systems and error correction protocols. A traditional data acquisition and processing setup, consisting of separate digitizer card for qubit readout, PC for processing and commercial arbitrary waveform generator (AWG) for qubit control, however, can have latency of at least several milliseconds and cannot meet the timing requirement of quantum feedback experiments. We have implemented an all-in-one system that contains a digitizer, a demodulator, a qubit-state estimator and an AWG on a commercial field-programmable-gate-array (FPGA) board. The FPGA system shows superior performance in terms of throughput, timing stability and on-the-fly programmability compared to traditional technology. Latency of the FPGA system can be on the order of only hundreds of nanoseconds. Results from our project of integrating the real-time processing power of the FPGA with a qubit + amplifier system will be shown.

10:00AM F25.00011 Stabilizer quantum error correction toolbox for superconducting qubits[1]

, SIMON NIGG, STEVEN GIRVIN, Yale University — Rudimentary quantum error correction (QEC) has been achieved in a superconducting qubit circuit [1]. Realization of topological protection and QEC based on stabilizer codes will require protocols for QND measurement of multi-qubit Pauli operators on arbitrary selected subsets of qubits. Initial progress towards this goal has been achieved with four-qubit stabilizer pumping in a trapped ion system [2]. We present a general protocol for stabilizer measurement and pumping in a system of N superconducting qubits. We assume always-on, fixed dispersive couplings χ to a single mode of a high-Q microwave resonator in the strong-dispersive limit defined by $\chi \gg 1/T_2, \kappa$, where T_2 is the qubit coherence time and κ is the cavity line width. In this limit, we show how to measure an arbitrary weight $M \leq N$ Pauli operator, by entangling the multi-qubit state with two distinguishable coherent states of the cavity. Together with a fast cavity readout ($T_{\rm meas} \ll 1/\kappa$), which can be achieved by tunable coupling to a low-Q cavity mode, this enables the efficient measurement of mulit-qubit Pauli operators.

10:12AM F25.00012 Autonomous stabilization of an entangled state of two transmon qubits[1]

, S. SHANKAR, Z. LEGHTAS, M. HATRIDGE, A. NARLA, U. VOOL, S.M. GIRVIN, Applied Physics Department, Yale University, M. MIRRAHIMI, Applied Physics Department, Yale University and INRIA, Paris-Rocquencourt, M.H. DEVORET, Applied Physics Department, Yale University — Recent circuit QED (cQED) experiments on superconducting transmon qubits have shown good progress towards measurement-based quantum feedback, that should allow the stabilization of interesting quantum states, such as an entangled state of two qubits. These experiments crucially depend on fast, high-fidelity, quantum non-demolition qubit readout using superconducting parametric amplifiers as well as high-speed room-temperature electronics. We describe an alternate autonomous-feedback strategy to stabilize two qubits dispersively coupled to a single cavity into an entangled state, while obviating the need for an optimized measurement chain. The system Hamiltonian is designed to be in the strong dispersive cQED regime where the dispersive shifts of the two qubits are tuned to be equal ($\chi/2\pi = 5$ MHz) and larger than the cavity linewidth ($\kappa/2\pi = 1.5$ MHz). By applying continuous microwave drives at the cavity and qubit frequencies, the system is forced into the desired quantum state. The stabilization rate of this scheme is of order κ which can be made much faster than all decoherence rates $1/\mathrm{T}_1$, $1/\mathrm{T}_\phi$ that take the system out of the entangled state. We will discuss initial experimental progress towards the goal of autonomous high-fidelity entanglement.

10:24AM F25.00013 Efficient Experimental Characterization of a Feedback Scheme for Qubit Initialization

, YVES SALATHE, CHRISTOPHER EICHLER, THOMAS KARG, PHILIPP KURPIERS, CHRISTIAN LANG, ANDREAS WALLRAFF, ETH Zurich — Quantum feedback based on high-efficiency projective measurements has a variety of potential applications such as active qubit initialization and quantum teleportation. Here, we experimentally investigate active initialization of a single transmon qubit in circuit quantum electrodynamics using parametric amplification similar to the experiment by Ristè *et. al.* [1]. We implement the feedback scheme using field-programmable gate array (FPGA) electronics which conditions a π-pulse on the outcome of a prior quantum nondemolition measurement. Our processing unit also records multi-dimensional histograms which reveal the correlations between the initial and final state of the feedback process. We use these histograms to characterize the efficiency of our feedback implementation without the necessity of storing all individual single-shot measurement traces. The presented histogram-based measurement technique has potential applications in other experiments which involve feedback such as quantum teleportation.

10:36AM F25.00014 Superconducting qubit parameter optimization for remote entanglement[1] , N. ROCH, M.E. SCHWARTZ, C. MACKLIN, R. VIJAY, I. SIDDIQI, QNL, UC Berkeley — The combination of coherent lifetimes in excess of 100 microseconds and robust operation of low noise parametric amplifiers has enabled experiments in which high fidelity continuous measurement can be performed, opening the door for measurement based quantum feedback. The first experiment realized in this regime aimed at stabilizing a dynamical state of a superconducting qubit using a closed feedback loop [1]. We explore the prospects of extending this unprecedented control to engineered networks comprised of several superconducting qubits and microwave cavities, with the particular goal of stabilizing a central feature of quantum mechanics: the entanglement. We will discuss the optimal choice of hardware—qubit, cavity, and circuitry—as well as measurement protocols for maximizing entanglement.

[1]This research was supported by the Army Research Office under a QCT grant.

10:48AM F25.00015 Progress towards measurement-induced entanglement of remote superconducting qubits[1] , M. E. SCHWARTZ, N. ROCH, C. MACKLIN, R. VIJAY, I. SIDDIQI, QNL, UC Berkeley — Generation and distribution of entanglement are critical capabilities for quantum computation and simulation. In superconducting qubits, entanglement can be achieved via direct qubit-qubit coupling on chip. In contrast to this type of local interaction, we present experiments and simulations targeted at generating entanglement between remote (non-coupled) 3D transmons. Entanglement is achieved via joint measurement in a basis that does not project, and thus does not dephase, the odd-parity Bell manifold (|01>/|10>). The experiments rely on coherent state detection, rather than photon-counting, and are a step towards deterministic feedback stabilization of remote qubit entanglement. We also model the effects of experimental realities, including excess amplifier noise, cable insertion loss, and finite qubit coherence times.

Session F26 GQI: Quantum Crytography, Quantum Communication, and Quantum Measurement 328 - Graeme Smith, IBM

8:00AM F26.00001 Quantum to classical randomness extractors , STEPHANIE WEHNER, CQT, Singapore, MARIO BERTA, ETH Zurich, OMAR FAWZI, McGill University — The goal of randomness extraction is to distill (almost) perfect randomness from a weak source of randomness. When the source yields a classical string X, many extractor constructions are known. Yet, when considering a physical randomness source, X is itself ultimately the result of a measurement on an underlying quantum system. When characterizing the power of a source to supply randomness it is hence a natural question to ask, how much classical randomness we can extract from a quantum system. To tackle this question we here introduce the notion of quantum-to-classical randomness extractors (QC-extractors). We identify an entropic quantity that determines exactly how much randomness can be obtained. Furthermore, we provide constructions of QC-extractors based on measurements in a full set of mutually unbiased bases (MUBs), and certain single qubit measurements. As the first application, we show that any QC-extractor gives rise to entropic uncertainty relations with respect to quantum side information. Such relations were previously only known for two measurements. As the second application, we resolve the central open question in the noisy-storage model [Wehner et al., PRL 100, 220502 (2008)] by linking security to the quantum capacity of the adversary's storage device.

8:12AM F26.00002 Quantum secret sharing with minimized quantum communication , BEN FORTESCUE, Southern Illinois University, GILAD GOUR, University of Calgary — Standard techniques for sharing a quantum secret among multiple players (such that certain subsets of the players can recover the secret while others are denied all knowledge of the secret) require a large amount of quantum communication to distribute the secret, which is likely to be the most costly resource in any practical scheme. Two known methods for reducing this cost are the use of imperfect "ramp" secret sharing (in which security is sacrificed for efficiency) and classical encryption (in which certain elements of the players' shares consist of classical information only). We demonstrate how one may combine these methods to reduce the required quantum communication below what has been previously achieved, in some cases to a provable minimum, without any loss of security. The techniques involved are closely-related to the properties of stabilizer codes, and thus have strong potential for being adapted to a wide range of quantum secret sharing schemes.

8:24AM F26.00003 Quantum teleportation over 143 kilometres using active feed-forward , XIAOSONG MA, THOMAS HERBST, THOMAS SCHEIDL, DAQING WANG, SEBASTIAN KROPATSCHEK, WILLIAM NAYLOR, ALEXANDRA MECH, IQOQI Vienna, BERNHARD WITTMANN, JOHANNES KOFLER, Univ of Vienna, ELENA ANISIMOVA, VADIM MAKAROV, THOMAS JENNEWEIN, IQC, RUPERT URSIN, ANTON ZEILINGER, IQOQI Vienna — Quantum teleportation is a quintessential prerequisite of many quantum information processing protocols. By using quantum teleportation, one can circumvent the no-cloning theorem and faithfully transfer unknown quantum states to a party whose location is even unknown over arbitrary distances. Ever since the first experimental demonstrations of quantum teleportation of independent qubits and of squeezed states, researchers have progressively extended the communication distance in teleportation. Here we report the first long-distance quantum teleportation experiment with active feed-forward in real time. The experiment employed two optical links, quantum and classical, over 143 km free space between the two Canary Islands of La Palma and Tenerife. To achieve this, the experiment had to employ a combination of advanced techniques such as a frequency-uncorrelated polarization-entangled photon pair source, ultra-low-noise single-photon detectors, and entanglement-assisted clock synchronization. The average teleported state fidelity was well beyond the classical limit of 2/3.

8:36AM F26.00004 Ultrafast quantum communications over long distances using quantum encoding , SRERAMAN MURALIDHARAN, LIANG JIANG, Yale University — Quantum repeaters provide a way of enabling long distance quantum communication by establishing entangled qubits between remote locations. The first generation quantum repeater protocols involve time consuming entanglement purification steps that demand a long lived quantum memory and two-way classical communication that makes them slow. This problem can be circumvented by the new generation quantum repeater protocols that use quantum encoding, one-way classical communication and classical error correction techniques. Furthermore, each quantum repeater station only needs short lived quantum memory bits, the number of which has favorable poly-logarithmic scaling with the distance. We investigate the tolerance of these schemes against photon losses and depolarizing errors, and discuss the possibility of realizing these schemes in physical systems with the current state of art.

8:48AM F26.00005 Generating and verifying entanglement of itinerant microwave modes , H.S. KU, W.F. KINDEL, JILA and University of Colorado at Boulder, S.C. GLANCY, E. KNILL, L.R. VALE, G.C. HILTON, K.D. IRWIN, NIST, K.W. LEHNERT, JILA, NIST and University of Colorado at Boulder — Entanglement is a critical resource for quantum information science. In particular, shared entanglement between pairs of electromagnetic fields propagating on two physically separate channels is required for quantum communication protocols with continuous variables. Moreover, the ability to entangle propagating microwave fields provides possible schemes to create quantum communication channels between localized superconducting qubits. In this talk, we will present an experimental demonstration of this type of entanglement. We generate the entangled state by combining a squeezed state and vacuum on a balanced beam splitter. The entanglement is then revealed by strong correlations between the quadrature amplitudes of the two output modes of the beam splitter. Crucial for an eventual teleportation demonstration, the two modes are measured efficiently and with independent choice of measured quadratures.

9:00AM F26.00006 Microwave Photon Counter Based on Josephson Junctions , GUILHEM RIBEILL, UMESHKUMAR PATEL, JOSEPH SUTTLE, ROBERT MCDERMOTT, University of Wisconsin - Madison Department of Physics — We describe progress in the development of a microwave photon counter based on the current biased Josephson junction; absorption of a single photon causes the junction to switch to the voltage state, producing a large and easily measured classical signal. We discuss a self-resetting bias scheme based on a superconducting kinetic inductor that causes the junction to reset automatically to the active state following photon absorption. We investigate detector quantum efficiency and dark rate, and discuss applications to mesoscopic noise and circuit quantum electrodynamics.

9:12AM F26.00007 Utilization of an Electron Multiplying CCD camera for applications in quantum information processing , MONIKA PATEL, JIAN CHEN, JONATHAN HABIF, Raytheon BBN Technologies — Electron Multiplying Charge-Coupled Device (EMCCD) cameras utilize an on-chip amplification process which boosts low-light signals above the readout noise floor. Although traditionally used for biological imaging, they have recently attracted interest for single-photon counting and entangled state characterization in quantum information processing applications. In addition, they exhibit some photon number-resolving capacity, which is attractive from the point-of-view of several applications in optical continous-variable computing, such as building a cubic phase gate. We characterize the Andor Luca-R EMCCD camera as an affordable tool for applications in optical quantum information. We present measurements of single-photon detection efficiency, dark count probability as well as photon-number resolving capacity and place quantitative bounds on the noise performance and detection efficiency of the EMCCD detector array. We find that the readout noise floor is a Gaussian distribution centered at 500 counts/pixel/frame at high EM gain setting. We also characterize the trade-off between quantum efficiency and detector dark-count probability.

9:24AM F26.00008 High-efficiency Cooper pair splitting demonstrated by two-particle conductance resonance and positive noise cross-correlation , YUVAL RONEN, ANINDYA DAS, MOTY HEIBLUM, DIANA MAHALU, ANDREY KRETININ, HADAS SHTRIKMAN, Weizmann Institute of Science, MOTY HEIBLUM LAB TEAM — Entanglement is at the heart of the Einstein-Podolsky-Rosen paradox, where the non-locality is a necessary ingredient. Cooper pairs in superconductors can be split adiabatically, thus forming entangled electrons. Here, we fabricate such an electron splitter by contacting an aluminum superconductor strip at the centre of a suspended InAs nanowire. The nanowire is terminated at both ends with two normal metallic drains. Dividing each half of the nanowire by a gate-induced Coulomb blockaded quantum dot strongly impeds the flow of Cooper pairs due to the large charging energy, while still permitting passage of single electrons. We provide conclusive evidence of extremely high efficiency Cooper pair splitting via observing positive two-particle correlations of the conductance and the shot noise of the split electrons in the two opposite drains of the nanowire. Moreover, the actual charge of the injected quasiparticles is verified by shot noise measurements.

9:36AM F26.00009 An operational approach to indirectly measuring tunneling time , YUNJIN CHOI, ANDREW JORDAN, University of Rochester — The tunneling time through an arbitrary one-dimensional barrier is investigated using the dwell time operator approach Since the tunneling time contains a natural post-selection (we only average over particles that successfully tunnel), the tunneling time can ve related to the weak value of the dwell time operator. We analyze the situation by considering a specific measurement context containing experimentally observable quantities, since measuring the dwell time operator directly is not strictly achievable in the laboratory. Therefore, we reconstruct the average value of the dwell time operator applying the contextual values formalism [J. Dressel and A. N. Jordan, Phys. Rev. A **85**, 022123 (2012)] for generalized measurements based on the Larmor clock [M. Büttiker, Phys. Rev. B **27**, 6178 (1983)].

9:48AM F26.00010 A Stochastic Path Integral Formulation for Continuous Quantum Measurement , AREEYA CHANTASRI, JUSTIN DRESSEL, ANDREW JORDAN, Department of Physics and Astronomy, University of Rochester, Rochester, New York 14627, USA — We consider the continuous quantum measurement of a two-level system, for example, a double-quantum dot weakly measured by a quantum point contact. In a weak measurement regime, the measurement outcome at each time step is non-deterministic and fluctuates around its mean value. While the stochastic master/Schrödinger equations are commonly used to study the state of the qubit, we propose an alternative formalism – the stochastic path integral – which can compute moments and correlation functions of the measurement outcomes, and the distributions of possible qubit states. By constructing a probability functional of the measurement outcomes in a path integral form, the moments can be computed from perturbative expansions, which can be resumed to exact solutions in some cases. We show that this approach reproduces and extends existing solutions derived using different methods, and introduces a new way to compute conditioned moments and correlation functions. We also show how real-time feedback can be naturally included in this approach.

10:00AM F26.00011 Weak values are universal in von Neumann measurements[1] , JUSTIN DRESSEL, ANDREW JORDAN, University of Rochester — We refute the widely held belief that the quantum weak value necessarily pertains to weak measurements. To accomplish this, we use the transverse position of a free particle as the detector for the conditioned von Neumann measurement of a system observable. For any coupling strength, any initial states, and any choice of conditioning, the averages of the detector position and momentum are completely described by the real parts of three generalized weak values in the joint Hilbert space. Higher-order detector moments also have similar weak value expansions. Using the Wigner distribution of the initial detector state, we find compact expressions for these weak values within the reduced system Hilbert space, demonstrating that the effective preselection for a measured system weak value is decohered by the detector. As an optical application of the approach, we consider an arbitrary Hermite-Gauss mode for a paraxial beam-like detector. For non-Gaussian modes the momentum shift involves the imaginary part of the system weak value plus an additional weak-value-like correction.

10:12AM F26.00012 Implementing general quantum measurements on linear optical and solid-state qubits[1] , YUKIHIRO OTA, SAHEL ASHHAB[2], FRANCO NORI[3], RIKEN — We show a systematic construction for implementing general measurements on a single qubit, including both strong (or projection) and weak measurements. We mainly focus on linear optical qubits. The present approach is composed of simple and feasible elements, i.e., beam splitters, wave plates, and polarizing beam splitters. We show how the parameters characterizing the measurement operators are controlled by the linear optical elements. We also propose a method for the implementation of general measurements in solid-state qubits. Furthermore, we show an interesting application of the general measurements, i.e., entanglement amplification.

10:24AM F26.00013 Embedded SIC-POVMs[1] , HOAN BUI DANG, Perimeter Institute for Theoretical Physics and University of Waterloo, KATE BLANCHFIELD, INGEMAR BENGTSSON, Stockholms University, MARCUS APPLEBY, Perimeter Institute for Theoretical Physics — Symmetric informationally complete (SIC) sets of quantum states have applications in foundational studies of quantum mechanics, quantum tomography, quantum communication, quantum cryptography, and classical signal processing. However, their existence in every dimension has not been proven, and no general construction has been known. During our study of linear dependencies in Weyl-Heisenberg orbits [1], we discovered 2-dimensional SICs embedded in a 6-dimensional Hilbert space. This offers a robust construction for 2-dimensional SICs, and may potentially impact the SIC existence problem. In this talk, I will explain how this construction works, and present numerical results for some other dimensions. References: [1] Hoan Bui Dang, Kate Blanchfield, Ingemar Bengtsson, D. M. Appleby, "Linear Dependencies in Weyl-Heisenberg Orbits," arXiv:1211.0215.

10:36AM F26.00014 A multiport scheme for performing SIC-POVMs[1] , GELO NOEL TABIA, Perimeter Institute for Theoretical Physics, University of Waterloo, and Institute for Quantum Computing — SIC-POVMs comprise a family of generalized quantum measurements known to be optimal for linear quantum tomography, according to fairly standard Hilbert-Schmidt measures of statistical efficiency [1]. Because of the practical significance of state estimation in quantum information processing, it should prove useful to develop experimental methods for implementing SIC-POVMs directly. Based on the idea of Naimark extensions for POVMs, I propose the design for a SIC-POVM experiment using multiport devices with path-encoded qudits and demonstrate how it can be realized with integrated linear optics for qubits and qutrits [2]. References: [1] A. J. Scott, J. Phys. A 39, 13507 (2006). [2] G. N. M. Tabia, arXiv:1207.6035 (2012).

Tuesday, March 19, 2013 8:00AM - 11:00AM –

Session F27 GQI: Physical Implementations of Qubits 329 - John Preskill, California Institute of Technology

8:00AM F27.00001 Majorana fermions in 1D superconducting wires subject to disorder and other spatial inhomogeneities , WADE DEGOTTARDI, Argonne National Laboratory, DIPTIMAN SEN, Indian Institute of Science, SMITHA VISHVESHWARA, University of Illinois at Urbana-Champaign — We present a systematic study of the role that disordered and quasiperiodic potentials play in the topology of 1D p-wave superconducting systems characterized by boundary Majorana modes. We forge a connection between Majorana wave functions and the localization properties of the corresponding normal state system (i.e, one which, though otherwise identical, lacks superconducting order). This enables the leveraging of the vast body of literature on Anderson localization to extensively map the topological phase diagram in superconducting wires. We find that the phase boundary is extremely sensitive to the detailed form of the potential. Our analysis provides a mapping between the limits of weak and strong disorder; in some cases, we are able to find the full phase boundary analytically. A noteworthy discovery is a tell-tale singularity in the phase boundary at the point corresponding to the quantum Ising model, a feature which offers a window into the physics of Majorana fermions. Our results can be directly applied to a spin-1/2 XY chain in a transverse magnetic field which is quasiperiodic or disordered.

8:12AM F27.00002 Universal transport signatures of Majorana fermions in superconductor-Luttinger liquid junctions , JASON ALICEA, California Institute of Technology, LUKASZ FIDKOWSKI, UC Berkeley, NETANEL LINDNER, California Institute of Technology, ROMAN LUTCHYN, Station Q, MATTHEW FISHER, UC Santa Barbara — One of the most promising proposals for engineering Majorana fermions employs a spin-orbit-coupled nanowire proximate to an s-wave superconductor. When only part of the wire's length contacts to the superconductor, the remaining conducting portion serves as a natural lead that can be used to probe these Majorana modes via tunneling. The enhanced role of interactions in 1D dictates that this configuration should be viewed as a superconductor-Luttinger liquid junction. We demonstrate that low-energy transport in such junctions is *universal*, and governed by fixed points describing either perfect normal reflection or perfect Andreev reflection. In addition to capturing (in some instances) the familiar Majorana-mediated zero-bias anomaly in a new framework, we show that interactions yield dramatic consequences in certain regimes. Implications for conductance and local density of states measurements will be discussed.

8:24AM F27.00003 Coherent oscillations between single fluxonium qubit and Majorana fermion qubit , CHANG-YU HOU, Caltech and UC Riverside, DAVID PEKKER, Caltech, VLADIMIR MANUCHARYAN, EUGENE DEMLER, Harvard University — We propose a hybrid device that couples a Majorana qubit to a superconducting fluxonium qubit. The devices consists of a conventional s-wave superconductor (e.g. Nb) ring interrupted by a narrow gap and a section of topological 1D wire bridging across the gap. Such topological 1D wire can be realized by using a semiconducting nanowire with strong spin orbit scattering (e.g. InSb) subjected by magnetic field. The nanowire hosts a topological qubit formed by four Majorana fermions and acts as a Josephson junction that completes the superconducting ring and makes a fluxonium qubit. As the current-phase relation of the Josephson junction is controlled by the state of the Majorana qubit, the fluxonium and Majorana qubit are naturally coupled. We demonstrate how this coupling can be exploited to construct two qubit operations. Remarkably, quantum information can be transformed between two distinct types of qubits solely using well-controlled operations on the fluxonium qubit.

8:36AM F27.00004 Majorana Zero Modes in Semiconductor Nanowires in Contact with Higher-Tc Superconductors , YOUNGHYUN KIM, JENNIFER CANO, UCSB, CHETAN NAYAK, Station Q, UCSB — We present the prospects for stabilizing Majorana zero modes in semiconductor nanowires that are proximity-coupled to higher-temperature superconductors. We begin with the case of iron pnictides which, though they are s-wave superconductors, are believed to have superconducting gaps that change sign. We then consider the case of cuprate superconductors. We show that a nanowire on a step-like surface, especially in an orthorhombic material such as YBCO, can support Majorana zero modes at an elevated temperature.

8:48AM F27.00005 Coherent population trapping of hyperfine-coupled single spins in diamond , ANDREW GOLTER, NIMA DINYARI, HAILIN WANG, University of Oregon — Coherent population trapping (CPT) provides a highly sensitive means for probing the energy level structure of an atomic system. For diamond nitrogen vacancy (NV) centers, this technique offers an alternative to the standard optically-detected magnetic resonance (ODMR) for measuring the hyperfine structure of the electronic ground states. Here, we report an experimental study using CPT to probe the hyperfine splitting of these states as well as the Autler-Townes effect induced by a strong resonant microwave field. This nuclear spin dependent CPT was also employed along with other coherent spin operations for the initialization and manipulation of hyperfine-coupled nuclear spins. In addition, the use of CPT process to incorporate NV centers into a cavity QED system will be discussed.

9:00AM F27.00006 Phonon sideband studies of the spin-triplet optical transition in diamond nitrogen-vacancy centers[1] , AUDRIUS ALKAUSKAS, Materials Department, University of California, Santa Barbara, DAVID M. TOYLI, BOB B. BUCKLEY, DAVID D. AWSCHALOM, Center for Spintronics and Quantum Computation, University of California, Santa Barbara, CHRIS G. VAN DE WALLE, Materials Department, University of California, Santa Barbara — In the past decade, the nitrogen-vacancy center in diamond has emerged as a promising solid-state system for quantum-information processing, and also for nanoscale magnetic, electric, and thermal sensing. All of these applications are partly enabled because the spin of the center can be measured through photoluminescence. This calls for a deeper understanding of the photoluminescence spectrum, in particular its phonon side-band. In this work we study the coupling of lattice vibrations to the triplet (^{3}E$\rightarrow^3$A$_2$) optical transition from first-principles electronic structure calculations. Our formulation includes both quasi-localized and bulk phonons, and leads to an excellent agreement of the calculated and the measured photoluminescence lineshape. This good agreement enables the application of the developed methodology to other defects in semiconductors that are currently being investigated as viable quantum bits.

9:12AM F27.00007 Measurement-Only Topological Quantum Computation via Tunable Interactions , PARSA BONDERSON, Station Q, Microsoft Research — I examine, in general, how tunable interactions may be used to perform anyonic teleportation and generate braiding transformations for non-Abelian anyons. I explain how these methods are encompassed by the "measurement-only" approach to topological quantum computation. The physically most relevant example of Ising anyons or Majorana zero-modes is considered in detail, particularly in the context of Majorana nanowires.

9:24AM F27.00008 Quantum information processing using quasiclassical electromagnetic interactions between qubits and electrical resonators[1] , ANDREW KERMAN, MIT Lincoln Laboratory — Electrical resonators are widely used in quantum information processing with any qubits that are manipulated via electromagnetic interactions. In most cases they are engineered to interact with qubits via real or virtual exchange of (typically microwave) photons, and the resonator must therefore have both a high quality factor and strong quantum fluctuations, corresponding to the strong-coupling limit of cavity QED. Although great strides in the control of quantum information have been made using this so-called "circuit QED" architecture, it also comes with some important disadvantages. In this talk, we discuss a new paradigm for coupling qubits electromagnetically via resonators, in which the qubits do not exchange photons with the resonator, but instead exert quasi-classical, effective "forces" on it. We show how this type of interaction is similar to that induced between the internal state of a trapped atomic ion and its center-of-mass motion by the photon recoil momentum, and that the resulting entangling operations are insensitive both to the state of the resonator and to its quality factor. The methods we describe are applicable to a variety of qubit-resonator systems, including superconducting and semiconducting solid-state qubits, and trapped molecular ions.

[1]This work is sponsored by the ASDR&E under Air Force Contract #FA8721-05-C-0002. Opinions, interpretations, recommendations and conclusions are those of the authors and are not necessarily endorsed by the United States Government.

9:36AM F27.00009 Generation and characterization of hypercubic cluster states in the optical frequency comb , MORAN CHEN, PEI WANG, Department of Physics, University of Virginia, NICOLAS MENICUCCI, School of Physics, The University of Sydney, OLIVIER PFISTER, Department of Physics, University of Virginia — We report on experimental progress toward generating and characterizing a very large quantum wire cluster state of the continuous electromagnetic variables ("Qmodes") in the optical frequency comb of an optical parametric oscillator (OPO). We also present a proposal for creating higher-dimensional graph states by entangling the linear cluster states of several OPOs, each OPO adding a dimension to the graph (line, square grid, cube, hypercube). Besides the scalable (in number, size, and dimension) creation of sophisticated quantum graphs over hundreds to thousands of Qmodes, this work also constitutes a considerable experimental simplification of our previous proposal for generating a square-grid cluster state in a single OPO.

9:48AM F27.00010 Entangled Photon Holes , TODD PITTMAN, JUNLIN LIANG, JAMES FRANSON, UMBC, Baltimore MD 21250 — Entangled photon hole (EPH) states represent a new form of entanglement that is based on the existence of "missing pairs" of photons in two optical modes. In contrast to the more familiar photon pairs entangled in polarization or other variables, the entanglement in EPH states arises from the absence of the photon pairs themselves. We will review recent experimental work on the generation of these states, and theoretical work showing that they can be relatively insensitive to loss and amplification noise in certain situations. We will also report on our recent efforts to generate time-bin EPH states which have different properties than energy-time EPH states.

10:00AM F27.00011 Information-efficient phase imaging with heralded single photons , REIHANEH SHAHROKHSHAHI, NIRANJAN SRIDHAR, OLIVIER PFISTER, Department of Physics, University of Virginia, SAIKAT GUHA, JONATHAN HABIF, Raytheon-BBN, AARON MILLER, Department of Physics, Albion College, ADRIANA LITA, BRICE CALKINS, THOMAS GERRITTS, ANTIA LAMAS-LINARES, SAE WOO NAM, National Institute of Standards and Technology — We report progress toward the experimental realization of information-efficient quantum imaging, here at two bits per photon. A heralded single-photon source ($g^2(0) < 0.08$) is used as the input to a 4x4 multiport interferometer, compactly implemented using both polarization and spatial degrees of freedom. The interferometer can be used to read out all 4 Hadamard phase codes with a single photon. We investigate the use of cavity-enhanced spontaneous parametric downconversion for the coherent source of heralded photons. The photon-number-resolving ability of high-quantum-efficiency transition edge sensors is used for the heralding and detection.

10:12AM F27.00012 A Two-Qubit Geometric Phase Gate for Localized Electron Spin Qubits using Cavity Polariton Resonance , SHRUTI PURI, NA YOUNG KIM, E. L. Ginzton Laboratory, Stanford University, California, USA, YOSHIHISA YAMAMOTO, E. L. Ginzton Laboratory, Stanford University, California, USA, National Institute of Informatics, Tokyo, Japan — We propose a two-qubit geometric phase gate, in which the interaction between a pair of localized electron spins, is mediated by quantum well microcavity exciton-polaritons. The entanglement between the electrons is a result of their spin dependent Coulomb exchange interaction with the exciton-polaritons. This optical coupling, resembling the electron-electron Ruderman-Kittel-Kasuya-Yosida (RKKY) interactions, offers high speed, high fidelity two-qubit gate operation with moderate cavity quality factor Q. The long ranged interaction by microcavity polaritons (order of micrometers) makes this gate suitable for fault tolerant operations. By the use of electrostatic quantum dots, the errors caused by unwanted excitations to charged excitons or trions are eliminated. The errors due to the finite lifetime of the polaritons can be minimized by optimizing the optical pulse parameters (duration and energy). The proposed design maximizes entanglement and ensures scalability.

10:24AM F27.00013 Quantum Computing using Photons , AHMED ELHALAWANY, MICHAEL LEUENBERGER, University of Central Florida — In this work, we propose a theoretical model of two-quantum bit gates for quantum computation using the polarization states of two photons in a microcavity. By letting the two photons interact non-resonantly with four quantum dots inside the cavity, we obtain an effective photon-photon interaction which we exploit for the implementation of an universal XOR gate. The two-photon Hamiltonian is written in terms of the photons' total angular momentum operators and their states are written using the Schwinger representation of the total angular momentum.

10:36AM F27.00014 Charge pumping by a surface acoustic wave in an undoped quantum well: a potential single-photon source , S.K. SON, Y. CHUNG, Cavendish Laboratory, University of Cambridge, UK, J. PEDROS, Technical University of Madrid, Spain, C.J.B. FORD, C.H.W. BARNES, J.P. GRIFFITHS, G.A.C. JONES, I. FARRER, D.A. RITCHIE, Cavendish Laboratory, University of Cambridge, UK — Single-electron transfer between distant quantum dots using the potential minima of surface acoustic waves (SAWs) has been demonstrated recently, with possible applications for quantum computation. We have developed a technique to induce electrons and holes in an undoped GaAs/AlGaAs quantum well in different regions of the same device using gates, and to transport a stream of single electrons or holes along a narrow, empty channel using SAWs. The potential has a steep slope at the edges of the inducing gates, but we have modelled the potential profile of the active region to find designs in which the potential slope is shallow enough to allow the SAW potential to drag electrons out of the induced region, towards the region of holes. Recombination of each electron with one of the holes should produce a photon and we are investigating the use of this device as a single-photon source. If the electrons are spin-polarised then their spins can be detected by measuring the circular polarisation of the photons, and this may be useful for spin readout in a quantum processor, or as part of a quantum repeater in quantum cryptography.

10:48AM F27.00015 ABSTRACT WITHDRAWN –

Tuesday, March 19, 2013 8:00AM - 11:00AM –

Session F28 GSNP: Physical Approaches to Social Modeling 336 - Bruno Goncalves, Indiana University

8:00AM F28.00001 Online Networks and the Diffusion of Protests , YAMIR MORENO, Institute for Biocomputation and Physics of Complex Systems, University of Zaragoza — Undoubtedly, online social networks have an enormous impact on opinions and cultural trends. Also, these platforms have revealed as a fundamental organizing mechanism in country-wide social movements. Recent events in the Middle East and North Africa (the wave of protests in the Arab world), across Europe (in the form of anti-cuts demonstrations or riots) and United States (the OWS movement) have generated much discussion on how digital media is connected to the diffusion of protests. In this talk, we investigate the mechanisms driving the emergence, development and stabilization of unrest movements in Spain and the USA by analyzing data from Twitter. Messages related to the protests are analyzed at both static and dynamic levels. We show that the online trace of the protests provides a unique opportunity to tackle central issues like recruitment patterns, information cascades and their spatiotemporal dynamics. Our findings shed light on the connection between online networks and social movements, and offer an empirical test to elusive sociological questions about collective action.

8:36AM F28.00002 Role of Committed Minorities in Times of Crisis , MALGORZATA TURALSKA, Duke University, PAOLO GRIGOLINI, University of North Texas, BRUCE J. WEST, Duke University — The surprising social phenomena of the Arab Spring and the Occupy Wall Street movement posit the question of whether the active role of committed groups may produce political changes of significant importance. Under what conditions are the convictions of a minority going to dominate the future direction of a society? We use a Cooperative Decision Making (CDM) model to study the effect of committed minorities on group behavior in time of crisis. The CDM model has been shown to generate consensus through a phase-transition process that at criticality establishes long-range correlations among the individuals within a model society. In a condition of high consensus, the correlation function vanishes, thereby making the network recover the ordinary locality condition. However, this state is not permanent and times of crisis occur when there is an ambiguity concerning a given social issue. The correlation function within the cooperative system becomes similarly extended as it is observed at criticality. This combination of independence (free will) and long-range correlation makes it possible for very small but committed minorities to produce substantial changes in social consensus.

8:48AM F28.00003 Beating the news using social media: the case study of American Idol , FABIO CIULLA, DELIA MOCANU, ANDREA BARONCHELLI, BRUNO GONCALVES, NICOLA PERRA, ALESSANDRO VESPIGNANI, Northeastern University — We present a contribution to the debate on the predictability of social events using big data analytics. We focus on the elimination of contestants in the American Idol TV shows as an example of a well defined electoral phenomenon to assess the predictive power of twitter signals. We provide evidence that Twitter activity during the time span defined by the TV show airing and the voting period following it allows the anticipation of the voting outcome. Twitter data have been analyzed to attempt the winner prediction ahead of the airing of the official result. We also show that the fraction of Tweets that contain geolocation information allows us to map the fanbase of each contestant, both within the US and abroad, showing that strong regional polarizations occur. The geolocalized data are crucial for the correct prediction of the final outcome of the show, pointing out the importance of considering information beyond the aggregated twitter signal. Although American Idol voting is just a minimal and simplified version of complex societal phenomena, this work shows that the volume of information available in online systems permits the real time gathering of quantitative indicators that may be able to anticipate the future unfolding of opinion formation events.

9:00AM F28.00004 Heterogeneity of Human Activity Levels Gives Rise to Power-Law Distribution in Online Social Networks , LEV MUCHNIK, The Hebrew University of Jerusalem, SEN PEI, City College of New York, Beihang University, LUCAS PARRA, City College of New York, SAULO REIS, JOSÉ ANDRADE, JR, Universidade Federal do Ceara, SHLOMO HAVLIN, Bar-Ilan University, HERNAN MAKSE, City College of New York — It is well established that the distribution of social ties (degree) of an individual in a social network follows a power-law. How this heavy-tailed distribution arises in practice, however, has not been conclusively demonstrated. Mechanisms of "preferential-attachment" and optimization are often cited as the origin of heavy-tailed degree distributions. Our data indicate that there is a different cause for these phenomena. For different social networks we find an intrinsic relationship degree and activity (number of posts, edits etc): The degree distribution is entirely random except for its mean value which depends deterministically on the volume of the users' activity. This suggests that heavy-tailed degree distribution is a consequence of the intrinsic activity of users. More importantly, human activity deterministically affects the mean success at establishing links in a social network, and the specific degree of a given user is otherwise random following a "maximum entropy attachment" model.

9:12AM F28.00005 Nonlinear Opinion Dynamics on Networks[1] , MICHAEL GABBAY, ARINDAM DAS, University of Washington — A model which treats group decision making as nonlinear opinion dynamics occurring over a network is presented. The model makes predictions regarding the interaction of network structure and initial disagreement level upon decision outcomes and consensus formation. The model displays bifurcations at high disagreement levels which lead to behaviors that are qualitatively distinct from those at low disagreement. For example, at high disagreement, the model exhibits asymmetric, majority rule outcomes that arise even when the system is symmetric with respect to the distribution of initial opinions and network structure. Analytical approximations for the bifurcation boundaries agree well with numerically-determined boundaries. An ongoing experimental effort involving the use of online discussion groups to test the model predictions is briefly described.

9:24AM F28.00006 Language Geography from Microblogging Platforms , DELIA MOCANU, ANDREA BARONCHELLI, NICOLA PERRA, Northeastern University, BRUNO GONÇALVES, Aix-Marseille Université, ALESSANDRO VESPIGNANI, Northeastern University — Microblogging platforms have now become major open source indicators for complex social interactions. With the advent of smartphones, the everincreasing mobile Internet traffic gives us the unprecedented opportunity to complement studies of complex social phenomena with real-time location information. In this work, we show that the data nowadays accessible allows for detailed studies at different scales, ranging from country-level aggregate analysis to the analysis of linguistic communities withing specific neighborhoods. The high resolution and coverage of this data permits us to investigate such issues as the linguistic homogeneity of different countries, touristic seasonal patterns within countries, and the geographical distribution of different languages in bilingual regions. This work highlights the potentialities of geolocalized studies of open data sources that can provide an extremely detailed picture of the language geography.

9:36AM F28.00007 The rise and fall of social communities: Cascades of followers triggered by innovators , YANQING HU, Levich Institute and Physics Department, City College of New York, New York, New York 10031, USA, SHLOMO HAVLIN, Minerva Center and Physics Department, Bar-Ilan University, Ramat Gan 52900, Israel, HERNAN MAKSE, Levich Institute and Physics Department, City College of New York, New York, New York 10031, USA — New scientific ideas as well as key political messages, consumer products, advertisement strategies and art trends are originally adopted by a small number of pioneers who innovate and develop the "new ideas". When these innovators migrate to develop the novel idea, their former social network gradually weakens its grips as followers migrate too. As a result, an internal "cascade of followers" starts immediately thereafter speeding up the extinction of the entire original network. A fundamental problem in network theory is to determine the minimum number of pioneers that, upon leaving, will disintegrate their social network. Here, we first employ empirical analyses of collaboration networks of scientists to show that these communities are extremely fragile with regard to the departure of a few pioneers. This process can be mapped out on a percolation model in a correlated graph crucially augmented with outgoing "influence links". Analytical solutions predict phase transitions, either abrupt or continuous, where networks are disintegrated through cascades of followers as in the empirical data. The theory provides a framework to predict the vulnerability of a large class of networks containing influence links ranging from social and infrastructure networks to financial systems and markets.

9:48AM F28.00008 Extraordinary variability and sharp transitions in a maximally frustrated dynamic network[1] , WENJIA LIU, BEATE SCHMITTMANN, R.K.P. ZIA, Department of Physics, Virginia Tech and Department of Physics and Astronomy, Iowa State University — Most previous studies of complex networks have focused on single, static networks. However, in the real world, networks are dynamic and interconnected. Inspired by the presence of extroverts and introverts in the general population, we investigate a highly simplified model of a social network, involving two types of nodes: one preferring the highest degree possible, and one preferring no connections whatsoever. There are only two control parameters in the model: the number of "introvert" and "extrovert" nodes, N_I and N_E. Our key findings are as follows: As a function of N_I and N_E, the system exhibits a highly unusual transition, displaying extraordinary fluctuations (as in 2nd order transitions) and discontinuous jumps (characteristic of 1st order transitions). Most remarkably, the system can be described by an Ising-like Hamiltonian with long-range multi-spin interactions and some of its properties can be obtained analytically. This is in stark contrast with other dynamic network models which rely almost exclusively on simulations.

10:00AM F28.00009 Self-organization of plutonomy in competitive societies , TAKASHI ODAGAKI, YUUNI TODATE, Tokyo Denki University, RYO FUJIE, Tokyo University — The plutonomy, where the top 1 percent of households accounts for more wealth than the bottom 99 percent, is an extreme form of hierarchy. It is an important question to find out what traits of competitive society lead to the extreme form of hierarchy. We investigate conditions for emergence of plutonomy in two model competitive societies. In a model where individuals make random walk and fight when they meet, we show that the order of move plays an important role and the plutonomy emerges when individuals have the same right to move first. For a model society where individuals participate in a competition with equal right, we show that the plutonomy can be self-organized when individuals grouped into several classes compete with those in the same class for a certain period (season) and they are regrouped at the end of every season. We also discuss various features of the emergence of plutonomy.

10:12AM F28.00010 Popularity-Driven Networking , ELI BEN-NAIM, Los Alamos National Laboratory, PAUL KRAPIVSKY, Boston University — We investigate the growth of connectivity in a network. In our model, starting with a set of disjoint nodes, links are added sequentially. Each link connects two nodes, and the connection rate governing this random process is proportional to the degrees of the two nodes. Interestingly, this network exhibits two abrupt transitions, both occurring at finite times. The first is a percolation transition in which a giant component, containing a finite fraction of all nodes, is born. The second is a condensation transition in which the entire system condenses into a single, fully connected, component. We derive the size distribution of connected components as well as the degree distribution, which is purely exponential throughout the evolution. Furthermore, we present a criterion for the emergence of sudden condensation for general homogeneous connection rates.

10:24AM F28.00011 Threshold model with multiple initiators[1] , P. SINGH, S. SREENIVASAN, B. SZYMANSKI, G. KORNISS, RPI — In social networks, adoption of a new behavior or opinion by an agent strongly depends on its neighborhood. We study the threshold model where every node is in one of two possible states (0 or 1) and a node in state '0' changes to '1' if at least a threshold fraction ϕ of its neighbors are already in state '1'[M. Granovetter, AJS, Vol. 83, No. 6]. Initially all nodes are in state '0' except initiators. Previous studies have shown that a small seed of such initiators can give rise to large cascades if ϕ is less than some critical ϕ_c. The focus of our work is the effect of the size of the initiator fraction p on the size of the cascade for different threshold values, on empirical networks as well as stylized models of social networks. We observe that global cascades are possible for arbitrary values of ϕ, if p is sufficiently large. We find that there exists a critical p_c (unique for every ϕ), such that $p \geq p_c$ results in global cascades whereas for $p < p_c$, cascades are only local.

[1]supported in part by ARL NS-CTA and ONR

10:36AM F28.00012 Spreading of infectious diseases considering age contact patterns for Latin America , ANA PASTORE Y PIONTTI, MARCELO F.C. GOMES, LUCA ROSSI, ALESSANDRO VESPIGNANI, Department of Physics, College of Computer and Information Sciences, Bouve' College of Health Sciences Northeastern University — The dynamics of infectious diseases strongly depends on the structure of the social contact patterns among individuals. In order to have an accurate estimate of the impact of epidemic outbreaks and which effective control measures to take, we need an appropriate description of these patterns. A simple way to improve the homogeneous mixing assumption is to introduce age contact patterns. Here we follow the approach of Fumanelli et al (PLoS Computational Biology, 8(9):e1002673, 2012) to estimate the age mixing patterns of virtual populations using highly detailed census data for Argentina, Brazil and Mexico. Considering age contact matrices for these countries we study the epidemiological relevant quantities and their relation with the sociodemographic data. Our results show that even for the same country the impact of epidemics outbreaks could be very different when we consider age contact matrices. This results can be explained as a result of a change in the average age of the population in the different regions of the countries. This study also provides the first estimates of contact matrices for Latin American countries.

10:48AM F28.00013 S-curves and the Mechanism of Propagation in Language Change , RICHARD BLYTHE, W. CROFT, University of Edinburgh — Linguists have proposed a wide variety of mechanisms for the propagation of a linguistic innovation through the speech community. The complexity of social systems makes it difficult to evaluate the different mechanisms empirically. We introduce a four-way typology of mechanisms and provide mathematical definitions based on the symmetries that may (or may not) be present between different speakers in the community and/or between different linguistic variants. As in physics, such symmetries impose strong constraints on the patterns of change that may emerge as a result. In particular, we conclude that the widely observed empirical pattern of an S-curve temporal trajectory of change can be captured only by theories that invoke a pre-existing shared preference among speakers for the incoming variant.

Tuesday, March 19, 2013 8:00AM - 11:00AM –

Session F29 GSNP: Focus Session: Spin Glasses: Advances, Algorithms, and Applications 337

- Jonathan Machta, University of Massachusetts Amherst

8:00AM F29.00001 Is there a de Almeida-Thouless line in finite-dimensional spin glasses?[1] , PETER YOUNG, University of California Santa Cruz — The question of whether there is a line of transitions in a magnetic field in an Ising spin glass (the de Almeida-Thouless, or AT, line) is important for two reasons: (i) its existence or otherwise is a major difference between the "droplet" and "replica symmetry breaking (RSB)" pictures of the spin glass state, and (ii) the spin glass in a field is argued to be quite similar to structural glasses, and, in this analogy, the spin glass AT line corresponds to the "ideal glass" transition of structural glasses. "Standard" finite-size scaling (FSS) methods do not find evidence for an AT line in three- or four-dimensional spin glasses. However, these results have been called into question by Leuzzi et al., Phys. Rev. Lett. 103, 267201 (2009) who perform a "non-standard" FSS analysis, in which they state that one should not include fluctuations at $k = 0$ since these are argued to have larger corrections to FSS than $k > 0$ fluctuations. Using the "non-standard" analysis Leuzzi et al. find an AT line in four dimensions and also in a one-dimensional long-range model which is a proxy for four dimensions. In this talk I will describe results of large-scale Monte Carlo simulations for one-dimensional models which are proxies for three and for four dimensions, analyzed using both the "standard" and "non-standard" FSS approaches. I will also briefly discuss the merits of these two approaches to FSS.

[1]Work in collaboration with D. Larson, H.G. Katzgraber and M.A. Moore, and supported by the NSF under grant DMR-1207036.

8:36AM F29.00002 Low-temperature behavior of the spin overlap distribution in one-dimensional long-range diluted spin glasses[1] , MATTHEW WITTMANN, Department of Physics, University of California Santa Cruz, HELMUT G. KATZGRABER, Department of Physics and Astronomy, Texas A&M University, J. MACHTA, Department of Physics, University of Massachusetts Amherst, A. P. YOUNG, Department of Physics, University of California Santa Cruz — Computer simulations of the spin glass state find that the *average* order parameter distribution $P(q)$ has a weight in the region of small overlap q which does not appear to decrease with size for the range of sizes that can be studied. This is in agreement with the "Replica Symmetry Breaking" (RSB) picture as opposed to the droplet picture which predicts $P(0) = 0$ in the thermodynamic limit. Recently, a detailed study [1] has been made of peaks in $P(q)$ for *individual samples* of a three-dimensional spin glass to gain more understanding of the situation. Here we pursue a similar approach but for long-range models in one dimension for which the interactions fall off with a power of the distance. Varying the power is analogous to varying the space dimension of a short-range model, so we can conveniently study models which are proxies for a *range* of space dimensions. We will present results on the nature of the peaks in $P(q)$ for individual samples for several such models, and interpret them in terms of the RSB and droplet pictures. References: [1] Phys. Rev. Lett. 109, 177204 (2012)

8:48AM F29.00003 Numerical evidence against both mean field and droplet scenarios of the Edwards-Anderson model , JULIO F. FERNANDEZ, Universidad de Zaragoza, Spain, JUAN J. ALONSO, Universidad de Granada, Spain — From tempered Monte Carlo simulations, we have obtained accurate probability distributions $p(q)$ of the spin-overlap parameter q for finite Edwards-Anderson (EA) and Sherrington-Kirkpatrick (SK) spin-glass systems at low temperatures. Our results for $p(q)$ follow from averages over 10^5 disordered samples of linear sizes $L = 4 - 8$ and over 15 000 samples for $L = 10$. In both the SK and EA models, at temperatures as low as $0.2T_{sg}$, where T_{sg} is the transition temperature, $p(q)$ varies insignificantly with L. This does not fit the trend that the droplet model predicts for large L. We have also calculated correlation functions, $F(q_1, q_2)$, from which rms deviations, δp, over different realizations of quenched disorder, as well as thermal fluctuations, w, of q values, follow. Our numerical results for δp and w scale as $\sqrt{L}$ and $1/L$, respectively, in the SK model. This fits in well with mean field predictions. On the other hand, our data for w and δp vary little, if at all, for the EA model.

9:00AM F29.00004 Evidence of Non-Mean-Field-Like Low-Temperature Behavior in the Edwards-Anderson Spin-Glass Model[1]

, BURCU YUCESOY, University of Massachusetts Amherst, HELMUT G. KATZGRABER, Texas A&M University, ETH Zurich, JONATHAN MACHTA, University of Massachusetts Amherst — The three and four-dimensional Edwards-Anderson and mean-field Sherrington-Kirkpatrick Ising spin glasses are studied via large-scale Monte Carlo simulations at low temperatures, deep within the spin-glass phase. Performing a careful statistical analysis of several thousand independent disorder realizations and using an observable that detects peaks in the overlap distribution, we show that the Sherrington-Kirkpatrick and Edwards-Anderson models have a distinctly different low-temperature behavior. The structure of the spin-glass overlap distribution for the Edwards-Anderson model suggests that its low-temperature phase has only a single pair of pure states.

9:12AM F29.00005 Overlap distributions in two-dimensional spin glasses[1]

, A. ALAN MIDDLETON, Syracuse University — Numerical results are presented for overlaps of configurations of two-dimensional Ising spin glasses. At low temperatures, the correlation length greatly exceeds the system size, so that spin-spin correlations are relatively long range and domain wall energies exhibit sensitive dependence to temperature,as seen in the low temperature phase of three-dimensional spin glasses. Exact sampling algorithms are used so that there is no doubt of equilibration. High statistics runs are carried out, with tens of thousands of samples of size $L^2 = 256^2$ simulated. The results of the size-dependent spin overlap distribution $P(q)$ are evaluated using statistics recently developed by Yucesoy, Katzgraber and Machta. The statistics for two-dimensional models at low temperature are found to be quite similar to those of three-dimensional spin glasses at finite temperatures below the spin-glass transition.

9:24AM F29.00006 Monte Carlo Simulation of three dimensional Edwards Anderson model with multi-spin coding and parallel tempering using MPI and CUDA[1]

, SHENG FENG, Department of Physics and Astronomy, Louisiana State University, YE FANG, Center for Computation and Technology, Louisiana State University, KA-MING TAM, Department of Physics and Astronomy, Louisiana State University, BHUPENDER THAKUR, ZHIFENG YUN, Center for Computation and Technology, Louisiana State University, KAREN TOMKO, Ohio Supercomputer Center, JUANA MORENO, Department of Physics and Astronomy, Louisiana State University, JAGANNATHAN RAMANUJAM, Center for Computation and Technology, Louisiana State University, MARK JARRELL, Department of Physics and Astronomy, Louisiana State University — The Edwards Anderson model is a typical example of random frustrated system. It has been a long standing problem in computational physics due to its long relaxation time. Some important properties of the low temperature spin glass phase are still poorly understood after decades of study. The recent advances of GPU computing provide a new opportunity to substantially improve the simulations. We developed an MPI-CUDA hybrid code with multi-spin coding for parallel tempering Monte Carlo simulation of Edwards Anderson model. Since the system size is relatively small, and a large number of parallel replicas and Monte Carlo moves are required, the problem suits well for modern GPUs with CUDA architecture. We use the code to perform an extensive simulation on the three-dimensional Edwards Anderson model with an external field.

9:36AM F29.00007 Extremal Optimization for Ground States of the Sherrington-Kirkpatrick Spin Glass with Levy Bonds[1]

, STEFAN BOETTCHER[2], Physics Dept., Emory University — Using the Extremal Optimization heuristic (EO),[3] ground states of the SK-spin glass are studied with bonds J distributed according to a Levy distribution $P(J) \propto 1/|J|^{1+\alpha}$ with $|J| > 1$ and $1 < \alpha < 4$. The variation of the energy densities with α, their finite-size corrections, their fluctuations, and their local field distribution are analyzed and compared with those for the SK model with Gaussian bonds.[4] We find that the energies attain universally the Parisi-energy of the SK when the second moment of $P(J)$ exists ($\alpha > 2$). They compare favorably with recent one-step replica symmetry breaking predictions well below $\alpha = 2$. Near $\alpha = 2$, the simulations deviate significantly from theoretical expectations. The finite-size corrections exponent ω decays from the putative SK value $\omega_{SK} = \frac{2}{3}$ already well above $\alpha = 2$. The exponent ρ for the scaling of ground state energy fluctuations with system size decays linearly from its SK value for decreasing α and vanishes at $\alpha = 1$.

9:48AM F29.00008 Equilibrium and nonequilibrium properties of Boolean decision problems on scale-free graphs with competing interactions with external biases

, ZHENG ZHU, Department of Physics and Astronomy, Texas A&M University, JUAN CARLOS ANDRESEN, Department of Physics, ETH Zurich, KATHARINA JANZEN, Institut fuer Mathematische Physik, TU Braunschweig, HELMUT G. KATZGRABER, Department of Physics and Astronomy, Texas A&M University — We study the equilibrium and nonequilibrium properties of Boolean decision problems with competing interactions on scale-free graphs in a magnetic field. Previous studies at zero field have shown a remarkable equilibrium stability of Boolean variables (Ising spins) with competing interactions (spin glasses) on scale-free networks. When the exponent that describes the power-law decay of the connectivity of the network is strictly larger than 3, the system undergoes a spin-glass transition. However, when the exponent is equal to or less than 3, the glass phase is stable for all temperatures. First we perform finite-temperature Monte Carlo simulations in a field to test the robustness of the spin-glass phase and show, in agreement with analytical calculations, that the system exhibits a de Almeida-Thouless line. Furthermore, we study avalanches in the system at zero temperature to see if the system displays self-organized criticality. This would suggest that damage (avalanches) can spread across the whole system with nonzero probability, i.e., that Boolean decision problems on scale-free networks with competing interactions are fragile when not in thermal equilibrium.

10:00AM F29.00009 Self-organized criticality in glassy spin systems requires long-range interactions

, JUAN CARLOS ANDRESEN, RUBEN S. ANDRIST, Deparment of Physics, ETH Zurich, HELMUT G. KATZGRABER, Department of Physics and Astronomy, Texas A&M University, VLADIMIR DOBROSAVLJEVIC, Department of Physics and National High Magnetic Field Laboratory, Florida State University, GERGERLY T. ZIMANYI, Department of Physics, University of California — We investigate the conditions required for general spin systems with frustration and disorder to display self-organized criticality, a property which so far has been established in spin models only for the infinite-range Sherrington-Kirkpatrick Ising spin-glass model [PRL 83, 1034 (1999)]. We study the avalanche and the magnetization jump distribution triggered by an external magnetic field in the short-range Edward-Anderson Ising spin glass for various space dimensions, between 2 and 8. Our numerical results, obtained on systems of unprecedented size, demonstrate that self-organized criticality is recovered only in the strict limit of infinite space dimensions (or equivalently of long-ranged interaction), and is not a generic property of spin-glass models in finite space dimensions.

10:12AM F29.00010 Minimal spanning trees at the percolation threshold: a numerical calculation[1] , SEAN SWEENEY, A. ALAN MIDDLETON, Syracuse University — Through computer simulations on a hypercubic lattice, we grow minimal spanning trees (MSTs) in up to five dimensions and examine their fractal dimensions. Understanding MSTs is imporant for studying systems with quenched disorder such as spin glasses. We implement a combination of Prim's and Kruskal's algorithms for finding MSTs in order to reduce memory usage and allow for simulation of larger systems than would otherwise be possible. These fractal objects are analyzed in an attempt to numerically verify predictions of the perturbation expansion developed by T. S. Jackson and N. Read for the pathlength fractal dimension d_s of MSTs on percolation clusters at criticality [T. S. Jackson and N. Read, Phys. Rev. E **81**, 021131 (2010)]. Examining these trees also sparked the development of an analysis technique for dealing with correlated data that could be easily generalized to other systems and should be a robust method for analyzing a wide array of randomly generated fractal structures.

10:24AM F29.00011 Are the diluted antiferromagnet in a field and the random-field Ising model in the same universality class? , HELMUT G. KATZGRABER, Texas A&M University, BJOERN AHRENS, ALEXANDER K. HARTMANN, Institut fuer Physik, Universitaet Oldenburg — We perform large-scale Monte Carlo simulations using the Chayes-Machta and parallel-tempering algorithms to study the critical behavior of both the diluted antiferromagnet in a field (30% dilution) and the random-field Ising model with Gaussian random fields for different field strengths. For small fields, analytical calculations by Cardy [Phys. Rev. B 29, 505 (1984)] predict that both models should share the same universality class. However, a detailed finite-size scaling analysis of both the Binder cumulant and the two-point finite-size correlation length suggests that even in the limit of small fields both models are not in the same universality class. Therefore, care should be taken when interpreting (experimental) data for diluted antiferromagnets in a field using the random-field Ising model. Finally, we present approximate analytical expressions based on our numerical data for the phase boundaries of both models.

10:36AM F29.00012 Universality in the three-dimensional random-field Ising model , VICTOR MARTIN-MAYOR, NIKOLAOS FYTAS, Departamento de Fisica Teorica I, Universidad Complutense de Madrid — We present the results of a large scale numerical simulation of the three-dimensional random-field Ising model at zero temperature. A combination of graph theoretical algorithms with a proper re-weighting scheme allows us to obtain data for systems with linear sizes $L \leq 192$ and extreme ensembles of disorder realizations, up to 5×10^7. Three types of field distributions are considered, namely the Gaussian, the Poissonian, and the double Gaussian for two values of its width. In particular, for the double Gaussian case we choose parameters such that the distribution of random fields is bimodal. Our finite-size scaling analysis, based on the quotients method and universal quantities, indicates the existence of a unique random fixed-point. Therefore, the random-field Ising model is ruled by a single universality class, in disagreement with early mean-field theory predictions and the current opinion in the literature. The complete set of critical exponents characterizing this universality class is given, including the correction-to-scaling exponent ω and the violation of hyper-scaling exponent θ. Finally, discrepancies with previous works are explained in terms of strong scaling corrections.

10:48AM F29.00013 Competing Antiferromagnetic and Spin-Glass phases in a hollandite structure , YANIER CRESPO HERNANDEZ, International Center for Theoretical Physics, ALEXEI ANDREANOV, Max Planck Institute for Physics of Complex Systems, NICOLA SERIANI, International Center for Theoretical Physics — We introduce a simple model to explain recent experimental results on spin freezing in a hollandite-type structure. We argue that geometrical frustration of the lattice with antiferromagnetic (AFM) interactions is responsible for the appearance of a spin-glass phase in presence of disorder. We check our predictions numerically using parallel tempering on a model that considers Ising spins and nearest-neighbor AFM interactions. The proposed model presents a rich phenomenology: in absence of disorder two ground states are possible, depending on the strength of the interactions, namely an AFM or a geometrically frustrated phase. Remarkably for any set of AFM couplings having an AFM ground state in the clean system, there exist a critical value of the disorder for which the ground state is replaced by a spin-glass one while maintaining all couplings AFM. To the best of our knowledge in the literature there is not a model that presents this kind of transition considering just short-range AFM interactions. Therefore we argue that this model would be useful to understand the relation between AFM coupling, disorder and the appearance of spin glasses phase.

Tuesday, March 19, 2013 8:00AM - 11:00AM –

Session F30 DCMP: Membranes, Micelles, Vesicles, Gels and Complex Fluids 338 - Elizabeth Mann, Kent State University

8:00AM F30.00001 For a Safe Diamide Extraction Process, Elucidated by Atomistic Simulations , BAOFU QIAO, Department of Materials Science and Engineering, Northwestern University, ROSS J. ELLIS, Chemical Sciences and Engineering Division , Argonne National Libboratory, MONICA OLVERA DE LA CRUZ[1], Department of Materials Science and Engineering, Northwestern University — The diamide extraction process has been successfully employed in separating trivalent actinides from used nuclear fuels. The extractant, which is an amphiphilic molecule with a metal-binding polar headgroup and hydrophobic tail, binds the actinides, thus extracting them from the aqueous phase into the oil phase. However, the oil phase will split into two phases, once a critical concentration of actinide is reached. This phase splitting is suspected to have caused the Red Oil events, which can decompose explosively. Therefore, it is extremely important for an extractant to have a high extraction efficiency, on one hand, and resist phase splitting, on the other. In comparison with DMDBTDMA, DMDOHEMA has both higher extraction efficiency and phase stability, which we suspect stem from the supramolecular aggregated structures influenced by the different extractant tails. To test our hypothesis, atomistic molecular dynamics simulations were performed on DMDBTDMA in bulk oil system and DMDOHEMA in bulk oil system. Our preliminary results indicate that DMBTDMA is more disposed toward formation of chain-like aggregates, especially at lower water concentration, in comparison with the branched structures observed in DMDOHEMA.

8:12AM F30.00002 Stochastic nature of clathrin-coated pit assembly , ANAND BANERJEE, ALEXANDER BEREZHKOVSKII, RALPH NOSSAL, National Insitutes of Health — Clathrin-mediated endocytosis is a complex process through which eukaryotic cells internalize various macromolecules (cargo). The process occurs via the formation of invaginations on the cell membrane, called clathrin-coated pits (CCPs). The dynamics of CCP formation shows remarkable variability. After initiation, a fraction of CCPs, called "productive pits", bind to cargo and then grow and mature into clathrin-coated vesicles (CCVs). In contrast, a large fraction of CCPs, called "abortive pits", fail to bind to cargo, grow only up to intermediate sizes and then disassemble. There is notable heterogeneity in the lifetimes of both productive and abortive pits. We propose a stochastic model of CCP dynamics to explain these experimental observations. Our model includes a kinetic scheme for CCP assembly and a related functional form for the dependence of free energy of a CCP on its size. Using this model, we calculate the lifetime distribution of abortive pits (via Monte Carlo simulation) and show that the distribution fits experimental data very well. By fitting the data we determine the free energy of CCP formation and show that CCPs without cargo are energetically unstable. We also suggest a mechanism by which cargo binding stabilizes CCPs and facilitates their growth.

8:24AM F30.00003 Budding transition of a self-avoiding polymer confined by a soft membrane adhering onto a flat wall[1] , YU-CHENG SU, JEFF Z. Y. CHEN, University of Waterloo — The Monte Carlo simulation is used to study the structural properties of the system consisting of a self-avoiding polymer chain confined between a fluid membrane and a flat hard surface. As the adhesion between the soft membrane and the hard-wall surface increases, the polymer is subject to a strong confinement; the state containing a pancake-shaped polymer conformation eventually yields to a bud state, through an abrupt, first-order phase transition. We explore the scaling behavior of the physical properties of the system as functions of the polymer's size, the membrane's surface tension, and the adhesion energy, for both pancake and bud states, in terms of Monte Carlo data and analytic scaling theories.

8:36AM F30.00004 Why square lattices are not seen on curved ionic membranes , CREIGHTON THOMAS, MONICA OLVERA DE LA CRUZ, Department of Materials Science and Engineering, Northwestern University — Ionic crystalline membranes on curved surfaces are ubiquitous in nature, appearing for example on the membranes of halophilic organisms. Even when these membranes buckle into polyhedra with square or rectangular sides, the crystalline structure is seen to have hexagonal symmetry. Here, we theoretically and numerically investigate the effects of curvature on square lattices. Our model system consists of both positive and negative ions with a 1:1 charge ratio adsorbed onto the surface of a sphere. In flat space, the lowest-energy configuration of this system can be a square lattice. This bipartite arrangement is favored because there are two types of ions. It leads to a fundamentally different defect structure than what has been seen when triangular lattices are favored. We classify these defects and find that curvature disrupts long-range square symmetry in a crystal. Through numerical simulations, we see that small square regions are possible in some cases, but this phase coexists with other structures, limiting the scale of these square-lattice microstructures. Thus, at large length scales, curvature leads to triangular structures.

8:48AM F30.00005 Amphiphilic lipids in solution: a simulational study of lipid bilayer formation[1] , THOMAS VOGEL, DAVID P. LANDAU, The University of Georgia, LILI GAI, KATIE A. MAERZKE, CHRISTOPHER R. IACOVELLA, CLARE M. MCCABE, Vanderbilt University, PETER T. CUMMINGS, Vanderbilt University and Oak Ridge National Laboratory — Amphiphilic molecules consisting of hydrophilic head and hydrophobic tail groups self-assemble into a wide variety of structures, such as bilayers (membranes), micelles, or vesicles (liposomes) when mixed with a suitable solvent. The understanding of this lipid self-assembly is essential for industrial, biological, or medical applications, but computer simulations are generally challenging due to the complex structure of the energy landscape. We show results for the lipid bilayer formation process obtained by newly developed parallel Wang–Landau Monte Carlo and statistical temperature molecular dynamics simulations. By applying those methods to a generic coarse-grained model for amphiphilic molecules in solution, we were able to obtain the thermodynamical data over the whole relevant temperature and energy range and to unravel the membrane formation process including all structural sub-transitions between different fluid and gel-phase bilayers.

9:00AM F30.00006 Study of vesicle size distribution dependence on pH value based on nanopore resistive pulse method , YUQING LIN, YAUHENI RUDZEVICH, ADAM WEARNE, DANIEL LUMPKIN, JOSELYN MORALES, KATHLEEN NEMEC, SUREN TATULIAN, OLEG LUPAN, LEE CHOW, Department of Physics, University of central Florida — Vesicles are low-micron to sub-micron spheres formed by a lipid bilayer shell and serve as potential vehicles for drug delivery. The size of vesicle is proposed to be one of the instrumental variables affecting delivery efficiency since the size is correlated to factors like circulation and residence time in blood, the rate for cell endocytosis, and efficiency in cell targeting. In this work, we demonstrate accessible and reliable detection and size distribution measurement employing a glass nanopore device based on the resistive pulse method. This novel method enables us to investigate the size distribution dependence of pH difference across the membrane of vesicles with very small sample volume and rapid speed. This provides useful information for optimizing the efficiency of drug delivery in a pH sensitive environment.

9:12AM F30.00007 Spontaneous Thermoreversible Formation of Cationic Vesicles in a Protic Ionic Liquid , DONGCUI LI, CARLOS LOPEZ-BARRON, LEO DERITA, MADIVALA BASAVARAJ, NORMAN WAGNER, University of Delaware — The search for stable vesicular structures is a long-standing topic of research because of the usefulness of these structures and the scarcity of surfactant systems that spontaneously form vesicles in true thermodynamic equilibrium. We report the first experimental evidence of spontaneous formation of vesicles for a cationic double tail surfactant (didodecyldimethylammonium bromide) in a protic ionic liquid (ethylammonium nitrate) [1-2]. Using small and ultra-small angle neutron scattering, rheology and bright field microscopy, we identify the coexistence of two vesicle containing phases in compositions ranging from 2 to 68 wt %. A low density highly viscous solution containing giant vesicles and a sponge phase coexists with a dilute high density phase containing large vesicles. Vesicles form spontaneously via different thermodynamic routes, with the same size distribution, which strongly supports that they exist in a true thermodynamic equilibrium. The formation of equilibrium vesicles and the L3 phase is facilitated by ion exchange between the cationic surfactant and the ionic liquid, as well as the strength of the solvophobic effect in the protic ionic liquid.

9:24AM F30.00008 Phase separation in a DMPC/Dchol mixed Langmuir Film: A combined Brewster Angle, Fluorescence and Light Scattering Microscopy study[1] , PRITAM MANDAL, FANINDRA BHATTA, Department of Physics, Kent State University, ARNE GERICKE, Department of Chemistry & Biochemistry, Worcester Polytechnic Institute, EDGAR KOOIJMAN, Department of Biology, Kent State University, Kent, DAVID ALLENDER, ELIZABETH MANN, Department of Physics, Kent State University — Fluorescence microscopy (FM) is one of the most direct imaging techniques for in situ observation of morphology and phase-separation at the macroscopic scale [1] in lipid mono- or bi-layers. However, the presence of fluorescent dye-molecules can affect the system. In Brewster Angle Microscopy (BAM), one can image monomolecular Langmuir films without probes. Here, using a composite set-up of BAM, FM and Light Scattering Microscopy (LSM), we present a comparative study of the three techniques on a binary lipid mixture in the presence of two different probes. In most cases, all three techniques show precisely the same domains. However, depending on conditions, some domain types were more evident in one technique than the others. This established, we can directly test the influence of probe on the domain structure.

[1]NSF CBET-0730475

9:36AM F30.00009 Mesoscopic Membrane Morphology Regulated by Molecular Crystallization , CHEUK-YUI LEUNG, LIAM PALMER, BAO FU QIAO, SUMIT KEWALRAMANI, RASTKO SKNEPNEK, CHRISTINA NEWCOMB, MEGAN GREENFIELD, GRAZIANO VERNIZZI, SAMUEL STUPP, MICHAEL BEDZYK, MONICA OLVERA DE LA CRUZ, Northwestern University — A grand challenge in self-assembly of multi-component systems is to control the crystal symmetries and the resulting geometries of co-assembled molecular structures. We generate here crystalline ionic bilayers in a large variety of geometries, which resemble unusual cellular shell shapes, by mixing +3 and -1 ionic amphiphiles. To structurally characterize the co-assembly from the mesoscopic to nanometer scale, we combine electron microscopy with small and wide angle x-ray scattering. We use pH to control the degree of ionization of the amphiphiles and hence their intermolecular electrostatic interactions. At low and high pH, closed faceted vesicles with 2D hexagonal molecular arrangements were observed, while at intermediate pH ribbons with rectangular-C packing of the amphiphiles were observed. Thus pH acts as a switch to control the morphology of the ionic bilayers via transitions in the crystalline lattice. This work promotes the design of nanocontainers for various applications and improves our understanding of the origin of polyhedral shells in nature.

9:48AM F30.00010 Thermodynamics of protein driven self assembly in membranes , RAMAKRISHNAN NATESAN, RICHARD TOURDOT, RYAN BRADLEY, RAVI RADHAKRISHNAN, Unviersity of Pennsylvania — Recent experimental evidences strongly point to the role of proteins and other membrane binding macromolecules in reshaping biological membranes, at length scales of the molecule and the structure enclosed by the membrane. In this work, we investigate the interplay between the membrane curvature induced at the molecular scale, mainly due to peripheral membrane proteins, and the resulting membrane morphologies, of varying complexity, observed at the mesoscale. The biological membrane, in our approach, is represented by a dynamically triangulated surface while the proteins are modeled as curvature fields on the membrane, which can either be isotropic or anisotropic. Thermal undulations in the membrane and cooperativity in the curvature field, due to the stabilization of a nematic phase, drives the membrane into conformations that resembles those in experiments in vivo and vitro. The stability of these structures are examined by two approaches to compute the free energy of the system: (i) Widom insertion technique to compute excess chemical potentials and (ii) thermodynamic integration using the Kirkwood coupling parameter to compute absolute free energies. Building on these methods, we propose a hybrid scheeme that couples both the approaches for computing free energies.

10:00AM F30.00011 Morphology and Performance of PLLA Based Porous Membranes by Phase Separation Control[1] , QIAN XING, XIA DONG, Beijing National Laboratory for Molecular Sciences, CAS Key Laboratory of Engineering Plastics, Institute of Chemistry, Chinese Academy of Sciences, RONGBO LI, PetroChina Petrochemical Research Institute, CHARLES C. HAN, DUJIN WANG, Beijing National Laboratory for Molecular Sciences, CAS Key Laboratory of Engineering Plastics, Institute of Chemistry, Chinese Academy of Sciences — Poly (L-lactic acid) (PLLA) porous membranes with different morphologies and properties were prepared through immersion precipitation method. It has been proved that the rate and level of phase separation between PLLA/dioxane solution and coagulation baths were the original drive force for the ultimate structure and corresponding performance of PLLA membranes. The equilibrium thermodynamic phase diagram of PLLA/solvent/nonsolvent and the kinetic diffusion rate between solvent and nonsolvent were systematically investigated.

[1]NSFC 50925313 and 51173195

10:12AM F30.00012 Correlating bulk properties and nanoscale rearrangement during UV-initiated gelation of hybrid nanoparticle/ block copolymer systems , K. ANNE JUGGERNAUTH, Macromolecular Sci. & Eng. Research Center, Dept of Materials Sci. & Eng., University of Michigan, Ann Arbor, SOENKE SEIFERT, X-Ray Sciences Division, Advanced Photon Source, Argonne National Labs, Argonne IL, BRIAN LOVE, Macromolecular Sci. & Eng. Research Center, Dept of Materials Sci. & Eng., University of Michigan, Ann Arbor — We use rheology and Small Angle X-Ray Scattering (SAXS) to investigate UV initiated gel formation in aqueous dispersions of clay nanoparticles in the presence of poly(ethyleneoxide-b-propyleneoxide-b-ethyleneoxide) block copolymer surfactants (Pluronics®) and small amounts of a photoacid generator (PAG). This material system demonstrates stable liquid-like behavior in the absence of UV but undergoes bulk gelation upon UV exposure. Rheology was used to monitor the bulk properties of a series of samples undergoing UV exposure and confirm bulk gel formation. We further probe nanoparticle rearrangement using time resolved synchrotron SAXS with simultaneous UV exposure. Time dependent SAXS indicate an absence of long range order and crystallinity while changes in the scattering profile are related to short range interparticle interactions leading to a stable or arrested structure. Finally, we compare the time scales for structural rearrangement of nanoparticles with the bulk gelation behavior. Our results show that the kinetics for local structural changes between particles and bulk gelation from UV exposure are strongly correlated.

10:24AM F30.00013 Cooperative Processes in Restructuring Gel Networks , JADER COLOMBO, Microstructure and Rheology, Institute for Building Materials, ETH Zurich, ASAPH WIDMER-COOPER, School of Chemistry, University of Sydney, EMANUELA DEL GADO, Microstructure and Rheology, Institute for Building Materials, ETH Zurich — Colloidal gel networks are disordered elastic solids that can form even in extremely dilute particle suspensions. Similarly to other network-forming soft materials, including many with important biological function or technological potential, they can locally restructure via breaking and reforming interparticle bonds. Although controlling the link between local restructuring and mechanical response bears enormous potential for designing smart nanocomposites, there is at present little understanding of how local bond changes affect the dynamics of the gel network and the stress transmission through it. Here, using numerical simulations of a model system and a space-resolved analysis of dynamical heterogeneities, we show that bond breaking has non-local consequences and induces cooperative relaxation further away along the network. This provides explicit microscopic insight into why non-local constitutive relations are required to rationalize the non-trivial mechanical response of colloidal gels.

10:36AM F30.00014 Elimination of branching in self assembled beta-hairpin based peptide hydrogels , SAMEER SATHAYE, DARRIN POCHAN, Department of Materials Science and Engineering, University of Delaware, DARRIN POCHAN RESEARCH GROUP TEAM — Hydrophobic collapse of amphiphilic β-hairpin peptides (e.g. MAX1 VKVKVKVKV^{D}PPTKVKVKVKV-NH_2) into fibrils and their hierarchical assembly into branched, hydrogel networks has been extensively studied. A physically crosslinked hydrogel network is formed due to fibrillar entanglement and branched defects in hydrophobic collapse during fibril formation. Alternating valine residues with side chains of the same size are responsible for the hydrophobic collapse of the molecule into a b-hairpin and fibril nanostructure with branching. In a new sequence LNK1 (LNK1 (Nal)K(Nal)KAKAKV^{D}PPTKAKAK(Nal)K(Nal)-NH_2) the non-beta turn valines were replaced with Napthylalanine and alanine amino acid residues, with hydrophobic side chains of larger and smaller volume, respectively, than valine. Thus, formation of a 'lock and key' type structure was attempted in the hydrophobic core of the peptide fibrils that would eliminate fibril branching. The folding and network formation of LNK1 has been studied by Circular Dichroism spectroscopy (CD), Transmission Electron Microscopy (TEM) and Oscillatory Rheology. Preliminary rheological characterization suggests the elimination of branching in the fibrils and also a possibility that LNK1 networks, unlike MAX1, are just nanofibrillar suspensions rather than permanently physically crosslinked hydrogels.

10:48AM F30.00015 Microstructure and rheology of a thermoreversible gel under large amplitude oscillatory shear (LAOS) deformation using time-resolved oscillatory rheo-small-angle neutron scattering (tOr-SANS) , JUNG MIN KIM, A. KATE GURNON, NORMAN WAGNER, University of Delaware, AARON EBERLE, NCNR NIST — Large amplitude oscillatory shear (LAOS) rheology is an effective way of studying the nonlinear dynamics of complex fluids. Here, we present a new method for a direct, quantitative study of the microstructure under LAOS deformation in the framework of the alignment factor, *Af*. We use a model thermoreversible adhesive hard-sphere system composed of octadecyl-coated silica particles suspended in n-tetradecane. With temperature the particle potential is controlled and the system is shifted from behaving as a near hard-sphere to an adhesive hard-sphere system leading to aggregation and ultimately a dynamical arrest transition to macroscopic gelation. Time-resolved oscillatory rheo-small-angle neutron scattering (tOr-SANS) measurements in the 1-3 plane are performed by stroboscopically probing the structural evolution as a function of time during LAOS. Under strong shear, the 2D scattering pattern of the system in the gelled state exhibits a strong anisotropy commonly known as a "butterfly" pattern, which corresponds to the stretching of the microstructure along the flow direction. The first structure-Lissajous plots of this model system are presented in terms of an order parameter and *Af* as a function of instantaneous strain and strain rate. This new analysis demonstrates a novel method for simultaneously measuring the rheology and microstructure during a time-dependent deformation (LAOS).

8:36AM F31.00002 Liquid Crystals of Disks of Controlled Aspect Ratios[1] , ZHENGDONG CHENG, MIN SHUAI, ANDRES F. MEJIA, Artie McFerrin Department of Chemical Engineering — Nanoparticles with quasi two-dimensional shapes serve as building blocks for discotic colloidal liquid crystals. However, due to difficulty of synthesis and especially shape-tuning of disk-shaped nanoparticles, good model systems for the study of discotic colloidal liquid crystals are hard to found. α-zirconium phosphate (ZrP) crystals synthesized through hydrothermal treatment has regular disk shapes and controllable size, thickness, as well as size polydispersity. We experimentally illustrate that aqueous suspensions of these ZrP disks form stable liquid crystal phase easily. By choosing the thickness of the disks, an iridescent liquid crystal phase has been achieved. The critical concentration of the phase transition was found to be dependent on aspect ratios. We will also discuss our recent results on the phase diagram of discotic liquid crystals as a function of aspect ratio and particle concentration using ZrP monolayers and wax disks.

8:48AM F31.00003 Synthesis and Self-Assembly Behaviors of Polyhedral Oligomeric Silsesquioxane Based Giant Molecular Shape Amphiphiles[1] , KAN YUE, XINFEI YU, CHANG LIU, WEN-BIN ZHANG, STEPHEN CHENG, Department of Polymer Science, The University of Akron — Recently, our group has focus on the synthesis and characterization of novel giant molecular shape amphiphiles (GMSAs) based on functionalized molecular nanoparticles (MNPs), such as polyhedral oligomeric silsesquioxane (POSS), tethered with polymeric tails. A general synthetic method via the combination of sequential ?click? reactions has been developed and several model GMSAs with various tail lengths and distinct molecular topologies, which can be referred as the ?giant surfactants?, ?giant lipids?, ?giant gemini surfactants?, and ?giant bolaform surfactants? etc., have been demonstrated. Studies on their self-assembly behaviors in the bulk have revealed the formation of different ordered mesophase structures with feature sizes around 10 nanometers, which have been investigated in detail by small angle X-ray scattering (SAXS) technique and transmission electron microscopy (TEM). These findings have general implications on understanding the underlying principles of self-assembly behaviors of GMSAs, and might have potential applications in nano-patterning technology.

9:00AM F31.00004 2D Smectic of a T-shaped Liquid Crystal Mesogen[1] , D. CHEN, D.A. COLEMAN, C. ZHU, N. CHATTHAM, Department of Physics and Liquid Crystal Materials Research Center, University of Colorado, Boulder, CO 80309-0390, USA, X. CHENG, C. TSCHIERSKE, Institute of Organic Chemistry, Martin-Luther-University, D-06108, Halle, Germany, J.E. MACLENNAN, M.A. GLASER, N.A. CLARK, Department of Physics and Liquid Crystal Materials Research Center, University of Colorado, Boulder, CO 80309-0390, USA — We report structural studies of a T-shaped mesogenic molecule. Upon cooling from the isotropic, the molecules first form a lamellar phase, with the molecular tails organized into sheets and the head groups isotropic in the plane of the lamellae. On further cooling, the head groups self-assemble into phases with 2D nematic and smectic order. The 2D smectic has only short-range positional correlations, with dislocations in the layering. The development of the 2D smectic reduces the long-range correlations of the fundamental lamellar structure, with the system evolving into a biaxial nematic with the T-shaped molecules ordered in three dimensions but with only short-range correlations.

9:12AM F31.00005 Hierarchical Structure in Liquid Crystalline Polymers and Block Copolymers[1] , RAJESWARI KASI, University of Connecticut — We are interested in developing general molecular engineering approaches to liquid crystalline and semicrystalline brush random and block copolymers. These polymers self-assemble into hierarchical supramolecular nano structures with organization over several length scales that allows for evolution for unique property and function. In these polymeric libraries, we exploit liquid crystalline units for its responsive optical and mechanical features and semicrystalline brush units for its mechanical and thermal features. These materials are useful for applications in 1D photonic band gap materials as well as templates for preparation of nanoporous scaffolds. A series of liquid crystalline monomers and semicrystalline brush macromonomers are synthesized and polymerized by ring opening metathesis methods to prepare liquid crystalline random brush copolymers and liquid crystalline block brush copolymers. All these copolymers exhibit atleast two levels of hierarchy: LC mesophase assembly and brush microphase segregation due to incompatibility with the LC phase. We investigate the phase evolution of these materials based on composition, molecular weight and length of the semicrystalline brush and we map out the phase behavior by a variety of techniques including thermal analysis, UV visible analysis, polarized optical microscopy, temperature controlled small angle x-ray, wide-angle x-ray, electron microscopy, dynamic mechanical analysis. In addition to thermal and microstructural analysis, we determine the order-disorder transition of the self-assembled copolymers. In closing, by exploiting molecular architecture and composition to modulate the self-assembly, hierarchical structure at multiple length scales can be obtained and preserved which allows for the creation of unique 1D-photonic band gap materials as well as nanoporous scaffolds.

9:48AM F31.00006 Triply Periodic Multiply Continuous Lyotropic Liquid Crystals Derived from Gemini Dicarboxylate Surfactants , GREGORY SORENSON, MAHESH MAHANTHAPPA, University of Wisconsin - Madison — A delicate balance of non-covalent interactions drives the supramolecular assembly of hydrated small molecule amphiphiles into aqueous lyotropic liquid crystals (LLCs). High symmetry multiply continuous phases, exemplified by the gyroid phase, are particularly desirable for many applications due to their interpenetrating hydrophilic and hydrophobic domains with well-defined chemical functionality decorating the interface between the two domains. However, these high symmetry assemblies are often difficult to obtain due to limited levels of hydration and temperature ranges over which they are accessible. Recent work suggests that small molecule amphiphiles known as "gemini" surfactants readily form these lyotropic network phases. Herein we report the lyotropic phase behaviors of a new class of dicarboxylate gemini surfactants that form stable, multiply continuous, high symmetry network structures over broad hydration and temperature ranges.

10:00AM F31.00007 Alignment and Stiffening of Liquid Crystal Elastomers under Dynamic Compression , ADITYA AGRAWAL, Rice University, PRABIR PATRA, University of Bridgeport, PULICKEL AJAYAN, WALTER CHAPMAN, RAFAEL VERDUZCO, Rice University — Biological tissues have the remarkable ability to remodel and repair in response to disease, injury, and mechanical stresses, a phenomenon known "functional adaptation" or "remodeling". Herein, we report similar behavior in polydomain liquid crystal elastomers. Liquid crystal elastomers dramatically increase in stiffness by up to 90 % under low-amplitude, repetitive (dynamic) compression. By studying a systematic series of materials, we demonstrate that the stiffness increase is directly influenced by the liquid crystal content of the elastomers, the presence of a nematic liquid crystal phase and the use of a dynamic as opposed to static deformation. Through a combination of rheological measurements, polarizing optical microscopy and 2-D X-ray diffraction, we demonstrate that self-stiffening arises due to rotations of the nematic director in response to dynamic compression, and show that the behavior is consistent with the theory for nematic rubber elasticity. Previous work with liquid crystal elastomers has focused primarily on 'soft elastic' deformations at large strains, but our findings indicate rich behavior at previously overlooked low-strain, dynamic deformations.

10:12AM F31.00008 Large area Magnetic alignment of a Cylindrical liquid crystalline Brush Block Copolymer for Generating Nanoporous Templates[1] , MANESH GOPINADHAN, Yale University, PRASHANT DESHMUKH, University of Connecticut, PAWEL MAJEWSKI, Yale University, RAJESWARI KASI, University of Connecticut, CHINEDUM OSUJI, Yale University, OSUJI LAB/KASI'S LAB TEAM — Magnetic fields have been shown to be a facile route to directing the self-assembly of both lamellar and cylinder forming diamagnetic block copolymer nanostructures over macroscopic areas. Here we present magnetic field directed self-assembly of a novel strongly segregated cylindrical block copolymer with polynorbonene backbone bearing a poly(lactic acid) PLA minority cylindrical brush block which is amenable to selective removal by chemical etching while a ciano-biphenyl species forms the liquid crystalline magneto-responsive block. We found that the PLA brush length is critical to obtain hexagonally packed cylindrical domains, while the system was not susceptible to magnetic field alignment due to large separation of LC clearing transition and order-disorder transition temperatures. Surprisingly, doping a small amount of free ciano-biphenyl mesogens induces strong and fast alignment of block copolymer microdomains under 5T magnetic field. Subsequent etching of the PLA block from the aligned material and cross-linking norbonene backbone by thiol-ene chemistry yield highly aligned nanoporous membranes which could potentially serve as templates for the synthesis of nanomaterials. Magnetic field directed self-assembly thus offer a simple route to generate nanoporous templates where porosity and the dimensions can be controlled by the molecular parameters.

[1]Funding from NSF via DMR-0847534 is acknowledged.

10:24AM F31.00009 Observations of phase behavior of chiral mesogens in diastereomeric domains of bent-core helical nanofilament networks[1] , B. HORANYI, D. CHEN, Department of Physics and Liquid Crystal Materials Research Center, University of Colorado, Boulder, CO 80309-0390, USA, E. KORBLOVA, D.M. WALBA, Department of Chemistry and Biochemistry and Liquid Crystal Materials Research Center, University of Colorado, Boulder, CO 80309-0215, USA, J.E. MACLENNAN, M.A. GLASER, N.A. CLARK, Department of Physics and Liquid Crystal Materials Research Center, University of Colorado, Boulder, CO 80309-0390, USA — Blends of NOBOW, a helical nanofilament-forming B4 bent-core liquid crystal with organic guest molecules are completely mixed in the high temperature, isotropic phase. Upon cooling, the B4 filaments nucleate from the isotropic melt and grow into a homochiral dendritic network which acts as a porous medium of large internal area, with the guest material confined to nanoscale interstitial volumes between the twisted filaments. A typical sample is a conglomerate of independently nucleated left- and right-handed B4 domains many tens of μm across. Polarized optical microscopy reveals that chiral liquid crystal guest materials nanoconfined in the helical nanofilament networks form diastereomeric domains with distinct thermal behavior.

10:36AM F31.00010 The Role of Confinement on Biologically Derived Liquid Crystals[1] , MARGUERITE BROWN, DANIEL BLAIR, Georgetown University Department of Physics and Institute for Soft Matter Synthesis and Metrology — Suspensions of stabilized, dilute microtubules provide a versatile model system for understanding the structure of confined liquid crystals. Microtubule solutions are easily transported as a simple monomeric fluid that can easily be polymerized into rod-like macromolecules after they are confined within quasi-2D geometries (microfluidics). Using polarization and confocal microscopy, we analyze the structure of liquid crystals in a variety of geometries. We will present results on the role of confinement, boundary conditions and concentration, specifically discussing how each variable alters nematic ordering.

10:48AM F31.00011 Bio-based liquid crystalline polyesters[1] , CAROLUS WILSENS, Eindhoven University of Technology, Department of Chemical Engineering and Chemistry, SANJAY RASTOGI, Department of Materials, Loughborough Univerity, England (UK), DUTCH POLYMER INSTITUTE COLLABORATION — The reported thin-film polymerization has been used as a screening method in order to find bio-based liquid crystalline polyesters with convenient melting temperatures for melt-processing purposes. An in depth study of the structural, morphological and chemical changes occurring during the ongoing polycondensation reactions of these polymers have been performed. Structural and conformational changes during polymerization for different compositions have been followed by time resolved X-ray and Infrared spectroscopy. In this study, bio-based monomers such as vanillic acid and 2,5-furandicarboxylic acid are successfully incorporated in liquid crystalline polyesters and it is shown that bio-based liquid crystalline polymers with high aromatic content and convenient processing temperatures can be synthesized.

11:00AM F31.00012 The liquid-crystal phase transition in suspensions of soft particles , MIGUEL PELAEZ-FERNANDEZ, ANTON SOUSLOV, School of Physics, Georgia Institute of Technology, L. ANDREW LYON, School of Chemistry & Biochemistry and the Petit Institute for Bioengineering & Bioscience, Georgia Institute of Technology, PAUL M. GOLDBART, ALBERTO FERNANDEZ-NIEVES, School of Physics, Georgia Institute of Technology — We experimentally determine the equation of state of swollen microgel suspensions: $\pi = \pi(\zeta, N_c)$, with π the suspension osmotic pressure, ζ the generalized volume fraction and N_c the number of chains per particle, which determines the microgel stiffness. We find that the melting and freezing lines shift to higher ζ as the particle becomes softer. Concomitantly, the liquid-crystal coexistence region becomes wider. We suggest that this behavior is due to the internal degrees of freedom of the microgel particles, which increase as the particle becomes softer. In this case, crystallization requires freezing some of these additional degrees of freedom resulting in the observed widening of the coexistence region. Our experiments provide the starting point to understand how the single-particle elasticity affects the phase behavior of colloidal suspensions.

8:00AM F32.00001 POLYMER PHYSICS PRIZE BREAK –

8:36AM F32.00002 Polystyrene Nanocomposites: Shear and Bulk Rheology and PVT Behavior , RAN TAO, SINDEE SIMON, Texas Tech University — One potential strategy to mitigate thermal residual stresses in polymer materials is to reduce the thermal pressure coefficient, a product of the bulk modulus and thermal expansion coefficient. Recent model predictions show that the liquid bulk modulus could decrease by incorporation of well-dispersed spherical nanoparticles into polymer matrix. In this work, the pressure-volume-temperature (PVT) behavior and pressure relaxation response of a 10 wt% silica nanoparticle-filled polystyrene nanocomposite sample are measured using a custom-built pressurizable dilatometer. The glass transition temperature (T_g) is calculated as a function of pressure from the PVT data, and the PVT data are fitted to the Tait equation. Isothermal pressure relaxation experiments are performed in the vicinity of the pressure-dependent T_g, from which the time-dependent bulk modulus is calculated. The temperature dependence of the horizontal shift factors is examined and compared to those obtained from the shear response. In addition, the retardation spectra for the bulk and shear responses are compared and the implications are discussed. The results are consistent with literature prediction indicating that bulk modulus will increase in aggregated nanocomposites system.

8:48AM F32.00003 Simulating Fiber Aggregation in Shear Flow with Dissipative Particle Dynamics , JUSTIN STIMATZE, DAVID EGOLF, JEFFREY URBACH, Department of Physics, Georgetown University — We have developed a mesoscale simulation of fiber aggregation using LAMMPS and its implementation of dissipative particle dynamics. Fiber-fiber interactions are approximated by combinations of standard pairwise forces, allowing exploration of multiple interaction-influenced fiber behaviors such as aggregation and bundling. We determine viscosity, stresses, fluid velocity field, and fiber forces while simulating the evolution of a model fiber system in shear flow. Preliminary simulations supported by AFOSR HPC resources have demonstrated several aggregate types dependent on system parameters. Explorations of fiber interaction mechanisms and parameters may enable greater insight into processes such as nanocomposite material manufacturing and silk fibrillation.

9:00AM F32.00004 Effects of functional groups and ionization on the structure of alkanethiol coated gold nanoparticles , DAN S. BOLINTINEANU, J. MATTHEW D. LANE, GARY S. GREST, Sandia National Laboratories — We report fully atomistic molecular dynamics simulations of alkanethiol coated gold nanoparticles solvated in water and decane. The structure of the coatings is analyzed as a function of various functional end groups, including amine and carboxyl groups in different neutralization states. We study the effects of charge in the end groups for two different chain lengths (10 and 18 carbons) and different counterions (mono- and divalent). For the longer alkanes we find significant local phase segregation of chains on the nanoparticle surface, which results in highly asymmetric coating structures. In general, the charged end groups attenuate this effect by enhancing the water solubility of the nanoparticles. Based on the coating structures and density profiles, we can qualitatively infer the overall solubility of the nanoparticles. The asymmetry in the alkanethiol coatings is also likely to have a significant effect on aggregation behavior. More importantly, our simulations suggest the ability to modulate end group charge states (e.g. by changing the pH of the solution) in order to control coating structure, and therefore control solubility and aggregation behavior.

9:12AM F32.00005 Shear and Extensional Flow-Induced Particle Orientation in Polypropylene/Clay Nanocomposites , WESLEY BURGHARDT, ERICA MCCREADY, Northwestern University — Synchrotron-based in situ x-ray scattering is used to monitor the orientation of dispersed particles in molten polypropylene/clay nanocomposite melts during flow. Nanocomposite samples were prepared via twin screw extrusion processing, and the degree of clay exfoliation assessed in terms of the magnitude of the low frequency enhancement in viscoelasticity. In shear flow, an annular cone and plate flow cell is used which allows measurement of the degree and direction of particle orientation in the flow-gradient (1-2) plane. Samples were also studied in extensional flow, using an SER extensional flow fixture installed in a custom-built convection oven that provides x-ray access. In both shear and extensional flow, only a moderate degree of particle orientation is observed. Extensional flow studies are complicated by (i) the tendency of samples to fail at moderate Hency strain, and (ii) a heterogeneous initial distribution of particle orientation in the SER specimens, prepared by compression molding of extruded pellets of the nanocomposite.

9:24AM F32.00006 Effect of Ionic Groups on the Assembly of Polymer-Grafted Magnetic Nanoparticles[1] , YANG JIAO, PINAR AKCORA, Stevens Institute of Technology — Hydrophobic iron oxide nanoparticles grafted with hydrophobic polymer chains at low grafting density assemble into long strings of nanoparticles. Brush-brush entanglement and the effective dipolar interactions of these elongated clusters drive this aggregation process. In this work, we investigate the influence of ionic attractions on the morphologies of these polymer functionalized nanoparticles at different grafting densities. The effect of sulfonic group locations incorporated into poly(styrene) chains on the aggregation state of nanoparticles will be discussed with small-angle x-ray scattering measurements in solution and melts.

9:36AM F32.00007 Synthesis and Assembly of Janus Gold Nanorods in Polymer Matrices , ROBERT C. FERRIER, HYUN-SU LEE, MICHAEL J.A. HORE, MATTHEW CAPORIZZO, DAVID M. ECKMANN, RUSSELL J. COMPOSTO, University of Pennsylvania — Gold nanorods (AuNRs) possess unique optical properties that depend on the local orientation and separation of the individual rods. Previous research focused on assembling AuNRs either end-to-end or side-by-side in solution. Our group has explored the dispersion of polymer grafted AuNRs in polymer matrices. The present work investigates the end-to-end assembly of polymer grafted Janus AuNRs (JNRs) in polymer thin films. JNRs are synthesized by exploiting the anisotropic surface chemistry of CTAB-coated AuNRs. Poly(ethylene oxide) (PEO) brushes are grafted to the side of the AuNR, while leaving the ends unmodified. Using alkane dithiols of different lengths, the JNRs are covalently linked in various solutions and the optical properties are characterized by UV/visible spectroscopy. Linked JNRs are spin-cast in poly(methyl metracrylate) (PMMA) or PEO thin films and characterized via electron microscopy and UV/visible spectroscopy. Using this procedure, linked JNRs can be dispersed in a polymer matrix and linked end-to-end to control the optical properties of coating.

9:48AM F32.00008 Dispersion of Polymer-Grafted Nanorods in Polymer Films , AMALIE L. FRISCHKNECHT, Center for Integrated Nanotechnologies, Sandia National Laboratories, MICHAEL J. A. HORE, RUSSELL J. COMPOSTO, Dept. of Materials Science and Engineering, University of Pennsylvania — Gold nanorods (NRs) exhibit unique optical properties, i.e. their surface plasmon resonances, which can be tuned by the separation between the NRs. One strategy for controlling the assembly of NRs in a polymer film is to coat them with a polymer brush. The resulting dispersion or aggregation of the rods depends on the details of their interactions, which we examine using both theory and experiment. Classical density functional theory (DFT) and self-consistent field theory calculations of the structure of the brush around an isolated NR in a polymer melt predict a gradual transition from a "wet" to a "dry" brush as the NR radius, the grafting density, and/or the ratio of matrix to brush chain lengths is increased. DFT calculations of the interaction free energy between two NRs find an attractive well at intermediate NR separations. The strength of the attraction increases as the brushes become more dry. Including the van der Waals attractions between the NRs gives an estimate of their total interaction free energy, which can be used to predict when the NRs are dispersed or aggregated. A dispersion map shows good agreement between DFT calculations and experimental observations. Our calculations can be used as a guide to the design rules for tuning NR assembly in polymer films.

10:00AM F32.00009 Dispersion of small nanoparticles in random copolymer melts , DEBAPRIYA BANERJEE, KENNETH S. SCHWEIZER, University of Illinois at Urbana-Champaign, BOBBY SUMPTER, Oak Ridge National Laboratory, MARK D. DADMUN, University of Tennessee and ORNL — Microscopic PRISM integral equation theory is applied to study the structure and miscibility of extremely small nanoparticles (e.g., C60 buckyballs) dissolved at low concentrations in a chemically heterogeneous random AB copolymer melt. The effects of polymer stiffness, melt isothermal compressibility, and the strength and spatial range of polymer-particle, polymer-polymer, and filler-filler attractions on the miscibility of the nanoparticles are studied. Complex, subtle and highly nonuniversal behavior is found. Appropriate tuning of the chemical interactions can result in the emergence of an intermediate range of random copolymer compositions where miscibility is maximized and larger than in either homopolymer limit. The physical origin involves a competition between depletion, steric stabilization, and bridging polymer-mediated interactions. When the direct interaction between the small fillers is tuned to model fullerenes, the potentials of mean force exhibit a competition between contact aggregation and bridging, and miscibility is enhanced with decreasing contact aggregation until the onset of bridging. Qualitative comparisons to recent experiments have been performed using attractive interaction strengths motivated by quantum chemical calculations.

10:12AM F32.00010 Dispersion of Soft Nanoparticles in a Chemically Identical Polymer Matrix , DILRU RATNAWEERA, D. BASKARAN, University of Tennessee, Knoxville TN 37996, D. HOLLEY, M. RUPPEL, Chemical Sciences Division, Oak Ridge National Laboratory, Oak Ridge, TN 37831, J. MAYS, University of Tennessee, Knoxville TN 37996, V. URBAN, Biology and Soft Matter Division, Oak Ridge National Laboratory, Oak Ridge, TN 37831, MARK DADMUN, University of Tennessee, Knoxville, TN 37996 and Chemical Sciences Division, Oak Ridge National Laboratory, Oak Ridge, TN 37831 — The mechanical, thermal and rheological properties of polymers can be improved by embedding organic nanoparticles (NPs). However, controlling the dispersion of NPs is often challenging due to thermodynamic and kinetic incompatibilities between particles and matrices. The current work focuses on the dispersion of chemically identical NPs in a polystyrene matrix. These NPs were made through a micro-emulsion technique using styrene and divinylbenzene (DVB) monomers. Polystyrene nanoparticles with controlled interfacial roughness and targeted styrene densities were achieved by controlling DVB volume fraction during synthesis. The dispersion of these NPs in deuterated polystyrene matrices was followed by Small Angle Neutron Scattering as a function of NP concentration and matrix molecular weight. At low NP concentrations, individual NPs are well distributed in the matrix, while aggregates were formed at higher concentrations in high molecular weight polymer matrices. Shape of the aggregates as well as the minimum concentration of NPs required to form aggregates were affected by the surface roughness and softness of the NPs.

10:24AM F32.00011 Using Polydispersity in Polymer Grafted Nanoparticles for Tuning Morphology in Polymer Nanocomposites , TYLER MARTIN, ARTHI JAYARAMAN, Department of Chemical and Biological Engineering, University of Colorado at Boulder — Polymer nanocomposites, consisting of nanoscale additives in a polymer matrix, are used in many applications where high thermal and wear resistance is important e.g. automotive tires. To achieve uniform mechanical and thermal properties of the nanocomposite, the nanoparticles need to be well dispersed in the polymer matrix. One way to control the nanoparticle spatial organization in the polymer matrix is by grafting the nanoparticle surface with polymers that are chemically similar to the matrix polymer and tuning the effective interactions between the particles by simply tuning the grafting density, graft length, matrix length, particle size, filler concentration, and matrix density. In this study, we demonstrate that polydisperse polymer grafts can stabilize dispersions of polymer grafted nanoparticles in a polymer matrix in cases where monodisperse grafts would cause aggregation of particles. The change in the effective inter-particle interactions with increasing polydisersity is because of increased wetting of the grafted polymers by the matrix polymers. The implication that polydispersity can stabilize particle dispersions in matrix shows that it can be used as a design tool to program inter-particle interactions in a polymer matrix.

10:36AM F32.00012 Synchrotron radiation studies of the evolution dynamics of self-assembled nanoparticle Langmuir films , YELING DAI, OLEG SHPYRKO, Department of Physics, University of California, San Diego, BINHUA LIN, MATI MERON, Center for Advanced Radiation Sources (CARS), University of Chicago, KYUNGIL KIM, Department of Chemistry and Biochemistry, University of California, Los Angeles, BRIAN LEAHY, Department of Physics, Cornell University — Nanoparticle Langmuir films self-assembled on a liquid sub-phase represent a class of systems that is of great interest for studies of phase transitions in quasi-2D systems, chemical self-assembly, surfactant behavior and biologically relevant monolayers and membranes. We utilize Grazing Incidence X-ray Off-Specular (GIXOS) scattering to study elastic properties, structure and surface fluctuating modes of these systems. We present here a comparison between the GIXOS and the X-ray Reflectivity (XR) measurements, where XR is conventionally used to provide structural information of samples along the surface-normal direction. We further present a detailed analysis of GIXOS data from the self-assembled nanoparticle films and describe how we use it to obtain quantitative, Angstrom-resolution details of the electron density profile normal to the surface, complementary to that obtained with XR. Additionally, GIXOS provides us with improved temporal resolution that allows us to directly study the evolution dynamics of self-assembled nanoparticle films in response to lateral compression.

10:48AM F32.00013 HipGISAXS: A Massively Parallel Code for GISAXS Simulation[1] , SLIM CHOUROU, ABHINAV SARJE, XIAOYE LI, Computational Research Division, Lawrence Berkeley National Lab, ELAINE CHAN, ALEXANDER HEXEMER, Advanced Light Source, Lawrence Berkeley National Lab, HIPGISAXS TEAM — Grazing Incidence Small-Angle Scattering (GISAXS) is a valuable experimental technique in probing nanostructures of relevance to polymer science. New high-performance computing algorithms, codes, and software tools have been implemented to analyze GISAXS images generated at synchrotron light sources. We have developed flexible massively parallel GISAXS simulation software "HipGISAXS" based on the Distorted Wave Born Approximation (DWBA). The software computes the diffraction pattern for any given superposition of custom shapes or morphologies in a user-defined region of the reciprocal space for all possible grazing incidence angles and sample rotations. This flexibility allows a straightforward study of a wide variety of possible polymer topologies and assemblies whether embedded in a thin film or a multilayered structure. Hence, this code enables guided investigations of the morphological and dynamical properties of relevance in various applications. The current parallel code is capable of computing GISAXS images for highly complex structures and with high resolutions and attaining speedups of 200x on a single-node GPU compared to the sequential code. Moreover, the multi-GPU (CPU) code achieved additional 900x (4000x) speedup on 930 GPU (6000 CPU) nodes.

8:36AM F33.00002 Pure Bending Loss in Nanowire Waveguides[1]

, JAEYEON PYO, JI TAE KIM, JEWON YOO, JUNG HO JE[2], Pohang University of Science and Technology — One of the major concerns in designing waveguides is unavoidable bending that causes energy loss due to the distortion of modal field. Bending loss in nanowire waveguides has been studied while including substrate coupling loss. Pure bending loss unaffected by substrate coupling in nanowire waveguides still remains unclear. A challenging task in study of pure bending loss is to introduce bending on nanowire waveguides in the air and to tune the radius of bending. We report the characterization of pure bending loss in nanowire waveguides by bending a vertical freestanding nanowire in the air. Specifically, vertical freestanding active nanowire waveguides of MEH-PPV have been fabricated by our meniscus-guided method. To characterize pure bending loss, desired bending was remotely introduced by applying electrostatic force near the top end of the waveguide. Finite-difference-time-domain simulation was performed to confirm the experimental result. We show that the bending losses, by conventional experimental approaches of nanowires rested on substrates, were strongly overestimated attributed to the coupling of the enhanced evanescent field to the substrate. We suggest that our system could be also utilized for studying various intrinsic properties of nanowire waveguides.

8:48AM F33.00003 Molecular shear and the induced massive enhancement of conjugated polymer MEH-PPV photoluminescence by solvent-dewetting

, CHI-CHING LIU, Dept. of Materials Science and Engineering, National Tsing Hua University, Taiwan, TSANG-LANG LIN, Dept. of Engineering and Systems Science, National Tsing Hua University, Taiwan, GUNTER REITER, Inst. of Physics, University of Freiburg, Germany, ARNOLD C.-M. YANG, Dept. of Materials Science and Engineering, National Tsing Hua University, Taiwan — The molecular flows triggered by dewetting above Tg in ultrathin polymer films were shown previously generating huge photoluminescence (PL) enhancements for conjugated polymers contained within. By means of annealing in solvent vapor at room temperature, MEH-PPV molecules dispersed in inert polystyrene (PS) manifested massive PL enhancements up to ~ 10 folds when flowed into tiny droplets and residual layer. The enhancement was independent of MEH-PPV chain length but, in contrast to thermal dewetting, decreasing with MEH-PPV concentration (c). In addition, the blue shift accompanying thermal dewetting was also reduced. As annealing continued on, the blue shift reversed, illustrating the increase of conjugation length under stretching. The transient blue shift increased with PS molecular weight, unveiling the alteration of inter-segmental chain entanglements up to this stage of dewetting. Surprisingly, vapor of poorer solvent induced larger PL enhancements with narrower transient blue shifts, revealing that solvent was effective in inducing molecular flows, even when in the plasticizing Feakean precursor, relaxing the residual stresses and simultaneously stretching polymer chains for dramatically enhanced optoelectronic efficiencies.

9:00AM F33.00004 Multilayer polymer light emitting devices

, ZACHARY BARCIKOWSKI, ADAM THOMAS, MARIAN TZOLOV, Lock Haven University of Pennsylvania — The interplay of device layers and their interfaces is a major area of study in Polymer Light Emitting Devices (PLEDs). Many factors such as the degradation, efficiency, and overall performance depend on how these layers interact with each other. A fundamental understanding of the interfaces of these layers can lend to better performing devices using a multitude of organic polymers deposited in conjunction with each other in several ways. We have studied basic PLED devices in which we vary the emissive layer used, along with final bake temperatures. Devices include a glass substrate with Indium Tin Oxide anode, Aluminum cathode, and Plexcore Hole Injection layer. The active polymer films were spin casted from solution of MEH-PPV and PFO. Single layer and dual layers of several polymers are studied by examining current-voltage characteristics, film densities, impedance measurements, light emission, and efficiency calculations. We have found that not only do dual layers positively alter the performance of the device in the majority of cases, but the solvents in which each layer is originally in when deposited affects the formation of the interface, thereby altering the device mechanisms.

9:12AM F33.00005 Color change in organic light-emitting diodes using the magnetic field effect

, TEK BASEL, DALI SUN, BHOJ GAUTAM, Department of Physics and Astronomy, University of Utah, Salt Lake City, UT 84112, EITAN EHRENFREUND, Physics Department, Technion-Israel Institute of Technology, Haifa, Israel, Z. VALY VARDENY, Department of Physics and Astronomy, University of Utah, Salt Lake City, UT 84112 — The magnetic field effect has been widely used to generate magneto-electroluminescence (MEL) in organic light-emitting diodes (OLEDs). We have used the MEL effect to change the emission color from OLED in which the active layer is composed of a host polymer with fluorescence (FL) emission and a guest, heavy atom-based molecule with phosphorescence (PH) emission. The color change has been studied as a function of the guest/host weight ratio, and the optimal ratio was determined. The underlying mechanism of the magnetic-field induced color change is the difference that exists between the MEL intensity of the FL emission band respect to that of the PH emission band. The MEL difference between the two types of emission bands will be thoroughly discussed within models used to explain the MEL in organic devices. Research sponsored by National Science Foundation-Material Science & Engineering Center (NSF-MRSEC), University of Utah.

9:24AM F33.00006 Highly efficient organic light-emitting diodes by delayed fluorescence

, CHIHAYA ADACHI, Kyushu University — Although typical organic molecules only contain carbon (C), hydrogen (H), nitrogen (N) and oxygen (O) atoms, the unique bonding of C involving sp3, sp2 and sp hybrid orbitals enables generation of very complicated molecular architectures that have extensive functions in a wide variety of organisms and industrial products. In the last two decades, the allure of the unlimited freedom of design of organic molecules has shifted a significant proportion of electronics research from inorganic into organic materials. In particular, great advances have been achieved in organic light-emitting diodes (OLEDs). First-generation OLEDs containing fluorescent molecules have progressed to second-generation ones using phosphorescent molecules, which is an attractive design for practical electronics. Herein, new organic electroluminescent (EL) molecules lacking precious metals are presented. The energy gap between the singlet (S1) and triplet (T1) excited states is minimized by strategic design, promoting highly efficient spin up-conversion from T1 to S1 states while maintaining a high radiative decay rate of >106/s, leading to a high fluorescence efficiency of $>90\%$. Using these unique molecules, a very high external EL efficiency of $>19\%$ is realised, which is comparable to those of high-efficiency phosphorescence-based OLEDs. These molecules harvest both singlet and triplet excitons for light emission through fluorescence decay channels. We call this new luminescence concept "hyperfluorescence."

10:00AM F33.00007 Kinetic Monte Carlo simulation of organic devices , ALISON WALKER, EDWARD WRIGHT, University of Bath — At Bath, we have developed a model of organic devices that links morphology (packing arrangements) to device characteristics. The model, based on the dynamical Monte Carlo approach pioneered in surface physics, allows us to include interaction processes between different species on many different timescales. In this talk I will show how we have used this approach to compare organic solar cells of rod, blend and gyroid morphologies and to model the influence of interlayers, layers added to improve efficiency and lifetime, in organic light emitting devices, OLEDs. We have developed the model to allow it to distinguish between triplet and singlet excitons and allows for the interactions of these species (triplet-triplet annihilation, triplet-singlet annihilation, triplet-polaron quenching). I will show our predictions for current-voltage-illumination characteristics (solar cells) and current-voltage-luminance characteristics (OLEDs). I will also show how through prediction of emission zone profiles in an OLED, we can gain insight into what determines changes in OLED efficiency with current and how in the longer term this approach can be used to address degradation.

10:12AM F33.00008 Carrier Conduction and Light Emission by Modification of Poly(alkylfluorene) Interface under Vacuum Ultraviolet Light Irradiation[1] , YUTAKA OHMORI, HIROTAKE KAJII, DAIKI TERASHIMA, YUSUKE KUSUMOTO, Osaka University — Organic field effect transistors (OFETs) have been extensively studied for flexible electronics. The characteristics of poly(9,9-dioctylfluorenyl-2,7-dyl) (F8) modified by thermal or light are strongly dependent on the carrier transport and optical characteristics. We investigate all solution-processed OFETs with Ag nano-ink as gate electrodes patterned by Vacuum Ultraviolet (VUV) (172 nm). Bi-layer gate insulators of amorphous fluoro-polymer CYTOP (Asahi Glass Corp.) and poly(methylmethacrylate) (PMMA) were used. Top-gate-type OFETs with ITO source/drain electrode utilizing F8 or poly(9,9-dioctylfluorene-co-benzothiadiazole) (F8BT) as an active layer were fabricated, and investigated the carrier conduction and emission characteristic. Without VUV irradiation, both OFETs showed the ambipolar and light-emitting characteristics. On the other hand, F8 devices with VUV exhibited only p-type conduction. The quenching centers were generated in F8 layer by VUV irradiation, which are related to the electron trap sites at the interface. OFETs with F8BT showed both p- and n-type conduction even after VUV. F8BT suffers less damage by VUV and maintain light emission. Light emitting transistors were realized utilizing F8BT patterned by VUV irradiation.

[1]This research was partially supported financially by MEXT. The authors thank Harima Chemicals Inc. for providing Ag nano-ink.

Session F34 DPOLY DCMP DBIO: Charged Colloids with Short-Range Attractions I 342 - Yun Liu, University of Delaware/NIST

8:00AM F34.00001 POLYMER PHYSICS PRIZE BREAK –

8:36AM F34.00002 A colloidal perspective of protein solutions manipulated by multivalent ions: Phase behavior and associated dynamics , FRANK SCHREIBER, Tuebingen University — After a brief overview of interactions in aqueous protein solutions, we will discuss how ions can be used to manipulate these interactions and the associated phase behavior as well as the diffusion dynamics. We show that multivalent ions do not only influence the ionic strength and the resulting interactions including effective attraction, but lead to qualitatively new effects. Particular attention will be given to the reentrant condensation of proteins (F. Zhang et al, PRL 101 (2008) 148101; F. Zhang et al, Soft Matter 8 (2012) 1313) and its relationship with liquid-liquid phase separation and protein crystallization. In particular, we attempt to rationalize crystallization controlled by trivalent ions and discuss the role of specific ions and their impact on the effective interaction potential. These results are compared to the diffusion dynamics in these systems studied using neutron spectroscopy and light scattering (F. Roosen-Runge et al, PNAS 108 (2011) 11815; Heinen et al, Soft Matter 8 (2012) 1404) and the question of transient clusters is discussed. Finally, we critically discuss to which extent proteins can be described by colloidal concepts. The work was performed in collaboration with F. Zhang, T. Seydel, M. Hennig, F. Roosen-Runge, M. Skoda, R. Jacobs and others.

9:12AM F34.00003 ABSTRACT WITHDRAWN –

9:24AM F34.00004 Protein clusters in biomembranes , NICOLAS DESTAINVILLE, University Paul Sabatier - Toulouse 3 — We propose that proteins embedded in lipidic bio-membranes can spontaneously self-organize into stable membrane nano-domains (or clusters), due to the competition between short-range attractive and longer-range repulsive forces between proteins, specific to these systems, and propagated by the lipidic membrane. We compare different long-range potentials (including notably three-body terms) and we demonstrate that the existence of cluster phases in this context should be quite generic. Furthermore, a real membrane contains hundreds of different protein species that are far from being randomly distributed in these nano-domains, which is crucial in terms of biological functions. We take this protein diversity into account by modulating protein-protein interactions both at short and longer range. Both theoretical and numerical investigations explain why protein clusters recruit only a few protein species, thus leading to cluster biological specialization. In this respect, we highlight that cluster phases can turn out to be an advantage at the biological level, for example by enhancing the cell response to external stimuli.

9:36AM F34.00005 Assembly of Spherical Colloids by Short-range Out-of-plane Attraction and Long-range In-plane Repulsion , FUDUO MA, DAVID T. WU, NING WU, Colorado School of Mines — The electric-field assembly of spherical colloids with isotropic surface properties has been studied in both two- and three- dimensions. Structures, such as FCC, HCP, and BCT crystals were observed. Recently, we have found surprisingly new types of structures within a previously unexplored experimental regime: low frequency regime (100 Hz to 10 kHz) and low salt concentrations (below 10^{-4} M). At low particle concentrations, a family of well-defined clusters, ranging from 3 to 10 was observed. Statistical analysis of the population distribution reveled non-trivial peaks for trimers, tetramers, hexamers, and nonamers. We attribute these new types of non-planar structures to a short-range out-of-plane (the plane refers to the substrate) attraction and a long-range in-plane repulsion. For example, the double layer and in-plane dipolar repulsion could make bottom particles in the clusters separate from each other. While the out-of-plane dipolar attraction and particle-substrate attraction could be responsible for the formation of the clusters, i.e., the top central sphere is associated with the bottom spheres. Phase diagrams from experiments and simulation will be compared. These clusters could be used as building blocks for making photonic crystal, filtration, and plasmonic structures.

9:48AM F34.00006 Colloidal stability in concentrated electrolyte solutions using large counterions , GUILLERMO GUERRERO GARCIA, Department of Materials Science, Northwestern University, Evanston, IL 60208, USA, PEDRO GONZALEZ MOZUELOS, Departamento de Fisica, Cinvestav del I. P. N., Av. Instituto Politecnico Nacional 2508, Distrito Federal, C. P. 07360, Mexico, MONICA OLVERA DE LA CRUZ, Department of Materials Science, Northwestern University, Evanston, IL 60208, USA — The stability of charged colloids in solution has been widely studied because it has ubiquitous applications in science and engineering. According to the classical DLVO theory, the electrostatic repulsion among charged colloids is significantly screened at high electrolyte concentrations. As a result, highly charged particles are expected to aggregate due to short-range van der Waals attractive interactions. Nevertheless, the classical DLVO theory relies in the linear Poisson-Boltzmann equation, which is usually restricted to low electrolyte concentrations and weakly charged colloids. In this work, we propose a novel mechanism beyond the classical DLVO picture that uses large counterions to prevent highly charged nanoparticles from aggregating in salt solutions with concentrations up to 1 M, in agreement with experimental observations.

10:00AM F34.00007 Size and interaction-strength effects on the phase behavior of colloidal particle assemblies , RAY SEHGAL, DAVID FORD, DIMITRIOS MAROUDAS, University of Massachusetts Amherst — We report the findings of a systematic computational study of the inherently complex phase behavior of thermodynamically small assemblies (clusters) of colloidal particles interacting via a potential that includes electrostatic repulsion and depletion-based short-ranged attraction. Using Monte Carlo umbrella sampling with coarse graining in two order parameters and a biasing scheme based on a genetic algorithm, we generate free-energy landscapes (FELs) that can indicate coexistence between fluid-like and crystalline phases. We have used the data mining technique of diffusion mapping to determine the dimensionality of the order-parameter space and assess the suitability of chosen order parameters that represent metrics of cluster density and crystallinity. Evaluation of phase behavior metrics from analysis of the FELs leads to predictions of conditions for formation of stable phases of such small colloidal clusters. A stable crystalline phase emerges as the number of particles in the assembly increases beyond a critical value. We find that the critical cluster size for the onset of crystallization decreases with increasing strength of the interparticle attraction. This FEL analysis also enables a mean-field description of the phase transitions undergone by these assemblies.

10:12AM F34.00008 Distinguishing cluster phases as a unique scenario of intermediate range order in colloidal suspensions and protein solutions , PAUL DOUGLAS GODFRIN, University of Delaware, RAMON CASTAÑEDA-PRIEGO, Universidad de Guanajuato, YUN LIU, National Institute of Standards and Technology, NORMAN J. WAGNER, University of Delaware — A state of stable clusters is characterized by the reversible aggregation of colloidal particles to a finite, energetically favored size. Clusters can arise from a competition between short range attraction, driving aggregation, and long range repulsion, stabilizing clusters. Recent interest in systems with these interactions has brought attention to the formation of a low-q peak in the structure factor and the proposition that this peak directly indicates cluster formation. To understand the structures that produce a low-q peak, Metropolis Monte Carlo simulations are performed to calculate the partial structure factors by decomposing the system into cluster-cluster, monomer-monomer, and cross-correlations. We find that a low-q peak appears in fluids with strong cluster-cluster correlations but also in systems dominated by monomer-monomer correlations and percolated states. Thus, this low-q peak is more appropriately termed the intermediate range order (IRO) peak. Consequently, an IRO peak does not necessarily signal the existence of a cluster state in solution. Rather, it reflects the presence of a preferred length scale related to the two competing potential features. Determining cluster formation is most accurately accomplished by combining experiment with simulation.

10:24AM F34.00009 Clustering and state diagram of charged colloids with short-range attraction in shear flows , ALESSIO ZACCONE, Cavendish Laboratory, University of Cambridge, MASSIMO MORBIDELLI, Department of Chemistry, ETH Zurich — Under static conditions, the superposition of short-range (e.g. van der Waals) attraction and electrostatic repulsion gives rise to interesting phases such as equilibrium clusters in globular protein suspensions. What is much less understood is their behavior under external flow, which is important for the physiological aggregation of proteins and for industrial systems as well. I will present theoretical and experimental results showing that clustering of these systems in shear flow is characterized by the crossover from a reaction-limited clustering kinetics at low shear into a convection-dominated aggregation regime at high Peclet numbers. The kinetics may rise by up to many orders of magnitude in the crossover regime. This behavior is due to the singularly-perturbed character of the governing diffusion equation where the shear drift term induces a singularity and a boundary-layer at large interparticle distances. This understanding, together with a theoretical description of cluster breakup, is used to rationalize the peculiar nonequilibrium state diagram (including gelation) of these colloidal suspensions in shear flow with applications ranging from microfluidic self-assembly to proteins.

10:36AM F34.00010 Percolation and local density fluctuations for a Colloidal System with competing interactions , NESTOR VALADEZ-PEREZ, NIST Center for Neutron Research and Science and Engineering Division, University of Guanajuato, YUN LIU, NIST Center for Neutron Research and Department of Chemical and Biomolecular Engineering, University of Delaware, RAMON CASTANEDA-PRIEGO, Science and Engineering Division, University of Guanajuato — The gelation is believed to result from the particle aggregation in a complex structure. The aggregate span in the entire volume gives it a capability for supporting stresses. Gelled systems possess a high degree of inhomogeneity, while locally the particles and their near neighbors present a defined array as can be seen in their coordination number and bonding angles. Using Monte Carlo simulations, we investigate the structure of a system of hard spheres interacting through a combined potential: a short-ranged Square Well (SW) and a long-ranged repulsive Yukawa potential (RY). We made an exhaustive study for several conditions of temperature (T*) and concentration (φ) corresponding to different repulsion strengths (A). Our results show that the percolation threshold is shifted to lower concentrations when the repulsion is increased, but this shift gradually disappears at low temperature. Besides we also computed the local density through the system; we particularly identified a length scale at which the density fluctuations are attenuated. This length coincides with the intermediated range order recently identified in protein systems.

10:48AM F34.00011 Drag coefficient of an electrophoretic colloidal particle , KATHRYN REDDY, Fordham University, MING-TZO WEI, Lehigh University, JOEL A. COHEN, University of the Pacific, H. DANIEL OU-YANG, Lehigh University — Electrophoretic mobility is a measure to determine the electric charges on a colloidal particle. Zeta potential, a concept originated by Smoluchowski, has been a standard for quantifying the surface charge density for the electric double-layers that are thin compared to the particle radius. Various models have been suggested to improve Smoluchowski's theory for systems with Debye length not thin compared to the particle radius. Central to the issue is that the fluid flow due to the external field-induced counter-ion motion is unknown. Using optical tweezers to trap a colloidal particle in a low-frequency electric field, we found the drag coefficient of the particle in the field to be non-Stokes. We discuss how the non-Stokes' drag coefficient as a function of salt concentration and particle size may be useful for interpreting different models of Zeta potential.

Tuesday, March 19, 2013 8:00AM - 11:00AM –

Session F35 DMP: HTSC: ARPES and TR-ARPES 343 - Lex Kemper, Lawrence Berkeley National Laboratory

8:00AM F35.00001 Determinining the Critical Condition for Superconductivity in $Bi_2Sr_2CaCuO_{8+\delta}$, T. REBER, S. PARHAM, Y. CAO, J. WAUGH, H. LI, University of Colorado, N. PLUMB, Paul Scherrer Institute, Q. WANG, Los Alamos National Lab, G. GU, Brookhaven National Lab, Y. YOSHIDA, Y. AIURA, H. EISAKI, AIST, G. ARNOLD, D. DESSSAU, University of Colorado — Using the tomographic density of states (TDoS) ARPES-based technique we present a detailed study of the temperature and doping dependences of the pair-forming, represented by the gap magnitude (Δ), and pair-breaking, represented by the scattering rate (Γ), processes in BSCCO. We find that Δ is finite through the superconducting transition, T_C, and ceases only at the higher temperature T_{Pair}, which corresponds with the T_{Onset} from Nernst experiments rather than the T* tied to the antinodal pseudogap. Furthermore, we find Γ is large and strongly temperature dependent and T_C is strongly correlated with the ratio of Δ/Γ. Consequently, the presence of pairs is not sufficient for superconductivity: the pair-breaking processes must also be diminished to the point that pairs have a long enough lifetime to develop long range coherence.

8:12AM F35.00002 The Effects of Impurities and Disorder on the ARPES lineshapes of Bi2212 , STEPHEN PARHAM, THEODORE REBER, YUE CAO, JUSTIN WAUGH, HAOXIANG LI, University of Colorado, Z. XU, J. SCHNEELOCH, R.D. ZHONG, GENDA GU, Brookhaven National Lab, HIROSHI EISAKI, Tokyo University, DANIEL DESSAU, University of Colorado — We present a study of $Bi_2Sr_2CaCuO_8$ doped with various magnetic impurities, Fe and Ni. Through the use of our Tomographic Density of States or TDoS technique, we show that these magnetic impurities decrease the lifetime of the Cooper pairs in this material, while leaving the superconducting gap essentially unchanged. These effects are masked using traditional MDC/EDC analyses and thus our results highlight the usefulness of the TDoS technique. Even without impurities, there is gap disorder in these materials that is readily seen in STM experiments. This gap disorder affects the TDoS lineshape, and we show that the disorder predicted from our TDoS technique is consistent with that measured through STM.

8:24AM F35.00003 Observation of symmetry-distinct states proximate to the Fermi level in a high-Tc cuprate family , RUI-HUA HE, Stanford U/Boston College, M. HASHIMOTO, Stanford U/SLAC, K. TANAKA, Osaka U, A. SORINI, Stanford U, S.-K. MO, ALS/LBNL, T. SASAGAWA, TIT, M. FUJITA, T. ADACHI, M. ENOKI, S. IIKUBO, Tohoku U, N. MANNELLA, U Tennessee, HONG YAO, Tsinghua U, M. YI, Stanford U, W. MEEVASANA, SUT, Y. HE, Stanford U, K. YAMADA, Y. KOIKE, Tohoku U, T. P. DEVEREAUX, SLAC, Z. HUSSAIN, ALS/LBNL, Z.-X. SHEN, Stanford U/SLAC — Current understanding of cuprate superconductivity is based exclusively on an effective one-band electronic band structure formed by states of in-plane dx2-y2 symmetry. By studying the La-based cuprates with polarization-dependent angle-resolved photoemission spectroscopy, here we uncovered another group of states of distinct c-axis symmetry that coexists with the dx2-y2-symmetry states near the Fermi level and eluded previous detection. As functions of momentum and doping, these new states show overall different dispersion relations yet a qualitatively similar low-energy (pseudo)gapping behavior as the dx2-y2-symmetry states, until they become closely degenerate above $\sim$20% doping.

8:36AM F35.00004 Fine doping and temperature dependent ARPES study in deeply undersoped LSCO system , YU HE, Department of Applied Physics, Stanford University; SIMES, RUIHUA HE, Department of Physics, Boston College, MAKOTO HASHIMOTO, SLAC, SUNG-KWAN MO, LBNL, SEIKI KOMIYA, Central Research Institute of Electric Power Industry, Japan, ZHI-XUN SHEN, Department of Applied Physics, Stanford University; SIMES — Deeply underdoped cuprates are known to be a host system for strong electron-phonon coupling physics. Set in the picture of lightly doped Mott insulator, extremely underdoped cuprates show prevailing evidence of polaron formation, as a natural result of strong bosonic interaction, which have gained support from both optical and transport measurements. Based on K. Shen and O. Roesch's pioneering work, we further studied fine doping and temperature dependence in the low-doping LSCO system, where antiferromagnetism and spin glass phases still persist. In this work, we will discuss the change in Fermi velocity in terms of doping, evolution of nodal gap as function of temperature and the possible contribution from lattice/spin degree of freedom in light of the small polaron's existence. Comparison with similar observations in manganites and iron-chalcogenides will be discussed to further address the ubiquity of the polaron physics in strongly correlated electron systems.

8:48AM F35.00005 Laser-ARPES studies of dispersion kinks in cuprate phase diagram , I.M. VISHIK, Stanford University, M. HASHIMOTO, Stanford Synchrotron Radiation Lightsource, S. JOHNSTON, IFW Dresden, W.-S. LEE, F. SCHMITT, R.G. MOORE, Stanford Institute for Materials and Energy Sciences, D.H. LU, Stanford Synchrotron Radiation Lightsource, T. SASAGAWA, Tokyo Institute of Technology, S. UCHIDA, S. ISHIDA, University of Tokyo, K. FUJITA, Cornell University, M. ISHIKADO, Japan Atomic Energy Agency, Y. YOSHIDA, H. EISAKI, National Institute of Advanced Industrial Science and Technology, Japan, R.-H. HE, Boston College, Z. HUSSAIN, Lawrence Berkeley National Laboratory, T.P. DEVEREAUX, Z.-X. SHEN, Stanford Institute for Materials and Energy Sciences — Angle-resolved photoemission spectroscopy (ARPES) reveals ubiquitous dispersion kinks in cuprates which are manifestations of electron-boson coupling, potentially related to the superconductivity pairing mechanism. We report new temperature-, momentum-, and doping- dependent laser-ARPES measurements of the energy and coupling strength of the ubiquitous kink near 70 meV in $Bi_2Sr_2CaCu_2O_{8+\delta}$ (Bi-2212). The apparent kink energy below T_c is related to the mode energy modulo the maximum of the d-wave superconducting gap, and the pseudogap similarly needs to be considered above T_c. Following improvements in data quality as well as recent comprehensive gap measurements throughout the phase diagram, we can better assess the phenomenology and origin of dispersion anomalies.

9:00AM F35.00006 Autocorrelation of ARPES Spectra in the Pseudogap State of the Underdoped Curpates[1] , JONATHAN RAMEAU, Brookhaven National Lab, HONGBO YANG, Stony Brook University, CHERISE BURTON, University of the Virgin Islands, TIM KIDD, University of Northern Iowa, MAURICE RICE, ETH Zurich, PETER JOHNSON, Brookhaven National Lab — It has long been known that the normal state of the underdoped cuprate high T_c superconductors is characterized by a pseudogap in the anti-nodal region of the Brillouin zone and a set of disconnected set of excitations at the chemical potential, in the nodal region, known as Fermi arcs. Recently, quantum oscillation and angle resolved photoemission spectroscopy (ARPES) experiments have indicated that these Fermi arcs actually represent one side of a Fermi surface reconstructed into nodal hole pockets. These pockets, as well as a number of consequences of their formation, have been shown to be well described by the phenomenological model of Yang Rice and Zhang (YRZ) for the single particle Green's function. Here, we show how the autocorrelation of ARPES spectra - so-called AC-ARPES – acquired in the normal pseudogap state of the cuprates may be used to examine this phenomenon.

[1]This work was supported by the Center for Emergent Superconductivity, an Energy Frontier Research Center funded by the US DOE, Office of Basic Energy Sciences.

9:12AM F35.00007 Examining Spin Fluctuations Pairing Model From Angle Resolved Photoemission Spectra[1] , VIVEK MISHRA, Materials Science Division, Argonne National Laboratory, Lemont, IL 60439, U. CHATTERJEE, Department of Physics, University of Virginia, Charlotteville, VA 22904, J.C. CAMPUZANO, Materials Science Division, Argonne National Laboratory, Lemont, IL 60439 and Department of Physics, University of Illinois, Chicago, IL 60607, M.R. NORMAN, Materials Science Division, Argonne National Laboratory, Lemont, IL 60439 — The mechanism of superconductivity is a long standing puzzle in the cuprates. Among various proposed models, pairing through the exchange of spin fluctuations is one of the leading candidates. Here we use spectral functions measured from angle resolved photoemission spectroscopy to calculate this pairing interaction within a random phase approximation, and then determine whether for a reasonable choice of the Hubbard parameter 'U', we obtain a reasonable T_c.

[1]This work was supported by the Center for Emergent Superconductivity, an Energy Frontier Research Center funded by the US DOE, Office of Science, under Award No. DE-AC0298CH1088.

9:24AM F35.00008 Weak doping dependence of nodal transverse velocity in underdoped cuprates: explanation and significant implications[1] , WEI KU, Brookhaven National Laboratory — Recent high resolution angular resolved photoemission spectroscopy has revealed a surprising nearly doping-independent transverse velocity in the nodal region of underdoped cuprates [1,2], in great contrast to the strong doping dependent superconducting transition temperature. This behavior is qualitatively incompatible with standard Bogoliubov quasi-particle picture currently employed in the field, and implies a fundamentally new regime of physics. Here, we will show analytically that this novel behavior follows naturally the recently derived kinetic nature of the quasi-particle gap in the strong binding limit [3]. This realization further confirms the strong pairing nature of the superconductivity and the novel nature of superconducting gap in underdoped cuprates. This study also suggests the crucial need for future experiments in the overdoped regime. [1] PRL 104, 207002 (2010) [2] PNAS 109, 18332 (2012) [3] PRX 1, 011011 (2011)

[1]Work supported by DOE DE-AC02-98CH10886.

9:36AM F35.00009 Deduction of the self-energy and bosonic spectrum of Bi2212 from ARPES experiments , JIN MO BOK, HAN-YONG CHOI, Sungkyunkwan University, JUNFENG HE, X.J. ZHOU, Chinese Academy of Sciences, CHANDRA M. VARMA, University of California, Riverside — We analyzed the ARPES intensity of slightly underdoped (T_c=89K)and overdoped (T_c=82K) Bi2212 superconductors. The diagonal and off-diagonal self-energy, Σ and ϕ, were extracted by performing MDC (momentum distribution curve) fitting using superconducting Green's function at the tilt angle θ with respect to the nodal direction. Using the extracted self-energy as input, the Eliashberg function $\alpha^2F^{(+)}$ and $\alpha^2F^{(-)}$ corresponding to Σ and ϕ were deduced by inverting the d-wave Eliashberg equation. Our main results are follows: (1) The deduced Eliashberg functions are similar for slightly underdoped and overdoped Bi2212. (2) The Eliashberg function $\alpha^2F^{(+)}$ has two peaks at 15meV and 50meV. Both peaks were enhanced as the tilt angle increases or temperature decreases. The Eliashberg function $\alpha^2F^{(-)}$ has one peak at 15meV. Its energy scale is almost the same as the energy scale of the low energy peak of $\alpha^2F^{(+)}$. Then, we will compare our results with other experiments and modal calculations.

9:48AM F35.00010 Quantum Monte Carlo simulations of ARPES spectra on correlated materials with electron-phonon coupling , ELIZABETH NOWADNICK, Stanford University and SLAC National Accelerator Laboratory, STEVEN JOHNSTON, University of British Columbia, BRIAN MORITZ, Stanford University and SLAC National Accelerator Laboratory, RICHARD SCALETTAR, University of California at Davis, THOMAS DEVEREAUX, Stanford University and SLAC National Accelerator Laboratory — Results from a variety of experiments have revealed the importance of the electron-phonon interaction in strongly correlated electron materials. In particular, ARPES experiments on the cuprates have observed signatures of polaron formation in the underdoped regime, indicative of strong electron-phonon coupling, as well as "kinks" in the dispersion in the doped compounds, which have been interpreted in a phonon picture. In order to study the role of electron-phonon coupling in strongly correlated systems, we simulate the single-band Hubbard-Holstein model using determinant quantum Monte Carlo, an approach that allows the non-perturbative study of strongly interacting systems, and treats the electron-electron and electron-phonon interactions on an equal footing. We present electronic spectral functions, which can be compared to ARPES results, as well as phonon spectral functions, which shed light on phonon renormalizations. In particular, we focus on an antiferromagnetic—charge density wave transition that occurs in the Hubbard-Holstein model at half filling, and present signatures of an emergent intermediate metallic phase that occurs between the two insulating phases. We also discuss the influence of phonons on the electronic dispersion.

10:00AM F35.00011 Phonon-mode couplings studied by pump-probe photoemission[1] , MICHAEL SENTEF, Stanford Institute for Materials and Energy Science (SIMES), SLAC National Accelerator Laboratory, Menlo Park, CA 94025, USA, ALEXANDER KEMPER, Lawrence Berkeley National Lab, 1 Cyclotron Road, Berkeley, CA 94720, USA, BRIAN MORITZ, Department of Physics, Northern Illinois University, DeKalb, IL 60115, USA, JAMES FREERICKS, Department of Physics, Georgetown University, Washington, DC 20057, USA, ZHI-XUN SHEN, THOMAS DEVEREAUX, Stanford Institute for Materials and Energy Science (SIMES), SLAC National Accelerator Laboratory, Menlo Park, CA 94025, USA — Motivated by recent pump-probe photoemission experiments on cuprate superconductors, we show how the coupling of electrons to phonon modes at the same time leads to a prominent kink in the equilibrium band dispersion and to a distinct behavior of relaxation time scales in nonequilibrium experiments. Here, using the nonequilibrium solution of a model photoexcited electron-phonon system we show that the return of the electrons to equilibrium is governed by the equilibrium self-energy so that the phonon frequency sets a window for"slow" versus "fast" relaxation. The overall structure of the relaxation spectroscopy in the time domain allows for a reliable and quantitative extraction of the electron-phonon coupling strength.

10:12AM F35.00012 Probing Many-Body Interactions in High-Tc Superconductor $Bi_2Sr_2CaCu_2O_{8+\delta}$ using Time- and Angle-Resolved Photoemission , TRISTAN MILLER, Department of Physics, University of California Berkeley, WENTAO ZHANG, Material Sciences Division, Lawrence Berkeley National Laboratory, CHRISTOPHER JOZWIAK, Advanced Light Source, Lawrence Berkeley National Laboratory, CHRISTOPHER SMALLWOOD, Material Sciences Division, Lawrence Berkeley National Laboratory, HIROSHI EISAKI, Electronics and Photonics Research Institute, National Institute of Advanced Industrial Science and Technology, DUNG-HAI LEE, Department of Physics, University of California Berkeley, ALESSANDRA LANZARA, Material Sciences Division, Lawrence Berkeley National Laboratory — Laser-based time- and angle-resolved photoemission spectroscopy (trARPES) is a technique that uses an initial laser pulse to pump a system, and a second pulse to probe it by photoemission. By using trARPES on the high temperature superconductor, $Bi_2Sr_2CaCu_2O_{8+\delta}$, we open a window into its many-body quasiparticle interactions. Here we report on the effect of pumping on the quasiparticle band structure of $Bi_2Sr_2CaCu_2O_{8+\delta}$. We will discuss the dynamics of this effect, and its relation to the superconducting state.

10:24AM F35.00013 Gap Dynamics in Bi2212 Studied by Time- and Angle-Resolved Photoemission , CHRISTOPHER SMALLWOOD, Department of Physics, UC Berkeley; and Materials Sciences Division, Lawrence Berkeley National Lab, WENTAO ZHANG, Materials Sciences Division, Lawrence Berkeley National Lab, TRISTAN MILLER, Department of Physics, UC Berkeley; and Materials Sciences Division, Lawrence Berkeley National Lab, CHRIS JOZWIAK, Advanced Light Source, Lawrence Berkeley National Lab, HIROSHI EISAKI, Electronics and Photonics Research Institute, National Institute of Advanced Industrial Science and Technology, ALESSANDRA LANZARA, Department of Physics, UC Berkeley; and Materials Sciences Division, Lawrence Berkeley National Lab — Recent developments in ultrafast spectroscopy have shown that irradiating cuprate superconductors with intense, short pulses of light can induce nonequilibrium dynamics that may hold clues for understanding why the critical temperature (Tc) in these materials exceeds that of almost all other superconductors by an order of magnitude or more. Using a 1.5 eV pump pulse, and 5.9 eV probe, we use time- and angle-resolved photoemission spectroscopy (trARPES) to characterize the non-equilibrium dynamics of the gap and transient quasiparticle population in the cuprate superconductor Bi2212 (optimally doped, Tc=91 K). Correlations between these two quantities reveal clues for the underlying mechanism that drives the formation of the pseudogap and superconducting states in the hole-doped cuprates.

10:36AM F35.00014 Time-resolved Ultrafast Spectroscopy Experiments on High Temperature Superconductor Bi2Sr2CaCu2O8 , JIANQIAO MENG, Condensed Matter and Magnet Science, Materials Physics and Applications Division, Los Alamos National Laboratory, Los Alamos NM, 87545, GEORGI L. DAKOVSKI, SLAC National Accelerator Laboratory, Menlo Park, CA 94025-7015, USA, JIAN-XIN ZHU, Physics of Condensed Matter and Complex Systems, Theoretical Division, Los Alamos National Laboratory, Los Alamos NM, 87545, USA, PETER S. RISEBOROUGH, Department of Physics, Temple University - Philadelphia, PA 19122, USA, GENDA GU, Condensed Matter Physics & Materials Science, Brookhaven National Laboratory, Upton, NY 11973, USA, STEVE M. GILBERTSON, GEORGE RODRIGUEZ, JINGBO QI, ANTOINETTE TAYLOR, Center for Integrated Nanotechnologies, Materials Physics and Applications Division, Los Alamos National Laboratory, Los Alamos NM, 87545, USA, TOMASZ DURAKIEWICZ, Condensed Matter and Magnet Science, Materials Physics and Applications Division, Los Alamos National Laboratory, Los Alamos NM, 87545 — Time-resolved ultrafast spectroscopy experiments have been carried out on various dopings of high temperature superconductor Bi2Sr2CaCu2O8In this talk, we will report our observation and analysis of ultrafast dynamics in Bi2Sr2CaCu2O8, with special emphasis on the quasiparticle dynamics in the pseudogap and SC gap regimes.

10:48AM F35.00015 Probing the Nodal Dynamical Electronic States in $Bi_2Sr_2CaCu_2O_8$ by Time- and Angle- Resolved Photoemission[1] , WENTAO ZHANG, Materials Sciences Division, Lawrence Berkeley National Laboratory, Berkeley, CA, CHRIS SMALLWOOD, TRISTAN MILLER, Department of Physics, University of California, Berkeley, CA 94720, USA, CHRIS JOZWIAK, Advanced Light Source, Lawrence Berkeley National Laboratory, Berkeley, CA, HIROSHI EISAKI, Nanoelectronics Research Institute (NeRI), National Institute of Advanced Industrial Science and Technology (AIST) Umezono 1-1-1 Tsukuba, Ibaraki 305-, DUNG-HAI LEE, ALESSANDRA LANZARA, Department of Physics, University of California, Berkeley, CA 94720, USA — Ultra-high resolution time- and angle- resolved photoemission (trARPES) measurements have been carried out on various dopings of $Bi_2Sr_2CaCu_2O_8$ high temperature superconductor. In this talk, we will report on the study of the dynamical quasiparticle excitation and recombination of the nodal electronic states in cuprate. The power of trARPES will be discussed in this talk.

Session F36 DCMP: Superconductivity: Josephson Effect 344 - Carmen Almasan, Kent State University

8:00AM F36.00001 High Temperature Superconducting Terahertz Emitters with Various Mesa Structures[1] , KAVEH DELFANAZARI, M. TSUJIMOTO, T. KASHIWAGI, Univ. of Tsukuba, CREST-JST, WPI-MANA, H. ASAI, AIST, T. KITAMURA, Univ. of Tsukuba, CREST-JST, WPI-MANA, T. YAMAMOTO, JAEA, M. SAWAMURA, K. ISHIDA, C. WATANABE, S. SEKIMOTO, H. MINAMI, M. TACHIKI, T. HATTORI, Univ. of Tsukuba, CREST-JST, WPI-MANA, R. A. KLEMM, Univ. of Central Florida, USA, K. KADOWAKI, Univ. of Tsukuba, CREST-JST, WPI-MANA — In 2007, the first observation of the coherent terahertz (THz) electromagnetic (EM) waves from a mesa structures of intrinsic Josephson junctions (IJJs) in high temperature superconductor $Bi_2Sr_2CaCu_2O_{8+\delta}$ (Bi-2212) is reported [1]. The ac-Josephson effect as well as the cavity resonance conditions is considered as the principle mechanism of the THz radiation [1, 2]. In order to understand the cavity effect in THz radiation from IJJ mesas more clearly, we studied mesas with various geometries; various kinds of triangles [3], and pentagonal mesas with various sizes and thicknesses. The focused ion beam (FIB) milling technique is used in all mesa fabrications. In this talk, we discuss our recent progress in THz emission observation in pentagonal mesas.

8:12AM F36.00002 Tunable THz radiation from intrinsic Josephson junctions in $Bi_2Sr_2CaCu_2O_{8+\delta}$ in a localized phase rotating mode[1] , MANABU TSUJIMOTO, KAVEH DELFANAZARI, TAKEO KITAMURA, MASASHI SAWAMURA, KAZUYA ISHIDA, SHUNSUKE SEKIMOTO, CHIHARU WATANABE, University of Tsukuba, TAKASHI YAMAMOTO, Japan Science and Technology Agency, TAKANARI KASHIWAGI, HIDETOSHI MINAMI, KAZUO KADOWAKI, University of Tsukuba — After the first report of intense continuous THz electromagnetic wave radiation from high-T_c superconductor $Bi_2Sr_2CaCu_2O_{8+\delta}$ [L. Ozyuzer *et al.*, Science **318**, 1291 (2007)] with remarkably higher intensity, a great deal of interest has been drawn not only to the physical mechanism of the radiation but also to the possible variety of applications in the vast fields of THz science and technology. Recently, the authors pointed out that the contributions to the output power from the Josephson current source was found to be comparable in magnitude [K. Kadowaki *et al.*, J. Phys. Soc. Jpn. **79**, 023703 (2010); M. Tsujimoto *et al.*, Phys. Rev. Lett. **108**, 107006 (2012)]. As R. Kleiner *et al.* observed in 1992 [R. Kleiner *et al.*, Phys. Rev. Lett. **68**, 2394 (1992)], the intrinsic junctions in the phase rotating mode produce an equal number of I-V characteristic branches. Here we show clear evidence that the mesas can emit radiation at many frequencies in various localized phase rotating modes, and that the resulting radiation is tunable over a broad range of frequencies, allowing us to construct a powerful THz source device that could fill the THz gap.

[1]JST-CREST, WPI-MANA

8:24AM F36.00003 Direct imaging of hot spot in $Bi_2Sr_2CaCu_2O_{8+\delta}$ mesa terahertz sources[1] , TIMOTHY BENSEMAN, KEN GRAY, ALEXEI KOSHELEV, WAI-KWONG KWOK, ULRICH WELP, VITALII VLASKO-VLASOV, Materials Science Division, Argonne National Laboratory, KAZUO KADOWAKI, HIDETOSHI MINAMI, University of Tsukuba, Japan — Stacks of intrinsic Josephson junctions (IJJs) made from high-temperature superconductors such as $Bi_2Sr_2CaCu_2O_{8+\delta}$ (Bi-2212) are a promising source of coherent continuous-wave terahertz radiation. When electrical power is applied to these devices, it is thought that hot spots may form due to resistive self-heating, and that these spots may be highly beneficial for the generation of high levels of THz power from Bi-2212 stacks. In order to better understand these hot spots, we have performed a thermal imaging study of BSCCO stacks which generate approximately 50 microwatts of radiation power at 0.59 THz. Utilizing the temperature-dependent 612nm fluorescence line of Eu^{3+}, we are able to directly measure the temperature distribution at the top surface of these stacks with a resolution of +/- 1K. The images reveal a highly non-uniform temperature distribution in which the temperature in the middle of the stack can exceed the superconducting transition temperature by tens of Kelvin under biasing conditions typical for THz-emission.

[1]This research was funded by the Department of Energy, Office of Basic Energy Sciences, under Contract No. DE-AC02-06CH11357.

8:36AM F36.00004 Magnetic field effects on THz radiation from $Bi_2Sr_2CaCu_2O_{8+\delta}$ mesa structures[1]

, TAKEO KITAMURA, TAKANARI KASHIWAGI, MANABU TSUJIMOTO, KAVEH DELFANAZARI, MASASHI SAWAMURA, KAZUYA ISHIDA, SHUNSUKE SEKIMOTO, CHIHARU WATANABE, University of Tsukuba, TAKASHI YAMAMOTO, Japan Atomic Energy Agency, HIDETOSHI MINAMI, MASASHI TACHIKI, KAZUO KADOWAKI, University of Tsukuba — In a previous our study, coherent and continuous electromagnetic radiation phenomena in mesa structures of $Bi_2Sr_2CaCu_2O_{8+\delta}$ single crystal have been investigated precisely in magnetic fields up to only 150 Oe [1]. This experimental result showed that the emission intensity decreases sharply for the field parallel to the c-axis, while it decreases gradually as increasing magnetic field for the in-plane field. In order to improve the measurement, we developed a new system with a better angular resolution and much wider magnetic field range up to 6 T, and a mesa having much stronger THz emission power. The mesa structure is also changed to the stand-alone type of mesa, which produces higher power THz radiation with ideal distribution of radiation [2]. In this presentation, the recent detailed results will be shown in magnetic fields both parallel and perpendicular to the *ab*-plane of Bi2212, where the Josephson and pancake vortices are playing an important role for THz radiation.

8:48AM F36.00005 Simultaneous observation of temperature distribution and THz emitting spectra of Bi2212 THz devices

, CHIHARU WATANABE, HIDETOSHI MINAMI, University of Tsukuba, TAKASHI YAMAMOTO, Quantum Beam Science Directorate, TAKANARI KASHIWAGI, KAZUO KADOWAKI, University of Tsukuba — When the intrinsic Josephson junctions in high-T_c superconductor $Bi_2Sr_2CaCu_2O_{8+\delta}$ are fabricated to a mesa structure and biased by a dc-voltage, it is known to emit coherent, stable and continuous THz electromagnetic waves [1] whose frequency lies between 0.3-1 THz with the line width of 0.5 GHz and the radiation maximum power of 30 μW. Recently, we have succeeded in measuring the temperature distribution of the mesa directly while the mesa is emitting THz radiation and found an extreme temperature inhomogeneity (hot-spot) in the mesa [2]. By this way, we could determine the temperature of a mesa, as a result we could observe inhomogeneous temperature distribution, and we found that relation between THz emitting characteristics and temperature distribution. The simultaneous observation of the emission frequency by FTIR strongly indicates that the THz emission phenomenon is not influenced by the formation of the hot-spot at all. In this meeting, we would like to discuss the relations between THz emission phenomena hot-spot formation.

9:00AM F36.00006 ABSTRACT WITHDRAWN –

9:12AM F36.00007 Control of Spin-Triplet Josephson Junctions with Perpendicular Anisotropy[1]

, ERIC GINGRICH, Michigan State University, SIMON DIESCH, University of Konstanz, WILLIAM PRATT, NORMAN BIRGE, Michigan State University — We present recent work on S/F'/F/F"/S Josephson Junctions with the magnetic multilayer Ni/[Co/Ni]$_n$ as the central F layer [1]. This multilayer possesses strong intrinsic perpendicular (out-of-plane) anisotropy at Co and Ni thicknesses of a few monolayers. If a hard ferromagnet is used for F', and a softer ferromagnet is used for F", both with magnetizations in plane, the direction of the F" layer's magnetization is predicted to control the state of the junction [2]. We are fabricating such junctions with the goal of controllably switching the junction between the 0 and π states. By integrating these junctions in a SQUID device, a measurement of the 0and π state of the junction can be performed. We will report on our progress.

9:24AM F36.00008 Search for $\pi/2$ state in large-area spin-triplet ferromagnetic Josephson junctions[1]

, YIXING WANG, NORMAN O. BIRGE, WILLIAM P. PRATT, JR., Department of physics and Astronomy, Michigan State University — The current-phase relationship of ferromagnetic spin-triplet Josephson junctions was predicted to be tuned by the magnetization orientations of different magnetic layers [1]. Given the random domain structure in large-area ferromagnetic junctions, the possibility of a random distribution of 0 or π sub-junctions across the area could lead to a global $\pi/2$ junction [2]. Critical current measurements as a function of area provide indirect evidence for $\pi/2$ coupling [3], but they do not provide phase-sensitive information. Unfortunately there are technical difficulties faced by a direct current-phase measurement, especially for large area junctions. We are currently working toward a SQUID-based experiment that should be able to distinguish the $\pi/2$ state from either the 0 or π states. In this talk we will report our progress toward this goal. 9:36AM F36.00009 Odd-Frequency Triplet Josephson Current Through an Exchange Spring[1]

, ANDREAS BILL, California State University Long Beach, THOMAS E. BAKER, California State University Long Beach and University of California, Irvine, ADAM RICHIE-HALFORD, ADAM K. MOKE, California State University Long Beach — The existence of an odd-frequency long range triplet component in the order parameter of a proximity system with singlet superconductors is a recent prediction that has garnered great interest. The experimental fingerprint of this phenomenon is difficult to establish. We investigate a hybrid structure in which the emergence of the long range triplet component may be measured and identified. We consider a superconductor - exchange spring - superconductor Josephson junction as a function of increasing twist of the magnetic domain wall in the exchange spring. We show that as the domain wall is generated the long range triplet component emerges and modifies the current flowing through the Josephson junction. The critical temperature is also affected by the increased twist of the domain wall. The calculations lead us to propose an experiment where the long range triplet component can unequivocally be identified.

9:48AM F36.00010 Spin-triplet supercurrent in planar geometry ferromagnetic Josephson junctions[1] , WILLIAM M. MARTINEZ, W.P. PRATT, JR., NORMAN O. BIRGE, Michigan State University — The spin-triplet supercurrent in ferromagnetic Josephson junctions is obtained by surrounding the central ferromagnet with noncollinear ferromagnetic layers, F' [1]. In metallic ferromagnets, the long-range nature of the spin-triplet supercurrent has only been tested to lengths of a few tens of nm [2]. In this work, we are fabricating and measuring S/F'/F/F'/S junctions where the central F layer has a lateral geometry with lengths up to a few hundred nm. We will report on our recent progress.

10:00AM F36.00011 Skewness and Kurtosis of the Switching Current Distribution in Superconductor-Graphene-Superconductor Junctions and Superconductor-Nanowire-Superconductor Devices , ANDREW MURPHY, THOMAS AREF, ULAS COSKUN, University of Illinois Urbana-Champaign, PHILLIP WEINBERG, ALEX LEVCHENKO, Michigan State University, VICTOR VAKARYUK, The Johns Hopkins University, ALEXEY BEZRYADIN, University of Illinois Urbana-Champaign — We study statistical properties of the switching current in superconductor-graphene-superconductor proximity junctions and superconductor-nanowire-superconductor devices. The fluctuations of the switching current are related to Little's phase slips, generated by thermal and quantum fluctuations of the superconducting order parameter. The study focuses on higher moments of the statistical probability distributions of the switching current. Namely we study the skewness, which defines the asymmetry of the distribution, and kurtosis, which is a measure of the "peakedness." The skewness is defined as sk= $m_3/m_2^{3/2}$ where m_2 is the second moment of the distribution, called the variance, and m_3 is the third moment. Kurtosis is defined as kur= m_4/m_2^2, where m_4 is the fourth moment of the distribution. It is known that for Gaussian distributions sk=0 and kur=3. On our devices we find, in most cases, sk $\sim$ -1 and kur $\sim$ 5. These results are in agreement with numerical simulations as well as an analytic model. Finally we present preliminary experimental results for a two-nanowire device. We have found that the standard deviation, skewness and kurtosis of the switching current distributions in these devices vary periodically with magnetic field.

10:12AM F36.00012 Realization of short ballistic vertical graphene Josephson junction , GIL-HO LEE, HU-JONG LEE, POSTECH — We realized short ballistic vertical graphene Josephson junctions (vGJJs), where a monolayer graphene sheet is sandwiched between two superconducting electrodes along the c-axis of graphene. To enhance the transparency between electrodes and graphene layer we thermally deposited aluminum superconducting electrodes on both surfaces of the graphene sheet by using a "flip-transfer" scheme instead of transferring graphene onto the bottom electrode. With the highly transparent contacts and atomically short channel length, vGJJ shows a very large value of I_cR_N product ($2.2\Delta_{Al}$). This value is in sharp contrast to much suppressed value of $I_cR_N < \Delta_{Al}$, observed in planar graphene Josephson junctions. Surprisingly, I_c decreases superlinearly with increasing temperature (T) from 50 mK up to the junction critical temperature, which is a typical character of a short ballistic Josephson junction. To our best knowledge, this feature has long been predicted but never been reported in proximity-coupled Josephson junctions. I_c-T curve fits well to the short ballistic Josephson junction model (KO-2)[1] with the transparency of 0.94.

10:24AM F36.00013 Direct measurements of the current-phase relation in graphene Josephson junctions , CHRISTOPHER ENGLISH, DAVID HAMILTON, DALE VAN HARLINGEN, NADYA MASON, University of Illinois at Urbana-Champaign — The current-phase relation (CPR) of a Josephson junction can provide key information about the microscopic processes and symmetries that control the supercurrent. In this talk, we present CPR measurements on Josephson junctions incorporating single-layer graphene as a weak link between Al superconducting electrodes with spacing <100nm that are in the quasi-ballistic regime. We use a phase-sensitive SQUID technique to determine the supercurrent amplitude and phase as a function of temperature and electrostatic doping (gate voltage). As the critical current is varied, we observe a crossover from forward skewing in the CPR that arises from the low density of discrete electronic states in the junction to backward skewing induced by noise-rounding in the CPR measurement. We compare our results to theoretical models.

10:36AM F36.00014 Josephson currents in semiconductor nanowire / s-wave superconductor nanostructures , LI MAO, Department of Physics, the University of Texas at Dallas, Richardson, TX, 75080 USA, SUMANTA TEWARI, Department of Physics and Astronomy, Clemson University, Clemson, SC, 29634 USA, CHUANWEI ZHANG, Department of Physics, the University of Texas at Dallas, Richardson, TX, 75080 USA — It has been theoretically predicted that a nanostructure composing of a semiconductor nanowire with strong spin-orbit coupling and an s-wave superconductor can support two Majorana fermions at the ends of the nanowire in the presence of a Zeeman field. Recently, following the theoretical proposals, some preliminary experimental signatures (e.g., zero-bias conductance peak) which may be related to the existence of Majorana fermions have been observed in the charge transport experiments. Here we investigate the Josephson currents with the zero-bias voltage in the topologically trivial region of a superconductor-insulator-superconductor junction in the presence of strong spin-orbit coupling and Zeeman field. This structure may be relevant to the Delft experiment by considering the possible proximity effect of the superconductor lead to the normal part of the nanowire. Our results indicate that the experimentally observed zero-bias conductance peak may not originate from Majorana fermions.

Tuesday, March 19, 2013 8:00AM - 11:00AM –

Session F37 DMP DCOMP: Focus Session: Fe-based Superconductors: Order Parameter Symmetry/Fe(Te,Se) Films 345/346 - Qiang Li, Brookhaven Natl Lab

8:00AM F37.00001 Symmetry measurements of the order parameter of $BaFe_2As_2$ superconductors[1] , JUAN ATKINSON, DALE VAN HARLINGEN, University of Illinois at Urbana-Champaign, PAUL CANFIELD, Iowa State University, DUCK CHUNG, Argonne National Laboratory — Since the discovery of the Fe-pnictide superconductors, extensive efforts have been directed toward understanding the symmetry and mechanism of the superconducting pairing. Extended s-wave models, predominately the s$\pm$ model, are predicted by many theories, but a definitive experimental verification has been elusive. We are using phase-sensitive Josephson interferometry to test for magnitude and phase anisotropy in electron (Co-doped) and hole (K-doped) $BaFe_2As_2$ single crystals. In particular, we are looking in the heavily K-doped regime that is predicted to exhibit d-wave symmetry characterized by a sign change in the order parameter. We are also searching for proximity-induced structure in the density-of-states of an s-wave superconductor proximity-coupled to an Fe-pnictide superconductor that is predicted to arise for s$\pm$ pairing (Koshelev, 2012).

[1]DOE BNL 150252 Center for Emergent Superconductivity

8:12AM F37.00002 Sign-changing nodal s-wave gap in heavily over doped $(Ba_{1-x}K_x)Fe_2As_2$ evidenced from thermal-transport measurement , DAIKI WATANABE, SHIGERU KASAHARA, TAKUYA YAMASHITA, TAKUMI OTA, TAKASADA SHIBAUCHI, YUJI MATSUDA, Department of Physics, Kyoto University, MINORU YAMASHITA, RIKEN, HIDETO FUKAZAWA, TAKU SAITO, YOH KOHORI, Department of Physics, Chiba University, SHIGEYUKI ISHIDA, KUNIHIRO KIHO, CHUL-HO LEE, AKIRA IYO, HIROSHI EISAKI, AIST, Tsukuba, ANTON VORONTSOV, Department of Physics, Montana State University — The superconducting state of hole-doped Fe-based superconductors, $(Ba_{1-x}K_x)Fe_2As_2$, changes from a fully-gapped state near the optimally doping ($x \sim$0.5) to a nodal one at the end material (x= 1)[1,2]. Here we report the results of thermal-transport measurements for heavily overdoped x=1, 0.93, 0.88, 0.76 crystals and discuss the doping evolution of the superconducting gap. For x=0.88, 0.93 and 1, the T-dependence of thermal conductivity in zero field shows a finite κ_0/T in the zero-temperature limit. In low magnetic fields, κ/T ($T \rightarrow 0$ K) increases as $\propto \sqrt{H}$. These results indicate the presence of gap nodes in the gap function. We find that the residual κ_0/T exhibits a non-monotonic x-dependence, which is inconsistent with d-wave symmetry. We show that the observed x-dependence can be explained by nodal s-wave pairing with sign change between zone centered hole pockets. [1] K. Hashimoto *et al.*, Phys. Rev. B **82**, 014526 (2010). [2] K. Okazaki *et al.*, Science **337**, 1314 (2012).

8:24AM F37.00003 Angle Dependent Specific Heat Study of $BaFe_2(As_{0.7}P_{0.3})_2$, LIAM MALONE, University of Bristol, YUTA MIZUKAMI, Kyoto University, PHILIP WALMSLEY, University of Bristol, S. KASAHARA, T. SHIBAUCHI, Y. MATSUDA, Kyoto University, ANTONY CARRINGTON, University of Bristol — The structure of the superconducting gap of the pncitide superconductors is an unresolved but crucial issue to understanding their mechanism of superconductivity. While some experiments and theories support a fully gapped s+/s- state, several experiments have revealed evidence for nodes in some families of pnictides. Detailed knowledge of the superconducting gap structure and how it varies between different families can be useful in helping to decide between microscopic theories. $BaFe_2(As_xP_{1-x})_2$ is a pnictide family where penetration depth and thermal conductivity measurements show evidence for nodes [1]. We have measured the specific heat of a single crystal of $BaFe_2(As_{0.7}P_{0.3})_2$ ($T_c \sim$29 K) at low fields and as a function of applied field angle. The angle dependence of specific heat at low fields and low temperature is expected to show minima whenever it is along a nodal direction and can be used to differentiate between gap symmetries [2]. Our results show a clear angle dependent component consistent with the presence of nodes and we discuss the implications on the gap structure of $BaFe_2(As_{0.7}P_{0.3})_2$.

8:36AM F37.00004 Isotropic superconducting gap structure in BaFe1.90Pt0.10As2 from low temperature thermal conductivity[1] , KEVIN KIRSHENBAUM, Center for Nanophysics and Advanced Materials, Dept. of Physics, University of Maryland, College Park, SHANTA SAHA, National Institute for Standards and Technology, Gaithersburg, MD, STEVEN ZIEMAK, RONGWEI HU, Center for Nanophysics and Advanced Materials, Dept. of Physics, University of Maryland, College Park, JEAN-PHILIPPE REID, RYAN GORDON, LOUIS TAILLEFER, Universite de Sherbrooke, Sherbrooke, QC, JOHNPIERRE PAGLIONE, Center for Nanophysics and Advanced Materials, Dept. of Physics, University of Maryland, College Park — In this study we present measurements of thermal transport down to 50 mK in single crystals of the iron-based superconductor BaFe1.90Pt0.10As2 with Tc = 23 K [1]. Magnetic fields up to 15 T were applied along the c-axis of the crystal as well as along the basal plane direction to probe the anisotropy of the superconducting gap. The lack of any significant residual electronic term in thermal conductivity for all field directions and values confirms the absence of nodes and places limits on the depth of gap minima in this system.

8:48AM F37.00005 Investigation of Pairing Symmetry in Pt-Substituted BaFe2As2[1] , S. ZIEMAK, K. KIRSHENBAUM, S.R. SAHA, R. HU, J. PAGLIONE, University of Maryland, College Park, Center for Nanophysics and Advanced Materials, J.-PH. REID, R. GORDON, L. TAILLEFER, Universite de Sherbrooke, A. IGNATOV, D. KOLCHMEYER, G. BLUMBERG, Rutgers University, D. EVTUSHINSKY, S. THIRUPATHAIAH, S.V. BORISENKO, IFW-Dresden — We present results from several measurements on BaFe1.9Pt0.1As2 single crystals designed to measure the superconducting gap structure. Low temperature thermal conductivity was measured in magnetic fields up to 15 T and will be compared to other materials. Point-contact Andreev reflection spectroscopy measurements were made using the needle-anvil technique and the spectra analyzed using BTK theory. Raman spectroscopy was used to probe excitations in multiple channels. Finally, angle-resolved photoemission spectroscopy was used to provide further information about the band structure and superconducting gap. We will discuss the implications that the combination of these results reveal about the superconducting order parameter in this system.

[1]Work at Maryland was supported by AFOSR-MURI FA9550-09-1-0603; at Rutgers by US DOE, Office of BES, Award DE-SC0005463; and at Dresden by DFG grants BO 1912/3-1 (SPP1458) and BO 1912/2-2.

9:00AM F37.00006 In-plane transport anisotropy study of oxygen doped iron telluride MBE thin films on LaAlO3 substrate[1] , CAN ZHANG, HUIHUO ZHENG, MAO ZHENG, BRIAN MULCAHY, XIAOXIAO WANG, University of Illinois at Urbana Champaign, YING JIA, ULRICH WELP, Argonne National Laboratory, JAMES ECKSTEIN, University of Illinois at Urbana Champaign — FeTe is well known for its simple crystal structure in the 11 family iron-based high temperature superconductors. We have observed two distinct in-plane transport phenomena in MBE grown FeTe thin films on LaAlO3 substrates. The first one is an unexpected global alignment of the in-plane transport anisotropy. A low temperature resistivity upturn feature has been observed in the neighborhood of the superconducting transition temperature as a function of transport direction. The resistivity upturn feature emerges from 8K to 20K. The second one is the coexistence of superconductivity with the low temperature resistivity upturn. We will report our studies of these distinct transport anisotropy experimental results comparing them with first principle simulations.

[1]This material is based upon work supported as part of the Center of Emergent Superconductivity, an Energy Frontier Research Center funded by the U.S. DoE, Office of Science, Office of Basic Energy Sciences under Award Number DE-AC0298CH10.

9:12AM F37.00007 Electric transport properties in FeSe0.3Te0.7 / Au c-axis tunneling junctions , YU TIEN SHEN, YOU SHENG LI, CHENG CHUNG CHI, None, DEPARTMENT OF PHYSICS, NATIONAL TSING HUA UNIVERSITY TEAM — Currently favored pairing symmetry in the iron-based superconductor is the nodaless S+- wave. Based on this theory, the conductance spectra of the normal metal to superconductor tunneling junctions do not exhibit ZBCP. We report the fabrication and the transport properties of c-axis tunneling junctions formed by FeSe0.3Te0.7 (FeSeTe) and Au. When FeSeTe is in its normal state, the conductance spectrum shows a V-shape background; while when FeSeTe becomes superconducting, the conductance spectrum shows some remarkable features: First, a pronounced ZBCP was obtained as temperature is just below Tc, and when the temperature was further decreased to below 4K, a clear double peak structure appears; Second, there were two dip structures at around 4 and 20mV. We found out that there is a linear dependence of the voltage difference between the double peaks versus applied field. Though the origin of the ZBCP, the double peak structure, and the dip structures were unclear and still under investigation, we believe that they all related to the superconducting gaps due to their dependence on applied magnetic fields and temperature. The existence of the prominent ZBCP is not consistent with the proposed S+- wave symmetry of the superconducting gap.

9:24AM F37.00008 New bi-epitaxial Grain boundary Josephson Junction of $FeSe_{0.3}Te_{0.7}$[1] , YOU-SHENG LI, Institute of Physics, Academia Sinica, Y.T. SHEN, Department of Physics, National Tsing Hua University, M.J. WANG, Institute of Astrophysics and Astronomy, Academia Sinica, M.K. WU, Institute of Physics, Academia Sinica, C.C. CHI, Department of Physics, National Tsing Hua University — We have successfully fabricated epitaxial $FeSe_{0.3}Te_{0.7}$films on MgO substrate with its in-plane crystalline axis either parallel to or rotated 45° with respect to the MgO lattice. We use this technique to fabricate the 45° grain-boundary Josephson junction. The IV-curve measured at 4.2 K can be fitted with the RSJ model, and the measured $I_cR_n$value is 9.24μV, which is in general agreement with the values obtained by previous results for Fe-based grainboundary junctions on bi-crystal substrates. We have also measured the dc Josephson current as a function of applied magnetic fields, which shows a clear Fraunhofer-like pattern. Hence we can rule out the possibility of d-wave symmetry in $FeSe_{0.3}Te_{0.7}$ superconductor. Upon applying 6 GHz microwave irradiation, the junction IV curve exhibits clear Shapiro steps. Thus we have demonstrated our ability to fabricate high quality grain-boundary Josephson junctions of this new class of material. Further physical properties, such as the noise power spectrum, are currently being investigated.

[1]We would like to acknowledge the support from grants of NSC 101-2112-M-007-013 and NSC 99-2112-M-001-028-MY3

9:36AM F37.00009 The tunneling spectra and superconducting gaps observed by using scanning tunneling microscopy near the (100)/(110) grain-boundary of FeSe0.5Te0.5 films , KUANG CHENG LIN, YOU-SHENG LI, CHENG-CHUNG CHI, National Tsing Hua University, NATIONAL TSING HUA UNIVERSITY TEAM — We have found that, using PLD method, the a- and b-axis of the $FeSe_{0.5}Te_{0.5}$ film deposited on pristine MgO substrate are parallel to those of MgO, while these axes of the film grown on MgO substrate treated with Ar-ion milling rotate 45° along its c-axis. Here, we prepared such film with two kinds of orientations (0° and 45° ab plane with respect to the substrate axis) on MgO substrate with the connection between them form a ramp at an angle about 30° to the substrate plane. We used STM to study the tunneling spectra of two orientations of c-axis planes and the connection ramp between them. In the planar region with different orientation, we have observed similar tunneling spectra with a superconducting gap about 5 meV. This gap value is consistent with the previous studies of a variety of FeSeTe samples. However, a much larger gap about 18 meV is observed in the ramp region. The only paper we found to have such a large gap in the family of Fe-based superconductors is the one by Xue et.al. They have shown a gap of 20 meV in one unit-cell thick of FeSe on STO substrate. Furthermore, we have also observed a small ZBCP inside the large gap at 4.3K. The ZBCP becomes smaller with increasing temperature and disappears near and above TC.

9:48AM F37.00010 Transport properties of transition-metal substituted FeTe0.65Se0.35 single crystals[1] , VALERIY L. BEZUSYY, DARIUSZ J. GAWRYLUK, ARTUR MALINOWSKI, MAREK BERKOWSKI, MARTA Z. CIEPLAK, Inst. of Physics, PAS, Warsaw, Poland — We use the ab-plane resistivity and Hall effect measurements to evaluate the influence of substitutions on the superconductivity and normal-state transport in $Fe_{1-y}M_yTe_{0.65}Se_{0.35}$ single crystals, where M=Co, Ni or Cu. The crystals, with $0 < y < 0.11$, are grown by Bridgman's method. We find that the Co impurity induces markedly different effects than the other two impurities. Superconducting transition temperature (T_c) is suppressed with the rate of about 1.3 K per at.% of Co impurity, while the rate is about 3.5 and 4 times larger in case of Ni and Cu, respectively. The resistivity at the T_c onset remains almost unaffected by Co doping, while it increases substantially for Ni and Cu. The Hall constant (R_H) is positive for all samples, indicating that hole carriers dominate the transport. However, while the R_H is gradually suppressed towards zero with increasing Co content suggesting that electron doping occurs, it remains almost unchanged by Ni or Cu doping, suggesting that these impurities are rather of isovalent nature. The implications of these results will be discussed.

[1]Supported by EC through the FunDMS Advanced Grant of the ERC (FP7 Ideas), by the Polish NCS grant 2011/01/B/ST3/00462, and by the French-Polish Program PICS 2012. Performed in the laboratories co-financed by NanoFun Project POIG.02.02.00-00-025/09.

10:00AM F37.00011 $FeSe_{0.5}Te_{0.5}$ thin film Josephson junction on $SrTiO_3$ bicrystal substrates , WEIDONG SI, CHENG ZHANG, XIAOYA SHI, QIANG LI, Brookhaven Natonal Laboratory — Josephson junctions were fabricated in the epitaxial $FeSe_{0.5}Te_{0.5}$ thin films on [100] tilted $SrTiO_3$ bicrystal substrates with a CeO_2 buffer layer. These junctions with a 24 degree of grain boundary misorientation show a typical resistive-shunt-junction like current-voltage behavior. Critical current densities across the grain boundary in these junctions were observed to be remarkably suppressed and modulated by the magnetic field. Films without the grain boundary show a critical current density much higher than those with the grain boundary. These results indicate a Josephson Effect in those grain boundary junctions.

10:12AM F37.00012 Planar tunnel junction on oxygen doped iron telluride thin films , MAO ZHENG, HAN ZHAO, CAN ZHANG, GUSTAF OLSON, BRIAN MULCAHY, University of Illinois at Urbana-Champaign, VALENTIN STANEV, ALEXEI KOSHELEV, Argonne National Laboratory Material Science Divsion, LAURA GREENE, JAMES ECKSTEIN, University of Illinois at Urbana-Champaign, UNIVERSITY OF ILLINOIS AT URBANA-CHAMPAIGN COLLABORATION, UNIVERSITY OF ILLINOIS AT URBANA-CHAMPAIGN COLLABORATION, ARGONNE NATIONAL LABORATORY MATERIAL SCIENCE DIVISION COLLABORATION — Since its discovery, iron based superconductivity has garnered much interest from the research community for its potential in both application and fundamental science. One of the questions awaiting an answer is the pairing symmetry of this new class of superconductors. Recently, Koshelev and Stanev proposed a fingerprint of s+- symmetry in the NIS tunneling spectrum where the iron based superconductor is proximity-coupled to a thin s-wave superconductor[1]. We have prepared oxygen doped iron telluride (FeTe:Ox) thin films, along with an in-situ grown tunnel barrier and top electrode by Molecular Beam Epitaxy (MBE). We have fabricated them into planar tunnel junction and will report the temperature dependence of both tunneling and point contact spectra. [1]. A. E. Koshelev and V. Stanev, EPL (Europhysics Letters) **96** (2), 27014 (2011).

10:24AM F37.00013 Non-Fermi liquid behavior in overdoped iron-pnictide Ba(Fe,Co,Ni)2As2[1] , ALEX HUGHES, YASUYUKI NAKAJIMA, KEVIN KIRSHENBAUM, SHANTA R. SAHA, TYLER DRYE, JOHNPIERRE PAGLIONE, Center for Nanophysics and Advanced Materials, Department of Physics, University of Maryland, College Park, MD 20742 — Very low-temperature specific heat was used to study a series of single-crystal iron-based intermetallic compounds with the ThCr2Si2 structure with transition metal substitution used to heavily over-dope the system. This system has been found to exhibit non-Fermi liquid characteristics in transport, magnetic and thermodynamic properties. We will present low-temperature specific heat capacity measurements of this compound in order to elucidate the non-Fermi liquid nature of the ground state and to help elucidate the origin of these properties and their relation to superconductivity.

[1]This work was supported by AFOSR-MURI FA9550-09-1-0603.

10:36AM F37.00014 Observation of a c-axis collapse in superconducting $FeTeO_x$ films below T_c[1] , LAHIRU NARANGAMMANA, University of Connecticut, Storrs, XUERONG LIU, Brookhaven National Laboratory, Upton, NY, YUEFENG NIE, Cornell University, Ithaca, NY, JOSEPH BUDNICK, University of Connecticut, Storrs, CT, CHRISTOF NIEDERMAYER, Paul Scherrrer Institut Villigen, PSI, Switzerland, JOHN HILL, GENDA GU, Brookhaven National Laboratory, Upton, NY, BARRETT WELLS, University of Connecticut, Storrs, CT — We compared the temperature dependent crystal structure of superconducting $FeTeO_x$ films and non superconducting $Fe_{1.02}Te$ single crystals. The primary difference between the two is that the superconducting $FeTeO_x$ films show a collapse of the c-axis below the superconducting transition temperature 13K. No such transition occurs in the single crystal. The room temperature structures of the two are similar and both show a tetragonal to monoclinic transition near 60K. Preliminary neutron diffraction studies indicate a suppression in antiferromagnetic order below T_c on superconducting $FeTeO_x$ thin films.

[1]Supported by DOE through contact DE-FG02-00ER45801.

10:48AM F37.00015 Effect of doping on the specific heat jump in iron-based superconductors[1] , DUSHKO KUZMANOVSKI, SAURABH MAITI, MAXIM VAVILOV, ANDREY CHUBUKOV, University of Wisconsin - Madison, Madison, WI, USA, FREDERIC HARDY, Karlsruhe Institute of Technology, Institute for Solid State Physics, 76021 Karlsruhe, Germany — In this talk we present a theoretical description of the jump of the specific heat at the transition to a superconducting phase of iron-based pnictides. We discuss both the overdoped regime, when the transition occurs between non-magnetic and superconducting phases, and the underdoped regime, when superconductivity emerges from a pre-emptive SDW phase. Both effects lead to a qualitatively similar phase diagram as a function of doping, but details differ. We presume that doping simultaneously modifies the Fermi surface of pnictides and introduces disorder. By fitting the transition temperatures for the SDW and SC phases, we establish the relative strengths of the the rigid band shift caused by doping and doping-induced disorder. We then evaluate the specific heat jump as a function of doping. Our theory is consistent with measurements made by Karlsruhe group of the specific heat jump in $BaFe_2As_2$ compounds with K- and Co-doping.

Tuesday, March 19, 2013 8:00AM - 11:00AM –

Session F38 FEd: Physics Education Programs, Policy and the Media 347 - Aaron Wade, University of West Florida

8:00AM F38.00001 Engaging community college students in physics research , MEGAN VALENTINE, MARIA NAPOLI, ARICA LUBIN, LIU-YEN KRAMER, OFELIA AGUIRRE, University of California, Santa Barbara, JENS-UWE KUHN, NICHOLAS ARNOLD, Santa Barbara City College — Recruiting talent and fostering innovation in STEM (Science, Technology, Engineering and Mathematics) disciplines demands that we attract, educate, and retain a larger and more diverse cohort of students. In this regard, Community Colleges (CC), serving a disproportionate number of underrepresented minority, female and nontraditional students, represent a pool of potential talent that, due to a misguided perception of its students as being less capable, often remains untapped. We will present our strategies to attract and support the academic advancement of CC students in the STEM fields through our NSF-sponsored Research Experience for Undergraduates program entitled Internships in Nanosystems Science Engineering and Technology (INSET). For more than a decade, INSET has offered a physics research projects to CC students. The key components of INSET success are: 1) the involvement of CC faculty with a strong interest in promoting student success in all aspects of program planning and execution; 2) the design of activities that provide the level of support that students might need because of lack of confidence and/or unfamiliarity with a university environment; and 3) setting clear goals and high performance expectations.

8:12AM F38.00002 Pathways to Excellence Scholarship Program for women in STEM fields[1] , JOSEPH DI RIENZI, Notre Dame of Maryland University — Notre Dame of Maryland University (NDMU) has an NSF S-STEM grant, Pathways to Excellence, that gives 10 scholarships annually to academically talented women undergraduates with demonstrated financial need who are pursuing degrees in mathematics, physics, computer information systems, or engineering. NDMU has been cited (Whitten, et al. (2007)) as providing a female friendly environment for the study of physics. In this program we are using a tri-part mentoring system involving a faculty member in the student's discipline, a peer mentor from the program and an external alumnae mentor. The program also has a thematic seminar course for the scholars. Each student in the program is tasked to construct a career development plan in assistance with her faculty mentor and set measured annual goals. In addition, all scholarship students are requested to have an experiential experience. As a result, NDMU aims to strengthen its role in increasing the numbers of well-educated and skilled women employees from diverse backgrounds, including mostly first-generation college students, in technical and scientific areas. Early assessment of the success of the program will be presented as well as modifications that resulted from the formative evaluation.

[1]This program is funded by a National Science Foundation S-STEM grant which is not responsible for its content.

8:24AM F38.00003 Diversity in Physics: Impact of Using Minimum Acceptable GRE Scores for Graduate Admissions[1] , CASEY W. MILLER, University of South Florida, Department of Physics — About 180 graduate programs in physics are listed in the AIP Graduate Programs book. $\sim$ 96% require the general GRE test; a quarter of these have an explicitly stated minimum score for admission, with the median stated cut-off being 700 (64^{th} percentile) on GRE Quantitative; $\sim$ 48% require the physics GRE; about half of these have an explicitly stated minimum score for admission, with the median being 600 (32^{nd} percentile). It does not seem unreasonable to expect students to be among the top test scorers, until you dissect the test results by race and gender. In this talk, I will present data showing that the use of minimum acceptable scores on the GRE exam will have (have had?) a negative impact on diversity in Physics. I will remind the community that this practice is in opposition to ETS's Guide to the Use of Scores. I will make some suggestions for admissions committees, based in part on analyses I have performed. I will then pose challenges related to reducing the influence of GRE scores to the community, ranging from the department and university administration, to ranking bodies and professional societies.

[1]Supported by NSF.

8:36AM F38.00004 Interdisciplinary Research and Education in STEM in a Discipline Dominated Academic Structure- Research and Education at the Cross Roads , SOLOMON BILILIGN, North Carolina A&T State University — Major issues in society - developing alternate sources of energy and a sustainable environment, improving health, and minimizing the effects of climate change require a collective effort by different disciplines working in interdisciplinary groups. Many major breakthroughs in science take place at the boundaries or intersections of disciplines. The need to create a new generation of students who combine a rigorous disciplinary depth with the ability to reach out to other disciplines and work in interdisciplinary teams is more urgent. There is a consensus that the current academic administrative structure is the most important barrier to interdisciplinary collaboration; other barriers like poor communication, etc., emanate from it. How can interdisciplinary education and research flourish while maintaining strong backgrounds in the disciplines? How can universities lower or remove barriers to faculty participation in interdisciplinary education and research and create porous, flexible, less redundant environment that facilitates the flow of ideas, people and resources across disciplinary boundaries? Is possible to have disciplines without disciplinary departments? In this short paper, the barriers and the challenges for developing interdisciplinary education and research will be summarized, lessons from some successful attempts and failures will be presented, and some approaches will be recommended for further discussion.

8:48AM F38.00005 Personifying self in physics problem situations involving forces as a student help strategy , A.E. TABOR-MORRIS[1], Georgian Court Univeristy — How can physics teachers best guide students regarding physics problem situations involving forces? A suggestion is made here to personify oneself as the object in question, that is, to pretend to be the object undergoing forces and then qualify and quantify those forces according to their vectors for the system at hand. This personification is not meant to empower the object to act, just to sense the forces it is experiencing. This strategy may be especially useful to beginning physics learners attacking problems that involve both multiple forces AND multiple objects, since each object acted upon needs to be considered separately, using the idea that one cannot be two places at once. An example of this type of problem expounded on here is Atwood's machine: two weights hung over a pulley with a single rope. Another example given is electromagnetic forces on one charge caused by other charges in the vicinity. Discussion is made on implementation of classroom strategies.

[1]Department of Physics

9:00AM F38.00006 High School Physics Teacher Outreach Programs at California State University Long Beach[1] , CHUHEE KWON, GALEN PICKETT, LAURA HENRIQUES, California State University Long Beach — One of the goals of the CSULB PhysTEC project has been to establish a physics teaching community that partners CSULB faculty, high school teachers, pre-service teachers, and physics students. In two years, we have created a solid sustainable Physics Teacher Network with local high school teachers. We will discuss the successful outreach programs for high school physics teachers at CSULB and the detailed logistics. Teacher-In-Residence (TIR), high school physics teachers working with the CSULB PhysTEC team, has provided invaluable input for designing and implementing outreach events. The department organizes biannual open house for local high school teachers and their students. The open house event is attended by pre-service teachers, physics undergraduate and graduate students, and faculty. We also host the monthly demo-sharing day that physics teachers bring and share topical demos, which has about 30 - 50 attendees each month. The CSULB PhysTEC project also distributes a monthly newsletter for local physics teachers with upcoming events and information about teaching, and this newsletter is organized and written by TIR.

[1]This work is supported by the PhysTEC grant.

9:12AM F38.00007 Using the science of granular materials to engage middle and high school students in the process of scientific enquiry[1] , JENNIFER PODEL, NALINI EASWAR, Smith College, Northampton, MA, SHUBHA TEWARI, KARL MARTINI, Western New England University, Springfield, MA, KRISTIN DOLCIMASCOLO, Amherst Regional Middle School, Amherst, MA, ERIC NEWMAN, Northampton High School, Northampton, MA — We describe outreach efforts that use the science of granular materials to engage middle and high school physics students in local public schools in scientific investigations. In the middle school, the students were provided with a set of questions, and starting materials to set up their experiments. Examples of investigations pursued by the students include looking at the influence of the size and shape of grains on (i) their rate of flow through a hopper and (ii) their tendency to desegregate in a flow. The high school students were introduced to the properties of granular materials via a series of activities that explored the complex behavior of these materials. Following this, groups of students were challenged to pose a question and design an experiment to investigate a particular aspect of the properties of granular materials. Examples of questions that the students chose to investigate include: How does the shape of grains influence how well they stack in a pile? What factors affect the probability of avalanches down an incline? Both sets of students worked in groups over a period of two months to take quantitative data to test their hypotheses. The investigations culminated in a set of presentations by the students to local faculty and students.

[1]Supported by APS Outreach grant and NSF DMR 0820506.

9:24AM F38.00008 Science Days: Graduate Student Run Outreach on a Budget[1] , JUSTIN K. PERRON[2], GEORGE P. LINDBERG, University at Buffalo, Department of Physics, Buffalo, NY 14260 — We will describe a new and ongoing program at the University at Buffalo (UB) aimed at exposing underrepresented K-12 students to the Science Technology Engineering and Math (STEM) fields. This program has been an entirely graduate student run effort, from idea to inception and finally through implementation. Graduate students, under supervision from faculty members, received a grant from NYSS-APS and matching funds from Physics, Chemistry, and Biology departments at UB. Graduate students set up an outreach program that buses students from inner city Buffalo to UB campus to participate in STEM-based activities. We have held two three hour events so far. Each event involved $\sim$30 students, 99% of which are from underrepresented demographics. Their responses to brief questionnaires showed overwhelming positive views of the event and their genuine interest in science. We will discuss what has made this program a success including what faculty members have done and can do, to support the effort while still leaving it entirely in the graduate students' hands.

[1]This project is funded by NYSS-APS- Graduate Science Days Award # 62313, The University at Buffalo/Buffalo Public School Interdisciplinary Science and Engineering Partnership Award # DUE-1102998

9:36AM F38.00009 Bringing education to your virtual doorstep , VITALIY KAUROV, Wolfram Research Inc. — We currently witness significant migration of academic resources towards online CMS, social networking, and high-end computerized education. This happens for traditional academic programs as well as for outreach initiatives. The talk will go over a set of innovative integrated technologies, many of which are free. These were developed by Wolfram Research in order to facilitate and enhance the learning process in mathematical and physical sciences. Topics include: cloud computing with Mathematica Online; natural language programming; interactive educational resources and web publishing at the Wolfram Demonstrations Project [1]; the computational knowledge engine Wolfram Alpha [2]; Computable Document Format (CDF) and self-publishing with interactive e-books; course assistant apps for mobile platforms. We will also discuss outreach programs where such technologies are extensively used, such as the Wolfram Science Summer School [3] and the Mathematica Summer Camp [4].

[3] http://www.wolframscience.com/summerschool
[4] http://www.mathematica-camp.org

9:48AM F38.00010 A Mobile Nanoscience and Electron Microscopy Outreach Program , TONYA COFFEY, KYLE KELLEY, Appalachian State University — We have established a mobile nanoscience laboratory outreach program in Western NC that puts scanning electron microscopy (SEM) directly in the hands of K-12 students and the general public. There has been a recent push to develop new active learning materials to educate students at all levels about nanoscience and nanotechnology. Previous projects, such as Bugscope, nanoManipulator, or SPM Live! allowed remote access to advanced microscopies. However, placing SEM directly in schools has not often been possible because the cost and steep learning curve of these technologies were prohibitive, making this project quite novel. We have developed new learning modules for a microscopy outreach experience with a tabletop SEM (Hitachi TM3000). We present here an overview of our outreach and results of the assessment of our program to date.

10:00AM F38.00011 The Good, The Bad, and The Ugly: Using Movies to Teach Science , JOANNE BUDZIEN, MacMurray College — Can the plane outrun the explosion? Could the heroes escape injury from the bomb by hiding in the bathtub? Are we in danger of being overrun by 50-foot-tall bugs that have been exposed to radiation? Many people in the general public do want to know the science behind much of what they see in the movies and on television. However, those people are unlikely to take a whole class because "everyone knows" that science classes are boring and irrelevant. On the other hand, an evening with an hour or so of video clips interspersed with explanations of the science can be a big hit both to raise general science fluency and recruit students into general education science classes. Film-editing technology has advanced to the point that anyone who has a computer and is willing to invest a couple days in learning to use the software can make a clips-with-PowerPoint DVD that can be shown to a local audience for discussion or used in a science class to show the exact scenes to save time. In this presentation, I'll show an example of my work and talk about how you can make your own DVD.

10:12AM F38.00012 The Physics of Babies , PHILIP SHEMELLA, Rensselaer Polytechnic Institute — Since the 2011 birth of my daughter I have been a 100% as a stay-at-home dad and 50% researcher. My "Routine Adventures" in the baby universe are the subject of this fun talk that presents the unique challenges of baby physics. Topics include "Schroedinger's Baby" and "The Entropy of Rice."

10:24AM F38.00013 An IYPT-based undergraduate physics tournament in China[1] , CHUANYONG LI, FENG SONG, YUBIN LIU, QIAN SUN, School of Physics, Nankai Universiy — International Young Physicists' Tournament (IYPT) is a team-oriented scientific competition of secondary school students. The participants present their solutions to scientific problems they have prepared over several months and discuss their solutions with other teams. It can also be implemented in university level as its physics problems are all open questions and have no standard answers, especially suitable for undergraduates' ability training in China. The annual tournament of physics learning of undergraduates in our school of physics was started in 2008. Each year, there are 15-18 teams, 20 more student volunteers and 30 more faculty jurors involved. The students benefited in different ways. It is project-based, requiring students to solve the problems in a research way. Team work is developed in both experimenting and discussing stages. The knowledge learned in classrooms can be used to solve these practical and life-related problems, raising their interest and initiative in physics learning. Finally, they are building up their skills in scientific presentation and communication. An IYPT-based program called CUPT (China undergraduate physics tournament) was launched in 2010 and annually attracts about 40 universities to attend. It gains its important role in physics education.

[1]National Fund for Talent Training in Basic Sciences (J1103208)

10:36AM F38.00014 Met The Press: What It's LIke to Talk to Reporters about Physics , REBECCA THOMPSON, American Physical Society — Someone from the Huffington Post just called you because they are doing a story about science and you are a physicist. The problem is that they need you to take time away from your grapheme experiments to talk about the physics of exploding anvils. It's been a long time since you've shot an anvil in the air so you think you might not be right for this. But, as long as you understand general physics and can explain things well, you can be a real asset. This talk will recount first-hand experiences talking to a range of news outlets from the PBS New Hour to Real Simple Magazine about everything from quick-freezing water to pumpkin boats. It will include helpful information about preparing for an interview, learning new physics fast, timelines and follow-up.

10:48AM F38.00015 Talking to Journalists about Your Research , JAMES RIORDON, American Physical Society — Many physicists have the opportunity to speak to members of the media from time to time. A journalist may want to ask about your work, or they may be in search of expert comments on the work of others in your field. I will offer some thoughts on ways to prepare for various types of interviews. I will also suggest some things you should always try to bring up in an interview, and others that you might want to avoid entirely. Finally, I will talk about what you can do when a reporter gets it wrong.

Tuesday, March 19, 2013 8:00AM - 10:48AM –

Session F39 GSCCM DCOMP DMP: Focus Session: Materials in Extremes: High Pressures

348 - Evan Reed, Stanford University

8:00AM F39.00001 Pressure-induced metallization and phase transitions in GeS_2[1] , RANGA DIAS, Department of Physics, Washington State University and Institute for Shock Physics, CHOONG-SHIK YOO, Department of Chemistry, Washington State University and Institute for Shock Physics — We have studied the pressure-induced structural and electronic phase transitions of crystalline GeS_2 ($P2_1/c$) to 50 GPa, using micro-Raman spectroscopy and electrical resistivity measurements in diamond anvil cells. The result shows a steady decrease in resistivity to that a metal at around 40GPa. The visual appearance of GeS_2 supports the insulator-metal transition: initially transparent GeS_2 becomes opaque and eventually reflective with increasing pressure. The Raman and X-ray diffraction result indicates that the metallization is preceded by a structural phase transition.

[1]The work has been supported by the NSF (DMR-1203834).

8:12AM F39.00002 Density Functional Theory Investigation of Sodium Azide at High Pressure , BRAD STEELE, AARON LANDERVILLE, IVAN OLEYNIK, University of South Florida — Sodium azide is intriguing because it could potentially be used as a precursor to a high-nitrogen energetic material. Furthermore, recent absorption and Raman spectroscopic results have shown that novel nitrogen structures may indeed be attainable from sodium azide. First-principles density functional theory calculations were performed to characterize possible novel crystalline structures of sodium azide including their atomic structure, vibrational properties, Raman spectra, and equation of state up to 90 GPa. Calculated Raman peaks and intensities show good agreement with experiment.

8:24AM F39.00003 Simple binary mixtures of hydrogen and ammonia under extreme pressures[1] , GUSTAV BORSTAD, Department of Physics, Washington State University and Institute for Shock Physics, CHOONG-SHIK YOO, Department of Chemistry, Washington State University and Institute for Shock Physics — Binary mixtures under pressure are of interest as fundamental systems in physics and chemistry as they allow the effects of the environment on the behavior of different chemical compounds to be examined. Furthermore, mixtures of simple molecular systems are of interest for applications in fuel cells and also to planetary science due to their presence in the interiors of the giant gas planets. In this presentation, Raman data on the ammonia and hydrogen system under pressure will be presented, and the extent and nature of the interactions in this mixture will be discussed.

[1]The work has been supported by NSF (DMR-0854618 and DMR-1203834); GB was also supported by the ISP scholarship at WSU.

8:36AM F39.00004 First-principles simulations on chemical transformation bonding pathways of compressed graphite , ANGUANG HU, FAN ZHANG, Defense R&D Canada-Suffield, Canada, Box 4000, Stn. Main Medicine Hat, Alberta, T1A 8K6 Canada — Chemical transformation bonding pathways for cubic diamond, hexagonal diamond, and cold compressed carbon has been investigated using first-principles simulations of the enthalpy minimization with various target pressures. The high-pressure bonding pathways of carbon from initial bonding conformations can be divided into three bonding evolution stages, which are defined as the van der Waals bonding destruction, bond breaking and forming reaction, and bonding equilibrium process. The principal stress tensor components were used to characterize the response of C-C bonds in graphite to compressive loading. It was found that the local stress field starts to rapidly increase towards the positive direction at the onset of the van der Waals bonding destruction. Bond breaking and forming reaction then takes place, leading to a cell volume collapse accompanied with a drop in stress components. The three bonding evolution stages demonstrated that the bonding evolution of the system towards chemical transformation under compression can be dictated by the local stress field together with the initial bonding conformation. Thus, the local stress field provides an understanding on how atoms and electrons move during the course of chemical transformation under compression.

8:48AM F39.00005 Thermo-Physical Properties of Ammonium Azide under High Pressure from First-Principles , AARON LANDERVILLE, BRAD STEELE, IVAN OLEYNIK, University of South Florida — Polynitrogen compounds offer tremendous promise for use as insensitive high-explosives or propellants. While the existence of such compounds have been observed in Diamond Anvil Cells (DAC) under high pressure, recovery to ambient pressure and temperature has proven problematic. A current thrust towards the recovery, and ultimate manufacture, of materials rich in polymeric nitrogen has brought renewed attention to various nitrogen-rich compounds, particularly crystalline azides, as possible precursors. We investigate the thermo-physical properties and Raman spectra of one azide candidate – ammonium azide – under hydrostatic compression using density functional theory with an empirical van der Waals correction. Additionally, we perform structural minima searches to discern possible polymorphs that may help to elucidate dynamical processes leading to the production of a material rich in polymeric nitrogen, as well as its recovery from DAC.

9:00AM F39.00006 Theory-driven discovery of an exotic CaB_6 high-pressure crystal structure phase , ALEKSEY KOLMOGOROV, Binghamton University, SUNY, SHEENA SHAH, ELENA MARGINE, University of Oxford, ANNETTE KLEPPE, Diamond Light Source, ANDREW JEPHCOAT, University of Oxford — We synthesized and solved an unexpectedly complex crystal structure of CaB6 under high pressures and temperatures [1]. The only known crystal structure in the large family of metal hexaborides, a simple cubic cP7 type, has been shown to transform into a tetragonal tI56 configuration comprised of unfamiliar 24-atom boron units above 30 GPa and remain metastable under ambient pressure. The interpretation of the convoluted x-ray diffraction pattern was accomplished with an ab initio evolutionary search implemented in MAISE [2] which identified the tI56 structure (28 atoms per primitive unit cell) without any parameter input, i.e. truly "from scratch." I will describe the performance of different ground state search techniques in such challenging cases.

9:12AM F39.00007 Modeling of the amorphous phase of poly-CO , I.G. BATYREV, US Army Research Laboratory — We studied theoretically the details of amorphous structure of extended CO solid obtained by isotropic compression of solid CO phases in the range of 3-25 GPa. We performed DFT simulations of 128, 432, and 1024 atom models. Structures of random networks found at zero temperature were used for equilibration at finite temperatures up to 50 ps by employing first principles MD. We found that the polymerization begins at 6 - 8 GPa and a random network of 4-7 atom rings obtained above 15 GPa could exist up to 0.1 -0.25 GPa. We studied pressure induced changes in topological characteristic of the random network based on the rings statistics, radial distribution function and average number of the nearest neighbors (NN). NN found to be 3.2 for C and 1.7 for O for 128 atom system at 15 GPa. We performed vibration analysis of the systems as a function of pressure and calculated in dipole approximation IR intensity with identification of contributions from several main motifs of the amorphous structure. To understand charge distribution and localization and to find the possible "weakest link" in the network we calculated electron localization function for the most common fragments of amorphous poly-CO structure.

9:24AM F39.00008 The role of anharmonicity in the ab-initio phase diagram of calcium , MARCO DI GENNARO, SRIJAN KUMAR SAHA, MATTHIEU JEAN VERSTRAETE, University of Liege — In the 32-119 GPa pressure range and at room temperature, a simple cubic phase was reported for calcium in many different experiments. Standard linear response theory, both within density functional perturbation theory and frozen phonon calculations, presents dynamical instabilities for simple cubic in the whole pressure range. Many other possible candidate phases, as well as several possible stabilization mechanisms for simple cubic phase, have been proposed as the result of *ab-initio* predictions but the role of temperature on the relative stability of the different phases has not been investigated systematically. We revisit the stability of three candidate phases of calcium for the intermediate pressure range and for various value of temperatures, taking explicitly into account thermal corrections relative to electronic as well as phononic entropy and anharmonic contributions. This corrects the discrepancies among previous theoretical results and experiments, and presents a different picture of the temperature driven phase transition, which results from dynamical anharmonic stabilization of simple cubic and de-stabilization of the tetragonal phase. Transport quantities are calculated in the stabilized phases, to provide additional points of comparison with experiments.

9:36AM F39.00009 Origin of Metallization of FeO at High Temperatures and Pressures from First-principles DFT-DMFT Computations , R.E. COHEN, Geophysical Lab, Carnegie Institution, KRISTJAN HAULE, Dept. Physics, Rutgers University — Experiments and theory show that FeO metallizes at high temperatures ($\sim$2000K) and pressures ($\sim$80 GPa) [1]. Here we use DFT+Dynamical Mean Field Theory (DMFT) with continuous time quantum Monte Carlo (CTQMC) to study the origin of the metallization. We find with increasing pressure in paramagnetic FeO in a cubic lattice a high-spin low-spin transition, with a wide transition region between characterized by intermediate occupancies of the t2g and eg states between. We find that at 300K cubic FeO remains insulating to a factor of two compression (over 600 GPa), except for a small region of high spin metal. However, at high temperatures (e.g. 2000K) a metallic state is found under compression. The metallization occurs from thermal fluctuations among different multiplets representing high- and low-spin states. We are now studying the AFM ground state, the Néel transition, and (Mg,Fe)O solid solutions. This work is supposed by NSF.

[1] Ohta, K., Cohen, R. E., Hirose, K., Haule, K., Shimizu, K. & Ohishi, Y. Experimental and Theoretical Evidence for Pressure-Induced Metallization in FeO with Rocksalt-Type Structure. Phys. Rev. Lett. 108, 026403 (2012).

9:48AM F39.00010 Towards a Predictive First-Principles Description of High Pressure Hydrogen with Density Functional Theory[1] , MIGUEL A. MORALES, LLNL, JEFFREY M. MCMAHON, UIUC, CARLO PIERLEONI, Univ. of L'Aquila, DAVID M. CEPERLEY, UIUC — We present a study of the influence of the main approximations employed in first-principles descriptions of high pressure hydrogen with Density Functional Theory. We focus on the importance of nuclear quantum effects (NQE) on equilibrium properties of both liquid and solid molecular hydrogen close to dissociation. We find that NQEs strongly influence intramolecular properties, such as bond stability, and are thus an essential part of the dissociation process. In addition, we show how the combination of both thermal and quantum effects make a drastic change to the predicted optical properties of the molecular solid, demonstrating the very limited value of predictions based on classical ions and static crystals. We also focus on the influence of the chosen exchange–correlation density functional on the predicted properties of hydrogen, including the location of the Liquid-Liquid Phase Transition and the pressure dependence of the band gap in the solid.

10:00AM F39.00011 Lattice dynamics beyond the harmonic approximation: a compressive sensing approach , FEI ZHOU, WESTON NIELSON, VIDVUDS OZOLINS, UCLA — First-principles modeling of materials in extreme conditions of increasing complexity has had profound impact on revealing and predicting the materials properties and explaining experimental results. Therefore methods and algorithms that can automatically scale to large systems with quantum mechanical accuracy are in dire need. Recently we have shown that a recently developed technique in the field of signal processing, compressed sensing (CS), provides a simple, general, and efficient way of constructing cluster expansion models for alloy systems. Here CS is applied to calculate force constants, including anharmonic effects up to high orders, in solids. CS performs well in extracting accurate lattice dynamics with highly competitive computational costs and reduced human efforts. Compressive sensing for lattice dynamics can be readily applied to much larger systems than ab initio methods can handle and with superior accuracy than classical force fields.

10:12AM F39.00012 ABSTRACT WITHDRAWN –

10:24AM F39.00013 Neon Hydrate at High Pressure: an in-situ Neutron Diffraction Study , XIAOHUI YU, Los Alamos Natioanl Lab — Clathrate hydrates are a group of ice-like, crystalline inclusion compounds which form through the combination of water and suitably sized "guest" molecules. There are mainly three crystallographic structures of the hydrate clathrate: SI, SII and SH, which are determined by the shape and size of the included gas molecular. However, when the neon gas pressure got increased to 0.48 GPa, we found that the neon gas could be enclathrate in the ice II frameworks which is totally different structure from the traditional cubic clathrate. Through the in-situ neutron diffraction study, the detail structure of Ne hydrate, including the atom positions, can be derived using the Rietveld refinements. The Ne atoms are just in the middle of H_2O channels and sandwiches by two H_2O rings The thermal equation of state was calculated and compared with pure ice II. We found that inclusion of Ne atoms could enlarge the ice II H_2O hexagonal rings, however, shortened the H_2O channels. Although the Ne atoms crystallized in ice II frameworks, the thermal vibration is significant compared to the host atoms. The distribution of Ne atoms are presented by MD simulations.

10:36AM F39.00014 Neutron Scattering Study of Hydrogen in Copper[1] , ALEXANDER I. KOLESNIKOV, Oak Ridge National Laboratory, VLADIMIR E. ANTONOV, Institute of Solid State Physics RAS, Chernogolovka, Russia, GARRETT E. GRANROTH, Oak Ridge National Laboratory, VALERY I. KULAKOV, MICHAIL A. KUZOVNIKOV, Institute of Solid State Physics RAS, Chernogolovka, Russia, KEN C. LITTRELL, EUGENE MAMONTOV, Oak Ridge National Laboratory — Until now, vibrational spectra of hydrogen in the group 1b metals, Cu, Ag and Au, have never been investigated. Meanwhile, these elements are often used in hydrogen containing atmospheres, therefore the properties of hydrogen in these metals are of significant interest. For the present study, Cu-H samples were synthesized by exposing bulk copper to a hydrogen gas at a pressure of 7 GPa and T=900 K and recovering the samples to ambient conditions. The samples were studied by inelastic (INS), quasielastic and small angle neutron scattering. Nearly all hydrogen ($\sim$10 at.%) contained in the samples proved to be in the form of H2 molecules trapped in large (>>100 A) pores/bubbles in the copper matrix. Para <=> ortho transitions in these molecules give intense peaks at +-14.4 and 28.8 meV in the INS spectra. On heating the sample, the molecular hydrogen melts in a temperature interval from 14 to 60 K corresponding to the gradual increase in the H2 pressure in the pores from 5 bar to 3 kbar. A small narrow peak at 73 meV is also observed in the INS spectra. The peak can only be assigned to a local mode of a 0.03 at.% H impurity in the copper bulk. This is the first observation of H vibrations in a group 1b metal.

Session F40 DCMP: Surfaces, Interfaces, and Thin Films: Molecules on Surfaces 349 - Daniel Dougherty, North Carolina State University

8:00AM F40.00001 Molecular Ordering in PCBM Monolayer Films on Ag and Au (111): From μ-aerosol deposited glasses to hcp packing , QIAN SHAO, University of Maryland-College Park, LEVAN TSKIPURI, None, JANICE REUTT-ROBEY, University of Maryland-College Park — Functionalized C_{60} and C_{70} fullerenes are increasingly employed as active components in organic electronic devices. The structure of the PCBM electrode interface is expected to strongly impact charge transfer processes in photovoltaic devices. Here we report molecularly-detailed studies of PCBM ordering at coinage metal surfaces. We have developed a vacuum-compatible liquid delivery source to generate thin films of C_{60}- and C_{70}- PCBM from organic solvents. Structure is tracked from the sub-monolayer to multilayer regime on (111)-oriented Ag and Au surfaces with molecular detail by UHV-STM. Glassy morphologies of as-grown films reflect solvent retention. Upon thermal annealing solvent molecules are released and films evolve into ordered packing arrangements that depend upon the PCBM density in the original films. The hcp monolayer phase of C_{60}-and C_{70}-PCBM are newly produced and characterized, indicating the accessibility of new growth phases by μ-aerosol deposition. Acknowledgement: This work was supported by the NSF-MRSEC at the University of Maryland, DMR 0520471.

8:12AM F40.00002 Doping of Grain Boundaries in diF TESADT Transistors[1] , CORTNEY BOUGHER, SHAWN M. HUSTON, Appalachian State University, JEREMY W. WARD, ABDUL OBAID, Wake Forest University, MARSHA A. LOTH, JOHN E. ANTHONY, University of Kentucky, OANA D. JURCHESCU, Wake Forest University, BRAD R. CONRAD, Appalachian State University — We utilize Atomic Force Microscopy (AFM) and Kelvin Probe Force Microscopy (KPFM) to characterize the dynamics of electronic transport across 2,8-difluoro-5,11-triethylsilylethynyl anthradithiophene (diF TESADT) grain boundaries. We show that the morphology of grain boundaries and the adsorption of atmospheric dopants at these local boundaries have a direct impact on the electrical behavior of diF TESADT in thin film transistor (TFT) devices. Device voltage drops at grain boundaries are characterized as a function of both atmospheric dopants and transition time between dopants. The morphology, including crystallization and packing motifs, of diF TESADT grown on thermally grown SiO_2 will be discussed and related to other semiconducting small organic molecules. This work will be put in the context of other, recent advances in small molecule organics.

[1]Funded by: Ralph E Powe Junior Faculty Enhancement Award, Appalachian State University Office of Student Research, and NC Space Grant Consortium.

8:24AM F40.00003 Scanning Tunneling Microscopy investigation of multilayer diF-TES-ADT on Au(111) , SHAWN HUSTON, Appalachian State University, JIUYANG WANG, North Carolina State University, MARSHA LOTH, JOHN ANTHONY, University of Kentucky, BRAD CONRAD, Appalachian State University, DANIEL DOUGHERTY, North Carolina State University — Organic thin film transistors (OTFT) partially composed of solution processed 2,8-difluoro-5,11-bis(triethylsilylethynyl)-anthradithiophene (diF-TES-ADT) have shown high performance with hole mobilities up to 1 $cm^2/(V\ s)$. Pretreatment of the gold electrodes results in growth of large diF-TES-ADT crystals extending well out into the channel of the OTFT. Without electrode pretreatment, the crystal sizes are small and possess a non-preferred molecular orientation. We have chosen to investigate the reasons for the reduced crystal size of these films on untreated gold electrodes by studying a model system generated by vapor deposition of multilayers of diF-TES-ADT on Au(111). The initial wetting layer forms a highly ordered film such that the anthradithiophene backbone is oriented parallel to the substrate and the unit cell is 1.49 nm x 1.25 nm with an included angle of 56.8°. The second layer is poorly ordered with only weak evidence of crystallinity in small regions. Growth beyond the second layer appears essentially bulk-like and crystalline with domain sizes that are potentially limited by the disordered bilayer growth.

8:36AM F40.00004 STM and optical investigations of molecules on graphene[1] , OZGUN SUZER, Center for Nanoscale Materials, Argonne National Laboratory, Argonne, IL 60439, USA, JOSEPH SMERDON, Surface Science Research Centre, University of Liverpool, Liverpool L69 3BX, UK, NATHAN GUISINGER, JEFFREY GUEST, Center for Nanoscale Materials, Argonne National Laboratory, Argonne, IL 60439, USA — We describe efforts to understand the structural, electronic and optical properties of an archetypal organic molecular building block for graphene-based nano-optical and photovoltaic devices, presenting UHV STM studies of pentacene (Pn) molecules deposited on graphene that was grown epitaxially on SiC(0001). Isolated electronic states are observed and associated molecular orbitals are resolved; also, a large HOMO-LUMO spacing indicates that we are probing a "transport gap" in the monolayer Pn. The electronic properties of this system indicate a de-coupling of the molecules from the graphene and underlying substrate, similar to results obtained for the complementary molecular system, C60 on graphene [Cho, et.al. Nano Letters 12, 3018 (2012)], suggesting a path for developing molecular-scale electronic and optically active devices that are not dominated by substrate interactions. We will also discuss our efforts to correlate these studies with the optical properties of the systems using a UHV STM that incorporates confocal optical microscopy and spectroscopy at the tip-sample junction.

[1]This work was supported by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences under Contract No. DE-AC02- 06CH11357 and SISGR Contract No. DE-FG02-09ER16109

8:48AM F40.00005 ABSTRACT WITHDRAWN –

9:00AM F40.00006 Bonding of anthracene derivatives to a Cu (111) surface: a combined STM and DFT study , JONATHAN WYRICK, YEMING ZHU, DANIEL SALIB, CONNOR HOLZKE, University of California at Riverside, ZHIHAI CHENG[1], The National Center for Nanoscience and Technology, China, LUDWIG BARTELS, University of California at Riverside — We compare and contrast three anthracene derivatives whose 9,10 hydrogens are replaced by the elements O, S, and Se respectively that act as "feet" binding the molecules to a Cu (111) substrate. DFT calculations are compared with and shed light on STM data for the three molecules. We analyze the three species in terms of their geometric and electronic structure upon adsorption, taking into account the competing effects that the "feet" have with the anthracene moiety in their interactions with the underlying Cu surface.

[1]At the time of contributed research, Zhihai was at University of California at Riverside

9:12AM F40.00007 Substrate Mediated Short-range and Long-range Adsorption Pattern of CO on Ag(110)[1] , WAI-LEUNG YIM YIM, Institute of High Performance Computing, Singapore, THORSTEN KLUENER, Institute for Pure and Applied Chemistry, Theoretical Chemistry, University of Oldenburg, Germany — Substrate-mediated intermolecular interactions were proposed in the literature to explain the adsorption of CO on Ag(110) but the underlying mechanism is yet to be known. Here, short-range and long-range relaxation patterns for CO adsorption on Ag(110) surfaces have been investigated. The relaxation mode can be explained by the interaction of heavy electrons on metal substrates in electron momentum space. We identified two relaxation modes for CO on Ag(110). The long-range relaxation involved a (6×6) commensurate phase, while the short-range relaxation involved an alleviation of Fermi surface nesting along the $\langle 1\bar{1}0\rangle$ direction of the Ag(110) substrate. The symmetry broken ground state structure at high CO coverage can be rationalized, and this structure is consistent with the interpretation of available experimental data.

9:24AM F40.00008 ABSTRACT WITHDRAWN –

9:36AM F40.00009 5,6,7-trithiapentacene-13-one on vicinal gold (788): a STM study , AMANDA LARSON, JEREMIAH VAN BAREN, JEREMY KINTIGH, JUN WANG, GLEN MILLER, KARSTEN POHL, University of New Hampshire — Scanning tunneling microscopy was used to examine the atomic interface between gold and 5,6,7-trithiapentacene-13-one (TTPO), an electron donor of potential interest for photovoltaic applications. TTPO is a polar species of pentacene with centered oxygen and sulfur bridge substituents. TTPO is a thermally and photo-oxidatively robust molecule with a HOMO-LUMO gap of 1.90 eV that can be thermally evaporated onto an electrode. The vicinal gold (788) surface is a well-studied surface on which pentacene molecules and other pentacene derivatives self assemble in long range order. We examined TTPO on gold to gain a better understanding of the structure of photovoltaic interfaces at the nanoscale.

9:48AM F40.00010 DFT based modeling of C60/Dichloropentacene on stepped Au surfaces , JUN WANG, JIAN-MING TANG, KARSTEN POHL, Department of Physics, University of New Hampshire — The co-assembly of functionalized pentacenes (electron-donor materials) and fullerenes (electron-acceptor materials) on metal substrates provides a model for studying the structural and electronic properties for novel organic photovoltaic (OPV) heterojunctions [1]. Our previous STM experimental results show C_{60} to form molecular chains on an intact single-domain, brick-wall structured 6,13-dichloropentacene (DCP) monolayer adsorbed on stepped Au(788) [2]. Here, we have included a stepped gold substrate in DFT calculations for the geometric and electronic structure of this interacting three-component system. Our calculations show that C_{60} molecular chain prefer to absorb on top of the DCP molecules on the upper step edge. We calculate the dipole moments for various C_{60} configurations. The stepped gold substrate interaction shows a major influence on this unique molecular chain formation. [1] J. Wang, I. Kaur, B. Diaconescu, J.-M. Tang, G. P. Miller, and K. Pohl, ACS Nano 5 (2011) 1792. [2] J. Wang, J.-M. Tang, G. P. Miller, and K. Pohl, in preparation.

10:00AM F40.00011 First Principles Study of the Electronic Structure of Organic Adsorbates on Cleaved GaP Surfaces[1] , MIN YU, PETER DOAK, JEFFREY NEATON, Lawrence Berkeley National Laboratory — We report a first principles calculations of structural, electronic, and spectroscopic properties of organic molecules, such as ethylene and benzene, adsorbed on cleaved GaP (110) surface to assess their potential to allow controlled coupling and to modify charge transport between light absorbing semiconductors and catalysts for applications in artificial photosynthesis. We compute adsorbate geometries, binding energetics, surface band structures, constant current scanning tunneling microscopy images, and electronic energy level alignment of organic molecules on GaP surfaces using density functional theory and many-body perturbation theory within the GW approximation. We quantify the impact of coverage, interface dipoles, hybridization, and nonlocal polarization effects on level alignment, and validate our understanding through direct comparison recent measurements. Work supported by JCAP and computational resources provided by NERSC.

[1]Work supported by JCAP and computational resources provided by NERSC.

10:12AM F40.00012 Low Temperature STM Study of Single-Molecule Attachment to GaP(110) , AARON BRADLEY, Department of Physics, UC Berkeley, M.M. UGEDA, M. YU, JCAP, LBNL, K.L. MEAKER, Department of Physics, UC Berkeley, J. NEATON, Molecular Foundary, LBNL; JCAP, LBNL; UC Berkeley, G. MOORE, I. SHARP, JCAP, LBNL, M.F. CROMMIE, Department of Physics, UC Berkeley; Materials Science Division, LBNL; JCAP, LBNL — Engineering efficient artificial photosystems for catalytic and photovoltaic (PV) purposes is a major challenge for the development of viable solar fuel generators. One possible route toward this goal is to employ molecular catalysts covalently attached to semiconductor light absorbers through molecular linkages. The effect of such linkage on local electronic structure, however, remains an important question. Scanning tunneling microscopy (STM) is a useful tool for answering this question since it enables characterization of molecular interfaces at the atomic level. Here we describe our progress at measuring the structural and electronic properties of single organic molecules adsorbed to a p-doped GaP(110) surface. Low temperature STM was used to explore the surface chemistry and reactivity of GaP(110) by exposing UHV-cleaved GaP surfaces to sub-monolayer coverages of ethylene (C2H4) and iodobenzene (IC6H6), the latter being a candidate linker for connecting catalysts and PV molecules to semiconducting light absorbers. Our high-resolution STM images in combination with DFT calculations provide guidance for future attachment strategies involving improved molecule/semiconductor interfaces.

10:24AM F40.00013 Interplay between dynamics of molecule and surface plasmons in scanning tunneling microscope-induced light emission , KUNIYUKI MIWA, MAMORU SAKAUE, HIDEAKI KASAI, Department of Applied Physics, Osaka University, Japan — Scanning tunneling microscope (STM)-induced light emission spectroscopy of molecules has unique advantage to investigate the luminescence properties of molecules with the atomic-scale spatial resolution. Recently, many attempts have been made to control the molecular luminescence by using the intense electromagnetic field generated by surface plasmons localized near the tip-substrate gap region. In this study, the nonequilibrium Green's function method are utilized to investigate effects of coupling between an exciton composed by electron and hole in the molecule and the surface plasmons on the luminescence properties of the molecule and the surface plasmons. It is found that the luminescence intensities of the molecule are suppressed due to the re-absorption of the surface plasmons by the molecule. Molecular absorption and enhancement by molecular electronic and vibrational modes lead to dip and peak structures in the luminescence spectra of the surface plasmons. Corresponding structures can be seen in a recent experiment. Moreover we found that the re-absorption by the surface plasmons plays important roles in determining the luminescence spectral profiles. We will discuss the detailed mechanisms of variation in these luminescence spectral profiles.

10:36AM F40.00014 In-situ spectro-microscopy on organic films: Mn-Phthalocyanine on Ag(100)[1] , ABDULLAH AL-MAHBOOB, JERZY T. SADOWSKI, Center for Functional Nanomaterials, Brookhaven National Laboratory, Upton, NY 11973, ELIO VESCOVO, Photon Sciences, Brookhaven National Laboratory, Upton, NY 11973 — Metal phthalocyanines are attracting significant attention, owing to their potential for applications in chemical sensors, solar cells and organic magnets. As the electronic properties of molecular films are determined by their crystallinity and molecular packing, the optimization of film quality is important for improving the performance of organic devices. Here, we present the results of in situ low-energy electron microscopy / photoemission electron microscopy (LEEM/PEEM) studies of incorporation-limited growth [1] of manganese-phthalocyanine (MnPc) on Ag(100) surfaces. MnPc thin films were grown on both, bulk Ag(100) surface and thin Ag(100)/Fe(100) films, where substrate spin-polarized electronic states can be modified through tuning the thickness of the Ag film [2]. We also discuss the electronic structure and magnetic ordering in MnPc thin films, investigated by angle- and spin-resolved photoemission spectroscopy.

10:48AM F40.00015 Adsorption structure analysis of co-adsorption dye-sensitized solar cells by the NEXAFS and XPS , MITSUNORI HONDA, MASATOSHI YANAGIDA, LIYUAN HAN, National Institute for Materials Science, NIMS TEAM — Adsorption structures of N719 dye alone and a N719+D131 co-adsorption system on a TiO_2 electrode were studied with the objective of increasing the efficiencies of dye-sensitized solar cells (DSCs). However, adsorption structure of isothiocyanate (R-N=C=S) in the alone and co-adsorption system was not completely understood because the surface morphology about nanocrystalline TiO_2 is complex. Therefore, we have investigated the adsorption structure on nanocrystalline TiO_2 surface using the Sulfur K absorption edge (S K-edge) and core level (S 1s) in details by using the near edge X-ray absorption fine structure (NEXAFS) and X-ray photoelectron spectroscopy (XPS), respectively. To consider the co-adsorption effect on DSCs, we analyze the depth profiling by the angle dependent NEXAFS spectroscopy and the chemical state on top of surface by the XPS analysis. As the results, we can determine the electronic structure around S atom in R-N=C=S in N719 on nanocrystalline TiO_2 surface. We clarify the adsorption structure of alone and co-adsorption system from the S K-edge NEXAFS and S 1s XPS analysis. I will talk about these results in my presentation.

Tuesday, March 19, 2013 8:00AM - 10:00AM –

Session F41 DAMOP: Rotation, Effective Fields, and Hydrodynamics in Atomic Gases 350 - Phil Johnson, American University

8:00AM F41.00001 Hydrodynamics and universality in cold atomic gases , ALEXANDER ABANOV, Stony Brook University, MANAS KULKARNI, Princeton University — Recent flurry of experiments on out-of-equilibrium dynamics in cold gases (Bosonic and Fermionic) has raised great interest in understanding collective behaviour of interacting particles. Although the dynamics of interacting gases depends on many details of the system, a great insight can be obtained in a rather universal limit of weak non-linearity, dispersion and dissipation. In this limit, using a reductive perturbation method we map many hydrodynamic models relevant to cold atoms to well known chiral one-dimensional equations such as Korteweg-de Vries (KdV), Burgers, KdV-Burgers, and Benjamin-Ono equations. This mapping [1] of rather complicated hydrodynamic equations to known chiral one-dimensional equations is of great experimental and theoretical interest. For instance, this mapping gives a simple way to make estimates for original hydrodynamic equations and to study phenomena such as shock waves, solitons and the interplay between nonlinearity, dissipation and dispersion. All these phenomena have been observed in experiments and are the hallmarks of nonlinear hydrodynamics.

8:12AM F41.00002 Time-of-flight expansion dynamics of a circulating ring BEC[1] , MARK EDWARDS, NOEL MURRAY, Georgia Southern University, KEVIN WRIGHT, GRETCHEN CAMPBELL, WILLIAM D. PHILLIPS, NIST and Joint Quantum Institute, CHARLES W. CLARK, Joint Quantum Institute — We have studied the effect of non–zero circulation on the time–of–flight expansion dynamics of a ring–shaped BEC, under conditions matching recent experiments at the Joint Quantum Institute/NIST in Maryland. We modeled the dynamics of the condensate by first solving the time–independent Gross–Pitaevskii equation (GPE) to obtain the initial condensate wavefunction, with the (quantized) circulation set by imprinting an azimuthal phase gradient. This state was then propagated using the time–dependent GPE in real time, with the trapping potential turned off. In the absence of circulation, the BEC expands and closes the central hole in a few milliseconds, eventually resulting in a density profile with a central peak surrounded by a pedestal modulated by weak concentric fringes. When the ring BEC is circulating, the central hole initially decreases in size but never closes due to the phase singularity. In the long–time limit, the size of the central hole scales nearly linearly with the winding number of the circulation state, in good agreement with the NIST experimental results.

8:24AM F41.00003 Driving phase slips in a neutral-atom analog of an RF SQUID , KEVIN C. WRIGHT[1], R.B. BLAKESTAD[2], J.G. LEE, S.P. ECKEL, C.J. LOBB[3], W.D. PHILLIPS, G.K. CAMPBELL, JQI/NIST/UMD — We can deterministically control the quantized circulation state of a toroidal atomic Bose-Einstein condensate by rotating a weak link around the ring above a critical velocity. We vary this critical velocity by controlling the strength of the repulsive optical dipole potential creating the weak link. This system is directly analogous to a superconducting loop in an external magnetic field, where the loop is interrupted by a weak link with a dynamically tunable current-phase relation.

8:36AM F41.00004 Observation of hysteresis in a superfluid Bose-Einstein condensate with a weak link , S. ECKEL, J.G. LEE, K.C. WRIGHT, W.D. PHILLIPS, Joint Quantum Institute, NIST, University of Maryland, C.J. LOBB, University of Maryland, Department of Physics, G.K. CAMPBELL, Joint Quantum Institute, NIST, University of Maryland — Hysteresis is a common feature of superfluid and superconducting systems with Josephson junctions. We have observed hysteresis in the persistent current state of a toroidally-shaped, Bose-Einstein condensate, stirred with a rotating barrier potential. The barrier, which is modeled as a weak link, induces phase slips in the superfluid between well-defined persistent current states. The rotation frequency at which these phase slips occur differ, depending on whether the phase slip results in an increase or decrease of the persistent current. Such behavior in a toroidal BEC is analogous to an RF SQUID, allowing this device to possibly be used as a sensitive rotation sensor.

8:48AM F41.00005 Stirring a ring Bose-Einstein condensate: vortices and overall circulation[1] , NOEL MURRAY, MARK EDWARDS, Georgia Southern University, CHARLES W. CLARK, Joint Quantum Institute — We have studied the process whereby stirring a superfluid Bose–Einstein condensate confined in a ring-shaped potential leads to an overall circulation. We solved the time-dependent Gross–Pitaevskii equation under conditions chosen to match those of an experiment recently conducted at NIST. Briefly, 500,000 Na atoms where confined at the ring-shaped intersection of a red-detuned horizontal light sheet and a vertically propagating Laguerre–Gauss beam. Stirring was carried via a blue–detuned gaussian beam. We found that, at first, the stirring spawned a number of vortex–antivortex pairs and then stopped. These vortices displayed a complicated dynamical behavior which slowly reduced the number of vortices pairwise via annihilation and singly via diffusion into surface modes of the condensate. At the end of this dynamics, the set of vortices was replaced by an overall circulation of atoms around the ring. We present examples of this behavior, give a simple model of vortex motion and vortex-vortex interaction, and show how the production and annihilation of vortices gets turned into a overall circulation of the ring Bose–Einstein condensate.

[1]Support in part by NSF grant #1068761.

9:00AM F41.00006 Quantum Hall states in rapidly rotating two-component Bose gases , SHUNSUKE FURUKAWA, MASAHITO UEDA, Dept. of Physics, University of Tokyo — Ultracold atomic gases under rapid rotation offer interesting analogues of quantum Hall systems with variable statistics and spins of constituent particles. Here we study strongly correlated phases of two-component (or pseudo-spin-$1/2$) Bose gases under rapid rotation by means of exact diagonalization. As the ratio of the inter-component contact interaction $g_{\uparrow\downarrow}$ to the intra-component one g increases, the two components are expected to be entangled to form novel ground states. For $g_{\uparrow\downarrow} = g$, we find the formation of gapped spin-singlet states at the filling factors $\nu = k/3 + k/3$ (the $k/3$ filling for each component) with integer k. In particular, we present numerical evidences that the gapped state with $k = 2$ is well described as a non-Abelian spin-singlet (NASS) state, in which excitations feature non-Abelian statistics. Furthermore, we find the phase transition from the product of composite fermion states to the NASS state by changing the interaction ratio $g_{\uparrow\downarrow}/g$. Reference: Phys. Rev. A 86, 031604(R) (2012).

9:12AM F41.00007 Vortex formation in a rotating reference frame[1] , MICHAEL RAY, THOMAS LANGIN, DAVID HALL, Amherst College — We create vortices in a trapped Bose-Einstein condensate by cooling the atomic sample through the phase transition in the presence of a rotating magnetic trapping potential. The thermal cloud remains in quasi-equilibrium during the cooling, ultimately producing condensates in the rotating ground state. We show that the trap rotation frequency at which a vortex first appears agrees closely with theoretical predictions. The number of vortices within the condensate is established by the rotation frequency at the phase transition; once the condensate has started to form, its vortex content is robust against frequency changes. Images of the condensate taken during evaporation suggest that the vortex spatial configuration is similarly determined early on in the growth of the condensate.

9:24AM F41.00008 Quantum Monte Carlo study of the drag coefficient for two-component BECs[1] , THOMAS GOLDSTEIN, CHRISTOPHER VARNEY, EGOR BABAEV, NIKOLAY PROKOFIEV, BORIS SVISTUNOV, University of Massachusetts, Amherst — Groundbreaking advances in experimental techniques for ultracold gases have resulted in considerable interest in multi-component systems, which exhibit richer physics than single species systems. Recent theoretical work has established the strong possibility of "entrainment" coupling between components in a two-component BEC. In this talk, we present quantum Monte Carlo simulations of the drag coefficient in a two-component Bose-Hubbard model. Next, we utilize Langevin dynamics to determine manifestations of the intercomponent drag in the ground state structure of vortices in multi-component superfluids.

[1]NSF Awards No. DMR-0955902 and No. PHY-1005543

9:36AM F41.00009 Periodically kicked quantum Hall system of cold atoms , MAHMOUD LABABIDI, INDUBALA SATIJA, ERHAI ZHAO, George Mason University — The integer quantum Hall state is characterized by chiral edge modes associated with the topological invariant, the Chern number. We numerically study a non-equilibrium, periodically driven quantum hall system of fermionic atoms in a square optical lattice. We show that periodically modulated tunneling gives rise to new edge states inside the quasi-energy band gaps. We present a phase diagram with a zoo of interesting phases as functions of driving parameters, along with the spectral evolution of the edge states through the topological quantum phase transitions.

9:48AM F41.00010 Experimental Validation of Interferometry Simulations on an Atom Chip , VIOLETA PRIETO, JASON ALEXANDER, CHRISTOPHER ROWLETT, WILLIAM GOLDING, PATRICIA LEE, Sensors and Electron Devices Directorate, US Army Research Laboratory, Adelphi, MD — We report on recent experimental results on manipulating cold atoms trapped on a chip for the development of a compact atom interferometer using a double-well potential. The experiment uses ^{87}Rb atoms magnetically confined in an atomic waveguide produced by wires on the surface of a lithographically patterned chip. The double-well potential is created by dynamically changing the current configuration on our atom chip. By dynamically powering traces on the atom chip while simultaneously varying external bias fields, we offer a means to coherently split the atomic cloud. We investigate real-time transformations, both adiabatic and non-adiabatic, between different double-well configurations and study their effects on the initially trapped atoms. We examine the coherence properties of the two atomic wavepackets and evaluate their potential use in an atom interferometer.

Tuesday, March 19, 2013 8:00AM - 11:00AM –

Session F42 DCP: Focus Session: Multiscale Modeling–Coarse-graining in Space and Time III

Hilton Baltimore Holiday Ballroom 3 - William Noid, Pennsylvania State University

8:00AM F42.00001 Adaptive Resolution Simulations: Applications and New Developments towards Open Systems MD , KURT KREMER, Max Planck Institute for Polymer Research — The relation between atomistic structure, architecture, molecular weight and material properties is a basic concern of modern soft matter science. A typical additional focus is on surface interface aspects or the relation between structure and function in nanoscopic molecular assemblies. Here computer simulations on different levels of resolution play an increasingly important role. To progress further adaptive schemes are being developed, which allow for a free exchange of particles (atoms, molecules) between the different levels of resolution. The lecture will concentrate on these methods, however will also include first approaches to connect particle based simulations to continuum as well as to include quantum effects. Furthermore the extension to open systems MD as well as new recent methodology advances will be explained. A general review on the first part can be found in M. Praprotnik et al. Ann. Rev. Phys. Chem. 59, 2008 and recent advances in S. Fritsch et al. PRL 108, 170602 (2012)

8:36AM F42.00002 Ions without Charges, Hydrogen-Bonds without Hydrogen: Coarse-Grained Models with Short-Range, Anisotropic Interactions , VALERIA MOLINERO, Department of Chemistry, University of Utah — Water, ions, hydrophilic and hydrophobic moieties are the building blocks of materials and biomolecules. Modeling of the hydrogen-bonded structure of water is particularly challenging for coarse-grained simulations. Nevertheless, reproducing the hydrogen-bonded order of water is necessary not only to reproduce the anomalous thermodynamics, structure and dynamics of liquid water, but also its properties as solvent of ions and hydrophobes, and water-driven interactions. In this talk I will discuss a strategy for the development of coarse-grained models based on short-range anisotropic interactions, and their application for the development of accurate and efficient coarse-grained models of water, solvated ions and DNA, methane and hydrophobic nanoparticles and cavities. These models are 100 to 1000 times computationally more efficient than atomistic models while having quite high fidelity in the description of the structure and -with some caveats- their thermodynamics. I will discuss the level of agreement of the coarse-grained simulations with experimental or atomistic results, and highlight some of their applications.

9:12AM F42.00003 Solving Multiscale Polymer Field Theory Simulations with Lattice Boltzmann Equation , HSIEH CHEN, YONGJOO KIM, ALFREDO ALEXANDER-KATZ, Massachusetts Institute of Technology — A new Lattice Boltzmann (LB) approach is introduced to solve for the modified diffusion equations in polymer field theory. This method bridges two desired properties from different numerical techniques, namely: (i) it is robust and stable as the pseudo-spectral method, and (ii) it is flexible and allows for grid refinement and arbitrary boundary conditions. While the LB method is not as accurate as the pseudo-spectral method, full self-consistent field theoretic (SCFT) simulations of block copolymers on graphoepitaxial templates yield indistinguishable results from pseudo-spectral calculations. Furthermore, we were able to achieve speedups of about 100x compared to single CPU core implementations by using graphics processing units (GPUs). We expect this method to be very useful in truly multi-scale studies where small length scale details have to be resolved, such as in strongly segregating block copolymer blends, nanoparticle-polymer interfaces, or polymer wetting phenomena.

9:24AM F42.00004 Model path-integral dynamics for nonadiabatic reactions in the condensed phase , NANDINI ANANTH, Cornell University, ARTUR MENZELEEV, THOMAS MILLER, California Institute of Technology — We introduce mapping-variable ring polymer molecular dynamics (MV-RPMD), a direct, real-time dynamic technique for the atomistic simulation of nonadiabatic reactions. The dynamics are based on the recently derived exact path-integral Stock-Thoss (PI-ST)representation for the quantum Boltzmann operator that has been previously used to calculate equilibrium properties for N-level systems, and as a way to initialize semiclassical trajectories for the calculation of thermal correlation functions. Both these methods use the Stock-Thoss (ST) mapping protocol to map from a discrete electronic states basis to a continuous Cartesian variables basis, providing the even-handed treatment of electrons and nuclei required to accurately describe their dynamically coupled motions and to describe resonance energy transfer. Like the existing RPMD approach, this method can be used to generate statistically meaningful ensembles of reactive trajectories but, unlike RPMD, it is applicable to photochemical reactions and reactions where proper electronic state quantization is essential. We present the results of simulations using MV-RPMD to calculate correlation functions for a series of model N-level systems over a wide range of nonadiabatic coupling strengths.

9:36AM F42.00005 Coarse-Grained Simulation of Solvated Cellulose Ib Microfibril , BINGXIN FAN, Department of Chemical Engineering, Penn State University, JANNA MARANAS, Department of Chemical Engineering and Material Science, Penn State University, DR. LINGHAO ZHONG AND DR. ZHEN ZHAO COLLABORATION — We construct a coarse-grained (CG) model of cellulose microfibrils in water. The force field is derived from atomistic simulation of a 40 glucose-unit-long microfibril by requiring consistency between the chain configuration, intermolecular packing and hydrogen bonding of the two levels of modeling. Intermolecular interactions such as hydrogen bonding are added sequentially until the force field holds the microfibril crystal structure. This stepwise process enables us to evaluate the importance of each potential and provides insight to ordered and disordered regions. We simulate cellulose microfibrils with 100 to 400 residues, comparable to the smallest observed microfibrils. Microfibrils longer than 100nm would form a bending region along their longitudinal direction. Multiple bends are observed in the microfibril containing 400 residues. Although the cause is not clear, the bending regions may provide us insights about the periodicity and the behavior of the disordered regions in the microfibril.

9:48AM F42.00006 Development and application of coarse-grained models for lipids[1] , QIANG CUI, UW-Madison — I'll discuss a number of topics that represent our efforts in developing reliable molecular models for describing chemical and physical processes involving biomembranes. This is an exciting yet challenging research area because of the multiple length and time scales that are present in the relevant problems. Accordingly, we attempt to (1) understand the value and limitation of popular coarse-grained (CG) models for lipid membranes with either a particle or continuum representation; (2) develop new CG models that are appropriate for the particular problem of interest. As specific examples, I'll discuss (1) a comparison of atomistic, MARTINI (a particle based CG model) and continuum descriptions of a membrane fusion pore; (2) the development of a modified MARTINI model (BMW-MARTINI) that features a reliable description of membrane/water interfacial electrostatics and its application to cell-penetration peptides and membrane-bending proteins. Motivated specifically by the recent studies of Wong and co-workers, we compare the self-assembly behaviors of lipids with cationic peptides that include either Arg residues or a combination of Lys and hydrophobic residues; in particular, we attempt to reveal factors that stabilize the cubic "double diamond" Pn3m phase over the inverted hexagonal H_{II} phase. For example, to explicitly test the importance of the bidentate hydrogen-bonding capability of Arg to the stabilization of negative Gaussian curvature, we also compare results using variants of the BMW-MARTINI model that treat the side chain of Arg with different levels of details. Collectively, the results suggest that both the bidentate feature of Arg and the overall electrostatic properties of cationic peptides are important to the self-assembly behavior of these peptides with lipids. The results are expected to have general implications to the mechanism of peptides and proteins that stimulate pore formation in biomembranes.

[1]Work in collaboration with Zhe Wu, Leili Zhang and Arun Yethiraj

10:24AM F42.00007 Coarse-Grained Molecular Simulation of Lipid Self-Assembly , WATARU SHINODA, National Institute of Advanced Industrial Science and Technology — The talk will review our recent work on understanding the behavior of lipid self-assembly using a coarse-grained (CG) force field model developed recently [1]. The CG model is designed to reproduce experimental surface/interfacial properties as well as distribution functions from all-atom (AA) molecular dynamics (MD) simulations. A series of MD simulations has elucidated that the CG model reproduces the phase diagram reasonably and produces the membranes with reasonable elastic moduli, surface and line tensions. With a help of technical development of free energy computation, we have evaluated the stability of liposome. [2] A comparison of CG-MD and a simple continuum theory for the free energy barrier to the vesicle-to-bicelle transformation reveals that the internal structural relaxation in the bilayer membrane plays an important role in lowering the free energy barrier in case of a small unilamellar vesicle. [2] The effects of lipid components and additives are also discussed in this talk. Especially the effect of fullerenes on the membrane properties will be discussed in details.[3] The behavior of fullerenes in the bilayer membrane and the resultant membrane properties depend on the size of fullerene and bilayer thickness quite sensitively. To discuss these details, we need a chemically accurate CG model constructed based on extensive AA-MD results.

Tuesday, March 19, 2013 8:00AM - 11:00AM –

Session F43 DCP: Focus Session: Motor dynamics—from Single Molecules to Cells I Hilton Baltimore Holiday Ballroom 2 - Zev Bryant, Stanford University

8:00AM F43.00001 Molecular Motors from DNA , ANDREW TURBERFIELD, University of Oxford — DNA is a wonderful material for nanoscale construction: its self-assembly can be programmed by making use of its information-carrying capability and its hybridization or hydrolysis can be used as to provide energy for synthetic molecular machinery. With DNA it is possible to design and build three-dimensional scaffolds, to attach molecular components to them with sub-nanometre precision–and then to make them move. I shall describe our work on autonomous, biomimetic molecular motors powered by chemical fuels and the use of synthetic molecular machinery to control covalent chemical synthesis. I shall demonstrate bipedal motors whose operation depends on the coordination of the chemomechanical cycles of two separate catalytic centres and burnt bridges motors that can be programmed to navigate networks of tracks. I shall also discuss the use of kinesin motor proteins to power synthetic devices.

8:36AM F43.00002 Remote control of molecular motors using light-activated gearshifting , ZEV BRYANT, Stanford University — Engineering molecular motors with dynamically controllable properties will allow selective perturbation of mechanical processes in vivo and provide sophisticated components for directed nanoscale transport in vitro. We previously constructed myosin motors that respond to a change in [Ca++] by reversing their direction of motion along the polarized actin filament [1]. To expand the potential applications of controllable molecular motors, we have now developed myosins that shift gears in response to blue light illumination. Light is a versatile control signal that can be readily modulated in time and space, and is generally orthogonal to cellular signaling. Using structure-guided protein engineering, we have incorporated LOV photoreceptor domains into the lever arms of chimeric myosins, resulting in motors that robustly speed up, slow down, or switch directions upon illumination. These genetically encoded motors should be directly deployable inside living cells. Our successful designs include constructs based on two different myosin classes, and we show that optical velocity control can be implemented in motors that move at microns/sec speeds, enabling practical biological and bioengineering applications.

[1] Chen, L., Nakamura, M., Schindler,T.D., and Bryant Z. (2012). Nat. Nanotechnol. 7, 252-6.

9:12AM F43.00003 Anomalous dynamics in intracellular transport , AARON DINNER, The University of Chicago — This talk will describe quantitative analyses of particle tracking data for systems with cytoskeletally associated molecular motors to better understand the motions contributing to intracellular transport and, more generally, means for characterizing systems far from equilibrium. In particular, we have studied the motions of insulin-containing vesicles (granules) in a pancreatic beta cell line. We find subdiffusive behavior with correlations in both space and time. These data can be modeled by subordinating an ergodic random walk process to a non-ergodic one. We relate the dynamics to the underlying microtubule structure by imaging in the presence of the drug vinblastine. Our results provide a simple physical mechanism for how diverse pools of insulin granules and, in turn, biphasic secretion could arise. Time permitting, these dynamics will be compared with those of actomyosin assemblies.

9:48AM F43.00004 Morphogenetic Functions of Actomyosin , STEPHAN W. GRILL, MPI-PKS Dresden — Morphogenesis refers to the generation of form in Biology. Much is known about molecular mechanisms of regulation, but little is known about the physical mechanisms by which an unpatterned blob of cells develops into a fully structured and formed organism. The actomyosin cortex is a thin layer underneath the cellular membrane that can self contract, which drives many of the large-scale morphogenetic rearrangements that are observed during development. How this cortex reshapes and deforms, and how such morphogenetic processes couple to regulatory biochemical pathways is largely unknown. I will discuss two emergent physical activities of the actomyosin cytoskeleton, an active contractile tension and an active torque, both of which can serve to drive flows and large-scale chiral rotations of the actomyosin cytoskeleton. Discussing two biological examples, polarization of the Caenorhabditis elegans zygote and epiboly during zebrafish gastrulation, I will illustrate how active tension drive flows, how molecular constituents of the cortex affect flows, and how morphogenetic patterns can be formed by coupling regulatory biochemistry to active cortical mechanics. A particular focus will be the investigation of how active chiral torques drive chiral flow, and the resulting functions of such chiral activities of the actomyosin cytoskeleton for left-right symmetry breaking in development.

10:24AM F43.00005 Force-balance model of suppression of multipolar division in cancer cells with extra centrosomes[1] , JIE ZHU, UC Davis — Cancer cells often possess extra centrosomes which have the potential to cause cell death due to catastrophic multipolar division. Many cancer cells, however, are able to escape multipolar mitosis by clustering the extra centrosomes to form bipolar spindles. The mechanism of centrosome clustering is therefore of great interest to the development of anti-cancer drugs because the de-clustering of extra centrosomes provides an appealing way to eliminate cancer cells while keeping healthy cells intact. We present a physical model assuming 1) dynamic centrosomal microtubules interact with chromosomes by both pushing on chromosome arms and pulling along kinetochores; 2) these microtubules interact with force generators associated with actin/adhesion structures at the cell boundary; and 3) motors act on anti-parallel microtubules from different centrosomes. We find via computer simulations that chromosomes tend to aggregate near the cell center while centrosomes can be either clustered to form bipolar spindles or scattered to form multipolar spindles, depending on the strengths of relative forces, cell shape and adhesion geometry. The model predictions agree with data from cells plated on adhesive micropatterns and from biochemically or genetically perturbed cells. Furthermore, our model is able to explain various microtubule distributions in interphase cells on patterned substrates.

Tuesday, March 19, 2013 8:00AM - 11:00AM –

Session F44 DBIO: Focus Session: Stochasticity in Cellular Networks Hilton Baltimore Holiday Ballroom 1 - Ilya Nemenman, Emory University

8:00AM F44.00001 Positive feedback produces broad distributions in maximum activation attained within a narrow time window in stochastic biochemical reactions[1] , JAYAJIT DAS, The Ohio State University — Stochastic fluctuations in biochemical reactions can regulate single cell decision processes. Using exact solutions and semi-analytical methods we calculate distributions of the maximum value (N) of species concentrations ($P_{max}(N)$) and the time (t) taken to reach the maximum value ($P_{max}(t)$) in minimal models of stochastic chemical reactions commonly found in cell signaling systems. We find, the presence of positive feedback interactions make $P_{max}(N)$ more spread out with a higher "peakedness" in $P_{max}(t)$. Thus positive feedback interactions may help single cells to respond sensitively to a stimulus when cell decision processes require upregulation of activated forms of key proteins to a threshold number within a time window. Moreover, unlike other models of strongly correlated random variables such as Brownian walks or fluctuating interfaces, the extreme value distributions for the chemical reactions display multiscaling behavior emphasizing the presence of many time scales in cell signaling kinetics.

[1]This work was funded by the Research Institute at the Nationwide Children's Hospital and a grant (1R56AI090115-01A1) from the NIH.

8:12AM F44.00002 The effect of extrinsic noise on cellular decision making , ELIJAH ROBERTS, Johns Hopkins University, MICHAEL ASSAF, Hebrew University of Jerusalem, ZAIDA LUTHEY-SCHULTEN, NIGEL GOLDENFELD, University of Illinois — Many cellular processes are not deterministic, i.e., genetically identical cells can display different phenotypic behavior even in identical environments. Such processes involve cellular decision making, in which individual cells randomly make choices determining their fate. One view is that the stochastic nature of cellular decision making is due to noise present in the biomolecular interaction networks. Most previous work has focused on the role of intrinsic noise of these networks. Yet, especially in the high copy-number regime, extrinsic noise may be much more significant, likely governing the overall dynamics. Here we develop a theoretical framework describing the combined effect of intrinsic and extrinsic noise on the stochastic dynamics of genetic switches responsible for cellular decision making. We do so by devising a semi-classical theory accounting for extrinsic noise as an effective species. Our theory, corroborated by extensive Monte-Carlo simulations, is tested on a simple bistable self-regulating gene model, and is then generalized to gain insight on the behavior of the lac genetic switch under extrinsic noise. We show that extrinsic noise not only significantly lowers the escape time from a phenotypic state, but can fundamentally change the actual escape process.

8:24AM F44.00003 Temporally Resolved Axonal Growth Rates: A Stochastic Study[1] , DANIEL RIZZO, ROSS BEIGHLEY, MATT WIENS, JAMES WHITE, TIMOTHY ATHERTON, CRISTIAN STAII, Tufts University, DEPARTMENT OF PHYSICS AND ASTRONOMY AND CENTER FOR NANOSCOPIC PHYSICS COLLABORATION — Description of neuron growth behavior is essential in elucidating the environmental factors that prompt the formation of neural networks. However, the staggering number of physical and chemical guidance cues that influence axonal growth prohibits understanding of growth behavior from a purely mechanistic perspective. Using a phenomenological approach, we record the distribution of growth speeds in neurons at several time points, under well-controlled conditions. Using these distributions in combination with a 1-dimensional Fokker-Planck equation, we solve for the velocity potential of axonal growth for our system as a function of time. In so doing, we aim to resolve time-sensitive growth events that are otherwise overlooked in post-growth studies.

[1]NSF-CBET 1067093 and Tufts University

8:36AM F44.00004 Coarse-graining stochastic biochemical networks[1] , ILYA NEMENMAN, Emory University — Biochemical processes typically involve huge numbers of individual reversible or irreversible steps, each with its own dynamical rate constants. Does the structural complexity of these biochemical networks necessarily result in complex dynamics? I will discuss a few examples where simple, nearly universal stochastic dynamical behaviors emerge from this complexity, and sometimes precisely because of this complexity.

[1]This work is partially supported by grants from NSF, HFSP, James S. McDonnell Foundation, and LANL LDRD program.

9:12AM F44.00005 The addition of a coarse-grained looping state enhances bistability in a gene expression model of lac , TYLER EARNEST, Department of Physics, University of Illinois at Urbana-Champaign, Urbana, IL, ELIJAH ROBERTS, Department of Biophysics, Johns Hopkins University, Baltimore, MD, MICHAEL ASSAF, KARIN DAHMEN, Department of Physics, University of Illinois at Urbana-Champaign, Urbana, IL, ZAIDA LUTHEY-SCHULTEN, Department of Chemistry, University of Illinois at Urbana-Champaign, Urbana, IL — Bistability of the *lac* genetic switch in *Escherichia coli* is known to depend on its ability to form DNA loops with the *lac* repressor. Here we present a stochastic gene–mRNA–protein model of the *lac* switch that includes a third transcriptional state describing the DNA loop. We introduce a novel geometric burst extension to the finite state projection method, which allows us to eliminate mRNA as an independent species and rapidly search the parameter space of the model. We evaluate how the addition of the third state changes the model's bistability properties and find a region of parameter space where the system behaves in a way consistent to that seen experimentally for *lac*. Induction in the looping model is preceded by a rare complete dissociation of the loop followed by an immediate burst of mRNA rather than a slower build up of mRNA as in the two-state model. The overall effect of the looped state is to allow for faster switching times while at the same time further separating the uninduced and induced phenotypes from each other. These properties of loop regulatory elements give them intriguing implications for use in synthetic biology.

9:24AM F44.00006 Large number of receptors may reduce cellular response time variation[1] , XIANG CHENG, LINA MERCHAN, MARTIN TCHERNOOKOV, Department of Physics, Emory University, ILYA NEMENMAN, Departments of Physics and Biology, Computational and Life Sciences Initiative, Emory University — Cells often have tens of thousands of receptors, even though only a few activated receptors can trigger full cellular responses. Reasons for the overabundance of receptors remain unclear. We suggest that the large number of receptors results in a competition among receptors to be the first to activate the cell. The competition decreases the variability of the time to cellular activation, and hence results in a more synchronous activation of cells. We argue that, in simple models, this variability reduction does not necessarily interfere with the receptor specificity to ligands achieved by the kinetic proofreading mechanism. Thus cells can be activated accurately in time and specifically to certain signals or ligands. We predict the minimum number of receptors needed to reduce the coefficient of variation for the time to activation following binding of a specific ligand. Further, we predict the maximum number of receptors so that the kinetic proofreading mechanism still can improve the specificity of the activation. These predictions fall in line with experimentally reported receptor numbers for multiple systems.

9:36AM F44.00007 Information flow through calcium binding proteins , JI HYUN BAK, WILLIAM BIALEK, Princeton University — Calcium signaling is a ubiquitous mode of biological communication, which regulates a great variety of vital processes in living systems. Such a signal typically begins with an elementary event, in which calcium ions bind to a protein, inducing a change in the protein's structure. Information can only be lost, from what was conveyed through this initial event, as the signal is further transduced through the downstream networks. In the present work we analyze and optimize the information flow in the calcium binding process. We explicitly calculate the mutual information between the calcium concentration and the states of the protein, using a simple model for allosteric regulation in a dimeric protein. The optimal solution depends on the dynamic range of the input as well as on the timescale of signal integration. According to our result, the optimizing strategy involves allowing the calcium-binding protein to be "activated" by a partial occupation of its sites, and tuning independently the strengths of cooperative interactions in the binding and unbinding processes.

9:48AM F44.00008 Noise and fidelity of information transmission through the Tumor Necrosis Factor signaling circuit , ANDRE LEVCHENKO, Johns Hopkins University — Molecular noise restricts the ability of an individual cell to resolve input signals of different strengths and gather information about the external environment. We developed an integrative theoretical and experimental framework, based on the formalism of information theory, to quantitatively predict and measure the amount of information transduced by molecular and cellular networks. Analyzing tumor necrosis factor (TNF) signaling revealed that individual TNF signaling pathways transduce information sufficient for accurate binary decisions, and an upstream bottleneck limits the information gained via multiple integrated pathways. Negative feedback to this bottleneck could both alleviate and enhance its limiting effect, despite decreasing noise. Bottlenecks likewise constrain information attained by networks signaling through multiple genes or cells. We further use this new analysis formalism to "map" the noise amplitude across different parts of the network. Finally, we show that the redundancy in signaling due to the existence of parallel pathways is not absolute, and that parallel pathways can transmit different types of information about the input, i.e., the duration vs. amplitude.

10:24AM F44.00009 Morphogenesis at criticality? , DMITRY KROTOV, Joseph Henry Laboratories of Physics, Lewis-Sigler Institute for Integrative Genomics, JULIEN DUBUIS, Joseph Henry Laboratories of Physics, Lewis-Sigler Institute for Integrative Genomics, Howard Hughes Medical Institute, ERIC WIESCHAUS, Lewis-Sigler Institute for Integrative Genomics, Department of Molecular Biology, and Howard Hughes Medical Institute, THOMAS GREGOR, WILLIAM BIALEK, Joseph Henry Laboratories of Physics, Lewis-Sigler Institute for Integrative Genomics — Embryonic development of many multicellular organisms begins with the generation of spatially varying patterns of morphogens that encode the body plan of the future organism. We study the spatial pattern formed by the gap gene proteins in the early fruit fly embryo, which is anchored by "crossing points" between expression levels of different genes; these are thought to result from mutual repression. We explore a broad class of models for such interacting genes and show that the parameters implied implied by recent quantitative measurements are non-generic, but rather tuned to certain values, so that the entire gap gene network operates close to the critical surface in its phase diagram. We develop a mean field description of this system as well as derive signatures of critical behavior in the structure of expression noise. One such signature is that fluctuations are dominated by a single "massless" mode, so that fluctuations of expression levels of different genes are highly correlated/anticorrelated. We find a surprisingly high degree of anticorrelation in the real experimental data. These results suggest an interesting possibility that the network of genes responsible for development is operating near criticality.

10:36AM F44.00010 Modeling the Dynamics of Bivalent Histone Modifications in Embryonic Stem Cells

, WAI LIM KU, Department of Physics, University of Maryland, College Park, GUO CHENG YUAN, Assistant Professor, Department of Biostatistics and Computational Biology, Dana-Farber Cancer Institute, FRANCESCO SORRENTINO, Department of Mechanical Engineering, the University of New Mexico, MICHELLE GIRVAN, EDWARD OTT, Department of Physics, University of Maryland, College Park — Epigenetic modifications to histones may either promote the activation or repression of the transcription of nearby genes. Recent experiments have discovered bivalent domains of nucleosomes in which the domain as a whole contains both active and repressive marks. These domains occur in the promoters of most lineage-control genes in embryonic stem cells. It is generally agreed that bivalent domains play an important role in stem cell differentiation, but the mechanisms remain unclear. Here we propose and study a dynamical model of histone modification which, unlike previous models, captures the general features of the bivalent domains observed in experiments. A key feature of our model is the existence of "A/R states," by which we mean states in which there are a significant number of nucleosomes *each* of which *individually* has both active and repressive marks. We use our model to investigate the formation and decay of A/R states, the localization of A/R nucleosomes, and the effect of DNA replication on the stability of A/R states. The goals of our model are to help understand the underlying principles and mechanisms of bivalent domain dynamics and to suggest directions for future experiments.

10:48AM F44.00011 Using entropy to cut complex time series[1]

, DAVID MERTENS, JULIA PONCELA CASASNOVAS, BONNIE SPRING, L.A.N. AMARAL , Northwestern University — Using techniques from statistical physics, physicists have modeled and analyzed human phenomena varying from academic citation rates to disease spreading to vehicular traffic jams. The last decade's explosion of digital information and the growing ubiquity of smartphones has led to a wealth of human self-reported data. This wealth of data comes at a cost, including non-uniform sampling and statistically significant but physically insignificant correlations. In this talk I present our work using entropy to identify stationary sub-sequences of self-reported human weight from a weight management web site. Our entropic approach–inspired by the infomap network community detection algorithm–is far less biased by rare fluctuations than more traditional time series segmentation techniques.

Session F45 DBIO DPOLY: Focus Session: Physics of Proteins I

Hilton Baltimore Holiday Ballroom 4 - Aihua Xie, Oklahoma State

8:00AM F45.00001 Exploring the landscape for protein folding: from function to molecular machines[1]

, JOSE ONUCHIC, Center for Theoretical Biological Physics, Rice University, Houston TX — Globally the energy landscape of a folding protein resembles a partially rough funnel with reduced energetic frustration. A consequence of minimizing energetic frustration is that the topology of the native fold also plays a major role in the folding mechanism. Some folding motifs are easier to design than others suggesting the possibility that evolution not only selected sequences with sufficiently small energetic frustration but also selected more easily designable native structures. The overall structures of the on-route and off-route (traps) intermediates for the folding of more complex proteins are also strongly influenced by topology. Going beyond folding, the power of reduced models to study the physics of protein assembly, protein binding and recognition, and larger biomolecular machines has also proven impressive. Since energetic frustration is sufficiently small, native structure-based models, which correspond to perfectly unfrustrated energy landscapes, have shown to be a powerful approach to explore larger proteins and protein complexes, not only folding but also function associated to large conformational motions. A discussion of how global motions control the mechanistic processes in the ribosome and molecular motors will be presented. For example, this conceptual framework is allowing us to envisage the dynamics of molecular motors and the ribosome from the structural perspective and it provides the means to make quantitative predictions that can be tested by experiments.

8:36AM F45.00002 Predicting folding-unfolding transitions in proteins without a priori knowledge of the folded state[1]

, OSMAN OKAN, DENIZ TURGUT, ANGEL GARCIA, RAHMI OZISIK, Rensselaer Polytechnic Institute — The common computational method of studying folding transitions in proteins is to compare simulated conformations against the folded structure, but this method obviously requires the folded structure to be known beforehand. In the current study, we show that the use of bond orientational order parameter (BOOP) Q_l [Steinhardt PJ, Nelson DR, Ronchetti M, Phys. Rev. B 1983, 28, 784] is a viable alternative to the commonly adopted root mean squared distance (RMSD) measure in probing conformational transitions. Replica exchange molecular dynamics simulations of the trp-cage protein (with 20 residues) in TIP-3P water were used to compare BOOP against RMSD. The results indicate that the correspondence between BOOP and RMSD time series become stronger with increasing l. We finally show that robust linear models that incorporate different Q_l can be parameterized from a given replica run and can be used to study other replica trajectories.

8:48AM F45.00003 Exploring Beta-Amyloid Protein Transmembrane Insertion Behavior and Residue-Specific Lipid Interactions in Lipid Bilayers Using Multiscale MD Simulations[1]

, LIMING QIU, MARK VAUGHN, KELVIN CHENG, Texas Tech University — Beta-amyloid (Abeta) interactions with neurons are linked to Alzheimer's. Using a multiscale MD simulation strategy that combines the high efficiency of phase space sampling of coarse-grained MD (CGD) and the high spatial resolution of Atomistic MD (AMD) simulations, we studied the Abeta insertion dynamics in cholesterol-enriched and -depleted lipid bilayers that mimic the neuronal membranes domains. Forward (AMD-CGD) and reverse (CGD-AMD) mappings were used. At the atomistic level, cholesterol promoted insertion of Abeta with high (folded) or low (unfolded) helical contents of the lipid insertion domain (Lys28-Ala42), and the insertions were stabilized by the Lys28 snorkeling and Ala42-anchoring to the polar lipid groups of the bilayer up to 200ns. After the forward mapping, the folded inserted state switched to a new extended inserted state with the Lys28 descended to the middle of the bilayer while the unfolded inserted state migrated to the membrane surface up to 4000ns. The two new states remained stable for 200ns at the atomistic scale after the reverse mapping. Our results suggested that different Abeta membrane-orientation states separated by free energy barriers can be explored by the multiscale MD more effectively than by Atomistic MD simulations alone.

[1]NIH RC1-GM090897-02

9:00AM F45.00004 Combined copper/zinc attachment to prion protein , MIROSLAV HODAK, JERRY BERNHOLC, North Carolina State University — Misfolding of prion protein (PrP) is responsible for diseases such as "mad-cow disease" in cattle and Creutzfeldt-Jacob in humans. Extensive experimental investigation has established that this protein strongly interacts with copper ions, and this ability has been linked to its still unknown function. Attachment of other metal ions (zinc, iron, manganese) have been demonstrated as well, but none of them could outcompete copper. Recent finding, however, indicates that at intermediate concentrations both copper and zinc ions can attach to the PrP at the octarepeat region, which contains high affinity metal binding sites. Based on this evidence, we have performed density functional theory simulations to investigate the combined Cu/Zn attachment. We consider all previously reported binding modes of copper at the octarepeat region and examine a possibility simultaneous Cu/Zn attachment. We find that this can indeed occur for only one of the known binding sites, when copper changes its coordination mode to allow for attachment of zinc ion. The implications of the simultaneous attachment on neural function remain to be explored.

9:12AM F45.00005 Direct observation of apolipoprotein B refolding at single molecule level by ultra sensitive fluorescence microscopy and solution transmission electron microscopy , CHIA-CHING CHANG, HSUEH-LIANG CHU, HSING-YUAN LEE, National Chiao Tung University, TSAI-MU CHENG, Taipei Medical University, GONG-SHEN CHEN, Mackay Memorial Hospital, FU-RONG CHEN, National Tsing Hua University — Apolipoprotein (apo) B is the only protein of low-density lipoprotein (LDL). The huge size and extreme hydrophobicity of apoB make examination of its lipidation process an experimental challenge. In this study, we showed that apoB lipidation and its intermediates could be observed at single molecule level by an on-path folding process. When carboxyl-terminal-truncated mutants apoB-29 and apoB-48, representing the amino-terminal 29% and 48%, respectively, of the full-length apoB (apoB-100), were used for comparison, we observed that the refolded apoB-100 resembled both native LDL and VLDL precursors. Thus the process of lipidation recapitulates that of pre-VLDL assembly, *in vitro*. These results suggest that the assembly of mature VLDL requires involvement of factors in addition to apoB-100 and lipids. Using solution transmission electron microscopy (TEM), we were able to detect incorporation of hydrophobic super-paramagnetic iron oxide nanoparticles into apoB-100 particles at the initial, but not final, stage of refolding. The current study thus demonstrates that VLDL assembly can be monitored at single molecule level, too.

9:24AM F45.00006 The strength of side chain hydrogen bonds in the plasma membrane , KALINA HRISTOVA, SARVENAZ SARABIPOUR, Johns Hopkins University — There are no direct quantitative measurements of hydrogen bond strengths in membrane proteins residing in their native cellular environment. To address this knowledge gap, here we use fluorescence resonance energy transfer (FRET) to measure the impact of hydrogen bonds on the stability of a membrane protein dimer in vesicles derived from eukaryotic plasma membranes, and we compare these results to previous measurements of hydrogen bond strengths in model lipid bilayers. We demonstrate that FRET measurements of membrane protein interactions in plasma membrane vesicles have the requisite sensitivity to quantify the strength of hydrogen bonds. We find that the hydrogen bond-mediated stabilization in the plasma membrane is small, only -0.7 kcal/mole. It is the same as in model lipid bilayers, despite the different nature and dielectric properties of the two environments.

9:36AM F45.00007 Molecular Dynamics Simulations of Hydrophobic Residues[1] , DIEGO CABALLERO, ALICE ZHOU, LYNNE REGAN, COREY O'HERN, Yale University — Molecular recognition and protein-protein interactions are involved in important biological processes. However, despite recent improvements in computational methods for protein design, we still lack a predictive understanding of protein structure and interactions. To begin to address these shortcomings, we performed molecular dynamics simulations of hydrophobic residues modeled as hard spheres with stereo-chemical constraints initially at high temperature, and then quenched to low temperature to obtain local energy minima. We find that there is a range of quench rates over which the probabilities of side-chain dihedral angles for hydrophobic residues match the probabilities obtained for known protein structures. In addition, we predict the side-chain dihedral angle propensities in the core region of the proteins T4, ROP, and several mutants. These studies serve as a first step in developing the ability to quantitatively rank the energies of designed protein constructs. The success of these studies suggests that only hard-sphere dynamics with geometrical constraints are needed for accurate protein structure prediction in hydrophobic cavities and binding interfaces.

9:48AM F45.00008 Solvation Free Energy and Classical Density Functional Theory[1] , ERIC MILLS, STEVEN PLOTKIN, Dept of Physics & Astronomy, University of British Columbia — The cell environment in which proteins fold and function is crowded with biological molecules, at densities of $\sim$300g/L. Treating these molecules explicitly in a MD simulation introduces enormous computational cost, so accurate ways of modelling their contribution to protein behaviour is desirable. I will discuss existing models and propose a new approach, which uses classical density functional theory to calculate the effect of these solutes on protein folding. I will discuss implementing this approach as both an implicit solvent and a post-processing method, and discuss some general conclusions we can derive from it.

10:00AM F45.00009 Hydrogen Bonding in the Electronic Excited State[1] , GUANG-JIU ZHAO, KE-LI HAN, Dalian Institute of Chemical Physics, Chinese Academy of Sciences, DICP1101 GROUP TEAM — Here, I will give a talk on our recent advances in electronic excited-state hydrogen-bonding dynamics and the significant role of excited-state hydrogen bonding on internal conversion (IC), electronic spectral shifts (ESS), photoinduced electron transfer (PET), fluorescence quenching (FQ), intramolecular charge transfer (ICT), and metal-to-ligand charge transfer (MLCT). The combination of various spectroscopic experiments with theoretical calculations has led to tremendous progress in excited-state hydrogen-bonding research. We first demonstrated that intermolecular hydrogen bond in excited state can be greatly strengthened or weakened for many chromophores. We have also clarified that intermolecular hydrogen-bond strengthening and weakening correspond to red-shifts and blue-shifts, respectively, in the electronic spectra. Moreover, radiationless deactivations (via IC, PET, ICT, MLCT, and so on) can be dramatically influenced by excited-state hydrogen bonding. 10:12AM F45.00010 Intermediate Resolution Models and Protein Folding and Allostery[1] , ABHIJEET KAPOOR, Iowa State University, ALEX TRAVESSET, Iowa State University and Ames Lab — Intermediate Resolution Models (IRM)s model proteins with nearly all atom precision but consider solvent implicitly, and treat electrostatics as short-range interactions. In this talk, we describe a new IRM. We discuss its differences from other existing IRMs and test it again a set of 13 proteins. The model successfully folds 12 of them into its native state, starting from a random configuration. The stability of the native state versus other states with different topologies (arrangement of the secondary structure) is also discussed. Implications for general protein motion are also presented.

10:24AM F45.00011 Using extremely halophilic bacteria to understand the role of surface charge and surface hydration in protein evolution, folding, and function , WOUTER HOFF, Oklahoma State University, RATNAKAR DEOLE, Northeastern State University, OSU COLLABORATION — Halophilic Archaea accumulate molar concentrations of KCl in their cytoplasm as an osmoprotectant, and have evolved highly acidic proteomes that only function at high salinity. We examine osmoprotection in the photosynthetic Proteobacteria Halorhodospira halophila. We find that H. halophila has an acidic proteome and accumulates molar concentrations of KCl when grown in high salt media. Upon growth of H. halophila in low salt media, its cytoplasmic K+ content matches that of Escherichia coli, revealing an acidic proteome that can function in the absence of high cytoplasmic salt concentrations. These findings necessitate a reassessment of two central aspects of theories for understanding extreme halophiles. We conclude that proteome acidity is not driven by stabilizing interactions between K+ ions and acidic side chains, but by the need for maintaining sufficient solvation and hydration of the protein surface at high salinity through strongly hydrated carboxylates. We propose that obligate protein halophilicity is a non-adaptive property resulting from genetic drift in which constructive neutral evolution progressively incorporates weakly stabilizing K+ binding sites on an increasingly acidic protein surface.

10:36AM F45.00012 Infrared Structural Biology of Proteins: Development of Vibrational Structural Markers for Probing the Structural Dynamics of COO- of Asp/Glu in Proteins , ZHOUYANG KANG, AIHUA XIE, Department of Physics, Oklahoma State University — Asp and Glu often play critical roles in the active sites of proteins. Probing the structural dynamics of functionally important Asp and/or Glu provides crucial information for protein functionality. Time-resolved infrared structural biology offers strong advantages for its high structural sensitivity and broad dynamic range (ps to ks). In order to connect the vibrational frequencies to specific structures of COO- groups, such as the number, type, and geometry of hydrogen bond interactions, we develop two vibrational structural markers (VSM), built on the symmetric and asymmetric COO- stretching frequencies. Extensive quantum physics (density functional theory) based computational studies, combined with 13C isotopic editing of Asp/Glu and experimental FTIR data on Asp/Glu in proteins, are used to establish a unique correlation between the symmetric and asymmetric COO- vibrations with more than 10 types of hydrogen bonding interactions. Development of the COO- VSM markers enhances the power of time-resolved infrared structural biology for the study of functionally important structural dynamics of COO- in proteins, including rhodopsin for biological signaling, bacteriorhodopsin for proton transfer, photosystem II for energy transformation, and HIV protease for enzymatic catalysis.

10:48AM F45.00013 Controlling allosteric networks in proteins , NIKOLAY DOKHOLYAN, University of North Carolina at Chapel Hill — We present a novel methodology based on graph theory and discrete molecular dynamics simulations for delineating allosteric pathways in proteins. We use this methodology to uncover the structural mechanisms responsible for coupling of distal sites on proteins and utilize it for allosteric modulation of proteins. We will present examples where inference of allosteric networks and its rewiring allows us to "rescue" cystic fibrosis transmembrane conductance regulator (CFTR), a protein associated with fatal genetic disease cystic fibrosis. We also use our methodology to control protein function allosterically. We design a novel protein domain that can be inserted into identified allosteric site of target protein. Using a drug that binds to our domain, we alter the function of the target protein. We successfully tested this methodology *in vitro*, in living cells and in zebrafish. We further demonstrate transferability of our allosteric modulation methodology to other systems and extend it to become ligh-activatable.

Tuesday, March 19, 2013 8:00AM - 10:48AM –

Session F46 SPS: SPS Undergraduate IV Hilton Baltimore Holiday Ballroom 5 - Crystal Bailey, American Physical Society

8:00AM F46.00001 Density Functional Study of the structural properties in Tamoxifen[1] , ROMEO DE COSS-MARTINEZ, JORGE A. TAPIA, Facultad de Ingenieria, Universidad Autonoma de Yucatan, RAMIRO F. QUIJANO-QUIÑONES, Laboratorio de Quimica Farmaceutica, Facultad de Quimica, Universidad Autonoma de Yucatan, GABRIEL I. CANTO, Centro de Investigacion en Corrosion, Universidad Autonoma de Campeche — Using the density functional theory, we have studied the structural properties of Tamoxifen. The calculations were performed with two methodological approaches, which were implemented in SIESTA and Spartan codes. For SIESTA, we considerate a linear combination of atomic orbitals method, using pseudopotentials and the van der Waals approximation for the exchange-correlation potential. Here we analyzed and compared the atomic structure between our results and other theoretical study. We found differences in the bond lengths between the results, that could be attributed to code approaches in each one.

8:12AM F46.00002 Cytotoxicity of Gold Nanoparticles with Varying Concentration and Under Low Dose Environmental Radiation on Human Embryonic Kidney 293 Cells (HEK-293) , SHALANA CRUDUP, BRUCE BRAENDER, Rowan University, CRISTINA IFTODE, Rowan University, Dept. of Biological Sciences, TABBETHA DOBBINS, Rowan University, Dept. of Physics & Astronomy — Nanomaterials are increasingly being used in medicine. Most research surrounding the health and safety effects of nanomaterials examine the cytotoxicity of nanoparticles alone. Few studies, as this one does, examines the combined effects of nanoparticle concentration and radiation exposure on cytotoxicity to human embryonic kidney 293 cells (HEK-293). Nanoparticles injected in the body are supposed to undergo biodegradation once they are done their specified task, however, some do not and accumulate in the cells (particularly at the liver and kidney) and this causes intracellular changes. Examples of intracellular changes are the disruption of organelle integrity or gene alterations. This will cause the cells to die because the cells are very sensitive to changes in their pH. The experiments reported here focus on the cytotoxicity of gold nanoparticles as a function of varying particle concentrations and also with and without exposure to UV radiation.

8:24AM F46.00003 Migration Modes in Cancer Cell Motility[1] , DI WU, HELIM ARANDA-ESPINOZA, University of Maryland, College Park — Cancer cell metastasis is a result of secondary tumor proliferation after single or collective cancer cell migration from a primary tumor. The biophysical mechanisms of cancer cell migration and transmigration through the body vasculature, while investigated, is not extensively quantified. In general, directed cell motility is traditionally viewed as the result of lamellipodia generation through which the cell moves by extending an actin protrusion and adhesion beneath its plasma membrane. However, cancer cells also exhibit motility through blebbing, which involves momentary membrane detachment from the actin cortex, membrane expansion and retraction. While blebbing, cancer cells do not form cell-substrate attachments as with lamellipodia. In vitro studies of single cancer cell migration through microfluidic microchannels of constant or linearly changing widths model in vitro conditions of single cell migration through capillary pores. We study both modes of motility and observe that cancer cell migration using lamellipodia or blebbing depends on channel width. Drug treatments to manipulate the cytoskeleton demonstrate that cancer cell migration changes speed but not the mode of migration.

[1]Human Frontier Science Project Award - RGP00582011

8:36AM F46.00004 Developing a Novel, Interdisciplinary Approach to Study Protein Unfolding[1] , IAN BENTLEY, Department of Biology, Xavier University, Cincinnati, OH, JUSTIN LINK, Department of Physics, Xavier University, Cincinnati, OH — The ability of a protein to function is a direct result of its ability to properly obtain its native, folded structure. In order to determine the structural stability of proteins and to gain knowledge of their folding mechanism, we must develop protocols that allow us to monitor the controlled unfolding of proteins. Here, we investigate the stability of cytochrome c, a well-studied, model protein, under denaturing conditions using circular dichroism (CD) and fluorescence. Using either a chemical denaturant (Guanidine HCl) or heat, we can cause a protein to gradually unfold. The changes in the fluorescence and CD spectra can provide insight into the stability of proteins by providing us with thermodynamic parameters such as the Gibbs free energy, melting temperature and enthalpy. Research in this lab has been explored with mutant proteins and change in CD signal, however further work must still be done to observe their unfolding monitored by fluorescence. This technique will allow us to determine which regions of native cytochrome c have the greatest impact on the protein folding process. The objective of this session is to present recent work in developing a protocol to observe the unfolding of wild type and mutant proteins with fluorescence.

8:48AM F46.00005 Optimization of radiation damage to proteins using X-ray nanofocusing optics[1] , SELWA BOULARAOUI, KUSTAR - Khalifa University, K. EVANS-LUTTERODT, BNL-NSLS, S. LEE, A.F. ISAKOVIC, KUSTAR - Khalifa University — The need to understand protein structure and perform treatment lead to the use of X-ray and particle-based radiation. Since the use of such radiation has undesirable side effects, mostly through the damage to proteins, it is important to continuously work on decreasing radiation damage. We outline the proposal to use the kinoform refractive optics to focus X-rays on the nanoscale to minimize the radiation damage to protein crystals under study. These optics devices are nanofabricated from low-Z elements (silicon, diamond) and can be used at synchrotron X-ray radiation facilities. We discuss the automated setup that performs nanopositioning of the nanofocusing element, and collects the chemical and structural protein solution under study. We offer simple mathematical models in irradiation and in treatment that help optimize the radiation parameters.

[1]This work is supported in part by Khalifa University IRF-Level 1 Fund. The work at BNL-NSLS is supported through US DOE, Office of Basic Energy Sciences.

9:00AM F46.00006 Driving Sodium-Potassium Pumps With An Oscillating Electric Field: Effects On Muscle Recovery In The Human Biceps Brachii[1] , MATT BOVYN, Northern Arizona University, WEI CHEN, University of South Florida, OLIVIA LANES, Dickinson College, JASON MAST, University of South Florida — Dr. Chen has developed a technique called synchronization modulation, which uses an oscillating electric field to increase the rate at which the sodium-potassium pumps in the cell membrane work. Because the sodium-potassium pump is integral in the recovery of skeletal muscle fibers after an action potential, we investigated the effects of applying synchronization modulation to muscles which had already undergone fatigue due to repeated action potentials during exercise. Fatigue was induced in human subjects' biceps brachii through isometric contraction. Surface electromyography measurements of fatigue index were used to quantify how the muscle recovered over the minutes following fatigue, both when synchronization modulation was applied and when it was absent. The preliminary results were inconclusive, but it is hoped that in later work it will be shown that applying synchronization modulation is effective in increasing the rate at which the muscle recovers to its initial state. This would demonstrate not only that synchronization modulation can be successfully applied to human muscle, but also that it has many potential applications in sports medicine and novel disease treatments.

[1]Work done as part of an REU program at the University of South Florida

9:12AM F46.00007 Driving Sodium/Potassium Pumps with an Oscillating Electric field: Effects on Muscle Fatigue , OLIVIA LANES, Dickinson College, MATTHEW BOVYN, North Arizonia State University, WEI CHEN, University of South Florida — Dr. Chen has developed a technique called Synchronization Modulation, which has already been proven to be an effective tool in synchronizing and speeding up the sodium/potassium pumps in cell membranes. When synchronized, it is thought that these pumps are more efficient because they require less ATP. We hypothesized that if this was correct, this technique may be used to reduce muscle fatigue. To test our hypothesis, we had multiple test subjects hold a 15 lb weight for as long as they could while isolating the bicep muscle and applying an oscillating electric field. We compared the EMG data we took during these trials to the control, which was done the same way but without applying the electric field. To compare how fatigued subjects were, we did a Fast Fourier Transform on the first and last 10 seconds of each trial to measure the Fatigue Index. Our preliminary results suggest that the Fatigue Index decreased at a slower rate in the trials where the subject held the weight with Synchronization Modulation.

9:24AM F46.00008 Multiscale MD Simulations of Folding Dynamics and Mobility of Beta-Amyloid Peptide on Lipid Bilayer Surfaces[1] , SCOTT VAN TILBURG, KELVIN CHENG, Trinity University — Early interaction events of beta-amyloid peptides with the neuronal membranes play a key role in the pathogenesis of Alzheimer's disease. We have used multiscale Molecular Dynamics (MD) simulations to study the protein folding dynamics and lateral mobility of beta-amyloid protein on the cholesterol-enriched and -depleted lipid nano-domains. Several independent simulation replicates of all-atom and coarse-grained MD simulations of beta-amyloid on different lipid bilayer nano-domains have been generated. Using Define Secondary Structure of Proteins (DSSP) algorithm and mean-square-distance (MSD) analysis, the protein conformation and the lateral diffusion coefficients of protein, as well as the lipid and water, were calculated as a function of simulation time up to 200 nanoseconds for atomistic and 2 microseconds for coarse-grained simulations per replicate in different bilayer systems. Subtle differences in the conformation and mobility of the protein were observed in lipid bilayers with and without cholesterol. The structural dynamics information obtained from this work will provide useful insights into understanding the role of protein/lipid interactions in the membrane-associated aggregation of protein on neuronal membranes.

9:36AM F46.00009 The structure of immiscible lipid phases as revealed by the Anton special purpose supercomputer , MICHAEL SANDAR, Department of Physics and Astrophysics at the University of Delaware, EDWARD LYMAN, Department of Physics and Astrophysics and Department of Chemistry and Biochemistry at the University of Delaware — We present simulation data for a bilayer composed of a ternary mixture of cholesterol, dioloeoyl phosphatidylcholine and dipalmitoyl phosphatidylcholine. The chosen composition is in the two-phase region and the temperature is in the vicinity of the miscibility transition. Using the Anton special purpose supercomputer to generate continuous trajectories longer than ten microseconds— which admits complete lipid mixing —we observe robust liquid-liquid phase coexistence. We characterize the phase separated state by considering the local composition fluctuations. Correlation functions of the position reveal that the structure of the domain is circular on average, but that the boundary is subject to significant fluctuations, as expected in the neighborhood of a critical point. The domain diffuses on a slower timescale than the lipids, but by way of lipid exchange, rather than as a well-defined cluster.

9:48AM F46.00010 Computational Analysis of ECGs , KEVIN WATERS, Indiana State University — Electrocardiogram is among the most powerful methods at present to diagnose heart conditions. Here we employed Fourier transform to analyze Electrocardiograms. The goal of the project is to find a way to isolate different wave signals in ways that today's technology is not capable of. Our focus was on building on a code that is capable of filtering out P, QRS, T waves and noise from the ECG, so we created frequency filters that omitted selected amount of data. We first deconstructed and then constructed the ECG this way to find an optimal code assembly for each ECG wave (P-wave, QRS-wave, T-wave). By focusing on one patient, we succeeded to disentangle the complicated ECG signal. We plan to extend this method to more patients.

10:00AM F46.00011 Nonlinear Dynamical Analysis of Fibrillation[1] , JOHN A. KERIN, Department of Physics, Georgetown University, JUSTIN M. SPORRER, Department of Neurosurgery, Shands Hospital, University of Florida, DAVID A. EGOLF, Department of Physics, Georgetown University — The development of spatiotemporal chaotic behavior in heart tissue, termed fibrillation, is a devastating, life-threatening condition. The chaotic behavior of electrochemical signals, in the form of spiral waves, causes the muscles of the heart to contract in an incoherent manner, hindering the heart's ability to pump blood. We have applied the mathematical tools of nonlinear dynamics to large-scale simulations of a model of fibrillating heart tissue to uncover the dynamical modes driving this chaos. By studying the evolution of Lyapunov vectors and exponents over short times, we have found that the fibrillating tissue is sensitive to electrical perturbations only in narrow regions immediately in front of the leading edges of spiral waves, especially when these waves collide, break apart, or hit the edges of the tissue sample. Using this knowledge, we have applied small stimuli to areas of varying sensitivity. By studying the evolution of the effects of these perturbations, we have made progress toward controlling the electrochemical patterns associated with heart fibrillation.

10:12AM F46.00012 Imaging The Genetic Code of a Virus[1] , JENNA GRAHAM, JUSTIN LINK, Department of Physics, Xavier University, Cincinnati, OH — Atomic Force Microscopy (AFM) has allowed scientists to explore physical characteristics of nano-scale materials. However, the challenges that come with such an investigation are rarely expressed. In this research project a method was developed to image the well-studied DNA of the virus lambda phage. Through testing and integrating several sample preparations described in literature, a quality image of lambda phage DNA can be obtained. In our experiment, we developed a technique using the Veeco Autoprobe CP AFM and mica substrate with an appropriate absorption buffer of HEPES and $NiCl_2$. This presentation will focus on the development of a procedure to image lambda phage DNA at Xavier University.

10:24AM F46.00013 Single Molecule Study on the Direct Transfer of *E. coli* Single-Stranded Binding protein between Single-Stranded DNA Molecules[1] , TECKLA AKINYI, Department of Physics, Xavier University, Cincinnati, OH, I-REN LEE, TAEKJIP HA, Department of Physics, University of Illinois at Urbana-Champaign — Single molecule fluorescence resonance energy transfer (smFRET) techniques allow a direct study of the mechanism of the spontaneous transfer of *Escherichia coli* Single-Strand Binding (SSB) protein from single-stranded DNA to a competitor single-stand (ss)DNA. This investigation attempts to understand the kinetics of dissociation and ultimately figure out how long can SSB remain bound to ssDNA in midst of competitor free ssDNA. Application of single molecule techniques as described by Taekjip Ha, (*Ha. Methods 25, 78–86 (2001)*) allow the quantification of the rapid dissociation of SSB from ssDNA as a function of ssDNA length and concentration. We also examined, whether the dissociation occurs with the SSB subunits released simultaneously or consecutively with the possibility of an intermediate state. The variation of dissociation time with DNA length and concentration of the competitive ssDNA demonstrate direct proportionality implying SSB is transferred between ssDNA molecules with a ratio of 1:1, with an abrupt transition from a high FRET state to a low FRET state indicating instantaneous dissociation limited by our time resolution.

10:36AM F46.00014 Images of Cone Photoreceptors Using Spatially Non-Coherent Light[1] , ALLISON HARTMAN, College of the Holy Cross, CHANGGENG LIU, MYUNG KIM, University of South Florida — In order to get clear images of the photoreceptors in a living human eye, we constructed a collimated beam of light with controllable spatial coherence. In the past, imaging techniques using coherent light have shown interference speckles that are the similar size and shape as photoreceptors; these experiments have been unable to differentiate the speckles and the photoreceptors that are in the retina of the eye. We used MatLab to create a simulation of the optical system using a light source with variable spatial coherence reflecting off of a resolution target and we were able to eliminate the speckle patterns. We then created an experimental setup to verify out simulation. We were able to get clear images of resolution targets and our future work will be to image retina samples using spatially non-coherent light and apply this technique in Digital Holography experiments.

[1]I would like to thank the National Science foundation for funding this project and University of South Florida and the Digital Holography and Microscopy Lab for hosting me.

Session F47 DBIO DCMP: Invited Session: Solid-State Nanopores: Translocation and Applications Hilton Baltimore Holiday Ballroom 6 - Gustavo Stolovitzky, IBM Research

8:00AM F47.00001 The time distribution of charged biopolymers translocation through voltage-biased solid-state nanopores[1] , JIALI LI, Department of Physics, University of Arkansas. Fayetteville, AR 72701 — When a charged DNA or protein molecule is passing through a voltage biased solid-state nanopore in an ionic solution, it generates a current blockage signal characterized by its amplitude and time duration (or translocation time). Many parameters such as solution viscosity, applied voltage, the size, conformation, charge, and the charge sequence of the molecule could all contribute to the translocation time and its distribution. By fitting the translocation times to the solution of a Smoluchowski-type equation for 1D-biased diffusion and using the Einstein relation, the viscous drag force on uniformly charged DNA molecules and the uncertainty in determining the DNA chain length due to the contribution of Brownian motion can be evaluated. Furthermore, the time distribution of globular shaped particles and not uniformly charged unfolded protein molecules will also be discussed.

8:36AM F47.00002 Controlling DNA Translocation Speed through Solid-State Nanopores by Surface Charge Modulation , AMIT MELLER, Boston University and The Technion, Haifa, Israel — The Nanopore method is an emerging technique, which extends gel-electrophoresis to the single-molecule level and allows the analysis of DNAs, RNAs and DNA-protein complexes. The strength of the technique stems from two fundamental facts: First, nanopores due to their nanoscale size can be used to uncoil biopolymers, such as DNA or RNA and slide them in a single file manner that allows scanning their properties. Consequently, the method can be used to probe short as well as extremely long biopolymers, such as genomic DNA with high efficiency. Second, electrostatic focusing of charged biopolymers into the nanopore overcomes thermally driven diffusion, thus facilitating an extremely efficient end-threading (or capture) of DNA. Thus, nanopores can be used to detect minute DNA copy numbers, circumventing costly molecular amplification such as Polymerase Chain Reaction. A critical factor, which determines the ability of nanopore to distinguish fine properties within biopolymers, such as the location of bound small-molecules, proteins, or even the nucleic acid's sequence, is the speed at which molecules are translocated through the pore. When the translocation speed is too high the electrical noise masks the desired signal, thus limiting the utility of the method. Here I will discuss new experimental results showing that modulating the surface charge inside the pore can effectively reduce the translocation speed through solid-state nanopores fabricated in thin silicon nitride membranes. I will present a simple physical model to account for these results.

9:12AM F47.00003 Advanced Solid State Nanopores Architectures: From Early Cancer Detection to Nano-electrochemistry[1] , RASHID BASHIR, University of Illinois at Urbana-Champaign — Solid-state nanopores (ssNPs) are potentially low-cost and highly scalable technologies for rapid and reliable se-quencing of the human diploid genome for under $1,000. The ssNPs detect ionic current changes while molecules translocate through the pore. Several key challenges must be overcome in order for ssNPs to become ubiquitous in the fields of medical diagnostics and personalized healthcare. One major challenge is to reduce the speed at which DNA translocates through the nanopore from microseconds to milliseconds per nucleotide, enabling reliable identification of single nucleotides. The other major challenge is to improve the sensitivity of the approach requiring new sensing modalities and novel device architectures. In this paper, we review our recent efforts to (i) develop ssNPs for early cancer detection, (ii) to embed graphene electrodes in dielectric nanolaminates to form 3 and 4 terminal nanopore devices, and (iii) we demonstrate a nanopore based structure consisting of stacked graphene and Al_2O_3 dielectric layers to study electrochemical activity at graphene edges. The electrochemical signal corresponding to the atomically thin graphene layer could also provide a pathway to DNA sequencing.

[1]Supported by National Institute of Health.

9:48AM F47.00004 Nonlinear transport of fd virus particles through a solid-state nanopore , XINSHENG LING, Brown University — In this talk I will discuss our recent experiments on fd virus particles. The fd particles provide an interesting model system for testing the first-passage time theory of electric-field-driven translocation. We find that the distribution of translocation time can be understood using Schrodinger's first-passage time distribution function. The extracted diffusion constant for fd is significantly larger than the expected value from the Stokes-Einstein relation. We also find that the extracted translocation velocity is a nonlinear function of the electric field. We attribute the large effective diffusion constant to a Taylor dispersion effect in the electroosmotic flow profile in the nanopore and the nonlinear electrophoretic mobility to a Stotz-Wien effect.

10:24AM F47.00005 Nanopore Graphene-based Electronic Devices[1] , MARIJA DRNDIC, Department of Physics and Astronomy, University of Pennsylvania — Graphene is an exceptional material for high-speed electronics, as well as a revolutionary membrane material due to its strength and atomic thickness. Nanopores in suspended graphene membranes are currently regarded as candidates for ultrafast DNA sequencing. When a single DNA molecule passes through a nanopore, it blocks the field-driven ions passing through the pore and is detected by measuring the ion current reduction. Due to the thin nature of graphene membranes and reduced pore resistance, we observe larger current signals than in the case of traditional solid-state nanopores. Use of graphene as a membrane material opens the door to a new class of nanopore devices in which electronic sensing and control are performed directly at the pore.

Session G1 DCMP: Invited Session: Anderson-Higgs Boson in Condensed Matter Physics Ballroom I - Subir Sachdev, Harvard University

11:15AM G1.00001 The "Higgs" amplitude mode at the two-dimensional superfluid-Mott insulator transition , IMMANUEL BLOCH, Max-Planck Institute of Quantum Optics — Spontaneous symmetry breaking plays a key role in our understanding of nature. In relativistic quantum field theory, a broken continuous symmetry leads to the emergence of two types of fundamental excitation: massless Nambu–Goldstone modes and a massive 'Higgs' amplitude mode. An excitation of Higgs type is of crucial importance in the standard model of elementary particle physics, and also appears as a fundamental collective mode in quantum many-body systems. Whether such a mode exists in low-dimensional systems as a resonance-like feature, or whether it becomes overdamped through coupling to Nambu–Goldstone modes, has been a subject of debate. Here we experimentally find and study a Higgs mode in a two-dimensional neutral superfluid close to a quantum phase transition to a Mott insulating phase. We unambiguously identify the mode by observing the expected reduction in frequency of the onset of spectral response when approaching the transition point. In this regime, our system is described by an effective relativistic field theory with a two-component quantum field, which constitutes a minimal model for spontaneous breaking of a continuous symmetry. Additionally, all microscopic parameters of our system are known from first principles and the resolution of our measurement allows us to detect excited states of the many-body system at the level of individual quasiparticles. This allows for an in-depth study of Higgs excitations that also addresses the consequences of the reduced dimensionality and confinement of the system. Our work constitutes a step towards exploring emergent relativistic models with ultracold atomic gases.

11:51AM G1.00002 Higgs Excitations in Dimer Antiferromagnets , CHRISTIAN RÜEGG, Paul Scherrer Institute — In three-dimensional dimer antiferromagnets a generic quantum critical point (QCP) separates a quantum-disordered ground state with a spin gap from a phase with long-range antiferromagnetic order and finite ordering temperature. While this QCP and related phases have been studied intensely in theoretical and numerical work using among other methods bond-operators and quantum Monte-Carlo, real materials in which they can be explored experimentally are rare. Structurally dimerised antiferromagnets are located on the disordered or ordered side of the QCP and application of pressure offers a way to control the ration of exchange interactions in the material across a critical value, if the compressibility and pressure dependence of the exchange are favourable. In $TlCuCl_3$ this QCP was realised for the first time and was studied in great detail by neutron scattering. These experiments provide unprecedented insights into the effects of thermal and quantum fluctuations, and of the elementary excitations near QCPs. A unique phenomena is the emergence of longitudinal modes near the QCP, which are the Higgs exceptions in dimer antiferromagnets proposed by S. Sachdev and coworkers. These Higgs exceptions follow precisely scaling predications and are involved in both the quantum and thermal melting of order in such systems.

12:27PM G1.00003 Higgs Bosons in Superconductors , CHANDRA VARMA, University of California, Riverside — Spurred by some strange experimental observations in some superconductors, the theory of a new collective mode[1] in superconductors and how it can be experimentally found very easily under certain circumstances was provided in 1981. It was called the "Amplitude Mode" to distinguish it from the "Phase Modes" which provide Josephson effects and which in homogeneous superconductors are coupled to charge density fluctuations and are at the energies of the plasmons. More generally,[2] this mode is the amplitude mode of a particle-hole symmetric $U(1)$ field, i.e the model treated by Higgs and others in the1960's whose generalization have played an important role in the standard model of particle physics. Recently the amplitude or Higgs mode for d-wave superconductors have also been discussed,[3] where its various cousins may also be found. I will tell the story of the above and why such modes were missed in the theory of superconductivity for so long and the applications of the ideas to modes for cold bosons and fermions in optical lattices. I will also comment, as a very interested outsider and an enthusiast, on the Higgs in particle physics being discovered at LHC from the point of view of the theory of superconductivity.

1:03PM G1.00004 Fate of the Higgs mode near quantum criticality , DANIEL PODOLSKY, Physics Department, Technion – Israel Institute of Technology — The Higgs mode is a ubiquitous collective excitation in condensed matter systems with broken continuous symmetry. It is expected in antiferromagnets, short coherence length superconductors, charge density waves, and lattice Bose condensates. Its detection is a valuable test of the corresponding field theory, and its mass gap measures the proximity to a quantum critical point. However, since the Higgs mode can decay into low energy Goldstone modes, its experimental visibility has been questioned. Here we show that the visibility of the Higgs mode depends on the symmetry of the measured susceptibility. Furthermore, we investigate the evolution of the Higgs mode upon approach to the Wilson-Fisher fixed point in 2+1 dimensions and demonstrate that the Higgs mode survives as a universal resonance in the scalar susceptibility arbitrarily close to the quantum critical point.

Tuesday, March 19, 2013 11:15AM - 2:15PM –

Session G2 DCMP: Invited Session: Superconductivity in Topological Insulators Ballroom II - Nitin Samarth, Pennsylvania State University

11:15AM G2.00001 High-temperature superconductivity in topological insulators , ALEX HAYAT, University of Toronto — Interest in the superconducting proximity effect has been reinvigorated recently by novel optoelectronic applications as well as by the possible emergence of the elusive Majorana fermion. However, all previously studied structures were based on low-T_c materials. We have produced high-temperature superconductivity in topological insulators Bi_2Se_3 and Bi_2Te_3 via proximity to $Bi_2Sr_2CaCu_2O_{8+\delta}$, using our new mechanical bonding technique. We have shown proximity-induced superconductivity up to a temperature of at least 80K – an order of magnitude higher than any previous observations. We have also demonstrated hybrid high-Tc-superconductor-semiconductor tunnel junctions combining $Bi_2Sr_2CaCu_2O_{8+\delta}$ with graphite, with bulk semiconductors and with semiconductor quantum wells. Our approach provides a simple method of constructing high-T_c tunnel junctions which can conceptually facilitate tunneling spectroscopy studies of novel materials.

11:51AM G2.00002 Topological superconductivity in IV-VI semiconductors , LIANG FU, Department of Physics, MIT — No abstract available.

12:27PM G2.00003 The Coexistence of Superconductivity and Topological Order in the Bi2Se3 Thin Films , JIN-FENG JIA, Department of Physics, Shanghai Jiao Tong University — No abstract available.

1:03PM G2.00004 Gate-tuned superconducting transport at the surface of a topological insulator , ALBERTO MORPURGO, Department of Condesed Matter Physics, Ecole de Physique — No abstract available.

1:39PM G2.00005 Majorana Bound States and Disclinations in Topological Crystalline Superconductors[1] , JEFFREY TEO, University of Illinois at Urbana-Champaign — We prove a topological criterion for the existence of zero-energy Majorana bound-state on a disclination, a rotation symmetry breaking point defect, in topological crystalline superconductors (TCS). We first establish a complete topological classification of TCS using the Chern invariant and a few integral rotation invariants. By analytically and numerically studying disclinations, we algebraically deduce a Z_2-index that identifies the parity of the number of Majorana zero-modes at a disclination. Surprisingly, we also find weakly-protected Majorana fermions bound at the corners of superconductors with trivial Chern and weak invariants.

[1]Simons Fellowship

Tuesday, March 19, 2013 11:15AM - 2:15PM –

Session G3 GERA: Invited Session: Progress in the New Energy Frontier Ballroom III - George Crabtree, Argonne National Laboratory

11:15AM G3.00001 Nanoscience by the megaton: Scalable technologies for a sustainable future , PETER LITTLEWOOD, Argonne National Laboratory — The US uses on average 3 TW of power, which is the average solar insolation on 10,000 km2 of desert. To harvest the solar spectrum, or its energy converted into wind, wave, and rain, we will have to develop a range of linked energy technologies for efficient generation, storage, transmission, and use. These provide many research targets for new materials and processes, where physics dictates we must control electrons on the nanoscale so as to reach acceptable performance levels, and cost requires manufacturing by the square mile. Perhaps with the exception of metal wires, we have no experience in developing functional materials technologies on the scale needed. With an eye on the pairing of photovoltaics and electrical storage, I will outline some of the challenges and the long-term efforts that will be needed to resolve them.

11:51AM G3.00002 Thermoelectric Phenomena, Materials, Devices, and Applications , ERIC TOBERER, Department of Physics — Thermoelectric materials, which can generate electricity from waste heat or be used as solid-state Peltier coolers, could play an important role in a global sustainable energy solution. However, advanced materials with improved conversion efficiency are required for widespread implementation. Improving thermoelectric efficiency requires reconciling competing electronic and thermal transport properties - a material must have both a large carrier effective mass and mobility and low lattice thermal conductivity. Historically, this has been achieved through engineering carrier scattering rates. This talk will focus on new approaches that achieve these conflicting properties through modifications of the electron and phonon band structures. Example materials such as $Yb_{14}MnSb_{11}$ and $Ba_8Ga_{16}Ge_{30}$ will be discussed and pathways towards further material improvements will be highlighted. Such tailored control of transport properties will be vital to realize the next generation of energy materials.

12:27PM G3.00003 When is a polymer conjugated? , JOHN LUPTON, University of Regensburg — When considering the nanoscale structure of an electronic material, one typically focuses on the arrangement in space and the interactions between different molecules. The molecule itself is thought of more in terms of a black box. Yet extrapolating from the chemical structure of a macromolecule, such as a conjugated polymer, to its physical function is by no means trivial. How can one be sure that all pi-bonds really are of the type insinuated by quantum chemistry? Time and frequency-domain spectroscopy - most notably pump-probe, upconversion and photon-echo techniques; and the single-molecule approach - have uncovered surprising heterogeneity in intramolecular couplings within nominally homogeneous pi-conjugated systems. The problem with any spectroscopic approach, however, lies in the fact that one and the same experiment is employed to extract both electronic and conformational information, which are intrinsically interrelated. We reverse this conventional approach of adopting the spectroscopy to a particular material and instead focus on a unique set of model systems with predefined physical shape in order to reveal the intricacies of electronic structure. Shape-persistent conjugated macrocycles can be synthesized with molecular weights comparable to those of short polymers, yet with unparalleled physical control over the actual pi-electron system. Such rings reveal, using single-molecule techniques, the effect of dynamic conjugation: spontaneous symmetry breaking of the pi-system due to interactions with the environment. Chromophores, the electronically-active subunits of pi-conjugated macromolecules, are found to form dynamically, leading to rapid jumps in the polarization of light emitted from such symmetric molecules. This insight reveals that nanoscale structure fundamentally begins at the level of individual carbon bonds, which can exhibit pronounced fluctuations.

1:03PM G3.00004 Materials for Electrochemical Energy Storage , MICHELLE JOHANNES, Naval Research Laboratory — Electrochemical energy storage is a primary concern of both the consumer and public energy sectors. Energy, once generated, must be stored, transported and retrieved efficiently. This is commonly done through the use of various kinds of batteries and recently through the use of capacitors. Optimal energy storage involves the complete electrochemical system, but many of the performance properties can be understood in terms of the constituent materials that make up the anode, cathode and electrolyte. In this talk will give a brief overview of electrochemical energy storage systems and the role of materials in improving them. Using computational methods as a framework, I will discuss how discuss how macroscopic properties, such as capacity, conductivity, voltage, and stability are determined by fundamental materials properties at the quantum mechanical level. Using the knowledge gained from understanding the underlying processes, I will discuss some common battery materials, such as $LiFePO_4$, layered transition metal oxides, and oxide electrolyte materials. I will show how predictions for better materials can be made using computational tools to save time and money by circumventing expensive screening in the laboratory. I will also discuss how tailoring the morphology of materials, for example by synthesizing at the nanoscale, can have extreme benefits for battery materials performance.

1:39PM G3.00005 Interfacial Effects in Polymer Membranes for Clean Energy , CHRISTOPHER SOLES, NIST — Polymeric membranes are critical components in several emerging clean energy technologies. Examples include proton exchange membranes for hydrogen fuel cells, anion exchange membranes for alkaline fuel cells, flow batteries, and even block copolymer membranes for solid electrolytes/separators in lithium ion and other battery technologies. In all of these examples the function of the membrane is to physically separate two reactive electrodes or reactants, but allow the transport or exchange of specific ions through the membrane between the active electrodes. The flow of the charged ionic species between the electrodes can be used to balance the flow of electrons through an external electrical circuit that connects the electrodes, thereby storing or delivering charge electrochemically. In this presentation I will review the use of polymeric membranes in electrochemical energy storage technologies and discuss the critical issues related to the membranes that hinder these technologies. In particular I will also focus on the role the polymer membrane interface on device performance. At some point the polymer membrane must be interfaced with an active electrode or catalyst and the nature of this interface can significantly impact performance. Simulations of device performance based on bulk membrane transport properties often fail to predict the actual performance and empirical interfacial impedance terms usually added to capture the device performance. In this presentation I will explore the origins of this interfacial impedance in the different types of fuel cell membranes (proton and alkaline) by creating model thin film membranes where all of the membrane can be considered interfacial. We then use these thin films as a surrogate for the interfacial regions of a bulk membrane and then quantify the structure, dynamics, and transport properties of water and ions in the confined interfacial films. Using neutron reflectivity, grazing incidence X-ray diffraction, and positron annihilation lifetime spectrocopy, we demonstrate that there can be substantial differences in the structure of the ion transport domains in these interfacial region. However, in-situ measurements including dynamic swelling with X-ray and neutron reflectivity, dynamic quartz crystal microbalance of mass uptake/loss, and dynamic phase modulated infrared absorption measurements and generally support both a reduced solubility and diffusivity of the ionic species in the interfacial region, consistent with enhanced interfacial impedance.

Tuesday, March 19, 2013 11:15AM - 2:15PM –

Session G4 FIAP: Invited Session: Frontiers in Nanomanufacturing: Atomic Scale Metrology, Large Scale Industry Technology Challegnes and Inherent Device Limitations

Ballroom IV - Ernesto Marinero, Hitachi Research Center, San Jose

11:15AM G4.00001 Time-Resolved, Atomic-Resolution Imaging of Metastable Atom Configurations[1] , CHRISTIAN KISIELOWSKI, Lawrence Berkeley National Laboratory, Berkeley CA 94720 — In the recent past significant initiatives are dedicated to the exploration of sustainable energy solutions. Certainly, related research must address a rich diversity of challenges because it is not only the static arrangement of matter that must be understood at a single atom level but also the collective behavior of molecular assemblies that leads to functionality. Moreover, hybrid materials are commonly employed that contain hard and soft matter components to artificially stimulate complex behavior. Electron microscopy is often considered a method of choice that may address these challenges if further improved. This paper reports on the development of in-line holography for atomic-resolution electron microscopy, which makes use of dose rates as low as a few atto Amperes per square Ångstrom and of variable acceleration voltages between 20 kV and 300 kV [1]. The approach allows for enhancing resolution in radiation sensitive materials and is especially well suited to study the time evolution of nanoscale objects with single atom sensitivity. For the first time temporary displacements of single atoms from their equilibrium lattice sites into metastable sites across a projected distance of only 0.07 nm and 0.10 nm are directly captured in images with a time resolution around one second. These temporary excitations seem relevant to the irreversible transformation of graphene into carbene and to self-diffusion in catalysts. In suitable experimental conditions, however, atom displacements of 0.05 - 0.1 nm are entirely reversible. Exploiting the reversible nature of such excitations, it may become feasible to probe for conformational object changes in beam sensitive materials at improved spatial resolution.

11:51AM G4.00002 TBD , THOMAS ALBRECHT, HGST, San Jose Research Center — No abstract available.

12:27PM G4.00003 Scalable fabrication of nanostructured devices on flexible substrates using additive driven self-assembly and nanoimprint lithography , JAMES WATKINS, University of Massachusetts — Roll-to-roll (R2R) technologies provide routes for continuous production of flexible, nanostructured materials and devices with high throughput and low cost. We employ additive-driven self-assembly to produce well-ordered polymer/nanoparticle hybrid materials that can serve as active device layers, we use highly filled nanoparticle/polymer hybrids for applications that require tailored dielectric constant or refractive index, and we employ R2R nanoimprint lithography for device scale patterning. Specific examples include the fabrication of flexible floating gate memory and large area films for optical/EM management. Our newly constructed R2R processing facility includes a custom designed, precision R2R UV-assisted nanoimprint lithography (NIL) system and hybrid nanostructured materials coaters.

1:03PM G4.00004 to be determined , ASEN ASENOV, University of Glasgow — No abstract available.

1:39PM G4.00005 Imagining and Imaging Future Devices: A Physicist's Dream , SCOTT LIST, Intel Corporation — In the past device scaling followed conventional Dennard scaling with recent introductions of stress to enhance mobility and high k dielectrics to reduce leakage. Future devices will initially need improved electrostatic confinement with associated geometrical complexity, mobility improvements through new materials, steeper sub-threshold slopes through bandgap engineering and 3D system integration. Eventually new state variables beyond electron charge will be necessary to provide both extremely low power and non-volatility. To enable these changes, improved atomic resolution metrology techniques for both complex 3D geometries and new state variables will be required. While there is still plenty of room at the bottom for the physics of these devices, we are more rapidly running out of room for measuring and controlling these devices. Physicists will have an increasingly important role for both imagining and imaging these devices.

Tuesday, March 19, 2013 11:15AM - 2:03PM –

Session G5 DMP DCOMP: Focus Session: Computational Discovery and Design of New Materials: Thermodynamics and Mechanical Properties 301 - Hyongki Park, Ohio State University

11:15AM G5.00001 Materials Design based on Predictive Ab Initio Thermodynamics , JOERG NEUGEBAUER, Max-Planck-Institut für Eisenforschung, Max-Planck-Str. 1, 40237 Düsseldorf, Germany — A key requirement in developing predictive multi-scale modeling is the availability of accurate computational tools determining energies not only at T = 0 K but also under realistic conditions, i.e., at finite temperature. Combining accurate first principles calculations with mesoscopic/macroscopic thermodynamic and/or kinetic concepts allows now to address this issue and to determine free energies and derived thermodynamic quantities such as heat capacity, thermal expansion coefficients, and elastic constants with an accuracy that matches and often even rivals available experimental data. In the talk a brief overview of the fundamentals and recent developments of combining modern fully parameter-free ab initio methods with thermodynamic concepts will be given with special emphasize on structural materials. The flexibility and the predictive power of these approaches and the impact they can have in developing new strategies in materials design will be discussed e.g. for modern high strength TWIP/TRIP steels, for understanding failure mechanisms such as hydrogen embrittlement, or for identifying chemical trends in the performance of light weight metallic alloys. Work has been done in collaboration with Fritz Kormann, Blazej Grabowski, and Tilmann Hickel.

11:51AM G5.00002 Metastable Al-rich phases in the Al-Sm system: A genetic-algorithm study , FENG ZHANG, ZHUO YE, Ames Laboratory, IAN MCBREATY, Department of Physics and Astronomy, Iowa State University, MIKHAIL MENDELEV, RYAN OTT, EUN SOO PARK, MATT KRAMER, CAI-ZHUANG WANG, KAI-MING HO, Ames Laboratory — Metallic glasses formed by Al and about 10% rare earths such as Sm are important high-strength-low-density materials. Various metastable crystalline phases are formed in the early stages of the devitrification of Al90Sm10 glasses. Identification of these phases is crucial to understand the phase selection during amorphization and devitrification processes, and thus provides critical information for the control of microstructures in order to obtain desired mechanical properties. In this study, we use a genetic algorithm to systematically study the low energy Al-rich phases of the Al-Sm system. We discovered a new Al5Sm phase that matches excellently with the experimentally detected M1 phase in lattice parameters as well as diffraction patterns. In addition, we established the energy landscape as a function of Al composition on the Al-rich side of the phase diagram, and found key geometries of Sm-centered local clusters which could serve as building blocks for other metastable phases.

12:03PM G5.00003 Prediction of previously unreported 18-electron ABC materials via first-principles thermodynamics[1] , XIUWEN ZHANG, Colorado School of Mines, Golden, CO, ANDRIY ZAKUTAYEV, NREL, Golden, CO, ARPUN NAGARAJA, THOMAS MASON, Northwestern University, Evanston, IL, DAVID GINLEY, National Renewable Energy Laboratory, Golden, CO, ALEX ZUNGER, University of Colorado, Boulder, CO — The eighteen electron s2p6d10 ABC compounds derived from an s2p6 binary plus a column X element such as Ni,Pd,Pt have recently been proposed as new topological insulators and thermoelectric materials. Yet, many potentially stable 18 electron compounds are not reported in standard compilations, raising the question if they are stable or unstable. Here we use "first-principles thermodynamics" [1] to evaluate the thermodynamic stability of the 401 currently undocumented s2p6d10 ABC materials in the groups I-X-VII, II-X-VI, III-X-V, IV-X-IV, II-IX-VII, III-IX VI, IV-IX-V, and V-IX-IV (but excluding the elements Cs, B, Tl, and Po). The calculation follows three steps: (1) Establishing the lowest energy structure of the ternary. (2) Calculating the energies of documented and undocumented potentially competing phases in the A-B-C system. (3) Examining the dynamic stability of the new compound. We report the stable structures, formation enthalpies (corrected for DFT errors) of the new stable compounds, and document the competing phases of the predicted unstable compounds. Recently one of the predicted stable compounds–TaCoSn–has been successfully synthesized. [1] X. Zhang, L. Yu, A. Zakutayev, and A. Zunger, Adv. Funct. Mater. 22, 1425, (2012).

12:15PM G5.00004 Computational Study of the Phase Diagram of Tungsten-Nitride , MICHAEL MEHL, Naval Research Laboratory, DANIEL FINKENSTADT, CHRISTIAN DANE, U.S. Naval Academy, STEFANO CURTAROLO, KESONG YANG, Duke University, GUS HART, Brigham Young University — There has been considerable interest in the Tungsten Nitride (WN) system, as various calculations predict that structures of WN_2, WN_3, and WN_4 may be ultra-compressible and perhaps as hard as diamond. The predicted stability of these structures is based on vibrational stability and a negative formation enthalpy (ΔH) relative to αN_2 and bcc W. A negative value of ΔH does not guarantee a compound exists, as it may be above the tie-line constructed from other compounds with lower enthalpies. The determination of the tie-line is complicated by the fact that the ground state of WN is not well determined by experiment or theory. We have used AFLOW, extended to include a large variety of Nitrogen containing structures, to compute the formation energy of the WN system over a large range of compositions. In this talk we discuss the ground state of the WN system, the relationship of our predicted structure to experiment, and the relative stability of the possible "superhard" WN_x compounds. We find that this behavior depends on whether a GGA or LDA functional is used, probably because of the inability of these functionals to handle van der Waals forces in N_2 crystals.

12:27PM G5.00005 Elastic Constants and Phonons of Tungsten-Nitride from First Principles , CHRISTIAN DANE, DANIEL FINKENSTADT, U.S. Naval Academy, MICHAEL MEHL, Naval Research Laboratory, STEFANO CURTAROLO, Duke University — Certain Tungsten Nitride (WN) crystal structures have been found to exhibit tendencies for exceptional hardness. Some researchers [S. Aydin et al., J. Mater. Res. 27, 1705 (2012)] have made the claim that these structures have hardness qualities that rival diamond. There are three specific structures with unique compositions that are of interest. By calculating the bulk and shear moduli as well as analyzing phonon dispersion plots, the properties of these structures can be compared to known structures like diamond. We used VASP density-functional methods implemented within the MedeA software package to strain each structure in a series of directions in increasing amounts. A simple linear fit of stress vs. strain found that the leading structure in terms of thermodynamic stability has elastic constants of C_{11} = 753 GPa, C_{12} = 126 GPa, and C_{44} = 172 GPa. These constants, while high, are significantly lower than diamond's. This indicates that previous calculations may have been mistaken in predicting the qualities of the WN system. Some of the difference between our results is due to the exchange-correlation functional chosen, namely, LDA vs. GGA.

12:39PM G5.00006 Building Symmetry During Crystal Structure Prediction , KYLE MICHEL, CHRISTOPHER WOLVERTON, Northwestern University — Unconstrained crystal structure prediction is difficult in large cells since the number of free variables increases rapidly with the number of atoms that are included. We describe a method that builds symmetry on the fly during crystal structure prediction and uses this symmetry to reduce the dimensionality of the search space. We apply this method to Monte Carlo-based crystal structure prediction and show that simulations that build symmetry greatly outperform those that do not, both in average and fastest times to find the ground state structure.

12:51PM G5.00007 Simulations of the Structure and Properties of Large Icosahedral Boron Clusters Based on a Novel Semi-Empirical Hamiltonian[1] , PAUL TANDY, MING YU, C.S. JAYANTHI, SHI-YU WU, University of Louisville, CONDENSED MATTER THEORY GROUP TEAM — A successful development of a parameterized semi-empirical Hamiltonian (SCED-LCAO) for boron based on a LCAO framework using a sp^3 basis set will be discussed. The semi-empirical Hamiltonian contains environment-dependency and electron screening effects of a many-body Hamiltonian and allows for charge self-consistency. We have optimized the parameters of the SCED-LCAO Hamiltonian for boron by fitting the properties (e.g., the binding energy, bond length, etc.) of boron sheets, small clusters and boron alpha to first-principles calculations based on DFT calculations. Although extended phases of boron alpha and beta have been studied, large clusters of boron with icosahedral structures such as those cut from boron alpha are difficult if not impossible to simulate with ab initio methods. We will demonstrate the effectiveness of the SCED-LCAO Hamiltonian in studying icosahedral boron clusters containing up to 800 atoms and will report on some novel boron clusters and computational speed. 1:03PM G5.00008 The Structure, Stability, and Properties of a One-Dimensional α-Boron Structure[1] , CHERNO BABA KAH, PAUL TANDY, MING YU, C.S. JAYANTHI, S.Y. WU, University of Louisville, CONDENSED MATTER THEORY GROUP TEAM — Boron is an electron deficient element exhibiting a complex and versatile chemistry. In this work we have performed a preliminary study on the structural stability and electronic properties of one-dimensional α-boron structures based on the SCED-LCAO molecular dynamics scheme (MD) [PRB 74, 15540 (2006)]. The one-dimensional α-boron structures were generated by constructing icosahedra B_{12} clusters, referred as α-boron balls, and arranging them in one-dimension. Such structures were stabilized through the simulated annealing based on the SCED-LCAO MD. We found that: (1) the α-boron ball is compressed in comparison to its bulk counterpart (α-phase); (2) the distance between "α-boron balls" is shorter in the center of the chain than that at the two ends and decreases as the length of the chain increases; (3) the HOMO-LUMO gap is very small ($\sim$1 meV) in the finite chains, but it opens up when the chain length becomes infinite. The optimized lattice constant of the infinite α-boron chain was found to be 2.998 Å and its energy gap is found to be 0.74 e. The stability and properties of ring-shaped one-dimensional α-boron structures will also be discussed.

1:15PM G5.00009 A framework for the design of nanomaterials with targeted applications[1] , VLADAN MLINAR, School of Engineering, Brown University, Providence, RI 02912, USA — Engineered nanomaterials are the key building blocks of modern optoelectronic devices and understanding their structure-property relationship can lead to breakthroughs in device design. Even if we suspect that there may be many structures that are consistent with the targeted property, finding a single one may be a daunting, but often also unnecessary, task because of the enormous space of material parameters. Here, I will show how to parametrize the structure via a set of structural features using the targeted physical property as a constraint. Structural features are extracted from our procedure such that they are relevant to the targeted property/ies and linked to the underlying full atomistic structure. I will discuss the conditions under which the representation of the structure via structural features can be very similar, ideally equivalent, to the full structure *only* relative to our targeted properties. Finally, I will demonstrate the importance and validity of the approach using the example application of engineered nanomaterials for third-generation photovoltaics solar cells.

1:27PM G5.00010 Optimizing the design of artificial lattices , LIANG Z. TAN, STEVEN G. LOUIE, Department of Physics, University of California at Berkeley and Materials Sciences Division, Lawrence Berkeley National Laboratory, Berkeley, CA 94720 — Artificial crystal lattices are a powerful tool for studying other condensed matter systems because they are easily tunable and may be controllably fabricated in the laboratory. For example, artificial graphene can be created out of arrays of CO molecules arranged on a Cu(111) surface. We generalize the idea of artificial graphene, and propose new, unusual band structures that can result from different types of artificial lattices. Because of the high degree of freedom in creating artificial lattices, the task of systematically designing artificial lattices that exhibit these unusual band structures is non-trivial. We address this optimization problem, and show that new physics can be observed in presently feasible artificial crystal lattices. This work was supported by NSF grant No. DMR10-1006184 and U.S. DOE under Contract No. DE-AC02-05CH11231. Computational resources have been provided by NERSC and XSEDE.

1:39PM G5.00011 Modeling fracture of random media via stochastic molecular mechanics , LEON DIMAS, TRISTAN GIESA, MARKUS BUEHLER, Massachusetts Institute of Technology — Inspired by recent experimental results suggesting that the heterogeneous distribution of the elastic modulus in bone tissue leads to increased toughness, we determine the toughness modulus of a flawed discrete particle system with stochastic elastic properties. We consider an elastic solid in plane strain conditions in uniaxial tension with a Young's modulus distribution modeled as a 2-d Gaussian process with covariance modeled as an exponential kernel. We solve the problem from a continuum perspective, both employing spectral methods with stochastic finite elements and Monte Carlo methods with conventional finite elements. We also analyze an equivalent discrete particle system, modeled as a spring bead network of FCC-lattices. Our results validate the persistence of the Cauchy Born rule in a stochastic system. We then analyze a flawed discrete particle system to assess the effect of heterogeneity on fracture properties. By studying the fracture mechanics of this system with a range of variance and correlation length parameters in the exponential kernel we gain fundamental insights in to the essential length scales of heterogeneity critical to enhanced fracture properties. This validated stochastic molecular mechanics framework further supports the inverse computation of local elastic properties, not accessible with continuum mechanics, to tailor global mechanical properties such as the fracture toughness. Specifically, Markov Chain Monte Carlo can be used to infer the elastic and geometric parameters. Our work sets the foundation for stochastic modeling in a micromechanical environment and unveils mechanisms by which mechanical behavior can be tailored due to increasingly heterogeneous mechanical properties.

1:51PM G5.00012 The unsuspected origin of gold's nobleness[1] , MARISOL ALCANTARA ORTIGOZA, SERGEY STOLBOV, University of Central Florida — Understanding the "inertness" of Au toward oxidizing agents - appreciated since long before the beginning of recorded history – has remained a challenge. Its nobleness has long been attached to its weak interaction with adsorbates, which contrasts with the fact that Au forms stable alloys and can be made reactive. Density-functional-theory (DFT) calculations of the binding energy (BE) of O on (111) surfaces, in fact, have shown that Au stands out for rendering the weakest BE. Here, we reveal the origin of gold's unique inertness by revising the adsorption of this prototype oxidizing agent on several (111) metal surfaces. We show via DFT that, judging by BE of O on Au(111) and Ag(111), e.g., *both* the d-band-center argument *and* analysis of the electronic density of states fail to describe the relatively low reactivity of Au. Nevertheless, we establish that, rather than failure of the above paradigms, a key element to understand BE of adsorbates has been left behind so far. Namely, we demonstrate that, although BE of O is higher on Ag(111) than on Au(111), (1) The local Au-O bonds are *indeed stronger* than the Ag-O ones; (2) the low BE of O on Au is, paradoxically, caused by an unusually large perturbation on Au-Au bonds upon O adsorption.

Session G6 DMP: Focus Session: CVD Graphene - Doping and Defects 302 - Abhay Pasupathy, Columbia University

11:15AM G6.00001 Dopants in Chemically Doped Monolayer Graphene , LIUYAN ZHAO, Physics Department, Columbia University — In monolayer graphene, substitutional doping during chemical vapor deposition (CVD) growth can be used to alter the electronic properties of graphene. To gain full understanding of such chemically doped monolayer graphene, it is essential to learn how the dopants distribute from at atomic scale up to at micron-meter scale, how the dopants modify the electronic structures of the graphene, and how the quasiparticles in graphene behave in the vicinity of the dopants. We use Scanning Tunneling Microscopy/Spectroscopy (STM/S), Micro-Raman spectroscopy, and X-ray absorption spectroscopy to address these questions. In this presentation, we will first show both Nitrogen and Boron atoms dope graphene in the graphitic form, and contribute electron and hole carriers into graphene respectively. Secondly, we will discuss the nature of inter-valley and intra-valley scattering in Nitrogen doped graphene due to the presence of graphitic Nitrogen dopants. Finally, we will show that Nitrogen dopants show sub-lattice clustering and avoid structural features such as domain boundaries of a graphene polycrystal.

11:51AM G6.00002 Nitrogen incorporation into epitaxial graphene formed on SiC[1] , EDWARD CONRAD, WANG WANG, School of Physics, Georgia Institute of Technology, GANG LIU, Electrical and Computer Eng., Rutgers Univ., SARA ROTHWELL, Electrical and Computer Eng., Univ. of Minnesota, LEONARD C. FELDMAN, Electrical and Computer Eng., Rutgers Univ., PHIL COHEN, Electrical and Computer Eng., Univ. of Minnesota — Substitutional doping is an important way to modify the electronic, chemical, optical and magnetic property of graphene. A significant body of work has shown that nitrogen can be introduced into the graphene structure during CVD growth or by plasma treatments [1,2]. These methods produce a variety of nitrogen defect sites. We present new results on the direct incorporation of nitrogen into graphene as it grows from SiC. The starting material is a sub-monolayer of N at the SiC/SiO2 interface introduced by NO annealing at 1175C [3]. The oxygen is chemically removed to leave ∼0.5 ML nitrogen layer that is stable on the SiC(000-1) surface up to 1550C. When heated to 1450C, nitrogen is introduced into the graphene as it grows from the SiC. Post growth studies with Raman Spectroscopy, ARPES, XPS, and LEED show that the N-doped graphene is entirely pyridinic and has a small finite bandgap. This method has an advantage in that the SiC/nitrogen surface can be pre-patterned to high resolution prior to graphene fabrication.

12:03PM G6.00003 Nitrogen-doped graphene: beyond single substitution and enhanced molecular sensing , SIMIN FENG, JUNJIE WANG, RUITAO LU, The Pennsylvania State University, USA, QING LI, Oak Ridge National Laboratory, USA, ANDRÉS R. BOTELLO-MÉNDEZ, XAVIER DECLERCK, AURÉLIEN LHERBIER, Université Catholique de Louvain, Belgium, AYSE BERKDEMIR, ANA LAURA ELÍAS, The Pennsylvania State University, USA, RODOLFO CRUZ-SILVA, MORINOBU ENDO, Shinshu University, Japan, HUMBERTO TERRONES, The Pennsylvania State University, USA, JEAN CHRISTOPHE CHARLIER, Université Catholique de Louvain, Belgium, MINGHU PAN, Oak Ridge National Laboratory, USA, JUN ZHU, The Pennsylvania State University, USA, MAURICIO TERRONES, The Pennsylvania State University, USA; Shinshu University, Japan — Large-area (~ 4 cm^2) and highly-crystalline monolayer nitrogen-doped graphene (NG) sheets have been synthesized on copper foils by ambient-pressure chemical vapor deposition (AP-CVD) method. Scanning tunneling microscopy (STM) and spectroscopy (STS) reveal that the nitrogen dopants in as-synthesized NG samples are separated by one carbon atom and sit consequently on the same sub-lattice of graphene. Based on our first principles and tight binding calculations, this unbalanced distribution of dopants on one of the graphene sub-lattices will promote the opening of an electronic band gap. We control the synthesis parameters and use Raman spectroscopy and electrical transport measurements to monitor the nitrogen doping levels. Finally, we will demonstrate that NG behaves as an efficient molecular sensor, especially when performing graphene-enhanced Raman scattering (GERS) of various organic and bio-molecules.

12:15PM G6.00004 Temperature-dependent gap opening in doped graphene , CHOONGYU HWANG, Materials Sciences Division,Lawrence Berkeley National Laboratory, CHRIS JOZWIAK, Materials Sciences Division, Lawrence Berkeley National Laboratory, SWANEE J. SHIN, EUGENE H. HALLER, Department of Materials Science and Engineering, University of California, Berkeley, ALESSANDRA LANZARA, Department of Physics, University of California, Berkeley, CA, and Materials Sciences Division, Lawrence Berkeley National Laboratory, Berkeley, CA — Fundamental physical properties of a material are strongly affected by electronic correlations, which typically reveal their origins through a temperature-dependence study. By using angle-resolved photoemission spectroscopy, we study unusual gap opening in doped graphene as a function of temperature, which poses a strong constraint on the charge carrier scattering mechanism in this system. Our finding provides a potentiality to realize new correlated states with unusual properties.

12:27PM G6.00005 Mapping the Electron Transport of Graphene Boundaries Using Scanning Tunneling Potentiometry[1] , KENDAL CLARK, XIAOGUANG ZHANG, IVAN VLASSIOUK, Oak Ridge National Laboratory, GUOWEI HE, Carnegie Mellon University, GONG GU, University of Tennessee, RANDALL FEENSTRA, Carnegie Mellon University, AN-PING LI, Oak Ridge National Laboratory — The symmetry of the graphene honeycomb lattice is a key element for determining many of graphene's unique electronic properties. Topological lattice defects, such as grain boundaries and step edges, break the sublattice symmetry and can affect the electronic properties, especially the transport of graphene. A complete understanding of the physical and electronic properties of defects and boundaries of graphene is needed for future applications. Using a scanning tunneling potentiometry method with a low temperature four-probe scanning tunneling microscope, two-dimensional maps of electrochemical potentials have been measured across individual grain boundaries of graphene films on SiO_2, as well as across 1ML to 1ML substrate steps and 1ML to 2ML transitions of graphene on SiC. An Atomic Force Microscope (AFM) is implemented to image the grain boundary that forms between coalesced individual graphene flakes on insulating surfaces where as a Scanning Tunneling Microscopy (STM) is implemented for characterizing the SiC grown graphene samples. Results of the influence that various boundaries have on the electronic transport of graphene will be presented.

[1]This research was conducted at the Center for Nanophase Materials Sciences, which is sponsored at Oak Ridge National Laboratory by the Office of Basic Energy Sciences, U.S. Department of Energy.

12:39PM G6.00006 Chemically decorated line defect as a transport barrier in graphene[1] , CARTER WHITE, Naval Research Laboratory, SMITHA VASUDEVAN, The George Washington University, DANIEL GUNLYCKE, Naval Research Laboratory — Graphene exhibits itinerant electrons propagating ballistically across its surface. To control electrons injected at a source contact, one needs transport barriers. With reliable transport barriers, electron flow could be directed and modified, a key requirement in nanoelectronics applications. In this presentation, we show that chemically decorated line defects in graphene could act as effective atomically-thin transport barriers. The considered 5-5-8 line defect has both been observed and controllably fabricated. Our density functional theory calculations indicate that diatomic hydrogen, oxygen, and fluorine react exothermically with the 5-5-8 defect inducing effective potentials along this line defect. Transport calculations show that these potentials reduce the electron transmission probability across the line defect converting it from semi-transparent to highly reflective to incoming electrons.

[1]This work was supported by the Office of Naval Research, directly and through the Naval Research Laboratory.

12:51PM G6.00007 Characterization of line defects in CVD graphene films with scanning plasmon interferometry , ZHE FEI, University of California, San Diego, ALEKSANDR RODIN, Boston University, WILL GANNETT, University of California, Berkeley, SIYUAN DAI, University of California, San Diego, WILLIAM REGAN, University of California, Berkeley, ALEXANDER MCLEOD, MARTIN WAGNER, University of California, San Diego, BENJI ALEMAN, University of California, Berkeley, MARK THIEMENS, University of California, San Diego, GERARDO DOMINGUEZ, California State University, San Marcos, ANTONIO CASTRO-NETO, National University of Singapore, ALEX ZETTLE, University of California, Berkeley, FRITZ KEILMANN, Max Planck Institute of Quantum Optics, MICHAEL FOGLER, DIMITRI BASOV, University of California, San Diego — Line defects that are omnipresent in graphene films fabricated with chemical vapor deposition method (CVD) were studied with scanning plasmon interferometry (SPI)—a technique capable of convenient nano-characterization of graphene devices in ambient conditions. The characteristic SPI patterns of line defects are plasmonic twin fringes, which are generated due to interference between surface plasmons (SPs) of graphene launched by a scanning probe and reflected by the line defects. The twin fringes allow us to visualize and distinguish various types of line defects including cracks, wrinkles, and even grain boundaries. Further modeling of the twin fringes provides detailed information on the electronic properties associated with these line defects.

1:03PM G6.00008 Direct Determination of the Chemical Bonding of Individual Impurities in Graphene[1] , MYRON KAPETANAKIS, WU ZHOU, MICAH PRANGE[2], SOKRATES PANTELIDES, Dept. of Physics and Astronomy, Vanderbilt University, Nashville, TN 37235, USA. MST Division, ORNL, Oak Ridge, TN 37831, USA, STEPHEN PENNYCOOK, MST Division, ORNL, Oak Ridge, TN 37831, USA. Dept. of Physics and Astronomy, Vanderbilt University, Nashville, TN 37235, USA, JUAN-CARLOS IDROBO, MST Division, ORNL, Oak Ridge, TN 37831, USA — Using a combination of Z-contrast imaging and atomically resolved electron energy-loss spectroscopy on a scanning transmission electron microscope, we show that the chemical bonding of individual impurity atoms can be deduced experimentally. We find that when a Si atom is bonded with four atoms at a double-vacancy site in graphene, Si 3d orbitals contribute significantly to the bonding, resulting in a planar sp^2d-like hybridization, whereas threefold coordinated Si in graphene adopts the preferred sp^3 hybridization. The conclusions are confirmed by first-principles calculations and demonstrate that [U+2028] chemical bonding of two-dimensional materials can now be explored an experimental probe at the single impurity level.

[1]Supported by NSF (DMR-0938330) (WZ), ORNL's (ShaRE) User Program (JCI), which is sponsored by the Office of BES, DoE, the DoE MSE Division, Office of BES (SJP, STP), and DoE grant DE-FG02-09ER46554 (MDK, MPP, STP).
[2]Present address: Pacific Northwest National Laboratory, Richland, WA 99352, USA.

1:15PM G6.00009 Effect of Defects on the Intrinsic Strength and Stiffness of Graphene , ARDAVAN ZANDIATASHBAR, Rensselaer Polytechnic Institute, GWAN HYOUNG LEE, Columbia University, HAMED PARVANEH, Rensselaer Polytechnic Institute, SUNG JOO AN, SUNWOO LEE, Columbia University, NITHIN MATHEW, CATALIN R. PICU, Rensselaer Polytechnic Institute, JAMES HONE, Columbia University, NIKHIL KORATKAR, Rensselaer Polytechnic Institute — Mechanical properties of defective mono-layer graphene sheets have been studied using experimental and computational tools. In experiments, elastic properties and breaking strength of free standing monolayer defective graphene membranes are measured by nanoindentation using an atomic force microscope. Defects have been introduced by exposure of membranes to oxygen plasma. Density of defects has been quantified using Raman and Auger electron spectroscopy, and also Transmission electron microscopy. Molecular dynamics simulations have been used to investigate the mechanical properties of free standing monolayer graphene membranes using reactive force fields. The effect of boundary conditions, as well as presence of defects in form of vacancies and bonded epoxide groups has been investigated and compared to experiments. Both experiments and simulations show decrease in Young's modulus and strength of graphene membranes by increasing defect density. However, the change in the elastic modulus is small below a certain defect density, which shows defective graphene membrane can still carry load and stay functional in different applications like decorated carbon based MOSFETs and graphene based nanocomposites.

1:27PM G6.00010 Stability and Electronic Structures of Al-, Si- and Au-incorporated Divacancy Graphenes: A First-principles Study , NA-YOUNG KIM, EUI-SUP LEE, YONG-HYUN KIM, Graduate School of Nanoscience and Technology (WCU), KAIST, Daejeon 305-701 — C, N, and O decorated divacancy pores in graphene have been reported as well. Especially, the N4 divacancy pore can strongly bind with the divalent 3d transition metals (TMs) because of the large enough pore size and the strong p-d hybridization. Recently, the Si- and Au-incorporated divacancy pore have been also proposed, but understanding of the stability or electronic properties is largerly lacking. In this work, we invesgated the stability and electronic structure of Al-, Si- and Au-incoporated divacancy graphenes decorated with reactangular CmNn, NnOl, and OlCm, based on first-principles density-functional theory (DFT) calculations. We found that the Al-CN3, Si-C2N2, and Au-CN3 are most stable configurations for each cations because the unpaired electrons of edge atoms of divacancy pore could be completely passivated. The binding energies are also higher than cohessive energies due to the strong p-p or p-d hybridization. Because of the strong hybridizaition, the restoration of π-network of graphene or small band-gap opening near the fermi-level are also observed.

1:39PM G6.00011 Impact of point defects in graphene systems , MIGUEL MORENO UGEDA, ANTONIO MARTÍNEZ-GALERA, IVÁN BRIHUEGA, JOSÉ MARÍA GÓMEZ-RODRÍGUEZ, Departamento de Física de la Materia Condensada, Universidad Autónoma de Madrid, E-28049 Madrid, Spain — Topological defects strongly influence the mechanical, electronic and even magnetic properties of low dimensional carbon-based systems. Taking advantage of the key role of defects in these systems, a unique route based on defect engineering is being developed to broaden the functionalities of graphene. In particular, vacancy-type defects are of an extraordinary importance as they are the key ingredient to understand the new properties shown by functionalized graphene after irradiation. While the role played by these vacancies as single entities has been extensively addressed by theory, experimental data available only refer to statistical properties of the whole heterogeneous collection of vacancies generated in the irradiation process. Scanning tunneling microscopy has great potential in this arena since it enables characterization of point defects at the atomic level. In our work, we first created well characterized individual vacancies on graphene layers by Ar+ ion irradiation and then, using low temperature scanning tunneling microscopy/spectroscopy, we individually investigated the impact of each type of such vacancies on the electronic, structural and magnetic properties of several graphene systems [1-3]. [1] M. M. Ugeda, et al, Phys. Rev. Lett 104, 096804 (2010). [2] M. M. Ugeda, et al. Phys. Rev. Lett 107, 116803 (2011). [3] M. M. Ugeda, et al Phys. Rev B,85, 121402 (R) (2012).

1:51PM G6.00012 Defect-induced amorphization of single-layer graphene: structure and mechanical properties , CORINNE CARPENTER, ASHWIN RAMASUBRAMANIAM, DIMITRIOS MAROUDAS, University of Massachusetts Amherst — Defect engineering of graphene provides a potential route for tuning its mechanical, electronic, and chemical properties. While individual defects in single-layer graphene have been investigated in much detail, collective interactions of multiple defects are less well understood. In this work, we address the effects of introducing populations of vacancies in single-layer graphene using classical molecular-dynamics simulations based on reliable bond-order potentials. We study random distributions of vacancies in a single graphene layer with vacancy concentration and temperature being the key parameters in the analysis. We demonstrate that a crystalline-to-amorphous structural transition occurs at vacancy concentrations of 5-10% leading to complete loss of long-range order in the graphene layer. We conduct a systematic parametric study of this phenomenon accompanied by a detailed structural analysis of the defective sheets. We also present systematic studies of tensile tests on these defective graphene sheets and identify trends for the ultimate tensile strength, failure strength, and toughness as a function of vacancy concentration. The implications of our findings for tuning the mechanical and electronic properties of single-layer graphene are discussed.

2:03PM G6.00013 Heterogeneous Catalysis on Defect-Engineered Graphene[1] , M. SAMY EL-SHALL, Virginia Commonwealth University — Graphene has attracted great interest for a fundamental understanding of its unique structural and electronic properties and also for important potential applications in nanoelectronics and devices. The combination of thermal, chemical and mechanical stability with the high surface area offers many interesting applications in a wide range of fields including heterogeneous catalysis where metallic and bimetallic nanoparticle catalysts can be efficiently dispersed on the graphene sheets. We have developed facile and scalable chemical and laser reduction methods for the synthesis of defect-engineered graphene, as well as metal and semiconductor nanoparticles dispersed on graphene. We recently discovered a remarkable catalytic activity of metal nanoparticles supported on defect-engineered graphene in a variety of chemical transformation including carbon-carbon cross coupling reactions and Fischer-Tropsch Synthesis of long chain liquid hydrocarbons. The results demonstrate the role of the defect sites on the graphene surface in providing favorable nucleation sites for the selective deposition of the metal nanoparticles and as a result, play a major role in imparting exceptional catalytic properties.

[1]We thank the National Science Foundation CHE-0911146 Grant for the support of this work.

Tuesday, March 19, 2013 11:15AM - 2:15PM –

Session G7 DMP: Focus Session: Graphene Devices V 303 - Masa Ishigami, University of Central Florida

11:15AM G7.00001 Coarse-grained quantum transport simulation for analyzing leakage-mobility antagonism in GNRFET , MASAKATSU ITO, SHINTARO SATO, NAOKI YOKOYAMA, National Institute of Advanced Industrial Science and Technology (AIST), CHRISTIAN JOACHIM, Centre d'Elaboration des Matériaux et d'Etudes Structurales (CEMES-CNRS) & MANA Satellite, GREEN NANOELECTRONICS CENTER TEAM, CEMES-CNRS & MANA SATELLITE COLLABORATION — Since it became clear that graphene transistors based on the classical MOSFET principle suffer from serious performance problems, researchers have explored new graphene device design using quantum transport simulations. A first-principle quantum transport simulation, however, still takes unaffordable computational cost to deal with a realistic size of graphene transistor ($> 10^4$ atoms). This motivated us to import ESQC (elastic scattering quantum chemistry) technique from the research field of molecular electronics and to develop its coarse-grained version. To eliminate the atomic scale details, we reformulated ESQC technique using the continuum limit description of graphene charge carriers, which is given by the massless Dirac equation. Since the potential function in this Dirac equation is electrostatic potential distribution, it can be obtained from Poisson equation with the boundary conditions of gate voltages in a self-consistent manner. We are now applying this coarse-grained quantum transport simulation to GNRFETs (graphene nanoribbon field effect transistors) for resolving the mobility-leakage antagonism, where opening a bandgap in a graphene channel improves its switching ability but at the same time deteriorates the electron channel mobility.

11:27AM G7.00002 Density of States and Its Local Fluctuations Determined by Capacitance of Strongly Disordered Graphene[1] , XIAOLONG CHEN, WEI LI, LIN WANG, YUHENG HE, ZEFEI WU, YUAN CAI, MINGWEI ZHANG, YANG WANG, YU HAN, ROLF W. LORTZ, ZHAO-QING ZHANG, PING SHENG, NING WANG, Hong Kong University of Science and Technology — We demonstrate that local fluctuations of the density of states (DOS) in strongly disordered graphene play an important role in determining the quantum capacitance of the top-gate device geometry. Depending on the strength of the disorder induced by metal-cluster decoration, the measured quantum capacitance of disordered graphene could dramatically decrease in comparison with pristine graphene (previous work on transport of metal-cluster decoration has been published on Phys. Rev. B 84, 045431, 2011). A quantitative model for correlating fluctuations of local density of states with the disorder strength and quantum capacitance is presented and discussed. The DOS of disordered graphene obeys a non-universal power law. By measuring the quantum capacitance of disordered graphene, we simultaneously determined both the DOS and its local fluctuations, which is in agreement with the lognormal distributions reported previously for localized samples.

11:39AM G7.00003 Understanding Quantum Transport and the Kondo Effect in 2D Carbon Systems , ROSS MCINTOSH, DMITRY CHUROCHKIN, SOMNATH BHATTACHARYYA, University of the Witwatersrand — The rich physics surrounding correlations between conduction electrons and local spins in quantum dot systems is of significant interest towards the development of spintronic quantum information devices. In this study we establish the Kondo effect in reduced graphene oxide (RGO) films through a metal-insulator transition in resistance versus temperature interpreted within the Fermi liquid description of the Kondo effect and negative magnetoresistance which scales with a Kondo characteristic temperature. With a microstructure consisting of intact graphene nano-islands embedded within residual functionalized regions where local magnetic moments may form, RGO is effectively a disordered quantum dot system. This work is augmented with a theoretical study of transport through nano-scale multiple quantum dot devices. Solving within a Keldysh formalism we scrutinize quasi-bound state formation in a range of geometrical quantum dot configurations in order to interpret coherent quantum interference effects. We demonstrate negative differential conductance and control over device parameters such as the characteristic time. This tandem approach illustrates the promise of innovative low dimensional carbon spintronic devices.

11:51AM G7.00004 An Essential Mechanism of Heat Dissipation in Nanocarbon Electronics[1] , SLAVA V. ROTKIN, Lehigh University, ALEXEY G. PETROV, Ioffe Institute — Nanocarbon materials were proposed and have been already used for fabricating electronic devices. These nanocarbon devices are not unlike other semiconductor devices and are subject to Joule losses. However the physics of heat dissipation in those materials is unlike the classical thermal physics. This talk focuses on near-field radiative heat dissipation mechanism in nanocarbon materials, the associated component of the heat transport across the interface with the substrate and remote Joule losses. Analytical theory was derived which allows one to trace the origin of anomalously large strength of the effect and predict dependence on the materials parameters. It was predicted to be very substantial and for certain surface morphology dominate over other mechanisms, as it was recently shown experimentally.

12:03PM G7.00005 Determination of dominant scatterer in Graphene on SiO_2 using atomic hydrogen , JYOTI KATOCH, Department of Physics and Nanoscience Center, University of Central Florida, Orlando, Fl, DUY LE, Department of Physics, University of Central Florida, Orlando, Fl, TALAT RAHMAN, Deparment of Physics, University of Central Florida, Orlando, Fl, MASA ISHIGAMI, Deparment of Physics and Nanoscience Center, University of Central Florida, Orlando, Fl — We have measured the impact of low energy atomic hydrogen ($<$ 250meV) on the transport property of graphene sheets as a function of hydrogen coverage and initial, pre-hydrogenation field-effect mobility. In order to understand the correlation between the field effect mobility and the apparent affinity of atomic hydrogen to graphene, we have performed a detailed temperature programmed desorption study on hydrogen-dosed graphene sheets. Atomic hydrogen is found to be desorbing with three different desorption energies. The physisorbed atomic hydrogen on graphene with desorption energy of 60 $\pm$ 30meV (consistent with our theoretical calculations), is found to be correlated to the native scatterers in graphene. The associated charge transfer expected for such small desorption energy indicates that atomic-scale defect sites are not responsible for determining the mobility of graphene on SiO_2 and that charged impurities, presumably in substrates, define the transport property of graphene on SiO_2.

12:15PM G7.00006 The zero-voltage conductance of nano-graphenes: Simple rules and quantitative estimates[1] , MATTHIAS ERNZERHOF, YONGXI ZHOU, University of Montreal, DIDIER MAYOU, Institute Néel, Grenoble — Zero-dimensional graphenes, also called nano-graphenes (NGs), consist of fragments of graphene with a finite number of hexagons. NGs can be viewed as a subset of the polycyclic aromatic hydrocarbons (PAHs) that continue to attract chemists attention. We develop a simple theory for the ballistic electron transport through NGs which combines elements of the electronic structure theory of graphene, intuitive methods for the calculation of the molecular conductance, and chemical concepts such as Kekulé structures. This theory enables one to analyze the relation between the structure of NGs and their conductance. General formulas and rules for the zero-voltage conductance as a function of the contact positions are derived. These formulas and rules require at most simple paper and pencil calculations in applications to systems containing several tens of carbon atoms.

12:27PM G7.00007 Graphene devices and its performance limitations and opportunities , TONY LOW, IBM TJ Watson Research Center — Being a two-dimensional membrane, its mechanical properties such as morphology, strains, phonons can significantly modifies the electronic properties of graphene. In fact, the coupling between the mechanical and electronic properties of graphene plays a key limiting role in the performance of electronics and optoelectronics devices. Modeling studies of several in-house experiments will be discussed to exemplify this point. Next, I will discuss how the modification of electronic properties of graphene via mechanical strains might lead to interesting electronics and electromechanical devices.

1:03PM G7.00008 Epitaxial Graphene on SiC for Ultra-high Frequency Transistors[1] , ZELEI GUO, RUI DONG, School of Physics, Georgia Institute of Technology, PARTHA SARATHI CHAKRABORTY, NELSON LOURENCO, School of Electrical and Computer Engineering, Georgia Institute of Technology, JAMES PALMER, YIKE HU, MING RUAN, JOHN HANKINSON, JAN KUNC, School of Physics, Georgia Institute of Technology, JOHN CRESSLER, School of Electrical and Computer Engineering, Georgia Institute of Technology, CLAIRE BERGER, WALT DEHEER, School of Physics, Georgia Institute of Technology — Electronic devices and systems operating at ultra-high frequencies have recently generated significant interest. Graphene is considered a promising candidate material for high-frequency electronics, due to its intrinsic low dimensionality, high carrier mobility and large carrier velocity. Field effect transistors made of exfoliated graphene flakes as the channel material have shown cut-off frequency (f_T) above 400 GHz. However, the maximum oscillation frequency (f_{max}) of graphene transistors, which sets the practical limit on useful circuit operation, to date have not exceeded 45 GHz. We report here record intrinsic f_{max} of 70 GHz, with f_T exceeding 100 GHz, for transistors based on epitaxial graphene on SiC. In addition to setting a new performance record for graphene technology, these epitaxial graphene transistors were fabricated using well-developed, robust, top-down processes compatible with a mass-production-compatible platform.

1:15PM G7.00009 Effect of back-gate bias on Graphene RF device performance , WENJUAN ZHU, DAMON FARMER, YANQING WU, BRUCE EK, KEITH JENKINS, PHAEDON AVOURIS, IBM T.J. Watson Research Center — Graphene is very promising for RF devices due to its high carrier mobility. High cut-off frequency graphene RF devices using CVD grown graphene and epitaxially grown graphene have been reported. Here we report the effect of the back-gate bias on the FET cut-off frequency and current saturation. We found that there are two peak cut-off frequencies corresponding to electron peak trans-conductance and hole peak trans-conductance maxima respectively, as we sweep the top-gate bias. The electron peak cut-off frequency can be significantly increased by applying a positive back-gate bias. The higher the voltage, the larger the maximum cut-off frequency. This can be explained by the additional electron doping introduced by the back-gate bias in the under-lap region, which forms an n-n+-n configuration. Similarly, the hole peak cut-off frequency can be significantly enhanced by applying negative back-gate bias to form the p-p+-p configuration. The shorter the channel, the more pronounced this effect. We also found that the current saturation is also improved by introducing the same type of carrier as the channel in the under-lap region.

1:27PM G7.00010 Can we reduce the OFF currents of graphene without hurting their ON currents? , FRANK TSENG, University of Virginia, GIANLUCA FIORI, University of Pisa, AVIK GHOSH, University of Virginia — The current-voltage characteristics of graphene can be understood from Landauer-Keldysh theory. The low bias conductivity is dominated by tunneling through closely spaced modes. The mid-voltage regime is dominated by Coulomb scattering from charge puddles and remote optical phonons that compete with each other towards quasi-saturation. Finally, the high bias physics is given by band-to-band (Zener) tunneling. The overall I-V, consistent with experiments is limited by the lack of a band-gap that compromises the overall gain and inverter characteristics, also seen experimentally. Conversely, structural band-gaps increase the effective mass of the electrons as well as their phase space for scattering, reducing their overall mobility. We show that a way around this dilemma is to engineer sequences of gates that stagger the Dirac point regions in the separately gated graphene segments (equivalently, bandgapped regions for nanoribbons and nanotubes) so as to effectively increase the transmission gap and suppressing subthreshold conduction by two orders of magnitude and extending current saturation without overall ON-current.

1:39PM G7.00011 Electrical Transport Properties of Graphene Oxide Transistor Using Step-by-Step Reduction , SEUNG JAE BAEK, MIN PARK, Seoul National University, BYUNG HOON KIM, YONGSEOK JUN, Ulsan National Institute of Science and Technology(UNIST), YUNG WOO PARK, Seoul National University — Step by step reduced graphene oxide(GO) thin film transistors were electrically characterized as a temperature and gate voltage. The GO transistors were prepared by thermally reduced using step by step method in same samples. The reduction temperature were subtracted from the inflection point of thermogravimetric analysis(TGA) plot and their points are 88, 158, 185, 215, 250, 300 degree Celsius. All GO condition at various reduction temperatures were defined using Raman spectroscopy and atomic force microscopy(AFM). Temperature dependence electrical measurements were carried out using two terminal technique and various temperatures up to unmeasurable condition. Our charge transport behaviors well fitted to 2 dimensional variable-range hopping(2D VRH) mechanism and fluctuation induced tunneling(FIT) model. Also the conductivity level of each step was increased more than 10^4 times.

1:51PM G7.00012 Mechanism of the doping dependence of 2D Raman band: Dirac-cone migration , KEN-ICHI SASAKI, NTT Basic Research Labs, YASUHIRO TOKURA, Tsukuba University, SATORU SUZUKI, TETSUOMI SOGAWA, NTT Basic Research Labs — The Raman G and 2D bands are informative characterization tools. The G band can be used to determine whether or not the position of the Fermi energy μ is close to the Dirac point, since the width broadens when $\mu \simeq 0$, which is known as the Kohn anomaly effect. By contrast, the width of the 2D band sharpens when $\mu \simeq 0$ [1]. We have explored the origin of the difference between the μ dependencies of the G and 2D bands, first intuitively by employing a concept of a shifted Dirac cone, and then more rigorously in terms of self-energy taking electron-phonon coupling into account[2]. By considering a direct transition in shifted Dirac cones, we clarified that the spectral features of a phonon show varieties of behavior that depend strongly on the value of the phonon momentum q. In particular, the resonance decay of a phonon satisfying $v_F q > \omega$ (ω is phonon's frequency) into an electron-hole pair is suppressed when $2\mu < \hbar v_F q - \hbar\omega$. The idea of shifted Dirac cone can be applied to a general phonon with a nonzero q, including the defect induced D and D′ bands, which are of prime importance in recent studies on graphene edges.

2:03PM G7.00013 Effect of gate-induced doping on the Raman spectra of disordered graphene , ISAAC CHILDRES, LUIS A. JAUREGUI, YONG P. CHEN, Purdue University, PURDUE UNIVERISTY, YONG P. CHEN GROUP TEAM — We report a Raman spectroscopy study of graphene field-effect transistors (GFET) after exposure to electron-beam irradiation, used to introduce a controlled amount of defects in graphene. Raman spectra are taken over a range of temperatures (4-300 K), back gate voltages and electron-beam exposures. We observe that the intensity ratio between Raman "D" and "G" peaks,I_D/I_G, commonly used to determine the amount of disorder in graphene, not only changes with the irradiation dosage, but also with gate-induced doping. At low temperature (4 K), we observe a peak in the plot of I_D/I_G versus back gate voltage at the Dirac point of the GFET. As the temperature increases, the back gate voltage at which this peak occurs decreases relative to the Dirac point. Our findings may be valuable for understanding the Raman spectra and electron-phonon physics in doped and disordered graphene.

Session G8 DCMP: Graphene: Nanoribbons, Dots, and Strain 307 - Vincent Meunier, Rensselaer Polytechnic Institute

11:15AM G8.00001 Towards a Rigorous Proof of Magnetism on the Edges of Graphene Nanoribbons[1] , HAMED KARIMI, IAN AFFLECK, University of British Columbia — A zigzag edge of a graphene nanoribbon supports localized zero modes, ignoring interactions. Based mainly on mean field arguments and numerical approaches, it has been suggested that interactions can produce a large magnetic moment on the edges. By considering the Hubbard model in the weak coupling limit, $U \ll t$, for bearded as well as zigzag edges, we argue for such a magnetic state, based on Lieb's theorem. Projecting the Hubbard interactions onto the flat edge band, we then prove that resulting 1 dimensional model has a fully polarized ferromagnetic ground state. We also study excitons and the effects of second neighbor hopping as well as a potential energy term acting on the edge only, proposing a simple and possibly exact phase diagram with the magnetic moment varying smoothly to zero. Finally, we consider corrections of second order in U, arising from integrating out the gapless bulk Dirac excitations.

[1]NSERC, CIFAR

11:27AM G8.00002 Quantum Monte Carlo study of edge-state magnetism on chiral graphene nanoribbons , MICHAEL GOLOR, Institute for Theoretical Solid State Physics, RWTH Aachen University, THOMAS C. LANG, Department of Physics, Boston University, STEFAN WESSEL, Institute for Theoretical Solid State Physics, RWTH Aachen University — We investigate the edge-state magnetism of chiral graphene nanoribbons using projective quantum Monte Carlo (QMC) simulations and a self-consistent mean-field approximation of the Hubbard model. Previous QMC simulations support edge-state ferromagnetism in sufficiently wide zigzag terminated ribbons. We extended these calculations to include the class of chiral graphene nanoribbons and investigate the influence of chirality and ribbon width on spin-spin correlations. The static magnetic correlations are found to rapidly increase with the width of the ribbons for all chiralities, such that already for ribbons of moderate widths we observe a strong trend towards mean-field-type ferromagnetic correlations along the edges. We extract dynamical edge state signatures which can be used to detect edge-state magnetism by scanning tunneling microscopy.

11:39AM G8.00003 Strain induced magnetism in graphene , LUCIAN COVACI, FRANCOIS PEETERS, University of Antwerp — Electron-electron interactions are believed not to be very important in graphene since the strength of the on-site Hubbard repulsion is moderate and the electron density of states is small near the Dirac points. Even so, graphene is believed to be in the proximity of a phase transition between a conducting state and an insulating one (antiferromagnetic or spin liquid). Finding a way to bring graphene across the transition is thus an important issue. We consider the effect of inhomogeneous strain from deformations induced by imperfections or steps in the substrate or from specific strain configurations that give almost constant pseudo-magnetic fields. We perform self-consistent mean field calculations for a tight-binding Hamiltonian where we consider only a repulsive on-site Hubbard term. We show that due to strain induced modifications of the kinetic energy, the staggered magnetization will become finite near regions where the strain is large. We also uncover that near deformations, spin-polarized states will appear, in a similar way the spin-polarized states appear at zig-zag edges of graphene nanoribbons.

11:51AM G8.00004 Friction, Adhesion, and Elasticity of Grahene Edges[1] , D. PATRICK HUNLEY, TYLER FLYNN, TOM DODSON, ABHISHEK SUNDARARAJAN, MATHIAS BOLAND, DOUGLAS STRACHAN, University of Kentucky, Department of Physics and Astronomy — Frictional, adhesive, and elastic characteristics of graphene edges are determined through lateral force microscopy. Measurements reveal a significant local frictional increase at exposed graphene edges, whereas a single overlapping layer of graphene removes this local frictional increase. Comparison of lateral force and atomic force microscopy measurements shows that local forces on the probe are successfully modeled with a vertical adhesion in the vicinity of the atomic-scale graphene steps. Lateral force microscopy performed with carefully maintained probes shows evidence of elastic straining of graphene edges which are consistent with out-of-plane bending of the edges.

[1]The work was supported in part by the NSF Grant DMR-0805136, the KY NSF EPSCoR award EPS-0814194, the UK Center for Advanced Materials (CAM), and a Research Support Grant from the UK Office of the Vice President for Research.

12:03PM G8.00005 Single point defect states in an armchair-graphene nanoribbon[1] , CHI-HSAUN CHIU, C.S. CHU, National Chiao Tung Universty, Taiwan — We investigate in detail the electronic states induced by a single or a few defects in an armchair-graphene nanoribbon (AGNR). A semi-analytical approach is developed for the Lippmann-Schwinger formulation within the tight-binding model. The dependences of the local density of states (LDOS) in the vicinity of the defects on both the defect locations and the nanoribbon widths are explored. In particular, the LDOS characteristics in the gapped or gapless AGNR will be discussed. Our results are compared with exact diagonalization approach. The effects of these point defect states on the transport property of the AGNR will also be presented.

[1]NSC 101-2112-M-009-014

12:15PM G8.00006 Ab initio electronic structure and transport studies of N_2^{AA}-doped armchair and zigzag graphene nanoribbons , JONATHAN OWENS, Rensselaer Polytechnic Institute, EDUARDO CRUZ-SILVA, University of Massachusetts Amherst, VINCENT MEUNIER, Rensselaer Polytechnic Institute — Recent work by Lu, et al. (Nature Scientific Reports, DOI: 10.1038) on large sheets of nitrogen-doped graphene, determined that a highly predominant amount of nitrogen dopants (80 %) form in pairs on the same sub-lattice. Graphene nanoribbons, which are essentially narrow strips of graphene, have a natural band gap and tunable electronic properties, making them a promising candidate for scalable nanoelectronics. In this work we explore various electronic structural (density of states, local density of states, and STM images) and transport properties of armchair (aGNR) and zigzag (zGNR) graphene nanoribbons under different orientations of the N_2^{AA} dopants with respect to the ribbon growth direction. For all configurations of zGNRs and aGNRs, we see a substantial decrease in conductance due the dopants, as well as spatially localized states opening around the dopant sites. Most notably, however, we observe the emergence of a new stable spin configuration, wherein the spin-up spin-down polarizations of the edges in zGNRs (denoted the antiferromagnetic state) flip near the doping sites, while being in the normal zGNR AFM ground state away from the dopants.

12:27PM G8.00007 Atypical structural, electronic, and thermoelectric properties of assembled graphene nanoribbons[1] , LIANGBO LIANG, VINCENT MEUNIER, Rensselaer Polytechnic Institute, EDUARDO CRUZ-SILVA, University of Massachusetts, EDUARDO GIRÃO, Universidade Federal do Piauí — Highly ordered assembly of individual graphene nanoribbons (GNRs) into graphene nanowiggles (GNWs) has been recently demonstrated using a surface-assisted bottom-up chemical approach. GNWs are characterized by a periodic repetition of wiggle-like junctions where armchair- or zigzag-edged GNRs sectors alternate. We employed both density functional theory (DFT) and Tight-Binding+U to demonstrate their versatile electro-magnetic properties [Girão et al, Phys. Rev. Lett. 107 (2011)]. The coexistence of parallel and oblique sectors leads GNWs to offer a broader set of geometrical parameters to fine tune the electronic band gap from 0.0 eV to 1.7 eV than GNRs [Girão et al, Phys. Rev. B 85 (2012)]. Also, the presence of wiggle-like edges dramatically degrades thermal conductance but retains excellent electronic conduction, resulting in significant enhancement of the thermoelectric performance [Liang et al, Phys. Rev. B 86 (2012)]. Finally, many-electron GW calculations show quasiparticle band gaps of GNWs generally more than twice of their DFT band gaps, reaching 3.7 eV. Furthermore, the gold substrate where GNWs are synthesized is found to lead to band gap reduction owing to substrate polarization effect, consistent with experiments [Liang et al, Phys. Rev. B 86 (2012)].

[1]Liangbo Liang is supported by New York State under NYSTAR con tract C080117. All the calculations were performed on resources from the Computational Center for Nanotechnology Innovation at Rensselaer Polytechnic Institute.

12:39PM G8.00008 Quasiparticle Band Gap modulation in Graphene Nanoribbons Supported on Weakly interacting Surfaces , XUEPING JIANG, Rensselaer Polytechnic Institute, NEERAV KHARCHE, Brookhaven National Laboratory, PAUL KOHL, Georgia Institute of Technology, TIMOTHY BOYKIN, The University of Alabama in Huntsville, GERHARD KLIMECK, Purdue University, MATHIEU LUISIER, Integrated Systems Laboratory,, PULICKEL AJAYAN, Rice University, SAROJ NAYAK, Rensselaer Polytechnic Institute — Low dimensional nanostructures such as graphene nanoribbons(GNRs) and hexagonal boron nitride (hBN) have been successfully synthesized in experiments and attract a lot of attention recently. The strong electron-electron interactions due to quantum confinement could alter band gaps of nanostructures, which has been studied thoroughly for GNRs. Band gaps could also be changed by the effect of dielectric screening arising from the surrounding materials such as the substrate. However, this effect has not been thoroughly investigated for GNRs. In contrast, in almost all the experiments GNRs are deposited on different dielectric substrates leaving a gap between theoretical estimates and experimental measurements. The effect of dielectric screening cannot be captured in an effective single particle theory such as the density functional theory (DFT) and the many-body approaches such as *GW* are required. We show the band gaps of the free standing GNRs are reduced as much as 1 eV in spite of weak van der Waals interactions between the GNR and the underlying substrate. This non-local effect can be explained by a semi-classical image charge model and such understanding is critical to the band gap engineering of graphene based devices.

12:51PM G8.00009 ABSTRACT WITHDRAWN –

1:03PM G8.00010 Snake states and Majorana's in graphene quantum dots in the presence of a p-n junction , FRANCOIS PEETERS, M. ZARENIA, Universiteit Antwerpen, Dept. Physics, J.M. PEREIRA, JR., G.A. FARIAS, UFC, Dept. de Fisica, Fortaleza, Ceara, Brazil — We investigate the magnetic interface states of graphene quantum dots that contain p-n junctions. Within a tight-binding approach, we consider rectangular quantum dots in the presence of a perpendicular magnetic field containing p-n, as well as p-n-p and n-p-n junctions. The results show the interplay between the edge states associated with the zigzag terminations of the sample and the snake states that arise at the p-n junction, due to the overlap between electron and hole states at the potential interface. Remarkable localized states are found at the crossing of the p-n junction with the zigzag edge having a dumb-bell shaped electron distribution. These states are localized Majorana states. The results are presented as function of the junction parameters and the applied magnetic flux.

1:15PM G8.00011 Evidence for edge state photoluminescence in graphene quantum dots , KIRAN LINGAM, RAMAKRISHNA PODILA, Department of Physics and Astronomy, Clemson University, Clemson, SC 29634, HAIJUN QIAN, Electron Microscope facility, Clemson research park, Clemson University, Anderson, SC USA 29625., STEVE SERKIZ, Savannah River National Laboratory, Aiken, SC USA 29808, APPARAO M. RAO, Department of Physics and Astronomy, Clemson University, Clemson, SC 29634 — For a practical realization of graphene-based logic devices, opening of a band gap in graphene is crucial and has proved challenging. To this end, several synthesis techniques including unzipping of carbon nanotubes, chemical vapor deposition and other bottom-up fabrication techniques have been pursued for the bulk production of graphene nanoribbons (GNRs) and graphene quantum dots (GQDs). However, only a limited progress has been made towards a fundamental understanding of the electronic and optical properties of GQDs. In particular, the origin of strong photoluminescence (PL) in GQDs, which has been attributed to the presence of emissive surface traps and/or the edge states in GQD, remains inconclusive to date. Here, we experimentally show that the PL is independent of the functional groups attached to the GQDs. Following a series of annealing experiments, we further show that the PL in GQDs originates from the edge states, and an edge-passivation subsequent to synthesis quenches PL. These results are consistent with comparative studies on other carbon nanostructures such as GNRs and carbon nano-onions.

1:27PM G8.00012 Spontaneous Gap Formation in an Uniaxially Strained Graphene , ANAND SHARMA, VALERI N. KOTOV, University of Vermont, ANTONIO H. CASTRO NETO, National University of Singapore — We study the condition of spontaneous gap generation due to Coulomb interaction between anisotropic Dirac fermions in an uniaxially strained graphene. The gap equation is realized as a self-consistent solution for the self- energy i.e., Dyson- Schwinger equation, within static Random Phase Approximation. The mass gap not only depends on the momentum due to long- range nature of the interaction but also on the anisotropy due to uniaxial strain. Using standard numerical analysis we solve the integral equation on a finite grid. We evaluate the mass gap as a function of dimensionless coupling constant for different values of anisotropy parameter and obtain the critical coupling at which the gap becomes non-zero. Our study indicates that with an increase in uniaxial strain in graphene, the critical coupling decreases which is in agreement with our perturbative renormalization group analysis.

1:39PM G8.00013 Band Gap Opening in Periodically Modified Graphene , MARC DVORAK, ZHIGANG WU, Department of Physics, Colorado School of Mines — The gapless electronic structure of graphene must be modified to allow a meaningful on-and-off ratio for use in field-effect transistors. Many attempts to create semiconducting graphene have been made; among them, application of periodic structural modifications, such as patterned defects or nanoscale perforation creating a graphene nanomesh, is particularly promising. Extensive theoretical efforts have been spent to investigate such graphene structures, but the precise role of periodic perturbation on band gap opening remains unclear. Here, we show analytically that band gap opening in graphene under a periodic perturbation can be accurately predicted by mapping the perturbative reciprocal lattice vectors onto Dirac points. The modified graphene alternates between a semi-metal and a semiconductor with 8/9 gapless and 1/9 semiconducting. Furthermore, semiconducting modified graphene can be mapped to exactly two corresponding semimetallic carbon nanotubes or graphene nanoribbons. These predictions reveal the fundamental physics of band gap opening in periodically defected graphene and are in excellent agreement with previous and present first-principles results for graphene nanomeshes.

1:51PM G8.00014 Gauge fields for rippled graphene membranes under central load , SALVADOR BARRAZA-LOPEZ, JAMES V. SLOAN, University of Arkansas, ALEJANDRO A. PACHECO, Universidad del Norte, CEDRIC M. HORVATH, University of Arkansas, ZHENG FEI WANG, University of Utah — Gauge fields on graphene are invariably expressed in the language of continuum elasticity. Following an approach where the atomic positions play the preponderant role, a model of strain on graphene was developed where all relevant quantities -including gauge fields- are directly expressed in terms of atomic displacements only. Suspended, rippled graphene membranes under cetral load by a sharp object were studied using this approach. The effects from both the pseudo-magnetic field and the deformation potential were included in calculations of the electron density at different spatial locations (the deformation potential acts as an on-site potential energy). The deformation potential -neglected without proper justification in many published works- appears to modify the electronic spectrum dramatically in a qualitative way. Discussion of experiments relevant to the model will also be given.

2:03PM G8.00015 Theory of electromechanical coupling in dynamical graphene , MIRCEA TRIF, PRAMEY UPADHYAYA, YAROSLAV TSERKOVNYAK, University of California, Los Angeles — We study the coupling between mechanical motion and Dirac electrons in a dynamical sheet of graphene. We show that this coupling can be understood in terms of an effective gauge field acting on the electrons, which has two contributions: $quasistatic$ and purely $dynamic$ of the Berry-phase origin. As is well known, the static gauge potential is odd in the K and K' valley index, while we find the dynamic coupling to be even. In particular, the mechanical fluctuations can thus mediate an indirect coupling between charge and valley degrees of freedom.

Tuesday, March 19, 2013 11:15AM - 2:15PM –

Session G9 FEd: Invited Session: Broadening Participation in Physics and Other STEM Fields

308 - Paul Cottle, Florida State University

11:15AM G9.00001 Broadening participation in Natural Sciences and Mathematics at the University of Maryland Baltimore County[1] , PHILIP ROUS, University of Maryland Baltimore County — Over the past two decades, UMBC has undertaken a series of efforts to broaden participation in the natural sciences and mathematics, beginning with the establishment of the Meyerhoff program. Using as examples the multiple initiatives that followed, and with a focus on the challenge of increasing access and success of all students who enter as both freshmen and transfer students, I will describe a model of culture change that we have employed repeatedly to understand and guide our efforts in broadening participation. Particular attention will be paid to the concept of cultural capital, the role of innovators and the challenge of scaling small-scale innovations towards institutional change.

[1]Supported by the National Science Foundation and the Bill and Melinda Gates Foundation.

11:51AM G9.00002 APS Initiatives for Broadening Participation , THEODORE HODAPP, American Physical Society — Women currently earn only about 20% of physics degrees, while African Americans and Hispanic Americans combined – representing 34% of the US population in their 20's – earn only 9% and 5-6% of the Bachelor and Doctoral degrees respectively. To address these disparities, and improve conditions for everyone who studies physics, the APS devotes significant resources to addressing these concerns and to enabling individuals and groups to work with the APS to advance these goals. In this presentation, I will outline several of our most significant programs, give data that informs decisions to adopt programs, and describe current plans. Included in this is the new APS Bridge Program (www.APSBridgeProgram.org) for increasing underrepresented minority participation at the PhD level, the APS Conferences for Undergraduate Women in Physics (go.aps.org/cuwip), and the APS Minority Scholars Program (www.MinoritiesInPhysics.org). Please bring your ideas and concerns for how we might improve participation for all.

12:27PM G9.00003 Drawing minority students into the physics community , PAUL GUEYE, Hampton University/National Society of Black Physicists — In the past few years, the number of African-American undergraduate physics students in the US had a steady decrease with dramatic consequences at many physics departments within Historically Black Colleges and Universities (HBCUs). A similar trend seems to also appear at the graduate level. HBCUs have been known to graduate more than 50% of undergraduate physics majors within this community for many years, a role that is now evaporating. The US African-American community cannot lose the historical and sometimes unnoticed impact of HBCUs in the physics community. The ability for these institutions to recruit, maintain and graduate students with the highest degree has turned a corner and is endangered with the recent closings of many programs. We not only must reverse this trend but also implement a sustainable growth for the future. This is an enormous task for the education community. While there are many outstanding and successful programs that have been developed over the years to target particular areas ranging from early K-12 exposure to producing MS and PhD students, each community/culture is different: one cannot transport someone else's experience and/or program and infuse it into another community. Moreover, the focus must now be comprehensive and not anymore single-centered. This talk will outline some ongoing efforts within the National Society of Black Physicists aimed at infusing a global approach to this problem that targets school districts (K-12) and after school programs, undergraduate and graduate programs within HBCUs, and the larger physic and scientific community.

1:03PM G9.00004 Drawing Women In: Engaging in Science and Engineering Disciplines , SENTA GREENE, Vanderbilt University — Recent data on the participation of women in the scientific, technological, engineering, and mathematical (STEM) disciplines shows a landscape that is somewhat different from our expectations in the past. For example, women who earn bachelors' degrees in physics go on to earn PhDs, be hired to faculty positions, and achieve promotions at the same rate as their male counterparts. However, such gains do not foretell equal participation of women in physics since, although girls make up about half of high school physics classes, the fraction of bachelor's degrees earned by women has been flat at around 20% for about a decade. This remains true even with significantly increased awareness of the need to attract more women to STEM fields and despite various interventions to attract and retain talented women. This talk will present an overview of data on women's participation in STEM disciplines, provide possible explanations for the continued failure to attract women to some STEM fields, and give a brief description of some current interventions.

1:39PM G9.00005 How Undergraduate Women Choose STEM Careers , ROXANNE HUGHES, National High Magnetic Field Laboratory — In 2010 women represented half of the US population and over half of current graduates from college (57%) but less than a third of undergraduate degrees in science and engineering (STEM). This underrepresentation is worse in certain fields such as physics (21%), and engineering (22%) compared to 52% in chemistry. This underrepresentation is not only a social and cultural issue, but it is also cause for alarm in regard to the United States' ability to maintain its technological and economic dominance in the global economy. STEM fields provide valuable contributions to the nation's economic and environmental security (Augustine, 2005; Chang, 2009; Riegle-Crumb and King, 2010; Robelen, 2010; Tessler, 2008), paying practitioners well and bringing in revenue for successful businesses and governments (National Science Board [NSB], 2008; Riegle-Crumb and King). Consequently, addressing the underrepresentation of women and increasing their persistence in STEM fields will increase the number of scientists and engineers contributing to these fields, which could, in turn, improve the nation's economy, safety, and technological revenues. Research indicates that there are internal and external factors that affect the ability of women to see future success in STEM and to identify with the STEM and consequently persist. This presentation will summarize the current literature on issues affecting undergraduate women's retention in STEM as well as present strategies to improve this retention. Part of this presentation will draw from my own research studies in this area. The findings from my study and others reveal that only women who participate in redefinition strategies related to their marginalized status are able to persist; those who cannot redefine their marginality in relation to the dominant discourse of STEM begin to lose interest or doubt their competence in the field, resulting in their departure from STEM.

Tuesday, March 19, 2013 11:15AM - 2:15PM –

Session G10 FOEP: Invited Session: Physics for the Public: Advice From the Pros 309 - James Kakalios, University of Minnesota

11:15AM G10.00001 6 Things Scientists Can Learn from Science Journalists , MAGGIE KOERTH-BAKER, BoingBoing.net, The New York Times Magazine — When you talk about your research, do you feel like you're talking to yourself? Have ever accidentally left a lay person more confused than they were before they met you? Does your left eye go twitchy every time a journalist calls? Communicating science is scary. Fortunately, the same lessons that turn cringe-worthy journalism into smart science reporting can help you do a better job of communicating your own work–whether directly to the public, or to journalists, themselves. Don't freak out. Don't give up. Instead, come to this presentation.

11:51AM G10.00002 Explaining Physics in a Minute (Or Two) , HENRY REICH, MinutePhysics and Perimeter Institute for Theoretical Physics — It's usually assumed that youtube is just for kittens, babies, and music videos. However, youtube is also one of the highest-traffic sites on the internet and it turns out it's actually a darn good place to teach people about physics! We'll start with the story and analysis of how the video series Minutephysics grew from a fun weekend project to one of the top channels on youtube, then discuss how media and technology (especially videos) can facilitate good (and bad) communication, and finally talk about how you can harness the power of the internet in your own physics outreach. Of course we'll watch a few cool videos along the way. As a primer, feel free to check out www.youtube.com/minutephysics (this abstract based on http://pirsa.org/11110110)

12:27PM G10.00003 Capturing Science in Action: From Exploring the Origin of the Universe to a Journey to the Ends of the Earth , PAUL STEINHARDT, Princeton University — The public, including aspiring young scientists, seldom gets a sense of what science really feels like as it is happening – the doubts, the fears, the twists and turns, the joy of victory and the agony of defeat. Even if the science is still uncertain, insights of this type have both inspirational and historic value. This talk will explore this issue using two very different examples from the speaker's own experience: an attempt to develop a theory of the origin of the universe that challenges the conventional big bang picture and a geological expedition to one of the most remote places on the planet in search of the first natural quasicrystal.

1:03PM G10.00004 All the Data That's Fit to Print: How Does the New York Times Cover Physics? , KENNETH CHANG, New York Times Science Editor — No abstract available.

1:39PM G10.00005 Science for the Public Through Collaboration and Humor , RICHARD WARGO, University of California, San Diego — The transformation of all things media and information into a dynamic environment of user access has created what seems infinite possibilities to inform the public in many different ways - as well as seemingly infinite possibilities to confuse. This talk will describe a rather non-conventional collaboration between two different creative cultures and its significance to maintaining scientific accuracy and devising strategies important to audience engagement - among them humor. While focusing on the award-winning effort "When Things Get Small" created by University of California Television producer R. Wargo in collaboration with condensed matter physicist I.K. Schuller and actor Adam J. Smith, with both NSF and private support, the case study provides insight into a model and modes which can be used successfully by other scientists to engage the public in what they do.

Tuesday, March 19, 2013 11:15AM - 2:15PM –

Session G11 DCOMP: Invited Session: Concurrent Multiple Length-Scale Modelling 310 - Qing Peng, Rensselear Polytechnical Institute

11:15AM G11.00001 Quantum Mechanics Based Multiscale Modeling of Materials[1] , GANG LU, Department of Physics, California State University Northridge — We present two quantum mechanics based multiscale approaches that can simulate extended defects in metals accurately and efficiently. The first approach (QCDFT) can treat multimillion atoms effectively via density functional theory (DFT). The method is an extension of the original quasicontinuum approach with DFT as its sole energetic formulation. The second method (QM/MM) has to do with quantum mechanics/molecular mechanics coupling based on the constrained density functional theory, which provides an exact framework for a self-consistent quantum mechanical embedding. Several important materials problems will be addressed using the multiscale modeling approaches, including hydrogen-assisted cracking in Al, magnetism-controlled dislocation properties in Fe and Si pipe diffusion along Al dislocation core.

[1]We acknowledge the support from the Office of Navel Research and the Army Research Office.

11:51AM G11.00002 *Ab initio* prediction of environmental embrittlement at a crack tip in aluminum , DEREK WARNER, Cornell University — This talk reports on our *ab initio* predictions of environmental embrittlement in aluminum. We have used an atomistic-continuum multiscale framework to simulate the behavior of a loaded crack tip in the presence of oxygen and hydrogen. The multiscale simulations and subsequent analysis suggest that electronegative surface impurities can inhibit dislocation nucleation from a loaded crack tip, thus raising the likelihood for incremental brittle crack growth to occur during near-threshold fatigue. The metal-impurity bonding characteristics have been analyzed using a Bader charge transfer approximation, and the effect of this bond on the theoretical slip distribution has been investigated using a continuum Peierls model. The Peierls model, which is a function of the position dependent stacking fault energy along the slip plane, was used to estimate the effects of several common environmental impurities.

12:27PM G11.00003 Concurrent multiscale modeling of amorphous materials[1] , VINCENT TAN, National University of Singapore — An approach to multiscale modeling of amorphous materials is presented whereby atomistic scale domains coexist with continuum-like domains. The atomistic domains faithfully predict severe deformation while the continuum domains allow the computation to scale up the size of the model without incurring excessive computational costs associated with fully atomistic models and without the introduction of spurious forces across the boundary of atomistic and continuum-like domains. The material domain is firstly constructed as a tessellation of Amorphous Cells (AC). For regions of small deformation, the number of degrees of freedom is then reduced by computing the displacements of only the vertices of the ACs instead of the atoms within. This is achieved by determining, a priori, the atomistic displacements within such Pseudo Amorphous Cells associated with orthogonal deformation modes of the cell. Simulations of nanoscale polymer tribology using full molecular mechanics computation and our multiscale approach give almost identical prediction of indentation force and the strain contours of the polymer. We further demonstrate the capability of performing adaptive simulations during which domains that were discretized into cells revert to full atomistic domains when their strain attain a predetermined threshold.

[1]The authors would like to acknowledge the financial support given to this study by the Agency of Science, Technology and Research (ASTAR), Singapore (SERC Grant No. 092 137 0013).

1:03PM G11.00004 Coarse-graining molecular dynamics models using an extended Galerkin method[1] , XIANTAO LI, The Pennsylvania State University — I will present a systematic approach to coarse-grain molecular dynamics models for solids. The coarse-grained models are derived by Galerkin projection to a sequence of Krylov subspaces. On the coarsest space, the model corresponds to a finite element discretization of the continuum elasto-dynamics model. On the other hand, the projection to the finest space yields the full molecular dynamics description. The models in between serve as a smooth transition between the two scales. We start with a molecular dynamics (MD) model, $m_i\ddot{\mathbf{x}}_i = -\frac{\partial V}{\partial \mathbf{x}_i}$. First, let Y_0 be the approximation space for the continuum model. By projecting the MD model onto the subspace, we obtain a coarse-grained model, $M\ddot{\mathbf{q}} = F(\mathbf{q})$. Using the Cauchy-Born approximation, this model can be shown to coincide with the finite element representation of the continuum elastodynamics model. This model has limited accuracy near lattice defects. One natural idea is to switch to the MD model in regions surround local defect. As a result, one creates an interface between the continuum and atomistic description, where coupling conditions are needed. Direct coupling methods may involve enforcing constraints or mixing the energy or forces. Such an approach may suffer from large phonon reflections at the interface, and introduce large modeling error. In order to seamlessly couple this model to MD, we successively expand the approximation space to the Krylov spaces, $K_\ell = Y_0 + AY_0 + \cdots + A^\ell Y_0$. Here A is the force constant matrix, computed from the atomistic model. Due to the translational invariance, only a smaller number of such matrices need to be computed. By projecting the MD model onto this new subspace, we obtain an extended system, $M\ddot{\mathbf{q}} = F_0(\mathbf{q}, \xi_1, \cdots, \xi_\ell), \ddot{\xi}_1 = F_1(\mathbf{q}, \xi_1, \cdots, \xi_\ell), \cdots\cdots, \ddot{\xi}_\ell = F_\ell(\mathbf{q}, \xi_1, \cdots, \xi_\ell)$. The additional variables ξ_j represent the coefficients in the extended approximation space. Using this systematic approach, one can build a hierarchy of models with increasing accuracy, each of which is a well-posed model. At the top of the hierarchy is the continuum model, represented on a finite element mesh. Then, on the same mesh, we obtain higher order approximations of MD. In the limit $\ell \to N$, the full MD description is recovered.

1:39PM G11.00005 Seamless bridging of quantum-mechanics with mechanics and electronic structure calculations at macroscopic scales , VIKRAM GAVINI, Department of Mechanical Engineering, University of Michigan, Ann Arbor — Defects play a crucial role in influencing the macroscopic properties of solids—examples include the role of dislocations in plastic deformation, dopants in semiconductor properties, and domain walls in ferroelectric properties. These defects are present in very small concentrations (few parts per million), yet, produce a significant macroscopic effect on the materials behavior through the long-ranged elastic and electrostatic fields they generate. The strength and nature of these fields, as well as other critical aspects of the defect-core are all determined by the electronic structure of the material at the quantum-mechanical length-scale. Hence, there is a wide range of *interacting* length-scales, from *electronic structure to continuum*, that need to be resolved to accurately describe defects in materials and their influence on the macroscopic properties of materials. This has remained a significant challenge in multi-scale modeling, and a solution to this problem holds the key for predictive modeling of complex materials systems. In an attempt to address the aforementioned challenge, this talk presents the development of a *seamless* multi-scale scheme to perform electronic structure calculations at macroscopic scales. The key ideas involved in its development are (i) a real-space variational formulation of electronic structure theories, (ii) a nested finite-element discretization of the formulation, and (iii) a systematic means of adaptive coarse-graining retaining full resolution where necessary, and coarsening elsewhere with no patches, assumptions or structure. This multi-scale scheme has enabled, for the first time, calculations of the electronic structure of multi-million atom systems using orbital-free density-functional theory, thus, paving the way for an accurate electronic structure study of defects in materials. The accuracy of the method and the physical insights it offers into the behavior of defects in materials is highlighted through studies on vacancies and dislocations. Current efforts towards extending this multi-scale method to Kohn-Sham density functional theory will also be presented.

Tuesday, March 19, 2013 11:15AM - 2:15PM –

Session G12 DMP: Focus Session: Complex Oxide Interfaces - Polar interfaces III 314 - Guneeta Singh Balla, University of California, Berkeley

11:15AM G12.00001 Gated $LaAlO_3/SrTiO_3$ based superconducting nanowires[1] , MICHELLE TOMCZYK, GUANGLEI CHENG, JOSHUA VEASEY, SHICHENG LU, University of Pittsburgh, CHANG-BEOM EOM, University of Wisconsin, PATRICK IRVIN, JEREMY LEVY, University of Pittsburgh — Oxide heterostructures have been shown to support a metal-insulator transition; additionally, below T_c, interface transport becomes superconducting. Control of this transition has been demonstrated at the nanoscale level in $LaAlO_3/SrTiO_3$ by AFM lithography[2]. Electrical transport at the 2D interface can be controlled through backgating. Tunability of one dimensional nanostructures created by AFM lithography is demonstrated through backgating of the heterostructure and through local capacitive effects from side gates. Side gates running parallel to the main channel can tune the Fermi level within the channel, facilitating modulation of a normal-superconducting transition in the wire. Local tuning of the carrier density may enable novel superconducting-normal junctions that could be useful for topological quantum computation.

11:27AM G12.00002 Tuning the carrier density at SrTiO3/LaAlO3 interface by La1-xSrxMnO3 capping layer , YUJUN SHI, DI WU, Physics Departmen,Nanjing University — The observation of a high-mobility quasi-two-dimensional electron gas (q2-DEG) at the interface between the insulators of SrTiO3 (STO) and LaAlO3 (LAO) has gained significant attention in recent years. The carrier density at these interfaces is usually tuned by controlling the growth conditions or applying an electric field in a three-terminal device. According to the polar catastrophe model, which is used to interpret the origin of the q2-DEG at the LAO-STO interfaces, the carrier density and the critical thickness of LAO for the metallic interfaces are related with the net charge of LaO and AlO2 layer in LAO. Here, we systematically study the growth of La1-xSrxMnO3 (LSMO-x), whose net charge is 1-x in each layer, on LAO ($<$ 4 u.c.)/STO to tune the interfacial carrier density and critical thickness. For LAO (3 u.c.)/STO, we found that the threshold thickness of LSMO (x=0.33) for the observation of q2-DEG is 2 u.c. The LAO (3 u.c.)/STO interfaces show a metal-insulator transition for x between 2/3 and 7/8. Importantly, the carrier density monotonically decreases as increasing Sr doping. Our results strongly support the polar catastrophe model and provide a new approach to tune the interfacial carrier density..

11:39AM G12.00003 Simultaneous electromechanical and capacitance characterization of top-gated $LaAlO_3/SrTiO_3$ heterostructures[1] , FENG BI, MENGCHEN HUNG, University of Pittsburgh, CHUNG WUNG BARK[2], SANG-WOO RYU, CHANG-BEOM EOM, University of Wisconsin-Madison, JEREMY LEVY, University of Pittsburgh — $LaAlO_3/SrTiO_3$ (LAO/STO) heterostructures exhibit a sharp, hysteretic metal-insulator transition (MIT) with enhanced capacitance beyond the geometric limit when the interface is tuned by a biased top gate. To understand the physical origin of these behaviors, we investigate the electromechanical response and capacitance spectroscopy of top-gated LAO/STO heterostructures. Piezoelectric Force Microscopy (PFM) measurements demonstrate local variations in the hysteretic response, and capacitance measurements show carrier density changes at the LAO/STO interface as the top gate bias is varied. A strong correlation between PFM signals and capacitance signals is established by doing simultaneous measurements. The enhanced capacitance at the MIT is correlated with charging/discharging dynamics of nanoscale conducting islands at the interface, which can be imaged by spatially-resolved PFM.

11:51AM G12.00004 A Gate-tunable Polarized Phase of Two-Dimensional Electrons at the $LaAlO_3/SrTiO_3$ Interface , ARJUN JOSHUA, JONATHAN RUHMAN, SHARON PECKER, EHUD ALTMAN, SHAHAL ILANI, Weizmann Institute of Science — We show using anisotropic magnetoresistance and anomalous Hall effect measurements that the $LaAlO_3/SrTiO_3$ interface has an unconventional phase diagram in the space of electron density and magnetic field. At high densities and fields we observe a polarized phase with crystalline anisotropy. Surprisingly, below a density-dependent critical field the polarization and anisotropy vanish and the resistivity sharply rises. This behavior, unobserved in other magnetic systems, indicates strong coupling between itinerant electrons and localized magnetic moments, enabling gate-tunable magnetism at this interface.

12:03PM G12.00005 Two-dimensional electron gas at the atomically smooth $LaAlO_3/SrTiO_3$ (111) interface , CHANG-BEOM EOM, University of Wisconsin-Madison — The two-dimensional electron gas (2DEG) at the $LaAlO_3/SrTiO_3$ (001) heterointerface has been widely investigated due to its diverse functionalities such as conductivity, ferromagnetism, and superconductivity. In this orientation, the $SrTiO_3$ is nonpolar, with charge-neutral AO and BO_2 planes, while +e of charge is transferred between AO and BO_2 planes in the $LaAlO_3$ layer. The (111) orientation is, however, qualitatively different in that the AO_3 and B lattice planes in both materials exhibit charge transfer between layers, and both have in principle a polar character. We have found that $LaAlO_3$ deposited on the (111) $SrTiO_3$ polar surface also supports an interfacial 2DEG. An atomically smooth step and terrace structure of (111) $SrTiO_3$ surface was prepared by buffered-HF and heat treatment. The step height of the treated (111) $SrTiO_3$ is $\sim$2.25Å, which is 1/3 of the diagonal of the cubic $SrTiO_3$ lattice along the [111] direction, consistent with the thickness of one AO_3/B (111) bilayer. $LaAlO_3$ was grown epitaxially in a layer-by-layer growth mode, with one oscillation of the reflection-high energy electron diffraction (RHEED) specular spot corresponding to this single step height. The (111) interfacial 2DEG shows a higher carrier concentration than LAO/STO (001) at room temperature. We find a $LaAlO_3$ critical thickness between 11.3 and 16 Å, with the transition between insulating and conducting regimes broader than that of LAO/STO (001). Surface X-ray diffraction with COherent Bragg Rod Analysis (COBRA) has been carried out to explore the possible structural reconstruction of (111) $SrTiO_3$. We will discuss the origin of 2DEG at this polar-polar interface. This work has been done in collaboration with S. Ryu, C. W. Bark, T. Hernandez, M. S. Rzchowski, H. Zhou and D. D. Fong, T. R. Paudel and E.Y. Tsymbal.

12:39PM G12.00006 Two-dimensional electron gasat the interface between two polar oxide materials , TULA PAUDEL, EVGENY TSYMBAL, University of Nebraska, Lincoln, NE — Following the discovery of a two-dimensional electron gas (2DEG) at the interface between polar $LaAlO_3$ (LAO) and non-polar $SrTiO_3$ (STO) grown in the [001] direction many related heterostructures with interesting physical phenomena have been proposed and explored. Here using the first-principles theory, we investigate the electronic band structure of the interface between two polar oxide materials – a wide materials group that can broaden the field for designing conducing interfaces with novel properties. As a model system, we consider a LAO/STO heterostructure stacking in the [111] direction. In this direction both free standing LAO and STO are polar with alternatively charged planes – $(LaO_3)^{3-}$ and Al^{3+} in LAO and $(SrO_3)^{4-}$ and Ti^{4+} in STO leading to inevitable interface reconstruction. Simple electrostatic arguments suggest that at the Ti/LaO_3 terminated interface of the LAO/STO(111) heterostructure this reconstruction may be achieved through depositing electron surface charge of $0.5e/\sqrt{3}a^2$ at the interface. This is by a factor of $\sqrt{3}$ smaller than that for the LaO/STO(001) interface which is expected to lead to a larger critical thickness of LAO(111) compared to LAO(001). These arguments are consistent with our first-principles calculations which predict a critical thickness of LAO(111) to be eight (LaO_3-Al) bilayers. Our findings are consistent with the experimental studies performed by S. Ryu, C. W. Bark, T. Hernandez, M. S. Rzchowski, H. Zhou, D. D. Fong, and C.-B. Eom.

12:51PM G12.00007 Effect of Surface Engineering on $LaAlO_3/SrTiO_3$ Interfaces , SANJAY ADHIKARI, West Virginia University, CHANG-BEOM EOM, University of Wisconsin, Madison, MICHAEL KLOPF, Jefferson Lab, CHENG CEN, West Virginia University — Carrier properties at the $LaAlO_3/SrTiO_3$ interfaces are highly sensitive to potential profile generated by $LaAlO_3$ top surface termination. In ambient environment, the uncontrolled surface exposure may introduce randomly distributed charge or polarization and therefore significantly impact interfacial transport by disorder related effect. As evidence, local fluctuation in carrier density and mobility has been observed in nanostructures defined by atomic force microscope (AFM) lithography. Here we report controlled modification of $LaAlO_3$ surface by solvent deposition. Surface desorption is first carried out by sample annealing in O_2 environment. The annealed $LaAlO_3$ surfaces are later coated with various solvents of controlled thicknesses by pulsed laser deposition using frozen targets. Coated surfaces are analyzed by pulsed force and frictional force microscopy. AFM lithography is also carried out to locally alter the surface charge state and modulate the potential disorder level. Effect of different controlled surface coatings on interface are studied by magneto-transport measurement

1:03PM G12.00008 A spectroscopic study of the superconductor at the $LaAlO_3/SrTiO_3$ interface , HANS BOSCHKER, CHRISTOPH RICHTER, JOCHEN MANNHART, Max Planck Institute for Solid State Research — The electron liquid at the $LaAlO_3/SrTiO_3$ interface is a model system for the study of superconductivity as it provides a two-dimensional superconductor whose properties can be tuned with an electrical gate field. We developed planar tunnel junctions to study the superconductivity spectroscopically. Our tunnel junctions give access to two important physical parameters: the size of the superconducting gap and the electron-phonon spectral function. We will present measurements of both as a function of the electric gate field. The likelihood of the convential electron-phonon coupling mechanism for superconducting pairing will be discussed.

1:15PM G12.00009 Nature of Charge Compensation Mechanism in Devices with Polar Catastrophe , RAPHAEL TSU, WATTAKA SITAPUTRA, UNC Charlotte — Polar catastrophe (PC) is well-known in surface science driving a charge compensation mechanism (CCM) at surface/interface, with properties unfound in natural solids [1]. Combining PC with superlattice and resonant tunneling, new device opportunity is wide opened. The strange results of oscillations in conductance, between two limits of $G = gG_o$ with $g = 2, ...$in units of $G_o = e^2/h = 39\mu S$, and hysteresis, were observed in nano-sized (tens of nm) crystalized silicon in amorphous silicon matrix, having native oxides, can be explained [2]. Recent observation of substantial enhanced mobility for very large transfer of carrier from Gd_2O_3 (100) / Si(100), in the order of $n \sim 10^{20}$ cm^{-3} near the interface may apply to high current MOSFET [3]. The field of PC is dominated by heterostructures. 3D structures are lacking defined interfacial orientation; it is compatible with the CCM incorporating resonant tunneling.

1:27PM G12.00010 Band alignments at the interface of complex oxides[1] , LARS BJAALIE, ANDERSON JANOTTI, CHRIS G. VAN DE WALLE, University of California Santa Barbara — The realization of a two-dimensional electron gas at the $SrTiO_3/LaAlO_3$ interface has spurred interest in the development of electronic devices based on complex oxides. In the design of such devices it is crucial to know the band alignment at the interface of the different oxides, a key quantity that governs carrier barrier heights and carrier confinement. Reported values for the valence-band alignment at the $SrTiO_3/LaAlO_3$ interface vary by more than 1 eV. Using first-principles calculations based on a hybrid functional we calculate the band alignment at the interface between various complex oxides, including the band insulators $SrTiO_3$, $SrZrO_3$, $LaAlO_3$, $CaTiO_3$, and $GaAlO_3$ and the Mott insulators $GdTiO_3$ and $YTiO_3$. This choice of materials allows us to analyze the effects of cation size, lattice parameters, band gaps, and lattice orientation on the band alignment.

1:39PM G12.00011 Understanding polarity compensation across polar $LaAlO_3$ films , G. SINGHBHALLA, LBL, UC Berkeley, P. ROSSEN, UCB, S. JAGANATH, G. PALSSON, D. YI, LBL, A. DASGUPTA, J. RAVICHANDRAN, UCB, V. RUIZ, U Munich, J. HERON, UCB, C. FADLEY, LBL, A. YADAV, UCB, R. PENTCHEVA, U Munich, R. RAMESH, UCB, LBL — Dipole screening mechanisms for polar crystals can manifest in a variety of ways depending on bandgaps, surface energies and environmental conditions. Here we study the polarity compensation process in $LaAlO_3$ thin film grown on the two different surface terminations of [001] $SrTiO_3$ crystals (SrO and TiO_2). An electron gas that appears at the interface between $LaAlO_3$ and TiO_2-$SrTiO_3$ surface (n-type) potentially screens the $LaAlO_3$ polarity, while the interface between $LaAlO_3$ and SrO-$SrTiO_3$ (p-type) remains insulating. To understand this asymmetry, we probed the $LaAlO_3$ surface using a variety of element-specific probes and observe a change in the $LaAlO_3$ stacking structure in the p-type geometry. Tunneling measurements reveal remnants of a built-in field reflective of $LaAlO_3$'s intrinsic polarity across the n-type structure, but no such signatures are detected for the p-type structure. When combined with density functional theory simulations, the results suggest that while free charge screens the $LaAlO_3$ dipole in the n-type geometry, a change in $LaAlO_3$'s structure during growth nullifies the dipole in the p-type geometry. In essence, $SrTiO_3$ surface layers drastically affect $LaAlO_3$ polarity compensation and in turn the electronic properties.

1:51PM G12.00012 Stoichiometry, defects, and the polar catastrophe in $LaAlO_3$ thin films on $SrTiO_3$, C. STEPHEN HELLBERG, Naval Research Lab — Careful growth of $LaAlO_3$ thin films on $SrTiO_3$ by molecular beam epitaxy has shown that the La/Al ratio of the nominal $LaAlO_3$ layer is key to the formation of a two-dimensional electron liquid at the interface—metallic conductivity is only observed in Al-rich films. The interfacial electron liquid forms due to the polar catastrophe, the diverging potential caused by the atomic layer arrangement at the interface when polar $LaAlO_3$ is grown on TiO_2-terminated non-polar $SrTiO_3$. The system eventually reconstructs, moving negative charges to the interface to screen the diverging potential. I will present density functional calculations of the defects that form in $LaAlO_3$ on $SrTiO_3$ to accomodate variations in stoichiometry. In La-rich films, the lowest energy defects are extended and allow cation vacancies to move to the interface to screen the diverging potential. Thus the interface between La-rich $LaAlO_3$ and $SrTiO_3$ remains insulating. In Al-rich films, the defects are localized and block cation motion. In this case a conducting electron liquid forms to screen the diverging potential.

2:03PM G12.00013 What can we learn from AC impedance study about the bipolar resistive switching effect in $LaAlO_3/Nb:SrTiO_3$ heterostructures , XINGLI JIANG, YONGGANG ZHAO, XIN ZHANG, MEIHONG ZHU, HUIYUN ZHANG, Department of Physics and State Key Laboratory of Low-Dimensional Quantum Physics, Tsinghua University,, DASHAN SHANG, JIRONG SUN, Beijing National Laboratory for Condensed Matter Physics, Chinese Academy of Sciences — Recently, resistive switching (RS) effect has attracted much attention due to its importance in potential applications in resistance random access memory. It has been shown that traps play an important role in RS effect. However, a direct and in-depth study on the characteristics of traps is still lacking so far, including the spatial and energy distribution of traps, relaxation of trapped carriers and transport of carriers via traps, especially the effect of historical process on the transport of carriers, which are important for understanding the mechanism of RS effect and also essential for optimizing devices. We studied the RS effect in heterostructures composed of $LaAlO_3$ (LAO) and Nb:$SrTiO_3$ (NSTO) from 80 to 300 K by using AC impedance technique. It was demonstrated that the bipolar RS effect originates from the LAO/NSTO interface and the resistance states are controlled by the filling status of traps via the trapping/detrapping of electrons. Moreover, the spatial and energy distributions of traps and the effect of history on the transport of carriers were obtained. A model was proposed to explain the experimental results. This work demonstrates that AC impedance technique is powerful for uncovering the mechanism of RS effect.

Session G13 DCMP: Topological Insulators: Theory II 315 - Roman Lutchyn, Microsoft Station Q

11:15AM G13.00001 The strong index classification of reflection symmetric topological insulators and superconductors , CHING-KAI CHIU, University of Illinois at Urbana-Champaign, HONG YAO, Institute for Advanced Study, Tsinghua University, SHINSEI RYU, University of Illinois at Urbana-Champaign — We discuss the topological invariants of topological insulators and superconductors protected by spatial reflection symmetry in any spatial dimensions. In the presence of both (non-spatial) discrete symmetries in the Altland-Zirnbauer classification and reflection symmetry, we introduce two new topological invariants: a mirror integral number and a binary integral number, which is determined by the larger one of the Z number and mirror integral number. We claim that the topological states are characterized by one of '0', Z_2, Z, and the two new topological invariants. Furthermore, those topological invariants are also determined by commutation or anticommutation relations between the discrete non-spatial symmetry operators and the reflection symmetry operator. By using the construction of bulk Dirac Hamiltonians, we provide the complete classification, which still has the same dimensional periodicities with the original Altland-Zirnbauer classification. When a boundary is introduced, which is reflected into itself, these non-trivial topological insulators and superconductors support gapless modes localized at the boundary.

11:27AM G13.00002 Symmetry protected topological phases from decorated domain walls , XIE CHEN, YUAN-MING LU, ASHVIN VISHWANATH, University of California, Berkeley — Symmetry protected topological phases are gapped quantum phases with gapless edge excitations protected by certain symmetries of the system. While SPT phases in lower dimensions (especially 1D) are relatively well understood, less is known about higher dimensional (2D and 3D) SPT phases including what their edge excitations are like and how to detect them. In this work, we present a construciton of d dimensional SPT phases with $Z_2 \times G$ symmetry by decorating the Z_2 domain walls in the d dimensional bulk with $d-1$ dimensional SPT phases with G symmetry. Such a construction not only provides a simple understanding of higher dimensional SPT phases starting from lower dimensional ones, but also reveals a special topological feature of such SPT phases. That is, on the boundary of the system, the domain wall end points/loops carry gapless edge states of the $d-1$ dimensional SPT phase with G symmetry. We discuss in detail a 2D SPT phase with $Z_2 \times Z_2^T$ symmetry and a 3D SPT phase with $Z_2 \times Z_2$ symmetry, which illustrate a more general hierarchical structure of SPT phases related to the cup product of group cohomology.

11:39AM G13.00003 Lattice model for the surface states of a topological insulator , MARCEL FRANZ, DOMINIC MARCHAND, University of British Columbia — A surface of a strong topological insulator (STI) is characterized by an odd number of linearly dispersing gapless electronic surface states. It is well known that such a surface cannot be described by an effective two-dimensional lattice model (without breaking the time-reversal symmetry), which often hampers theoretical efforts to quantitatively understand some of the properties of such surfaces, including the effect of strong disorder, interactions and various symmetry-breaking instabilities. Here we describe a lattice model that can be used to describe a pair of STI surfaces and has an odd number of Dirac fermion states with wavefunctions localized on each surface. The Hamiltonian consists of two planar tight-binding models with spin-orbit coupling, representing the two surfaces, weakly coupled to each other by terms that remove the redundant Dirac points from the low-energy spectrum. The utility of this model is illustrated by studying the magnetic and exciton instabilities of the STI surface state driven by short-range repulsive interactions.

11:51AM G13.00004 3D Dirac Electrons on a Cubic Lattice with Noncoplanar Multiple-Q Order , SATORU HAYAMI, TAKAHIRO MISAWA, YOUHEI YAMAJI, YUKITOSHI MOTOME, Dept. of Appl. Phys., Univ. of Tokyo — Noncoplanar multiple-Q orders often lead to new low-energy excitations and/or topologically nontrivial states. In particular, triple-Q orders have attracted much interest due to the emergence of topological (Chern) insulators and associated anomalous quantum Hall effects. In the present study, we explore the possibility of such multiple-Q orderings on a simple cubic lattice and their influence on the electronic structure. We find that a four-sublattice triple-Q magnetic order significantly affects the low-energy single-particle spectrum which is described by the three-dimensional massless Dirac electrons. In order to clarify the stability of such noncoplanar magnetic order in microscopic models, we investigate the ground-state phase diagram of an extended periodic Anderson model on a cubic lattice by mean-field approximation. As a result, we find that the triple-Q phase appears in a wide range of parameters at 3/2 filling. The 3D Dirac nature gives rise to a characteristic gapless surface state. We discuss the bulk and surface electronic states in details. We also discuss a possible realization of a topological insulating phase by opening an energy gap in the triple-Q phase.

12:03PM G13.00005 Fermi loop in interface states and surface flat bands in diamond lattice models , RYUJI TAKAHASHI, SHUICHI MURAKAMI, Tokyo Institute of Technology — Previously we have shown the gapless interface states between two topological insulators with different chiralities by means of the mirror Chern number [1]. In this presentation we use the Fu-Kane-Mele tight-binding model on diamond lattice *with* the spin-orbit interaction, and calculate their gapless interface states. We find that when the particle-hole symmetry is imposed in the whole system the Fermi surface of the gapless states becomes a loop in the interface Brillouin zone. We show how to characterize the existence of such Fermi loop in terms of topology. Next we report flat band states in the surface of the diamond lattice model with anisotropic hopping integrals *without* the spin-orbit interaction. When anisotropy is not so strong, the surface flat band exits in some part of the Brillouin zone. Moreover when the anisotropy becomes sufficiently strong, the surface flat bands cover the whole surface Brillouin zone. [1] R. Takahashi, S. Murakami, Phys. Rev. Lett. 107,166805 (2011).

12:15PM G13.00006 Effect of electron-phonon interaction on the velocity renormalization of the surface state of 3D topological insulator[1] , QIUZI LI, SANKAR DAS SARMA, University of Maryland-College Park — Explicitly taking into account of electron-phonon interaction, we consider the velocity renormalization of the surface state of 3D topological insulator. The velocity renormalization is shown to be strongly dependent on the carrier density of the system. We compare our theoretical calculation to recent experimental data. We further consider the correction to the compressibility arising from electron-phonon coupling, and discuss its implication in experiments.

12:27PM G13.00007 ABSTRACT WITHDRAWN –

12:39PM G13.00008 2D compressibility of surface states on 3D topological insulators[1] , DAVID ABERGEL, SANKAR DAS SARMA, University of Maryland — We develop a theory for the compressibility of the surface states of 3D topological insulators and propose that surface probes of the compressibility via scanning single electron transistor microscopy will be a straightforward way to access the topological states without interference from the bulk states. We describe the single-particle nature of the surface states taking into account an accurate Hamiltonian for the bands and then include the contribution from electron-electron interactions and discuss the implications of the ultra-violet cutoff, including the universality of the exchange contribution when expressed in dimensionless units. We also compare the theory with experimentally obtained $\frac{d\mu}{dn}$ as extracted from angle-resolved photoemission spectroscopy measurements. Finally, we point out that interaction-driven renormalization of the Fermi velocity may be discernible via this technique.

[1]We thank the US-ONR for support.

12:51PM G13.00009 Dislocations in topological phases of matter and their topological terms , AKIHIRO TANAKA, TORU KIKUCHI, National Institute for Materials Science — When dislocations are present in topological insulators/superconductors and their variants, they are known to endow subgap boundstates. We revisit their physics from the viewpoint of topological field theories, discussing sevral issues among which are 1) the interplay of the Nieh-Yan torsional invariant with other topological terms, 2) possibile appearance of Nieh-Yan-like terms in nonlinear sigma models of competing orders, 3) the subtle controversy on the absence/existence of Callan-Harvey-like anomaly-inflow in the dual formulation.

1:03PM G13.00010 Massless Axions: the Callan-Harvey effect revisited , TORU KIKUCHI, AKIHIRO TANAKA, National Institute for Materials Science — Axion-like degrees of freedom appear in the low energy physics of various condensed matter systems, which range from quantum spin systems and superconductors to topological insulators and their variants. When topological defects such as domain walls and vortices are formed by the axion fields, their responses to external fields are dominated by the current inflow from the surrounding bulk (Callan-Harvey effect). However, a dual reformulation due to Izquierdo-Townsend is known to present a controversy regarding the existence of this inflow in the case when axions are massless, and can have important consequences. We revisit this problem and discuss its possible relevance to condensed matters.

1:15PM G13.00011 Semi-metal-insulator transition at the surface of a topological insulator with in-plane magnetization[1] , FLAVIO NOGUEIRA, ILYA EREMIN, Theoretische Physik III, Ruhr-Universitaet Bochum — We discuss the role of quantum fluctuations when the surface of a topological insulator (TI) is used as a substrate for a layered ferromagnetic (FM) material. As is well known, an out-of-plane magnetization gaps the surface states and modifies the Landau-Lifshitz-Gilbert equation in an essential way, due to the topological magnetoelectric effect. On the other hand, for the case of in-plane magnetization the surface states are gapless. We show that quantum fluctuations may modify this picture if the exchange interaction between the TI and the FM is sufficiently large. Indeed, we will show that a gap is dynamically generated in this case, turning in this way the semi-metallic state into an insulating one. Another situation of interest where a similar mechanism applies involves the Coulomb interaction between the fermions at the interface between the TI and the FM. The interplay between the magnetization dynamics and the Coulomb interaction is discussed in detail.

1:27PM G13.00012 Theory of a quantum critical phenomenon in a topological insulator: (3+1)-dimensional quantum electrodynamics in solids , HIROKI ISOBE, NAOTO NAGAOSA, Department of Applied Physics, University of Tokyo — We study theoretically the quantum critical phenomenon of the phase transition between the trivial insulator and the topological insulator in (3+1) dimensions, which is described by a Dirac fermion coupled to the electromagnetic field. The intriguing result is the recovery of the Lorentz invariance in the infrared limit, and the electrons in solids obey the conventional QED. In detail, the renormalization group (RG) equations for the running coupling constant α, the speed of light c, and electron v are derived by using perturbative RG method to one-loop level. The almost exact analytic solutions to these RG equations are obtained to reveal that (i) c and v approach to the common value with combination c^2v being almost unrenormalized, (ii) the RG flow of α is the same as that of usual QED with c^3 being replaced by c^2v, and (iii) there are two crossover momentum/energy scales separating three regions of different scaling behaviors. The dielectric and magnetic susceptibilities, angle-resolved photoemission spectroscopy (ARPES), and the behavior of the gap are discussed from this viewpoint. Reference: H. Isobe and N. Nagaosa, Phys. Rev. B **86**, 165127 (2012).

1:39PM G13.00013 Nonequilibrium Transport Through a Gate-Controlled Barrier on the Quantum Spin Hall Edge[1] , RONI ILAN, University of California, Berkeley, JEROME CAYSSOL, Max-Planck-Institut für Physik Komplexer Systeme, Dresden, Germany and LOMA (UMR-5798), CNRS and University Bordeaux, Talence, France, JENS BARDARSON, JOEL MOORE, University of California, Berkeley and the Materials Sciences Division, Lawrence Berkeley National Laboratory, Berkeley, CA — The quantum spin Hall insulator is characterized by the presence of gapless helical edge states where the spin of the charge carriers is locked to their direction of motion. In order to probe the properties of the edge modes, we propose a design of a tunable quantum impurity realized by a local gate under an external magnetic field. Using the integrability of the impurity model, the conductance is computed for arbitrary interactions, temperatures and voltages, including the effect of Fermi liquid leads. The result can be used to infer the strength of interactions from transport experiments.

1:51PM G13.00014 Magnetic translation algebra with or without magnetic field , CHRISTOPHER MUDRY, Paul Scherrer Institute, CLAUDIO CHAMON, Boston University — The magnetic translation algebra plays an important role in the quantum Hall effect. Murthy and Shankar have shown how to realize this algebra using fermionic bilinears defined on a two-dimensional square lattice. We show that, in any dimension d, it is always possible to close the magnetic translation algebra using fermionic bilinears, be it in the continuum or on the lattice. We also show that these generators are complete in even, but not odd, dimensions, in the sense that any fermionic Hamiltonian in even dimensions that conserves particle number can be represented in terms of the generators of this algebra, whether or not time-reversal symmetry is broken. As an example, we reproduce the f-sum rule of interacting electrons at vanishing magnetic field using this representation. We also show that interactions can significantly change the bare band width of lattice Hamiltonians when represented in terms of the generators of the magnetic translation algebra.

2:03PM G13.00015 Spin-orbital Texture in Topological Insulators , CHAOXING LIU, Department of Physics, Pennsylvania State University, HAIJUN ZHANG, SHOU-CHENG ZHANG, Department of Physics, McCullough Building, Stanford University — Relativistic spin-orbit coupling plays an essential role in the field of topological insulators and quantum spintronics. It gives rise to the topological non-trivial band structure and enables electric manipulation of the spin degree of freedom. Because of the spin-orbit coupling, rich spin-orbital coupled textures can exist both in momentum and in real space. For three dimensional topological insulators in the Bi2Se3 family, topological surface states with pz orbitals have a left-handed spin texture for the upper Dirac cone and a right-handed spin texture for the lower Dirac cone. In this work, we predict a new form of the spin-orbital texture associated with the px and the py orbitals. For the upper Dirac cone, a left-handed (right-handed) spin texture is coupled to the "radial" ("tangential") orbital textures, whereas for the lower Dirac cone, the coupling of spin and orbital textures is the exact opposite. A spin-resolved and photon polarized angle-resolved photoemission spectroscopy experiment is proposed to observe this novel spin-orbital texture.

Session G14 GMAG DMP: Focus Session: Magnetic Nanoparticles II 316 - Brian Kirby, National Institute of Standards and Technology

11:15AM G14.00001 Strong exchange coupling in conventional and inverse ferrimagnetic hard/soft and soft/hard core/shell heterostructured nanoparticles[1] , JOSEP NOGUES, Catalan Institute of Nanotechnology (ICN), Campus UAB, Bellaterra (Barcelona), Spain — Bi-magnetic core/shell nanoparticles are becoming increasingly appealing for diverse fields such as for permanent magnets, microawave absorption, biomedical applications, sensing applications, or future magnetic recording media. Ferrromagnetic (FM)/ antiferromagnetic (AFM) core/shell nanoparticles (or inverted AFM/FM) have been extensively studied. However, exchange coupled hard/soft, or inverse soft/hard, core/shell nanoparticles have been far less investigated. Interestingly, most bi-magnetic core/shell systems are derived by simple partial oxidation of the core, e.g., Co/CoO (FM/AFM) or FePt/Fe_3O_4 (hard/soft) and only few studies of heterostructured (where core and shell are formed by different magnetic ions) can be found in the literature. We have investigated conventional hard/soft and inverted soft/hard core/shell hetroestructured nanoparticles based on magnetically soft iron oxide (Fe_3O_4) and magnetically hard manganese oxide (Mn_3O_4). The core/shell samples were synthesized by seeded growth using either Fe_3O_4 or Mn_3O_4 nanoparticles as seeds. Subsequently, thin layers of the complementary material were grown by thermal decomposition of the corresponding metallorganic precursors. The structure characterization (X-ray diffraction and electron diffraction) confirms the presence of cubic (Fe_3O_4) and tetragonal (Mn_3O_4) phases both at the bulk and local levels. In addition, high resolution transmission electron microscopy (HR-TEM) with electron energy loss spectroscopy (EELS) mapping confirms the core/shell structure of the nanopartciles. Magnetic characterization and element-selective hysteresis loops obtained by x-ray magnetic circular dichroism (XMCD) reveal a strong exchange coupling between the core and the shell which results in homogeneous loops with moderate coercivity. Moreover, the magnetic properties can be tuned by controlling the core diameter or shell thickness. However, the results depend only weakly on the hard/soft or inverse soft/hard morphology.

[1]In collaboration with A. Lopez-Ortega, M. Estrader, G. Salazar-Alvarez, S. Estrade, F. Peiro, I.V. Golossvsky, M. Vasilakaki, K.N. Trohidou, R.K. Dumas, D.J. Keavney, M. Laver, K. Krycka, J. Borchers, M. Varela, S. Suriñach, M.D. Baro, J. Sort

11:51AM G14.00002 Magnetic Reversal of Onion-Like Fe_3O_4|MnO|γ-Mn_2O_3 Core|Shell|Shell Nanoparticles , KATHRYN KRYCKA, JULIE BORCHERS, NIST Center for Neutron Research, MARK LAVER, Paul Scherrer Institute, GERMAN SALAZAR-ALVEREZ, Stockholm University, ALBERTO LOPEZ-ORTEGA, CIN2(ICN-CSIC) and Universitat Autonoma de Barcelona, MARTA ESTRADER, Stockholm University, SANTIAGO SURINACH, MARIA BARO, Universitat Autonoma de Barcelona, JORDI SORT, Universitat Autonoma de Barcelona and ICREA, JOSEP NOGUES, CIN2(ICN-CSIC) and Universitat Autonoma de Barcelona and ICREA, FM—AFM—FM NANOPARTICLES COLLABORATION — Magnetic nanoparticles offer potential for biomedical and data storage applications, especially with exchange bias to overcome the superparamagnetic limit. Here we study the role of an antiferromagnetic layer sandwiched between a soft ferrimagnetic core and hard ferrimagnetic shell. The nanoparticles studied consist of 3 nm (diameter) Fe_3O_4 |50-60 nm thick MnO shell |5 nm thick γ-Mn_2O_3 shell [1]. Small-angle neutron scattering (SANS) probes both structural and magnetic morphology. SANS reveals that during reversal from 5 T to -5 T at 5 K, there is an increase in spins oriented perpendicular to the applied field. As the temperature is increased to 150 K (above the 123 K Néel temperature of MnO) evidence of an enhanced magnetism from within the MnO shell is observed. Finally, the scattering pattern shifts (indicating a change in the relative magnetism as a function of radius) between 5 K and 50 K.

12:03PM G14.00003 The Heisenberg Pentamer: Understanding the inelastic neutron scattering selection rules for magnetic clusters , JASON HARALDSEN, Los Alamos National Laboratory — Assuming Heisenberg interactions and the symmetric case of a spin S-S' pentamer, the energy eigenstates can be determined exactly. With the energies known, the inelastic neutron scattering intensities are then calculated for the special case of a 1-1/2 pentamer. Through an analysis of these results, two main insights are gained. (1) Because of symmetry constraints, not all $\Delta S_{tot} = \pm 1$ transitions are accessible by inelastic neutron scattering (INS). This constrains the standard selections rules for magnetic excitations. (2) The INS signatures of magnetic clusters are directly dependent on the state and component that is excited.

12:15PM G14.00004 Chemical attachment of magnetic nanoparticles through "click chemistry"[1] , YUE LIU, ANDREW Y. TEPLYAKOV, Department of Chemistry & Biochemistry, University of Delaware, GEORGE C. HADJIPANAYIS, Department of Physics & Astronomy, University of Delaware — Iron nanoparticles were used as a test system to explore the functionalization and attachment of magnetic nanoparticles with two different functionalities through "click chemistry." Two different samples of iron nanoparticles were modified with 5-azidopentanoic acid and with 5-hexynoic acid, respectively. This modification was followed by click chemistry to change the morphology of agglomeration. A combination of density functional theory calculations, Fourier-transform infrared spectroscopy, and X-ray photoelectron spectroscopy was used to monitor each step of the process. Spectroscopies confirmed the success and completion of click reaction. Scanning electron microscopy images showed the change in size and morphology of the iron nanoparticles before and after click chemistry. Vibrating sample magnetometer study showed the majority of the magnetic properties were retained following functionalization and click reaction. Exploring similar approach for two types of materials with functionalization and attachment of hard magnetic materials and soft magnetic materials will be presented based on our initial studies of SmCo nanoparticles in a combination with iron nanoparticles.

12:27PM G14.00005 Magnetic Quenching of Plasmon-photonic Activities in Fe_3O_4-Elastomer Composite[1] , DANHAO MA, DUSTIN HUSS, PRALAV SHETTY, The Pennsylvania State University, RICHARD BELL, The Pennsylvania State University, Altoona College, MAURICIO TERRONES, The Pennsylvania State University, KOFI ADU, The Pennsylvania State University, Altoona College — We report for the first time, a systematic study of polarization dependence and the effect of particle size on the optical response of Fe_3O_4-silicone elastomer composites in the presence of external magnetic field. The optical response of composites containing 2wt%, 5wt% and 15wt% of 20nm$\leq$d $\leq$30nm, 40 nm$\leq$d$\leq$ 60nm and d$\leq$ 500nm Fe_3O_4 particles were aligned in- and out-of-plane in the elastomer host. We observed a systematic redshift in the optical response of the out-of-plane composite samples (containing nanoparticles 20nm$\leq$d$\leq$30nm) with increasing static magnetic field strength, which saturated near 600 Gauss. There were no observable shifts in the in-plane samples, suggesting that the orientation (polarization) of the magnetic dipole and the induced electric dipole play a crucial role in the optical response. However, we observed a dramatic suppression to near quenching of the plasmonic activities in the micron size particles (d $<$ 500nm) elastomer composite, suggesting particle size limitations in modulation of plasmon-photonics by external magnetic field. Dipole approximation model is used to explain the quenching phenomenon.

12:39PM G14.00006 Magnetic properties of Fe and Fe-Pt nanoparticles: application of nano-DFT+DMFT[1] , ALAMGIR KABIR, Department of Physics, University of Central Florida, VOLODYMYR TURKOWSKI, TALAT S. RAHMAN, Department of Physics and NanoScience Technology Center, University of Central Florida, Orlando, FL — We apply a combined density-functional theory and dynamical mean-field theory (DFT + DMFT) approach [1] to handle reliably nanosized systems which display strong electron correlations. The code that we have recently developed allows one to examine systems containing several hundred atoms with feasible computational time. In particular, we calculate the magnetization of iron and iron-platinum nanoparticles by changing the system size (from 27 to 147 atoms), shape and composition. We demonstrate that the experimentally observed non-monotonous dependence of the magnetization as function of nanoparticle size can be rather accurately reproduced within DFT+DMFT, contrary to DFT and DFT+U approaches.

12:51PM G14.00007 A comprehensive study of the structure and magnetic properties of Gd13 Cluster , KUN TAO, PURU JENA, Department of physics, Virginia Commonwealth University, Richmond, VA — Several experimental and theoretical studies of Gd13 cluster have led to confusing results. While experimental studies using Stern-Gerlach technique yield different magnetic moments, theoretical studies provide different spin orientations and structures. We have carried out a comprehensive study of the structure-magnetic property relationship of Gd13 cluster by examining different isomers. Our calculations are based on density functional theory with GGA+U and takes into account spin-orbit interactions and spin canting. The cluster with icosahedra structure and collinear spins has the lowest energy irrespective of the level of theory used. However, the magnetic coupling between the central and surface atoms does depend upon the value of U. For U=0 the magnetic coupling in the ground state structure is antiferromagnetic between the central and surface atoms. The coupling changes to ferromagnetic when U >4. The effect of temperature on the observed magnetic moment is also studies using Monte Carlo simulation.

1:03PM G14.00008 Microwave absorption properties of $BaGd_xFe_{12-x}O_{19}$ nanoparticles synthesized by wet milling process[1] , MEHMET BURAK KAYNAR, SADAN OZCAN, SNTG Lab. Physics Engineering Dept. Hacettepe University Turkey, S. ISMAT SHAH, Department of Materials Science and Engineering, University of Delaware, Newark, DE 19716, United States — It is a big demand to have a wide band, easy to synthesize microwave absorption materials with a high absorption ratio according to their weight. As a solution, nanoparticles are used for the couple of years because of their tunable frequencies by just changing their particle size. Most interesting nano structures for this objective are ferrites. In this work as a microwave absorber, BaFe12O19 and BaGd2Fe10O19 nanoparticles with different particles size are synthesized by the wet milling process. Their crystal structure analyzed by XRD, mean particle sizes were calculated from XRD patterns using rietveld analysis and from TEM images. Magnetic properties are analyzed by using Quantum design VSM. Microwave absorption properties are measured by using coaxial transmission method with an Agilent E5071 VNA. With the change of the last milling time from 0 to 20-hour crystalline sizes are changed from 48 nm to 13 nm. Decrease of particle size give rise to a decrease at coercivity and saturation magnetization of the samples. Change at the hysteresis loops gives a clue to the change of the microwave absorption frequency which is directly observed from the microwave measurements.

1:15PM G14.00009 Investigation of Local Structures and Magnetism in (Y, Co) codoped CeO2 Nanoparticles[1] , T.S. WU, H.D. LI, Y.W. CHEN, S.F. CHEN, Department of Physics, National Tsing Hua University, Taiwan, S.L. CHANG, National Synchrotron Radiation Research Center, Taiwan, Y.L. SOO, Department of Physics, National Tsing Hua University, Taiwan — Nanocrystals of (Y, Co) codoped CeO2 with different Y concentration prepared by a Polyol method were studied by X-ray diffraction (XRD), high-resolution transmission electron microscopy (HR-TEM), Raman spectroscopy, x-ray absorption fine structures (XAFS), and superconducting quantum interference device (SQUID) techniques to monitor the structural and magnetic variations of the samples. As revealed by the XRD data, all nanocrystal samples under investigation have similar average particle size. The concentration of O vacancies in the samples was found to increase with Y doping level as indicated by the Raman spectroscopy and XAFS data. Such increase of O vacancies is also accompanied by enhanced ferromagnetism as observed by SQUID measurements. Our experimental results demonstrate clear correlation between magnetism and O vacancies induced by Y doping and therefore are consistent with the bound magnetic polaron model.

1:27PM G14.00010 ABSTRACT HAS BEEN MOVED TO U43.00003 –

1:39PM G14.00011 Ferrofluid based micro-electrical energy harvesting , VISWAS PUROHIT, Symbiosis Institute of Technology, Near Lupin Research Park, Lavale, Mulshi, Pune-412115, MAH, India, BAISHAKHI MAZUMDER, Materials Department, University of California, Santa Barbara, CA93106, GRISHMA JENA, MADHUSHA MISHRA, Symbiosis Institute of Technology, Near Lupin Research Park, Lavale, Mulshi, Pune-412115, MAH, India, MATERIALS DEPARTMENT, UNIVERSITY OF CALIFORNIA, SANTA BARBARA, CA93106 COLLABORATION — Innovations in energy harvesting have seen a quantum leap in the last decade. With the introduction of low energy devices in the market, micro energy harvesting units are being explored with much vigor. One of the recent areas of micro energy scavenging is the exploitation of existing vibrational energy and the use of various mechanical motions for the same, useful for low power consumption devices. Ferrofluids are liquids containing magnetic materials having nano-scale permanent magnetic dipoles. The present work explores the possibility of the use of this property for generation of electricity. Since the power generation is through a liquid material, it can take any shape as well as response to small acceleration levels. In this work, an electromagnet-based micropower generator is proposed to utilize the sloshing of the ferrofluid within a controlled chamber which moves to different low frequencies. As compared to permanent magnet units researched previously, ferrofluids can be placed in the smallest of containers of different shapes, thereby giving an output in response to the slightest change in motion. Mechanical motion from 1- 20 Hz was able to give an output voltage in mV's. In this paper, the efficiency and feasibility of such a system is demonstrated.

Session G15 GMAG DMP: Focus Session: Quasi-Triangular Frustrated Magnets 317 - John Schlueter, Argonne National Laboratory

11:15AM G15.00001 Phase transition in $Ba_2Ti_{13}O_{22}$ with Ti^{3+} quasi-triangular lattice , T. KATSUFUJI, K. TAKAYAMA, Department of Physics, Waseda University, T. KOYAMA, S. MORI, Department of Materials Science, Osaka Prefecture University, J. FUJIOKA, Y. TOKURA, Department of Applied Physics, University of Tokyo — In $Ba_2Ti_{13}O_{22}$, Ti^{3+} ($3d^1$) ions form quasi-triangular lattices, and three layers of them ("trilayer") compose a building block for the crystal structure. We found that this compound exhibits a phase transition at $T_c \sim 200$ K, below which the electrical resistivity increases and magnetic susceptibility decreases. We found by electron diffraction measurement that the space group changes at T_c from $Cmce$ to $C2/m$, which means that one trilayer and the next trilayer become inequivalent. We also found that a pseudogap appears in the optical conductivity spectra below 0.3 eV at low temperatures. These experimental results suggest that the phase transition is caused by the formation of charge density wave (CDW). However, the almost T-linear dependence in the decrease of the magnetic susceptibility below T_c is not what is observed in the conventional CDW state, and suggest an exotic nature of the state below T_c in the present compound.

11:27AM G15.00002 Magnetic-filed and angular dependence of magnetism in the triangular Mott insulator k-(BEDT-TTF)2Cu2(CN)3 investigated by 13C NMR , KAZUYA MIYAGAWA, KENTARO UMEDA, K. INUI, KAZUAHI KANODA, University of Tokyo — The organic conductors, κ-(BEDT-TTF)$_2$X, are prototype for investigating Mott physics and spin frustrations. The X=Cu[N(CN)$_2$]Cl is a Mott insulator which undergoes an antiferromagnetic phase transition. On the other hand, title compound which has a triangular lattice does not show a long range magnetic ordering. This suppression is believed to deeply relate to strong spin frustrations. While X=Cu$_2$(CN)$_3$ does not show magnetic ordering, we previously reported anomalous behaviors in ^{13}C NMR around 6 K, where heat capacity, thermal conductivity and lattice constant show anomalies as well. So, the 6 K anomaly is a key phenomenon for understanding the origin of absence of magnetic order. We have measured external-filed angular dependence of ^{13}C NMR under magnetic fields up to 15 T for clarifying the origins of the line broadening and the $1/T_1$ anomaly around 6K. At room temperature, angular dependence of spectra is well explained by a crystal structure. We will show the detailed experimental results and discuss the low temperature states.

11:39AM G15.00003 Frustration dependence of elementary excitation in a quantum spin liquid , M. YAMASHITA, K. UEDA, H. CUI, R. KATO, Riken, H.M. YAMAMOTO, Institute for Molecular Science, T. FUKUNAGA, Tokyo Univ. of Science, T. TERASHIMA, S. UJI, NIMS — A quantum spin liquid state (QSL) with a magnetic gapless excitation has been found in the organic Mott insulator EtMe$_3$Sb[Pd(dmit)$_2$]$_2$ with nearly identical 2D triangular lattices of $S = 1/2$ [1]. To examine the nature of the QSL, it is essential to determine the phase diagram, especially how the gapless QSL evolves when the degree of frustration is changed. Although the gapless QSL is shown to be robust against deuteration of the cation EtMe$_3$Sb [1], the difference of frustration caused by the deuteration is not clear. We study the frustration dependence of the elementary excitation in the mixed-cation materials (Me$_4$Sb)$_{1-x}$(EtMe$_3$Sb)$_x$[Pd(dmit)$_2$]$_2$ in which the degree of frustration is directly reduced by mixing the smaller cation. Magnetic torque measurements showed that spin susceptibilities of the mixed cation ($x = 0.32$ and 0.35) were temperature independent down to 30 mK and were almost the same with that of $x = 1$, indicating that the QSL exists as a quantum critical phase, rather than a point, when the frustration is varied. We will also present magnetic torque and thermal transport measurements of mixed-cation materials with different x.

11:51AM G15.00004 Spin freezing in the quasi-triangular layered magnet, $Cu_2(OH)_3NO_3$, S.A. SOLIN, F.M. WERNER, Washington University in St. Louis, JASON GARDNER, Indiana University, GEORG EHLERS, SNS, Oak Ridge National Laboratory — We have investigated the structural and magnetic properties of the spin S = 1/2 antiferromagnetic quasi-triangular lattice materials: $Cu_{2(1-x)}Zn_{2x}(OH)_3NO_3$ ($0 < x < 0.65$) using a.c. susceptibility, heat capacity [1,2] and neutron scattering. The spin 1/2 Cu planes in these layered compounds form a very slightly ($\sim$ 1%) distorted triangular lattice. We will briefly describe the techniques for synthesizing the hydrogenated, deuterated and intercalated forms of these compounds and also present a brief introduction to the bulk properties of this family of materials. We will discuss recent neutron scattering results from the pure compound. The temperature dependence of the quasielastic scattering reveals an abundance of slow spin dynamics at elevated temperatures. This scattering collapses as the system is cooled through its ordering temperature (11 K) and several magnetic Bragg reflections and a Q-independent mode are observed at finite energy. We will contrast these results with those seen in triangular systems with a Kagome motif.

12:03PM G15.00005 Microscopic models of Pd(dmit)$_2$-based organic charge transfer salts , ANTHONY JACKO, HARALD O. JESCHKE, ROSER VALENTI, Institut für Theoretische Physik, Goethe-Unversität Frankfurt, Max-von-Laue-Str. 1, 60438 Frankfurt, Germany — Organic charge transfer salts based on the molecule Pd(dmit)$_2$ display strong electronic correlations and geometrical frustration, leading to spin liquid, valence bond solid, and superconducting states, amongst other interesting phases. The low energy electronic degrees of freedom of these materials are often described by a single band model; a triangular lattice with a molecular orbital representing a Pd(dmit)$_2$ dimer on each site. We use *ab initio* electronic structure calculations to construct and parametrize low energy effective model Hamiltonians for a class of Me$_{4-n}$Et$_n$$X$[Pd(dmit)$_2$]$_2$ (X=N, As, Sb) salts and investigate how well these systems are described by an anisotropic triangular lattice.

12:15PM G15.00006 Spin-liquid versus spiral-order phases in the anisotropic triangular lattice , LUCA F. TOCCHIO, HELENE FELDNER, Institut für Theoretische Physik, Goethe-Universität Frankfurt/Main, 60438 Frankfurt, Germany, FEDERICO BECCA, CNR-IOM-Democritos National Simulation Centre and SISSA, Via Bonomea 265, I-34136, Trieste, Italy, ROSER VALENTI, CLAUDIUS GROS, Institut für Theoretische Physik, Goethe-Universität Frankfurt/Main, 60438 Frankfurt, Germany — We study the competition between magnetic and spin-liquid phases in the Hubbard model on the anisotropic triangular lattice, which is described by two hopping parameters t and t' in different spatial directions and is relevant for layered organic charge-transfer salts. By using a variational approach that includes spiral magnetic order, we provide solid evidence that a spin-liquid phase is stabilized in the strongly-correlated regime and close to the isotropic limit $t'/t = 1$. Otherwise, a magnetically ordered spiral state is found, connecting the (collinear) Néel and the (coplanar) 120° phases. The pitch vector of the spiral phase obtained from the unrestricted Hartree-Fock approximation is substantially renormalized in presence of electronic correlations, and the Néel phase is stabilized in a wide regime of the phase diagram, i.e., for $t'/t < 0.75$. We discuss these results in the context of organic charge-transfer salts

12:27PM G15.00007 Magnetic Soft Modes in the Distorted Triangular Antiferromagnet α-$CaCr_2O_4$, BELLA LAKE, Helmholtz Zentrum Berlin für Materialien und Energie — We have explored the phase diagram and excitations of a distorted triangular lattice antiferromagnet. The unique two-dimensional distortion considered here is very different from the "isosceles"-type distortion that has been extensively investigated. We show that suprisingly it is able to stabilize the 120° spin structure (typical of the undistorted triangular antiferromagnet) for a large range of exchange interaction values, with new structures found only for extreme distortions. A physical realization of this model is α-CaCr$_2$O$_4$. Despite its highly symmetric 120° spin structure, the magnetic excitation spectrum of α-CaCr$_2$O$_4$ is very complex. The unique pattern of nearest-neighbor exchange interactions as well as the substantial next-nearest-neighbor interactions place it close to the phase boundary of the 120° structure as is clearly revealed by the presence of low energy modes acting as soft modes of the neighboring structure. Indeed, fitting to linear spin-wave theory favors a set of exchange parameters within the nearby multi-k phase in contradiction to the observed 120° order, and quantum fluctuations may be necessary to stabilize α-CaCr$_2$O$_4$ within the 120° phase.

1:03PM G15.00008 Phase diagram and unusual magnetic excitations in distorted triangular lattice antiferromagnet α-$CaCr_20_4$[1]

SAMUEL DUCATMAN, NATALIA PERKINS, Department of Physics, UW Madison — While it is well known that the ground state of the isotropic Heisenberg model on a triangular lattice is the so called 120° structure, its appearance on the distorted triangular lattice is rather unusual. This case has been recently observed in the distorted triangular lattice antiferromagnet α-$CaCr_2O_4$ [S. Toth et al, PRB 84, 054452 (2011)] which shows the onset of the 120° long-range magnetic order below $T_N = 42.6K$. Recent neutron scattering experiments also revealed that this compound has unusual magnetic excitations with a dispersion with roton-like minima at momenta different from those corresponding to its 120°-magnetic order [S. Toth et al, PRL 109, 127203 (2012)]. Motivated by these experimental findings, we calculate a magnetic phase diagram and excitation spectrum of anisotropic Heisenberg Hamiltonian on triangular lattice. We showed that at the parameters characterizing α-$CaCr_2O_4$ compound, the ground state is indeed the 120°-structure, however, other possible magnetic orderings are very close in energy. We compute the dispersion of magnetic excitations to order 1/S and compare it with the neutron scattering data.

1:15PM G15.00009 Spin dynamics of the triangular lattice antiferromagnet α-$SrCr_2O_4$[1]

M. MOURIGAL, J.-J. WEN, Y. WAN, S. KOOHPAYEH, R. VALDÉS AGUILAR, N.P. ARMITAGE, O. TCHERNYSHOV, C.L. BROHOLM, Johns Hopkins, S. DUTTON, R.J. CAVA, Princeton, T. BIROL, H. DAS, C.J. FENNIE, Cornell, L. LIN, J.-M. LIU, Nanjing University, M.B. STONE, W. TIAN, Oak Ridge National Laboratory — We study the spin dynamics of the layered $S = 3/2$ triangular lattice antiferromagnet α-$SrCr_2O_4$ by means of inelastic neutron scattering on powder and single-crystal specimen. While the incommensurate long-range order observed below T_N=43K resembles the usual 120°-structure predicted for the perfect triangular lattice antiferromagnet, a spin-wave theory fit to the entire single-crystal dataset reveals strongly distorted exchange interactions. The extreme sensitivity of direct-exchange interactions to the small static Cr^{3+}-Cr^{3+} distance variations reported by neutron diffraction, is quantitatively confirmed by *ab-initio* calculations that corroborate the spin-wave theory results.

1:27PM G15.00010 Low-lying magnetic excitations in the distorted triangular lattice antiferromagnet α-$CaCr_2O_4$

MICHAEL SCHMIDT, ZHE WANG, Experimental Physics V, Center for Electronic Correlations and Magnetism, Institute of Physics, University of Augsburg, D-86135 Augsburg, Germany, S. TOTH, B. LAKE, A.T.M.N. ISLAM, Helmholtz-Zentrum Berlin fuer Materialien und Energie, D- 14109 Berlin, Germany, A. LOIDL, J. DEISENHOFER, Experimental Physics V, Center for Electronic Correlations and Magnetism, Institute of Physics, University of Augsburg, D-86135 Augsburg, Germany — We will discuss our results on α-$CaCr_2O_4$ obtained by FIR and Terahertz spectroscopy. This compound orders below T_N = 42.6 K in a proper screw 120° magnetic order, but shows additional low-lying magnetic modes indicative for the vicinity of a more complex magnetic order [1-2]. Our spectra obtained by FTIR and THz-TD spectroscopy show several optical magnons appearing below the magnetic ordering with anomalous temperature dependence. We will discuss their polarization dependence and a possible magnetoelastic coupling of these modes.

1:39PM G15.00011 Raman Evidence for Symmetry Breaking in $SrCr_2O_4$[1]

MICHAEL VALENTINE, Department of Physics and Astronomy, The Johns Hopkins University, Baltimore, MD 21218, USA, SIÂN DUTTON, Department of Chemistry, Princeton University, Princeton, NJ 08544, USA, SEYED KOOHPAYEH, Department of Physics and Astronomy, The Johns Hopkins University, Baltimore, MD 21218, USA, ROBERT CAVA, Department of Chemistry, Princeton University, Princeton, NJ 08544, USA, COLLIN BROHOLM, Department of Physics and Astronomy, The Johns Hopkins University, Baltimore, MD 21218, USA, TURAN BIROL, HENA DAS, CRAIG FENNIE, Cornell University, Ithaca, New York 14853 USA, NATALIA DRICHKO, Department of Physics and Astronomy, The Johns Hopkins University, Baltimore, MD 21218, USA, INSTITUTE FOR QUANTUM MATTER COLLABORATION — Raman spectra from 400 cm^{-1} to 650 cm^{-1} were acquired from single crystalline $SrCr_2O_4$ to probe magneto-elastic effects on its frustrated magnetism. The compound contains two-dimensional sheets of CrO_2, where spin-3/2 Cr atoms with direct exchange interactions form a distorted triangular lattice with helical magnetic order below 43K [1]. Even in the paramagnetic phase, the spectra show mode splitting beyond predictions for space-group P_{mmn} that describes powder x-ray diffraction data. This splitting occurs at the 480 cm^{-1} A_g mode and is enhanced below T_N, which suggests it may be associated with magneto-elastic effects.

1:51PM G15.00012 Geometric frustration on a $1/9^{th}$ site depleted triangular lattice[1]

JOHN HOPKINSON, Brandon University and University of Manitoba, JARRETT BECK, Brandon University — In the searches both for new spin liquid and spin ice (artificial and macroscopic) candidates, geometrically frustrated two-dimensional spin systems have played a prominent role. Here we present a study of the classical antiferromagnetic Ising (AFI) model on the sorrel net, a $1/9^{th}$ site depleted and $1/7^{th}$ bond depleted triangular lattice. The AFI model on this corner-shared triangle net is found to have a large residual entropy per spin $\frac{S}{N} = 0.48185 \pm 0.00008$, indicating the sorrel net is highly geometrically frustrated. Anticipating that it may be difficult to achieve perfect bond depletion, we investigate the physics resulting from turning back on the depleted bonds (J_2). We present the phase diagram, analytic expressions for the long range partially ordered ground state spin structure for antiferromagnetic J_2 and the short range ordered ground state spin structure for ferromagnetic J_2, the magnetic susceptibility and the static structure factor. We briefly comment on the possibility that artificial spin ice on the sorrel lattice could by made, and on a recent report [T. D. Keene *et al.*, Dalton Trans. **40** 2983 (2011)] of the creation of a $1/9^{th}$ depleted cobalt hydroxide oxalate.

2:03PM G15.00013 Hints of possible spin-liquid state in the spin-1/2 triangular-lattice Heisenberg antiferromagnet[1] , NIKOLAY PROKOFIEV, University of Massachusetts, Amherst, MA 01003, SERGEY KULAGIN[2], Institute for Nuclear Research of the Russian Academy of Sciences, Moscow, 117312, OLEG STARYKH, University of Utah, Salt Lake City, UT 84112, BORIS SVISTUNOV, CHRISTOPHER VARNEY, University of Massachusetts, Amherst, MA 01003 — We calculate magnetic susceptibility of the triangular-lattice quantum antiferromagnet in the correlated paramagnet regime and reveal surprising microscopic correspondence between quantum and classical models at all accessible temperatures $T > 0.375J$. Namely, we observe a perfect match between the quantum static (zero Matsubara frequency) response $\chi(r)$, where r is the spatial coordinate, and its classical counterpart calculated at temperature $T_{cl}(T)$. The correspondence curve is rather featureless and smoothly extrapolates to a finite value of $T_{cl} = 0.28J$ when $T/J \to 0$. If this extrapolation indeed holds true, then finite value of $T_{cl}(0)$ implies that spins are not ordered in the ground state and form a spin liquid. Existing numerical evidence would *not* be in contradiction with the spin liquid state because the spin correlation length for the classical Heisenberg model at $T_{cl} \approx 0.28J$ is > 1000 lattice periods and simulations dealing with small system sizes $L < 10$ would misidentify the ground state as ordered. Our results are based on the high-order skeleton Feynman diagrams within the fermionization framework.

Tuesday, March 19, 2013 11:15AM - 2:15PM –
Session G16 GMAG DMP: Focus Session: Quantum Spins 318 - Mark Meisel, University of Florida

11:15AM G16.00001 Excitations in a perfect magnetized quantum spin ladder[1] , ANDREY ZHELUDEV, DAVID SCHMIDIGER, SEBASTIAN MUEHLBAUER[2], GVASALIYA SEVERIAN, ETH Zurich, PIERRE BOUILLOT, CORINNA KOLLATH, THIERRY GIAMARCHI, U. Geneva, TATIANA GUIDI, ROBERT BEWLEY, ISIS, GEORG EHLERS, ORNL — The strong-leg $S = 1/2$ Heisenberg spin ladder system $C_7(D_{10}N)_2CuBr_4$ is investigated in applied magnetic fields using inelastic neutron scattering anf DMRG calculations. The spectrum in the high-field Tomonaga-Luttinger spin liquid phase is found to be qualitatively different from that in the low-field spin gap phase. In the former, numerous spectral featrures, including incommensurate excitations and multi-spinon continua are identified. In contrast, the latter is dominated by long-lived magnon excitations and two-magnon bound states [1]. An unprecedented quantitive agreement between experiment and numerical claculations is achieved.

11:27AM G16.00002 The Phase Diagram of the Quantum Magnet SrCu2(BO3)2 , SARA HARAVIFARD, University of Chicago / Argonne National Lab, ARNAB BANERJEE, University of Chicago, JONATHAN LANG, GEORGE SRAJER, Argonne National Lab, DANIEL SILEVITCH, University of Chicago, STEFAN KLOTZ, University P&M Curie, BRUCE GAULIN, McMaster University, THOMAS HANSEN, Institut Laue-Langevin, HANNA DABKOWSKA, McMaster University, THOMAS ROSENBAUM, University of Chicago — SrCu2(BO3)2(SCBO) is one of the few real-world materials that corresponds to the Shastry-Sutherland model, with corner-sharing Cu S=1/2 dimers lying on a square lattice. The application of pressure can be used to tune the ground state of the system. High-resolution x-ray synchrotron experiments on SCBO at pressures up to 6 GPa reveal new structural peaks as a result of lattice distortions at low temperatures that we associate with long-range antiferromagnetic order. Additionally we have conducted high-pressure neutron diffraction measurements at pressures up to 7 GPa investigating the magnetic structure of SCBO and its link to structural distortions as a function of temperature.

11:39AM G16.00003 Asymmetric thermal linehape broadening in a dimerised antiferromagnet - evidence for strong correlations at finite temperature , B. LAKE, Helmholtz Zentrum Berlin fur Materialien und Energie, Germany (HZB), D.L. QUINTERO-CASTRO, A.T.M.N. ISLAM, (HZB), E.M. WHEELER, Institut Laue Langevin, Grenoble, France, C. BALZ, (HZB), M. MANSSON, Laboratory for Solid State Physics, ETH Zurich, Switzerland (ETHZ), K.C. RULE, (HZB), S. GVASALIYA, A. ZHELUDEV, (ETHZ) — In the conventional picture of thermal effects in magnetism, the excitations are long-lived at low temperatures and their lifetime decreases with temperature. The explanation is that thermally activated excitations collide with each other limiting their lifetimes - observed experimentally as a symmetric Lorentzian energy broadening of the lineshape. This is confirmed for gapless magnets with long-range magnetic order. Here the excitations interact only weakly and fluctuate among the large range of available states in an uncorrelated manner. The damping is due simply to loss of coherence associated with the reduced lifetime. The concept of thermal decoherence and symmetric Lorentzian linewidth broadening is assumed to apply to all magnetic systems. This presentation will discuss $Sr_3Cr_2O_3$ which is 3-dimensional network of antiferromagnetic dimers with gapped magnon excitations. High resolution inelastic neutron scattering reveals that its lineshape broadens $asymmetrically$ with increasing temperature. This indicates that far from becoming increasingly incoherent with temperature, the excitations behave collectively like a strongly correlated gas of hard-core Bosons.

11:51AM G16.00004 Magnetism of $Ba_4Ru_3O_{10}$ revealed by density functional calculations: Structural trimers behaving as coupled magnetic dimers , ANDRES SAUL, CINaM/CNRS, GUILLAUME RADTKE, IM2NP, YANNICK KLEIN, GWENAELLE ROUSSE, IMPMC/CNRS — From a simple ionic picture, the only magnetically active ions in this compound are the three Ru^{4+} atoms which form trimers of faced shared RuO_6 octahedral. The Ru atom in the middle of the trimer (named Ru(1)) is cristallographically inequivalent to the ones at the corners (named Ru(2)). A naïve analysis of the magnetic properties of this compound compatible with the expected low spin magnetic configuration of the Ru ions would predict a complicate magnetic order at low temperature involving the Ru(1) and Ru(2) ions and a high temperature susceptibility corresponding to three S=1 ions per unit cell. In spite of that, we demonstrate in this work, from density functional calculations, that under the influence of Ru-Ru covalent bonding, the structural trimers behave in an extended range of temperature from 0 to 600K, as strong ($S = 1$) antiferromagnetic dimers. Our calculations of the effective exchange interactions show a strong intra-dimer interaction and a weaker inter-dimer one which explains the antiferromagnetic order observed below $T_N = 105K$ and the magnetic susceptibility in the intermediate and high temperature range (from T_N=105K up to 612 K).

12:03PM G16.00005 Wilson ratio of a Tomonaga-Luttinger liquid in a spin-1/2 Heisenberg ladder[1]

, TAO HONG, Quantum Condensed Matter Division, Oak Ridge National Laboratory, K. NINIOS, Y.H. KIM, University of Florida, T. MANABE, C. HOTTA, Kyoto Sangyo University, G. TREMELLING, S.N. HERRINGER, M.M. TURNBULL, C. LANDEE, Clark University, H.-J. KANG, NIST, K.P. SCHMIDT, G.S. UHRIG, TU Dortmund, H.B. CHAN, University of Florida, C. BROHOLM, The Johns Hopkins University, Y. TAKANO, University of Florida
— We report a comprehensive study of a strong-leg spin-1/2 ladder compound (C7H10N)2CuBr4 (DIMPY) by specific heat, magnetocaloric effect, magnetization and inelastic neutron scattering measurements. DIMPY is shown to be a perfect one-dimensional Heisenberg antiferromagnet with a spin gap=0.32 meV. Above a critical field Hc and at temperature below 1 K, the specific heat exhibits asymptotic linear-T behavior, characteristic of a Tomonaga-Luttinger liquid (TLL). In this field and temperature region, the specific heat in conjunction with the susceptibility yields the Wilson ratio R_W. The result supports the relation $R_W = 4K$, where K is the TLL parameter.

12:15PM G16.00006 High magnetic field studies of a spin-half dimmer

, KIM MODICK, ROSS MCDONALD, JOHN SINGLETON, Los Alamos National Lab, PAUL GODDARD, University of Oxford, JAMIE MANSON, Easstern Washington University, NATIONAL HIGH MAGNETIC FIELD LABORATORY COLLABORATION, UNIVERSITY OF OXFORD COLLABORATION, EASTERN WASHINGTON UNIVERSITY COLLABORATION
— We present high magnetic field studies of an organic molecular magnet system comprising of spin half copper dimmers. DC and pulsed field magnetometry combined with EPR indicate a small ($\sim$ 2 K) singlet triplet gap, and can be used to infer the sign of the triplon dispersion. Furthermore the low magnetic-exchange energy scales combined with the relatively soft organic framework of exchange pathways, indicate that the magnetic order can be readily tuned by temperature, magnetic field and pressure. The anisotropy between the effective mass of the top and bottom of the triplon band are analyzed in terms of the relative upper and lower critical fields for the onset of triplon condensation and magnetic saturation respectively.

12:27PM G16.00007 Magnetic engineering with molecular bricks

, STEPHEN BLUNDELL, University of Oxford
— Magnetic materials can be constructed using molecular components to build up novel and unusual architectures. This approach provides an exciting opportunity for exploring the physics of magnetism. Gaining control of the building blocks of magnetic materials and thereby achieving particular characteristics will make possible the design and growth of bespoke magnetic devices. While progress in the synthesis of molecular materials, and especially coordination polymers, represents a significant step towards this goal, the ability to tune the magnetic interactions within a particular framework remains in its infancy but promising advances are being made, including the production of single molecule magnets and a variety of extended structures. We have recently found a chemical method which achieves dimensionality selection via preferential inhibition of the magnetic exchange in an S = 1/2 antiferromagnet along one crystal direction, switching the system from being quasi-two- to quasi-one-dimensional while effectively maintaining the nearest-neighbour coupling strength [1]. We have also demonstrated that single molecule magnets can be used to store quantum information and have devised a strategy for extending the spin coherence time by chemical adjustment [2]. Very recently we have found that introduction of a molecular spacer layer can produce a greater than fourfold enhancement in the superconducting transition temperature of iron selenide [3]. The experimental techniques used in this work include ESR, muSR and high magnetic fields.

1:03PM G16.00008 Low-temperature studies of a 2D Quantum Heisenberg Antiferromagnet

, CHRISTOPHER LANDEE, FAN XIAO, Department of Physics, Clark University, MARK TURNBULL, Department of Chemistry, Clark University, JUAN BARTOLOMÉ, Instituto de Ciencia de Materiales de Aragón, CSIC-Universidad de Zaragoza
— A recent inelastic neutron scattering experiment of a 2D Quantum Heisenberg Antiferromagnet (2DQHAF) in an applied field [1] revealed novel features in the energy spectrum but the field was limited to $<0.3\ H_{SAT}$ due to the exchange strength (J = 17.5 K) of the material under study. (Quinolinium)$_2$CuBr$_4$·2H$_2$O is known [2] to be a molecular-based version of a strongly 2D QHAF with a significantly smaller exchange strength of 6.2 K and a saturation field of 15 T. We report the low-temperature properties (T $<$ 1.8 K) of (Quinolinium)$_2$CuBr$_4$·2H$_2$O and discuss its applicability for further investigations.

1:15PM G16.00009 Control of Crystal Structure and Magnetism in Copper(II) Fluoride Based Coordination Polymers[1]

, JOHN SCHLUETER, SAUL LAPIDUS, Argonne National Laboratory, JAMIE MANSON, Eastern Washington University
— Whereas magnetic copper (II) halide (halide = chloride or bromide) coordination polymers have been frequently studied, the copper(II) fluoride analogs have been much less investigated. This is due in part to synthetic challenges associated with solubility and reactivity. In analogy to cuprates, Cu-F-Cu linkages are expected to provide strong magnetic superexchange. The magnetic structure of such systems can be tuned by choice of ancillary ligand. Herein, we describe the use of various pyridines, diazines, and triazoles that have the ability to define the structural and magnetic dimensionality. Hydrogen bonding to the fluoride ligand provides an additional opportunity for designing molecule-based materials through a 'crystal-engineering' approach. Competition for intermolecular interactions frequently enables stimuli responsive behavior, including pressure-induced phase transitions. This will be illustrated for the CuF$_2$(H$_2$O)$_2$(pyrazine) coordination polymer and the five-coordinate CuF$_2$(H$_2$O)$_2$(3-chloropyridine) molecular solid. The use of new synthetic methods, including the use of high pressure, will be described. Subtle changes in reaction conditions leads to significant changes in structural and magnetic properties.

1:27PM G16.00010 Finite-temperature valence-bond-solid transition of quantum spins in two dimensions[1]

, SONGBO JIN, ANDERS SANDVIK, Boston University
— The $S = 1/2$ Heisenberg model on the 2D square lattice with four- or six-neighbor spin interactions (JQ model) hosts a quantum phase transition between Néel and valence-bond-solid (VBS) ground states. The deconfined quantum critical (DQC) point, predicted by the theory of Senthil *et al.*[1], may be realized in this model [2]. Here we study the finite-temperature phase transition between the VBS (Z_4 symmetry breaking) to the paramagnetic state. We find continuously changing exponents with the correlation-length exponent ν close to the Ising value far from the $T = 0$ critical point, and diverging when the critical temperature $T_c \to 0^+$. This is in accord with the DQC theory, according to which the transition for $T_c \to 0^+$ should approach a Kosterlitz-Thouless fixed point.

1:39PM G16.00011 Ordering in weakly coupled random singlet spin chains , MATTHIAS THEDE, Laboratory for Solid State Physics, ETH Zurich, Zurich, Switzerland, F. XIAO, Department of Physics, Clark University, 950 Main St., Worcester, MA 01610, USA, CH. BAINES, Laboratory for Muon Spin Spectroscopy, Paul Scherrer Insitut, Villigen-PSI, Switzerland, C. LANDEE, Department of Physics, Clark University, 950 Main St., Worcester, MA 01610, USA, E. MORENZONI, Laboratory for Muon Spin Spectroscopy, Paul Scherrer Insitut, Villigen-PSI, Switzerland, A. ZHELUDEV, Laboratory for Solid State Physics, ETH Zurich, Zurich, Switzerland — We study the effect of bond randomness on long range magnetic ordering in quasi-one-dimensional antiferromagnets, where the introduction of arbitrary weak bond randomness gives rise to the so-called random singlet phase. We investigated weakly coupled spin chain systems by local (muon spin rotation/relaxation) and bulk measurements (susceptibility and specific heat). The material $Cu(py)_2(Cl_{1-x}Br_x)_x$ is an organic tunable spin chain which has an average intrachain coupling constant between J = 2.3 meV (x=0) and J = 4.5 meV (x = 1). The disorder free end materials order magnetically at T_N = 1.15 K (x=0) and T_N = 0.72 K (y=0), respectively. Bond disorder strongly affects the magnetically ordered phase. In apparent contradiction with chain mean field theory [1] bond randomness strongly suppresses both the ordered moment and the ordering temperature T_N [2]. We will also report about similiar results in $BaCu_2(Si_1 - xGe_x)_2O_7$.

1:51PM G16.00012 Pressure-Induced Ferromagnetic Interactions in the Molecule-based Magnet $Mn(dca)_2$[1] , P.A. QUINTERO, M.K. PEPRAH, M.W. MEISEL, Dept. Phys. and NHMFL, Univ. Florida, D. RAJAN, D.R. TALHAM, Dept. Chem., Univ. Florida — Using SQUID magnetometry, we have studied the pressure dependence of the magnetization of the three-dimensional antiferromagnetic coordination polymer $Mn(N(CN)_2)_2$, referred to as $Mn(dca)_2$, up to 1.2 GPa and down to 5 K. The isostructural compounds $M(dca)_2$, where M = Fe, Co, and Ni, have been previously studied by others and are known to show variations in their transition temperatures of up to 26% for pressures as large as 1.7 GPa.[2] Our results on $Mn(dca)_2$ indicate a linear dependence of the transition temperature on the applied pressure, where a change of 48% is measured at 1.2 GPa. In addition, a marked difference in the behavior of the magnetization is observed above and below 0.8 GPa. Specifically, for P $<$ 0.8 GPa, the magnetization decreases with increasing pressure, and for P $>$ 0.8 GPa, the behavior is inverted. These results indicate that external pressure changes the angle along the Mn-[N(1)-C-N(2)]-Mn superexchange path, thereby favoring ferromagnetic interactions.[3]

2:03PM G16.00013 Quantum critical dynamics in the one-dimensional spin chain compound copper pyrazine dinitrate probed by NMR spectroscopy , HANNES KUEHNE, A.P. REYES, P.L. KUHNS, Florida State University/National High Magnetic Field Laboratory, A.A. ZVYAGIN, ILTPE, Kharkov, Ukraine, S. GROSSJOHANN, W. BRENIG, IThP, TU Braunschweig, Germany, M. GUENTHER, H.-H. KLAUSS, IFP, TU Dresden, Germany, C.P. LANDEE, M.M. TURNBULL, Carlson School of Chemistry and Department of Physics, Clark University, Massachusetts — The metalorganic compound copper pyrazine dinitrate is known to be one of the best realizations of the antiferromagnetic $S = 1/2$ Heisenberg chain model with a comparatively small nearest neighbor exchange constant J/k_B = 10.7 K. The zero temperature saturation field B_c = 14.6 T corresponds to a quantum critical point (QCP), where the system is driven from a Luttinger liquid state to ferromagnetic polarization. With an emphasis on the vicinity of the QCP, a comprehensive comparison of our experimental findings from ^{13}C NMR spectroscopy with both numerical (quantum Monte Carlo) and analytical (conformal field theory) approaches is presented. In particular, this comparison reveals a well-defined maximum of $1/T_1$ (B,T) *below* B_c as the signature of essential one-dimensional spin-spin interactions in the Luttinger liquid regime.

Session G17 DMP GMAG: Focus Session: Improper Ferroelectrics 319 - Taner Yildirim, NIST Center for Neutron Research

11:15AM G17.00001 Coupling of Magnetic and Ferroelectric Order Parameters in Improper Ferroelectrics , A. BROOKS HARRIS, University of Pennsylvania — This talk concerns systems for which the onset of incommensurate magnetic order induces ferroelectricity. I review how Landau theory [1,2] provided a convenient phenomenological explanation of this phenomenon. In the simplest and most frequent scenario, as the temperature is lowered, one first induces collinear incommensurate magetic order. At a lower temperature transition, transverse magnetic components appear and these two different symmetry magnetic order parameters combine to induce ferroelectricity via a trilinear magnetoelectric coupling. I will present several examples of this mechanism, subsequently discussed by Mostovoy[3] within a model of spiral magnetic order. Landau theory also explains [4] a contrasting scenario in which ferroelectric and magnetic can order within a single phase transition as in $RbFe(MoO_4)_2$, whose magnetic spiral contradicts the Mostovoy construction, but which Kaplan[5] has subsequently shown to be consistent with a more complete symmetry analysis of microscopic interactions. Other more exotic higher order magnetoelectric couplings, not easily accessible to an analysis of microscopic interactions, are also possible, especially in the presence of nonuniform magnetic order. I close with a few remarks on microscopic models for magnetically induced ferroelectricity.

11:51AM G17.00002 A route to high polarization multiferroics , PRIYA MAHADEVAN, HIRAK CHANDRA, KAPIL GUPTA, ASHIS NANDY, S.N.Bose National Centre for Basic Sciences — Large ferroelectric polarizations are usually seen in d^0 ferroelectrics, while those with a finite d-electron count usually have a polarization which is two orders of magnitude smaller. The route then to high polarization multiferroics, seems quite obvious - examine if we can stabilize the d^0 type distortions in finite d-electron systems. The way we went about this was to dope carriers into $BaTiO_3$ and examine if ferroelectricity survived. Considering the example of V doping in $BaTiO_3$, we found that ferroelectricity was strongly stabilized, much stronger that in the undoped limit. Microscopic modeling coupled with ab-initio calculations revealed that part of the stability of the ferroelectric distortions about the V site emerged from first-order Jahn-Teller effects. The dilute doping limit was used to identify some design principles and helped us to design new multiferroics.

12:03PM G17.00003 Exchange Constants from Combined Light and Neutron Scattering Experiments: Application to Magnetoelectric $LiMnPO_4$[1]

, CESAR J. CALDERON FILHO, PAULO F. GOMES, ALI F. GARCÍA-FLORES, GASTON E. BARBERIS, UNICAMP - Univ. Estadual de Campinas, DAVID VAKNIN, Ames Laboratory and Iowa State University, EDUARDO GRANADO, UNICAMP - Univ. Estadual de Campinas — Two-magnon Raman scattering is observed in magnetoelectric $LiMnPO_4$, carrying quantitative information on the magnetic interactions between local Mn^{2+} moments. A simulated annealing fitting procedure using these Raman data combined with magnon dispersion curves from neutron diffraction is demonstrated to greatly improve the accuracy and reliability of the determined exchange constants up to at least fifth-nearest neighbors. First-nearest neighbor interactions are shown to be largely dominant in $LiMnPO_4$, ruling out magnetic frustration as a relevant ingredient for this material. This methodology may be instrumental to investigate other magnetoelectric and multiferroic materials as well as superconductors at the border of magnetism, where knowledge of exchange constants without ambiguity is important to pin down the relevant physics.

12:15PM G17.00004 A Model of Magnetic Phase Diagrams of Monoclinic Multiferroics CuO and $MnWO_4$

, GUY QUIRION, Memorial University, R. VILLARREAL, University of Geneva, M.L. PLUMER, Memorial University, M. POIRIER, University of Sherbrooke, T. USUI, T. KIMURA, Osaka University — A mean-field Landau-type free energy model developed using symmetry arguments is used to investigate the magnetic field - temperature phase diagrams of monoclinic multiferroics such as CuO and $MnWO_4$. Our analysis supports the necessity of having an intermediate collinear phase between the paramagnetic and magnetoelectric spin spiral phases. The numerical predictions agree well with the experimental phase diagram of CuO (**H**$\|$**b**) determined recently by high resolution ultrasonic velocity measurments [1] which reveal a new transition at $T_{N3} = 230.0$ K associated with collinear ordering, just above the spiral phase at $T_{N2} = 229.5$ K. The model also reproduces the magnetic phase diagrams reported for $MnWO_4$ with the applied field along the three principal axes [2] and elucidates the nature of newly identified high-field phases.

12:27PM G17.00005 Muon spectroscopy as a probe for multiferroic materials

, CARLOS ARISTIZABAL, ALAN DREW, DONNA ARNOLD, FINLAY MORRISON, LAURA NUCCIO, VISWANATHAN MOHANDOSS, ANDREI ROTARU, NICOLA MORLEY, FRANCIS PRATT, SEAN GIBLIN, MICHAEL CARPENTER, None — Multiferroic magnetoelectrics are materials that exhibit both, ferromagnetic and ferroelectric ordering in the same phase. Thus, they have a spontaneous magnetization that can be manipulated with an applied magnetic field, a spontaneous ferroelectric polarization that can be switched by an applied electric field, and in some cases, there exist some form of coupling between the two order parameters. Such coupling is of great technological importance as it offers the possibility of new multifunctional devices such as transducers, actuators, sensors and memories [1]. Muon spectroscopy (MS) [2] has shown itself to be an extremely versatile and powerful probe of magnetic properties of materials as well as a flexible technique in terms of experimental set up to be able to show magnetic behaviour under an applied electric field. By means of MS and other complementary techniques, I will present, in an entirely new tetragonal tungsten bronze (TTB) class of multiferroic material, a direct coupling in the form of an internal magnetic field that varies hysteretically with an applied electric field. [1] N. A. Spaldin et al., Science 309, 391 (2005) [2] S. J. Blundell, Contemp. Phys. 40, 175, (1999).

12:39PM G17.00006 Magneto–optical properties of complex oxides[1]

, PENG CHEN, BRIAN HOLINSWORTH, KENNETH O'NEAL, TANEA BRINZARI, JANICE MUSFELDT, University of Tennessee, NARA LEE, LUO XUAN, SANG CHEONG, Rutgers University, NYRISSA ROGADO, ROBERT CAVA, Princeton University, YAQI WANG, BERND LORENZ, University of Houston, STEVE MCGILL, National High Magnetic Field Laboratory — We investigated the magneto-optical properties of α-Fe_2O_3, frustrated system $Ni_3V_2O_8$, and rare earth indium oxides like $DyInO_3$ in order to understand the interplay between charge and magnetism. We discovered that hematite appears more red in applied magnetic field than in zero field conditions, an effect that is amplified by the presence of the spin flop transition. Furthermore, magnetic field aligns the spins into fully polarized state and induces optical band gap change in $Ni_3V_2O_8$. As a consequence, $Ni_3V_2O_8$ appears more green in 35 T. f electron excitations in $DyInO_3$ changes dramatically in applied magnetic field because of enormous spin-orbit coupling effect in the rare earth elements. These findings advance our understanding of spin-charge coupling and motivate spectroscopic work on other functional materials under extreme conditions.

[1]This work is supported by the U.S. Department of Energy.

12:51PM G17.00007 Effects of rare earth ion size on the stability of the coherent Jahn-Teller distortions in undoped perovskite manganites[1]

, K.H. AHN, T.F. SEMAN, Department of Physics, New Jersey Institute of Technology, Newark, New Jersey 07102, USA, T. LOOKMAN, A. SAXENA, A.R. BISHOP, Theoretical Division, Los Alamos National Laboratory, Los Alamos, New Mexico 87545, USA, P.B. LITTLEWOOD, Physical Sciences and Engineering Division, Argonne National Laboratory, Argonne, Illinois 60439, USA — We present a theoretical study on the relation between the size of the rare earth ion, often known as chemical pressure, and the stability of the coherent Jahn-Teller distortions in undoped perovskite manganites. Using a Keating model expressed in terms of atomic scale symmetry modes for a simplified two- dimensional model, we show that there exists a coupling between the uniform shear distortion and the staggered buckling distortion within the Jahn-Teller energy term. It is found that this coupling provides a mechanism by which the coherent Jahn-Teller distortion is more stabilized by smaller rare earth ion. We analyze the appearance of the uniform shear distortion below the Jahn-Teller ordering temperature, estimate the Jahn-Teller ordering temperature and its variation among LaMnO3, PrMnO3, and NdMnO3 and obtain the relations between distortions. We find good agreement between theoretical results and experimental data.

[1]This work was supported by US DOE/LANL Award No. DE-AC52-06NA25396/170590-1 (T.F.S., K.H.A.), ANL XSD Visitor Program (K.H.A.), and DOE FWP 70069 (P.B.L.).

1:03PM G17.00008 Magnetic Coupling in the multiferroic hexagonal $ErMnO_3$[1]

, HUIBO CAO, Quantum Condensed Matter Division, Neutron Sciences Directorate, Oak Ridge National Laboratory, Oak Ridge, TN 37831, USA, JUN ZHAO, Lawrence Berkeley National Lab, Berkeley, CA 94720-8197, TAO HONG, JIE MA, BRYAN CHAKOUMAKOS, Quantum Condensed Matter Division, Neutron Sciences Directorate, Oak Ridge National Laboratory, Oak Ridge, TN 37831, USA — Hexagonal $ErMnO_3$ is one of the rare earth manganites $RMnO_3$ and has attracted renewed interest due to its multiferroic properties. Understanding the coupling between spin, charge, and lattice degrees of freedom is crucial to explore and design strong magnetic-ferroelectric coupled materials. We measured the crystal and magnetic structures of $ErMnO_3$ at selected temperatures and magnetic fields by single crystal neutron diffraction. Combined with planned inelastic neutron scattering measurements, the magnetic-magnetic and magnetic-lattice interactions will be discussed.

1:15PM G17.00009 Vortex interactions and formation of vortex networks in hexagonal $YMnO_3$, SERGEY ARTYUKHIN, KARIN M. RABE, DAVID VANDERBILT, Rutgers University, MAXIM MOSTOVOY, University of Groningen — Multiferroic materials with their coexisting magnetic and ferroelectric orders are of pressing interest for spintronics and information storage technology. In hexagonal manganites there is an additional order, structural trimerization, which strongly interacts with both charge and spin degrees of freedom [1,2]. This results in the clamping of structural, ferroelectric and antiferromagnetic domain walls and gives rise to the appearance of multiferroic vortices [3,4,2]. Motivated by the recent experiments of the group of S-W. Cheong visualizing vortex networks formed in $YMnO_3$ at different cooling rates, we use Landau-type theory and electronic structure calculations to study vortex network formation and interpret experimental observations. Our results emphasize the importance of strains for the understanding of vortex interactions in this material.

1:27PM G17.00010 Interplay of octahedral distortions in electronic and structural phase transitions in ABO_3 perovskites[1] , PRASANNA V. BALACHANDRAN, JAMES M. RONDINELLI, Department of Materials Science and Engineering, Drexel University, Philadelphia, PA 19104 — In this work, we investigate group-subgroup relationships afforded to ABO_3 perovskites from combinations of BO_6 distortions – bond stretching and bond angle rotations – with the objective of identifying new pathways for tuning their properties through electron-lattice interactions. Using nickelate and bismuthate perovskite compounds as a template, we decompose their low-symmetry structures into orthonormal symmetry-breaking lattice modes of the parent cubic space group. Statistical analysis of mode decomposition data uncovers previously unappreciated relationships between microscopic octahedral distortion modes and macroscopic physical properties. Finally, we propose novel crystal engineering strategies to study perovskites near phase boundaries that are otherwise extremely difficult to probe experimentally.

1:39PM G17.00011 Cation Ordering in Layered Nickelates , BRITTANY NELSON-CHEESEMAN, School of Engineering, University of St. Thomas & Materials Science Division, Argonne National Laboratory, HUA ZHOU, Advanced Photon Source, Argonne National Lab, ANTONIO CAMMARATA, Dept of Materials Science and Engineering, Drexel University, JASON HOFFMAN, Materials Science Division, Argonne National Lab, PRASANNA BALACHANDRAN, JAMES RONDINELLI, Dept of Materials Science and Engineering, Drexel University, ANAND BHATTACHARYA, Materials Science Division & Center for Nanoscale Materials, Argonne National Lab — The single layer Ruddlesden-Popper nickelates present a model system to understand how the effects of digital dopant cation ordering may affect the properties of 2-dimensional conducting sheets. We investigate the effects of aliovalent A-site cation order on $LaSrNiO_4$ films. Using molecular beam epitaxy, we interleave full layers of SrO and LaO in a series of chemically equivalent films, varying the pattern of SrO and LaO layers relative to the NiO_2 layers. Through synchrotron surface x-ray diffraction and Coherant Bragg Rod Analysis (COBRA), we directly investigate the A-site cation order and the resulting atomic displacements for each ordering pattern. We correlate these results with theoretical calculations and transport measurements of the layered nickelate films.

1:51PM G17.00012 Total energy calculations of correlated electron compounds: theory and application to rare earth nickelates[1] , HYOWON PARK, Department of Applied Physics and Applied Mathematics & Department of Physics, Columbia University, ANDREW MILLIS, Department of Physics, Columbia University, CHRIS MARIANETTI, Department of Applied Physics and Applied Mathematics, Columbia University — We use density functional theory (DFT) plus dynamical mean field theory (DMFT) method, along with DFT+U and Hartree-Fock methods to compute the electronic energy as a function of crystal structure for rare earth nickelates. We show that full charge self-consistency can be essential for obtaining qualitative agreement with experiment and that the choice of double counting correction has an important effect on the energy. Furthermore, the precise definition (projector vs Wannier) of the correlated d-orbitals has a minimal effect. We show that charge self-consistent DFT+DMFT, as opposed to DFT+U, is critical to describing the magnetic-insulator to paramagnetic-metal phase boundary in the rare earth nickelate phase diagram.

2:03PM G17.00013 Neutron Scattering in Multiferroics $Ba_2CoGe_2O_7$, MINORU SODA, TAKATSUGU MASUDA, Institute for Solid State Physics, University of Tokyo, MASASHIGE MATSUMOTO, Department of Physics, Shizuoka University, SEVERIAN GVASALIYA, MARTIN MANSSON, ANDREY ZHELUDEV, Laboratory for Solid State Physics, ETH Zurich — $Ba_2CoGe_2O_7$ having the noncentrosymmetric crystal structure shows a staggered antiferromagnetic structure in the (001) plane below T_N=6.7 K. In the magnetically ordered state, a ferroelectric polarization is observed even at a magnetic field H=0, and largely enhanced under H. In $Ba_2CoGe_2O_7$, Murakawa and co-workers have shown that the ferroelectricity is induced by the spin-dependent d-p hybridization mechanism. Furthermore, the 4 meV excitation, which is an electric-active mode through the coupling between spin and electric-dipole, was observed in the electromagnetic wave absorption. In the present study, the neutron scattering measurements were carried out in $Ba_2CoGe_2O_7$ under the magnetic field. We found one acoustic and two optical modes in zero field, which are reasonably reproduced by the extended spin wave theory. Furthermore, our result indicates that the anisotropy of the magnetic moments also connects with the multiferroic property of $Ba_2CoGe_2O_7$.

Session G18 DCMP: Two Dimensional Topological Insulators II: Graphene and Related Materials 320 - Shaffique Adam, Yale University

11:15AM G18.00001 Is graphene on the edge of being a topological insulator? , JOSE GONZALEZ, Instituto de Estructura de la Materia (CSIC), Madrid, Spain — We show that, at sufficiently large strength of the long-range Coulomb interaction, a mass term breaking parity (so-called Haldane mass) is dynamically generated in the many-body theory of Dirac fermions describing the graphene layer. While the tendency towards a conventional excitonic instability is stronger than for the dynamical breakdown of parity at spatial dimension D greater than 2, we find that the situation is reversed at D = 2. The need to regularize the many-body theory in a gauge-invariant manner (taking the limit D = 2 from below) is what leads to the dominance of the parity-breaking pattern in graphene. We compute the critical coupling for the generation of a parity-breaking mass from the finite radius of convergence of the ladder series supplemented with electron self-energy corrections, finding a value quite close to the effective interaction strength for graphene in vacuum after including Fermi velocity renormalization and static RPA screening of the Coulomb interaction.

11:27AM G18.00002 ABSTRACT WITHDRAWN –

11:39AM G18.00003 Excahnge and correlation energy of electrons dressed with circularly-polarized light in graphene and three-dimensional topological insulators , ANDRII IUROV, Hunter College and Graduate Center, CUNY, GODFREY GUMBS, Hunter College, CUNY — We have formulated a theory for investigating the conditions which are required to achieve entangled states of electrons on graphene and three-dimensional (3D) topological insulators. We consider the quantum entanglement of spins by calculating the exchange energy. A gap is opened up at the Fermi level between the valence and conduction bands at zero doping when graphene as well as 3D topological insulators are irradiated with circularly-polarized light. This energy band gap is dependent on the intensity and frequency of the applied electromagnetic field. The electron-photon coupling also gives rise to a unique energy dispersion of the dressed states which is different from either graphene or the conventional two-dimensional electron gas (2DEG). In our calculations, we obtain the dynamical polarization function for imaginary frequencies. The polarization function is determined by both the energy dispersion and the overlap of pseudo-spin wave functions. The correlation energy is calculated in the random phase approximation (RPA). The application of the derived results to quantum computation will be discussed.

11:51AM G18.00004 Stabilizing topological phases in graphene via random adsorption , JIANG JIANG, International Center for Quantum Materials, Peking University, Beijing 100871, China, ZHENHUA QIAO, Department of Physics, The University of Texas at Austin, Austin, Texas 78712, USA, HAIWEN LIU, Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China, JUNREN SHI, QIAN NIU, International Center for Quantum Materials, Peking University, Beijing 100871, China — We study the possibility of realizing topological phases in graphene with randomly distributed adsorbates. When graphene is subjected to periodically distributed adatoms, the enhanced spin-orbit couplings can result in various topological phases. However, at certain adatom coverages, the intervalley scattering renders the system a trivial insulator. Using both finite-size scaling method and transport calculation, we show that when the adatom distribution becomes random, the intervalley scattering is weakened, but other quantities (e.g. spin-orbit couplings, and exchange field) are not affected. This finding points out that the topological states are graphene-favored ground states in the presence of randomly distributed adtoms.

Hua Jiang, Zhenhua Qiao, Haiwen Liu, Junren Shi and Qian Niu, Phys. Rev. Lett. **109**, 116803 (2012).

12:03PM G18.00005 Bound States of Conical Singularities in Graphene-Based Topological Insulators , ANDREAS RUEGG, UC Berkeley, CHUNGWEI LIN, University of Texas at Austin — We investigate the electronic structure induced by wedge-disclinations (conical singularities) in a honeycomb lattice model realizing Chern numbers $\gamma = \pm 1$. We establish a correspondence between the bound state of (i) an isolated $\Phi_0/2$-flux, (ii) an isolated pentagon $(n = 1)$ or heptagon $(n = -1)$ defect with an external flux of magnitude $n\gamma\Phi_0/4$ through the center and (iii) an isolated square or octagon defect without external flux, where $\Phi_0 = h/e$ is the flux quantum. Due to the above correspondence, the existence of isolated electronic states bound to the disclinations is robust against various perturbations. These results are also generalized to graphene-based time-reversal invariant topological insulators.

12:15PM G18.00006 Topological kink states at the tilt boundary in gated multi-layer graphene , EUN-AH KIM, ABOLHASSAN VAEZI, Cornell University, YUFENG LIANG, Washington University, DARRYL NGAI, Cornell University, LI YANG, Washington University — Search for new realization of symmetry protected topological states with protected edge states is an active area of research. We show that a tilt boundary in gapped multi-layer graphene supports topologically protected gapless kink states. We investigate such kink states from two perspectives: the microscopic perspective of tight-binding model and an ab-initio calculation on bilayer, and the perspective of symmetry protected topological (SPT) states for general multi-layer. We show that the bilayer tilt boundary supports gapless kink states that are undeterred by strain concentrated at the boundary. Further we establish the kink states as concrete examples of edge states of *time-reversal symmetric* Z-type SPT, protected by T and two $U(1)$ symmetries in the absence of inter-valley mixing. Recent observations of such boundaries in multi-layer samples suggest that transport through these topological kink states might explain the long standing puzzle of sub-gap conductance. We discuss possible topological phase transitions upon breaking subset of symmetries from SPT perspective.

12:27PM G18.00007 Topological Proximity Effects in Graphene Nanoribbon Heterostructures , GUFENG ZHANG, Univ. of Sci. & Tech. of China, Fudan University, XIAOGUANG LI, Fudan University, Univ. of Sci. & Tech. of China, GUANGFEN WU, Univ. of Sci. & Tech. of China, Shenzhen Institutes of Advanced Technology, JIE WANG, DIMITRIE CULCER, Univ. of Sci. & Tech. of China, EFTHIMIOS KAXIRAS, Harvard University, ZHENYU ZHANG, Univ. of Sci. & Tech. of China, Harvard University — Topological insulators (TI) are bulk insulators that possess robust chiral conducting states along their interfaces with normal insulators. A tremendous research effort has recently been devoted to TI-based heterostructures, in which conventional proximity effects give rise to many exotic physical phenomena. Here we establish the potential existence of "topological proximity effect" at the interface of a topological graphene nanoribbon (GNR) and a normal GNR. Specifically, we show that the location of the topological edge states exhibits versatile tunability as a function of the interface orientation, as well as the strengths of the interface coupling and spin-orbit coupling in the normal GNR. For zigzag and bearded GNRs, the topological edge state can be tuned to be either at the interface or outer edge of the normal ribbon. For armchair GNR, the potential location of the topological edge state can be further enriched to be at the edge of or within the normal ribbon, at the interface, or diving into the topological GNR. We also discuss potential experimental realization of the predicted topological proximity effects, which may pave the way for integrating the salient functionality of TI and graphene in future device applications.

12:39PM G18.00008 Designer quantum spin Hall phase transition in molecular graphene , POUYAN GHAEMI, University of Illinois at Urbana-Champaign, SARANG GOPALAKRISHNAN, University of Illinois at Urbana-Champaign, Harvard University, TAYLOR HUGHES, University of Illinois at Urbana-Champaign — Graphene was the first material predicted to be a time-reversal-invariant topological insulator; however, the insulating gap is immeasurably small owing to the weakness of spin-orbit interactions in graphene. A recent experiment demonstrated that designer honeycomb lattices with graphene-like "Dirac" band structures can be engineered by depositing a regular array of carbon monoxide atoms on a metallic substrate. Here, we argue that by growing such designer lattices on metals or semiconductors with strong spin-orbit interactions, one can realize an analog of graphene with strong intrinsic spin-orbit coupling, and hence a highly controllable two-dimensional topological insulator. We estimate the range of substrate parameters for which the topological phase is achievable, and consider the experimental feasibility of some candidate substrates.

12:51PM G18.00009 Topological Classification of Crystalline Insulators with Point Group Symmetry[1] , DI XIAO, Carnegie Mellon University, PRIYAMVADA JADAUN, QIAN NIU, SANJAY BANERJEE, The University of Texas at Austin — We show that in crystalline insulators point group symmetry alone gives rise to a topological classification based on the quantization of electric polarization. Using C_3 rotational symmetry as an example, we first prove that the polarization is quantized and can only take three inequivalent values. Therefore, a Z_3 topological classification exists. A concrete tight-binding model is derived to demonstrate the Z_3 topological phase transition. Using first-principles calculations, we identify graphene on BN substrate as a possible candidate to realize the Z_3 topological states. To complete our analysis we extend the classification of band structures to all 17 two-dimensional space groups. This work will contribute to a complete theory of symmetry conserved topological phases and also elucidate topological properties of graphene like systems.

1:03PM G18.00010 Surface band topology of Ge on Ag(111)[1] , ATHANASIOS DIMOULAS, EVANGELOS GOLIAS, EVANGELIA XENOGIANNOPOULOU, DIMITRA TSOUTSOU, POLIXRONIS TSIPAS, SIGIAVA GIAMINI, NCSR DEMOKRITOS, Athens, Greece — While compelling evidence for silicene on Ag (111) has been recently published [1], the existence of germanene remains elusive. We have performed MBE growth of (sub) monolayer Ge on single crystal Ag (111) substrates, supported by DFT calculations, with the aim to obtain germanene. RHEED data indicate a $\left(\sqrt{3} \times \sqrt{3}\right) R30^0$ superstructure, while *in-situ* ARPES reveals a rich surface band structure consisting of linearly, highly dispersive cone-like features with hexagonal and snow-flake warping clearly imaged in the constant energy contour plots k_x-k_y. Unlike the case of graphene-like 2D crystals where Dirac cones are expected at the K-points, here the cone-like features appear at the center (Γ points) of the surface Brillouin zone similar to what is observed in topological insulators. This suggests the possibility to witness a non-trivial surface band topology triggered by intrinsic spin-orbit coupling as predicted [2] for 2D honeycomb Ge lattices or by strong Ge and Ag p orbital hybridization in an ordered surface alloy Ag_2Ge.

1:15PM G18.00011 Polarization-driven topological insulator transition in a GaN/InN/GaN quantum well[1] , M.S. MIAO, Q. YAN, C.G. VAN DE WALLE, Materials department and materials Research Lab, University of California Santa Barbara, California 93106-5050, USA, W.K. LOU, L.L. LI, K. CHANG, SKLSM, Institute of Semiconductors, Chinese Academy of Sciences, Beijing 100083, P. R. China — Topological insulators (TIs), a new state of quantum matter, have recently attracted significant attention, both for their fundamental research interest and for their potential device applications. Although many families of TI materials have been found, the realization of TI in conventional semiconductors remains elusive, mainly due to their sizable gaps and small spin-orbit interactions (SOI). Based on advanced first-principles calculations combined with an effective low-energy k·p Hamiltonian, we show that the intrinsic polarization of materials can be utilized to simultaneously reduce the energy gap and enhance the SOI, driving the system to a TI state. The proposed system consists of ultrathin InN layers embedded into GaN, a layer structure that is experimentally achievable. We found that the TI transition happens at GaN/InN/GaN quantum well with 3 to 4 InN atomic layers. Since polarization fields occur in many materials, a similar mechanism may apply to other systems as well. Our approach may pave the way toward integrating controllable TIs with conventional semiconductor devices.

1:27PM G18.00012 Electronic Structure calculations in a 2D SixGe1-x alloy under an applied electric field[1] , JOSÉ EDUARDO PADILHA, University of São Paulo, RENATO B. PONTES, Federal University of Goiás, LEANDRO SEIXAS, ANTÔNIO J.R. DA SILVA, ADALBERTO FAZZIO, University of São Paulo — The recent advances and promises in nanoscience and nanotechnology have been focused on hexagonal materials, mainly on carbon-based nanostructures. Recently, new candidates have been raised, where the greatest efforts are devoted to a new hexagonal and buckled material made of silicon, named Silicene. This new material presents an energy gap due to spin-orbit interaction of approximately 1.5 meV, where the measurement of quantum spin Hall effect(QSHE) can be made experimentally. Some investigations also show that the QSHE in 2D low-buckled hexagonal structures of germanium is present. Since the similarities, and at the same time the differences, between Si and Ge, over the years, have motivated a lot of investigations in these materials. In this work we performed systematic investigations on the electronic structure and band topology in both ordered and disordered SixGe1-x alloys monolayer with 2D honeycomb geometry by first-principles calculations. We show that an applied electric field can tune the gap size for both alloys. However, as a function of electric field, the disordered alloy presents a W-shaped behavior, similarly to the pure Si or Ge, whereas for the ordered alloy a V-shaped behavior is observed.

1:39PM G18.00013 Reflection from surface step defect in topological insulator nanofilm , THAKSHILA M. HERATH, Department of Physics and Astronomy, Georgia State University, Atlanta, GA 30303, USA, PRABATH HEWAGEEGANA, Department of Physics, University of Kelaniya, Kelaniya 11600, Sri Lanka, VADIM M. APALKOV, Department of Physics and Astronomy, Georgia State University, Atlanta, GA 30303, USA — Ultrathin topological insulator nanofilm with a step-like defect, which divides two regions of nanofilm with different thicknesses, is considered. Electron, propagating along the nanofilm surface, is reflected from the step. We calculate the reflectance of such electron for different parameters of the nanofilm and different parameters of the defect. We demonstrate that such system has an interesting property. Namely, the incident electron wave not only produces the reflected and transmitted waves, but also generates the mode, localized at the step-like defect. Such mode results in an enhancement of the electron density at the defect by $\sim$20%. The strength of such enhancement depends on the parameters of the nanofilm and the height of the step.

Session G19 DCMP: URu2Si2 Hidden Order and other U-based Systems 321 - Jason Jeffries, Lawrence Livermore National Lab

11:15AM G19.00001 Precursor Hidden Order Fluctuations in URu_2Si_2[1] , PETER RISEBOROUGH, Physics Department, Temple University — It has been proposed that the Hidden Order phase in URu_2Si_2 is a combined spin-orbit density wave, which is stabilized by the effect of the spin-flip part of the inter-orbital Hund's rule exchange. The transition involved the nesting of bands with different orbital characters and results in a partial gapping of the Fermi-surface. Above the transition temperature, the system exhibits combined spin and orbital fluctuations whose lifetimes and amplitudes increase as the temperature is reduced towards the critical temperature. These fluctuations produces hot-spots on the Fermi-surface, modifies the electronic structures as precursor to the opening of the gap. We examine the dependence of precritical fluctuations on the transition temperature. As the critical temperature is reduced to zero, it is found that the nature of the transition changes from second-order to first-order.

11:27AM G19.00002 Charge-$2e$ Skyrmion condensate in a hidden order state[1] , CHEN-HSUAN HSU, SUDIP CHAKRAVARTY, University of California, Los Angeles — A higher angular momentum ($l = 2$) d-density wave, a mixed triplet and a singlet, interestingly, admits skyrmionic textures. The Skyrmions carry charge $2e$ and can condense into a spin-singlet s-wave superconducting state. In addition, a charge current can be induced by a time-dependent inhomogeneous spin texture, leading to quantized charge pumping. The quantum phase transition between this mixed triplet d-density wave and skyrmionic superconducting condensate likely leads to deconfined quantum critical points. We suggest connections of this exotic state to electronic materials that are strongly correlated, such as the heavy fermion URu_2Si_2. At the very least, we provide a concrete example in which topological order and broken symmetry are intertwined, which can give rise to non-BCS superconductivity.

11:39AM G19.00003 Evidence for an orbital moment in the superconducting state of URu_2Si_2[1] , GANG LI, QIU ZHANG, DANIEL RHODES, BIN ZHENG, PALLAB GOSWAMI, National High Magnetic Field Lab, P. TOBASH, FILIP RONNING, JOE D. THOMPSON, ERIC D. BAUER, Los Alamos National Lab, LUIS BALICAS, National High Magnetic Field Lab — URu_2Si_2 was suggested to be a chiral d-wave superconductor with a $k_z(k_x \pm ik_y)$ orbital component for the Cooper pair wave-function. This state breaks time-reversal symmetry due to the orbital moment associated with this pair wave-function. Here, we report torque magnetometry in URu_2Si_2 at high fields and very low temperatures revealing a change in the sign of the magnetic hysteresis for $H \rightarrow H_{c2}$, and for angles 15° away from the *ab*-plane, i.e. from a clear diamagnetic response dominated by the pinning of vortices to a state with a much smaller but paramagnetic-like hysteretic response which *disappears* at H_{c2}. If diamagnetism results from screening super-currents, we conclude that this hysteretic paramagnetic response must result from super-currents circulating in the opposite sense which generate an effective moment as expected for a chiral superconductor.

[1]Supported by DOE-BES through award DE-SC0002613.

11:51AM G19.00004 Global k-space perspective of temperature-dependent U f-states in URu_2Si_2[1] , J.D. DENLINGER, Lawrence Berkeley National Lab, L. DUDY, U. Wuerzburg, Germany, J.-S. KANG, Catholic U. of Korea, J.W. ALLEN, U. of Michigan, N.P. BUTCH, U. of Maryland, M.B. MAPLE, UC San Diego — In recent years, high-resolution angle-resolved photoemission (ARPES) measurements [1] have identified a narrow band of f-states close to the Fermi level in URu_2Si_2 whose temperature dependent spectral weight and/or energy shifts correlate to the hidden order transition at 17.5K. These f-states have been observed close to normal emission at a few select photon energies of $\sim$ 6, 21 and 30 eV corresponding to momentum space locations close to Z, Γ and Z points respectively. We attempt to provide a more global k-space context for the presence of such f-states and their relation to the bulk Fermi surface topology using synchrotron-based wide-angle and photon energy-dependent ARPES mapping of the electronic structure. In addition, x-ray polarization and small-spot spatial dependences are exploited to assist identification of these narrow-band f-states and their relation to specific U- or Si-terminations of the cleaved surface.

[1]Supported by U.S. DOE at the Advanced Light Source (DE-AC02-05CH11231), at UM (DE-FG02-07ER46379) and UCSD (FG02-04ER46105 & FG02-04ER46178), and by NSF at UCSD (DMR08-02478).

12:03PM G19.00005 Formation of coherent heavy fermion states at the hidden order transition in URu_2Si_2, as seen by ARPES , SHOUVIK CHATTERJEE, Cornell University, JAN TRINCKAUF, TORBEN HANKE, Leibnitz Institute for Solid State and Materials Research, IFW Dresden, DANIEL SHAI, JOHN HARTER, Cornell University, TRAVIS WILLIAMS, GRAEME LUKE, McMaster University, JOCHEN GECK, Leibnitz Institute for Solid State and Materials Research, IFW Dresden, KYLE SHEN, Cornell University — We present high-resolution angle-resolved photoemission (ARPES) spectra that allow us to delineate the evolution of the low energy electronic structure of the heavy-fermion superconductor URu_2Si_2 across the hidden order (HO) transition. By employing a range of excitation photon energies, we are able to disentangle various features in the electronic structure which, to date, have not been clearly identified. In contrast to the conventional Kondo lattice scenario, we find that precisely at T_{HO}, the low energy electronic structure changes due to hybridization from incoherent and localized f states to a coherent heavy fermion liquid. We also observe a sharp drop in the scattering rate upon cooling through T_{HO}, suggesting that the large scattering rate is caused by fluctuations in the order parameter. Our findings place clear constraints on the possible theoretical models for the HO state while clarifying a few of the apparently inconsistent observations of the previous ARPES measurements.

12:15PM G19.00006 Heavy fermion phases probed by temperature dependent tunneling spectroscopy , ANA MALDONADO, Laboratorio de Bajas Temperaturas, Departamento de Fisica de la Materia Condensada, Universidad Autonoma de Madrid, 28049 Madrid, Spain, ISABEL GUILLAMÓN, H. H. Wills Physics Laboratory, University of Bristol, Tyndall Avenue, Bristol BS8 1TL, UK, JOSE GABRIEL RODRIGO, HERMANN SUDEROW, SEBASTIÁN VIEIRA, Laboratorio de Bajas Temperaturas, Departamento de Fisica de la Materia Condensada, Universidad Autonoma de Madrid, 28049 Madrid, Spain, DAI AOKI, JACQUES FLOUQUET, INAC, SPSMS, CEA Grenoble, 38054 Grenoble, France — Heavy fermions offer a rich physical phenomenology at very low temperatures, exhibiting different phase transitions on cooling that determine their electronic properties. Their ground states cover many electronic interactions, such as Kondo effect, superconducting or long range magnetic ones and, eventually, their coexistence. Thus, exploring the local electronic properties of these systems using scanning tunneling microscopy/spectroscopy (STM/S) at different temperatures is essential. In this communication, tunneling spectroscopy measurements using a superconducting tip of Al in the superconducting phase of URu_2Si_2[1] and using one of Au in the paramagnetic and antiferromagnetic phases of, respectively, $CeRu_2Si_2$ and $CeRh_2Si_2$[2] will be discussed. The features found in the tunneling spectroscopy of each compound at 0.15K and their respective thermal evolution reflect the formation of different electronic ground states.

12:27PM G19.00007 From hidden order to magnetic order: Optical conductivity reveals new behavior in URu_2Si_2[1] , JESSE HALL, McMaster University, NORAVEE KANCHANAVATEE, MARC JANOSCHEK, KEVIN HUANG, University of California, San Diego, NICHOLAS BUTCH, Lawrence Livermore National Lab, BRIAN MAPLE, University of California, San Diego, THOMAS TIMUSK, McMaster University — As a new generation of experimental techniques is brought to bear against the heavy-Fermion compound URu_2Si_2, striking new details about the electronic structure changes at the mysterious hidden order (HO) transition are becoming clear. Far infrared optical conductivity measurements were performed on oriented samples of URu_2Si_2 doped with both Fe and Re. While Re-doping pushes the material towards ferromagnetism, Fe-doping substitutes for hydrostatic pressure and enhances the temperature of the HO transition slightly before pushing the material into antiferromagnetism. Optical conductivity measurements have revealed new information about the charge dynamics at the transition, and how these evolve with doping. Both the structure and energy of the gap are altered as the material is pushed towards magnetic ordering. Comparison is made between the gap seen in optical conductivity and the charge gaps seen in scanning tunneling spectroscopy and ARPES, as well as the gaps in the magnetic excitation spectrum seen in neutron scattering.

12:39PM G19.00008 NMR Evidence for psuedogap in URu_2Si_2[1] , KENT SHIRER, ADAM DIOGUARDI, JOHN CROCKER, NICHOLAS APROBERTS-WARREN, ABIGAIL SHOCKLEY, CHING LIN, DAVID NISSON, University of California - Davis, JASON COOLEY, Los Alamos National Laboratory, BRIAN MAPLE, University of California - San Diego, JASON HARALDSEN, MATTHIAS GRAF, Los Alamos National Laboratory, NICHOLAS CURRO, University of California - Davis — We report ^{29}Si NMR measurements in single crystals and aligned powders of URu_2Si_2 in the hidden order and paramagnetic phases. In the paramagnetic phase, the spin lattice relaxation data reveal evidence of spin fluctuations of U moments. Furthermore, we find evidence for partial suppression of density of states below 30 K.

[1]Work at UC Davis was supported by UCOP-TR01, the NNSA under the SSAA program through DOE Research Grant #DOE DE-FG52-09NA29464, and the NSF under Grant No. DMR-1005393.

12:51PM G19.00009 Spin Correlations in the Different Phases of URu_2Si_2 , TRAVIS J. WILLIAMS, McMaster University, H. BARATH, Johns Hopkins University, Z. YAMANI, Canadian Neutron Beam Centre, NRC Chalk River, J.A. RODRIGUEZ-RIVERA, J.B. LEAO, NIST Center for Neutron Research, J.D. GARRETT, G.M. LUKE, McMaster University, W.J.L. BUYERS, Canadian Neutron Beam Centre, NRC Chalk River, C. BROHOLM, NIST Center for Neutron Research — We report a neutron scattering study of the magnetic excitation spectrum in three temperature and pressure driven phases of URu_2Si_2: the paramagnetic, 'hidden order' and antiferromagnetic phases. The experiment was conducted using the novel neutron scattering spectrometer MACS at the NIST Center for Neutron Research[1]. Wide-angle detector coverage offers comprehensive scattering data covering an entire plane in momentum space with excellent energy resolution. The ambient pressure data show a magnetic excitation spectrum characteristic of Fermi surface nesting in the paramagnetic phase and the development of a gap in the excitation spectrum upon cooling through the $T_C = 17.5$ K phase transition. The efficiency of MACS allowed a comprehensive data set in the high-pressure phase. Throughout the (H0L) scattering plane we find qualitatively similar excitations as in the hidden order phase though with a substantial reduction in the overall spectral weight and an upward shift in energy. These data should allow a critical evaluation of recent theoretical work to understand the small and large moment phases of URu_2Si_2. [1] J.A. Rodriguez-Rivera, Meas. Sci. Technol. 19, 034023 (2008).

1:03PM G19.00010 Phonon Behavior in the Hidden Order state of the Heavy Fermion Superconductor URu_2Si_2 , DILLON GARDNER, CRAIG BONNOIT, Massachuesetts Institute of Technology, TRAVIS WILLIAMS, GRAEME LUKE, McMaster University, YOUNG LEE, Massachusetts Institute of Technology — The heavy fermion compound URu_2Si_2 has generated much interest after the initial discovery of coexisting superconductivity and magnetism. Subsequent measurements revealed a phase transition at T=17.5 K into what is referred to as the "hidden order" state. The order parameter of this state remains unknown. Anomalous behavior in both the lattice component of thermal conductivity and thermal expansion parameters suggest that the phonons may also exhibit anomalous behavior that can shed light on the nature of the Hidden Order. We present inelastic X ray scattering measurements of lattice dynamics in both the hidden order phase and high temperature phase.

1:15PM G19.00011 Anisotropic phonon softening in URu_2Si_2 , NICHOLAS BUTCH, MICHAEL MANLEY[1], JASON JEFFRIES, Lawrence Livermore National Laboratory, MARC JANOSCHEK[2], KEVIN HUANG, BRIAN MAPLE, UC San Diego, JEFFREY LYNN, NIST Center for Neutron Research — We studied the low-energy phonons of URu_2Si_2 via inelastic neutron scattering. At the wave-vectors associated with magnetic excitations, the phonons show surprisingly little modification. However, we find important temperature and direction dependence of the phonons in the basal plane. Possible ramifications for the symmetry of the hidden order will be discussed.

[2]current address: Los Alamos National Laboratory

1:27PM G19.00012 High-magnetic field magnetostriction and thermal expansion in URu_2Si_2 , V.F. CORREA, CAB-CNEA, Bariloche, Río Negro, Argentina, S. FRANCOUAL, M. JAIME, N. HARRISON, A. LACERDA, MPA-CMMS, LANL, Los Alamos, New Mexico 87545, USA, T.P. MURPHY, E.C. PALM, S.W. TOZER, NHMFL, FSU, Tallahassee, Florida 32310, USA, P.A. SHARMA, MPA-CMMS, LANL, Los Alamos, New Mexico 87545, USA, J.A. MYDOSH, Kamerlingh Onnes Laboratory, Leiden University, NL-2300 RA Leiden, The Netherlands — We report high magnetic field (up to $\mu_0 H = 45$ T) c-axis thermal expansion and magnetostriction experiments on URu_2Si_2 single crystals. The sample length change $\Delta L_c(T_{HO})/L_c$ associated with the transition to the "hidden order" phase becomes increasingly discontinous as the magnetic field is raised above 25 T. The re-entrant ordered phase III is clearly observed in both the thermal expansion $\Delta L_c(T)/L_c$ and magnetostriction $\Delta L_c(B)/L_c$ above 36 T, in good agreement with previous results. The sample length is also discontinous at the boundaries of this phase, mainly at the upper boundary. A change in the sign of the coefficient of thermal-expansion is observed at the metamagnetic transition (B_M ? 38 T) which is likely related to the existence of a quantum critical end point. See V.F. Correa et al., Phys. Rev. Lett. (in the press).

1:39PM G19.00013 Revealing the electronic structure of USb_2 using femtosecond optical pulses , JINGBO QI, TOMASZ DURAKIEWICZ, E. BAUER, R. BAUMBACH, K. GOFRYK, Los Alamos National Laboratory, T. KLIMCZUK, ITU Karlsruhe, P. RISEBOROUGH, Temple University, ANTOINETTE TAYLOR, ROHIT PRASANKUMAR, Los Alamos National Laboratory — USb_2 is a very interesting moderately heavy system, as it displays dispersive 5f bands as well as the first example of a clear kink structure in f-electron systems. This material also exhibits a renormalized zone-centered hole-like band, driven by boson-mediated interband scattering processes. Employing ultrafast optical spectroscopy, we explored the nature of the boson participating in this band renormalization, and explicitly characterized the gap structures near the Fermi surface in USb_2 for the first time. Our results reveal new physical properties of this material, which have not previously been unveiled by other experimental methods.

1:51PM G19.00014 Non-Fermi vs. Inhomogeneous-Fermi Liquid behaviour in UCu_4Ni in the context of the Kondo Disorder Model[1] , ARIANA VALDEZ[2], OSCAR BERNAL, Department of Physics and Astronomy, California State University, Los Angeles, CA 90032, G.R. STEWART, J.S. KIM, Department of Physics, University of Florida, Gainsville FL 32611 — UCu_4Ni is a site-disordered material with diverging thermodynamic and anomalous transport properties. Local nuclear magnetic resonance (NMR) experiments in combination with bulk magnetic susceptibility χ measurements performed on the same samples indicate that the low-temperature divergence of χ might be due in part to the presence of paramagnetic impurities. In this contribution, we describe the magnetization in terms of a Kondo disorder model and extract a set of parameters of the distribution of Kondo temperatures, which indicate that the low temperature side of the distribution does not have sufficient area to accommodate a non-Fermi liquid divergence. We use the same parameters to subsequently calculate the specific heat C and to extrapolate to low temperatures, which allows us to compare with the known divergence of the magnetic contribution to C/T below 10 K. We discuss to what extent the physics of this material is that of a non-Fermi liquid as opposed to an inhomogeneous Fermi fluid.

2:03PM G19.00015 The Effects of Grinding on the Magnetic Susceptibility of $UCu_{3.95}Ni_{1.05}$, CARLOS SANCHEZ, CARMEN QUEN, EDITH SOTO, OSCAR BERNAL[1], Physics and Astronomy Department, California State University, Los Angeles, CA, G.R. STEWART, Physics Department, University of Florida, Gainesville, FL — The effects of grinding on the magnetic susceptibility of $UCu_{3.95}Ni_{1.05}$ were studied in order to understand magnetization measurements in this material. Substantial information was recovered from these experiments, which were done at temperatures ranging from 3K to 300K and magnetic fields from 500 Oe to 4.75 kOe. For instance, a new and unexpected ferromagnetic (FM) phase transition was found at about 150 K in both ingot and powder samples. Similarly the magnetic properties of the powder seem to differ slightly from the ingot's. The powder's magnetic susceptibility $\chi_{\rm pwd}$ appears greater than the ingot's $\chi_{\rm ing}$ at all temperatures measured, with the difference $\Delta\chi = \chi_{\rm pwd} - \chi_{\rm ing}$ increasing with decreasing temperature. We analyze the observed $\Delta\chi$ in terms of two potential sources: impurities added to the powder during the grinding process and the effects of sample geometries in combination with the presence of a second (FM) phase in the studied material. We discuss how the measured differences might affect the study of the physics of this non-Fermi liquid/quantum critical compound.

11:15AM G20.00001 Rare earth doped upconverting particles for different photonic applications[1] , MADHAB POKHREL, AJITH KUMAR GANGADHARAN, DHIRAJ KUMAR SARDAR, University of Texas at San Antonio — Trivalent rare earth ions especially erbium (Er^{3+}) and ytterbium (Yb^{3+}) co-doped in various host nanoparticles are known for their extraordinary spectroscopic properties. A thorough optical characterization including the absolute upconversion quantum yield (QY) measurement is of critical importance in evaluating their potential for various photonic applications. In this paper, we will be presenting a measured absolute upconversion QYs for Yb^{3+} and Er^{3+} doped in La_2O_2S under 980 and 1550 nm excitation at various power densities. Comparison of absolute QYs for different concentrations of Yb^{3+} and Er^{3+} doped in La_2O_2S will be made for all the upconversion emissions with respect to reported most efficient upconverting phosphor $NaYF_4$ doped with 20% Yb^{3+} and 2% Er^{3+}. Furthermore, applications of these phosphors in different areas such as bio-imaging, solar cell, security, etc. will be explored depending on the measured absolute upconversion quantum yields. In addition, preliminary results on in vitro imaging using upconverting nanoparticles as a contrast agent will be reported.

11:27AM G20.00002 Characterization and light emission from Erbium Oxide Nanoparticles , MUHAMMAD MAQBOOL, LYNDA WILKINSON, Ball State University, IFTIKHAR AHMAD, University of Malakand — The present work reports light emission from Erbium Oxide nanoparticles. The nanoparticles, with 43 nm diameter, were obtained in the form of nanopowder with 99.9% purity. These nanoparticles were characterized for their light emission under a 532 nm Nd:YAG laser excitation. A Photoluminescence (PL) system was used to detect fluorescence emission from the nanoparticles. The PL system consisted of Pixis brand CCD camera with a range of 300 to 2000 nm. The Erbium Oxide nanoparticles were also mixed in distilled water to obtain spectrum. Two emission peaks were observed at 554 nm and 813 nm. The green emission at 554nm was obtained as a result of $^4I_{15/2} \rightarrow {}^4S_{3/2}$ transition, and the near infrared emission from $^4I_{15/2} \rightarrow {}^4I_{13/2}$ transition. The process was also repeated in vacuum and it was found that the green emission enhances tremendously when the nanoparticles are excited in vacuum. This enhanced luminescence from the Erbium Oxide nanoparticles shows their potential importance in the optical devices and Biomedical applications.

11:39AM G20.00003 The Vibrational and Photoluminescence Properties of TiO_2 Nanoparticles Reacted with Eu^{3+} Ions under Hydrothermal Conditions , L. FARRIS, H. YAN, P. MCCART, R. MAYANOVIC, Missouri State University, MISSOURI STATE UNIVERSITY TEAM — TiO_2 has been shown to be an effective material for environmental purification and photocatalysis. The catalytic activity of TiO_2 nanoparticles (NPs) is enhanced due to the increase in the ratio of surface area to volume at the nano-scale. The enhancement of catalytic activity is further increased by the modification of the surface due to the adsorption of transition-metal ions on TiO_2 NPs. The reactivity of Eu^{3+} ions with anatase TiO_2 nanoparticles under various pH and pressure-temperature (P-T) conditions in aqueous fluids has been investigated. A hydrothermal reactor was used to modify the surface of the TiO_2 nanoparticles with Eu^{3+} ions in aqueous fluids at high P-T conditions. The Eu-reacted and untreated TiO_2 NPs were examined using XRD, SEM, and Raman and photoluminescence spectroscopy. The modifications of the vibrational and photoluminescence properties of the TiO_2 NPs due to the surface-adsorption of Eu^{3+} ions are discussed.

11:51AM G20.00004 Optical Spectroscopy of Single Gold Nanoparticles , MICHEL ORRIT, Leiden University — Compared to electron microscopy or to scanning probe microscopy, the optical selection of individual nanoparticles in a far-field microscope provides non-invasive probing of deep layers and commands a wide range of time-resolved and frequency-resolved techniques. Optical signals provide unique insights into the dynamics of nano-objects and of their surroundings [1]. I shall illustrate applications of single-nanoparticle optics with recent topics from our group. i) We study single gold nanoparticles by photothermal and pump-probe microscopy [2]. These experiments can be done in an optical trap, where a single nanorod orients along the trapping polarization, and studied the acoustic damping of gold nanoparticles. ii) Photothermal microscopy opens the study of non-fluorescent absorbers, down to single-molecule sensitivity [3]. Combining photothermal contrast with photoluminescence, we can measure the luminescence quantum yield on a single-particle basis. Moreover, the high signal-to-noise ratio opens up uses of individual gold nanoparticles for local plasmonic and chemical probing, down to single-protein level [4]. iii) Gold nanorods generate strong field enhancements near their tips. By matching the rod's aspect ratio to a dye's fluorescence and excitation spectra, we could observe thousand-fold enhancements for the fluorescence of single Crystal Violet molecules [5]. Gold nanorods can produce local fields as high as those of bow-tie antennas, thanks to their narrow plasmon resonance, but they are much easier to synthesize, functionalize and disperse in solution than lithographically made nanostructures. 12:27PM G20.00005 Physical property control of nanoparticles for effective light-energy use , SUNGSOOK AHN, SUNG YONG JUNG, SANG JOON LEE, Pohang University of Science and Technology (POSTECH), POSTECH TEAM — Up-to-now only limited materials are useful for solar energy harvesting, which makes the expansion of available photoactive materials important. In this point of view, physical property control is one of the reasonable solutions rather than creation of new materials. In this study, as a representative light-responsive metal nanoparticle (NP), gold NPs of a fixed size (average diameter of 20 nm) are surface-activated in pH-controlled aqueous solutions or chemically cross-linked, followed by electron-beam treatment. Chemical-interlinking of NPs behaves like a polymerization, generating characteristic structures (Fractal dimension). The absorbance at UV-vis and THz regions are significantly modified depending on the surface-modification and controlled cluster structures of NPs. Electron beams of different doses are applied to change the surface energy of NPs forming a specific surface layer (proximity length) and the structural modification of NP clusters. This changes the absorption energy band toward shorter-wavelength UV-vis light, benefiting solar energy harvesting. This study contributes to fundamental understanding on nanoparticle technology and provides general information for new metamaterial design for effective light energy use.

12:39PM G20.00006 Size and shape dependence of electronic and optical excitations in TiO_2 nanocrystals[1] , KOPINJOL BAISHYA, SERDAR OGUT, University of Illinois at Chicago — We present results for the electronic structures, quasi-particle gaps, and the absorption spectra of TiO_2 nanocrystals of both rutile and anatase phases with various shapes, sizes, and surfaces exposed. We study the size and shape dependences of these electronic and optical properties, computed both within time-dependent density functional theory and many-body perturbation methods such as the GW-BSE, using appropriately passivated nanocrystals to mimic bulk termination. Surface effects are examined by using nanocrystals of various sizes with particular surfaces, such as (110) in rutile and (101) in anatase phases, exposed. We interpret the resulting optical absorption spectra of these nanocrystals in terms of the bulk spectra and compare them with predictions from classical Mie-Gans theory.

12:51PM G20.00007 Pattern curvature to control pore shape and its ordering , GUIDUK YU, KYUSOON SHIN, Seoul National University — Triangular pore in inverse-hexagonal packing was fabricated by anodizing Al with convex pattern in hexagonal packing. The convexly patterned Al was prepared *via* replication of the concave structure formed in self-assembled anodized aluminum oxide (AAO). Self-assembled AAO without pre-patterning produces hexagonal packing circular pores. Exploitation of the inversed structure was found to create well-defined triangular pores in inverse-hexagonal packing. Anisotropic pore feature was discussed to come from the alternating distance between the pits and the curvature of the pattern. Also, by controlling the topography of the convex pattern around pits, we investigated the effect of pattern topography on pore initiation.

1:03PM G20.00008 Patterning of GaAs and Si substrates using self-organized Al_2O_3 templates and epitaxial growth of GaAs nanostructures , ARCHANA KUMARI, JOHN HATCH, JAESUK KWON, XIN ZHANG, EVERETT FRASER[1], CHAE HYUN KIM, HAO ZENG, HONG LUO, University at Buffalo, The State University of New York — Reactive ion etching is used with Al_2O_3 templates to pattern SiO_2 films deposited on GaAs and Si substrates. The technique allows nanopatterning of substrates without photo or e-beam lithography. The SiO_2 film pattern consists of holes of about 80 nm diameter with a pitch of about 100 nm. GaAs nanostructures are grown on the patterned substrates by molecular beam epitaxy. The observed arrays of nanostructures closely follow the patterns on SiO_2. Several types of structures are observed depending on the growth conditions, including pillars with flat hexagonal tops and pyramidal triangular tops. Characterization of the structures will be discussed. This work was supported by NSF DMR1006286.

1:15PM G20.00009 Nanostructures Using Anodic Aluminum Oxide[1] , ILYA VALMIANSKI, CARLOS M. MONTON, JUAN PEREIRO, ALI C. BASARAN, IVAN K. SCHULLER, Center for Advanced Nanoscience, Department of Physics, University of California, San Diego — We present two fabrication methods for asymmetric mesoscopic dot arrays over macroscopic areas using anodic aluminum oxide templates. In the first approach, metal is deposited at 45^o to the template axis to partially close the pores and produce an elliptical shadow-mask. In the second approach, now underway, nanoimprint lithography on a polymer intermediary layer is followed by reactive ion etching to generate asymmetric pore seeds. Both these techniques are quantified by an analysis of the lateral morphology and lattice of the pores or dots using scanning electron microscopy and a newly developed MATLAB based code (available for free download at http://ischuller.ucsd.edu). The code automatically provides a segmentation of the measured area and the statistics of morphological properties such as area, diameter, and eccentricity, as well as the lattice properties such as number of nearest neighbors, and unbiased angular and radial two point correlation functions. Furthermore, novel user defined statistics can be easily obtained. We will additionally present several applications of these methods to superconducting, ferromagnetic, and organic nanostructures.

1:27PM G20.00010 Spectroscopic ellipsometric studies of randomly distributed plasmonic Gallium nanoparticles , YANG YANG, Physics Dept, Duke, TONG-HO KIM, ECE Dept, Duke, NESET AKOZBEK, AEgis Technologies, APRIL BROWN, ECE Dept, Duke, HENRY EVERITT, Physics/ECE, Duke; Bowden Laboratory, Army Aviation and Missile RD&E Center — Ultraviolet surfaced-enhanced Raman scattering (UV-SERS) was recently observed using randomly distributed Gallium nanoparticles (Ga NPs) deposited on sapphire by molecular beam expitaxy at room temperature. Atomic force and scanning electron microscopies revealed that the radii of the hemispheroid NPs follow unimodal or bimodal pseudo Gaussian distributions whose mean diameters increase with increasing Ga dosage (i.e. growth time). Variable angle spectroscopic ellipsometric measurements were then performed on Ga NP ensembles to explore the correlation between the polarimetric optical response and the local morphology. An effective medium composed of single or double Lorentzian oscillators was found to reproduce the optical response of Ga NP ensembles with resonance frequencies that decrease monotonically with increasing NP size. In addition, a strong depolarization response was observed for near-normal incidence. Interestingly, the sample for which the depolarization peak was closest to the 325nm laser excitation wavelength was the sample with the highest SERS enhancement factor.

1:39PM G20.00011 Optical Properties of Focused Ion Beam-Induced Plasmonic Ga Nanoparticle Arrays on Compound Semiconductor Surfaces[1] , MYUNGKOO KANG, JIA-HUNG WU, TIMOTHY SAUCER, ALI AL-HEJI, JIEUN LEE, VANESSA SIH, RACHEL GOLDMAN, University of Michigan — Recently, metallic nanoparticles (NPs) on semiconductor surfaces have enabled the generation of surface plasmon resonances (SPR) which are promising for enhanced light emission, highly-efficient solar cell, ultra-sensitive biosensors, and negative refractive index metamaterials. Ion sputtering-induced surface pattern formation has the potential to become a cost-effective method for achieving metallic NP arrays. Here, we report optical properties of focused ion beam (FIB)-induced plasmonic Ga NP arrays on compound semiconductor surfaces. To date, we have examined SPR energy of FIB-induced Ga NP arrays. The SPR energies increase with decreasing NP or chain diameter, due to particle diameter-dependent dipole interactions within the metallic NPs. We have utilized SPR of FIB-induced Ga NPs for the enhancement of GaAs photoluminescence (PL) efficiency. The maximum PL enhancement occurs for the Ga NP diameter predicted to exhibit a SPR energy corresponding to the GaAs donor-acceptor pair emission energy. When the SPR energy matches the energy of the free carriers in GaAs, it is transferred to the Ga NPs, inducing an enhancement of the spontaneous emission rate. These results suggest that FIB-induced Ga NPs can be a promising alternative plasmonic material.

1:51PM G20.00012 Engineering structured light with Vogel spiral arrays of nanoparticles , NATE LAWRENCE, Department of Electrical Engineering, Boston University, JACOB TREVINO, Division of Material Science, Boston University, LUCA DAL NEGRO, Department of Electrical Engineering, Boston University — We present a general analytical model for light scattering by arbitrary Vogel spiral arrays of circular apertures uniformly illuminated at normal incidence. This model suffices to unveil the fundamental mathematical structure of their complex Fraunhofer diffraction patterns and enables the engineering of optical beams carrying multiple values of orbital angular momentum (OAM). By performing analytical Fourier-Hankel decomposition of spiral arrays and far field patterns, we rigorously demonstrate the ability to encode specific numerical sequences onto the OAM values of diffracted optical beams. In particular, we show that these OAM values are determined by the rational approximations of the continued fraction expansions of the irrational angles utilized to generate Vogel spirals. Finally, we experimentally demonstrate structured light carrying multiple values of OAM in the far-field scattering region of Vogel spiral arrays of metallic nanoparticles. Using Fourier-Hankel mode decomposition analysis and interferometric reconstruction of the complex amplitude of scattered waves, we show the ability to encode well-defined numerical sequences, determined by the aperiodic spiral geometry, into azimuthal OAM values, in excellent agreement with analytical scattering theory. The generation of sequences of OAM values by light scattering from engineered aperiodic surfaces is relevant to a number of device applications for secure optical communication, classical and quantum cryptography.

2:03PM G20.00013 Bandgap analysis and emission enhancement from Aperiodic Vogel Spiral Arrays of dielectric nanopillars , JACOB TREVINO, Division of Materials Science and Engineering, Boston University, GARY WALSH, LUCA DAL NEGRO, Department of Electrical and Computer Engineering, Boston University — We report on an experimental and theoretical investigation of the structural and photonic mode properties of Vogel spiral arrays of dielectric cylinders in air. We have designed and fabricated hydrogenated amorphous silicon (aSi:H) golden angle spiral nanopillar arrays with localized bandedge modes at the emission wavelength of a commercial near-infrared (NIR) laser dye. Variable-angle reflectance measurements are utilized to experimentally investigate the photon dispersion diagram of spiral arrays and to locate photonic bandgaps. Experimental results are found to be in good agreement with rigorous coupled-wave analysis (RCWA) calculations. These findings offer the opportunity to create novel photonic devices that leverage radially localized and isotropic bandedge modes to enhance light-matter coupling, such as optical sensors, light sources, concentrators, and broadband optical couplers.

Session G21 DMP: Focus Session: Theories of Electric, Elastic, Magnetic and Cross-coupling Terms in Ferroic Lattices 323 - Philippe Ghosez, Universite de Liege

11:15AM G21.00001 Converse Piezoelectricity , MICHAEL SPRINGBORG, University of Saarland, BERNARD KIRTMAN, University of California, Santa Barbara — Piezoelectricity results from a coupling between responses to mechanical and electric perturbations and leads to changes in the polarization due to strain or stress or, alternatively, the occurrence of strain as a function of an applied external, electrostatic field (i.e., converse piezoelectricity). Theoretical studies of those properties for extended systems require accordingly that their dipole moment or polarization can be calculated. However, whereas the definition of the operator for the dipole moment for any finite system is trivial, it is only within the last 2 decades that the expressions for the equivalent operator in the independent-particle approximation for the infinite and periodic system have been presented. Here, we demonstrate that the so called branch dependence of the polarization for the infinite, periodic system is related to physical observables in contrast to what often is assumed. This is related to the finding that converse piezoelectric properties depend both on the surfaces of the samples of interest even for samples with size well above the thermodynamic limit. However, we shall demonstrate that these properties can be calculated without explicitly taking the surfaces into account. Both the foundations and results for real system shall be presented.

11:27AM G21.00002 Are Polarization and Magnetization really Bulk Properties?[1] , RAFFAELLO BIANCO, RAFFAELE RESTA, Physics Dept., U. Trieste — Microscopic understanding of P and of (orbital) M was achieved only recently; the modern theories express both as BZ integrals. Since k-space is an artificial construct, all bulk properties must be embedded in the ground state density matrix $\rho(\mathbf{r},\mathbf{r}')$, "nearsighted" in insulators, independently of the boundary conditions, either periodic (PBCs) or open (OBCs). A basic tenet of the modern theory is that the bulk electron distribution determines P only modulo a "quantum": therefore P is not independent of the boundaries. Instead M is not affected by any quantum indeterminacy and an expression in terms of the bulk ρ is not ruled out: we explicitly find such expression. In a finite homogeneous sample, within OBCs, the macroscopic magnetization is cast as a function of the bulk $\rho(\mathbf{r},\mathbf{r}')$. Remarkably, our approach applies even to topological (Chern) insulators, where M explicitly depends on the chemical potential. The boundary currents contribute to M, but even their contribution is "bulk" in the above sense; the value of M is robust and cannot be altered by acting on the boundaries only. Instead, P can be varied (by a quantum) by acting on the boundaries only. Simulations performed on a 2d model Hamiltonian within OBCs demonstrate our approach.

11:39AM G21.00003 Noncollinear magnetism and single-ion anisotropy in multiferroic perovskites , ERIC BOUSQUET, University of Liège, CARLO WEINGART, NICOLA SPALDIN, ETH Zurich — The link between the crystal distortions of the perovskite structure and the magnetic exchange interaction (J), the single-ion anisotropy (SIA), and the Dzyaloshinsky-Moriya (DM) interaction are investigated by means of density-functional calculations in $AFeO_3$ systems. We explore the effect of the crystal distortions (Antiferrodistortive-AFD and Ferroelectric) as well as the effect of the A-cation chemistry on the 3 magnetic properties, J, SIA and DM. Our analysis shows a never explored but possible switching of the weak ferromagnetism in the $R3c$ phase of $BiFeO_3$ through the competition of the SIA shapes induced by the AFD and the ferroelectric distortions. We also found that-in spite of the d^5 electronic configuration of Fe^{3+}, the SIA is very large in some structures and is surprisingly strongly sensitive to the chemistry of the A-site cation of the ABO_3 perovskite. To clarify the origin of this unexpected effect, we analyze the crystal field splitting by means of Wannier functions.

11:51AM G21.00004 First-principles theory of flexoelectricity , DAVID VANDERBILT, Rutgers University — Flexoelectricity is the linear response of polarization to a strain gradient. Because strain gradients break inversion symmetry, flexoelectricity occurs in all insulating crystals. The flexoelectric effect is negligible on conventional length scales, but it can become very strong at the nanoscale where large strain gradients can significantly affect the functional properties of dielectric thin films and superlattices. Previous theories have tended to focus either on the lattice [1-3] or the electronic (i.e., frozen-ion) [4-5] contribution, and have involved some approximations or limitations. Here we develop a general first-principles theory of the flexoelectric tensor, formulated in such a way that the tensor elements can be computed directly in the context of density-functional calculations. Special attention will be paid to several subtleties, including surface contributions, pseudopotential dependence, the calculation of transverse components, fixed E vs. fixed D boundary conditions, and a degree of non-uniqueness that is present for some strain gradients. We introduce several practical supercell-based methods for calculating the flexoelectric coefficients from first principles, and demonstrate them by computing the coefficients for a variety of insulating materials.(Work done in collaboration with Jiawang Hong. Supported by ONR N00014-12-1-1035.)

12:27PM G21.00005 First-principles calculations of flexoelectric coefficients , JIAWANG HONG, DAVID VANDERBILT, Rutgers University — Flexoelectricity, which is the linear response of polarization to a strain gradient, can have a significant effect on the functional properties of dielectric thin films, superlattices and nanostructures. Despite growing experimental interest, there have been relatively few theoretical studies of flexoelectricity, especially in the context of first-principles calculations. In this talk, we present a complete theory of both the electronic (or "frozen-ion")[1] and lattice contributions to flexoelectricity, and demonstrate a supercell method for calculating the flexoelectric coefficients using first-principles density-functional methods. Results are presented for cubic materials including CsCl and $SrTiO_3$. In order to obtain all the elements of the flexoelectric tensor, transverse as well as longitudinal, we carry out calculations on supercells extended along different orientations (e.g., [110] as well as [100]), taking special care to carry out conversions between objects calculated under fixed E or fixed D electric boundary conditions in different parts of the procedure. In this way, all the elements of both the electronic and lattice contributions to the flexoelectric tensor are determined.

[1]J. Hong and D. Vanderbilt, Phys. Rev. B, **84** 180101(R) (2011).

12:39PM G21.00006 Linear Magnetoelectric Effect by Orbital Magnetism , ANDREA SCARAMUCCI, Materials Theory, ETH Zurich, ERIC BOUSQUET, Institut de Physique, Université de Liège, MICHAEL FECHNER, Materials Theory, ETH Zurich, MAXIM MOSTOVOY, Zernike Institute for Advanced Materials, University of Groningen, NICOLA SPALDIN, Materials Theory, ETH Zurich — The linear magnetoelectric effect is the linear induction of a static magnetization (electric polarization) by an applied static electric (magnetic) field. Using symmetry analysis and ab initio calculations we show that, in addition to mechanisms involving magnetic moments of spins, such an effect can originate from the response of orbital magnetic moment to polar distortions induced by an applied electric field. Considering $LiFePO_4$ as model compound, we show that spin-orbit coupling partially lifts the quenching of 3d orbitals and causes small orbital magnetic moments at the magnetic ions sites. An applied electric field modifies the sizes of these orbital magnetic moments and results in a net magnetization. Furthermore, we discuss the link between this mechanism and the electric field dependence of magnetocrystalline anisotropy.

12:51PM G21.00007 Longitudinal magnetoelectric susceptibility of Cr2O3: First-principles calculations using the converse approach , SAI MU, A. L. WYSOCKI, K.D. BELASHCHENKO, Department of Physics and Astronomy, University of Nebraska-Lincoln — Temperature-dependent longitudinal magnetoelectric (ME) susceptibility of Cr2O3 is calculated as a response of the magnetization M to the applied electric field E. The ionic displacements are found using the calculated force constant matrix and Born effective charges. The exchange parameters are calculated using total energy calculations for different spin configurations on the perturbed lattice, and the magnetization is evaluated using the pair cluster approximation to the quantum spin-3/2 Hamiltonian. When similar approximations are used, the results agree with the inverse approach of Mostovoy et al. [Phys. Rev. Lett. 105, 087202 (2010)]. The electronic contribution is found to be approximately 40% of the ionic contribution and opposite in sign to it. The ME susceptibility is found to depend strongly on the choice of the Hubbard U parameter, increasing as U is increased. On the other hand, the ME response is only weakly depressed by the inclusion of intersite spin correlations within the pair cluster approximation. The methodology developed here can facilitate the search for new materials with desirable ME properties.

1:03PM G21.00008 A theoretical study of the dynamical magnetic charge tensor in crystalline Cr_2O_3 , MENG YE, DAVID VANDERBILT, Rutgers University — Magnetoelectric (ME) materials are of fundamental interest and are investigated for their broad potential for technological applications. The search for, and eventually the theoretical design of, materials with large ME couplings present challenging issues. First-principles methods have only recently been developed to calculate the full ME response tensor α including both electronic and ionic (i.e., lattice-mediated) contributions.[1] In several materials, the dominant contribution to the ME response has been shown to be the ionic term $\alpha_{\rm ion}$, which is proportional to both the Born dynamical electric charge $Z^{\rm e}$ and its analogue, the dynamical magnetic charge $Z^{\rm m}$.[2] Here we present a theoretical study whose ultimate goal is to understand the mechanisms that would enhance the magnetic charge $Z^{\rm m}$. Using first-principles density-functional methods within a relativistic framework with the inclusion of the spin-orbit interaction, we calculate the atomic magnetic charge tensors $Z^{\rm m}$ for both Cr and O atoms in Cr_2O_3, and discuss how these contribute to the ME response in this material.

[1]A. Malashevich et al., Phys. Rev. B, **86**, 094430 (2012).
[2]J. Íñiguez, Phys. Rev. Lett. **101**, 117201 (2008).

1:15PM G21.00009 Ferroelectricity induced by interatomic magnetic exchange interaction , CHUNGANG DUAN, Key Laboratory of Polar Materials and Devices, Ministry of Education, East China Normal University, XIANGANG WAN, Department of Physics and National Laboratory of Solid State Microstructures, Nanjing University, Nanjing 210093, China, HANG-CHEN DING, Key Laboratory of Polar Materials and Devices, Ministry of Education, East China Normal University, SERGEY Y. SAVRASOV, Department of Physics, University of California — Multiferroics, where two or more ferroic order parameters coexist, is one of the hottest fields in condensed matter physics and materials science. To search multiferroics, currently most researches are focused on frustrated magnets, which usually have complicated magnetic structure and low magnetic ordering temperature. Here, we argue that actually simple interatomic magnetic exchange interaction already contains a driving force for ferroelectricity, thus providing a new microscopic mechanism for the coexistence and strong coupling between ferroelectricity and magnetism. We demonstrate this mechanism by showing that even the simplest antiferromagnetic (AFM) insulator MnO, can display a magnetically induced ferroelectricity under a biaxial strain.

1:27PM G21.00010 Domain wall fluctuations in ferroelectrics , RICHARD BRIERLEY, University of Cambridge, PETER LITTLEWOOD, Argonne National Laboratory — Ferroelectric domain walls typically have 90- or 180-degree orientations due to the long-range constraints of dipolar and ferroelastic interactions. We calculate the excitation spectrum for deviations from ideal flat walls in these orientations. In the presence of ferroelastic interactions, fluctuations in the polarization orientation must be matched by changes in local strain. The finite acoustic phonon velocity implies a retarded response of the strain fields. This retardation produces a gap as $k \to 0$, limiting the domain wall motion.

1:39PM G21.00011 Theory of Relaxor Ferroelectric Electrocalorics , GIAN GUZMAN-VERRI, Materials Science Division, Argonne National Laboratory, PETER LITTLEWOOD, Physical Sciences and Engineering, Argonne National Laboratory — Conventional perovskite ferroelectrics are the material of choice in many modern day technologies such as capacitive energy storage devices, infrared sensors, and random access memories. Conventional ferroelectrics, however, have not been exploited in cooling applications mainly because their narrow region of critical fluctuations of polarization results in a small electrocaloric effect (a few miliKelvin per volt). Relaxor ferroelectrics, on the other hand, exhibit a broad region of critical fluctuations which makes them promising candidates for large electrocalorics. In this talk, we present a theoretical study of electrocalorics in relaxor ferroelectrics. We compute isothermal changes in entropy and adiabatic changes in temperature within a model of polarizable unit cells with local short-range forces, dipolar forces, and compositional disorder.

1:51PM G21.00012 ABSTRACT WITHDRAWN –

2:03PM G21.00013 Dynamical mean field studies on mid-gap states of $SrTiO_3$[1] , CHUNGWEI LIN, ALEXANDER A. DEMKOV, Department of Physics, Unversity of Texas at Austin — We study the mid-gap states obtained by photon luminescence of $SrTiO_3$ using dynamical mean field theory. The 2.4 eV peak observed in the $SrTiO_3$ luminescence experiment is attributed to the strong electron-optical phonon coupling when an electron is excited from oxygen 2p bands to titanium 3d bands, and is conventionally modeled by Franck-Condon model which contains only one fermion and one phonon field. Here we extend this model to a realistic lattice described by the tight-binding approximation, using dynamical mean field theory with exact diagonalization solver. We found the main features of Franck-Condon model preserve. The effects of correlation on oxygens will be discussed.

Tuesday, March 19, 2013 11:15AM - 2:15PM –

Session G22 DCMP: Electronic Phenomena of Nanostructures 324 - Nancy Sandler, Ohio University

11:15AM G22.00001 Fermi liquid nature of the ground state of multiple-quantum dots in parallel , MANAS KULKARNI, Princeton University, ROBERT KONIK, Brookhaven National Laboratory — We argue through a combination of 1/N diagrammatic expansion, slave boson mean field theory and the Bethe ansatz that the ground state of multiple quantum dots arranged in parallel is a singlet Fermi-liquid ground state. This conclusion is arrived at by showing the validity of Friedel Sum Rule (a fingerprint of Fermi-liquid physics) and finding that impurity entropy vanishes in the limit of zero temperature (singlet). Our conclusion is in contradiction to other studies that predict a non-Fermi liquid ground state. We discuss possible reasons for this discrepancy.

11:27AM G22.00002 Coupled collective modes in electronic systems of different dimensionalities[1] , BEN YU-KUANG HU, The University of Akron, EUYHEON HWANG, Sungkungkwan University, South Korea and The University of Maryland, College Park, SANKAR DAS SARMA, The University of Maryland, College Park — We consider electronic collective modes in coupled systems in which the individual components have different dimensionalities. Many-body diagramnatic techniques are used to derive formal results for the screened intra- and inter-system Coulomb interaction. We specifically investigate the case of a quasi-one-dimensional quantum wire in close proximity to a two-dimensional electron gas. We evaluate the screened intra- and inter-system Coulomb interaction within the random phase approximation, and find the existence of modes which have hybrid properties characteristic of both one- and two-dimensional systems. We also investigate the spatial dependence of the coupled 1-d + 2-d collective modes within the two-dimensional electron gas, and show that the coupled modes within that layer vary from being purely two-dimensional in character far away from the quantum wire to being strongly hybridized close to the wire.

[1]Supported by LPS-CMTC and US-ONR.

11:39AM G22.00003 Influence of Rashba spin-orbit interactions on the Kondo effect[1] , ARTURO WONG, KEVIN INGERSENT, U. of Florida, MAHDI ZAREA, Northwestern U., SERGIO ULLOA, NANCY SANDLER, Ohio U. — Recent studies [1] have pointed out that the thermodynamics of the Kondo effect are essentially unaltered by the presence of Rashba spin-orbit interactions in a host two-dimensional electron gas. However, it has also been proposed [2] that the presence of bulk Rashba interactions induces a coupling between a magnetic impurity and conduction electrons with nonzero orbital angular momentum about the impurity site. In this work we revist this problem using the numerical renormalization group. In agreement with previous studies, we find only minor changes in the Kondo temperature scale when the Rashba coupling is increased at fixed Fermi energy. However, for fixed band filling, increasing the spin-orbit coupling can move the Fermi energy near to a Van Hove singularity in the effective density of states, leading to an exponential enhancement of the Kondo scale. Static spin correlations confirm that the impurity couples to conduction channels of nonzero orbital angular momentum. We also explore the effects of a magnetic field applied in the plane of the host system.

11:51AM G22.00004 Spin-polarized conductance in double quantum dots: Interplay of Kondo, Zeeman and orbital effects[1] , LUIS DIAS DA SILVA, Instituto de Fisica, Universidade de Sao Paulo, EDSON VERNEK, Instituto de Fisica, Universidade Federal de Uberlandia, KEVIN INGERSENT, Department of Physics, University of Florida, NANCY SANDLER, SERGIO ULLOA, Department of Physics and Astronomy, and Nanoscale and Quantum Phenomena Institute, Ohio University — We study the effect of an external magnetic field in the Kondo regime of a double-quantum-dot system in which a strongly correlated dot is coupled to a noninteracting dot that is also connected to external leads. In zero field, the spectral function of the hanging dot has previously been shown to exhibit a split-peak structure near the Fermi level due to "Kondo resonance filtering" by the noninteracting dot. We show, using the numerical renormalization group, that application of a magnetic field leads to a subtle interplay between electronic interference, Kondo physics, and Zeeman splitting with nontrivial consequences for the spectral and transport properties. The value of the correlated-dot spectral function at the Fermi level exhibits a nonuniversal field dependence that can be explained using a generalized Friedel sum rule for a Kondo system with energy-dependent hybridization. By tuning gate voltages and the magnetic field, one can achieve complete spin polarization of the linear conductance between the leads, raising the prospect of applications of the device as a highly tunable spin filter.

[1]Supported in part by NSF-Materials World Network (DMR-0710540, 1107814, 0710581, 110828) and, in Brazil, by CNPq (493299/2010-3), FAPESP (2010/20804-9) and FAPEMIG (CEX-APQ-02371-10).

12:03PM G22.00005 Controlling entanglement and spin-correlations in double quantum dots with electrical currents in the non-equilibrium regime[1] , C. A. BUSSER, Ludwig-Maximilians-Universität, München, F. HEIDRICH-MEISNER, FAU Erlangen-Nuremberg and LMU Munich — We study the non-equilibrium dynamics in a parallel double-quantum dot structure induced by a large bias voltage. By applying both a magnetic flux and a voltage, it is possible to generate spin-spin-correlations between the two quantum dots. The sign and absolute value of these correlations can be controlled by changing the bias voltage. Using a canonical transformation we argue that the mechanism that drives the spin-spin correlations can be understood in terms of an effective Ruderman-Kittel-Kasuya-Yosida (RKKY) interaction that is mediated by the current. Our study is based on the Anderson-impurity model and we use time-dependent density matrix renormalization group simulations to obtain currents and spin-correlations in the non-equilibrium regime. We also perform quench in the Hamiltonian to prove the stability of the entangled state.

12:15PM G22.00006 SU(4) Kondo effect in a double quantum dot , ANDREW KELLER, Stanford University, SAMI AMASHA, MIT Lincoln Laboratory, ILEANA RAU, IBM Research - Almaden, LUCAS PEETERS, Stanford University, JORDAN KATINE, HGST, HADAS SHTRIKMAN, Weizmann Institute of Science, DAVID GOLDHABER-GORDON, Stanford University — Lateral quantum dots are highly tunable experimental systems ideal for exploring the interplay of spin and charge correlations. We present studies of a parallel-coupled double quantum dot system in a GaAs/AlGaAs heterostructure. In the limit of negligible inter-dot tunneling, the conductance through both dots is enhanced at inter-dot orbital degeneracies, where the energy for an electron to be on either dot is the same. We show how at four-fold orbital and spin degeneracies, signatures in the zero-bias conductance, the temperature dependence, and the bias spectroscopy suggest an SU(4) Kondo effect may be realized, combining spin and pseudospin.

12:27PM G22.00007 What Is Measured in the Scanning Gate Microscopy of a Quantum Point Contact? , STEVEN TOMSOVIC, Department of Physics and Astronomy, P.O. Box 642814, Washington State University, Pullman, WA 99164-2814, USA, RODOLFO A. JALABERT, WOJCIECH SZEWC, DIETMAR WEINMANN, Institut de Physique et Chimie des Matériaux de Strasbourg, UMR 7504, CNRS-UdS, 23 rue du Loess, B.P. 43, 67034 Strasbourg Cedex 2, France — The conductance change due to a local perturbation in a phase-coherent nanostructure is calculated. The general expressions to first and second order in the perturbation are applied to the scanning gate microscopy of a two-dimensional electron gas containing a quantum point contact. The first-order correction depends on two scattering states with electrons incoming from opposite leads and is suppressed on a conductance plateau; it is significant in the step regions. On the plateaus, the dominant second-order term likewise depends on scattering states incoming from both sides. It is always negative, exhibits fringes, and has a spatial decay consistent with experiments.

12:39PM G22.00008 Understanding Nanocontacts with atomic precision , CARLOS SABATER, MARIA JOSE CATURLA, University of Alicante, JUANJOSE PALACIOS, University Autonoma of Madrid, CARLOS UNTIEDT, University of Alicante, UNIVERSITY OF ALICANTE TEAM, UNIVERSITY AUTONOMA OF MADRID TEAM — Measuring the variations of the conductance indentation experiments between two electrodes, we can obtain information on the changes in the atomic structure of the contact. We have analysed the Jump-to-Contact(JC) phenomenon which can observed as the first contact when the two metals approach each other. Moreover, we have studied the Jump-out-of-contact(JOC) phenomenon which is the last contact before breaking the two electrodes. Secondly, as we further approach the two electrodes and when the indentation depth is limited to a certain value of conductance, almost the exact behaviour in the evolution of the conductance can be obtained for hundreds of cycles of formation and rupture. That is, the same sequence of atomic configurations was followed. Both processes are rationalized using MD simulations together with DFT transport calculations, which show: a) the most probable atomic configurations in the first atomic contact following the JC or JOC processes; b) that after repeated indentations the two metallic electrodes are shaped into tips of a reproducible structure formed through a mechanical annealing process. These results improve our understanding of atomic-sized contacts and the evolution of their structural characteristics.

12:51PM G22.00009 Emergent Localization from Many-Body Physics in Clean Quantum Point Contacts , CASPAR H. VAN DER WAL, M.J. IQBAL, E.J. KOOP, J.B. DEKKER DEKKER, J.P. DE JONG, J.H.M. VAN DER VELDE, University of Groningen, The Netherlands, D. REUTER, A.D. WIECK, Ruhr-University Bochum, Germany, R. AGUADO, Instituto de Ciencia de Materiales de Madrid, Spain, Y. MEIR, Ben-Gurion University of the Negev, Israel — Quantized conductance in quantum point contacts (QPCs) is the signature of control over electron transport at the nanoscale. As a function of channel width the conductance then increases in steps of $G_0 = 2e^2/h$. However, experiments often show an additional feature with a conductance plateau near $0.7G_0$, known as the 0.7 anomaly. This has been studied since 1995 but its full understanding is still an open problem. Spontaneous localization due to many-body effects in open QPCs, and the associated Kondo effect, has emerged as a promising theory for the 0.7 anomaly [1]. This theory work predicted that the many-body effects should for certain QPC geometries not give a single localized state but a pair of localized states, but signatures of this were till now not reported. For the first time, we have fabricated length-tunable QPCs in clean semiconductors and we discovered a periodic modulation of the 0.7 anomaly as a function of length. This modulation correlates with signatures for single and paired quasi-localized states, in the form of single- and two-impurity Kondo physics. Our results demonstrate that Friedel oscillations and emergent impurity states from many-body physics are fundamental to these phenomena. [1] T. Rejec and Y. Meir, Nature 442, 900 (2006).

1:03PM G22.00010 Electrolyte gating of gold point contacts , TREVOR PETACH, MENYOUNG LEE, DAVID GOLDHABER-GORDON, Stanford University — Gold point contacts are fabricated in-situ by electromigration in an ionic liquid bath. These contacts are shown to be stable at room temperature at conductances as small as 50 G_0. By electrolyte gating the contacts using a counter electrode in the ionic liquid, conductance changes of 25% are observed, corresponding to accumulation of more than one electron per gold surface atom. Double step chronocoulometry and x-ray reflectometry suggest that ion ordering in the ionic liquid near the gold interface are consistent with the observed changes in conductance.

1:15PM G22.00011 Electron energy spectra in two dimensional quantum rings consisting of two nanoelements , AVAG SAHAKYAN, RUZAN MOVSESYAN, The State Engineering University of Armenia, ARMEN KOCHARIAN, California State University, Los Angeles — Electron spectrum and ground state properties in two dimensional confined quantum rings with $R_{1,2}$ radiuses consisting of the two different (materials) nanoelements divided by two sectored finite size quantum wells with various potentials and spanning angles, is studied in the presence of transverse magnetic field. The calculated wave function shows oscillations along the radial direction which are progressing by approaching to the internal radius of the ring, R_2. Situation here is similar to the problem of fall of the particle on the attractive center. However, these oscillations are interrupted on the internal ring boundary by providing the new ground state which is sensitive to the change of magnetic flux. For shallow energy levels some energy states are undergoing changes controlled by magnetic field accompanied with the persistent current and abrupt phase transitions. Magnetization and magnetic susceptibility show characteristic two dimensional anomalous behaviors different from one found in one dimensional ring.

1:27PM G22.00012 Lateral quantization of two-dimensional electron states by embedded Ag nanocrystals[1] , CHRIS VAN HAESENDONCK, KOEN SCHOUTEDEN, Laboratory of Solid-State Physics and Magnetism, KU Leuven, BE-3001 Leuven, Belgium — We show that quantization of image-potential state (IS)electrons *above* the surface of nanostructures can be experimentally achieved by Ag nanocrystals that appear as stacking fault tetrahedrons (SFTs) at Ag(111) surfaces. By means of cryogenic scanning tunneling spectroscopy the $n = 1$ IS of the Ag(111) surface is revealed to split up in discrete energy levels, which is accompanied by the formation of pronounced standing wave patterns that directly reflect the eigenstates of the SFT surface. The IS confinement behavior is compared to that of the surface state electrons *in* the SFT surface and can be directly linked to the particle-in-a-box model. ISs provide a novel playground for investigating quantum size effects and defect induced scattering *above* nanostructured surfaces.

1:39PM G22.00013 MoS_2 grain-boundary: First-principles investigations[1] , DUY LE, TALAT S. RAHMAN, Department of physics, University of Central Florida, Orlando, FL 32816, USA — We present results of our first-principles electronic structure investigations, using the spin-polarized density-functional-theory, of the electronic and geometric structures of various models of grain-boundaries formed between different MoS_2 domains when grown as a single layer. From analysis of electronic band structures, we find, in all considered models, that the grain-boundaries exhibit metallic behavior. More interestingly, we find signatures of magnetism in the grain-boundary formed between two sulfur edges with 0% sulfur coverage. Details analysis of the geometric structures lead us to the conclusion that certain grain-boundaries undergo (2×1) reconstructions. We provide full details of the electronic and spin density states and change redistribution at the domain boundaries. We make contact with recent experimental observations and discuess the modifications in the characteristics for MoS_2 grown on Cu(111) [1].

1:51PM G22.00014 Ab initio Simulations of charge transfer properties at Quantum Dot/TiO_2 Interface in Quantum Dot-Sensitized Solar Cells , XUKAI XIN, Georgia Institute of Technology, RANA BISWAS, Iowa State University, ZHIQUN LIN, Georgia Institute of Technology — Quantum dot-sensitized solar cells (QDSSCs) have emerged as a very promising solar architecture for next generation photovoltaics. The QDSSCs exhibit a remarkably fast electron transfer from the quantum dot (QD) donor to the TiO_2 acceptor with size quantization properties that allows for the modulation of QD band gaps to control the photoresponse and photoconversion efficiency of QDSSCs. To understand the mechanisms that underpin this rapid charge transfer, the electronic properties of CdSe and PbSe QDs on the TiO_2 substrate were simulated using a rigorous ab initio method. In contrast to the plane wave approaches, this method capitalized on localized orbital basis set that is computationally less intensive, and provides excellent electronic structure of the constituent systems. We consider QDs grown on TiO_2 without functional ligands passivating the QD surface. We find a remarkable set of electron bridging states between QDs and TiO_2 occurring via the strong bonding between the conduction bands of QDs and TiO_2. Such bridging states account for the fast adiabatic charge transfer from the QD donor to the TiO_2 acceptor, and may be a general feature for other strongly coupled donor/acceptor systems and nanostructured semiconductor interfaces.

2:03PM G22.00015 Effect of hydrogen passivation on the electronic structure of ionic semiconductor nanostructures , HUIXIONG DENG, National Renewable Energy Laboratory, SHU-SHEN LI, JINGBO LI, Institute of Semiconductors, Chinese Academy of Sciences, SU-HUAI WEI, National Renewable Energy Laboratory, INSTITUTE OF SEMICONDUCTORS, CHINESE ACADEMY OF SCIENCES COLLABORATION — In theoretical studies of thin film and nanostructured semiconductors, pseudohydrogen (PH) is widely used to passivate the surface dangling bonds. Based on these calculations, it is often believed that nanostructured semiconductors, due to quantum confinement, have a larger band gap than their bulk counterparts. Using first- principles band structure theory calculation and comparing systematically the differences between PH-passivated and real-hydrogen–passivated (RH-passivated) semiconductor surfaces and nanocrystals, we show that, unlike PH passivation that always increases the band gap with respect to the bulk value, RH passivation of the nanostructured semiconductors can either increase or decrease the band gap, depending on the ionicity of the nanocompounds. The difference between PH and RH passivations decreases when the covalency of the semiconductor increases and can be explained using a band coupling model. This observation greatly increases the tunability of nanostructured semiconductor properties, especially for wide-gap ionic semiconductors.

Session G23 DMP: Focus Session: Dopants and Defects in Semiconductors V 325 - John Lyons, University of California at Santa Barbara

11:15AM G23.00001 Modeling of Threading Dislocation Core Fields and of Point Defects in GaN , JENNIFER R. SNIVELY, Wright State University, Dayton OH, STEFAN C. BADESCU, Air Force Research Laboratory, WPAFB OH — Point defects and dislocations in GaN are involved in failure mechanisms of GaN-based electronic devices. Compared to bulk material, the electronic states and diffusivities of point defects are modified by dislocation elastic fields. For accurate descriptions atomistic calculations have to take into account both the long (Volterra) and the short-range components of the latter. We present an atomistic picture of defect energy levels and diffusion barriers for vacancies, interstitials and impurities next to threading dislocations in GaN. We include the dislocation core field derived from stress calculations using periodic supercells. We show that this increases significantly the point defect-dislocation interaction by comparison to the Volterra field and that the diffusion energy barriers are changed by as much as 50%. The dependence of charged energy levels on the Fermi level is also modified on many lattice spacings away from the dislocations. We discuss in more detail the charged N vacancies and the Ga and Al interstitials.

11:27AM G23.00002 Carrier-Induced Lattice Instability in Amorphous Oxide Semiconductors , YONG-SUNG KIM, HO-HYUN NAHM, Korea Research Institute of Standards and Science, DAE-HWAN KIM, Kookmin University — Amorphous oxide semiconductors (AOS's) have high electron mobility even in amorphous phase. The AOS-based thin film transistors (TFTs) are nowadays intensively pursued to be adopted into high-resolution flat-panel displays. However, a facing bottleneck of the AOS-based TFT display applications is the instability problem under bias and illumination stress conditions. Especially, by negative bias and illumination stress (NBIS) or only by illumination stress (IS), the threshold voltage of the AOS TFTs is largely negative-shifted. In this work, we study the instability mechanism of the AOS's based on first-principles calculations. The valence band tail states of the AOS's are found to be characterized by the O-O ppσ* anti-bonding state. The excited localized-holes thus give lattice instability and form O-O bonds through the ppσ-hybridized interaction. The ppσ* level is heightened up into the conduction bands along with the O-O bond formation, and two electrons left from the created O-vacancy (V_O) occupy the delocalized conduction band states. The O-O and V_O complex (a peroxide defect) is found to be a meta-stable donor defect and suggested as an origin of the NBIS and IS instabilities in AOS TFTs. Based on the suggested mechanism, we propose a direction to improve the stability of AOS thin films with optimizing the cation compositions.

11:39AM G23.00003 Shuffle-Glide Transition of Dislocations in Silicon , ZHI LI, NITHIN MATHEW, CATALIN PICU, Rensselaer Polytechnic Institute — Dislocation motion in diamond cubic Si can take place either on the shuffle or glide set of {111}planes. It is commonly accepted that shuffle planes are active at low temperatures and high applied stresses, while the glide planes become active at high temperatures and lower stresses. The transition of dislocations from one plane to the other is still a matter of debate, with some authors suggesting that such transition is impossible, and others proposing intermediate metastable states and transition barriers. In this work we show a mechanism by which shuffle dislocations may move to the glide plane without any intermediate state and evaluate the activation barrier (and activation volume) for the transition. We also support the previously observed sensitivity of dislocation mobility in the shuffle plane to the stress acting normal to the glide plane, and link this sensitivity to the nature of the gamma surface. The role of the normal stress in the shuffle-glide transition is also discussed.

11:51AM G23.00004 Role of defects in resistive switching TiO_2- and $SrTiO_3$-based devices , MAREK SKOWRONSKI, Carnegie Mellon University — Oxide-based resistive switching devices hold promise of being the next generation of non-volatile high density memory. While small size, fast switching and long retention time have been demonstrated, many questions remain pertaining the switching mechanism. In particular, the role of point and extended defects in resistance switching remains to be elucidated. Most proposed interpretations invoke oxygen vacancy redistribution as the origin of the resistance change. However, the measurements of the vacancy drift in the Schottky barriers on $SrTiO_3$ indicated that mobility at room temperature is eight orders of magnitude too low to account for the reported switching times. This difficulty could be alleviated by faster vacancy motion along the dislocation lines and/or local Joule heating during switching. Careful mapping of the dislocation distribution before and after switching in nanoscale devices did not find a good correlation between dislocations and the I-V characteristics. Lateral $SrTiO_3$ devices with no dislocations have similar switching behavior to the ones fabricated on high dislocation density materials. The only correlation present was the generation of dislocations in devices with dissipated power level above 10 mW. The apparent mechanism is the thermal stress driven plastic deformation. While the Joule heating could speed up the defect motion, it could not explain the long retention times. This is frequently interpreted as due to formation of oxygen-deficient phases in TiO_2-based memristors. Transmission Electron Microscopy analysis of nanoscale vertical devices has revealed numerous physical changes with the extent strongly dependent on the level of dissipated power. Optimized device structures that switch with the power dissipation below 2 mW exhibited very limited degree of crystallization and no new phases. Many of the initially posed questions remain unanswered.

12:27PM G23.00005 Oxygen vacancies at the surface of $SrTiO_3$ thin films[1] , ALEXANDRE R. SILVA, GUSTAVO M. DALPIAN, Universidade Federal do ABC — The 2-D electron gas at the interface between $LaAlO_3$ (LAO) and $SrTiO_3$ (STO), two band insulators, has been the subject of intense research owing to the fact that this interface can show metallic, superconducting, and magnetic effects, properties that are absent in the bulk counterparts. The metallic behavior has also been observed at the STO surface, without the need of the oxides' interface. Although the reason of this behavior is not well defined, there are three hypotheses for this: the polar catastrophe; the oxygen vacancies produced in the experiment, and cations intermixing. In this work, first principles calculations based on the density functional theory and using hybrid functionals were performed to reveal the atomic and the electronic structure of vacancies at the (001) surface of STO films. We have analyzed both the TiO_2 and SrO-terminated surfaces. For pure surfaces, we observed atomic relaxations up to the 5^{th} atomic layer. The surface band structure of ideal STO slabs shows that the STO thin films are insulating in both terminations, but insert surface levels in the gap of bulk STO. Defective STO slabs are observed to be metallic, and we observe a strong tendency for the oxygen vacancies to migrate into the surface.

12:39PM G23.00006 Persistent photoconductivity in strontium titanate[1] , MATTHEW MCCLUSKEY, MARIANNE TARUN, Washington State University — Strontium titanate ($SrTiO_3$) is often used as a substrate for oxide thin films such as high-temperature superconductors. It has the perovskite structure and an indirect band gap of 3.25 eV. Our prior work showed that hydrogen impurities form a defect complex that contains two hydrogen atoms. The complex was tentatively attributed to a passivated strontium vacancy. Alternatively, it could be a partially passivated titanium vacancy. In order to suppress strontium vacancies (and create titanium vacancies), we annealed samples in an evacuated ampoule with SrO powder. These samples show unexpected behavior. After illuminating with light (405 nm, 3.06 eV), the free-electron concentration increases significantly. After the light is turned off, the high conductivity persists at room temperature. We tentatively attribute this effect to the excitation of an electron from a titanium vacancy into the conduction band, with a high barrier for recapture.

12:51PM G23.00007 A hybrid density functional study on energetics of native defects in anatase TiO_2 , ADISAK BOONCHUN, National Institute for Materials Science (NIMS), Japan, PAKPOOM REUNCHAN, Kasetsart University, Thailand, NAOTO UMEZAWA, (1) National Institute for Materials Science (NIMS), Japan (2) JST PRESTO (3) TU-NIMS Joint Research Center, Tianjin University, China, JINHUA YE, (1) National Institute for Materials Science (NIMS), Japan (2) WPI-MANA (3) TU-NIMS Joint Research Center, Tianjin University, China — The energetics and electronic structures of native defects in anatase TiO_2 have been studied by means of hybrid density-functional calculations. Here, we show that oxygen vacancy (V_O) and titanium interstitial (Ti_i) are both shallow donors and are likely to form with a substantial concentration in an oxygen poor condition. While titanium vacancies (V_{Ti}) is a deep acceptor. The charge neutrality showed that Fermi level is pinned at the conduction band minimum in good agreement with the common observations of n-type conductivity in a reduced TiO_2. Self-trap hole (O_O) states are localized at oxygen anions. On the other hand the self-trapped electron (Ti_{Ti}) cannot be produced in the bulk. Although, Ti_i is the strongest candidate for the unintentional n-type conductivity owning to its low formation energy, we show that the post-growth of V_O in anatase is also possible under annealing temperature and pressure.

1:03PM G23.00008 DFT-based first-principle calculation of the carrier activation ratio in the F-doped anatase TiO_2 and the thermodynamic analysis of the formation of $TiOF_2$ phase , HIDEYUKI KAMISAKA, NANAKO MIZUGUCHI, KOICHI YAMASHITA, TETSUYA HASEGAWA, The University of Tokyo — The F-doped anatase TiO_2 (FTO) could be an alternative transparent conductive oxide, but the experimentalists have reported low carrier activation ratio of 20 - 30%, and that the formation of $TiOF_2$ hampers its production when using the PLD method. We investigated this system using the standard DFT-based band structure method. The PBE functional was adapted with the Hubburd +U terms. The value of +U parameters was adjusted to meet the generalized Koopman's theorem (gKT). We found that the formation energy of F_O (F dopant substituting O) and F_O^+ is quite close to each other, and the two crosses when the Fermi level is slightly above the conduction band minimum. Combining the Burstein-Moss effect and this crossing of the formation energies, a simple statistical analysis was made. The calculated activation ratio was about 10% - 32%, which agreed with the experimental data. The free energies of bulk TiO_2, 3% FTO, 6% FTO and $TiOF_2$ were compared using the DFT result. Contributions from the distribution entropy of the anions, lattice vibrations, free energy of conductive electrons, and the entropy from the spin state of trapped electrons was considered with relevant approximations. We found that the free energy of TiO_2, 3% FTO, and $TiOF_2$ come close to each other under the condition of T=800K and $P(O_2) = 10^{-5}$ Torr, which coincides the experimental report.

1:15PM G23.00009 Origins of Persistent Photoconductivity in GaAsN Alloys , R.L. FIELD III, Department of Physics, University of Michigan, Y.Q. WANG, Materials Science and Technology Division, Los Alamos National Laboratory, C. KURDAK, Department of Physics, University of Michigan, R.S. GOLDMAN, Department of Materials Science and Engineering, University of Michigan — In $GaAs_{1-x}N_x$ alloys, we observe significant persistent photoconductivity (PPC) at cryogenic temperatures for $x > 0.006$, with the PPC strength increasing with increasing x and decreasing upon rapid-thermal annealing (RTA). Since the RTA-induced suppression is accompanied by a reduction of the interstitial N fraction, the N-induced donor state is likely associated with N pairs. PPC is attributed to the promotion of carriers from a ground N-pair state to the conduction band edge, inducing modifications in the N-pair molecular bond configuration. When illumination is terminated, an energy barrier hinders the return of carriers to the N-pair induced complex. With the addition of thermal energy, the original N-pair configuration is restored and the N-pair induced complex is then able to accept carriers. We use PPC at cryogenic temperatures to go through a metal-insulator transition in GaAsN by increasing the carrier density with illumination. For different illumination durations we determine the minimum metallic conductivity, giving us the critical carrier density, n_c, at the transition point. We then determine the effective mass, $m*$, using the Mott criterion $n_c^{1/3} a_H = 0.26$ where $a_H = (4\pi\varepsilon\hbar^2)/(e^2 m^*)$ is the Bohr radius. We use PPC to induce a metal-insulator transition in GaAsN. We will discuss the effective mass as a function of N concentration and compare to the predictions of the band anticrossing model.

1:27PM G23.00010 Defect Related Magnetism and Conduction in As-grown and Annealed Pulsed Laser Deposited SnO_2:Co Thin Films[1] , GRATIELA M. STOIAN, Florida State University, P.A. STAMPE, R.J. KENNEDY, Florida A&M University, E. LOCHNER, Florida State University, Y. XIN, National High Magnetic Field Laboratory, Tallahassee, S. VON MOLNAR, Florida State University, FLORIDA STATE UNIVERSITY TEAM, FLORIDA A&M UNIVERSITY TEAM, NATIONAL HIGH MAGNETIC FIELD LABORATORY, FL COLLABORATION — Magnetic semiconductor SnO_2:Co films were grown on r-cut sapphire substrates via Pulsed Laser Deposition from a doped target with a nominal Co concentration of 5 at.%. To study the role of oxygen vacancies and other defects in tuning the ferromagnetic (FM) and electrical properties of these materials, films were deposited at different growth rates, temperatures and oxygen pressures. In addition, some films were annealed at various conditions. Magnetometry data show that films grown at optimal conditions are FM at room temperature with a saturation magnetization of 20 emu/cm^3. The moment per unit area varies linearly with the film thickness, suggesting the magnetism in our materials is a volume property. Magnetization decreases monotonically with the growth rate. A transition from a semiconducting, magnetic material to an insulating, non-magnetic material was observed below a film thickness of 50 Å. Annealing films grown at a higher than optimal deposition rate under the same conditions used for their growth, led to an initial rapid increase in the magnetization followed by constant magnetization after further annealing. We also report on the temperature dependence of the electro-magnetic properties.

[1]Grant no. NSF DMR-0605734

1:39PM G23.00011 Exploring nanoscale fluctuations and ferroelectric phase stabilization in S doped PbTe thermoelectrics , KEVIN KNOX, EMIL BOZIN, Brookhaven National Laboratory, CHRISTOS MALLIAKAS, MERCOURI KANATZIDIS, Northwestern University, SIMON BILLINGE, Columbia University, Brookhaven National Laboratory — PbTe is one of the most important commercial thermoelectric materials for applications above room temperature. A paraelectric phase of fluctuating ferroelectric-like Pb structural dipoles emerges in PbTe at elevated temperatures, although it adopts an average rock-salt structure at all temperatures. These intrinsic nanoscale fluctuations are believed to improve the thermoelectric properties of PbTe by limiting the lattice thermal conductivity. Additionally, alloying and chemical substitution in PbTe appreciably improve the thermoelectric figure of merit, as is the case in $PbTe_{1-x}S_x$. However, the exact mechanism for this enhancement is not well understood. It has been shown that $PbTe_{1-x}S_x$ exhibits a peak in resistivity at a doping dependent temperature. By analogy with Ge doped PbTe, this anomalous resistivity may be the signature of a ferroelectric phase stabilization. In this talk, we explore this possibility by characterizing the average and the local structure of $PbTe_{1-x}S_x$ as a function of temperature and doping using a neutron based atomic pair distribution function (PDF) approach.

1:51PM G23.00012 H_2 exposure induced structural and electrical modulation in MoS_2 , MIN PARK, Seoul National Univerisy, SUNG JIN CHANG, Division of Materials Science, Korea Basic Science Institute, HU YOUNG JUNG, UNIST Central Research Facility and School of Mechanical and Advanced Materials Engineering, Ulsan National Institute of Science and Technology, SEUNG JAE BAEK, Department of Nanoscience and Technology, Seoul National Univerisy, YONGSEOK JUN, BYUNG HOON KIM, Interdisciplinary School of Green Energy, KIER-UNIST Advanced Center for Energy, Ulsan National Institute of Science and Technology, YUNG WOO PARK, Department of Physics and Astronomy, Seoul National University — We have demonstrated the structural modulation at the edge of MoS_2 due to H_2 exposure with spatially resolved Raman spectroscopy and the electrical characteristics of few-layer MoS_2 with respect to H_2 pressure from vacuum to 20 bars at 295 K $< T <$ 350 K. Upon H_2 exposure, the significant change of the edge in E_{2g} mode was observed. The conductance increases and threshold voltage (V_{th}) shifts toward a negative gate voltage region, indicating n-type doping. These behaviors are enhanced by high temperature and long exposure time (t). The results reveal the creation of vacancy at the edge sites of MoS_2 in H_2 atmosphere causing the enhancement of n-type doping due to increase of metallic region.

2:03PM G23.00013 Discovery of Burstein-Moss shift in Re-doped MoS_2 nanoparticles[1] , QI SUN, Department of Chemistry, University of Tennessee, LENA YADGAROV, RITA ROSENTSVEIG, Department of Materials and Interfaces, Weizmann Institute of Science, GOTTHARD SEIFERT, Physikalische Chemie, Technische Universitat, RESHEF TENNE, Department of Materials and Interfaces, Weizmann Institute of Science, JANICE MUSFELDT, Department of Chemistry, University of Tennessee — We investigated the optical properties of Re-doped MoS_2 nanoparticles and compared our findings with the pristine and bulk analogs. Our measurements reveal that confinement softens the exciton positions and reduces spin-orbit coupling whereas doping has the opposite effect. We model the doping-induced exciton blue shift in terms of the Burstein-Moss effect. These findings are important for understanding doping and finite length scale effects in model nanoscale materials.

Session G24 DCOMP: Focus Session: Computational Studies of Interactions between Electromagnetic Fields and Materials II 326 - kalman varga, Vanderbilt

11:15AM G24.00001 Plasmon enhanced light harvesting , PETER NORDLANDER, Department of Physics, Rice University — Plasmon energies can be tuned across the spectrum by simply changing the geometrical shape of a nanostructure. Plasmons can efficiently capture incident light and focus it to nanometer sized hotspots which can enhance electronic and vibrational excitations in nearby structures. Another important but still relatively unexplored property of plasmons, is that they can be efficient sources of hot energetic electrons which can transfer into nearby structures and induce a variety of processes. This process is a quantum mechanical effect: the decay of plasmon quanta into electron-hole pairs. I will discuss how plasmon induced hot electrons can be used in various applications: such as to induce chemical reactions in molecules physisorbed on a nanoparticle surface; to inject electrons directly into the conduction band of a nearby substrate; to dramatically enhance the light harvesting efficiency of a photovoltaic device; and to induce local doping of a nearby graphene sheet.

11:51AM G24.00002 Ab Initio Simulation of Fragmentation in Polyatomic Molecules by Short Intense Laser Pulses , ARTHUR RUSSAKOFF, SERGIY BUBIN, KALMAN VARGA, Vanderbilt University — We study ionization and fragmentation of polyatomic molecules induced by short intense laser pulses by performing ab initio simulations within the formalism of Time Dependent Density Functional Theory. Within this formalism we investigate intra-molecular electron dynamics during a fragmentation reaction on a pre-chemistry time-scale. The time-scale of the dynamics bridges the time-domain of sub-femtoseconds, on which the electrons move, and that of the much slower motion of the heavier ions (e.g. carbon ions), which proceeds on a time-scale of tens to hundreds of femtoseconds. The kinetic energy spectrum of the fragments and the charge state of the molecule prior to fragmentation are calculated and compared to experiment.

12:03PM G24.00003 Laser-Induced High Harmonic Generations in Nano-Graphene Molecules[1]

, MINGQIANG GU, Nanjing University and Indiana State University, GUOPING ZHANG, Indiana State University, XIAOSHAN WU, Nanjing University — Nano graphene molecules is a promising material for the non-linear optical devices. We performed a first-principles calculation on Graphene Molecules. Two distinct signals are noticed: the integer higher-order harmonic generation (HHG) and the intrinsic emissions. Due to the small gap between HOMO and LUMO of graphene molecule, the HHG can be generated for the infrared laser pulse with the photon energy ranging from 20 meV to 1 eV. The intrinsic emission corresponds to the electron excitation between eigen states. They can be generated using a relatively low intensity laser pulse (0.05 eV/Å) through the multiphoton process. Moreover, these signals are very sensitive to the molecule size and the hydrogen passivation. They can be the fingerprints for detecting the product in fabrication.

[1]Supported by DOE(No. DE-FG02-06ER46304), NKPBRC(2010CB923404) and NNSFC(No. 11274153, No. 10974081, No. 10979017)

12:15PM G24.00004 Surface Integral Formulations for the Design of Plasmonic Nanostructures

, CARLO FORESTIERE, Boston University, GIOVANNI IADAROLA, GUGLIELMO RUBINACCI, Universita' degli Studi di Napoli Federico II, ANTONELLO TAMBURRINO, Universita' di Cassino e del Lazio Meridionale, LUCA DAL NEGRO, Boston University, GIOVANNI MIANO, Universita' degli Studi di Napoli Federico II, BOSTON UNIVERSITY TEAM, UNIVERSITA' DEGLI STUDI DI NAPOLI FEDERICO II TEAM, UNIVERSITA' DI CASSINO E DEL LAZIO MERIDIONALE TEAM — Numerical formulations based on surface integral equations (SIEs) provide an accurate and efficient framework for the solution of the electromagnetic scattering problem by three-dimensional plasmonic nanostructures in the frequency domain. In this work, we present a unified description of SIE formulations with both singular and nonsingular kernel and we study their accuracy in solving the scattering problem by metallic nanoparticles with spherical and nonspherical shape. In fact, the accuracy of the numerical solution, especially in the near zone, is of great importance in the analysis and design of plasmonic nanostructures, whose operation critically depends on the manipulation of electromagnetic hot spots. Four formulation types are considered: the N-combined region integral equations, the T-combined region integral equations, the combined field integral equations and the null field integral equations. A detailed comparison between their numerical solutions obtained for several nanoparticle shapes is performed by examining convergence rate and accuracy in both the far and near zone of the scatterer as a function of the number of degrees of freedom. A rigorous analysis of SIE formulations can have a high impact on the engineering of numerous nano-scale optical devices.

12:27PM G24.00005 Dynamics of irradiation: from molecules to nano-objects and from material science to biology

, ERIC SURAUD, PHUONG MAI DINH, Laboratoire de Physique Théorique, Université Paul Sabatier 118 Route de Narbonne, 31062 Toulouse cedex, France, PAUL-GERHARD REINHARD, Institut fuer Theoretisch Physik, Universitaet Erlangen Staudstrasse 7, D91058 Erlangen, Germany — We discuss microscopic mechanisms of irradiation in clusters and molecules considering the case of isolated molecules/clusters [1] and/or in an environment [2]. We use Time Dependent Density Functional Theory (for electrons) coupled to Molecular Dynamics (for ions) and follow explicitly in time irradiation and response of the system. Examples are taken from free metal clusters, fullerenes, molecules of biological interest and clusters deposited on a surface or embedded in a matrix [3,4]. We analyse in particular properties of emitted electrons (photo electron spectra, angular distributions...) which provide a key tool of analysis of properties of irradiated clusters and molecules [5]. We also discuss pump and probe scenarios (opening the road to manipulation at the molecular scale) with help of dedicated laser pulses, exploring in particular very short times scales down towards the attosecond domain.

12:39PM G24.00006 Time-dependent transition density matrix for visualizing charge-transfer excitations in photoexcited organic donor-acceptor systems[1]

, YONGHUI LI, CARSTEN ULLRICH, University of Missouri — The time-dependent transition density matrix (TDM) is a useful tool to visualize and interpret the induced charges and electron-hole coherences of excitonic processes in large molecules. Combined with time-dependent density functional theory on a real-space grid (as implemented in the octopus code), the TDM is a computationally viable visualization tool for optical excitation processes in molecules. It provides real-time maps of particles and holes which gives information on excitations, in particular those that have charge-transfer character, that cannot be obtained from the density alone. Some illustration of the TDM and comparison with standard density difference plots will be shown for photoexcited organic donor-acceptor molecules.

12:51PM G24.00007 Density functional studies of plasmons, hybridizations and electron diffractions in carbon fullerene nanomaterials[1]

, HIMADRI CHAKRABORTY, Northwest Missouri State University, Maryville, USA, LAMINE MADJET, Center for Free Electron Laser Science, Hamburg, Germany — Quantized plasma waves in carbon valence electron clouds driven by photon or charged particle fields create plasmon resonances in the ionization of fullerene nanomaterials [1]. If the materials have composite structures, like nested fullerenes (buckyonions) or fullerenes endohedrally doped by an atom (endofullerenes), then plasmonic motions dynamically hybridize, leading to spectacular effects in the emission spectra [2,3]. Further, for fast ejected electrons, diffraction type modulations in the momentum space of emission intensities enrich the ionization process which offer an unusual spectroscopic route to image the charge cloud geometry [4,5]. Using a time-dependent local density functional methodology, but smearing the ionic core into a jellium, we recently completed some studies of such processes for fullerene nanomaterials. Results have shown good agreements with measurements. [1] Madjet et al., J. Phys. B 41, 105101 (2008); [2] McCune et al., J. Phys. B Fast Track Comm. 44, 241002 (2011); [3] Madjet et al., Phys. Rev. 1:03PM G24.00008 Non-Linear Optical Response Simulations for Strongly Corellated Hybrid Carbon Nanotube Systems[1]

, AREG MELIKSETYAN, IGOR BONDAREV, North Carolina Central University, MAXIM GELIN, Technical University of Munich, Germany — Hybrid carbon nanotube systems, nanotubes containing extrinsic atomic type species (dopants) such as semiconductor quantum dots, extrinsic atoms, or ions, are promising candidates for the development of the new generation of tunable nanooptoelectronic devices – both application oriented, e.g., photovoltaic devices of improved light-harvesting efficiency, and devices for use in fundamental research. Here, we simulate non-linear optical response signals for a pair of spatially separated two-level dipole emitters (to model the dopants above) in the regime where they are coupled strongly to a low-energy surface plasmon resonance of a metallic carbon nanotube. Such a coupling makes them entangled [1], and we show that the cross-peaks in 2D photon-echo spectra are indicative of the bipartite entanglement being present in the system [2]. We simulate various experimental conditions and formulate practical recommendations for the reliable experimental observation of this unique quantum phenomenon of relevance to the solid-state quantum information science.

1:15PM G24.00009 Dynamical density matrix renormalization group study of non-linear optical response of one-dimensional strongly correlated electron system

, SHIGETOSHI SOTA, RIKEN AICS, SEIJI YUNOKI, RIKEN AICS, RIKEN ASI, CREST, TAKAMI TOHYAMA, YITP, Kyoto University — We studied the third-order non-linear optical response of one-dimensional Mott insulators by using the dynamical density matrix renormalization group method. We employed an one-dimensional extended Hubbard model which corresponds to the one-dimensional Mott insulators. Also, we introduced a Holstein-type electron-phonon interaction which is important for understanding the optical response in the one-dimensional Mott insulators. We calculated the non-linear optical response using the parameters corresponding to Sr_2CuO_3 which is known as a kind of the one-dimensional Mott insulators. Our calculated results show a relatively large effect of the electron-phonon interaction on the calculated third-order non-linear optical response.

1:27PM G24.00010 Real-time TDDFT calculations of core-hole spectral functions[1]

, J.J. KAS, J.J. REHR, A.J. LEE, F.D. VILA, U. Washington — Core-hole response is important in a variety of x-ray spectra, including x-ray absorption, resonant and non-resonant inelastic x-ray scattering, and x-ray photo-electron spectroscopy, but has usually been treated within the adiabatic approximation. Here we explore the dynamic response of valence electrons to the sudden appearance of a deep core-hole using real time time dependent density functional theory (RT-TDDFT). The core-hole is treated as a transient time dependent potential which excites the valence electrons, as in the edge-singularity theory of Nozieres and De Dominicis. RT-TDDFT provides an efficient approach for treating response to time-dependent external fields including interactions among the valence electrons, which has recently been applied to calculations of optical and x-ray spectra.[2] Here we generalize this approach to explore the role of the strength and localization of the core-hole potential and its effects on the spectral function and various x-ray spectra, together with comparisons to the adiabatic approximation.

1:39PM G24.00011 Quantal Density Functional Theory (QDFT) in the Presence of an Electromagnetic Field[1]

, XIAO-YIN PAN, Ningbo University, VIRAHT SAHNI, Brooklyn College, CUNY — We derive the QDFT equations of electrons in an external time-dependent field $\mathcal{E}(\mathbf{r}\sqcup) = -\boldsymbol{\nabla}\, v(\mathbf{r}t)$ and in the presence of an electromagnetic field characterized by the magnetic induction $\mathbf{B}(\mathbf{r}t) = \boldsymbol{\nabla} \times\mathbf{A}(\mathbf{r}t)$ and electric field $\mathbf{E}(\mathbf{r}t) = -\boldsymbol{\nabla}\,\Phi(\mathbf{r}t) - (1/c)\partial\mathbf{A}(\mathbf{r}t)/\partial t$. The QDFT is comprised of the mapping from this system to one of noninteracting fermions with the same density $\rho(\mathbf{r}t)$ and physical current density $\mathbf{j}(\mathbf{r}t)$. The mapping is in terms of 'classical' fields representative of the different electron correlations that must be accounted for. On deriving the 'quantal Newtonian' second law for the interacting and model systems, we obtain the local electron-interaction potential $v_{ee}(\mathbf{r}t)$ of the latter to be the work done in a conservative effective field $\mathcal{F}^{\rm eff}(\mathbf{r}\sqcup)$. The components of $\mathcal{F}^{\rm eff}(\mathbf{r}\sqcup)$ are representative of correlations due to the Pauli exclusion principle and Coulomb repulsion and the Correlation-(Kinetic, Current Density, Electric, and Magnetic) effects.

1:51PM G24.00012 Basic Variables in the Presence of a Magnetostatic Field[1]

, VIRAHT SAHNI, Brooklyn College, CUNY, XIAO-YIN PAN, Ningbo University — We present our recent understanding of the issue of what properties constitute the basic variables in quantum mechanics for electrons in the presence of external electrostatic $\mathcal{E}(\mathbf{r}) = -\boldsymbol{\nabla}\, v(\mathbf{r})$ and magnetostatic $\mathbf{B}(\mathbf{r}) = \boldsymbol{\nabla} \times\mathbf{A}(\mathbf{r})$ fields. In this case, the relationship between the potentials $\{v, \mathbf{A}\}$ and the ground state wave function Ψ can be many-to-one. We discuss our prior work[2] in which we claimed that the basic variables are the ground state density $\rho(\mathbf{r})$ and physical current density $\mathbf{j}(\mathbf{r})$. We prove here more fully this to be the case for the nondegenerate ground state for which Ψ is real. The proof explicitly accounts for the many-to-one relationship between $\{v, \mathbf{A}\}$ and Ψ. We also draw parallels between our work on the density and physical current density functional theory and those of the Hohenberg-Kohn and Percus-Levy-Lieb definitions of density functional theory.

2:03PM G24.00013 The magnetization of periodic solids from time-dependent current-density-functional theory

, ARJAN BERGER, Laboratoire de Chimie et Physique Quantiques (LCPQ), Universite Paul Sabatier, Toulouse, France and European Theoretical Spectroscopy Facility (ETSF), NATHANIEL RAIMBAULT, Laboratoire de Chimie et Physique Quantiques (LCPQ) and Laboratoire de Physique Théorique (LPT), Université Paul Sabatier, Toulouse, France, PAUL DE BOEIJ, Scientific Computing & Modelling (SCM), Amsterdam, The Netherlands, PINA ROMANIELLO, Laboratoire de Physique Théorique (LPT), Université Paul Sabatier, Toulouse, France and European Theoretical Spectroscopy Facility (ETSF) — The evaluation of the macroscopic magnetization of solids is problematic when periodic boundary conditions are used because surface effects are artificially removed. This poses a problem unless surface effects can be reformulated in terms of bulk quantities. For example, in case of the macroscopic polarization one can express the contribution of the charge density accumulated at the surface in terms of the bulk current density through the continuity equation. Therefore one can work in the framework of time-dependent current-density functional theory to efficiently calculate the macroscopic polarization [1,2]. In this presentation we will show how also the magnetization can be described within this framework.

Session G25 GQI: Itinerant Photons, Squeezed States, and Entanglement 327 - Lev Bishop, University of Maryland

11:15AM G25.00001 Qubit-Photon Entanglement and Hong-Ou-Mandel Interference with Propagating Microwaves , CHRISTOPHER EICHLER, CHRISTIAN LANG, JOHANNES FINK, JOONAS GOVENIUS, LARS STEFFEN, STEFAN FILIPP, ANDREAS WALLRAFF, ETH Zurich, MATTHEW WOOLLEY, ALEXANDRE BLAIS, Universite de Sherbrooke — Itinerant microwave photons offer an attractive carrier of quantum information in superconducting circuits. However, until recently it remained challenging to measure photon statistics and coherence properties of microwave fields beyond the Gaussian level – mainly due to the absence of efficient detectors in this frequency range. Here, we present the on-demand generation and efficient characterization of microwave radiation and its entanglement with stationary qubits. Based on novel tomography techniques and low noise parametric amplification we are able to resolve all relevant quantum correlations between the propagating field and the superconducting qubit to demonstrate entanglement with high fidelity [1,2]. We have also created entangled microwave fields traveling in two spatially separated modes. Making use of the two-photon interference at a microwave beamsplitter we are able to prepare propagating NOON-type states, which we fully characterize by measuring the joint photon statistics of the two modes. The possibility to synthesize, guide and detect entanglement correlations between itinerant microwave photons and stationary qubits put microwave based quantum network experiments within reach. [1] arXiv:1209.0441v1 [2] C. Eichler et al., Phys. Rev. A 86, 032106 (2012)

11:27AM G25.00002 Catching Microwave Photons in a Superconducing Resonator with Tunable Coupling , JAMES WENNER, YI YIN, YU CHEN, R. BARENDS, B. CHIARO, J. KELLY, M. MARIANTONI, A. MEGRANT, J. MUTUS, C. NEILL, S. OHYA, D. SANK, T. WHITE, A.N. CLELAND, JOHN M. MARTINIS, University of California, Santa Barbara — When transferring a quantum state from a freely propagating mode to a resonator, reflections must be minimized to avoid energy loss. Performing this transfer with high fidelity requires tunable coupling. We experimentally studied a 50 Ohm transmission line with tunable coupling to a 6GHz superconducting coplanar waveguide resonator, which in turn is capacitively coupled to a phase qubit for calibration. We classically drove the resonator while measuring the reflected and captured signals using a HEMT amplifier. Following theory by Korotkov (PRB 84, 014510, 2011), we find that the photon capture efficiency is maximized with an exponentially increasing drive; further improvements come from varying pulse duration and dynamic coupling. With these techniques, we reduce reflections so that presently over 80% of the pulse energy is captured by the resonator.

11:39AM G25.00003 Radiative decay of a superconducting qubit in squeezed vacuum[1] , S.J. WEBER, K.W. MURCH, QNL, UC Berkeley, K.M. BECK, Department of Physics and Research Laboratory of Electronics, Massachusetts Institute of Technology, E. GINOSSAR, Advanced Technology Institute and Department of Physics, University of Surrey, I. SIDDIQI, QNL, UC Berkeley — When the conventional vacuum fluctuations of the electromagnetic environment are replaced by the asymmetric, reduced fluctuations associated with squeezed vacuum, the radiative properties of an atom are predicted to be dramatically altered. We present measurements of the transverse and longitudinal decay rates of a superconducting qubit that couples predominantly to a continuum of squeezed electromagnetic vacuum. We use a lumped element Josephson parametric amplifier to squeeze vacuum fluctuations by up to 10dB with a bandwidth of 20 MHz. The amplifier output is directly coupled to a transmon qubit in a microwave cavity. We observe a dependence of the transverse decay rate on the relative angle between the squeezed axis and the qubit. In particular, at certain angles, we observe an improvement in the qubit T2 time above its nominal value.

11:51AM G25.00004 Lossless, coherent Josephson three-wave combiner[1] , BALEEGH ABDO, KATRINA SLIWA, FLAVIUS SCHACKERT, Applied Physics Department, Yale University, NICOLAS BERGEAL, LPEM-UMR8213/CNRS-ESPCI ParisTech-UPM, MICHAEL HATRIDGE, LUIGI FRUNZIO, DOUGLAS STONE, MICHEL DEVORET, Applied Physics Department, Yale University — We designed and operated a three-wave beam-splitter/combiner, based on Josephson parametric converters, which performs frequency conversion without introducing losses and thus adding no noise to the processed signal. We in particular show that the unitary signal-idler scattering parameters of the device can be fully modulated in-situ by varying the intensity and phase of the pump tone feeding the system. By operating the device as a 50/50 beam-combiner, we interfere coherently two input coherent microwave beams with different frequencies and demonstrate that the resulting interference fringes generated by the relative phase of the pump is in agreement with theoretical predictions. Potential applications of the device include quantum information transduction and realization of an ultra-sensitive interferometer with controllable feedback.

12:03PM G25.00005 Extracting Past-Future Vacuum Correlations Using Circuit QED[1] , BORJA PEROPADRE[2], Instituto de Física Fundamental, CSIC, CARLOS SABIN[3], School of Mathematical Sciences, The University of Nottingham, MARCO DEL REY, Instituto de Física Fundamental, CSIC, EDUARDO MARTIN-MARTINEZ[4], Institute for Quantum Computing, Dept. Applied Math., University of Waterloo & Perimeter Institute — In this work we propose a realistic circuit QED experiment to test the extraction of past-future vacuum entanglement to a pair of superconducting qubits. A qubit P –for past– interacts with a quantum field along an open transmission line for an interval T_{on} and then, after a time-lapse T_{off} of no interaction, a second qubit F –for future– starts interacting for a time T_{on} in a symmetric fashion. After this protocol, past-future quantum correlations will have transferred to the qubits, even if the qubits do not coexist at the same time. We show that this experiment can be realized with current technology and discuss its utility as a possible implementation of a quantum memory.

12:15PM G25.00006 Observation of the squeezed state of microwave photon by resolving the even-number Fock states in circuit QED[1] , KYUNGSUN MOON, Dept. of Physics, Yonsei Univ. — We theoretically propose an elegant way to detect the microwave parametric down conversion in the circuit QED system. The qubit energy splitting E_{01} is tuned to be quite close to the fundamental frequency ω_1 of the microwave photon and the frequency of the pump beam is chosen to be ω_2. We place the qubit at the two-thirds away from the center of the central resonator, which will make the capacitive coupling to the third harmonic mode to be negligible. Since the qubit acts as an optical coupler in our system, one may expect that the following process $a_2^+ a_1^+ a_3$ may appear and compete with the squeezing process $a_1^+ a_1^+ a_2$, which will seriously degrade the quality of squeezing by mixing into the channel. Since the coupling to the third harmonic mode is negligible for our system, we expect instead to observe the clear squeezing of the microwave photon with frequency ω_1. We calculate the absorption spectrum of the qubit, which is experimentally measurable and will clearly reveal the squeezed states as the coherent superposition of the even-number Fock states.

12:27PM G25.00007 Generation of Nonclassical States of Microwave Radiation via Single Photon Detection , EMILY PRITCHETT, LUKE GOVIA, FRANK WILHELM, Saarland University — We describe the creation of nonclassical states of microwave radiation via ideal dichotomic single photon detection, i.e., a detector that only indicates presence or absence of photons. Ideally, such a detector has a back action in the form of the subtraction operator. Using the non-linearity of this back action, it is possible to create nonclassical states of microwave radiation, including squeezed and cat-like states, starting from a coherent state. We discuss the applicability of this protocol to current experimental designs of Josephson Photomultipliers (JPMs).

12:39PM G25.00008 Path Entanglement of Continuous-Variable Quantum Microwaves , E. P. MENZEL, F. DEPPE, P. EDER, L. ZHONG, M. HAEBERLEIN, A. BAUST, E. HOFFMANN, A. MARX, R. GROSS, Walther-Meissner-Institut and TU Muenchen, Germany, R. DI CANDIA, E. SOLANO, Universidad del Pais Vasco UPV/EHU and Ikerbasque, Spain, D. BALLESTER, University College London, UK, M. IHMIG, TU Muenchen, Germany, K. INOMATA, RIKEN Advanced Science Institute, Japan, T. YAMAMOTO, NEC Smart Energy Research Laboratories and RIKEN, Japan, Y. NAKAMURA, The University of Tokyo and RIKEN, Japan — Entanglement is a quantum mechanical phenomenon playing a key role in quantum communication and information processing protocols. Here, we report on frequency-degenerate entanglement between continuous-variable quantum microwaves propagating along two separated paths. In our experiment, we combine a squeezed and a vacuum state via a beam splitter. Overcoming the challenges imposed by the low photon energies in the microwave regime, we reconstruct the squeezed state and, independently from this, detect and quantify the produced entanglement via correlation measurements (E. P. Menzel *et al.*, arXiv:1210.4413). Our work paves the way towards quantum communication and teleportation with continuous variables in the microwave regime.
This work is supported by SFB 631, German Excellence Initiative via NIM, EU projects SOLID, CCQED and PROMISCE, MEXT Kakenhi "Quantum Cybernetics", JSPS FIRST Program, the NICT Commissioned Research, EPSRC EP/H050434/1, Basque Government IT472-10, and Spanish MICINN FIS2009-12773-C02-01.

12:51PM G25.00009 Cooper Pair Transistor Embedded in a dc-Biased High-Q Microwave Cavity , JULIANG LI, FEI CHEN, JOEL STETTENHEIM, Dartmouth College, A.J. SIROIS, University of Colorado, Boulder, R.W. SIMMONDS, National Institute of Standards and Technology, Boulder, M.P. BLENCOWE, A.J. RIMBERG, Dartmouth College — A Cooper pair transistor (CPT) is directly coupled to a high-Q microwave cavity, which allows introduction of a dc bias to the CPT without significantly degrading the cavity Q. In the subgap region of the CPT, the dc bias generates a tunable oscillating current through the CPT via the ac Josephson effect. Evidence of such self-oscillations has been observed as current peaks in our dc measurements, which are in good agreement with calculated cavity modes, and indicate the strong coupling between the CPT and the cavity. Tunneling Cooper pairs can both emit photons into and absorb photons from microwave cavity modes. Photons emitted into the cavity are also directly probed and are in good agreement with dc measurements. Recent experimental results including the importance of careful filtering of the DC bias lines will be discussed. This work is supported by the NSF, AFOSR and DARPA.

1:03PM G25.00010 Photon Emission from a Self-Oscillating Cavity-Embedded Cooper Pair Transistor[1] , FEI CHEN, JULIANG LI, JOEL STETTENHEIM, Dartmouth College, A. J. SIROIS, University of Colorado, Boulder, R. W. SIMMONDS, National Institute of Standards and Technology, Boulder, M. P. BLENCOWE, A. J. RIMBERG, Dartmouth College — A strongly non-linear superconducting device consisting of a Cooper pair transistor embedded in a dc voltage biased microwave cavity is investigated. The cavity-embedded Cooper pair transistor (CCPT) is driven via the ac Josephson effect by an applied dc bias and exhibits self-oscillation without an external ac drive. Photon emission arising from both sequential tunneling and cotunnelling processes of Cooper pairs has been observed. We have characterized the measured photon field by heterodyne quadrature detection and have reconstructed its quasi-probability distribution by implementing an iterative procedure for maximum-likelihood estimation of its density matrix. The CCPT offers an interesting system for studying nonlinear quantum dynamics and the quantum-to-classical transition.

[1]This work is supported by the NSF, AFOSR and DARPA

1:15PM G25.00011 The Quantum-Classical Correspondence for a Self-Oscillating Cavity-Embedded Cooper Pair Transistor System[1] , ERIND BRAHIMI, FEI CHEN, JULIANG LI, JOEL STETTENHEIM, Dartmouth College, ANDREW ARMOUR, University of Nottingham, ALEX RIMBERG, MILES BLENCOWE, Dartmouth College — We provide a theoretical model for our recent experiment involving a dc voltage biased Cooper pair transistor (CPT) that strongly drives a high quality factor microwave cavity via the ac Josephson effect. Depending on the tunable dc voltage bias, the model shows that the CPT can generate a range of non-trivial cavity quantum states involving large average microwave photon number. Using a Floquet basis approach to solving for the quantum dynamics and a Wigner function representation of the system state, we compare some of the model photon state predictions with experiment. The good agreement validates the low noise, dc biased cavity-CPT system for exploring the quantum-classical correspondence in strongly nonlinear, macroscopic systems.

1:27PM G25.00012 Shaping the Spontaneous Emission Pulse from a Superconducting Qubit[1] , SRIKANTH SRINIVASAN, YANBING LIU, GENGYAN ZHANG, Princeton University, TERRI YU, Yale University, JAY GAMBETTA, IBM T.J. Watson Research Center, STEVEN GIRVIN, Yale University, ANDREW HOUCK, Princeton University — We report on measurements of spontaneous emission in a circuit quantum electrodynamics system. A superconducting qubit with tunable coupling to a coplanar waveguide cavity is operated in a regime where the qubit relaxation time, and consequently the spontaneous emission rate, is dominated by the interaction strength. This fast control knob on the coupling strength is used to shape the emitted single photon's wavepacket. The independent control over the coupling allows the dressed qubit frequency to remain truly constant during the emission. The wavepacket shape becomes important in experiments where quantum information needs to be transported between various nodes in a quantum network. The transfer can happen with a very high fidelity if the wavepacket is time-symmetric, since emission by the source and absorption by the destination become time reversed processes.

[1]Authors would like to thank IARPA for their generous support.

1:39PM G25.00013 Emergent Non-Adiabatic Wavefunctions for Strongly Dissipative Qubits , SOUMYA BERA, SERGE FLORENS, Institute Neel, Grenoble, HAROLD BARANGER, Duke University, NICOLAS ROCH, ENS, Paris, AHSAN NAZIR, Imperial College London, ALEX W. CHIN, University of Cambridge — We show that a qubit strongly interacting with its environment leads to highly entangled states with emerging non-adiabatic features (Schrodinger-cat-like states of the environment). The model we consider is a two-level-system (qubit) coupled to a continuum of quantum oscillators (bosons), which can be realized, for instance, by a superconducting qubit coupled to a transmission line of photons. We show that the joint system is remarkably well described by a generalized variational coherent state ansatz, an ansatz which is justified by comparing with exact quantum tomography of the states found through Numerical Renormalization Group (NRG) calculations. Our coherent state ansatz includes not only the well-known polaronic contributions but also non-adiabatic anti-polaron contributions; these later contributions are critical for an accurate description of the strong coupling regime. We calculate the entanglement entropy of the qubit plus a single bosonic mode with the rest of the system; this joint entropy peaks for a bosonic mode around the Kondo scale, an effect due to the anti-polaronic contribution.

1:51PM G25.00014 Coherence and indistinguishability of single electron wavepackets emitted by independent sources , GWENDAL FEVE, ERWANN BOCQUILLON, VINCENT FREULON, JEAN-MARC BERROIR, Laboratoire Pierre Aigrain, Ecole Normale Supérieure, PASCAL DEGIOVANNI, Ecole Normale Supérieure de Lyon, BERNARD PLAÇAIS, Laboratoire Pierre Aigrain, Ecole Normale Supérieure, ANTONELLA CAVANNA, YONG JIN, Laboratoire de Photonique et Nanostructures — Using two independent on-demand electron sources [1], the emission of two single-electron wavepackets is triggered at different inputs of an electronic beamsplitter. Whereas classical particles would be randomly partitioned by the splitter, we observe two-particle interferences resulting from quantum exchange in this electronic analog [2,3] of the optical Hong-Ou-Mandel [4] experiment. Both electrons, emitted in indistinguishable wavepackets with synchronized arrival time on the splitter, exit in different outputs as recorded by the low frequency current noise. Full random partitioning is recovered when the arrival of one electron is delayed with respect to the other. This two-electron interference experiment demonstrates the possibility to generate on-demand coherent and indistinguishable single-electron wavepackets for quantum information processing in quantum conductors. Session G26 GQI: Quantum Characterization, Verification, and Validation II 328 - Robin Blume-Kohout, Sandia National Laboratories

11:15AM G26.00001 Quantum process verification methods and applications to superconducting qubits[1] , JAY GAMBETTA, IBM T.J. Watson Research Center — Determining how well a quantum gate is implemented on a quantum device is of fundamental importance. Such a characterization allows a direct comparison between different architectures for computation as well as an understanding of the performance of the building blocks of a quantum computer. In this talk I will show that the standard approach of process tomography is grossly inaccurate in the case where the states and measurement operators used to interrogate the system are generated by gates that have some systematic error, a situation all but unavoidable in any practical setting. I will then present some recent proposals with experimental implementations that are resilient to this type of noise.

[1]We acknowledge support from IARPA under contract W911NF-10-1-0324.

11:51AM G26.00002 Quantum State Tomography of Spin Qubits , OLIVER DIAL, Harvard University (now IBM) — Quantitative and accurate state tomography is becoming increasingly necessary to establish gate fidelities, entanglement measures, and optimize the increasingly complex gate sequences needed to perform experiments. In singlet-triplet spin qubits, to perform state tomography single-qubit rotations are used to map different axes of the Bloch sphere to the singlet-triplet axis, followed by projective measurement onto the singlet-triplet axis. The two nominally orthogonal rotations needed are provided by two physically distinct mechanisms: magnetic field gradients and exchange rotations. The complex interplay between these mechanisms, noise sources, and pulse distortions make it difficult to accurately predict the angle and axis of rotations from first principles, leading to a circular problem: how can one calibrate tomographic rotations without any calibrated tomography? We describe and experimentally demonstrate a method which, using minimal assumptions, makes it possible to detect and correct for both axis errors in tomography and losses during rotations associated with state tomography. Unlike conventional tomography tuning schemes, this technique is not iterative, allowing it be used to post-correct data with minimal overhead and effort. The technique is easily adaptable to other implementations of qubits, and should be of value wherever accurate tomography is needed but tuning up a complete set of ideal rotations is unnecessary. Finally, we will discuss the influence of non-Markovian noise on state tomography and possible approaches to circumvent state estimation errors arising thereof. Together these techniques allow us to perform state tomography with unprecedented precision in spin qubits.

12:27PM G26.00003 Compressed Sensing Quantum Process Tomography of Superconducting Qubit Gates[1] , ANDREY RODIONOV, ALEXANDER N. KOROTKOV, University of California, Riverside, ROBERT L. KOSUT, SC Solutions, Sunnyvale, CA, MATTEO MARIANTONI, DANIEL SANK, JAMES WENNER, JOHN M. MARTINIS, University of California, Santa Barbara — We characterize the quantum gates based on superconducting phase qubits using the Quantum Process Tomography (QPT) with strongly reduced set of initial states and/or measurement configurations. This is done by applying the Compressed Sensing (CS) method to estimate the process matrix χ. Using experimental data for 2-qubit controlled-Z gate, we show that the CS-QPT method gives an estimate of the χ-matrix with reasonably high fidelity, compared with full QPT. The method works well even when the amount of used data is so small, that the standard QPT would have an underdetermined system of equations. The CS-QPT is also applied to the analysis of a three-qubit Toffoli gate with numerically added noise. Similarly, we show that the method works reasonably well for a strongly reduced set of data, including the underdetermined case.

[1]Supported by IARPA/ARO and ARO MURI

12:39PM G26.00004 Xmons: Transmon qubits for a scalable architecture , RAMI BARENDS, J. KELLY, D. SANK, J. BOCHMANN, B. CAMPBELL, Y. CHEN, B. CHIARO, E. JEFFREY, M. MARIANTONI, A. MEGRANT, J. MUTUS, C. NEILL, P. O'MALLEY, S. OHYA, P. ROUSHAN, A. VAINSENCHER, J. WENNER, T. WHITE, A.N. CLELAND, J.M. MARTINIS, UC Santa Barbara — We have developed a new type of transmon qubit, the Xmon, which shows long coherence, allows for straightforward coupling to multiple elements, and has a low parasitic coupling. The Xmon is UCSB's building block for a superconducting multiqubit processor. The Xmon easily couples to four elements and is dispersively read out, making it compatible for use in a surface code quantum processor. At present, we are experimentally testing multiqubit chips for demonstrating single and two qubit state preparation and gates with high fidelity.

12:51PM G26.00005 Benchmarking gates in a qubit-bus-qubit tunable transmon architecture , JULIAN KELLY, R. BARENDS, J. BOCHMANN, B. CAMPBELL, Y. CHEN, B. CHIARO, E. JEFFREY, M. MARIANTONI, A. MEGRANT, J. MUTUS, C. NEILL, P. O'MALLEY, S. OHYA, P. ROUSHAN, D. SANK, A. VAINSENCHER, J. WENNER, T. WHITE, A.N. CLELAND, J.M. MARTINIS, UC Santa Barbara — Using a newly developed frequency tunable transmon qubit ("Xmon"), we are beginning to construct the fundamental gates and architecture for a quantum computer. We show experimental data for gates in a qubit-bus-qubit configuration. We quantify the fidelity of a set of single qubit gates with both randomized benchmarking and tomography. We also investigate the fast swap style cPhase gate [Strauch PRL 2003], where the control qubit is swapped into the bus and interacts dispersively with the target qubit, as a fundamental two-qubit interaction.

1:03PM G26.00006 Characterization of addressability by simultaneous randomized benchmarking[1] , JOHN SMOLIN, IBM Research, JAY GAMBETTA TEAM, ANTONIO CORCOLES TEAM, SETH MERKEL TEAM, IBM QUANTUM COMPUTING GROUP TEAM — The control and handling of errors arising from cross-talk and unwanted interactions in multi-qubit systems is an important issue in quantum information processing architectures. We introduce a benchmarking protocol that provides information about the amount of addressability present in the system and implement it on coupled superconducting qubits. The protocol consists of randomized benchmarking each qubit individually and then simultaneously, and the amount of addressability is related to the difference of the average gate fidelities of those experiments. We present the results on two similar superconducting transmon qubits with different amounts of cross-talk and unwanted interactions, which agree with predictions based on simple models for the amount of residual coupling.

[1]We acknowledge support from IARPA under contract W911NF-10-1-0324.

1:15PM G26.00007 Implementation of a Robust Tomography Toolbox , COLM RYAN, BLAKE JOHNSON, MARCUS DA SILVA, Raytheon BBN Technologies, SHELBY KIMMEL, Massachusetts Institute of Technology, THOMAS OHKI, Raytheon BBN Technologies, IBM MQCO TEAM — Recent advances in coherence times and control techniques have dramatically improved gate fidelities in superconducting qubits. Already, estimates of these small errors are dominated by errors in the state preparation and measurment pulses of quantum process tomography. Randomized benchmarking (RB) provides a way to isolate gate errors, but only for estimating the fidelity of Clifford operations. Here we implement several extensions to RB that provide more detailed information about specific gates while maintaining the key RB advantage of being robust to state and measurement errors. We will show: interleaved benchmarking results to characterize the average fidelity of specific gates; simultaneous benchmarking to characterize addressabilty errors with multiple qubits; and robust tomography results that show a full unital characterization of a trace preserving operation. Taken together these provide a full suite of characterization tools useful to any quantum experimentalist.

1:27PM G26.00008 Robust Tomography using Randomized Benchmarking[1] , MARCUS SILVA, Quantum Information Processing Group, Raytheon BBN Technologies, SHELBY KIMMEL, Center for Theoretical Physics, MIT, BLAKE JOHNSON, COLM RYAN, THOMAS OHKI, Quantum Information Processing Group, Raytheon BBN Technologies — Conventional randomized benchmarking (RB) can be used to estimate the fidelity of Clifford operations in a manner that is robust against preparation and measurement errors — thus allowing for a more accurate and relevant characterization of the average error in Clifford gates compared to standard tomography protocols. Interleaved RB (IRB) extends this result to the extraction of error rates for individual Clifford gates. In this talk we will show how to combine multiple IRB experiments to extract all information about the unital part of *any* trace preserving quantum process. Consequently, one can compute the average fidelity to *any* unitary, not just the Clifford group, with tighter bounds than IRB. Moreover, the additional information can be used to design improvements in control.

[1]MS, BJ, CR and TO acknowledge support from IARPA under contract W911NF-10-1-0324.

1:39PM G26.00009 Experimental realization of non-abelian geometric gates with a superconducting three-level system , ABDUFARRUKH ABDUMALIKOV, J. M. FINK, K. JULIUSSON, M. PECHAL, S. BERGER, A. WALLRAFF, S. FILIPP, Department of Physics, ETH Zurich — Geometric gates hold promise to provide the building blocks for robust quantum computation. In our experiments, we use a superconducting three-level system (transmon) to realize non-adiabatic non-abelian geometric gates. As computational basis we choose the ground and second excited states, while the first excited state acts as an ancilla state. The gates are realized by applying two resonant drives between the transmon levels. During the geometric gate ration of the amplitudes of the two drive tone is kept constant. Different gates are obtained for different ratio of the drive tones. We implement a Hadamard, a NOT and a phase gates with the fidelities of 95%, 98%, and 97% as determined by full process tomography and maximum likelihood methods. We explicitly show the non-abelian nature of gates by applying two non-commuting gates in alternating order. The demonstrated holonomic gates are not exclusive to superconducting quantum devices, but can also be applied to other three level systems with similar energy level structure.

1:51PM G26.00010 Implementation of a five-cavity / four-qubit 3D circuit QED system[1] , DOUGLAS MCCLURE, CHAD RIGETTI, JAY GAMBETTA, STEFANO POLETTO, ERIK LUCERO, MARK KETCHEN, MATTHIAS STEFFEN, IBM T.J. Watson Research Center — Surface code error correction schemes, which have emerged as a guiding paradigm for the development of small prototype quantum processors, have a natural implementation on a skew square 2D lattice of cavities and qubits. We describe the experimental realization of a modular segment containing a unit cell of this lattice in a device consisting of five 3D waveguide cavities and four superconducting transmon qubits. In this system, we demonstrate high-fidelity one- and two-qubit gates with low crosstalk. Moreover, this device provides an extensible framework for tests of protocols needed for error correction in much larger systems.

[1]We acknowledge support from IARPA under contract W911NF-10-1-0324.

2:03PM G26.00011 Quantum lost property: A possible operational meaning for the Hilbert-Schmidt product , MATTHEW PUSEY, TERRY RUDOLPH, Imperial College London — Minimum error state discrimination between two mixed states ρ and σ can be aided by the receipt of "classical side information" specifying which states from some convex decompositions of ρ and σ apply in each run. I will quantify this phenomena by the average trace distance, and give lower and upper bounds on this quantity as functions of ρ and σ. The lower bound is simply the trace distance between ρ and σ, trivially seen to be tight. The upper bound is $\sqrt{1-\mathrm{tr}(\rho\sigma)}$, and we conjecture that this is also tight. I will show how to reformulate this conjecture in terms of the existence of a pair of "unbiased decompositions", which may be of independent interest. Time permitting, I will outline the evidence for this conjecture. Based on http://arxiv.org/abs/1208.2550

Session G27 GQI: Quantum Error Correction and Quantum Control 329 - Leonid Pryadko, University of Californa, Riverside

11:15AM G27.00001 Towards Fault-Tolerant Dynamical Decoupling , GREGORY QUIROZ, DANIEL LIDAR, University of Southern California — Dynamical Decoupling (DD) is a error suppression technique which combats decoherence by applying strong and fast pulses to a quantum system to effectively average system-environment interactions. Although many DD constructions have been designed which exhibit suppression of interactions to high orders in time-dependent perturbation theory, this result is predominately in the ideal pulse limit as DD effectiveness degrades significantly in the presence of additional errors generated by faulty pulses. Here, we present a decoupling scheme which provides robustness to certain forms of pulse errors and utilizes concatenation to attain high order error suppression. Using numerical simulations, we convey the advantages of this scheme over additional robust DD constructions and provide evidence for the possibility of arbitrary order error suppression in the presence of pulse errors.

11:27AM G27.00002 Fault-Tolerant Storage of Quantum Information by Large Block Codes , CHING-YI LAI, TODD BRUN, University of Southern California, USC TEAM — An important issue in the implementation of a quantum computer is to protect quantum information from decoherence. Concatenated quantum codes and topological quantum codes are extensively studied for fault-tolerant quantum computation. However, there is not much research on large block codes in any fault-tolerant scheme. Here we propose a method for storage of quantum information by a large block code, which has a high code rate and high distance. To access or protect the quantum information stored in a large block code requires only the fault-tolerant implementation of the gates from the Clifford group. We derive the lifetime of the quantum information stored in a large block code by CSS code construction.

11:39AM G27.00003 Progress in analytical investigations of the achievement of fault tolerance in quantum computing[1] , GERALD GILBERT, YAAKOV WEINSTEIN, MITRE Quantum Information Science Group — We describe progress made in understanding and assuring fault tolerance in quantum computation. We introduce and explore analytical techniques for explicitly determining the logical state of a quantum computer undergoing dynamical evolution according to an arbitrary quantum algorithm. We carry out detailed analyses of the effects of errors, paying special attention to the general case of non-equiprobable errors, i.e., the important and realistic situation in which the probabilities for sigma_x, sigma_y and sigma_z errors are not necessarily the same (sigma_x, sigma_y and sigma_z are the Pauli operators).

[1]The authors acknowledge support from the MITRE Innovation Program

11:51AM G27.00004 Simulating the Transverse Ising Model on a Quantum Computer: Error Correction with the Surface Code , HAO YOU, MICHAEL GELLER, PHILLIP STANCIL, Department of Physics and Astronomy, University of Georgia — We estimate the resource requirements for the quantum simulation of the ground state energy of the one-dimensional quantum transverse Ising model (TIM), based on the surface code implementation of a fault-tolerant quantum computer. The surface code approach has one of the highest known tolerable error rates ($\sim$1%) which makes it currently one of the most practical quantum computing schemes. Compared to results of the same model using the concatenated Steane code, the current results indicate that the simulation time is comparable but the number of physical qubits for the surface code is 1-2 orders of magnitude larger than that of the concatenation code. Considering that the error threshold requirements of the surface code is four orders of magnitude higher than the concatenation code, building a quantum computer with a surface code implementation appears more promising given current physical hardware capabilities. We would like to acknowledge valuable discussions with Joydip Ghosh, Matteo Mariantoni, Andrew Sornborger, James Whitfield and Zhongyuan Zhou. This work was supported by the National Science Foundation through grant CDI 1029764.

12:03PM G27.00005 Multi-Run Quantum Error Correction in Coupled Electron-Nuclear Systems[1] , ROBABEH RAHIMI DARABAD, DANIEL K. PARK, Institute for Quantum Computing, and Department of Physics and Astronomy, University of Waterloo, JONATHAN BAUGH, Institute for Quantum Computing, and Department of Chemistry, University of Waterloo, RAYMOND LAFLAMME, Institute for Quantum Computing, and Department of Physics and Astronomy, University of Waterloo, Perimeter Institute for Theoretical Physics — It has been a milestone in realizing quantum computing, to enhance our control over physical systems so that making quantum processors performing accurately and precisely in presence of environmental noise. For practical uses, quantum error correction should be employed in multi-run cycles in order to keep the encoded qubit, that is carrying the information, safe from noise. We have been working towards implementing multi-run quantum error correction in molecular systems that involve electron and nuclear spins. Electron spins of a molecular sample are used for pumping up the nuclear spin polarizations, in addition to addressing and manipulating the nuclear spins. The required experimental conditions for having access to refreshable ancilla qubits are very much enhanced by a careful design of the molecular sample. We report the progress and prospects towards overcoming the experimental challenges in terms of sample preparation; irradiation imposed free electron samples, free radical molecular spin systems, and triplet state photoexcitable co-crystal samples.

[1]Industry of Canada, and CIFAR

12:15PM G27.00006 Resilience of topological error-correction codes to concurrent qubit and measurement errors , RUBEN S. ANDRIST, Department of Physics, ETH Zurich, HECTOR BOMBIN, Perimeter Institute for Theoretical Physics, MIGUEL ANGEL MARTIN-DELGADO, Departamento de Fisica, Universidad Complutense, HELMUT G. KATZGRABER, Department of Physics and Astronomy, Texas A&M University and ETH Zurich — Topologically-protected quantum computing schemes avert decoherence by storing quantum information in nonlocal degrees of freedom while actively correcting for local errors. To date, the effects of individual error sources, such as, for example, bit flips, phase flips, or measurement errors have been studied. A more realistic assessment of the error stability is given by studying the combination of different error sources, such as bit flips and measurement errors. So far this has only been accomplished under the assumption that both bit-flip and measurement errors occur with the same probability [New J. Phys. 13, 083006 (2011)]. Here we study in detail the interplay between bit-flip and measurement errors, and analyze the resilience of topological error-correction codes to concurrent, nonsymetric bit flips and measurement errors. The error threshold is determined by mapping the problem onto classical, disordered lattice gauge theories, that are investigated using large-scale Monte Carlo simulations and improved estimators for systems with local gauge symmetries.

12:27PM G27.00007 Quantum error correction with soft-pulse dynamically corrected gates with always-on qubit couplings on bipartite lattices[1] , AMRIT DE, LEONID P. PRYADKO, University of California - Riverside — We suggest a scalable implementation of a universal set of high fidelity quantum gates on a bipartite lattice with always-on Ising couplings using dynamical decoupling (DD) sequences with second-order self-refocusing pulses. In addition to decoupling the unwanted parts of the inter-qubit interaction, the constructed gates also protect the qubits against low-frequency phase noise. This allows heterogeneous concatenation of DD and quantum error correction. We illustrate the technique by simulating the encoding/decoding and repeated ancilla based measurements for 4- and 5-qubit quantum error detecting/correcting codes on a spin chain and on a star graph.

[1]This research was supported in part by the U.S. Army Research O?ce under Grant No. W911NF-11-1-0027, and by the NSF under Grant No. 1018935

12:39PM G27.00008 Protecting OAM states of light from the decoherence effects of a turbuent atmosphere , JOSE RAUL GONZALEZ ALONSO, TODD BRUN, University of Southern California — While there are many advantages to using the polarization of photons to encode quantum information, a major disadvantage is that the limited dimension of the Hilbert space that describes the polarization state allows only the encoding of one qubit per photon. However, if one uses the the orbital angular momentum (OAM) of photons then the Hilbert space that describes the OAM state of a photon is infinite dimensional. Thus, it is possible to encode more than one qubit per photon. This advantage can be exploited in quantum key distribution (QKD) and in quantum secure direct communications. However, unlike the polarization of a photon, the OAM is prone to the decoherence effects produced by interactions with a turbulent atmosphere. In this work, we derive an expression for these decohering effects, and numerically simulate them to find a Kraus error map. We then theoretically demonstrate encoding and information recovery methods that could mitigate such unwanted effects.

12:51PM G27.00009 Unitary Transformations in a Large Hilbert Space , BRIAN ANDERSON, HECTOR SOSA MARTINEZ, AARON SMITH, University of Arizona, CARLOS RIOFRIO, CHARLIE BALDWIN, IVAN DEUTSCH, University of New Mexico, POUL JESSEN, University of Arizona — Quantum systems with Hilbert space dimension greater than two (qudits) provide an alternative to qubits as carriers of quantum information, and may prove advantageous for quantum information tasks if good laboratory tools for qudit manipulation and readout can be developed. We have implemented a protocol for arbitrary unitary transformations in the 16 dimensional hyperfine ground manifold of Cesium 133 atoms, using phase modulated rf and microwave magnetic fields to drive the atomic evolution. Our phase modulation waveforms are designed numerically using a variant of the highly efficient GRAPE algorithm. The fidelity of the resulting transformations is verified experimentally through randomized benchmarking, which indicates an average fidelity better than 97% across a sample of random unitaries. Our toolbox for quantum control is in principle applicable for a broad class of physical systems, such as large spins or anharmonic oscillators.

1:03PM G27.00010 Resonant Microwave Control of a Symmetric Exchange-Only Spin Qubit[1] , J. MEDFORD, Harvard University, J. BEIL, Center for Quantum Devices, Niels Bohr Institute, University of Copenhagen, J. M. TAYLOR, Joint Quantum Institute, NIST, H. LU, A. C. GOSSARD, Materials Department, University of California, Santa Barbara, C. M. MARCUS, Center for Quantum Devices, Niels Bohr Institute, University of Copenhagen — We demonstrate two-axis control of an exchange-only spin qubit in a GaAs triple quantum dot using a resonant microwave excitation. The qubit is operated in a regime where two separate exchange interactions are active simultaneously, suppressing leakage out of the qubit subspace and providing some immunity to charge noise. Spectroscopic probes of the qubit reveal that the resonance frequency can be adjusted between 100 MHz and 1.5 GHz with a voltage applied to the middle quantum dot. We find a coherence time $T_2 \sim 20$ μs for a 64 pulse Carr-Purcell-Meiboom-Gill dynamical decoupling sequence. Finally, analysis of the coherence time for multiple sequences reveals a power spectrum $S(\omega) \sim \omega^{-0.9}$, which suggests that the fluctuating Overhauser fields are not the dominant source of dephasing in this system.

[1]Support from IARPA MQCO, DARPA QuEST, and NSF Materials World Network.

1:15PM G27.00011 Decay of the rotating-frame spin echo and its application to sensing the local environment of a NV center[1] , VAGHARSH MKHITARYAN, XIAO-XUAN HUANG, VIATCHESLAV DOBROVITSKI, Ames Laboratory and Iowa State University, Ames, Iowa 50011, USA — We study a NV electron spin subjected to a strong driving field, which reverses its sign with the period τ (multi-pulse Solomon echo), and analyze the rotating-frame echo decay at long times (large number of reversals). The form and the rate of the echo decay is calculated analytically and numerically, by modelling the decohering spin environment as a magnetic noise. For short τ the decay is strongly suppressed, being of the 4th order in τ (vs. 3rd order in the regular Carr-Purcell decoupling, and 2nd order in the standard continuous-wave decoupling). This ensures exceptional decoupling stability with respect to the slow fluctuations of the external magnetic field. Moreover, we find that the decay rate depends non-monotonically on the correlation time of the environment, decreasing for both very fast and very slow spin baths. Using these results, we demonstrate how the multi-pulse version of the Solomon echo can be harnessed to sense and analyze in detail the local spin environment of the NV center.

1:27PM G27.00012 Sudden Decoherence Transitions for Quantum Discord[1] , HYUNGJUN LIM, ROBERT JOYNT, University of Wisconsin-Madison — We formulate the computation of quantum discord in terms of the generalized Bloch vector, focusing on the case of 2 qubits. This provides useful insights on the time evolution of quantum coherence for the open stem, particularly the comparison of entanglement and discord. We introduce a numerical method for calculating quantum discord for a special class of multipartite states. In agreement with previous work in low-dimensional cases (L. Mazzola et al., Phys. Rev. Lett. 104, 200401 (2010), we find situations in which there is a sudden transition from classical to quantum decoherence characterized by the discord remaining relatively robust (classical decoherence) until a certain point from where it begins to decay quickly whereas the classical correlation decays more slowly (quantum decoherence). We propose a general condition to observe this phenomenon.

[1]This project was supported by DRPA-QuEst Grant No. MSN118850.

1:39PM G27.00013 Correlation Dynamics of Qubit-Qutrit Systems in a Classical Dephasing Environment[1] , GOKTUG KARPAT, BARIS CAKMAK, ZAFER GEDIK, Faculty of Engineering and Natural Sciences, Sabanci University — We study the time evolution of classical and quantum correlations for hybrid qubit-qutrit systems in independent dephasing environments. Our discussion involves a comparative analysis of the Markovian dynamics of negativity, quantum discord, geometric measure of quantum discord and classical correlation. In the presence of multilocal dephasing noise, we demonstrate the phenomenon of frozen quantum discord for qubit-qutrit states. We show that geometric discord can also get frozen for a class of separable states in this case. On the other hand, when only the qutrit is under the action of a dephasing channel, we observe that the partial coherence left in the system might enable quantum discord to remain invariant throughout the whole dynamics even though the entanglement in the qubit-qutrit state disappears in a finite time interval.

Tuesday, March 19, 2013 11:15AM - 2:15PM –

Session G28 GSNP: Statistical Mechanics of Social Systems 336 - Stefan Boettcher, Emory University

11:15AM G28.00001 Characterizing production and consumption in Physics , QIAN ZHANG, FABIO CIULLA, BRUNO GONCALVES, NICOLA PERRA, ALESSANDRO VESPIGNANI, Northeastern University — We analyze the entire database of publications in the American Physical Society and generate longitudinal (50 years) citation networks at two different geographical levels. We define the knowledge diffusion proxy and Scientific Production Ranking algorithms to capture the complex nature of citation networks, and to provide a global view of spatial distributions of production and consumption of knowledge in Physics as well as its temporal evolution. Using the knowledge diffusion proxy we identify the key actors in producing and consuming knowledge in Physics as a function of time. The ranking results from the Scientific Production Ranking algorithm allow us to characterize the top countries/cities in the world for Physical sciences. Among all the results, we find that in 50 years major states and cities in US stably rank on the top and have been main knowledge producers, whereas the major European countries, Japan and Russia have greatly improved their their ranking since 1990. Interestingly, we notice that China and Spain as well as major cities in those countries have gradually become major knowledge consumers in the last two decades.

11:27AM G28.00002 The possible role of resource requirements and academic career-choice risk on gender differences in publication rate and impact[1] , XIAOHAN ZENG, Northwestern University, JORDI DUCH, MARTA SALES-PARDO, FILIPPO RADICCHI, Universitat Rovira i Virgili, SHAYNA OTIS, TERESA WOODRUFF, LUIS AMARAL, Northwestern University — Many studies demonstrate that there is still a significant gender bias, especially at higher career levels, in many areas including science, technology, engineering, and mathematics (STEM). We investigated field-dependent, gender-specific effects of the selective pressures individuals experience as they pursue a career in academia within seven STEM disciplines. We built a unique database that comprises 437,787 publications authored by 4,292 faculty members at top United States research universities. Our analyses reveal that gender differences in publication rate and impact are discipline-specific. Our results also support two hypotheses. First, the widely-reported lower publication rates of female faculty are correlated with the amount of research resources typically needed in the discipline considered, and thus may be explained by the lower level of institutional support historically received by females. Second, in disciplines where pursuing an academic position incurs greater career risk, female faculty tend to have a greater fraction of higher impact publications than males. Our findings have significant, field-specific, policy implications for achieving diversity at the faculty level within the STEM disciplines.

11:39AM G28.00003 Analysis of Science and Technology Trend Based on Word Usage in Digitized Books , JINHYUK YUN, Department of Physics, KAIST, South Korea, PAN-JUN KIM, Asia Pacific Center for Theoretical Physics, South Korea, HAWOONG JEONG, Department of Physics & KI for BioCentury, KAIST, South Korea — Throughout mankind's history, forecasting and predicting future has been a long-lasting interest to our society. Many fortune-tellers have tried to forecast the future by "divine" items. Sci-fi writers have also imagined what the future would look like. However most of them have been illogical and unscientific. Meanwhile, scientists have also attempted to discover future trend of science. Many researchers have used quantitative models to study how new ideas are used and spread. Besides the modeling works, in the early 21st century, the rise of data science has provided another prospect of forecasting future. However many studies have focused on very limited set of period or age, due to the limitations of dataset. Hence, many questions still remained unanswered. Fortunately, Google released a new dataset named "Google N-Gram Dataset." This dataset provides us with 5 million words worth of literature dating from 1520 to 2008, and this is nearly 4% of publications ever printed. With this new time-varying dataset, we studied the spread and development of technologies by searching "Science and Technology" related words from 1800 to 2000. By statistical analysis, some general scaling laws were discovered. And finally, we determined factors that strongly affect the lifecycle of a word.

11:51AM G28.00004 The Knowledge Economy , BRUNO GONÇALVES, Aix-Marseille Université, NICOLA PERRA, FABIO CIULLA, QIAN ZHANG, ALESSANDRO VESPIGNANI, Northeastern University — Although the study of scientific and citation networks is well developed, the way in which ideas and concepts flow between scientific groups scattered around the world is still an open problem. We take a first step in this direction by using the citation patterns over the course of decades to shed light on how areas and fields in the general area of physics have evolved both temporally and geographically. By geocoding the affiliations associated with each article published by the APS journals to the country level, and by borrowing concepts from the field of economics and international trade we can explore how ideas produced in one country are exported, through citations, to other countries. An objective way of ranking countries based on their contributions to the overall scientific effort is also proposed as well as a map of how the different subfields of Physics are related to each other.

12:03PM G28.00005 Power Law Distributions of Patents as Indicators of Innovation , DION O'NEALE, Industrial Research Ltd, SHAUN HENDY, Victoria University of Wellington — The total number of patents produced by a country (or the number of patents produced per capita) is often used as an indicator for innovation. Such figures however give an overly simplistic measure of innovation within a country. Here we present evidence that the distribution of patents amongst applicants within many countries is well-fitted to a power law distribution with exponents that vary between 1.66 (Japan) and 2.37 (Poland). We suggest that this exponent is a useful new metric for studying innovation. Using simulations based on simple preferential attachment-type rules that generate power laws, we find we can explain some of the variation in exponents between countries, with countries that have larger numbers of patents per applicant generally exhibiting smaller exponents in both the simulated and actual data. Similarly we find that the exponents for most countries are inversely correlated with other indicators of innovation, such as research and development intensity or the ubiquity of export baskets. This suggests that in more advanced economies, which tend to have smaller values of the exponent, a greater proportion of the total number of patents are filed by large companies than in less advanced countries.

12:15PM G28.00006 Discrete Lognormal Model as an Unbiased Quantitative Measure of Scientific Performance Based on Empirical Citation Data[1] , JOAO MOREIRA, XIAOHAN ZENG, LUIS AMARAL, Northwestern University — Assessing the career performance of scientists has become essential to modern science. Bibliometric indicators, like the h-index are becoming more and more decisive in evaluating grants and approving publication of articles. However, many of the more used indicators can be manipulated or falsified by publishing with very prolific researchers or self-citing papers with a certain number of citations, for instance. Accounting for these factors is possible but it introduces unwanted complexity that drives us further from the purpose of the indicator: to represent in a clear way the prestige and importance of a given scientist. Here we try to overcome this challenge. We used Thompson Reuter's Web of Science database and analyzed all the papers published until 2000 by $\sim$1500 researchers in the top 30 departments of seven scientific fields. We find that over 97% of them have a citation distribution that is consistent with a discrete lognormal model. This suggests that our model can be used to accurately predict the performance of a researcher. Furthermore, this predictor does not depend on the individual number of publications and is not easily "gamed" on.

12:27PM G28.00007 Information theory in econophysics: stock market and retirement funds

, EUGENIO VOGEL, G. SARAVIA, Universidad de La Frontera, Temuco, Chile, J. ASTETE, J. DÍAZ, R. ERRIBARREN, F. RIADI, Universidad Austral de Chile, Valdivia, Chile — Information theory can help to recognize magnetic phase transitions, what can be seen as a way to recognize different regimes. This is achieved by means of zippers specifically designed to compact data in a meaningful way at is the case for compressor wlzip [1]. In the present contribution we first apply wlzip to the Chilean stock market interpreting the compression rates for the files storing the minute variation of the IPSA indicator. Agitated days yield poor compression rates while calm days yield high compressibility. We then correlate this behavior to the value of the five retirement funds related to the Chilean economy. It is found that the covariance between the profitability of the retirement funds and the compressibility of the IPSA values of previous day is high for those funds investing in risky stocks. Surprisingly, there seems to be no great difference among the three riskier funds contrary to what could be expected from the limitations on the portfolio composition established by the laws that regulate this market.

12:39PM G28.00008 DebtRank a centrality measure for financial systems and beyond

, GUIDO CALDARELLI, IMT Alti Studi Lucca, STEFANO BATTISTON, MICHELANGELO PULIGA, RAHUL KAUSHIK, PAOLO TASCA, Chair of System Design ETH Zurich, CHAIR OF SYSTEM DESIGN COLLABORATION, IMT ALTI STUDI LUCCA COLLABORATION — Use of network theory made possible to measure quantitatively many features of social and technological systems. In this spirit, inspired by traditional measures of centrality we introduce DebtRank a novel measure of systemic impact. We that we intend the risk of default of a large portion of the financial system, depends on the network of financial exposures among institutions. As an application, we analyse a new and unique dataset on the USD 1.2 trillion FED emergency loans program to global financial institutions during 2008–2010. We find that a group of 22 institutions, which received most of the funds, form a strongly connected graph where each of the nodes becomes systemically important at the peak of the crisis. Moreover, a systemic default could have been triggered even by small dispersed shocks. Other application to different systems are also presented.

12:51PM G28.00009 ABSTRACT WITHDRAWN –

1:03PM G28.00010 Cascading failures in Europe's transmission system[1]

, ANDREA ASZTALOS, SAMEET SREENIVASAN, BOLESLAW SZYMANSKI, G. KORNISS, Rensselaer Polytechnic Institute — Cascading failures constitute an important vulnerability of infrastructure networks, hence understanding the origin and propagation of these failures is of great interest. To this end, we study cascades of overload failures within the framework of the cascade model introduced by Motter and Lai (2002) applied for flows that have a distributed character. We investigate numerically the properties of these failures in the high-voltage European electric power transmission system from 2002 (Zhou and Bialek, 2005). The network consists of 1254 nodes (substations) specified by geographical locations, and 1812 links (transmission lines) that are assumed to be undirected. We find that assigning excess capacities in proportion to initial loads does not significantly mitigate cascading failures. Moreover, increasing the fractional excess capacity does not yield monotonically increasing gains. Using a simple model of spatial network - random geometric graph - we investigate methods beyond the proportional excess capacity allocation in order to improve the gains in mitigating such failures.

1:15PM G28.00011 Cascade Failures in Power Grids with Distributed Generation[1]

, ANTONIO SCALA, CNR-ISC, SAKSHI PAHWA, CATERINA SCOGLIO, Kansas State University, ISC INSTITUTE FOR COMPLEX SYSTEMS TEAM, DEPARTMENT OF ELECTRICAL AND COMPUTER ENGINEERING TEAM — Power grids are nowadays experiencing a transformation due to the introduction of Distributed Generation based on Renewable Sources. At difference with classical Distributed Generation, where local power sources mitigate anomalous user consumption peaks, Renewable Sources introduce in the grid intrinsically erratic power inputs. By introducing a simple schematic (but realistic) model for power grids with stochastic distributed generation, we study the effects of erratic sources on the robustness of several IEEE power grid test networks with up to 2×10^3 buses. We find that increasing the penetration of erratic sources causes the grid to fail with a sharp transition. We compare such results with the case of failures caused by the natural increasing power demand.

1:27PM G28.00012 Distribution of Betweenness in Networks Failing by Overload

, MARK TUCHMAN, GILAD BARACH, SERGEY BULDYREV, GABRIEL CWILICH, Department of Physics, Yeshiva University — We study the Motter and Lai [1] model of cascading failures based on the betweenness centrality of the nodes, for a random regular network. After removing a fraction of the nodes, we study the size of the giant component at the end of the cascade of failures, as a function of the fraction of the nodes that survived the initial attack. We find that the type of transition through which the network disintegrates changes from first order to second order as the maximum capacity of the nodes increases. We examine the distribution of the betweenness of the nodes in the vicinity of the critical fraction of initial surviving nodes, and we look at the distribution at different stages of the cascade. We explore the disintegration of the network when the size of the initial attack approaches the percolation threshold of the network. We compare our results with an analytical ansatz of the role of subcomponents of the network nearly isolated from the giant component.

1:39PM G28.00013 Cascading Failures in Networks with Proximate Dependent Nodes

, YOSEF KORNBLUTH, STEVEN LOWINGER, GABRIEL CWILICH, SERGEY BULDYREV, Department of Physics, Yeshiva University — We study a system composed of two identical, random regular, interdependent networks. When a fraction of nodes in the first network are eliminated by failure or attack, further nodes that become isolated or lose their dependent node fail in turn, initiating a process of cascading failures. In contrast to previous models, these networks are constructed such that interdependent nodes are no more than a set distance away, with the distance defined by the number of intervening nodes. We find that as the maximum distance and the degree of connectivity increase, the disintegration of the system shifts from being similar to that of a single network to resembling the failure found in other models of interdependent networks. As the distance and degree increase, the collapse at the critical threshold changes from a second-order transition to a first-order one. The critical threshold monotonically increases as the distance increases.

1:51PM G28.00014 Comparative advantage between traditional and smart navigation systems[1] , JEONGKYU SHIN, Dept. of Physics, Pohang University of Science and Technology, Pohang 790-784, Korea, PAN-JUN KIM, Asia-Pacific Center for Theoretical Physics, Pohang 790-784, Korea, SEUNGHWAN KIM, Dept. of Physics, Pohang University of Science and Technology, Pohang 790-784, Korea — The smart navigation system that refers to real-time traffic data is believed to be superior to traditional navigation systems. To verify this belief, we created an agent-based traffic model and examined the effect of changing market share of the traditional shortest-travel-time algorithm based navigation and the smart navigation system. We tested our model on the grid and actual metropolitan road network structures. The result reveals that the traditional navigation system have better performance than the smart one as the market share of the smart navigation system exceeds a critical value, which is contrary to conventional expectation. We suggest that the superiority inversion between agent groups is strongly related to the traffic weight function form, and is general. We also found that the relationship of market share, traffic flow density and travel time is determined by the combination of congestion avoidance behavior of the smartly navigated agents and the inefficiency of shortest-travel-time based navigated agents. Our results can be interpreted with the minority game and extended to the diverse topics of opinion dynamics.

2:03PM G28.00015 The Cancho i Ferrer - Solé model does not explain Zipf's Law[1] , RONALD DICKMAN, Universidade Federal de Minas Gerais, NICHOLAS MOLONEY, London Mathematical Laboratory — We examine the cost-minimization problem posed by Ferrer i Cancho and Solé in their information-theory based communication model [1], proposed in efforts to explain Zipf's Law (that is a power-law frequency-rank relation for words in written texts). Using a simple inequality, we obtain the exact minimum-cost solution as a function of the parameter λ, as obtained previously via other methods [2-4]. (λ defines the relative weights of speaker's and listener's costs.) We show that at the phase transition, the minimum-cost solutions do not correspond to a power law except for a vanishingly small subset, even if we impose the additional condition of equal costs to speaker and listener. Finally we consider the model at finite temperature using mean-field theory and entropic Monte Carlo simulation, and find a line of *discontinuous* phase transitions in the λ-T plane. The simulations yield no evidence of a power-law frequency-rank distribution. 1. R. Ferrer i Cancho and R. V. Solé, PNAS **100**, 788 (2003).

Session G29 FIAP: FIAP Prize Session 337 - Mark Bernius, Dow Chemical Company

11:15AM G29.00001 George E. Pake Prize Lecture: Crystalline Silicon Photovoltaics: Accelerating to Grid Parity , MARK PINTO, Applied Materials — Lost in recent headlines about solar company failures, reduced government support and depressed stock valuations is the fact that photovoltaic (PV) systems continue to be installed at an extremely healthy rate – a ten-fold increase between 2007 and 2012, to a cumulative 100GWp of installations worldwide. The primary factor behind this remarkable growth has been cost reduction at the installed system level afforded by manufacturing and technology improvements to the crystalline silicon (c-Si) PV cell. In fact in the past 2 years, c-Si module cost learning curves have accelerated over their historical norms as a function of both volume and time, and as a result c-Si PV has reached parity with conventional forms of electricity in 20+ countries worldwide. In this presentation future c-Si technology paths will be reviewed along with market implications, leading to the projection that between 2015 and 2020, c-Si based PV electricity will be cost-effectively delivered to >95% of the world's population.

11:51AM G29.00002 Prize for Industrial Applications of Physics Lecture: A physicist in Business , JOHN WOOLLAM, Active — In the 1980s I inherited a famous ellipsometry laboratory. To speed up data acquisition and analysis I associated myself with creative scientists and engineers. We started a company which grew. Together we rapidly improved acquisition speed, accuracy, precision, spectral range, and types of applications. Yet, a business is much more than technology. In this talk I outline how a high-tech business functions, and illustrate the role of physicists and engineers in making a company successful. It is fast-paced, exciting, and enormously gratifying to provide quality instruments for researchers and industry.

Tuesday, March 19, 2013 11:15AM - 2:15PM –

Session G30 DCMP: Self-Assembly 338 - Bulent Akgun, National Institute of Standards and Technology

11:15AM G30.00001 Is a hierarchical dynamics the best route to the self-assembly of a hierarchical structure? , THOMAS HAXTON, STEPHEN WHITELAM, Lawrence Berkeley National Laboratory — Mimicking nature's ability to assemble functional hierarchical materials will require understanding how to promote the self-assembly of structure on multiple lengthscales while avoiding kinetic traps. We use computer simulation to study the self-assembly of a simple hierarchical structure, a square lattice whose repeat unit is a tetramer. Although the target material is organized hierarchically, it self-assembles most reliably when its assembly pathway consists of the sequential addition of monomers to a single structure. Hierarchical assembly pathways via dimer and tetramer intermediates result in lower yield, because these intermediates tend to associate in ways incompatible with the target structure. In addition, assembly via tetramers results in the formation of incomplete building blocks (trimers) that cannot combine to form the target crystal. We use analytic theory to relate assembly pathways to the underlying thermodynamics, identifying two principles for optimal assembly: 1) make the free energy gap between the target phase and the most stable fluid phase comparable to the thermal energy, and 2) ensure that no other dense phases (liquids or close-packed solids of monomers or oligomers) or fluids of incomplete building blocks fall within this gap.

11:27AM G30.00002 Optimized assembly and steady-state length-scale control in dissipative systems of photo-switchable colloids[1] , ANTONIO OSORIO-VIVANCO, University of Michigan, MONICA OLVERA DE LA CRUZ, Northwestern University, SHARON GLOTZER, University of Michigan — Photo-switchable nanoparticles, such as those developed by Wei et al.,[2] can be assembled into a broad range of structures using light exposure as a control parameter. Jha et al.[3] explored the evolution of these structures using kinetic Monte Carlo simulations. In this work, we build on these studies using Molecular Dynamics with a Langevin thermostat to, by judicious choice of exposure parameters that control the dissipative nature of the system, engineer and optimize the self-assembly pathways as well as control the length scales of the steady-state structures.

11:39AM G30.00003 Self organization of exotic oil-in-oil phases driven by tunable electrohydrodynamics , ANAND YETHIRAJ, Department of Physics & Physical Oceanography, Memorial University of Newfoundland, St. John's, NL, Canada, ATUL VARSHNEY, SHANKAR GHOSH, S. BHATTACHARYA, Department of Condensed Matter Physics and Materials Science, Tata Institute of Fundamental Research, Homi Bhabha Road, Mumbai 400-005, India — The tuning of electrostatic interactions has helped to elucidate when coherent crystalline structures or incoherent amorphous structures form in colloidal systems. However, there is little understanding of self-organization in situations where hydrodynamic interactions are also present. We present a minimal two-component oil-in-oil model system where we can control the strength and length scale of the electrohydrodynamic interactions by tuning the amplitude and frequency of the imposed electric field. As a function of the hydrodynamic length scale, we observe a rich phenomenology of exotic structure and dynamics, from incoherent cloud-like structures and chaotic droplet dynamics, to polyhedral droplet phases, to coherent droplet arrays.

11:51AM G30.00004 Novel Behavior in Self-Assembled Superparamagnetic Nanoparticle Monolayers at the Air-Water Interface , JACOB STANLEY, LEANDRA BOUCHERON, YELING DAI, Department of Physics, University of California, BINHUA LIN, MATI MERON, Argonne National Lab and University of Chicago, OLEG SHPYRKO, Department of Physics, University of California — Iron oxide nanoparticles, coated with an oleic acid ligand, have been found to form self-assembled monolayers when deposited at the air-water interface. Even for low particle densities these particles aggregate into hexagonally close-packed islands which merge into a uniform layer at higher densities. Using Grazing Incidence Small Angle X-Ray Scattering (GISAXS) we were able to measure the first through fifth order diffraction peaks. By analyzing the positions and shapes of these peaks we investigated the in-plane structure of these monolayers and characterized how the structure changes as a function of compression in a Langmuir-Blodgett trough. Since iron oxide nanoparticles are known to be super-paramagnetic, we sought to investigate the role magnetic effects may have on the interparticle interactions and ordering within the film. We performed Grazing Incidence Diffraction (GID) measurements on the film while varying an external magnetic field. We will discuss the results of our findings.

12:03PM G30.00005 Structure and dynamics of self-assembly , HENRIK VAN LENGERICH, RICHARD JAMES, University of Minnesota — We investigate structures that are composed of many identical building blocks. Of particular interest are equilibrium structures where every building block sees the same environment - we call these "objective structures". For example, carbon nanotubes and virus capsids are both objective structures. The dynamics of assembly is investigated through experiments and simulations. The experiment consist of a macro-scale shaker containing identical neutrally buoyant magnetic particles. Simulations model the translation and rotation of particles using Langevin dynamics. This kind of modelling is applicable to both our experiment and to molecular assembly.

12:15PM G30.00006 How to Maximize Self-Assembly in Free Surface Films by Resonant Wavelength Excitations , SANDRA TROIAN, NAN LIU, California Institute of Technology, MC 128-95, Pasadena, CA 91125 — Application of an external force probe on self-assembly processes in thin liquid films can offer significant insight into the fundamental dynamics of pattern formation. Less appreciated is the fact that modulation of such forces can induce resonant excitation effects in linearly unstable systems. While temporal modulation is rather common, there has been less emphasis on spatial forcing as a method for corralling emergent structure formation; such studies have also been strictly limited to 2D. In this talk, we call attention to a novel 3D hydrodynamic instability in nanoscale films whose free surface is exposed to a large uniform thermal gradient. Such films spontaneously develop arrays of nanopillars whose uniformity is often compromised by nanoscale inhomogeneities in film thickness, temperature and surface defects. In this talk we focus on resonant wavelength excitations induced by spatial modulation of the external thermal field near the linear stability point. Linear stability, weakly nonlinear analysis and simulations of the full nonlinear interface equation demonstrate the existence of a spatial coherence regime leading to more rapid growth and denser packing of perfectly uniform arrays, of significance to recent advances in lithographic patterning.

12:27PM G30.00007 Analysis of pattern formation in systems with competing range interactions , VYACHESLAV R. MISKO, HAIJUN ZHAO, FRANCOIS M. PEETERS, University of Antwerp — Pattern formation is governed by competing interaction. Examples include: Langmuir monolayers, colloids and gels, ferrofluids, magnetic garnet thin films, type-I superconductors, the pasta phase in neutron stars, etc. We analyzed pattern formation and identified various morphologies in a system of particles interacting through a non-monotonic potential with a competing range interaction characterized by a repulsive core ($r < r_c$) and an attractive tail ($r > r_c$), using molecular-dynamics simulations [1]. Depending on parameters, the interaction potential models the inter-particle interaction in various physical systems ranging from atoms, molecules and colloids to vortices in superconductors. We constructed a "morphology diagram" in the plane "critical radius r_c – density n" and proposed a new approach to characterize the patterns. Namely, we elaborated a set of quantitative criteria in order to identify the different pattern types, using the radial distribution function (RDF), the local density function and the occupation factor. We also discuss the dynamics of the obtained patterns [2].

12:39PM G30.00008 Crystallographic Tailoring: Self-Assembling Complex Crystals Through Building Block Design , PABLO F. DAMASCENO, Applied Physics, MICHAEL ENGEL, Chemical Engineering Department, SHARON C. GLOTZER, Materials Science and Engineering Department, University of Michigan, Ann Arbor MI — A primary challenge for the development of bulk, scalable and high yield materials with interesting properties is the limited number of structures that can be obtained via self-assembly of nano and micrometer sized particles. To increase this variability, several suggestions have been proposed among which the exploration of new anisotropic building blocks have received much attention. Here we present the results of a systematic and extensive computational study of hard polyhedral particles [1,2] and their subsequent assembly into a diverse range of complex structures. Our results show that 1) by utilizing more complex, anisotropically designed building blocks new structures can be self-organized purely from entropy maximization principles and, 2) a predictive criteria for assembly can be formulated, allowing for specific choices of building blocks given a target structure to be self-assemble. [1] Pablo F. Damasceno, Michael Engel & Sharon C. Glotzer. ACS NANO (2012). [2] Pablo F. Damasceno, Michael Engel & Sharon C. Glotzer. SCIENCE (2012).

12:51PM G30.00009 Design Rules for the Self-Assembly of Voronoi Particles[1] , BENJAMIN SCHULTZ, University of Michigan, Dept. of Phys., PABLO DAMASCENO, University of Michigan, Dept. of App. Phys., MICHAEL ENGEL, University of Michigan, Dept. of Chem. Eng., SHARON GLOTZER, University of Michigan, Dept. of Phys., App. Phys., Chem. Eng. — Recent theoretical advances have developed methodologies for predicting the assembly of hard, polyhedral particles. In this work, we use the Voronoi tessellation to generate polyhedral shapes that form space-filling superlattices that are isostructural to well-known atomic crystals. We focus on the assembly of these polyhedra into crystalline superlattices with orientational and positional order. Analogous to potentials designed to stabilize crystals at zero temperature, these particles are designed to stabilize the space-filling tiling at infinite pressure. We study a set of these particles in simulation and characterize how their symmetry and other geometric features affect their assembly characteristics at finite pressure. We calculate the relative stability of competing structures for several shapes that do not assemble their target structure and discuss how features of the shape affect this stability. From our conclusions, we demonstrate how to move beyond the concept of Voronoi tessellation for the design of hard polyhedral particles targeted for self-assembly.

[1]This material is based upon work supported by, or in part by, the U. S. Army Research Office under Grant Award No. W911NF-10-1-0518.

1:03PM G30.00010 Self-assembly of binary space-tessellating compounds , MIHIR KHADILKAR, UMANG AGARWAL, FERNANDO ESCOBEDO, Cornell University — Self-assembly of polyhedral nanoparticles and their mixtures has been a topic of interest in both experimental and simulation studies due to its potential to help engineer novel materials. Hard-core mixtures that tessellate space are particularly interesting since they are expected to form entropy-driven high-pressure ordered structures. Using Monte Carlo simulations, we study three such binary tessellating mixtures; namely, cuboctahedra + octahedra (Mixture 1), octahedra + tetrahedra (Mixture 2), and truncated cubes + octahedra (Mixture 3). We see that upon gradual compression of the isotropic system, Mixtures 1 and 2 form a metastable, glassy disordered phase while Mixture 3 demixes into a disordered phase and an unusual 'semi-crystalline' phase where truncated cubes form a cubic lattice while the octahedra remain disordered occupying interstitial pockets. While our results identify some relations between properties of individual species and their mixtures, they also illustrate the potential of tessellating mixtures as designable materials that can lead to novel equilibrium phases or serve as entropic glass formers. Preliminary results on non-tessellating binary mixtures will also be briefly discussed to provide a broader context of the results for the tessellating cases.

1:15PM G30.00011 Targeted self-assembly of complex lattices and meta materials from isotropic interactions , OSKAR LINDGREN, ERIK EDLUND, MARTIN NILSSON JACOBI, Chalmers University of Technology — I will present an analytical method for designing isotropic interactions causing particles to self-assemble into complex lattices. The method is direct as opposed to previous trial and error schemes where the interactions are modified and tested until the desired pattern self-assembles. Since a naive implementation of the design scheme generally yields interaction potentials too complicated to implement experimentally, we provide a systematical simplification scheme to minimize the interaction potentials' complexity without changing which pattern is produced by the self-assembly process. We also prove that our suggested simplification scheme is optimal. The method has been tested using simulated systems and proven to work for a wide range of patterns, ranging from chiral 2D surfaces to 3D diamond-like crystals. The recent improvements in simplicity for the designed potentials makes experimental realization feasible. The interactions can also be designed so that the self-organizing systems obtain different material properties like directional sound propagation or stealth-like properties via the diffraction pattern.

1:27PM G30.00012 Rheology of Self-Assembling Colloidal Chains[1] , KAZEM V. EDMOND, STEFANO SACANNA, ZACHARY D. FORBES, ANDREW D. HOLLINGSWORTH, DAVID J. PINE, New York University — We probe the rheology of self-assembling chains of "pacman" particles using a Zimm viscometer, a modified Couette apparatus. Pacman particles are microscopic spherical particles specially designed to have a spherical indentation on their surface. In the presence of a depletant, overlap between the indentation and another particle's surface maximizes the excluded volume between the two interacting particles, resulting in a selective attraction between them. Careful tuning of the interaction strength in a suspension of particles induces the formation of long chains. Shearing this material can twist, stretch, and break the chains, causing the material to exhibit unique rheological properties.

[1]NSF Grant No. DMR-1105455

1:39PM G30.00013 Shaping Colloids for Self-Assembly , STEFANO SACANNA, NYU, GI-RA YI, Sungkyunkwan University, DAVID PINE, NYU — The creation of a new material often starts from the design of its constituent building blocks at a smaller scale. From macromolecules to colloidal architectures, to granular systems, the interactions between basic units of matter can dictate the macroscopic behavior of the resulting engineered material and even regulate its genesis. Information can be imparted to the building units by altering their physical and chemical properties. In particular, the shape of building blocks plays a fundamental role at the colloidal scale, as it can govern the self-organization of particles into hierarchical structures and ultimately into the desired material. Herein we report a simple and general approach to generate an entire zoo of new anisotropic colloids. Our method is based on a controlled deformation of multiphase colloidal particles that can be selectively liquified, polymerized, dissolved and functionalized in bulk. We further demonstrate control over the particle functionalization and coating by realizing patchy and Janus colloids.

1:51PM G30.00014 Probing transition pathways of self-assembled colloidal clusters[1] , REBECCA W. PERRY, Harvard University, School of Engineering and Applied Sciences, MIRANDA HOLMES-CERFON, New York University, Courant Institute of Mathematical Sciences, MICHAEL P. BRENNER, Harvard University, School of Engineering and Applied Sciences, VINOTHAN N. MANOHARAN, Harvard University, School of Engineering and Applied Sciences and the Department of Physics — Clusters of colloidal particles bound by weak interactions explore rich energy landscapes characterized by a few minima and many higher-energy, non-rigid configurations. To investigate how such systems transit through their energy landscapes, we designed a two-dimensional system that lends itself to simple observations with brightfield video microscopy. In our aqueous system, a short-range depletion interaction strongly confines the diffusion of the spherical polystyrene colloids to a shallow volume close to a glass cover slip. The same depletion interaction provides reversible bonds between the spheres. Analyzing time series of clusters of 3, 4, and 6 spheres allows us to compare the free energy of rigid configurations to that of the transition states and to measure the kinetics of the transitions. Combining experimental measurements of the kinetics with a recent theory using a geometrical approach for calculating energy landscapes leads to a new understanding of how hydrodynamics effect transitions rates between energy minima.

2:03PM G30.00015 Optical assembly of thermodynamically stable colloidal clusters mediated by depletion , BHASKAR JYOTI KRISHNATREYA, STEFANO SACANNA, KAZEM EDMOND, DAVID PINE, DAVID G. GRIER, New York University — Colloidal particles with complementary shapes can self-organize into composite structures under the influence of entropic attractions mediated by depletion. What structures can form is governed by the colloidal components' shapes. The structures' stability can be tuned by adjusting the strength of the depletion attraction. Even when a particular colloidal cluster configuration is thermodynamically stable, achieving the stable structure typically involves substantial kinetic barriers. We overcome these kinetic barriers by assembling geometrically organized colloidal clusters using holographic optical tweezers in three dimensions. Once formed, the structures are stable and undergo three-dimensional shape fluctuations that can be measured with video microscopy.

Session G31 DPOLY: Padden Award Symposium 339 - Nitash Balsara, University of California at Berkeley

11:15AM G31.00001 Scaling Reversible Adhesion in Synthetic and Biological Systems , MICHAEL BARTLETT, Polymer Science and Engineering Department, University of Massachusetts Amherst, DUNCAN IRSCHICK, Department of Biology, University of Massachusetts Amherst, ALFRED CROSBY, Polymer Science and Engineering Department, University of Massachusetts Amherst — High capacity, easy release polymer adhesives, as demonstrated by a gecko's toe, present unique opportunities for synthetic design. However, without a framework that connects biological and synthetic adhesives from basic nanoscopic features to macroscopic systems, synthetic mimics have failed to perform favorably at large length scales. Starting from an energy balance, we develop a scaling approach to understand unstable interfacial fracture over multiple length scales. The simple theory reveals that reversibly adhesive polymers do not rely upon fibrillar features but require contradicting attributes: maximum compliance normal to the substrate and minimum compliance in the loading direction. We use this counterintuitive criterion to create reversible, easy release adhesives at macroscopic sizes (100 cm^2) with unprecedented force capacities on the order of 3000 N. Importantly, we achieve this without fibrillar features, supporting our predictions and emphasizing the importance of subsurface anatomy in biological adhesive systems. Our theory describes adhesive force capacity as a function of material properties and geometry and is supported by over 1000 experiments, spanning both synthetic and biological adhesives, with agreement over 14 orders of magnitude in adhesive force.

11:27AM G31.00002 Cavitation in block copolymer modified epoxy[1] , CARMELO DECLET-PEREZ, LORRAINE FRANCIS, FRANK BATES[2], Department of Chemical Engineering and Materials Science, University of Minnesota — Today, brittleness in epoxy networks limits most commercial applications. Significant toughness can be imparted by adding small amounts of micelle forming block copolymers (BCP) without compromising critical properties such as high use temperature and modulus. Curing the network locks in the self-assembled BCP micellar structures formed in the monomer resin providing control of the resulting morphology. Despite significant research over the last decade, a complete description of the parameters influencing toughness in block copolymer modified epoxies is still lacking. In this presentation we compare the ultimate mechanical behavior of epoxies modified with spherical micelle forming BCP's containing rubbery and glassy cores using real-time in-situ small-angle X-ray scattering (SAXS) performed during tensile deformation. Striking differences in the 2D SAXS patterns were documented for epoxies modified with rubbery (PEP) versus glassy (PS) micelle cores. Rubbery cores dilate by 100% in volume upon specimen yielding, while the glassy micelle cores deform at approximately constant volume. These results provide direct evidence of a cavitation mediated mechanism for toughness in block copolymer modified epoxies. We further interpret characteristic butterfly features in the 2D SAXS patterns in terms of epoxy network deformation.

11:39AM G31.00003 Polymer Welding and Self-healing: Strength Through Entanglements[1] , TING GE, MARK O. ROBBINS, Johns Hopkins University, DVORA PERAHIA, Clemson University, GARY S. GREST, Sandia National Laboratories — Polymer interfaces are crucial in determining the mechanical strength of many systems. A common means of welding joints or self-healing cracks is to apply heat and allow polymers to interdiffuse. As the microscopic mechanism of interface strengthening is difficult to isolate experimentally, we probe the molecular origins of interfacial strength using large scale molecular simulations of welding and self-healing of cut systems. Systems are heated well above the glass temperature T_g and then quenched below T_g for mechanical testing. The interfacial strength is characterized by the maximum shear stress $\sigma_{\max}$ before failure. As strength grows, the dominant failure mode changes from chain pullout at the interface to chain scission, as in the bulk. In all simulations, $\sigma_{\max}$ saturates long before polymers diffuse by their own size. Bulk strength is observed for miscible welds, while strength is suppressed for cut systems due to short chain segments that remain near the interface. Entanglements are tracked using the Primitive Path Analysis. We find that the bulk response is not fully recovered until the density of entanglements at the interface reaches the bulk value. Moreover, the increase of $\sigma_{\max}$ before saturation is proportional to the number of interfacial entanglements between chains from opposite sides, which correlates linearly with the interdiffusion depth.

11:51AM G31.00004 Magnetically aligned polymer-nanowire composites for solar energy harvesting[1] , PAWEL MAJEWSKI, CANDICE PELLIGRA, CHINEDUM OSUJI, Yale University — We present a solution-based approach of producing aligned arrays of ZnO nanowire-polythiophene composites for photovoltaic applications. We employ a two-step hierarchical self-assembly to maximize the efficiency of electron and hole transport in the system. First, we coat the wires with the polymer utilizing nanowire surface-directed crystallization and alignment of the polymer backbones along the long axes of the wires, then we employ magnetic fields to direct the assembly of the composites into the ordered arrays. We present quantitative SAXS data taken in-situ during the alignment process addressing the influence of paramagnetic doping level of ZnO and the magnetic field strength on the quality of the alignment. We compare the electrical conductivity of the aligned arrays of the composites to non-aligned ones and discuss the possible degree of conductivity enhancement upon the alignment in this and in analogous systems.

12:03PM G31.00005 Self-similarity and energy dissipation in stepped polymer films[1] , JOSHUA MCGRAW, Department of Physics & Astronomy and the BIMR, McMaster University, Hamilton, ON, Canada, THOMAS SALEZ, Laboratoire de Physico-Chimie Theorique, UMR CNRS Gulliver 7083, ESPCI, Paris, France, OLIVER BAEUMCHEN, Department of Physics & Astronomy and the BIMR, McMaster University, Hamilton, ON, Canada, ELIE RAPHAEL, Laboratoire de Physico-Chimie Theorique, UMR CNRS Gulliver 7083, ESPCI, Paris, France, KARI DALNOKI-VERESS, Department of Physics & Astronomy and the BIMR, McMaster University, Hamilton, ON, Canada — We have recently learned how to prepare polymer films whose only feature is a step in the height profile. In the melt, Laplace pressure drives a flow that levels the topography, with the excess energy of the height step being dissipated by viscosity. It has been observed that the profiles are self-similar in time for a variety of molecular weights and geometries. Given the surface tension, this simple observation allows a precise measurement of the viscosity by comparison with numerical solutions of the thin film equation. It is also possible to derive a master expression for the time dependence of the excess surface energy as a function of the material properties and film geometry. Thus, all geometries and molecular weights fall on a single temporal curve. The material parameter allowing this collapse is the capillary velocity – the ratio of the surface tension to the viscosity.

12:15PM G31.00006 The Consequence of Donor-acceptor Miscibility on Charge Transport and Photovoltaic Device Performance , KIARASH VAKHSHOURI, DEREK KOZUB, Chemical Engineering, The Pennsylvania State University, CHENCHEN WANG, ALBERTO SALLEO, Materials Science and Engineering, Stanford University, ENRIQUE GOMEZ, Chemical Engineering, The Pennsylvania State University — Recent energy-filtered transmission electron microscopy studies revealed that amorphous mixed phases are ubiquitous within mesostructured polythiophene/fullerene mixtures. The role of mixing within nanophases on charge transport of organic semiconductor mixtures, however, is not fully understood. Through the combination of Flory-Huggins theory and energy-filtered transmission electron microscopy, we have estimated the miscibility limit of polythiophene/fullerene blends. We have also demonstrated the interplay between miscibility and percolation to describe field-effect mobilities as a measure of the conductive pathways present in a model organic semiconductor mixture (amorphous polythiophene/fullerene blends). Our studies reveal that the miscibility of the components strongly affects electron transport within amorphous blends. Immiscibility promotes efficient electron transport by promoting percolating pathways within organic semiconductor mixtures. However, strongly immiscible systems would readily phase separate into large domains, preventing efficient charge separation in organic photovoltaics. Consequently, an optimum degree of miscibility between donor/acceptor mixtures exists for the application of such mixtures to organic solar cells.

12:27PM G31.00007 Theory of Polymers in Poor Solvent: Phase Equilibrium, Nucleation Behavior and Globule-to-Coil Transition , RUI WANG, ZHEN-GANG WANG, California Institute of Technology — We study the phase equilibrium and nucleation behavior of polymers in poor solvent by accounting for the large, localized fluctuations in the form of single-chain globules and multi-chain clusters. The density profile and free energy of the globule and clusters are obtained by self-consistent-field theory, which is then used in the dilute solution thermodynamics to investigate the cluster size distribution, solubility limit, as well as nucleation in the supersaturated state. Our results show that the solubility of the polymer in the dilute side of the solution is enhanced by several orders of magnitude relative to the prediction of the Flory-Huggins (F-H) theory, which scales with the chain length to the 2/3 power rather than a linear power as predicted from the F-H theory. In the supersaturated state, we work out an effective spinodal where the nucleation barrier to phase separation via growth of the clusters becomes comparable to the thermal energy. For a given supersaturation, we find that the nucleation barrier is quadratic in the chain length, suggesting a much slower precipitation rate for longer polymer chains. Tracking the density profile of the globule with decreasing χ, we find the critical χ for the globule-to-coil transition of an infinitely long chain.

12:39PM G31.00008 Dramatic role of fragility in determining the magnitude of T_g perturbations to ultrathin film layers and near-infinitely dilute blend components , CHRISTOPHER EVANS, JOHN TORKELSON, Northwestern University, NORTHWESTERN UNIVERSITY TEAM — Using fluorescence, we measure the glass transition temperatures (T_g) of ultrathin (11-14 nm) polystyrene (PS, bulk T_g = 103 °C) layers which can be tuned over $\sim$ 80 °C when sandwiched between two bulk neighboring layers of poly(4-vinyl pyridine) (P4VP), polycarbonate, poly(vinyl chloride) (PVC) or poly(tert-butyl acrylate). Between P4VP, an ultrathin PS layer has its dynamics slaved and reports the T_g of bulk P4VP. In contrast, an ultrathin PS layer is weakly perturbed (T_g = 97 °C) when placed between PVC. These perturbations to the PS T_g become evident even for layers 10s of nanometers in thickness. Additionally, binary blends were prepared with 0.1 wt% PS components surrounded by the same neighboring polymers as in the trilayers. The T_g reported by an ultrathin PS layer and a 0.1 wt% PS blend component are the same for a given polymer pair indicating that the T_g perturbations in these two systems arise from a common physical origin. The strength of perturbations to PS correlate with the fragility of the neighboring domain in both blends and multilayers indicating that it is a key variable in determining the strength of T_g-confinement effects. Fragility also tracks with the magnitude of T_g-confinement effects observed in single layer polymer films supported on silicon wafers.

12:51PM G31.00009 Confined Crystallization in Poly(3-alkylthiophene)-containing Diblock Copolymers , VICTOR HO, RACHEL SEGALMAN, Unviersity of California, Berkeley — Organic optoelectronic device active layers require optimization of both the crystalline structure and the morphology at the nanometer length scale. These can be controlled simultaneously with a block copolymer in which one component is a crystalline conjugated polymer such as poly(3-alkylthiophene) (P3AT). While self-assembly of these systems requires balancing the driving forces of crystallization and self-assembly, in many systems, crystallinity dominates resulting in significant distortion or destruction of the melt phase structure. However, we show that judicious selection of the alkyl side chain in P3ATs results in melting transitions which can be controlled over a range of 150 C, and when incorporated into a block copolymer, these depressed melting transitions lead to regions of phase space for which the strength of segregation is sufficiently high at crystallization to allow for self-assembly. Phases such as crystalline majority-phase hexagonally-packed cylinders and lamellae are observed, and importantly the crystallinity of the conjugated polymer is retained in these confined geometries.

Session G32 DPOLY: Focus Session: Polymer Nanocomposites: Active Particles 340 - Russell

Gorga, North Carolina State University

11:15AM G32.00001 Magnetic Field Driven Alignment of Cobalt Nanoparticles and Directional Strengthening Effect in Polystyrene Matrix Nanocomposites , HONGYI YUAN, The University of Akron, JEFFREY PYUN, The University of Arizona, ALAMGIR KARIM, The University of Akron, THE UNIVERSITY OF AKRON TEAM, THE UNIVERSITY OF ARIZONA TEAM — Nanocomposite thin films of Polystyrene (PS) and PS-coated cobalt (Co) nanoparticles were prepared by solution-mixing and flow-coating. Ferromagnetic Co nanoparticles were either randomly dispersed or aligned in 1-D by applying a weak magnetic field during the flow-coating process. AFM and TEM images show nano-chain formation by self-assembly of the Co nanoparticles in the concentration range of 2-10 wt% relative to PS in the presence of magnetic field. The technique of Strain-Induced Elastic Buckling Instability for Mechanical Measurements (SIEBIMM) was employed to determine the elastic moduli of neat PS and PS / Co nanocomposite thin films, which were calculated from the buckling patterns generated by applying and releasing tensile stresses. Strengthening effect was found in nanocomposite thin films depending on the alignment direction of the dispersed Co nanoparticles. The effect of shape and concentration of nanoparticles on the elastic modulus of nanocomposite thin films will be discussed.

11:27AM G32.00002 Magnetic field gradient driven self-assembly of superparamagnetic nanoparticles using programmable magnetically-recorded templates , L. YE, University of South Carolina, B. QI, T.G. LAWTON, O.T. MEFFORD, Clemson University, C. RINALDI, University of Florida, S. GARZON, HGST, a Western Digital company, T.M. CRAWFORD, University of South Carolina — Using the enormous magnetic field gradients (100 MT/m @ z=20 nm) present near the surface of magnetic recording media, we demonstrate the fabrication of diffraction gratings with lines consisting entirely of magnetic nanoparticles assembled from a colloidal fluid onto a disk drive medium, followed by transfer to a flexible and transparent polymer thin film. These nanomanufactured gratings have line spacings programmed with commercial magnetic recording and are inherently concave with radii of curvature controlled by varying the polymer film thickness. The diffracted intensity increases non-monotonically with the length of time the colloidal fluid remains on the disk surface. In addition to comparing longitudinal and perpendicular magnetic recording, a combination of spectral diffraction efficiency measurements, magnetometry, scanning electron microscopy and inductively coupled plasma atomic emmission spectroscopy of these gratings are employed to understand colloidal nanoparticle dynamics in this extreme gradient limit. Such experiments are necessary to optimize nanoparticle assembly and obtain uniform patterned features. This low-cost and sustainable approach to nanomanufacturing could enable low-cost, high-quality diffraction gratings as well as more complex polymer nanocomposite materials assembled with single-nanometer precision.

11:39AM G32.00003 Self-assembly and Photo-patterning in Polymer-fullerene Nanocomposite Thin Films , HIM CHENG WONG, Imperial College London, ANTHONY HIGGINS, Swansea University, ANDREW WILDES, Institut Laue-Langevin, JACK DOUGLAS, The National Institute of Standards and Technology, JOAO CABRAL, Imperial College London — We report the directed self assembly of fullerenes in polymer thin films. The fullerenes are found to assemble spontaneously into spinodally coordinated clusters upon thermal annealing. The process yields well-defined structures, ranging from sparse heterogeneous nucleation to dense spinodal-like morphologies with tuneable characteristic spatial frequency and amplitude which coarsen with time, following well-defined scaling laws [1]. Mapping of this self assembly process utilized both real and reciprocal space techniques: optical and scanning force microscopy and neutron reflectivity. With external fields: light exposure and substrate surface energy, we demonstrate further tuneability over nanocomposite thin film morphology and substantial improvement on ultrathin film stability. By modulating the external fields on nanocomposite film with photomask, followed by thermal annealing, the film morphology and stability can be directed into various patterns, including a prototype polymer-fullerene circuit [2]. These results provide insights into fullerene self assembly in polymers and underscore their photoactive nature, an effect of great interest in the performance and stability of organic photovoltaics (OPV). [1] Wong H C and Cabral J T 2010 Phys. Rev. Lett. 105 038301 and 2011 Macromolecules 44 4530. [2] Wong H C, Higgins A M, Wildes A, Douglas J F, Cabral J T 2012 Adv. Mater. In Press.

11:51AM G32.00004 Co-assembly of Nanorods and Photosensitive Polymer Blends[1] , YA LIU, OLGA KUKSENOK, ANNA BALAZS, University of Pittsburgh — Using computational modeling, we establish means of controlling structure formation in nanocomposites comprising nanorods and a photosensitive binary blend. The complex cooperative interactions in the system include the preferential wetting between the rods and one of the phases in the blend, steric repulsion between the coated rods and the response of the binary blend to light. Namely, under uniform illumination, the binary mixture undergoes both phase separation and a reversible chemical reaction, leading to a morphology resembling that of a microphase-separated diblock copolymer. When a second, higher intensity light source is rastered over the sample, the binary blend and the nanorods co-assemble into regular, periodically ordered structures. In particular, the system displays an essentially defect-free lamellar morphology, with the nanorods localized in the energetically favorable domains. By varying the speed at which the secondary light is rastered over the sample, we can control the directional alignment of rods within the blend. Our approach provides an effective route for achieving morphological control of both the polymeric components and nanoparticles, providing an effective means of tailoring the properties and ultimate performance of the composites.

[1]The work was funded by DOE

12:03PM G32.00005 Anisotropic Thermal Processing of Polymer Nanocomposites via the Photothermal Effect of Gold Nanorods[1] , J.R. BOCHINSKI, S. MAITY, L.I. CLARKE, Dept. of Physics, NC State University, Raleigh, NC 27695, K.A. KOZEK, W. WU, J.B. TRACY, Materials Science and Engineering, NC State University, Raleigh, NC 27695 — Embedding metal nanoparticles within polymeric materials enables spatially-selective, in-situ thermal polymer processing [1,2]. When irradiating such a nanocomposite with light resonant with the particle's surface plasmon resonance, the photothermal effect efficiently transforms the energy into localized heat. Utilizing anisotropically-shaped particles enables further heating control based on the polarization sensitivity of the light-particle interaction. Photothermal heating from oriented gold nanorods selectively heats polymeric nanofibers by melting fibers lying only along a chosen direction while leaving the remaining material largely unaffected [3]. Fluorescence-based temperature-sensing measurements confirms heating in selected fibers and its absence in counter-aligned fibers. Such facile thermal processing of a specified subset of a sample, while the remainder is unchanged cannot be achieved through conventional heating. Results on spatially-selective heating and nanoscale temperature measurements within polymer systems doped with active nanoparticles will be discussed.

12:15PM G32.00006 Responsive and Hybrid Nanostructures through Self-Assembly of Polymeric Macroions, Inorganic Nanoclusters and Dyes , FRANZISKA GROEHN, JASMIN DUERING, DANIEL MOLDENHAUER, University Erlangen-Nuernberg, INTERDISCIPLINARY CENTER FOR MOLECULAR MATERIALS TEAM — Recently we have introduced a novel type of self-assembled "nano-objects" in solution: From the association of macroions and multivalent counterions well-defined and stable structures in the shape of spheres, rod, rings, hollow spheres and networks can form in solution. Using light-addressable counterions, it is possible to switch the particle size through UV irradiation. Building blocks can be of organic or inorganic nature: Using gold or cadmium sulphide nanoclusters results in hybrid assemblies which also functionally combine nanoparticle and dye. Thermodynamic studies in combination with a detailed structural characterization yield insight into driving forces and structural control in the self-assembly process. Crucial is the delicate interplay of ionic, $\pi - \pi$, and Hamaker interaction. The concept is particularly attractive, as it relies on general physical effects - that is the combination of different non-covalent interactions - and hence is very versatile. Great potential of the structures presented lies in areas such as catalysis and energy conversion.

12:27PM G32.00007 Utilizing Matrix-Filler Interactions in the Design of Stimuli-Responsive, Mechanically-Adaptive Electrospun Composites , NANDULA WANASEKARA, DAVID STONE, GARY WNEK, LASHANDA KORLEY, Case Western Reserve University — A new class of all-organic, stimuli-responsive and mechanically-adaptive electrospun nanocomposites, which have the ability to alter their stiffness upon hydration, were developed. These materials were fabricated by incorporating an electrospun mat of poly(vinyl alcohol) (PVA) as the filler in a polymeric matrix consisting of either poly(vinyl acetate) (PVAc) or ethylene oxide-epicholorohydrin copolymer (EO-EPI). The incorporation of high stiffness, high aspect ratio PVA filler mat significantly enhanced the tensile storage modulus of EO-EPI based composites, while modulus enhancement was only noticed above the glass transition for PVAc-based composites. Composite materials based on a rubbery EO-EPI host polymer and PVA filler exhibit an irreversible reduction by a factor of 12 of the tensile modulus upon hydration. In contrast, composites comprised of PVAc show a reversible reduction of modulus by a factor of 280 upon water uptake. The mechanical morphing of the electrospun composites is the result of the filler crystallinity, and matrix-filler interactions facilitated by the surface hydroxyl groups of the PVA filler. The choice of polymer matrix and electrospun nanofiber fillers allow control of matrix-filler interactions in a new series of all-organic composites to achieve desired stimuli-responsiveness and mechanical-adaptability upon exposure to various stimuli.

12:39PM G32.00008 Structure and Transport Anomalies in Soft Colloids , SAMANVAYA SRIVASTAVA, LYNDEN ARCHER, Cornell University — We present structure, dynamics and rheology measurements for model nanoparticle suspensions comprising of silica nanoparticles, densely grafted with oligomeric polyethylene glycol (PEG) chains and suspended in similar PEG oligomers. Small angle X-ray scattering reveals anomalous structural trends wherein the particle-particle correlations are found to decrease as the particle volume fraction rises beyond the point of particle overlap. Upon further increase in the particle loading, investigation of the particle dynamics through X-ray photon correlation spectroscopy points towards an unusual speeding up of the nanoparticles. Analogous "cascade of anomalies" are observed in systems including complex molecular fluids like water and silica as well as in systems interacting via soft repulsive potentials, and similar forces are expected to lead to the origin of these anomalous trends in all the cases.

12:51PM G32.00009 Simulations of Nanoparticle Ordering in Polymer Brush/Solvent Mixtures , GARY S. GREST, SHENGFENG CHENG, MARK J. STEVENS, Sandia National Laboratories — Organizing nanoparticles into a desired super-structure is crucial for their technological applications. We present molecular dynamics simulations of the assembly of nanoparticles during the evaporation of solvent from 3-component mixtures of nanoparticles and solvent in contact with an end-grafted polymer brush. The organization of nanoparticles strongly depends on their interaction with polymer chains. For relatively weak attraction between the nanoparticles and brush, the nanoparticles straddle the brush surface and form an ordered lattice. For a strong attraction between the nanoparticles and polymer, the nanoparticles are engulfed inside the brush and the packing quality diminishes, because the lateral diffusion of the nanoparticles is suppressed. The opposite trend is observed in the case in which the polymer chains are not grafted to a substrate. In this case, a layer of nanoparticles is entrapped in the concentrated polymer film at the interface and assemble into a close-packed hexagonal lattice for strong mutual attraction, while for weak interactions the nanoparticles are mostly dispersed in the relatively solvent-rich solution below the interface and remain disordered.

1:03PM G32.00010 Tailoring Surface Roughness by Grafting Nanoparticles to Random Copolymer Films[1] , MATTHEW CAPORIZZO, RAMI EZZIBDEH, RUSSELL COMPOSTO, The University of Pennsylvania — The effect of random copolymer composition on surface attachment and sinking of amine functionalized silica nanoparticles (d=45 nm) is investigated. Films of poly(styrene-ran-tert-butyl acrylate) (StBA) with 37% tBA are converted to poly(S-ran-acrylic acid) (SAA) by annealing for 15h at temperatures ranging from 135C to 200C. The conversion of the tBA ranges from under 10% to 100% and is monitored by ellipsometry and ATR-FTIR. At complete conversion (25 wt% AA), SAA forms nano-phase separated domains that result in particle aggregation within AA rich domains. At lower AA conversion, a disordered polymer morphology leads to grafting sites which are randomly distributed. NPs graft from nearly a complete monolayer to multilayers depending the percent of AA. Both the rate of NP attachment and the maximum loading of NPs into the film scale with the fraction of AA; this behavior is attributed to a reduction in the energetic barrier for the particle to sink into the film with increased swelling (more hydrophilic). A particularly attractive outcome of this systematic study is that optically transparent films with controlled roughness can be routinely prepared. Such films are of interest for investigating biomolecular adsorption and superhydrophobic, clear, non-fouling coatings.

1:15PM G32.00011 Photothermally-induced rotation of gold nanorods within a polymer matrix to probe local nanocomposite properties[1] , SOMSUBHRA MAITY, LAURA CLARKE, JASON BOCHINSKI, NC State University — The photothermal effect of gold nanorods embedded in polymer thin films produces localized heat depending upon the relative orientation of the rod and incident light field polarization. Simultaneous application of electric and light fields enables creation of thin films having aligned nanorods from those with initially randomly-oriented particles, as well as subsequent manipulation of rod orientation within the material environment. This is due to local melting of the polymer in the immediate vicinity of the particles which facilitates particle re-orientation. Conversely, solely under sufficient resonant light irradiation, initially aligned nanorods tend to randomize their orientation when the local environment melts. The rotational dynamics of the rods (i.e., alignment fidelity and rotation speed) depends on the polymer melt viscosity and thus directly reflects the local temperature around the rods which may vary significantly from the bulk temperature: conveniently, both rod orientation and bulk temperature can be simultaneously determined using optical methods. Thus, this combined approach provides both an in situ post-fabrication technique to manipulate alignment of rods and a tool to probe local temperature in polymer nanocomposites.

[1]NSF CMMI-0829379,CMMI-1069108,DMR-1056653

1:27PM G32.00012 Polymer Nanocomposite Films: Dispersion of Polymer Grafted Nanorods and Optical Properties[1] , RUSSELL COMPOSTO, University of Pennsylvania — The thermodynamic factors that affect the dispersion of polymer-brush grafted gold nanorods (NR) in polymer matrix films have been studied by experiment and theory. When brush and matrix have a favorable interaction, such as poly(ethylene oxide) (PEO)-NR/ poly(methyl methacrylate) (PMMA) and polystyrene (PS)-NR / poly(2,6-dimethyl-p-phenylene oxide) (PPO), nanorods are uniformly dispersed. For PEO-NRs in PMMA, the NRs are regularly spaced and well dispersed, independent of the ratio of the degree of polymerization of the matrix (P) to that of the brush (N), namely P/N. As the NR volume fraction increases, the local orientation of the nanorods increases, whereas the macroscopic orientation remains isotropic. When the brush and matrix are similar (i.e., PS-NR / PS and PEO-NR / PEO), the nanorods randomly disperse for $P/N < 2$ (i.e., wet brush), but align side-by-side in aggregates for $P/N > 2$. UV-visible spectroscopy and discrete dipole approximation (DDA) calculations demonstrate that surface plasmon coupling leads to a blue shift in the longitudinal surface plasmon resonance (LSPR) as P/N increases. For $P/N > 2$, self-consistent field theory (SCFT) calculations and Monte Carlo (MC) simulations indicate that nanorod aggregation is caused by depletion-attraction forces. Starting with a dry brush system, namely, a PS matrix where $P/N = 30$, these attractive forces can be mediated by adding a compatibilizing agent (e.g., PPO) that drives the NRs to disperse. Finally, dry and wet brush behavior is observed for NR aspect ratios varying from 2.5 to 7. However, compared at the same volume fraction, long rods for the dry case exhibit much better local order than lower aspect ratio nanorods, suggesting that long rods may exhibit nematic-like ordering at higher loadings.

2:03PM G32.00013 Self-assembly of defect-free particle monolayers on flexible films , MD.SHAHADAT HOSSAIN, BHAVIN DALAL, SATHISHKUMAR GURUPATHAM, IAN FISCHER, PUSHPENDRA SINGH, New Jersey Institute of Technology, NADINE AUBRY, Carnegie Mellon University — We have recently shown that the capillarity-based process for self-assembling particle monolayers on fluid-liquid interfaces can be improved by applying an electric field in the direction normal to the interface. The electric field gives rise to repulsive dipole-dipole forces amongst the particles causing them to move apart, and thus allowing them to move freely without blocking one another. The latter is important in the formation of virtually defect-free monolayers with long-range order. In this talk, we present a technique for freezing these expanded monolayers onto the surface of a flexible thin film. The technique involves assembling the monolayer on the interface between a UV-curable resin and a fluid which can be air or another liquid, and then curing the resin by applying UV light. The monolayer becomes embedded on the surface of the solidified resin film.

Session G33 DMP: Focus Session: Organic Electronics and Photonics - Theoretical Photophysics and Excited State Dynamics 341 - Richard Lunt, Michigan State University

11:15AM G33.00001 Polaritons in Organic Microcavities: The Effect of Phonons on the Dicke Model , JUSTYNA CWIK, JONATHAN KEELING, University of St Andrews — We study the effect of vibrational excitations on the condensation of polaritons. Recently, a lot of attention has been focused on microcavities based on organic semiconducting materials since, unlike their inorganic counterpart, they provide a suitable environment for the formation of a room temperature Bose-Einstein condensate. In order to model such materials we add terms to the usual Dicke Hamiltonian to account for the coupling of each two-level system to vibrational excitations (phonons). A mean field treatment, at zero temperature, gives us insights into the phase diagram of the Hamiltonian. In particular, we discuss the origin of the first order phase transition between two superradiant states which occurs as the coupling between the phonons and two-level systems is varied. An extension of the mean field treatment leads to the discussion of the equilibrium luminescence spectrum in the presence of phonons. We also present the way in which these results are modified at finite temperature.

11:27AM G33.00002 Estimating the Magnitude of Exciton Delocalization in Regioregular P3HT through Computational Modeling and Transient Absorption Spectroscopy , MICHAEL HEIBER, ALI DHINOJWALA, The University of Akron — Exciton delocalization has been shown to have a potentially strong impact on the performance of organic solar cells. However, very few attempts have been made to estimate the magnitude of exciton delocalization in common semiconducting polymers. We show how the magnitude of exciton delocalization can be extracted from two types of femtosecond transient absorption spectroscopy experiments using computational modeling tools. By fitting exciton delocalization models to previously published experimental data, we extract two separate estimates of the magnitude of exciton delocalization in regioregular poly(3-hexylthiophene) (P3HT). First, fitting exciton-exciton annihilation behavior in pristine P3HT films leads to an estimation of the exciton delocalization radius of 1.6$\pm$0.25 nm. Second, dynamic Monte Carlo modeling of the exciton dissociation dynamics for a P3HT:PCBM blend film results in a second approximation of the exciton delocalization radius of 1.9$\pm$0.6 nm. These estimates are significantly smaller than previously published values and provide strong evidence for less delocalization than used in previous device models.

11:39AM G33.00003 Influence of *trans* and *cis* defects on the localization of charged excitations in π-conjugated organic polymers , IFFAT NAYYAR, Theoretical Div., Los Alamos National Laboratory, NM, NanoScience Technology Center and Dept. of Physics, University of Central Florida, Orlando, FL, ENRIQUE BATISTA, Theoretical Div., Los Alamos National Laboratory, NM, SERGEI TRETIAK, Theoretical Div. and Center for Integrated NanoTechnologies, Los Alamos National Laboratory, NM, AVADH SAXENA, DARRYL SMITH, RICHARD MARTIN, Theoretical Div., Los Alamos National Laboratory, NM — Optoelectronic devices with π-conjugated polymers are in demand for use in light-emitting diodes (LED), solar cells and lasers. A recent study predicted differences in the response of the hyperfine field by polaronic species in organic LEDs. The improved fluorescence exhibited by different isomeric forms of PPV derivatives in these devices motivated us to investigate the influence of various conformational defects of *trans* and *cis* nature on the energetics and localization of positive (P^+) and negative (P^-) polarons using density functional theory. We observe the P^+ and P^- states are highly sensitive on the structural conformation and atomic charge distributions. The P^- state is observed to be more localized than P^+ in consistent with recent experiments when the polarization effects are included. These defects not only break the particle-hole symmetry but demonstrate higher charge-carrier mobilities for holes than electrons. This helps in tuning the charge-transport and photo-physical properties of organic materials by understanding their structure-property correlations for technological innovations.

11:51AM G33.00004 The role of exciton diffusion in the Forster-type energy transfer in hybrid organic-inorganic nanocomposites , BURAK GUZELTURK, Bilkent University, PEDRO LUDWIG HERNANDEZ MARTINEZ, Nanyang Technological University and Bilkent University, DONUS TUNCEL, Bilkent University, HILMI VOLKAN DEMIR, Nanyang Technological University and Bilkent University — The role of exciton diffusion in the Forster-type energy transfer in hybrid organic-inorganic nanocomposite is essential for devices applications. To understand the underlying interplay between the exciton transfer and exciton diffusion, we investigate the temperature dependent nonradiative energy transfer (NRET) in polymer-quantum dot (QDs) nanocomposites at high and low QD loading levels. For the low QD loading, the diffusion coefficient (D) is estimated to be greater than 1000 nm2/ns and the diffusion length (LD) is approximately 13 nm at room temperature. However, significant modifications of D and LD are observed in the case of high QD loading, where D is estimated to be 150 nm2/ns and LD is smaller than 5 nm. This suppression is attributed to the increased rates of NRET from the polymer to the QDs, with a smaller effective donor-acceptor separation at high QD loadings. In summary, the exciton diffusion plays a critical role in the resulting exciton dynamics of such polymer-QD nanocomposites, and the experimental evidence and supporting theoretical model suggest that the exciton diffusion is weak at the high loading levels when the exciton transfer dominates.

12:03PM G33.00005 First-principles simulations of exciton diffusion in organic semiconductors , XU ZHANG, ZI LI, GANG LU, Department of Physics and Astronomy, California State University Northridge — Exciton diffusion is of great importance to the performance of organic optoelectronic devices, including organic photovoltaics and solid-state lighting. The ability to control exciton diffusion in organic semiconductors is crucial to the design of efficient optoelectronic devices. However, such ability can only be achieved through a fundamental understanding of exciton diffusion mechanism. We have proposed a first-principles based frame work that can predict exciton dynamics in organic semiconductors.The framework is based on time-dependent density functional theory to provide the energy and many-body wave functions of excitons. Nonadiabatic *ab initio* molecular dynamics is used to calculate phonon-assisted transition rates between localized exciton states. Using Monte Carlo simulations, we determine exciton diffusion length, lifetime, diffusivity, and harvesting efficiency in poly(3-hexylthiophene) polymers at different temperatures, and the results agree very well with corresponding experimental values. We find that exciton diffusion is primarily determined by the density of states of low-energy excitons; a widely speculated diffusion mechanism has been confirmed and elucidatedby the simulations. Some general guidelines for designing more efficient organic solar cells can be gleaned from the simulation results

12:15PM G33.00006 Relating Crystal Structure and the Charge-Transfer Nature of Excitons in Pentacene from First Principles[1] , SAHAR SHARIFZADEH, Molecular Foundry, LBNL, PIERRE DARANCET, Molecular Foundry, LBNL and Department of Applied Physics and Applied Mathematics, Columbia University, LEEOR KRONIK, Department of Materials and Interfaces, Weizmann Institute of Science, JEFFREY NEATON, Molecular Foundry, LBNL — The nature of low energy optical excitations within pentacene has been the subject of many experimental and theoretical studies, with much disagreement as to the degree of their charge-transfer character. Here, we use many-body perturbation theory to study singlet excitons within different solid phases of pentacene and demonstrate that inter-molecular interactions lead to delocalized, charge-transfer-like excitations in the bulk crystalline phase. Using the Bethe-Salpeter two-particle correlation function, we demonstrate that the interplay between intermolecular hybridization, local exchange interactions, and attractive electron/hole interactions controls the nature of the exciton. Additionally, we explore simple models to understand and predict the nature of the excitonic wavefunction, in particular whether it has charge-transfer character.

12:27PM G33.00007 Exploring the correlation between molecular conformation and optoelectronic properties of conjugated polymers : side-chain versus main-chain electron acceptors[1]

, YU-CHEN HUANG, Ph.D student , CHING-I HUANG, Professor at Institute of Polymer Science and Engineering — Polythiophene derivatives have been shown among the most promising materials for solar cell application because of their high charge mobility and light absorption. In the mostly studied, a recombination process often occurs, which is mainly due to the fact that the mobility of hole is much lower than that of electron. Hence, research about conjugated polymers containing donor-accepter pairs (such as PT-TPD) becomes quite popular because these materials have narrow band-gaps. Interestingly, these experimental studies have indicated a much more complex correlation between the optoelectronic properties and molecular conformation for polymers with acceptor units on either main or side chain. However, the effects associated with the molecular packing on the resultant chain conformation behavior and thereafter the optoelectronic properties have not been systematically discussed. In order to clarify the effects of the molecular conformation as well as the optoelectronic properties, we employ molecular dynamics and quantum mechanical methods to examine PBTTPD molecules with acceptor unit (TPD) on either main or side chain

12:39PM G33.00008 Band structure of polyethylene from many-body perturbation theory

, ARIEL BILLER, Weizmann Institute of Science, Israel, SAHAR SHARIFZADEH, Lawrence Berkeley National Laboratory, USA, LIOR SEGEV, Weizmann Institute of Science, Israel, SOHRAB ISMAIL-BEIGI, Yale University, USA, JEFFREY B. NEATON, Lawrence Berkeley National Laboratory, USA, LEEOR KRONIK, Weizmann Institute of Science, Israel — The electronic structure of polyethylene is an important benchmark and the infinite chain limit for the electronic properties of many molecules, monolayers, and oligomers. Therefore, the band structure of the ideal, one-dimensional polyethylene chain has been extensively researched, from both the experimental and the theoretical viewpoints. Despite this extensive effort, to the best of our knowledge agreement between theoretical calculations and the electronic structure obtained from photoelectron spectroscopy could only be obtained using artificial shifting and "stretching" of the computed data. Here, we present a quantitative quasi-particle band-structure for polyethylene using many-body perturbation theory. The approach is employed within the G_0W_0 approximation, based on a starting point calculated within the generalized gradient approximation to density functional theory. We compare our calculated band-structure to angle resolved photoemission spectroscopy measurements for various long saturated carbohydrates, demonstrate a much improved agreement with experiment, and discuss remaining discrepancies and their possible origins within both theory and experiment.

12:51PM G33.00009 Ideal Energy-Level Alignment at the ZnO/P3HT Photovoltaic Interface[1]

, KEIAN NOORI, FELICIANO GIUSTINO, Department of Materials, University of Oxford — Despite the significant progress made during the past decade, hybrid organic-inorganic photovoltaic devices comprising P3HT and ZnO still suffer from low short-circuit currents and moderate open-circuit voltages. These barriers call for a detailed examination of the atomic-scale physics underlying the energy-level alignment at the ZnO/P3HT interface, which is of critical importance if we are to understand what is the maximum ideal open-circuit voltage for this class of solar cell. Here we present the results of a first-principles study [1] on large model interfaces between ZnO and P3HT. Using a combination of density-functional theory (DFT) and post-DFT methods based on hybrid functionals, we analyze the atomic structure and energetics of the semiconductor/polymer interface, as well as the interfacial energy-level alignment. We explore the effect of charge transfer on the ideal open-circuit voltage and identify a failure in the standard electron affinity rule. We determine a maximum ideal open-circuit voltage of $\sim$2 V, which suggests that there is significant room for enhancing the performance of ZnO/P3HT solar cells by optimizing the interface at the nanoscale.

1:03PM G33.00010 Interactions between linear organic chromophores: an improved line-dipole approximation

, JEAN-CHRISTOPHE DENIS, Institute for Photonics and Quantum Sciences, School of Engineering and Physical Sciences, SUPA, Heriot-Watt University, Edinburgh EH14 4AS, UK, STEFAN SCHUMACHER, Physics Department and Center for Optoelectronics and Photonics Paderborn, Universität Paderborn, Warburger Strasse 100, 33098 Paderborn, Germany, IAN GALBRAITH, Institute for Photonics and Quantum Sciences, School of Engineering and Physical Sciences, SUPA, Heriot-Watt University, Edinburgh EH14 4AS, UK — Modelling accurately the interactions between chromophores is key for realistic simulations of the dynamics of exciton transfer and annihilation in organic semiconductor films. In the framework of Förster theory, it is required to calculate the interaction matrix elements for all relative orientations and separations of chromophores. Therefore a fast and robust approximation is necessary to simulate extended multi-chromophoric systems. From this perspective, using the line-dipole approximation is a very natural approach. However, by a comparative study of the dipole approximation with quantum chemistry (TD-DFT) we demonstrate that the usual line-dipole theory, while successful for short molecules, does not describe well the interactions of longer molecules, where separations are smaller than the interacting chromophores - a limit typically reached in polymer films. As an alternative, we propose an improved way of distributing the sub-dipole moments within a line. This approach remains simple enough to be used in large-scale calculations, while the agreement with the quantum chemistry is significantly improved for all relative orientations.

1:15PM G33.00011 Identifying molecular features that maximize the second hyperpolarizability

, CHRISTOPHER BURKE, TIMOTHY ATHERTON, Department of Physics and Astronomy, Tufts University, JOSEPH LESNEFSKY, Department of Physics, University of Illinois at Chicago, ROLFE PETSCHEK, Department of Physics, Case Western Reserve University — Designing materials with high nonlinear optical properties is of importance for a variety of applications ranging from optical switching to chemical sensing. A key figure of merit is the intrinsic molecular second hyperpolarizability γ_{int}, a dimensionless quantity which measures how close a molecule's second hyperpolarizability is to the theoretical maximum. By modeling a molecule as a one dimensional linear piecewise potential, γ_{int} was optimized with respect to the shape of the potential. The number of parameters needed to describe the potential was varied. Searches were carried out for extrema in both the positive and negative directions, finding optimum potentials with γ_{int} of 0.60 and -0.15. The optimum potentials possess parity symmetry and are specified by a very small number of parameters due to our simple and well chosen representation. Based on the shape of the optimized potentials, we use these results to suggest possible routes for synthesizing molecules with high γ_{int}.

1:27PM G33.00012 Photoexcitation and Photochemical Stability of Organic Photovoltaic Materials from First Principles[1] , NA SAI, The University of Texas at Austin, KEVIN LEUNG, Sandia National Laboratory — The development of high efficiency organic photovoltaics (OPV) has recently become enabled by the synthesis of new conjugated polymers with low band gap that allow light absorption over a broader range of the spectrum. Stability of these new polymers, a key requirement for commercialization, has not yet received sufficient attention. Here, we report first-principles theoretical modeling of photo-induced degradation of OPV polymers carried out using ab-initio density functional theory (DFT). We report photooxidation routes and reaction products for reactive species including superoxide oxygen anions and hydroxyl groups interacting with the standard workhorse OPV polymer, poly(3-hexyl-thiophene) (P3HT). We discuss theoretical issues and challenges affecting the modeling such reactions in OPV polymers. We also discuss the application of theoretical methods to low-band-gap polymers, and in particular, the effect of the chemical substitution on the photoexcitation properties of these new polymers. Sandia National Laboratories is a multiprogram laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Deparment of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

1:39PM G33.00013 Understanding the influence of solvent field and fluctuations on the stability of photo-induced charge-separated state in molecular triad[1] , D. BALAMURUGAN, University of Houston, ADELIA AQUINO, HANS LISCHKA, Texas Tech University, FRANCIS DIOS, LIONEL FLORES, MARGARET CHEUNG, University of Houston — Molecular triad composed of fullerene, porphyrin, and carotene is an artificial analogue of natural photosynthetic system and is considered for applications in solar energy conversion because of its ability to produce long-lived photo-induced charge separated state. The goal of the present multiscale simulation is to understand how the stability of photo-induced charge-separated state in molecular triad is influenced by a polar organic solvent, namely tetrahydrofuran (THF). The multiscale approach is based on combined quantum, classical molecular dynamics, and statistical physics calculations. The quantum chemical calculations were performed on the triad using the second order algebraic diagrammatic perturbation and time-dependent density functional theory. Molecular dynamics simulations were performed on triad in a box of THF solvent with the replica exchange method. The two methods on different length and time scales are bridged through an important sampling technique. We have analyzed the free energy landscape, structural fluctuations, and the long- range electrostatic interactions between triad and solvent molecules. The results suggest that the polarity and re-organization of the solvent is critical in stabilization of charge-separated state in triad.

1:51PM G33.00014 Quantum dynamics simulations of interfacial charge-transfer in organic dye-sensitized solar cells[1] , LUIS G.C. REGO, Department of Physics, Universidade Federal de Santa Catarina, R. DA SILVA, Department of Chemistry, Universidade Federal de Santa Catarina, D.A. HOFF, Department of Physics, Universidade Federal de Santa Catarina — We describe a novel time-dependent quantum-mechanics/molecular-mechanics method for studying electron transfer in dye sensitized semiconductor interfaces, that takes into account the interacting electron-hole quantum dynamics, the underlying nuclear fluctuations and solvation dynamics. We provide a comprehensive investigation of the quantum dynamics, the electronic and the structural properties of prototypical D-π-A organic dyes sensitizing the TiO2 anatase surface, both in vacuum and solvated by liquid acetonitrile. The organic dyes are comprised of an electron donating moiety and an anchoring acceptor moiety, conjugated by thiophene bridges. Although interfacial electron transfer is very efficient, it is demonstrated that the coupling between the photoexcited electron and the hole delays the electron injection. Simulations demonstrate that the solvent screens the dye from the surface, narrowing the absorption peaks and delaying the electron injection. We have also studied several aspects that are relevant for the recombination process, such as the role played by surface defects and the interaction of redox species with the TiO2 surface, and the effect of additives.

2:03PM G33.00015 First principles modeling of panchromatic dyes for solar cells applications. , ROSA DI FELICE, ARRIGO CALZOLARI, Centro S3, CNR Istituto di Nanoscienze, Modena, Italy, RUI DONG, North Carolina State University, MARCO BUONGIORNO NARDELLI, University of North Texas — The state-of-the-art dye in Grätzel solar cells, N719, exhibits a total solar-to-electric conversion efficiency of 11.2%. However, it severely lacks absorption in the red and the near infrared regions of the electromagnetic spectrum, which represent more than 70% of the solar radiation spectrum. Using calculations from first principles in the time-dependent domain, we have studied the electronic and optical response of a novel class of panchromatic sensitizers that can harvest solar energy efficiently across the visible and near infrared regions, which have been recently synthesized [A. El-Shafei, M. Hussain, A. Atiq, A. Islam, and L. Han, J. Mater. Chem. **22**, 24048 (2012)]. Our calculations show that, by tuning the properties of antenna groups, one can achieve a substantial improvement of the optical properties.

Tuesday, March 19, 2013 11:15AM - 2:03PM –

Session G34 DPOLY: Polymer Blends 342 - Julie Albert, North Carolina State University

11:15AM G34.00001 An unusual route to develop poly(lactic acid) based materials with deformation-recovery properties , SAHAS RATHI, DAVID NG, E. BRYAN COUGHLIN, SHAW HSU, University of Massachusetts Amherst, CHARLES GOLUB, GERALD LING, MIKE TZIVANIS, Saint Gobain — A novel method based on co-crystallizing polymer blends was developed to obtain Poly(lactic acid) (PLA) based materials with deformation recovery properties. Two sets of blends were studied. One based on the PDLA-soft polymer-PDLA triblock copolymer and PLLA, where D and L refer to the two chiral isomers of PLA, while the other was based on homopolymer blends of PDLA/soft polymer/PLLA having identical chemical composition. The mechanical properties and morphological features of the two sets of blends were completely different. The triblock copolymer/ PLLA blends gave rise to flexible, tough semicrystalline materials while the corresponding homopolymer blends exhibited very low strains at break and high dissipative/dampening properties. The drastically different stereocomplex crystallization kinetics in the two sets of blends led to interspherulitic segregation of the amorphous chains in the triblock blends while intraspherulitic segregation occurred in the homopolymer blends. The presence of significant connectivity between the stereocomplex crystallites formed, in the triblock copolymer/ PLLA blends, was important for the deformation shape recovery characteristics observed. In addition, it was found that the use of ether-ester based plasticizers significantly reduced the glass transition temperature and enhanced the recovery property of the triblock copolymer based PLA blends.

11:27AM G34.00002 Nanoporous polystyrene samples through the selective removal of low-Mw component in PS/PS blend samples , JAMES FORREST, CHAD DALEY, SONIA ZHANG, SHARON YANG, STEFAN IDZIAK, University of Waterloo — We present here a novel technique for producing low density nanoporous polystyrene samples. The method hinges upon the ability to selectively dissolve away the low-M_w component from blend samples which consist of high- and low-M_w atactic polystyrenes with drastically different M_w's. Given the chemical similarity between the two components it is possible to prepare blend samples while avoiding microscopic phase separation. Removal of the low-M_w component then leaves behind a sample with nanoscopic voids on the order of 10's of nm. This is in contrast to porous polymer materials prepared through the removal of chemically distinct polymer species, where larger scale pores are the end result. Tuning of the initial fraction of the low-M_w component allows for variation in the density of the porous material; ellipsometric measurements indicate samples with densities lower than 0.5 g/cm^3. Characterization of the samples using ellipsometry, AFM, and X-ray diffraction will be discussed.

11:39AM G34.00003 Effect of critical molecular weight of PEO in epoxy/EPO blends as characterized by advanced DSC and solid-state NMR , XIAOLIANG WANG, Department of Polymer Science and Engineering, Nanjing University, SHOUDONG LU, PINGCHUAN SUN, College of Chemistry, Nankai University, GI XUE, Department of Polymer Science and Engineering, Nanjing University — The differential scanning calorimetry (DSC) and solid state NMR have been used to systematically study the length scale of the miscibility and local dynamics of the epoxy resin/poly(ethylene oxide) (ER/PEO) blends with different PEO molecular weight. By DSC, we found that the diffusion behavior of PEO with different Mw is an important factor in controlling these behaviors upon curing. We further employed two-dimensional 13C-{1H}PISEMA NMR experiment to elucidate the possible weak interaction and detailed local dynamics in ER/PEO blends. The CH2O group of PEO forms hydrogen bond with hydroxyl proton of cured-ER ether group, and its local dynamics frozen by such interaction. Our finding indicates that molecular weight (Mw) of PEO is a crucial factor in controlling the miscibility, chain dynamics and hydrogen bonding interaction in these blends.

11:51AM G34.00004 Effect of Supercritical Carbon Dioxide on Polymer Blend Miscibility , NICHOLAS YOUNG, SEBNEM INCEOGLU, University of California, Berkeley, ANDREW JACKSON, None, STEPHANE COSTEAUX, Dow Chemical Company, NITASH BALSARA, University of California, Berkeley — Supercritical fluids have been investigated as environmentally benign solvents for the processing of polymers on the industrial scale. In this work, we study the effect of supercritical carbon dioxide ($scCO_2$) on the phase behavior of a blend of a random copolymer and a homopolymer. Styrene-acrylonitrile copolymer (SAN) and poly(methyl methacrylate) (PMMA) are known to display lower critical solution temperature-type phase behavior, undergoing a transition from a homogeneous mixture to a phase-separated blend upon heating. Depending on certain parameters such as SAN composition (w_{AN}) and blend fraction (ϕ_{SAN}), the miscibility window for the two polymers can be tuned over a significant temperature range by introducing $scCO_2$ into the system. Using small angle neutron scattering, the thermodynamic interactions between SAN and PMMA as described by the Flory-Huggins parameter χ are shown to be strongly dependent on $scCO_2$ activity.

12:03PM G34.00005 Microphase-Separated Structures of Gold Nanoparticle Grafted with Two Immiscible Polymers , DAISUKE KAWAGUCHI, TATSUHIRO NAKANO, YUSHU MATSUSHITA, Department of Applied Chemistry, Nagoya University — It is important to control structures of organic-inorganic hybrid materials to make functional devices. If gold-nanoparticle (AuNP) grafted with two immiscible polymers can self-assemble into microphase-separated structures, it can be expected that AuNP arranges on their own microphase-separated interface in nanometer scale. In this study, we prepared AuNP grafted with polyisoprene (PI) and polystyrene (PS) which were immiscible polymers and investigated their microphase-separated structures by small-angle X-ray scattering (SAXS) and transmission electron microscopy (TEM). The AuNP complexes form various microphase-separated structures such as lamellar, cylindrical and spherical structures with changing polymeric composition. The TEM image and SAXS profile for the AuNP complexes for the symmetric composition shows that PS and PI form lamellar structures and the AuNPs are forced into the PS/PI interface.

12:15PM G34.00006 Improving the Compatibility between Polystyrene and Polybutadiene by Adding Silica Nanoparticles , YUPING XIE, Columbia University, DAMIEN MAILLARD, National Research Council Canada, SANAT KUMAR, Columbia University, BRANDON CASH, Bluestar Silicones USA Corp., BRIAN BENICEWICZ, University of South Carolina — The compatibility between polystyrene (PS) and polybutadiene (PB) was improved by adding bare silica or PS-grafted silica nanoparticles. The grafting density varies from 0.01 chains/nm^2 to 0.10 chains/nm^2. Thin sections are obtained by cryomicrotome at -140 °C for TEM analysis. Without adding nanoparticles, bulk phase separation occurs for the PS-PB blend, although a few droplets of PS are found presumably due to the viscoelastic phase separation. When the grafting density is less than 0.05 chains/nm^2, the particles are found to partition between the PS-PB interface and the continuous PS phase. However, when the grafting density is greater than or equal to 0.05 chains/nm^2, the particles are found to locate only in the dispersed PS phase, and the size of the PS phases decreases with increasing grafting density. Phase inversion also occurs at 70 wt% of PS when the grafting density is fixed at 0.10 chains/nm^2.

12:27PM G34.00007 Application of Self-consistent Field Theory to Compressible Polymer Blends: χ, interfacial tension, and anomaly[1] , JUNHAN CHO, Dankook University — The self-consistent field (SCF) theory, which was first developed by Helfand, is generalized to compressible polymer blends in order to investigate pressure dependence of interfacial behavior for those systems. A statistical mechanical off-lattice equation-of-state model is incorporated with the formalism and proper SCF equations for saddle points are presented. Taking typical blends as our model system, the relationship between effective Flory-Huggins parameter and interfacial tension is considered on a temperature-pressure window. Anomaly in those physical properties regarding their pressure dependence is discussed.

[1]We acknowledge the financial support from NRF through Basic Research Program.

12:39PM G34.00008 Morphology and Rheology of the Phase-separating Polybutadiene /Polyisoprene Blend under Small Amplitude Oscillatory Shear[1] , XIA DONG, FASHENG ZOU, DUJIN WANG, CHARLES C. HAN, Joint Laboratory of Polymer Science and Materials, Institute of Chemistry, Chinese Academy of Sciences — We are mainly focusing on the late stage of phase separation process where the two phases have reach their equilibrium compositions and the droplet dimension or interface area is the key factor in influencing the dynamic moduli. Two kinds of phase-separating structure evolutions of the PB/LPI blend have been investigated. For the near-critical and symmetric blend LPI50, the co-continuous phase-separating structures are observed and lead to a power law behavior of the dynamic storage modulus at low frequencies. With the growth of the co-continuous structure, the storage modulus at low frequency decreases dramatically. For the off-critical and asymmetric blend LPI70, the droplet/matrix two-phase structures appear and result in a rather complex elastic behavior at the mediate and low frequency region. It is observed that with the droplet size increases, the storage modulus at the mediate frequencies generally decreases while the storage modulus at the low frequencies usually increases. Besides, the platform and terminal moduli at a given frequency can be scalable with the phase separation time and the characteristic relaxation time and domain size of the droplets can be obtained by rheology.

12:51PM G34.00009 Effective Mixing of UHMWPE with Polyethylene: Rheological, Mechanical and Crystallization Behavior of Novel Blends Made by Solid-State Shear Pulverization , MIRIAN DIOP, JOHN TORKELSON, Northwestern University Evanston, IL 60208-3120 — In comparison with conventional polyolefins, ultrahigh molecular weight polyethylene (UHMWPE) possesses outstanding mechanical properties, including impact strength, making it highly desirable for applications ranging from body armor to implants. Unfortunately, UHMWPE comes with a downside: an ultrahigh melt viscosity that renders common melt processes useless for making products from UHMWPE. Attempts to overcome this problem by blending UHMWPE with polyethylene (PE) by conventional melt mixing have been unsuccessful because of the enormous viscosity mismatch and have led to suspensions of UHMWPE particles within a PE matrix. Here, we show the utility of solid-state shear pulverization (SSSP) to effectively and intimately mix UHMWPE/PE blends. Oscillatory shear rheology of blends containing up to 20 wt% UHMWPE shows both the major impact of the UHMWPE fraction in strongly modifying the low shear rate flow behavior and the very muted effect of that fraction on the high shear rate flow behavior. The latter effect indicates that such blends can be processed by melt extrusion and injection molding. Differential scanning calorimetry supports the presence of co-crystallization in these blends. Mechanical properties of these blends, including impact strength, will also be discussed.

1:03PM G34.00010 Assessing the Strength Enhancement of Heterogeneous Networks of Miscible Polymer Blends[1] , CARL GILLER, American Society for Engineering Education, MIKE ROLAND, Naval Research Lab — At the typical crosslink densities of elastomers, the failure properties vary inversely with mechanical stiffness, so that compounding entails a compromise between stiffness and strength. Our approach to circumvent this conventional limitation is by forming networks of two polymers that: (i) are thermodynamically miscible, whereby the chemical composition is uniform on the segmental level; and (ii) have markedly different reactivities for network formation. The resulting elastomer consists of one highly crosslinked component and one that is lightly or uncrosslinked. This disparity in crosslinking causes their respective contributions to the network mechanical response to differ diametrically. Earlier results showed some success with this approach for thermally crosslinked blends of 1,2-polybutadiene (PVE) and polyisoprene (PI), as well as ethylene-propylene copolymer (EPM) and ethylene-propylene-diene random terpolymer (EPDM), taking advantage of their differing reactivities to sulfur. In this work we demonstrate the miscibility of polyisobutylene (PIB) with butyl rubber (BR) (a copolymer of PIB and polyisoprene) and show that networks in which only the BR is crosslinked possess greater tensile strengths than neat BR over the same range of moduli.

1:15PM G34.00011 Investigation of Flame Retardancy, Mechanical Properties, and Bicompatibility of Polystyrene Blends[1] , LIUDI ZHANG, SEONGCHAN PACK, MIRIAM RAFAILOVICH, Stony Brook University — Our research focused on thermal, mechanical properties, and cytotoxicity of Polystyrene system. Brominated Polystyrene was incorporated to replace halogenated Flame Retardant in Polystyrene blends. We have previously shown that ditallow functionalized clays could become nearly universal class of compatiblizers [si-2006]. Here we show that a new type of surface with Resorcinol bis (biphenyl phosphate) (RDP) could achieve the same goal. We demonstrate the strong compatibilization on this highly immiscible system. Furthermore, we show that this system also works well, when a flame retardant Antimony Trioxide (AO) is added. Tensile test, dynamic mechanical analysis, and UL-94 flame test were applied to investigate this system. We found that the amount of AO used could be minimized by adding RDP clay, which could also increase some mechanical properties that Cloisite 20A clay couldn't. Besides, we evaluated the cytotoxicity of Cloiste 20A and RDP clay. These clays were tested both within PS blends and as a monolayer film. Langmuir-Blodgett trough and atomic force microscopy were used to make and check monolayer clay. Confocal laser scanning microscopy was used to assess cell morphology. The results showed RDP clay has potential for biomaterial applications.

1:27PM G34.00012 Avalanches of dewetting holes in viscoelastic phase separation , CHANGQIAN YU, SUNG CHUL BAE, STEVE GRANICK, University of Illinois at Urbana-Champaign — Textbook ideas fails regarding phase separation of polymer solutions, because of viscoelastic effects. Here with fluorescence microscopy we visualize in real time this process. Quasi two dimensional polymer solutions of polystyrene near the critical concentration are confined between non-wetting surfaces. Apart from a double phase separation induced by rapid hydrodynamic coarsening, we observe novel avalanched dewetting of solvent-enriched holes, not only in the polymer-enriched phase but also near the walls. Strikingly, this occurs at the late stage of the spinodal decomposition. These dewetting holes govern pattern evolution of the phase-separated polymer network.

1:39PM G34.00013 Coalescence of Pickering emulsion droplets induced by electric-field[1] , GUO CHEN, PENG TAN, Department of Physics, CUHK, Hong Kong, SHUYU CHEN, Department of Physics, HKUST, Hong Kong, JIPING HUANG, Department of Physics, Fudan University, Shanghai, China, WEIJIA WEN, Department of Physics, HKUST, Hong Kong, LEI XU, Department of Physics, CUHK, Hong Kong — Combining high-speed photography with electric current measurement, we investigate the coalescence of Pickering emulsion droplets. Under high enough electric field, the originally-stable droplets coalesce via two distinct approaches: normal coalescence and abnormal coalescence. In the normal coalescence, a liquid bridge grows continuously and merges two droplets together, similar to the classical picture. In the abnormal coalescence, however, the bridge fails to grow indefinitely; instead it breaks up spontaneously due to the geometric constraint from particle shells. Such connecting-then-breaking cycles repeat multiple times, until a stable connection is established. In depth analysis indicates that the defect size in particle shells determines the exact merging behaviors: when the defects are larger than a critical size, normal coalescence will show up; while abnormal coalescence will appear for smaller defects.

[1]This project is supported by the Hong Kong GRF Grant (Project No. CUHK404211).

1:51PM G34.00014 Arrested of coalescence of emulsion droplets of arbitrary size , BADEL L. MBANGA, CHRISTOPHER BURKE, Department of Physics and Astronomy, Tufts University, DONALD W. BLAIR, Department of Physics, University of Massachusetts Amherst, TIMOTHY J. ATHERTON, Department of Physics and Astronomy, Tufts University — With applications ranging from food products to cosmetics via targeted drug delivery systems, structured anisotropic colloids provide an efficient way to control the structure, properties and functions of emulsions. When two fluid emulsion droplets are brought in contact, a reduction of the interfacial tension drives their coalescence into a larger droplet of the same total volume and reduced exposed area. This coalescence can be partially or totally hindered by the presence of nano or micron-size particles that coat the interface as in Pickering emulsions. We investigate numerically the dependance of the mechanical stability of these arrested shapes on the particles size, their shape anisotropy, their polydispersity, their interaction with the solvent, and the particle-particle interactions. We discuss structural shape changes that can be induced by tuning the particles interactions after arrest occurs, and provide design parameters for the relevant experiments.

Tuesday, March 19, 2013 11:15AM - 2:15PM –

Session G35 DMP: Focus Session: Search for New Superconductors I 343 - Horst Rogalla, University of Colorado

11:15AM G35.00001 Superconductivity and New Compounds in the Bi-O-S System , DAVID WALLACE, KATHRYN ARPINO, W. ADAM PHELAN, KEN LIVI, The Johns Hopkins University, CHE SEABORNE, ANDREW SCOTT, University of Leeds, TYREL MCQUEEN, The Johns Hopkins University — Recent reports of superconductivity in $Bi_4O_4S_3$ and $LaO_{1-x}F_xBiS_2$ have stimulated interest in a potentially new family of layered superconductors based on BiS_2 units. The most interesting structural feature of the reported crystal structure of $Bi_4O_4S_3$ is that it contains both reduced sulfides (S^{2-}) and oxidized sulfates (S^{6+}) within the same compound. However, the scattering factors of oxygen and sulfur relative to bismuth make the precise structure of $Bi_4O_4S_3$ difficult to determine by x-ray diffraction, and limit the ability to compare with theoretical predictions of electronically driven structural distortions. Here we report the results of studies on the structure and physical properties of compounds in the Bi-O-S system through electron diffraction, high resolution transmission electron microscopy, synchrotron x-ray diffraction, and IR spectroscopy, including the discovery of two new ternary Bi-O-S phases.

11:27AM G35.00002 Phonon-mediated superconductivity in electrostatically and chemically doped single-layer MoS2[1] , YIZHI GE, AMY Y. LIU, Georgetown University — MoS_2 is a semiconductor with a layered structure that can be exfoliated to make few-layer and single-layer samples. Superconductivity has recently been reported in electrostatically doped few-layer MoS_2 samples, with a transition temperature above 9 K, which is higher than the maximum T_c found in intercalated bulk MoS_2. Here we report a density functional theory study of electron-phonon coupling in doped single-layer MoS_2. With electrostatic n-type doping at levels comparable to those achieved in MoS_2 field-effect transistors, the electron-phonon coupling constant is calculated to be consistent with a superconducting T_c of 5-10 K. While deposition of alkali atoms on the surface also introduces carriers into the conduction band, we find that in some cases, it creates significant changes in the electronic structure, leading to a weaker interaction between electrons and phonons. The dependence of the electron-phonon interaction on carrier concentration, for both n-type and p-type doping, will be discussed.

11:39AM G35.00003 Superconductivity in $Nb_3Pd_{0.75}Se_7$, DANIEL RHODES, QIU ZHANG, BIN ZHENG, GANG LI, ANDHIKA KISWANDHI, TIGLET BESARA, THEO SIEGRIST, LUIS BALICAS, National High Magneti Field Lab — Here, we report the discovery of superconductivity in the transition metal chalcogenide $Nb_3Pd_{0.75}S_7$ with a transition temperature $T_c = 1.9$ K. In extremely thin, needle like single crystals we observe upper critical fields $H^b_{c2}(T \to 0\ \text{K}) \simeq 14$ T for fields directed along the needle axis, or the crystallographic *b*-axis. This value is 4 times larger than the expected weak coupling Pauli limiting field. For fields applied along two directions perpendicular to the *b*-axis, we observe considerably smaller but anisotropic upper critical fields. For fields along and perpendicular to the b-axis we observe a temperature-dependent anisotropy $\gamma = H^b_{c2}/H^{\perp b}_{c2}$ as large as 6 (as $T \to T_c$). This behavior suggests that this compound is a multi-band superconductor. The low symmetry of its crystallographic structure implying low electronic dimensionality, coupled to multi-band behavior and very high upper critical fields, suggests an unconventional superconducting ground-state.

11:51AM G35.00004 The Search for Higher Temperature Superconductors: Two Case Studies[1] , MALCOLM BEASLEY, Stanford University — The recent confluence of optimism in the prospects for higher temperature superconductivity and the documented need for new higher temperature superconductors (if electric power applications above liquid nitrogen temperatures are to be possible) has simulated several focused programs in the search new and improved high-Tc superconductors. In this talk, we review these motivating factors and present the results of two case studies. The first is the study of the high Tc bismuthate superconductors to understand the mechanism of their superconductivity and the factors governing Tc. We find that the bismuthates are moderately correlated materials with a dynamically enhanced electron-phonon interaction that exhibit dimorphism and a sensitivity of Tc to disorder. The second is the study of Cu/CuO interfaces (for which evidence of trace high temperature superconductivity has been reported) at which we find a new proximity effect in which antiferromagnetism is induced into a metal (Cu) by proximity to a charge transfer insulator (CuO).

[1]This work has been a collaborative effort carried out under AFOSR MURI support involving Stanford (Beasley and Fisher), Princeton (Cava) and Rutgers (Kotliar).

12:27PM G35.00005 Electronic properties of α-$FeSi_2$ – single crystal study[1] , WOJCIECH MIILLER, Stony Brook University, JAN TOMCZAK, Rutgers University, JACK SIMONSON, GREG SMITH, Stony Brook University, MEIGAN ARONSON, Stony Brook University and Brookhaven National Laboratory — The discovery of high temperature superconductivity (HTS) in Fe pnictides has simulated a lot of work in field of Fe-based materials. We focus on the tetragonal (high-temperature) form of the iron disilicide, which crystal structure resembles one of the HTS, LiFeAs (T_{sc} =18 K). Single crystals of α-$FeSi_2$ with $Fe_{0.83}Si_2$ composition were grown and magnetic, transport and heat capacity studies were performed in consistent way. Magnetic susceptibility of α-$FeSi_2$ increases in a linear fashion with increasing temperature, as was commonly observed among Fe HTS. In a contrast to superconducting pnictides, where $\chi(T) \sim T$ is associated to antiferromagnetic fluctuations, in α-$FeSi_2$ this behavior is rather related to the electronic structure of this metal. In Fe-based HTS proximity of the SDW instability seems to be crucial for the emergence of superconducting state – in α-$FeSi_2$ the experimental data do not find evidence for any strong electronic correlations. Our LDA and DMFT calculations results find low density of states, supporting weakness of correlations and suggest electronic configuration of Fe close to d^6.

12:39PM G35.00006 Magnetic Excitations in LaMnPO , DANIEL MCNALLY, JACK SIMONSON, Department of Physics and Astronomy, Stony Brook University, Stony Brook, NY 11794, GREG SMITH, Department of Physics, The Ohio State University, Columbus, Ohio 43210, JEFF LYNN, YANG ZHAO, NIST Center for Neutron Research, National Institute of Standards and Technology, Gaithersburg, Maryland 20899, MEIGAN ARONSON, Department of Physics and Astronomy, Stony Brook University, Stony Brook, NY 11794 — We performed inelastic neutron scattering experiments on LaMnPO at the BT-7 triple-axis spectrometer at NIST Center for Neutron Research. LaMnPO is an insulating pnictide compound and is antiferromagnetically ordered below $T_N = 375$ K. Constant energy scans were performed above T_N, and revealed spin-spin correlations in the paramagnetic state with characteristic wavevector Q = 1.6 Å^{-1}, near the antiferromagnetic ordering wavevector $Q_{AFM} = 1.55$ Å^{-1}. We performed constant wavevector scans above and below T_N and these show there is a q-dependent and temperature-dependent energy gap in the magnetic excitations that vanishes at $T_N = 375$ K. Constant energy scans below T_N show the peak in the magnetic excitations does not change up to a measured energy transfer of 15 meV, suggesting exchange interactions are quite strong. The magnetic excitations in LaMnPO are similar to those observed in the parent compounds of the iron pnictide superconductors. Research supported by a National Security Science and Engineering Faculty Fellowship by the AFOSR

12:51PM G35.00007 Pressurized LaMnPO: antiferromagnetic insulator to magnetic metal , J.W. SIMONSON, Department of Physics and Astronony, Stony Brook University, M. PEZZOLI, Department of Physics and Astronony, Stony Brook University and Department of Physics and Astronomy, Rutgers University, J. GUO, Institute of Physics and Beijing National Laboratory for Condensed Matter Physics, Chinese Academy of Sciences, J. LIU, Institute of High Energy Physics, Chinese Academy of Sciences, L.L. SUN, Institute of Physics and Beijing National Laboratory for Condensed Matter Physics, Chinese Academy of Sciences, G. KOTLIAR, Department of Physics and Astronomy, Rutgers University, M.C. ARONSON, Department of Physics and Astronony, Stony Brook University — It is felt that high temperature superconductivity stems from proximity to an electron delocalization transition, such as the metal-insulator transitions exhibited by the cuprates or the antiferromagnetic transitions of the iron pnictides. We subjected the manganese pnictide LaMnPO to hydrostatic pressures up to 43 GPa, measured x-ray diffraction patterns, and solved the crystal structures at various pressures. We then performed LSDA electronic structure calculations using the observed lattice constants and atomic parameters to obtain the magnitudes of the insulating gap and the ordered state magnetic moment. While the calculations found the gap to close near 10 GPa, the magnetic moment persisted until a structural collapse at 31 GPa. These results imply that the metal-insulator transition and the antiferromagnetic transition are separated within the pressure phase diagram of LaMnPO. We discuss these results in light of the inherent differences between Mott-like and Hund's-like systems.

1:03PM G35.00008 Complex magnetic properties in multilayer rare earth oxypnictides[1] , JIAKUI WANG, CHIH-WEI CHEN, EMILIA MOROSAN, Department of Physics and Astronomy, Rice University — Intensive research interest on layered transition metal pnictide materials was stimulated by the discovery of high temperature superconductivity in Fe-pnictides a few years ago. To study the relationship between superconductivity, crystal structure and magnetism, and to search for novel superconductors of better application potential, more transition metal pnictides are worth investigating. In this talk, I will discuss physical properties of members of a particular class of layered oxypnictides, with four transition metal pnictogen layers per unit cell. While varying the rare earth ion, we find that one compound is a low temperature superconductor (Tc $\sim$ 2.1 K), and others show diverse magnetic properties, including ferromagnetic or antiferromagnetic order, or spin glass behavior. I will show our observation from measurements of DC and AC magnetization, specific heat and resistivity. The understanding of the physical properties of these isostructual compounds may serve as a guide in the search for superconductivity in these systems.

1:15PM G35.00009 Angle Resolved Photoemission Spectroscopy Study on Layered Oxy-pnictide BaTi2As2O , HAICHAO XU, MIN XU, QINGQIN GE, RUI PENG, YAN ZHANG, Fudan University, XIANGFENG WANG, XIANHUI CHEN, USTC, M. ARITA, K. SHIMADA, Hisor, DONGLAI FENG, Fudan University, FUDAN UNIVERSITY COLLABORATION[1], USTC COLLABORATION[2], HISOR COLLABORATION[3] — Recently, superconductivity has been discovered in $Ba_{1-x}Na_xTi_2Sb_2O$, a titanium-based oxy-pnictide with an anti-CuO_2 type Ti_2O plane and a CDW/SDW anomaly at 54K. The isostructured $BaTi_2As_2O$, where signs of CDW/SDW at 200K has been observed, could be viewed as one of the parent compounds of this new family of superconductors. Here we report the Angle Resolved Photoemission Spectroscopy Study on $BaTi_2As_2O$. Parallel sections were found in Fermi surface structure, indicating possible nesting condition. The orbital character of bands supports the important role of Ti-Ti direct interaction. No abrupt change was observed at the critical temperature; however, spectral weight change takes place at wide energy scale both above and below the critical temperature, revealing the strong electron-lattice coupling effect in this system.

1:27PM G35.00010 Investigation of the normal and superconducting states of $Ba_xNa_{1-x}Ti_2Sb_2O$ ($0 \geq x \geq 0.33$) : a pnictide oxide compound with hole doped titanium-oxygen layers , M. GOOCH, B. LORENZ, TcSUH, Dept of Physics, University of Houston, P. DOAN, Z.J. TANG, J. TAPP, A. MÖLLER, A.M. GULOY, TcSUH, Dept of Chemistry, University of Houston, D. PRATT, J. LYNN, NIST, Center for Nuetron Research, C.W. CHU, TcSUH, Dept of Physics, University of Houston and Lawrence Berkeley National Laboratory — The interest in layered transition metal oxides/pnictides was re-ignited by the discovery of the iron pnictides; 2 such as examples are, $Na_2Ti_2Pn_2O$ and $BaTi_2As_2O$. Both compounds are comprised of a layered structure and exhibit a SDW/CDW, similar to the iron pnictide parent compounds. It is well established that by suppressing the SDW, superconductivity emerges in pnictides; therefore, can a similar approach be used for these titanium based pnictide oxides? To date, the lowering of the critical temperature for the SDW/CDW has been reported, but no superconductivity was seen for $BaTi_2As_2O$. We report the effects of hole doping on $BaTi_2Sb_2O$ and its influence on the SDW and superconducting states. Initial findings from neutron scattering will also be discussed. Our parent compound, which is similar to the $BaTi_2As_2O$ in structure, shows a SDW/CDW at 57 K. A systematic lowering of the critical temperature is seen for the SDW/CDW with increased doping. In addition, the superconducting temperature increases up to 6 K. The phase diagram as a function of doping is derived from the normal and superconducting states of the system. The lowering of the critical temperature of the SDW/CDW seems to be the key for the emergence of superconductivity.

1:39PM G35.00011 Crystal structure and superconducvitiy in $BaPbO_3/BaBiO_3$ thin films[1] , G.W.J. HASSINK, K. MUNAKATA, R.H. HAMMOND, M.R. BEASLEY, Geballe Laboratory for Advanced Materials, Stanford University, Stanford, CA 94305, USA — Thin bilayers of $BaPbO_3$ and $BaBiO_3$ were grown on $SrTiO_3$ by e-beam evaporation in the hope of testing the proximity effect route to high T_c superconductivity suggested by Kivelson et al [Phys.Rev.B 78, 094509]. X-ray diffraction measurements show that the bilayers are single-phase, but fully relaxed. Depth-profiling by XPS showed that for a deposition temperature of 500 °C there is a gradual intermixing of Pb and Bi in the top $BaPbO_3$ layer. This could result in a superconducting Ba(Pb,Bi)O_3 film, but XRD points to well-resolved layers. Superconductivity in these films is BCS-like, with $\xi_{GL}(0) \sim 10$ nm comparable to bulk values. However, the superconductivity was not primarily correlated with the Bi content as determined from surface XPS scans, but by the crystal structure. The superconducting films consistently have a larger unit cell volume, mostly due to larger in-plane lattice constants. This increase coincides with a higher Ba/Pb elemental ratios, which in literature has been linked to the occurrence of the tetragonal form of Ba(Pb,Bi)O_3 [Sol.State.Comm. 60, 897-900]. This larger unit cell may result in a lower tilt angle of the oxygen octahedra, which has a positive influence on the superconductivity [Phys.Rev.B 83, 174512].

1:51PM G35.00012 Multigap Superconductivity at 5.4 K in β-Bi_2Pd , YOSHINORI IMAI, FUYUKI NABESHIMA, TAIKI YOSHINAKA, KOSUKE MIYATANI, ATSUTAKA MAEDA, Dept. of Basic Science, the University of Tokyo, RYUSUKE KONDO, Dept. of Physics, Okayama University, SEIKI KOMIYA, ICHIRO TSUKADA, Central Research Institute of Electric Power Industry — We report the superconducting properties of new multigap superconductor Bi_2Pd(β-Bi_2Pd; space group: $I4/mmm$)[1]. β-Bi_2Pd single crystals were grown via a melt-growth method. The temperature dependences of the electrical resistivity and the magnetic susceptibility reveal that the superconducting transition occurs at 5.4 K in the β-Bi_2Pd single crystal. This value is greater than the value of 4.25 K reported in the previous paper [2]. Here, it is interesting to note that the T_c of β-Bi_2Pd reported here is almost the same as that of Pd-intercalated Bi_2Te_3 with a very small superconducting volume fraction ($< 1\%$) in ref. [3], where the possibility that the topological insulator Bi_2Te_3 can be made into an SC by Pd intercalation between the Bi_2Te_3 layers is argued. In addition, the temperature dependences of the upper critical magnetic field and the specific heat suggest that β-Bi_2Pd is a multiple-band/multiple-gap superconductor.

2:03PM G35.00013 Different doping from apical and planar oxygen vacancies in $Ba_2CuO_{4-\delta}$ and $La_2CuO_{4-\delta}$, THOMAS JARLBORG, DPMC, 24 Quai E-Ansermet, University of Geneva, CH1211 Geneva 4, BERNARDO BARBIELLINI, ROBERT MARKIEWICZ, ARUN BANSIL, Dep. of Physics, Northeastern University, Boston, Mass 02115, USA — First principles band-structure calculations for large supercells of $Ba_2CuO_{4-\delta}$ and $La_2CuO_{4-\delta}$ with different distributions and concentrations of oxygen vacancies show that the effective doping on copper sites strongly depends on where the vacancy is located. A vacancy within the Cu layer produces a weak electron doping effect while a vacancy located at an apical oxygen site acts as a stronger electron dopant on the copper layers and gradually brings the electronic structure close to that of $La_{2-x}Sr_xCuO_4$. These effects are very robust and only depend marginally on lattice distortions. Our results show that deoxygenation can reduce the effect of traditional La/Sr or La/Nd substitutions. Our study clearly identifies location of the dopant in the crystal structure as an important factor in doping of the cuprate planes.

Tuesday, March 19, 2013 11:15AM - 2:03PM –

Session G36 DCMP: Superconductivity: Transport Properties 344 - Zhuan Xu, Zhejiang University, China

11:15AM G36.00001 c-axis resistivity, pseudogap, superconductivity and Widom line in doped Mott insulators , GIOVANNI SORDI, Institut Laue-Langevin, Grenoble, France, PATRICK SEMON, Universite de Sherbrooke, K. HAULE, Rutgers University, A.-M. S. TREMBLAY, Universite de Sherbrooke and Canadian Institute for Advanced Research — Layered doped Mott insulators, such as the cuprates, show unusual temperature dependence of the resistivity. We calculate the c-axis resistivity ρ_c for the two-dimensional Hubbard model within plaquette cellular dynamical mean-field theory. The temperature and doping dependencies of ρ_c are controlled by the first-order transition between pseudogap and correlated metal phases from which superconductivity can emerge. On the large doping side of the transition $\rho_c(T)$ is metallic, while on the low-doping side $\rho_c(T)$ changes from metallic to semi-conducting behavior with decreasing T. As a function of doping, the jump in ρ_c across the first-order transition evolves into a sharp crossover at higher temperatures. This crossover coincides with the pseudogap temperature T^* in the single-particle density of states, the spin susceptibility and other observables. Such coincidence in crossovers is expected along the continuation of the first-order transition into the supercritical regime, called the Widom line. This implies that not only the dynamic and the thermodynamic properties but also the DC transport in the normal state are governed by the hidden first-order transition. Refs: G. Sordi et al, Sci. Rep. 2, 547 (2012); G.Sordi et al, arXiv:1211.1702 (2012)

11:27AM G36.00002 C-Axis Conductivity of a Layered Superconductor in a Transverse Magnetic Field , SHIMUL AKHANJEE, ROBERT KONIK, CMPMS Dept. Brookhaven National Laboratory — We study the temperature and field dependence of Josephson pair tunneling between parallel superconducting films in the presence of a transverse magnetic field, modeled as a 2+1 dimensional XY model, transformed under the Villain duality. The magnetic field-induced diamagnetism is treated using a variational scheme developed by Benfatto et. al (2007) and the conductivity is described in terms of correlations between quantum phase slip events. We find that the universal point contact conductivity is modified by characteristic power laws.

11:39AM G36.00003 Low-frequency Electronic Transport Noise in $La_{2-x}Ba_xCuO_4$ Nanowires[1] , ADAM WEIS, YIZHOU XIN, DALE VAN HARLINGEN, University of Illinois at Urbana-Champaign — In the pseudogap regime, high temperature superconductors often exhibit electronic structure, such as charge stripes. Charge stripes pinned to disorder have been predicted to contribute to low-frequency resistance fluctuations when sample dimensions are comparable to the size of stripe domains (Carlson, 2006). We are extending our previous studies of resistance fluctuations in $YBa_2Cu_3O_{7-\delta}$ (Bonetti, 2004; Caplan, 2010) to thin films of La-based cuprates expected to have a more stable stripe phase, particularly in the regime near 1/8-filling. We present measurements of the low-frequency electronic transport in $La_{2-x}Ba_xCuO_4$ nanowires fabricated by pulsed laser deposition and lithographic techniques. We discuss temperature dependence of the power spectral density and its relevance to correlated electron phases above T_c.

11:51AM G36.00004 Hall effect and ghost critical field in disordered superconducting films , NICHOLAS BREZNAY, AHARON KAPITULNIK, Stanford University — abstract-We observe a peak in the Hall resistance ocurring at a magnetic field H* in superconducting disordered thin films. Below the zero-field transition temperature Tc0, H* exactly tracks the upper critical field, Hc2, all the way to zero temperature. Near Tc0, H* becomes vanishingly small, while above Tc0 the peak again scales to higher fields as the temperature is further increased. Companion measurements of the fluctuation magnetoconductivity at temperatures above Tc0 allow precise and indpendent determination of the 'ghost critical field' Hgc, the field scale for suppression of superconducting fluctuations above Tc0. We find that H* and Hgc are distinct quantities but show similar scaling above Tc0, and compare these results to similar findings in studies of the Nernst effect in thin films [A. Pourret et al. Phys. Rev. B 76, 214504, (2007)] and high-temperature superconductors [J. Chang et al. Nature Physics 8, 751 (2012)].

12:03PM G36.00005 Comparing the specific heat to the cyclotron mass in two dopings of YBCO in the underdoped regime[1] , JONATHON KEMPER, Florida State University/NHMFL, SCOTT C. RIGGS, Stanford University, O. VAFEK, Florida State University/NHMFL, A. MIGLIORI, J.B. BETTS, B.J. RAMSHAW, R.D. MCDONALD, F.F. BALAKIREV, Los Alamos Nat'l Lab/NHMFL, R. LIANG, D.A. BONN, University of British Columbia, G.S. BOEBINGER, Florida State University/NHMFL — Two underdoped High T_c superconductors, $YBa_2Cu_3O_{6.51}$ and $YBa_2Cu_3O_{6.56}$, show finite electronic specific heat even in vanishing magnetic field and temperature as well as quantum magneto-oscillations at high magnetic fields. Previous results show the high-field electronic specific heat up to 45 T to be a sum of contributions from superconducting vortices and quantum magneto-oscillations, the latter a signature of an un-gapped Fermi surface. The vortex contribution appears as a smooth square-root field dependence of the Sommerfeld coefficient that shows no sign of diminished superconductivity up to 45 T. We present new results which allow a comparison between the cyclotron mass from high field experiments to the zero field Sommerfeld coefficient in the same crystal. The discussion will include implications of the new results on the interpretation of the previous data.

[1]Work funded in part by the DOE, NSF, and State of Florida.

12:15PM G36.00006 Exfoliated Bi2Sr2CaCu2O8+x thin flakes for electronic transport experiments , MENYOUNG LEE, MICHAEL NEUMANN, DAVID GOLDHABER-GORDON, Stanford University, LUKE SANDILANDS, KENNETH BURCH, University of Toronto, ZHIJUN XU, ALINA YANG, GENDA GU, Brookhaven National Lab — Bismuth-based cuprates are the model high-temperature superconductor of choice for experimental probes that are spectroscopic and sensitive to the surface (STM, ARPES), while studies of transport properties have typically focused on rare-earth element-based compounds. We will first discuss preparation methods for and characterization of tape-exfoliated single crystal thin (few to tens nm) flakes of the $Bi_2Sr_2CaCu_2O_{8+x}$ compound, in particular focusing on protocols designed to produce exposed conducting surfaces that are atomically smooth over several microns, and addressing the factors that influence the surface morphology and Raman scattering properties of BSCCO thin flakes. In addition, data from electronic transport measurements, aimed at observing a modulation of critical temperature and an insulator to superconductor transition as a function of hole density in the compound, will be presented.

12:27PM G36.00007 Nonlinear transport properties of La_2CuO_4/ $La_{2-x}Sr_x$ CuO_4 heterostructures in the resistive state[1] , BO WEN, ROMAN YAKOBOV, M.P. SARACHIK, SERGEY VITKALOV, Physics Department, City College of the City University of New York, New York 10031, USA, A. BOLLINGER, I. BOZOVIC, Brookhaven National Laboratory, USA, A. SERGEEV, SUNY Research Foundation, SUNY at Buffalo, Buffalo, NY14226, USA — We report measurements of the nonlinear transport properties of oxide heterojunctions $La_2CuO_4/La_{2-x}Sr_xCuO_4$ in the vicinity of the superconducting transition. The transition occurs over a wide temperature range (7-15K) and shifts to lower temperatures in the presence of a magnetic field, as expected. Strongly nonlinear behavior is observed for the $V-I$characteristic. At low bias currents the nonlinearity has a non-thermal origin close to the transition temperature and is strongly sensitive to magnetic fields. Above the middle of the superconducting transition the nonlinear behavior is consistent instead with electron heating with a value of electron-phonon thermal conductance of $\sim 10^{-6}$ W/K per square micron, which is significantly smaller than the thermal conductance of Nb and NbN ultrathin superconducting films. Our results indicate that this novel low-dimensional superconducting material shows great promise for substantial enhancement of direct detection and wide band mixing of radiation.

[1]Work was supported by National Science Foundation (ECCS-1128459).

12:39PM G36.00008 Tuning the static spin stripe phase and supercoductivity in $La_{2-x}Ba_xCuO_4$ ($x = 1/8$) by hydrostatic pressure , ZURAB GUGUCHIA, Physik-Institut der Universitat Zurich, ALEXANDER SHENGELAYA, Department of Physics, Tbilisi State University, ALEXANDER MAISURADZE, Physik-Institut der Universitat Zurich. Laboratory for Muon Spin Spectroscopy, Paul Scherrer Institute, GIORGI GHAMBASHIDZE, Department of Physics, Tbilisi State University, EKATERINA POMJAKUSHINA, KAZIMIERZ CONDER, Laboratory for Developments and Methods, Paul Scherrer Institute, HUGO KELLER, Physik-Institut der Universitat Zurich — Muon spin rotation (μSR) and magnetization measurements were performed in stripe-stabilized $La_{1.875}Ba_{0.125}CuO_4$ as a function of pressure up to $p \simeq 2.25$ GPa. At ambient pressure this system exhibits static spin stripe order below $T_{SO} \approx 30$ K. Zero-field μSR experiments indicate that the volume fraction ω of static spin-stripe order significantly decreases with increasing p, while the size of the ordered moment and the ordering temperature remain constant. The magnetization measurements show that the sample exhibits a tiny superconducting (SC) volume fraction at ambient pressure. However, by the application of pressure the SC phase volume increases proportionally to the non-magnetic volume fraction (1-ω). These results indicate that in $La_{1.875}Ba_{0.125}CuO_4$ magnetism and superconductivity occur in mutually exclusive spatial regions.

12:51PM G36.00009 Spin fluctuations on the verge of Mott localization[1] , HIMADRI BARMAN, N.S. VIDHYADHIRAJA, Theoretical Sciences Unit, Jawaharlal Nehru Centre for Advanced Scientific Research, Bengaluru 560064, India — We investigate the effects of local, transverse spin fluctuations on transport and thermodynamic quantities in the proximity of a paramagnetic Mott transition. Low temperature Fermi liquid coherence is seen to cross over to universal power laws in resistivity, optical conductivity and specific heat at higher temperatures and frequencies. Striking agreement with the normal phase properties of LSCO and BSSCO series of high temperature superconductors (HTS) is found. We conclude that the anomalous properties of HTS above the superconducting dome originate from spin fluctuation scattering concomitant to Mott localization.

1:03PM G36.00010 Resistivity of Sr_2 RuO_4 under uniaxial stress , DANIEL BRODSKY, CLIFFORD HICKS, ANDREW P. MACKENZIE, University of St Andrews — We report high precision resistivity measurements on single crystals of Sr_2RuO_4 under in-plane uniaxial stress. A specially built probe enables the stress to be varied continuously whilst the sample is at low temperature. The needle-like shape of the samples ensures that the strain is homogeneous in the region probed. We compare results for different directions of applied stress relative to the crystal axes.

1:15PM G36.00011 Circuit influence on electron transport in hybrid superconductor—normal-metal nanostructures , VLADIMIR BUBANJA, Measurement Standards Laboratory of New Zealand, Industrial Research Ltd, Wellington, New Zealand, SHUICHI IWABUCHI, Department of Physics, Nara Women's University, Nara, Japan — We study the effects of the circuit impedance on transport properties of hybrid structures consisting of a superconductor tunnel-coupled to two normal-metal electrodes. At subgap conditions (i.e. at low voltages and temperatures with respect to the superconducting energy gap) the dominant transport mechanism of Cooper pairs is by Andreev reflection. We derive the analytic expressions for the direct and crossed Andreev current, and the elastic cotunneling current. The results can be used for improving the accuracy of hybrid devices employed in electrical metrology and for noise measurements in quantum information processing.

1:27PM G36.00012 Micro-mechanical and Structural Properties and Activation Energy Calculation of Nd_2O_3 Added $Bi_2Sr_2Ca_1Cu_2O_y$ Superconducting System , OZGUR OZTURK, ELIF ASIKUZUN, MURAT COSKUNYUREK, SEYDANUR KAYA, Kastamonu University, Department of Physics 37100 Kastamonu-Turkey, MUSTAFA YILMAZLAR, Faculty of Education, Sakarya University 54300 Hendek, Sakarya-Turkey, GURCAN YILDIRIM, CABIR TERZIOGLU, Abant Izzet Baysal University, Department of Physics 14280 Bolu-Turkey — Nd added Bi-2212 superconducting samples with x=0, 0.001, 0.005, 0.01, 0.05 and 0.1 were prepared by conventional solid state reaction method and annealed at 840°C for 72 h. For the comparison, an undoped sample was produced to the same conditions. The effects of Nd addition on structural and micromechanical properties were systematically investigated. The volume fraction, lattice parameters, crystal structure and grain size of the samples were characterized using the X-ray diffractometer and Scanning Electron Microscope. In addition, this study includes determination of the activation energy of Nd in the Bi-2212 system using the magnetoresistivity measurements. And also, we were investigated the mechanical properties for all samples using the Vickers microhardness measurements. Microhardness values of the samples decrease with increasing adding and applied load. The Vickers hardness of the samples studied, exhibits the typical indentation size effect (ISE).

1:39PM G36.00013 Analysis of Indentation Size Effect (ISE) Behavior in Low-Load Vickers Microhardness Testing of $(Sm123)_{1-x}(Nd123)_x$ Superconductor System , SUKRU CELIK, R.T.E.U., Department of Physics, Rize, Turkey, OZGUR OZTURK, 2Kastamonu University, Department of Physics, Kastamonu, Turkey, ELVAN COŞKUN, R.T.E.U., Department of Physics, Rize, Turkey, ELIF ASIKUZU, 2Kastamonu University, Department of Physics 37100 Kastamonu, Turkey, KEMAL OZTURK, K.T.U., Department of Physics, Trabzon, Turkey, CABIR TERZIOGLU, A.I.B.U., Department of Physics, Bolu, Turkey — Indentation size effect (*ISE*) for $(Sm123)_{1-x}(Nd123)_x$ superconducting samples which were fabricated by the solid state reaction technique for values of x=0.00, 0.05, 0.10, 0.20, and 0.30 was investigated by analyzing the theoretical models. When the experimental data of a number of single crystals which have the different crystal structure and different chemical bonding inside the polycrystallined samples were analyzed with the *ISE* models, the sample encountering with resistance and elastic deformation was observed as well as plastic deformation. The microhardness values on different surfaces of materials were calculated by using Meyer Law, *PSR* model, MPSR model, *EDP* (Elastic / Plastic Deformation model) model and the Hays-Kendall (*HK*) approach. The results showed that the Hays- Kendall approach was determined as the most successful model. Furthermore, XRD and SEM measurements were analyzed for superconducting properties of $(Sm123)_{1-x}(Nd123)_x$ superconductor system. The results showed that while Nd123 concentration is increasing, microhardness values at the minimum load and averaged plateau region of load.

1:51PM G36.00014 Investigation of Indentation Size Effect (ISE) of $Bi_2Sr_2CaNd_xCu_2O_y$ Superconducting System using Vickers Microhardness Test Method , ELIF ASIKUZUN, OZGUR OZTURK, SEYDANUR KAYA, MURAT COSKUNYUREK, Kastamonu University, Department of Physics, Kastamonu, Turkey, NEVIN SOYLU, AHMET VARILCI, CABIR TERZIOGLU, Abant Izzet Baysal University, Department of Physics, Bolu, Turkey — In this work, the effects of Nd doping on the structural and mechanical properties of the samples were analyzed. Nd_2O_3 doped Bi-2212 superconductors were obtained using solid state reaction method. Microhardness measurements were made to analyze the mechanical properties. XRD and SEM measurements were done for determination of crystal structure and surface morphology and calculation of the lattice parameters. The Vickers microhardness was calculated for undoped and doped samples. The experimental results of the microhardness measurements were analyzed using Kick's Law, PSR (proportional specimen resistance), modified PRS (MPSR) and Hays–Kendall (HK) approach. The microhardness values of the samples decreased with increasing Nd doping and applied load. Finally, the Hays-Kendall *(HK)* approach was determined as the most successful model describing the mechanical properties of our samples.

Session G37 DMP DCOMP: Focus Session: Fe-based Superconductors: RPA and Beyond/Gap Structure 345/346 - Peter Hirchfeld, Univ. Florida

11:15AM G37.00001 Development of orbital and spin fluctuations in Fe-based superconductors based on the self-consistent vertex correction (SC-VC) method , HIROSHI KONTANI, Nagoya University — To achieve unified understanding of the whole phase diagram of Fe-based superconductors, we analyze the multiorbital Hubbard model going beyond the random phase approximation (RPA). The 2nd-order non-magnetic structure transition at $T_S(> T_N)$, nematic order as well as large softening of shear modulus C_{66} indicate the strong orbital fluctuations in the normal state. However, only the spin fluctuations develop within the RPA. To resolve this discrepancy, we develop the self-consistent vertex correction (SC-VC) method beyond the RPA, and find the mutual development of orbital and spin fluctuations due to the Aslamazov-Larkin VC, which describes the Kugel-Khomskii type spin-orbital coupling [1]. We find that (i) both the antiferro-orbital and ferro-orbital (=nematic) fluctuations develop for $J/U > 0.17$ by including the self-energy correction (=SC-VΣ method): Both fluctuations contribute to the s-wave superconductivity, and the nematic fluctuations are the origin of the structure transition and the softening of C_{66}. (ii) The coexistence of orbital and spin fluctuations can induce the loop-shape nodes on the electron-pockets in $BaFe_2(As,P)_2$, as well as (impurity-induced) smooth $s_\pm \to s_{++}$crossover with high T_c [2,3]. Also, the horizontal node on the z^2-orbitlal hole-pocket predicted by RPA is filled by the inter-orbital fluctuations due to the VC, consistently with laser ARPES and other bulk experiments of 122 compounds. (iii) The same orbital nematic fluctuations are obtained in a simple two-orbital model for $Sr_3Ru_2O_7$, not only by the SC-VC method [4] but also by the two-dimensional RG method [5]. Therefore, the VC is expected to be the origin of novel orbital physics in various multioritital d- and f-electron systems.

11:51AM G37.00002 Theoretical Study of 3D Superconducting Gap Structure in Iron Based Superconductors , TETUSRO SAITO, SEIICHIRO ONARI, HIROSHI KONTANI, Nagoya University — The mechanism and symmetry of the superconducting (SC) gap in Fe-based superconductors have been studied actively, and both the spin fluctuation-mediated $s_\pm$-wave SC state and orbital fluctuation-mediated s_{++}-wave SC state had been proposed. To obtain important information on the pairing mechanism, we analyze the Eliashberg gap equation using the 3-dimensional 10-orbital model. When we perform the RPA by considering only the Coulomb interaction, only the spin fluctuations develop, and the SC gap of z^2-orbital dominant part on the hole pockets is almost zero. The resultant horizontal node is inconsistent with several measurements. However, the orbital fluctuations develop by introducing the quadrupole interaction g (due to the vertex correction) and it is found that (i) the horizontal node disappears and (ii) the crossover from $s_\pm$-state to s_{++}-state is realized. During the crossover, we obtained the loop-node structures on the electron pockets, which are actually observed by ARPES measurements in $BaFe_2(As,P)_2$. We expect that optimally doped $BaFe_2(As,P)_2$ is in the crossover regime between s_{++}-state and $s_\pm$-state.

12:03PM G37.00003 Pressure dependence of critical temperature of bulk FeSe from spin fluctuation theory[1]

, PETER HIRSCHFELD, ANDREAS KREISEL, YAN WANG, Department of Physics, University of Florida, Gainesville, FL 32611-8440, USA, MILAN TOMIC, HARALD JESCHKE, ANTHONY JACKO, ROSER VALENTI, Institut für Theoretische Physik, Universität Frankfurt, 60438 Frankfurt, Germany, THOMAS MAIER, Center for Nanophase Materials Sciences and Computer Science and Mathematics Division, Oak Ridge National Laboratory, Oak Ridge, TN 37831-6494, USA, DOUGLAS SCALAPINO, Department of Physics, University of California, Santa Barbara, CA 93106-9530, USA — The critical temperature of the 8K superconductor FeSe is extremely sensitive to pressure, rising to a maximum of 40K at about 10GPa [1]. We test the ability of the current generation of fluctuation exchange pairing theories to account for this effect, by downfolding the density functional theory electronic structure for each pressure to a tight binding model. The Fermi surface found in such a procedure is then used with fixed Hubbard parameters to determine the pairing strength using the random phase approximation for the spin singlet pairing vertex. We find that the evolution of the Fermi surface captured by such an approach is alone not sufficient to explain the observed pressure dependence, and discuss alternative approaches.

12:15PM G37.00004 Effect of realistic finite-size impurities on Tc in Fe-based superconductors

, YOUICHI YAMAKAWA, SEIICHIRO ONARI, HIROSHI KONTANI, Nagoya University — Recently, the phase diagram of $LaFeAsO_{1-x}H_x$ is reported and two-dome structure of superconducting state, first dome for $x < 0.2$ with $T_c^{\max} = 29$K and second dome for $0.2 < x < 0.5$ with $T_c^{\max} = 36$K, has attract great attention[1]. To clarify the origin of the second superconducting dome, we construct tight-binding models for each doping level x and investigate the spin and orbital fluctuations based on the random phase approximation. We fined that the nesting between electron-hole Fermi surfaces is monotonically weakened with x and spin density wave order with momentum $\mathbf{q} = (\pi, \pi)$ disappears. In the over-doped regime for $x > 0.2$, however, the nesting between electron-electron Fermi surfaces increases, and an incommensurate spin density wave order emerges. The orbital order also shows a re-entrant phase diagram. The spin and orbital fluctuations due to the incommensurate nesting would then be the origin of the second superconducting dome reported in the H-over-doped LaFeAsO. The obtained electronic states for $x = 0.5$ are very similar to that for KFe_2Se_2[2], which is a heavily electron doped system(0.5 electron/Fe). [1] S. Iimura, *et al.*, Nat. Commumn. **3**, 943 (2012). [2] T. Saito, *et al.*, Phys. Rev. B **83**, 140512 (2011).

12:27PM G37.00005 Magnetic degeneracy and C_4 symmetric magnetic phase in iron-based superconductors

, ILYA EREMIN, Ruhr-Universitaet Bochum, Theoretische Physik III, 44801 Bochum, Germany, ANDREY V. CHUBUKOV, Department of Physics, University of Wisconsin-Madison, Madison,Wisconsin 53706, USA — We analyze the magnetic phase diagram of iron pnictides by going beyond Ginzburg-Landau expansion and solving full non-linear equation for magnetic order parameter within itinerant model with hole pockets centered around (0,0) and electron pockets centered at (π,0) and (0, π) in the unfolded Brillouin zone. We extend our previous analysis of the itinerant model to higher carrier concentrations when Fermi surface nesting is weaker, and find that the phase diagram is richer than previously anticipated. We show that, in addition to stripe SDW order which breaks C_4 rotational symmetry, there exists, in some range of parameters, a different type of SDW order which preserves C_4 symmetry. The order parameter in this new phase is equally weighted combination of SDW components with wavevectors $Q_X = (\pi,0)$ and $Q_Y = (0,\pi)$. The new phase emerges from the stripe phase via a second transition at $T < T_N$. Such a phase is highly unlikely in the orbital scenario for magnetism in iron-based superconductors, because in this scenario the breaking of the symmetry between Q_X and Q_Y is the pre-condition for the magnetic transition. We discuss recent experiments in which the second low-T magnetic phase which does not break the symmetry between Q_X and Q_Y has been detected and argue that its observation is a strong indication that the magnetic order is of magnetic rather than of orbital origin.

12:39PM G37.00006 Pairing strength and gap functions in multiband superconductors: 3D effects[1]

, ANDREAS KREISEL, YAN WANG, PETER HIRSCHFELD, Department of Physics, University of Florida, Gainesville, FL 32611-8440, USA, THOMAS MAIER, Center for Nanophase Materials Sciences and Computer Science and Mathematics Division, Oak Ridge National Laboratory, Oak Ridge, TN 37831-6494, USA, DOUGLAS SCALAPINO, Department of Physics, University of California, Santa Barbara, CA 93106-9530, USA — We examine the superconducting pairing symmetry in Fe-based superconductors using spin-fluctuation pairing theory. It has been shown in multi-orbital models that the different matrix elements of the pairing vertex are essential in determining the symmetry. In our approach we perform a 10-orbital spin-fluctuation calculation to account for the full matrix elements and the 3 dimensional character of the bandstructure which is most important in the systems under consideration (LiFeAs and $K_xFe_{2-y}Se_2$). Our approach contains both, the deviations from tube-like Fermi surface that also allows different pairing strengths in the z-direction, and the hybridization of the Fermi surface. Starting from the tight-binding Hamiltonian corresponding to the real crystal cell, we find several competing 3D gap structures and compare with ARPES experiments.

[1]PJH, YW, AK were supported by DOE DE-FG02-05ER46236.

12:51PM G37.00007 Spin fluctuation theory of pairing in AFe_2As_2

, THOMAS MAIER, Oak Ridge National Laboratory, YAN WANG, ANDREAS KREISEL, PETER HIRSCHFELD, University of Florida, DOUGLAS SCALAPINO, University of California, Santa Barbara — The absence of Fermi surface hole pockets in the alkaline iron selenides has challenged the usual spin fluctuation arguments leading to the most popular s+- superconducting gap structure in the closely related iron pnictide superconductors. Thus they provide a new venue to study the nature of pairing in a system with only electron pockets. Here, we present the results of spin fluctuation calculations of the pairing interaction based on realistic descriptions of the bandstructure of the iron selenides. In particular, we will discuss the predictions of these studies with regard to the gap structure in the absence of hole pockets, its consequences for the magnetic neutron scattering spectrum, and their evolution with doping.

1:03PM G37.00008 Phase diagram of doped $BaFe_2As_2$ superconductor under broken C_4 symmetry

, YUAN-YEN TAI, Department of Physics, University of Houston, JIAN-XIN ZHU, MATTHIAS J. GRAF, Theoretical Division, Los Alamos National Laboratory, C.S. TING, Department of Physics, University of Houston, DEPARTMENT OF PHYSICS, UNIVERSITY OF HOUSTON TEAM, THEORETICAL DIVISION, LOS ALAMOS NATIONAL LABORATORY TEAM — We developed a minimal multi-orbital tight-binding model with realistic hopping parameters that breaks the symmetry of the point group by lowering it from C_4 to D_{2d}. The model accurately describes the Fermi surface evolution of the electron, $BaFe_{2-x}Co_xAs_2$, and hole, $Ba_{1-y}K_yFe_2As_2$, doped compounds. Since in this class of materials the competing superconductivity and co-linear antiferromagnetism rely on the evolution of the Fermi surface with doping, we investigated the phase diagram with a mean-field t-U-V Bogoliubov-de Gennes equation. Our results match the experimental electron-doped phase diagram. Furthermore, the model is in reasonable agreement with the experimental hole-doped part with only one set of t, U and V parameters. The self-consistently calculated superconducting order parameter exhibits s+/-d pairing symmetry in the entire doping range. It is the subtle result of competing interactions in the multi-orbital mean-field Hamiltonian based on the broken C_4 symmetry and might be observable in STM and ARPES experiments.

1:15PM G37.00009 Hidden (π,0) instability as an itinerant origin of bicollinear antiferromagnetism in $Fe_{1+x}Te$[1] , YU-ZHONG ZHANG, MING-CUI DING, School of physics science and engineering, Tongji University, Shanghai 200092, China, HAI-QING LIN, Beijing computational science research center, Beijing, China — By calculating orbitally resolved Pauli susceptibilities within maximally localized Wannier orbital basis transformed from first principles band structures, we find that magnetism in $Fe_{1+x}Te$ still has its itinerant origin even without Fermi surface nesting, provide orbital modulation of particle-hole excitations are considered. This leads to strong magnetic instabilities at wave vector (π,0)/(0,π) in d_{xz}/d_{yz} orbitals that are responsible for bicollinear antiferromagnetic state as extra electrons donated from excess Fe are considered. Magnetic exchange coupling between excess Fe and in-plane Fe further stabilizes the bicollinear antiferromagnetic order. Our results reveal that magnetism and superconductivity in iron chalcogenides may have different orbital origin, as Pauli susceptibilities of different orbitals evolves differently as a function of concentration of excess Fe and height of chalcogen atom measured from iron plane.

[1]Sponsored by National Natural Science Foundation of China (No. 11174219), Shanghai Pujiang Program (No. 11PJ1409900) and Research Fund for the Doctoral Program of Higher Education of China (No. 20110072110044)

1:27PM G37.00010 Fluctuation of Valley Density Wave in Iron Pnictides[1] , JIAN KANG, ZLATKO TESANOVIC[2], Institute for Quantum Matter and Department of Physics and Astronomy, The Johns Hopkins University, Baltimore, MD 21218 — We studied the fluctuations within the U(n)*U(n) [1] theory, which was developed to explain the magnetic and structural transitions in the parent compound of iron pnictides. The self-energy of the fermion contains singularity in low energy scale. It behaves similar to marginal Fermi liquid theory and depends on n. The optical conductivity and spin lattice relaxation time are calculated and compared with some experiment on "pseudogap" in iron pnictides. More experiments are proposed to provide a direct view our U(4)*U(4) theory being assembled as one moves from low to high energies.

1:39PM G37.00011 Superconducting energy gap and nodes in the doped BaFe2As2 system , SHIK SHIN, Institute for Solid State Physics, University of Tokyo — Angle resolved photoemission spectroscopy (ARPES) is very powerful to know the solid state properties. We have developed low-temperature high-resolution laser-based ARPES system and recently achieved the highest energy resolution of $\sim$ 100 μeV and the lowest sample temperature of $\sim$ 1.0 K. We would like to show our recent results of superconducting-gap measurements on the iron-based superconductors by laser-ARPES, mainly for $Ba_{1-x}K_xFe_2As_2$ [1-3]. Little Fermi-surface dependent superconducting gap sizes are found for the $Ba_{0.6}K_{0.4}Fe_2As_2$ that has the maximum Tc around 40K [1]. Inter-orbital interaction is important as well as intra-orbital interaction. On the other hand, KFe_2As_2 is an extremely hole-doped compound in $Ba_{1-x}K_xFe_2As_2$ system and no longer has electron Fermi surfaces. Regardless of this, KFe_2As_2 still exhibits superconductivity with Tc of 3.4 K and the existence of nodes in its superconducting gap has been suggested by the several transport measurements. Our ultrahigh-resolution laser ARPES [2] unveils that KFe_2As_2 is a nodal s-wave superconductor with highly unusual FS-selective multi-gap structure: a nodeless gap on the inner FS, an unconventional gap with octet-line nodes on the middle FS, and an almost-zero gap on the outer FS. This gap structure may arise from the frustration between competing pairing interactions on the hole FSs causing the eightfold sign reversal. Our results suggest that the A1g superconducting symmetry is universal in iron-pnictides, in spite of the variety of gap functions.

Session G39 GSCCM DCOMP DMP: Matter at Extreme Conditions: Experiment 348 - Renata Wentzcovitch, University of Minnesota

11:15AM G39.00001 Powder X-ray diffraction of dynamically-compressed tantalum and lead in the terapascale pressure regime , AMY LAZICKI, JON EGGERT, RYAN RYGG, FEDERICA COPPARI, DAYNE FRATANDUONO, DAVE BRAUN, GILBERT COLLINS, Lawrence Livermore National Laboaratory — We will present advances in powder x-ray diffraction methods for measuring crystal structure in the Terapascale pressure regime on laser ramp-compressed solids, and will show results for dynamically compressed tantalum up to 750 GPa and lead up to 600 GPa. Both of these systems show signatures of high pressure phase transitions not yet seen in static high pressure studies. We will discuss the possible effects of temperature and kinetics on high pressure phase transitions in ramp-compressed materials. This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.

11:27AM G39.00002 Kinetics studies across the melting line of metals using *dynamic*-DAC , JING-YIN CHEN, ZSOLT JENEI, HYUNCHAE CYNN, MAGNUS LIPP, WILLIAM EVANS, High Pressure Physics Group, Lawrence Livermore National Laboratory — We utilize the time-resolved synchrotron x-ray diffraction and *in-situ* optical spectroscopy to study the dynamic properties of several metals across the melting lines under different compression rates at different temperatures. The dynamic properties of metals across the pressure-induced liquid-solid transitions, such as the nucleation time and the mechanism of recrystallization are lacking. Time scales for metal nucleation and growth rates are challenging to obtain. X-ray diffraction under rapid compression will provide unique insight to understand the melting and crystallization mechanisms. In addition, the dynamical pressure changes can dramatically influence the microstructure and even phase boundaries, further affecting the properties of metals. This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory in part under contract W-7405-Eng-48 and in part under Contract DE-AC52-07NA27344. This work was funded by the Laboratory Directed Research and Development Program at LLNL under project tracking code 11-ERD-046.

11:39AM G39.00003 Experimental Measurement of Speeds of Sound in Liquid Carbon Monoxide and Development of High-Pressure, High-Temperature Equations of State , JOSEPH ZAUG, JEFFREY CARTER, SORIN BASTEA, LAURENCE FRIED, Lawrence Livermore National Laboratory — We report the adiabatic sound speeds for liquid carbon monoxide along two isotherms, from 0.17 to 2.13 GPa at 297 K and from 0.31 to 3.2 GPa at 600 K. The carbon monoxide was confined in a resistively heated diamond-anvil cell and the sound speed measurements were conducted *in situ* using a recently reported variant of the photoacoustic light scattering effect. The measured sound speeds were then used to parameterize a polarized exponential-6 intermolecular potential for carbon monoxide. PρT thermodynamic states, sound speeds, and shock Hugoniots are calculated using the newly parameterized intermolecular potential and compared to previously reported experimental results. Additionally, we present an analytical equation of state for carbon monoxide that was generated by fitting to a grid of calculated PρT states over a range of 0.1-10 GPa and 150-2000 K. * This work was performed under the auspices of the U.S. Department of Energy jointly by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.

11:51AM G39.00004 More than doubled ambient superconducting transition in a heavily compressed aromatic hydrocarbon[1]

, XIAO-JIA CHEN, TAKAKI MURAMATSU, WENGE YANG, VIKTOR STRUZHKIN STRUZHKIN, HO-KWANG MAO, Geophysical Laboratory, Carnegie Institution of Washington, Washington, DC 20015, QINGZHEN HUANG, NIST Center for Neutron Research, National Institute of Standards and Technology, Gaithersburg, MD 20899, ZHEN-XING QIN, Department of Physics, South China University of Technology, Guangzhou 510640, China, X.F. WANG, J.J. YING, P. CHENG, Z.J. XIANG, X.H. CHEN, Hefei Natl Lab for Physical Science at Microscale and Department of Physics, University of Science and Technology of China, Hefei, Anhui 230026, China — Exploring superconductivity at higher transition temperatures T_cs in light elements such as hydrogen and carbon and their organic compounds has long been an attractive issue. Cation-doped aromatic hydrocarbons have been discovered to be superconductive with an increasing T_c by adding more hydrocarbon rings. Here we present a discovery of an enhancement of T_c from the ambient 4.8 K to 12.2 K in compressed $Ba_{1.5}$Phenanthrene by magnetic susceptibility measurements up to 61 GPa. In contrast to the existence of superconductivity within a very narrow pressure range in fullerides, we find that this organic compound maintains superconductivity at more than doubled ambient T_c even at 61 GPa. A phase transition in the region between 3.0 and 5.4 GPa and an orientational disorder at around 28 GPa are identified using synchrotron X-ray diffraction technique. A nice correction between T_c and the angle between two crystal axes indicates the essential role of electronic correlations.

[1]This work is supported by the U.S. DOE under Grant No. DE-SC0001057.

12:03PM G39.00005 Stable External Heating of Diamond Anvil Cell: Examples and Issues[1]

, HYUNCHAE CYNN, ZSOLT JENEI, Lawrence Livermore National Laboratory, JESSE SMITH, CHANGYONG PARK, Geophysical Laboratory, Carnegie Institute, Washington D.C., HANS-PETER LIERMANN, DESY, PETRA-III, WILLIAM EVANS, Lawrence Livermore National Laboratory — While laser heating has been applied to successfully study materials at extreme conditions, external heating also has been extensively developed and applied for material studies at moderate temperature below ∼1000 K at high pressures. We have tested various external heating methods to accomplish stable heating at high pressures. Experimental measurements using two mini coil heaters at 900 K and 580 K to 100 GPa and 185 GPa, respectively and isobaric heating at 95 GPa up to 1000 K will be presented. New measurements using a graphite gasket heater will be compared along with internal heating methods. We will present comparison among different external heating methods and different temperature measurements using various examples. HP-CAT is supported by CIW, CDAC, UNLV, and LLNL through funding from DOE-NNSA, DOE-BES, and NSF. The APS is supported by DOE-BES under Contract No. DE-AC02-06CH11357.

12:15PM G39.00006 Homoepitaxial Boron Doped Diamond Anvils as Heating Elements in a Diamond Anvil Cell

, JEFFREY MONTGOMERY, GOPI SAMUDRALA, SPENCER SMITH, GEORGIY TSOI, University of Alabama at Birmingham, YOGESH VOHRA, Spencer J Smith ¡sjs605@uab.edu¿, SAMUEL WEIR, Lawrence Livermore National Laboratory — Recent advances in designer-diamond technology have allowed for the use of electrically and thermally conducting homoepitaxially-grown layers of boron-doped diamond (grown at 1200 °C with a 2% mixture of CH_4 in H, resulting in extremely high doping levels $\sim 10^{20}/cm^3$) to be used as heating elements in a diamond anvil cell (DAC). These diamonds allow for precise control of the temperature inside of the diamond anvil itself, particularly when coupled with a cryostat. Furthermore, the unmatched thermally conducting nature of diamond ensures that no significant lateral gradient in temperature occurs across the culet area. Since a thermocouple can easily be attached anywhere on the diamond surface, we can also measure diamond temperatures directly. With two such heaters, one can raise sample temperatures uniformly, or with any desired gradient along the pressure axis while preserving optical access. In our continuing set of benchmark experiments, we use two newly created matching heater anvils with 500μm culets to analyze the various fluorescence emission lines of ruby microspheres, which show more complicated behavior than traditional ruby chips. We also report on the temperature dependence of the high-pressure Raman modes of paracetamol ($C_8H_9NO_2$) up to 20 GPa.

12:27PM G39.00007 Phase transition dynamics in high-pressure VO_2

, WEN-PIN HSIEH, Stanford Institute for Materials and Energy Sciences, Stanford University and SLAC National Accelerator Laboratory, MARIANO TRIGO, Stanford PULSE Institute, SLAC National Accelerator Laboratory, ZHAO ZHAO, Department of Physics, Stanford University, DAVID A. REIS, Stanford PULSE Institute, SLAC National Accelerator Laboratory and Department of Applied Physics, Stanford University, WENDY L. MAO, Stanford Institute for Materials and Energy Sciences, SLAC National Accelerator Laboratory and Geological & Environmental Sciences, Stanford Univ. — Vanadium dioxide VO_2 is a prototypical strongly correlated material which presents an insulator-metal transition at both ambient and high pressures. We use synchrotron X-ray diffraction combined with a diamond anvil cell to determine the pressure-temperature phase diagram of VO_2. We also use ultrafast coherent phonon spectroscopy to study its phase transition dynamics at high pressure. We find that, in contrast with ambient pressure experiments where strong photoexcitation promptly changes the lattice potential symmetry, at pressures as high as P=11 GPa the coherent phonons are still observed upon the photo-driven phase transition to the metallic state. The mechanism of the phase transition dynamics will be discussed.

12:39PM G39.00008 Vanadium and V-Ti alloys at high pressure[1]

, ZSOLT JENEI, HYUNCHAE CYNN, WILLIAM J. EVANS, Lawrence Livermore National Laboratory, SIMON MACLEOD, Atomic Weapons Establishment, UK, STANISLAV SINOGEIKIN, YUE MENG, HPCAT — Experimental studies of vanadium found that during compression it undergoes a phase transition from the low pressure body centered cubic crystal structure to a rhombohedral phase at 65 GPa when compressed under quasihydrostatic conditions (PRB 83, 054101). Theoretical studies are in reasonable agreement with the transition pressure and predict that upon further compression above 200 GPa the bcc phase becomes stable again. The latest study (PRL 103, 235501) predicts that alloying vanadium with small amounts of the neighboring elements can increase or decrease the stability of the bcc phase relative to the rhombohedral phase. We performed powder x-ray diffraction experiments in diamond anvil cell of pure vanadium and V-Ti alloys at ambient temperature to very high pressures. We will discuss our results, including the equation of state and the stability of the rhombohedral phase at high pressures.

[1]This work performed under the auspices of the US DOE by LLNL under Contract DE-AC52-07NA27344. HPCAT use is supported by DOE-BES, DOE-NNSA, NSF, and the W.M. Keck Foundation. APS is supported by DOE-BES, under Contract No. DE-AC02-06CH11357.

12:51PM G39.00009 Nuclear magnetic resonance at pressures of up to 10.1 GPa detects an electronic topological transition in aluminum metal

, JÜRGEN HAASE, THOMAS MEISSNER, Faculty of Physics and Earth Science, University of Leipzig, Germany, SWEE K. GOH, Cavendish Laboratory, University of Cambridge, United Kingdom, MANUEL RICHTER, KLAUS KOEPERNIK, HELMUT ESCHRIG[1], Leibniz Institute for Solid State and Materials Research Dresden, Germany — We present high sensitivity ^{27}Al nuclear magnetic resonance (NMR) measurements on metallic aluminum under high pressures of up to 10.1 GPa. The measured Knight shift and spin-lattice relaxation rate indicate an unexpected negative curvature in the pressure dependence of the electronic density of states (DOS) that violates a free electron behavior. Based on a careful analysis of the Fermiology of aluminum metal with numerical LDA calculations we attribute the observed change in the DOS to a pressure induced electronic topological transition. We discuss an unexpected increase of the NMR linewidth above 4.2 GPa that is not in agreement with the metal's cubic symmetry.

1:03PM G39.00010 Ultrasonic Investigation of Cerium under High Pressure , MAGNUS LIPP, ZSOLT JENEI, HYUNCHAE CYNN, CHANTEL ARACNE-RUDDLE, WILLIAM EVANS, Lawrence Livermore National Laboratory, YOSHIO KONO, CURTIS KENNEY-BENSON, CHANGYONG PARK, HPCAT, Advanced Photon Source, Carnegie Institute of Washington — The contribution of the lattice to the famous volume collapse transition in cerium is re-evaluated using a unique combination of several techniques available at sector 16 BMB / HPCAT. These eliminate any indirect /iterative procedures employed previously: Energy dispersive X-ray scattering provides the pressure of the sample (as well as quality control about the state of the sample), X-ray radiography delivers a shadow image allowing a precise length measurement and the ultrasound pulse overlap method gives the transit time of the longitudinal and transverse pulses. Our preliminary analysis indicates a larger contribution by the lattice as previously thought. This work was performed under the auspices of the US DOE by LLNL under Contract DE-AC52-07NA27344. The X-ray studies were performed at HPCAT (Sector 16), APS/ANL. HPCAT is supported by CIW, CDAC, UNLV and LLNL through funding from DOE-NNSA, DOE-BES and NSF. APS is supported by DOE-BES, under Contract No. DE-AC02-06CH11357.

1:15PM G39.00011 High Pressure Crystalline Structure and Resistance of Vanadium Dioxide to 13.5 GPa[1] , NATHANIEL BRADY, University of Alabama at Birmingham, KANNATASSEN APPAVOO, Vanderbilt University, JEFFERY MONTGOMERY, YOGESH VOHRA, University of Alabama at Birmingham, RICHARD HAGLUND, Vanderbilt University, DAVID HILTON, University of Alabama at Birmingham — We have investigated the insulator-to-metal transition in thin film vanadium dioxide as a function of pressure at ambient temperature using a designer diamond anvil cell (DAC). Four-point probe resistance measurements show a monotonic decrease over the entire pressure range studied with no significant discontinuity. High-pressure X-ray diffraction measurements observe an M_1 ($\mathrm{P2}_1/\mathrm{c}$) phase at 0 GPa, an M_2 (C2/m) phase from 0.8 GPa to 1.1 GPa, and a reentrant M_1 phase from 1.1 GPa to 13.5 GPa. Crystal refinement above 1.1 GPa shows a monotonically decreasing a, b and c lattice constants and a minimum in the monoclinic angle, β, near 8.5±0.5 GPa. The atomic positions show that the first V-V nearest neighbor distance (d) decreases over the entire pressure range, the second nearest neighbor distance (s) increases until 5 GPa after which it is constant with $s{\approx}f{\approx}3.2$ Å. The next most closely spaced V-V distance (f), which corresponds to V atoms in different unit cells, is approximately constant across the entire pressure range measured.

1:27PM G39.00012 Unraveling Convoluted Structural and Electronic Transitions in SnTe at High Pressure[1] , DAN ZHOU, QUAN LI, Department of Physics and High Pressure Science and Engineering Center, University of Nevada, Las Vegas, Nevada 89154, USA, YANMING MA, QILIANG CUI, State key Laboratory of Superhard Materials, Jilin University, Changchun 130012, China, CHANGFENG CHEN, Department of Physics and High Pressure Science and Engineering Center, University of Nevada, Las Vegas, Nevada 89154, USA — The longstanding uncertainty in high-pressure structural evolution of SnTe has greatly impeded the understanding of its complex electronic properties. Here we unravel the convoluted high-pressure phase transitions of SnTe using angle-dispersive synchrotron x-ray diffraction combined with first-principles structural search. We identify three coexisting intermediate phases of Pnma, Cmcm, and GeS type structure and establish the corresponding phase boundaries. We further unveil the intricate pressure-driven evolution of the energetics, kinetics and lattice dynamics of SnTe to elucidate its distinct phase-transition mechanisms. Subsequent electronic band calculations reveal pressure-induced metallization, superconductivity and topological phase transition in SnTe. These findings resolve structures and predict intriguing properties of SnTe, which have broad implications for other IV-VI semiconductors that likely harbor similar novel high-pressure phases and properties.

1:39PM G39.00013 Compression of $HgCr_2S_4$ and $HgCr_2Se_4$ spinels , I. EFTHYMIOPOULOS, Dept. Physics, OU, MI-48309, A. YARESKO, MPI-FKF, D-70569, Stuttgart, V. TSURKAN, IAP, MD-2028 Chisinau & University of Augsburg, D-86159, J. DEISENHOFER, A. LOIDL, University of Augsburg, D-86159, C. PARK, HPCAT, Argonne, IL-60439, Y. WANG, Dept. Physics, OU, MI-48309, WANG GROUP TEAM, YARESKO COLLABORATION, IAP COLLABORATION, LOIDL COLLABORATION, HPCAT COLLABORATION — The family of ACr_2X_4 spinels constitutes a prototype system for studying magnetism in solids [1]. More recently, members of this series were found to exhibit multiferroicity [2]. The origin of the ferroic properties is unknown; the role of the structure, however, appears to be important [3]. Given the strong interplay between structural and ferroic properties in these systems, structural tuning by pressure can provide valuable hints for multiferroicity. We have performed high-pressure structural investigations on the multiferroic $HgCr_2S_4$ and the $HgCr_2Se_4$ compounds. $HgCr_2S_4$ exhibits three structural transitions: the starting cubic phase adopts a tetragonal structure at 20 GPa, at 27 GPa an orthorhombic distortion occurs, and a third transition takes place above 37 GPa. As for $HgCr_2Se_4$, our studies detect a structural transition at 14 GPa, near the theoretically predicted band gap closure [4]. We discuss the possible mechanisms for the observed phase transitions for both Cr-spinels.

1:51PM G39.00014 Electron-phonon interaction of GaAs nanowires under pressure , WEI ZHOU, Key Laboratory of Materials Physics, Institute of Solid State Physics, Chinese Academy of Sciences, JIAN-BO ZHANG, Department of Physics, South China University of Technology, XIN-HUA LI, YUQI WANG, XIAOJIA CHEN, Key Laboratory of Materials Physics, Institute of Solid State Physics, Chinese Academy of Sciences, ALEXANDER GONCHAROV, Geophysical Laboratory, Carnegie Institution of Washington — We present resonant Raman scattering (RRS) investigation of wurtzite and zinc-blende phase GaAs nanowires under hydrostatic pressure up to 30 GPa. The Raman spectra are excited by 532 nm and 488 nm laser lines. High order longitudinal optical modes 2LO and 3LO are observed under the resonant conditions. Pressure dependence of band gap of WZ and ZB nanowires has been obtained from the corresponding resonant pressures, and band gap of WZ nanowires is found to be larger than that of ZB nanowires. When applying pressure at 21 GPa, Raman signals of WZ and ZB phases disappear, manifesting phase change to a high-pressure phase.

2:03PM G39.00015 Response of Aluminum under ramp Compression to Mbar , MU LI, JIANHENG ZHAO, Institute of Fluid Physics, CAEP, CHENGWEI SUN, Shanghai Institute of Laser Plasma, HONGPING ZHANG, Institute of Fluid Physics, CAEP, FENG WANG, Laser Fusion Research Center,CAEP, GUANGHUA CHEN, Institute of Fluid Physics, CAEP, HUA SHU, Shanghai Institute of Laser Plasma — Laser-Produced X-ray drive is an important tool for ramp compression to very high pressure. Its application was often limited by the length of rise pulse, the peak pressure was not higher than 400GPa for metal steps. A new method was developed using heavy reservoir film, that can absorb high energy Au M-band x rays generated within the halfraum which otherwise could preheat the step sample. Meanwhile, heavy reservoir can also produce higher pressure peak and longer rise time.Results from this reservoir shot (4.5Mbar) at the SG-III prototype are presented. Al/LiF interface velocities versus time for multiple sample thicknesses were measured and converted to p-v relations using backward integration.

Tuesday, March 19, 2013 11:15AM - 2:27PM –

Session G40 DAMOP: Spin-Orbit Coupling in Ultracold Atom Systems 349 - Carlos Sa De Melo, Georgia Institute of Technology

11:15AM G40.00001 Synthetic gauge fields for ultracold atoms , ROSS WILLIAMS, Joint Quantum Institute, NIST and University of Maryland — Ultracold atoms represent a unique system in which to investigate quantum many-body physics with unprecedented experimental control. The properties of these systems can be tailored to realize model many-particle Hamiltonians, familiar from condensed matter physics, in their most pure and essential form. Magnetic fields, and gauge fields in general, play an important role in collective phenomena in electronic systems, leading to iconic phenomena such as the fractional quantum Hall effect. More complex, matrix valued, gauge fields can be used to describe spin-orbit coupling: itself an essential ingredient in many topological insulators, and in spintronic devices. Given the charge neutrality of ultracold atoms it is not immediately obvious how such physics could be explored in a cold atom context. In this talk I will describe the experimental techniques we use to engineer artificial gauge fields for ultracold neutral atoms using Raman transitions. I will also describe the latest results from the NIST group.

11:51AM G40.00002 Search for Majorana fermions in Spin-Orbit Coupled Ultra-cold Fermi Gases[1] , CHUANWEI ZHANG, Department of Physics, The University of Texas at Dallas, Richardson, Texas 75080, USA — Topological quantum matter has been an active research field in physics in the past three decades with numerous celebrated examples, including quantum Hall effect, chiral superconductor, topological insulator, etc. In topological materials, Majorana fermions, first envisioned by Majorana in 1935 to describe neutrinos, often emerge as topological quasiparticle excitations of the systems. Majorana fermions are intriguing because they can be construed as their own anti-particles and follow non-Abelian anyonic statistics under a pair-wise exchange of the many-particle wave function, unlike Dirac fermions where electrons and positrons (holes) are distinct. Although the emergence of Majorana fermions in any condensed matter or atomic system is by itself an extraordinary phenomenon, they have also come under a great deal of recent attention due to their potential use in fault tolerant quantum computation. Motivated by the recent experimental realization of spin-orbit coupling for cold atoms, in this talk, I will discuss the emergence of Majorana fermions in spin-orbit coupled Fermi cold atomic superfluids. I will talk about various experimental relevant issues for the observation of Majorana fermions in such cold atomic systems.

12:27PM G40.00003 Majorana fermions in one-dimensional spin-orbit coupled Fermi gases , RAN WEI, ERICH MUELLER, Cornell University — We theoretically study trapped one-dimensional Fermi gases in the presence of spin-orbit coupling induced by Raman lasers. The gas changes from a conventional (non-topological) superfluid to a topological superfluid as one increases the intensity of the Raman lasers above a critical chemical-potential dependent value. Solving the Bogoliubov-de Gennes equations self-consistently, we calculate the density of states in real and momentum space at finite temperatures. We study Majorana fermions (MFs) which appear at the boundaries between topologically trivial and topologically non-trivial regions. We linearize the trap near the location of a MF, finding an analytic expression for the localized MF wavefunction and the gap between the MF state and other edge states.

12:39PM G40.00004 Phase diagram of 1D spin-orbit coupled Fermi gases in optical lattices[1] , CHUNLEI QU, MING GONG, CHUANWEI ZHANG, Department of Physics, The University of Texas at Dallas, Richardson, TX, 75080 — We consider a one dimensional spin-orbit coupled Fermi gas in optical lattices with open boundary condition. This system belongs to the BDI symmetry class because the Hamiltonian can be made real when the Zeeman field is assumed to be along the z direction, thus the topological superfluid is characterized by Z, instead of Z_2 class. In the optical lattice system, each site admits at most two fermions. The system can host plenty of phases depending on the filling factor and the Zeeman field. At finite Zeeman field we observe a strong competition between the topological superfluid phase and the Fulde-Ferrell-Larkin-Ovchinnikov (FFLO) phase. The latter phase is more likely to be observed near the half filling. The spin-orbit coupling plays the role of enhancing the topological superfluid phase and suppressing the FFLO phase, which the Hartree shift plays an utterly opposite role. The possible observation of topological phase is also discussed in the presence of a harmonic trap.

[1]This work is supported by ARO, AFOSR, and NSF

12:51PM G40.00005 Topological Quantum Phase Transition of Fermi Gases and its Detections in a Synthetic Non-Abelian Gauge Potential[1] , FADI SUN, XIAO-LU YU, JINWU YE, Department of Physics and Astronomy, Mississippi State University, P. O. Box 5167, Mississippi State, MS 39762, USA, HENG FAN, WU-MING LIU, Beijing National Laboratory for Condensed Matter Physics, Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China — We investigate the topological quantum phase transition of Fermi gases trapped in a honeycomb lattice in the presence of a synthetic non-Abelian gauge potential. We develop a systematic fermionic effective field theory to describe a topological quantum phase transition tuned by the non-Abelian gauge potential and explore its various important experimental consequences. We obtain the critical exponents at zero temperature, dynamic compressibility, uniform compressibility, specific heat and Wilson ratio at finite temperatures. We analyze the effects of atom-atom interactions and possible disorders in generating the non-Abelian gauge fields. We also perform direct numerical calculations on the lattice scale and compare with the results achieved from the fermionic effective field theory. When discussing various feasible experimental detections of the topological quantum phase transition, we stress the important roles of the gauge invariance to distinguish gauge invariant quantities from non-gauge invariant ones.

[1]This work was mainly supported by NSF-DMR-1161497.

1:03PM G40.00006 Trapped Fermi gases with Rashba spin-orbit coupling[1] , MENDERES ISKIN, Koc University — We use the Bogoliubov-de Gennes formalism to analyze harmonically trapped Fermi gases with Rashba-type spin-orbit coupling in two dimensions. We consider both population-balanced and -imbalanced Fermi gases throughout the BCS-BEC evolution, and study the effects of spin-orbit coupling on the spontaneously induced countercirculating mass currents and the associated intrinsic angular momentum. In particular, we find that even a small spin-orbit coupling destabilizes Fulde-Ferrel-Larkin-Ovchinnikov (FFLO)-type spatially modulated superfluid phases as well as the phase-separated states against the polarized superfluid phase. We also show that the continuum of quasiparticle and quasihole excitation spectrum can be connected by zero, one or two discrete branches of interface modes, depending on the number of interfaces between a topologically trivial phase (e.g. locally unpolarized/low-polarized superfluid or spin-polarized normal) and a topologically nontrivial one (e.g. locally high-polarized superfluid) that may be present in a trapped system.

1:15PM G40.00007 Superfluid transition temperature across the BCS-BEC crossover induced by a synthetic non-Abelian gauge field[1] , JAYANTH P. VYASANAKERE, VIJAY B. SHENOY, Indian Institute of Science — A non-Abelian gauge field that induces a spin-orbit coupling on the motion of fermions engenders a BCS-BEC crossover even for weakly attracting fermions. The transition temperature at large spin-orbit coupling is known to be determined by the mass of the emergent boson – the rashbon. We obtain the transition temperature of the system as a function of the spin-orbit coupling by constructing and studying a Gaussian fluctuation (Nozieres-Schmitt-Rink) theory. These results will help guide the upcoming experiments on spin-orbit coupled fermions. In addition, this work suggests a route to enhance the transition temperature of a weakly attracting fermionic system by tuning the spin-orbit coupling.

[1]Work supported by CSIR, DST, DAE India

1:27PM G40.00008 Fulde-Ferrell-Larkin-Ovchinnikov Phases in Two-dimensional Spin-Orbit Coupled Degenerate Fermi gas , ZHEN ZHENG, Key Laboratory of Quantum Information, University of Science and Technology of China, MING GONG, Department of Physics, The University of Texas at Dallas, YICHAO ZHANG, XUBO ZOU, Key Laboratory of Quantum Information, University of Science and Technology of China, CHUANWEI ZHANG, Department of Physics, The University of Texas at Dallas, GUANGCAN GUO, Key Laboratory of Quantum Information, University of Science and Technology of China, KEY LABORATORY OF QUANTUM INFORMATION, UNIVERSITY OF SCIENCE AND TECHNOLOGY OF CHINA TEAM, DEPARTMENT OF PHYSICS, THE UNIVERSITY OF TEXAS AT DALLAS TEAM — We examine the Fulde-Ferrell-Larkin-Ovchinnikov (FFLO) phase in two dimensional spin-orbit coupled degenerate Fermi gas using mean-field theory at zero temperature. The FFLO phase has been greatly enhanced due to the deformation of the Fermi surface, which arise from the interplay between spin-orbit coupling and in-plane Zeeman field. The emergence of FFLO phase has been carefully examined from different angles, and the properties of the BCS superfluid, the FFLO phase and normal gas have also been studied. The in-plane Zeeman field break the rotation symmetry thus the eigenvalues no longer appear in pairs. The experimental signatures for the observation of FFLO phase is also discussed.

1:39PM G40.00009 FFLO and Topological Superfluid Phases in 2D Spin-Orbit Coupling Fermionic Optical Lattices[1] , YONG XU, CHUNLEI QU, MING GONG, CHUANWEI ZHANG, The University of Texas at Dallas — We investigate the phase diagram of 2D spin-orbit coupled ultra-cold Fermi atoms confined in a square lattice. By numerically solving the corresponding Bogoliubov-de Gennes equation self-consistently, we show that a finite Zeeman field can induce Fulde-Ferrell-Larkin-Ovchinnikov (FFLO) and /or topological superfluid phases (which support Majorana fermions) in the presence of spin-orbit coupling. We find that the perpendicular Zeeman field favors the topological superfluid phase, while the in-plane Zeeman field favors the FFLO state. A simple physical explanation for the above results is also provided.

[1]This work is supported by ARO, AFOSR, and NSF.

1:51PM G40.00010 Finite-Momentum Dimer Bound State in Spin-Orbit Coupled Fermi Gas[1] , LIN DONG, Rice University, LEI JIANG, Joint Quantum Institute, University of Maryland and National Institute of Standards and Technology, HUI HU, ARC Centre of Excellence for Quantum-Atom Optics, Centre for Atom Optics and Ultrafast Spectroscopy, Swinburne University of Technology, HAN PU, Rice University — We investigate the two-body properties of a spin-1/2 Fermi gas subject to a spin-orbit coupling induced by laser fields. When attractive s-wave interaction between unlike spins is present, the system may form a dimer bound state. Surprisingly, under proper conditions, the bound state obtains finite center-of-mass momentum, whereas under the same condition but in the absence of the two-body interaction, the system has zero total momentum. This unusual result can be regarded as a consequence of the broken Galilean invariance by the spin-orbit coupling. Such a finite-momentum bound state will have profound effects on the many-body properties of the system.

[1]HP is supported by the NSF, the Welch Foundation (Grant No. C-1669), and DARPA. HH is supported by the ARC Discovery Projects (Grant No. DP0984522) and the National Basic Research Program of China (NFRP-China, Grant No. 2011CB921502).

2:03PM G40.00011 Ultra-cold fermions in the flatland: evolution from BCS to Bose superfluidity in two-dimensions with spin-orbit and Zeeman fields[1] , LI HAN, CARLOS SA DE MELO, Georgia Institute of Technology — We discuss the evolution from BCS to Bose superfluidity for ultracold fermions in two-dimensions and in the presence of simultaneous spin-orbit and Zeeman fields. We analyze several thermodynamic properties to characterize different superfluid phases including pressure, compressibility, induced polarization, and spin susceptibility. Furthermore, we compute the momentum distribution and construct topological invariants for each of the superfluid phases.

[1]We thank ARO (Contract No. W911NF-09-1-0220) for support.

2:15PM G40.00012 Flow induced superfluidty and other novel effects in spin orbit coupled fermionic quantum gases[1] , VIJAY B. SHENOY, Indian Institute of Science — Recent experiments on fermions with synthetic gauge fields produce systems with spin-orbit coupling, detuning and Zeeman fields. We show by theoretical considerations that such systems have many interesting features when the fermions experience a contact attraction. In particular, a flow (finite centre of mass momentum) produces a "stronger" superfluid. In addition, we show that such systems can be tuned to have very interesting normal states paving way for studying spin-orbit coupled Fermi liquids.

Tuesday, March 19, 2013 11:15AM - 2:15PM –

Session G41 DAMOP: Attosecond Physics and Optics 350 - Stephen Eckel, National Institute of Standards and Technology

11:15AM G41.00001 Simulated Photoelectron-Based Imaging of Localized Surface Plasmons with Attosecond Resolution , JAMES PRELL, LAUREN BORJA, ANDREY GANDMAN, DESIRE WHITMORE, DANIEL NEUMARK, STEPHEN LEONE, University of California, Berkeley — Simulations of proposed photoelectron streaking experiments in the presence of an oscillating plasmon field are presented. The results indicate that localized surface plasmon dephasing can be imaged with attosecond resolution using electron time-of-flight (TOF) or velocity map imaging (VMI) techniques. In the simulation, localized surface plasmons are excited in metal nanoparticles by a few-cycle infrared or visible laser pulse. Using time-delayed single, isolated attosecond x-ray pulses, electrons are photoemitted from the metallic nanoparticles and streaked by both the plasmon and laser electric fields. The effects of these two fields in the streaking spectra and images can be separated so that the temporal evolution of the plasmon electric field can be directly extracted. The plasmon electric field induces a broadening of the photoelectron speed distribution with an envelope directly proportional to that of the plasmon dipole moment. Plasmon-induced oscillation of the angular distribution in VMI is predicted to report the spatial distribution of the plasmon electric field for nanoparticles with high aspect ratios. The simulations indicate that these techniques can be used to map plasmon dynamics with unprecedented temporal resolution.

11:27AM G41.00002 Metal nanofilm in strong ultrafast optical fields: subcycle Bloch oscillations[1] , VADYM APALKOV, MARK STOCKMAN, Georgia State University — We predict theoretically that a metal nanofilm subjected to an ultrashort optical pulse of a high field amplitude ~ 3 V/Å shows semimetal behavior. At such high pulse intensity, the reflectivity of metal nanofilm is greatly reduced, while the transmissivity and the optical field inside the metal are greatly increased. The temporal profiles of the optical fields are predicted to exhibit pronounced subcycle oscillations which are attributed to the Bloch oscillations and formation of the Wannier-Stark ladder of electronic states. These effects are promising for applications as nanoplasmonic modulators and field-effect transistors with petahertz bandwidth.

[1]This work was supported by the U.S. Department of Energy, Grants No. DE-FG02-01ER15213 and DE-FG02-11ER46789.

11:39AM G41.00003 Attosecond Streaking Chronoscopy of Surfaces , JOACHIM BURGDOERFER, Institute for Theoretical Physics, Vienna University of Technology — With the advent of sub-femtosecond ultrashort XUV pulses and of phase-stabilized IR pulses with sub-cycle time resolution, novel pathways have been opened up for studying time-resolved electronic quantum dynamics on the attosecond scale. These experiments pose challenges for theory: How do short pulses interact with matter? Which novel information can be extracted from time-resolved spectroscopies that cannot be gained from precision experiments in the spectral domain? In this talk we discuss attosecond chronoscopy by streaking photoelectron emission from solid surfaces. Experimental photoemission data reveal a time delay between conduction electrons and core electrons on the $\sim$50 attosecond scale. We show that the temporal information accessible for such a many-electron system in the condensed phase includes both the coherent wavepacket dynamics characterized by the Eisenbud-Wigner-Smith (EWS) time delay as well as decohering processes in transport and relaxation. Extensions to nanostructures will be discussed.

12:15PM G41.00004 Strong-Field Emission From High Aspect Ratio Si Emitter Arrays[1] , PHILLIP KEATHLEY, MICHAEL SWANWICK, ALEXANDER SELL, WILLIAM PUTNAM, STEPHEN GUERRERA, LUIS VELÁSQUEZ-GARCÍA, FRANZ KÄRTNER[2], Massachusetts Institute of Technology — We discuss photoelectron emission from an arrays of high aspect ratio, sharp Si emitters both experimentally and theoretically. The structures are prepared from highly doped single-crystal silicon having a pencil-like shape with end radii of curvature of around 10 nm. The tips were illuminated at a grazing incidence of roughly 84deg.with a laser pulse having a center wavelength of 800 nm, and a pulse duration of 35 fs from a regenerative amplifier system. Native oxide coated Si tips were characterized using a time of flight (TOF) electron energy spectrometer. An annealing process was observed, resulting in a red shift of the energy spectra along with an increased electron yield. Total current yield from samples having the oxide stripped were also studied. Apeak total emission of 0.68 pC/bunch, corresponding to around 1.5×10^3 electrons/tip/pulse was observed at a DC bias of 70 V . Both spectral and current characterization results are consistent with a stong-field photoemission process at the surface of the tip apex.

12:27PM G41.00005 Laser Beam Shaping For Lithography on Inclined and Curved Surfaces Using a liquid crystal Spatial Light Modulator , JAVAD R. GATABI, WILHELMUS GEERTS, Physics Department, Texas State University at San Marcos, DAN TAMIR, Department of Computer Science, Texas State University at San Marcos, KUMAR PANDEY, Department of Electrical Engineering, Texas State University at San Marcos — An exposure tool for lithography on non-flat substrates that includes a real time photoresist thickness and surface topography monitor is under development at Texas State University. Exposure dose and focusing are corrected on curved parts of the sample using novel laser beam shaping techniques: two approaches using a Holoeye liquid crystal spatial light modulator (LC-SLM) are being investigated: (1) the implementation of multiple lenses with different focal lengths to split the beam into several parts and keeping each part in focus depending on sample topography; (2) the implementation of a tilted lens function resulting in a tilt of the image plane. Image quality is limited by quantization aberration, caused by the phase modulator's bit depth limitation, and pixelation aberration, caused by the modulator's pixel size. A statistical analysis on lenses with different focal lengths provides a detailed description of the mentioned aberrations. The image quality, i.e. resolution and contrast of both techniques, are determined from developed photoresist patterns on curved samples and compared to the theory.

12:39PM G41.00006 Imaging the signals emitted by multiple sources originating from a turbid medium , GABRIEL CWILICH, Department of Physics, Yeshiva University, New York, USA, JUAN JOSE SAENZ, Departamento de Fisica de la Materia Condensada, Universidad Autonoma de Madrid, Spain , LUIS FROUFE PEREZ, Instituto de Estructura de la Materia, CSIC, Madrid, Spain — We studied the problem of spatially closely positioned sources which emit waves inside a turbid medium, through fluorescence or other mechanisms. While for many of the traditional imaging methods, including FRET, the disorder might impose an insurmountable obstacle for the detections of the sources, the interference of the waves in the case of multiple scattering, gives raise, due the coherent propagation of the signals at the mesoscopic scale , to important effects both in the correlations and the fluctuations of the intensity being detected at a point lying outside the medium. The information obtained that way can be used to monitor the displacement of the sources and their degree of coherence even at scales below the wavelength of the radiation being emitted.

12:51PM G41.00007 Attosecond view of the photoelectric effect and optical-field-induced current in dielectrics , RALPH ERNSTORFER, Fritz-Haber-Institut der Max-Planck-Gesellschaft — Fundamental electronic processes in condensed matter like electron transport on atomic length scales, the plasmonic response in metals or the dielectric response in insulators occur on attosecond time scales. In the first part of my talk, I discuss how a streak camera operating at optical frequencies provides a time-resolved view of the photoelectric effect [1]. Photoelectrons emitted from metal surfaces by an attosecond extreme ultraviolet laser pulse are time-stamped by a few-cycle visible/near-infrared laser pulse. This technique allows for measuring the relative emission time of valence and core electrons with a precision of tens of attoseconds, thereby addressing the intrinsic dynamics of the photoemission. I present recent studies of a free-electron metal [2] as well as of oxygen-covered tungsten single crystals. The origin of the observed attosecond delays in the emission of photoelectrons from different initial states is discussed. In the second part of the talk, I report on electric current in dielectrics induced and controlled by ultrashort optical fields [3]. For very short periods of time, electric fields exceeding 10 V/nm, i.e. fields significantly beyond the threshold for dc dielectric breakdown, can be applied to insulators. In this regime, insulators exhibit a highly nonlinear dielectric response, resulting in an increase in conductivity by many orders of magnitude. Applying 1.5-cycle laser pulses to unbiased metal-dielectric-metal nanogaps, we demonstrate the generation of directly measurable photocurrents whose magnitude and directionality can be controlled with the carrier-envelope phase of the laser pulse, i.e. by the shape of the laser electric field. Such currents can be switched on and off on sub-femtosecond timescales as evidenced by employing two cross-polarized and time-delayed pulses. The ultrafast field-controlled current generation in a dielectric nanostructure may represent a first step towards the realization of optical-field-controlled electronics.

1:27PM G41.00008 Nondiffracting accelerating wave packets beyond the paraxial limit , PENG ZHANG, University of California, Berkeley, YI HU, Institut National de la Recherche Scientifique, Canada, TONGCANG LI, University of California, Berkeley, DRAKE CANNAN, San Francisco State University, XIAOBO YIN, University of California, Berkeley, ROBERTO MORANDOTTI, Institut National de la Recherche Scientifique, Canada, ZHIGANG CHEN, San Francisco State University, XIANG ZHANG, University of California, Berkeley — Self-accelerating Airy wave packets have stimulated rapidly growing research interest in the past five years. However, optical Airy beams are inherently subjected to the paraxial limit. Here, we demonstrate both theoretically and experimentally linear and nonlinear self-accelerating beams propagating along circular trajectories beyond the paraxial approximation. Such nonparaxial accelerating beams are exact solutions of the Helmholtz equation. Furthermore, we introduce and demonstrate nonparaxial Mathieu and Weber accelerating beams, generalizing the concept of all previously found accelerating wave packets. We show that such beams bend into large angles along elliptical or parabolic trajectories but still retain nondiffracting and self-healing capabilities. The circular nonparaxial accelerating beams can be considered as a special case of the Mathieu accelerating beams, while an Airy beam is only a special case of the Weber beams at the paraxial limit. Not only do generalized nonparaxial accelerating wave packets open up many possibilities of beam engineering for applications, but the fundamental concept developed here can be applied to other linear wave systems in nature, ranging from electromagnetic and elastic waves to matter waves.

1:39PM G41.00009 Mapping of focused Laguerre-Gauss beams , JOSE R. RIOS LEITE, Departamento de Física, Universidade Federal de Pernambuco, 50670-901 Recife, PE, Brazil, VASILY KLIMOV, P.N. Lebedev Physical Institute, Russian Academy of Sciences, 53 Leninsky Prospekt, Moscow 119991, Russia, MARTIAL DUCLOY, DANIEL BLOCH, Laboratoire de Physique des Lasers, Universite Paris 13, Sorbonne Paris-Cite and CNRS, UMR 7538, 99 Ave. J.B. Clement, F-93430, BRAZIL-FRANCE CAPES456/04-COFECUBPH740/12 COLLABORATION, ("P.I.C.S." NO. 5813) BETWEEN C.N.R.S. AND THE RUSSIAN FOUNDATION FOR BASIC RESEARCH COLLABORATION — We study the detection of propagating optical fields bearing axial symmetry in the situation of an extreme focusing, when the paraxial approximation no longer holds. The results, obtained by general arguments based upon the vectorial nature of electromagnetic fields, show the rapid spatial variations of fields with "complicated" spatial structure [1]. Laguerre-Gauss beam, notably beams bearing a l = 2 orbital angular momentum for which a magnetic field and a gradient of the electric field are present on axis have been examined in their behavior upon an atomic size light detector sensitive to quadrupole electric transitions as well as to magnetic dipole transitions. nd apply it to the case of a Laguerre-Gauss beam.We detail how the mapping of such a beam depends on the nature and on the specific orientation of the detector. We also show that the interplay of mixing of polarization and topological charge, respectively associated to spin and orbital momentum when the paraxial polarization holds, modifies the apparent size of the beam in the focal plane.

1:51PM G41.00010 Photonic temperature sensor based on microring resonators[1] , HAITAN XU, JQI, University of Maryland-College Park and NIST, ZEESHAN AHMED, NIST, MOHAMMAD HAFEZI, JQI, University of Maryland-College Park and NIST, JINGYUN FAN, GREGORY STROUSE, ALAN MIGDALL, NIST, JACOB TAYLOR, JQI, University of Maryland-College Park and NIST — Temperature needs to be controlled accurately and precisely in various areas, yet it is one of the most inaccurately measured physical quantities. We consider a new measurement method for temperature using the thermal response of a microring resonator built using Silicon-on-Insulator. The temperature-dependence of the index refraction maps temperature to the resonance frequency of the resonator, which can be measured with higher precision. We study the resolution and accuracy of our device, as well as future challenges for this approach for temperature metrology.

2:03PM G41.00011 A new bound on excess frequency noise in second harmonic generation in PPKTP at the 10^{-19} level[1] , DAVID YEATON-MASSEY, RANA ADHIKARI, Caltech — Several experiments at the forefront of precision metrology and frequency standards use optical harmonic generation in their experiments. These include iodine stabilized Nd:YAG lasers, optical frequency combs, measurement of optical frequency ratios, and precision atomic spectroscopy. We present an experimental bound on the relative frequency fluctuations introduced in the nonlinear second harmonic generation process using PPKTP to double a 1064nm Nd:YAG laser. We report a measured amplitude spectral density of frequency noise with total RMS frequency deviation of 3mHz and a minimum value of 20 μHz/Hz$^{1/2}$ over 250 seconds with a measurement bandwidth of 128 Hz, corresponding to an Allan deviation of 10^{-19} at 20 seconds.

Session G42 DCP: Focus Session: Physics of Glasses and Viscous Liquids I Hilton Baltimore Holiday Ballroom 3 - Patrick Charbonneau, Duke University

11:15AM G42.00001 Glass Transition of Polymers near Their Free Surface[1] , ZAHRA FAKHRAAI, Department of Chemistry, University of Pennsylvania — Recent experiments have indicated that the relaxation dynamics near a free polymer surface may become fundamentally different from bulk α relaxation times. The dynamics lose many of the characteristics commonly associated with glasses. The dynamic properties lose their typical Vogel-Fulcher-Tammann (VFT) temperature dependence and take on an Arrhenius dependence. There is also evidence that the dynamic properties become more homogeneous near the free surface. Such direct measurements of the relaxation dynamics are rare and extremely difficult to perform on a wide range of polymeric systems. It has been shown that cooling rate-dependent glass transition temperature ($\mathrm{T_g}$) measurements can be used as an effective and simple method to estimate the relaxation dynamics of the free surface. The cooling rate is inversely proportional to the relaxation time of the film at the temperature at which the system falls out of equilibrium, $\mathrm{T_g}$. In thin polymer films, as the film thickness is decreased the dynamics of the film are affected more strongly by surface dynamics and therefore they provide a lower bound to the surface relaxation times. In thin polystyrene films measurements of $\mathrm{T_g}$ as a function of cooling rate indicate a clear onset of deviations from bulk properties at a temperature a few degrees above the bulk $\mathrm{T_g}$. We hypothesize that this could be due to either a new mode of relaxation that is exclusively available near the surface, or typical glassy dynamics that have faster time scales near the surface. In this study we investigate the effect of molecular weight and the polymer structure on the value of the onset temperature to verify whether the properties are consistent with one of these hypotheses. It is also observed that under certain conditions, where the dynamics of the free surface and the bulk relaxation dynamics are many decades apart, the system exhibits two distinct $\mathrm{T_g}$s associated with either bulk or surface relaxations. This data can be used to estimate the length scale of the surface dynamics and the length scale over which the effects penetrate into the bulk of the film.

11:51AM G42.00002 Anharmonicity and Fragility of Protic Ionic Liquids , JENNY KIM, National Institute of Standards and Technology, AUSTEN ANGELL, KAZUHIDE UENO, Arizona State University, MADHU TYAGI, CHRISTOPHER SOLES, KEVIN MASSER, National Institute of Standards and Technology — Supercooled liquids are often characterized by their fragility which is associated with physicochemical properties. However, the origin of fragility is still controversial. Superfragile liquid, decahydroisoquinoline (DHiQ) is chosen as a parent molecule to systematically investigate the relationship between anharmonicity and fragility of supercooled liquids. Earlier study by Ueno et al. (J. Phys. Chem. B 2012, 116) demonstrated that the protonation of DHiQ by different Bronsted acids results in the loss of superfragility. To understand the nature of fragile liquids, we conducted inelastic/quasielastic (IE/QE) neutron scattering measurements to examine low frequency vibrational dynamics (boson peak) and the relaxation behavior of DHiQ (high fragility) and DHiQ-based ionic liquids with intermediate (formate, Fm) and low (trifluoromethansulfonimide, TFSI) fragilities. With the protonation, molecular acids will be hydrogen-deficient and the scattering will be dominated by cation, [$\mathrm{DHiQ^+}$]. This strategy simplifies our interpretation in terms of understanding the fitting result from IENS/QENS spectra. By protonating DHiQ with stronger acids, large shift in low frequency vibrational modes and smaller mean square displacements were examined at temperatures higher than Tg. We illustrate how the degree of protonation and ionicity plays a role in the loss in superfragility of DHiQ.

12:03PM G42.00003 Acoustic properties in glycerol glass-former: Molecular dynamics simulation , REMI BUSSELEZ, THOMAS PEZERIL, Universite du Maine, INSTITUT DES MATERIAUX ET MOLECULES DU MANS TEAM — Study of high-frequency collective dynamics around TeraHertz region in glass former has been a subject of intense investigations and debates over the past decade. In particular, the presence of the Boson peak characteristic of glassy material and its relation to other glass anomalies. Recently, experiments and simulations have underlined possible relation between Boson peak and transverse acoustic modes in glassy materials. In particular, simulations of simple Lennard Jones glass former have shown a relation between Ioffe-Regel criterion in transverse modes and Boson peak. We present here molecular dynamics simulation on high frequency dynamics of glycerol. In order to study mesoscopic order (0.5-5$\mathrm{nm^{-1}}$), we made use of large simulation box containing 80000 atoms. Analysis of collective longitudinal and transverse acoustic modes shows striking similarities in comparison with simulation of Lennard-Jones particles. In particular, it seems that a connection may exist between Ioffe-Regel criterion for transverse modes and Bose Peak frequency. However,in our case we show that this connection may be related with structural correlation arising from molecular clusters.

12:15PM G42.00004 Fast Scanning Calorimetry study of non-equilibrium relaxation in fragile organic liquids[1] , VLAD SADTCHENKO, DEEPANJAN BHATTACHARYA, LIAM O'REILLY, The George Washington University — Fast scanning calorimetry (FSC), capable of heating rates in excess of 1000000 K/s, was combined with vapor deposition technique to investigate non-equilibrium relaxation in micrometer thick viscous liquid films of several organic compounds (e.g.2-ethyl-1-hexanol, Toluene, and 1-propanol) under high vacuum conditions. Rapid heating of samples, vapor deposited at temperatures above their standard glass softening transition (Tg), resulted in observable endotherms which onset temperatures were strongly dependent on heating rate and the deposition temperature. Furthermore, all of the studied compounds were characterized by distinct critical deposition temperatures at which observation of endotherm became impossible. Based on the results of these studies, we have developed a simple model which makes it possible to infer the equilibrium enthalpy relaxation times for liquids from FSC data. We will discuss implications of these studies for contemporary models of non-equilibrium relaxation in glasses and supercooled liquids.

12:27PM G42.00005 Elementary excitations and flow in the liquid[1] , TAKESHI EGAMI, U of Tennessee/Oak Ridge National Lab — A new mode of excitation is introduced to elucidate the dynamics in simple liquids at the atomic scale. Some properties of liquid defy easy explanations. For instance, in liquids phonons are overdamped with a very short lifetime. Nevertheless the Dulong-Petit law ($\mathrm{C_V} \sim 3\mathrm{k_B}$) is widely observed at high temperatures. As temperature is reduced the specific heat markedly increases in the supercooled state, only to drop down sharply at the glass transition. Viscosity shows an Arrhenian behavior at high temperatures, but increases rapidly toward the glass transition in the supercooled state. We suggest that these perplexing observations can be naturally explained in terms of the local configurational excitations (LCE's) which locally change the atomic connectivity by an atom losing or gaining one nearest neighbor. We show that the lifetime of LCE, τ_{LC}, is equal to the Maxwell relaxation time, τ_M, at temperatures above the crossover temperature, T_A. Above $\mathrm{T_A}$ the phonon mean-free path, $\xi = c_T\tau_{LC}$, where c_T is the transverse sound velocity, becomes shorter than the interatomic distance, resulting in phonon localization. Therefore LCE's are the elementary excitations in the liquid. They are independent of each other above T_A, but below T_A LCE's interact through phonon exchange, resulting in the rapid increase in τ_M, culminating in the glass transition. LCE's are also the mechanism of flow at low temperature under strong shear stress. In this case, however, losing and gaining of the neighbors are strongly coupled, so that $\tau_M = \tau_{LC}$ /2 [1]. We also discuss dynamic heterogeneity in terms of LCE interactions.

1:03PM G42.00006 Ab-initio atomic level stresses in Cu-Zr crystal, liquid and glass phases[1] , MADHUSUDAN OJHA, University of Tennessee and Oak Ridge National Laboratory, DON M. NICHOLSON, Oak Ridge National laboratory, TAKESHI EGAMI, University of Tennessee and Oak Ridge National Laboratory — The Cu-Zr system provides interesting playground for the study of glass structure, stability, and formability and liquid dynamics. Glasses form over a wide range of concentrations while they compete against various intermetallic compounds. We have calculated from first-principles the atomic level stresses, a new tool to characterize materials, within the local approximation to Density Functional Theory (DFT) for Cu-Zr glasses and compounds from low temperature to 4500K. Comparisons between ordered crystalline compounds and liquids and glasses allow us to relate atomic level stress to relaxation of chemical short-range order and structural relaxation. The results are counter-intuitive at times; a smaller atom is under higher compressive pressure, whereas geometrically they should be under tension. Ab-initio calculations were done using Vienna Ab-initio Simulation Package (VASP) and Locally Self-consistent Multiple Scattering (LSMS) codes.

1:15PM G42.00007 Computer Simulations of Non-Equilibrium Dynamics in Silica[1] , CHRISTOPHER H. GORMAN, Wabash College, USA, KATHARINA VOLLMAYR-LEE, Bucknell University, USA, HORACIO E. CASTILLO, Ohio University, USA, AZITA PARSAEIAN, Northwestern University, USA — We present results from molecular dynamics computer simulations of aging silica (modeled by the BKS model). The system is equilibrated at $T_{\rm i} = 5000$ K and quenched instantaneously to $T_{\rm f} = 2500$ K. After a waiting time $t_{\rm w}$ we investigate the dynamics of the Si- and O-atoms as the system evolves over time t. Our simulations run long enough in order to observe the transition from out-of-equilibrium to equilibrium dynamics. We determine for our system the generalized incoherent intermediate scattering function $C(q, t_{\rm w}, t_{\rm w} + t)$ and the dynamic susceptibility $\chi_4(q, t_{\rm w}, t_{\rm w} + t)$ where q corresponds to the wavevector. Curves corresponding to different waiting times $t_{\rm w}$ collapse on the scaling plot $\chi_4(q, t_{\rm w}, t_{\rm w} + t)/\chi_4^{\rm max}(q, t_{\rm w})$ as a function of $(1 - C(q, t_{\rm w}, t_{\rm w} + t))$, which agrees with a prediction from spin glass theory.

1:27PM G42.00008 Persistent medium-range order and anomalous liquid properties of $Al_{1-x}Cu_x$ alloys[1] , JOONGOO KANG, JUNYI ZHU, SU-HUAI WEI, National Renewable Energy Laboratory, Golden, CO, USA, ERIC SCHWEGLER, Lawrence Livermore National Laboratory, Livermore, CA, USA, YONG-HYUN KIM, KAIST, Daejeon, Korea — The development of short-to-medium-range order in atomic arrangements–that is, the aggregation or packing of short-range order (SRO) atomic clusters–has generally been observed in noncrystalline solid systems such as metallic glasses. Whether such medium-range order (MRO) can exist in materials at well above their melting or glass-transition temperature, manifesting itself in some observable property such as a liquid–liquid transition, has been a long-standing important scientific challenge. Here, using *ab initio* molecular dynamics simulations, we show that a novel, persistent MRO exists in liquid Al-Cu alloys, both in the nano- and bulk phases, near the composition of $CuAl_3$. In a sense, the MRO liquid lies in between glasses and normal liquids, and thus it exhibits anomalous liquid properties. Our *ab initio* calculations provide a detailed atomistic description of the MRO as well as a microscopic explanation for its formation via a percolation-like transition. Interestingly, we find that the appearance of MRO in the liquid phase manifests itself in a substantially enhanced viscosity that is consistent with a previously unexplained experimental observation of a peak in the viscosity of Al-Cu alloys.

1:39PM G42.00009 Transient Networks and Dense Colloidal Suspensions: From Viscous Flow to Elastic Instabilities[1] , ELISABETH BOUCHAUD, CEA-Saclay/ESPCI — In order to analyze the mechanical response of viscoelastic materials in highly non-linear regimes, we have designed a new kind of Hele-Shaw cell where both viscous liquids and soft elastic solids can be tested at a controlled loading rate. We first consider model Maxwell liquids – characterized by a single relaxation time – with the project of benchmarking the response of complex, glassy systems. We use several solutions of microemulsions connected by telechelic polymers. We show that these materials undergo instability in a broad range of loading rates. At low rates, this instability is shown to be of the viscous Saffman-Taylor type. At high rates, we observe a purely elastic bulk instability discovered recently in the context of soft elastomers. A microfluidic version of our cell makes it possible to study the response of colloidal suspensions. We use more or less concentrated PNIPA aqueous solutions for which temperature controls the volume fraction. Observations are interpreted in the light of our understanding of their viscoelastic properties.

Session G43 DCP: Focus Session: Motor dynamics—from Single Molecules to Cells II Hilton Baltimore Holiday Ballroom 2 - Sean Sun, Johns Hopkins University

11:15AM G43.00001 Operation mechanism of rotary molecular motor F_1 probed by single-molecule techniques , RYOTA IINO, The University of Tokyo — F_1 is a rotary motor protein. Three catalytic β-subunits in the stator $\alpha_3\beta_3$ ring are torque generators, and rotate the rotor γ-subunit by sequential and cooperative conformational changes coupled with adenosine triphosphate (ATP) hydrolysis reaction. F_1 shows remarkable performances such as rotation rate faster than 10,000 rpm, high reversibility and efficiency in chemo-mechanical energy conversion. I will introduce basic characteristics of F_1 revealed by single-molecule imaging and manipulation techniques based on optical microscopy and high-speed atomic force microscopy. I will also discuss the possible operation mechanism behind the F_1, along with structurally-related hexameric ATPases, also mentioning the possibility of generating hybrid molecular motors.

11:51AM G43.00002 Simultaneous measurement of DNA motor protein conformation and activity with combined optical trap and single-molecule fluorescence[1] , YANN CHEMLA, University of Illinois, Urbana-Champaign — We present single-molecule measurements of Superfamily 1 UvrD helicase DNA unwinding that reveal directly how helicase stoichiometry and conformation regulate motor activity. Using a new instrument that combines high resolution optical tweezers with single-molecule fluorescence microscopy, we record DNA unwinding activity with base pair-scale resolution (via optical tweezers) simultaneously with helicase stoichiometry and conformation (via fluorescence). Quantifying the fluorescence signal from labeled UvrD, we observe that pairs of UvrD molecules are required for long distance unwinding but that individual molecules exhibit limited, non-processive unwinding activity. UvrD is also known to exhibit two different conformations, 'closed' and 'open', based on the orientation of its 2B regulatory domain. The function of these conformations has remained elusive. Measuring the fluorescence of FRET labeled proteins, we detect directly the conformation of the 2B domain of individual UvrD molecules during unwinding activity. We observe that UvrD is in the 'closed' conformation during DNA unwinding but surprisingly switches to the 'open' conformation upon reversal of helicase direction, i.e. when UvrD switches strands and translocates on the opposing strand with the DNA junction rezipping behind it. We hypothesize that the 2B domain acts as a conformational switch that controls DNA unwinding vs. re-annealing.

12:27PM G43.00003 How Interactions Affect Multiple Kinesin Dynamics , ANATOLY KOLOMEISKY, Rice University — Intracellullar transport is supported by several classes of enzymatic molecules known as motor proteins. Cellular cargos are frequently transported by teams of motor proteins, and recent experimental and theoretical studies uncovered many features of such complex dynamics. Here we investigate theoretically the role of nonmechanical interactions between kinesin motor proteins and microtubules in the collective motion of motor proteins. Our analysis is based on stochastic model that explicitly takes into account all chemical and mechanical transitions. Nonmechanical interactions are assumed to affect kinesin mechanochemistry only when the motors are separated by less than 3 microtubule lattice sites, and it is shown that relatively weak interaction energies can have a significant effect on collective motor dynamics. In agreement with optical trapping experiments on structurally defined kinesin complexes, the model predicts that these effects primarily occur when cargos are transported against loads exceeding single-kinesin stalling forces. These results highlights the complex dynamics of multiple motor proteins in cellular transport phenomena.

1:03PM G43.00004 Molecular mechanism of motion and force generation by cytoplasmic dynein[1] , ARNE GENNERICH, Albert Einstein College of Medicine — Cytoplasmic dynein is an intricate microtubule (MT) motor with four AAA (ATPase associated with various cellular activities) ATPases per head domain. Dynein homodimers take hundreds of consecutive steps, during which the leading and trailing heads experience intramolecular tension in opposite directions. We hypothesize that this asymmetry may differentially regulate the MT-binding and ATPase functions in each head, thereby facilitating processive movement. Here, we elucidate the function of tension in regulating dynein-MT interactions, and dissect the roles of its multiple AAA subunits in effecting and modulating this behavior. Using optical tweezers to measure unbinding forces of single S. cerevisiae dynein heads in the absence of nucleotide, we show that intrinsic dynein-MT binding is significantly weaker under forward (MT-minus-end directed) tension than under rearward tension. Thus, forward tension likely promotes rear head detachment in the dimeric motor. The nucleotide states of specific AAA sites modify this intrinsic behavior. Mutational analysis shows that ATP binding to AAA1 substantially weakens MT binding. Moreover, ADP binding to AAA3 'locks' dynein in a previously undescribed, weak MT-binding state with a relatively symmetric response to tension. Interestingly, tension also affects nucleotide affinity: ADP affinity is lower under rearward than under forward load, suggesting that the front head preferentially releases ADP (likely from AAA3), perhaps driving a transition from an ADP state with relatively weak MT attachment to a strongly MT-attached, nucleotide-free state. Our analysis suggests that intramolecular tension is key to dynein motility, and highlights the importance of including multiple AAA ATPases in models for dynein mechanochemistry.

[1]NIH R01GM098469

1:39PM G43.00005 Motor-motor interactions in ensembles of muscle myosin: using theory to connect single molecule to ensemble measurements , SAM WALCOTT, University of California, Davis — Interactions between the proteins actin and myosin drive muscle contraction. Properties of a single myosin interacting with an actin filament are largely known, but a trillion myosins work together in muscle. We are interested in how single-molecule properties relate to ensemble function. Myosin's reaction rates depend on force, so ensemble models keep track of both molecular state and force on each molecule. These models make subtle predictions, e.g. that myosin, when part of an ensemble, moves actin faster than when isolated. This acceleration arises because forces between molecules speed reaction kinetics. Experiments support this prediction and allow parameter estimates. A model based on this analysis describes experiments from single molecule to ensemble. In vivo, actin is regulated by proteins that, when present, cause the binding of one myosin to speed the binding of its neighbors; binding becomes cooperative. Although such interactions preclude the mean field approximation, a set of linear ODEs describes these ensembles under simplified experimental conditions. In these experiments cooperativity is strong, with the binding of one molecule affecting ten neighbors on either side. We progress toward a description of myosin ensembles under physiological conditions.

Tuesday, March 19, 2013 11:15AM - 2:15PM –

Session G44 DBIO: Multi-cellular Processes and Development Hilton Baltimore Holiday Ballroom 1 - Karen Kasza, Sloan-Kettering Institute

11:15AM G44.00001 The Mechanics of Angiogenesis in Collagen Tubes , JOLIE BREAUX, ABIGAIL DE LA PENA, MELANIE SUARIS, STEVEN ZEHNDER, THOMAS ANGELINI, University of Florida — Cells in all types of tissue are sensitive to their mechanical environment. Understanding cell mechanics in tissue growth can lead to advancements in important medical applications, like technologies that enhance angiogenesis during wound healing. Great progress has been made in understanding the mechanics of angiogenesis with assays performed in flat bottomed culture dishes. Here we present results from an in vitro study of collective endothelial cell mechanics in a 3D culture system that mimics the geometry of a real endothelium. Human Aortic Endothelial Cells were grown inside of a collagen tube supported by a rigid cylindrical scaffold. We developed a time-lapse small angle light scattering method to directly measure the radial distribution of cells in the 3D matrix over time. Accompanying live-cell time-lapse microscopy was performed to monitor the cells' collective movement and organization. We find that the cells generate sufficient contractile force to detach the collagen matrix from the support scaffold while maintaining a macroscopic cylindrical arrangement, creating a fiber. Cell sensitivity to scaffold material properties, curvature, and symmetry will be discussed.

11:27AM G44.00002 Instabilities and topology changes in planar polarized epithelial sheets[1] , DAVID LUBENSKY, University of Michigan — Epithelia–sheets of cells joined together by specialized junctional structures–are one of the basic building blocks of tissues and organs in animals. In many epithelia, rotational symmetry is broken and cells become polarized in a particular direction in the plane of the sheet. Here, we study the interplay between such planar cell polarity and the shape and packing of individual cells. Using general symmetry arguments and simple phenomenological models, we give a classification of the instabilities that can occur in such a coupled system. In particular, we show that two routes to chiral symmetry breaking are possible, both of which require that cells first become elongated along one axis. We also consider the evolution of the cell packing after an initial instability, including how planar polarity affects T1 topological transitions. We close with possible applications of these results to development in *Drosophila* and in zebrafish.

11:39AM G44.00003 Imaging the Population Dynamics of Bacterial Communities in the Zebrafish Gut , MATTHEW JEMIELITA, MICHAEL TAORMINA, Department of Physics, University of Oregon, ADAM BURNS, Institute of Ecology and Evolution, University of Oregon, W. ZAC STEPHENS, JENNIFER HAMPTON, KAREN GUILLEMIN, Institute of Molecular Biology, University of Oregon, RAGHUVEER PARTHASARATHY, Department of Physics, Institute of Molecular Biology, and Material Science Institute; University of Oregon — The vertebrate gut is home to a diverse microbial ecosystem whose composition has a strong influence on the development and health of the host organism. While researchers are increasingly able to identify the constituent members of the microbiome, very little is known about the spatial and temporal dynamics of commensal microbial communities, including the mechanisms by which communities nucleate, grow, and interact. We address these issues using a model organism: the larval zebrafish (Danio rerio) prepared microbe-free and inoculated with controlled compositions of fluorophore-expressing bacteria. Live imaging with light sheet fluorescence microscopy enables visualization of individual bacterial cells as well as growing colonies over the entire volume of the gut over periods up to 24 hours. We analyze the structure and dynamics of imaged bacterial communities, uncovering correlations between population size, growth rates, and the timing of inoculations that suggest the existence of active changes in the host environment induced by early bacterial exposure. Our data provide the first visualizations of gut microbiota development over an extended period of time in a vertebrate.

11:51AM G44.00004 In-plane video force microscopy of morphogenesis in epithelia[1] , M. SHANE HUTSON, DAVID MASHBURN, Vanderbilt University, ERIC COPENHAVER, University of Akron, W. TYLER MCCLEERY, Vanderbilt University, JIM VELDHUIS, STEVEN KIM, G. WAYNE BRODLAND, University of Waterloo — Video force microscopy (VFM) is a technique that takes segmented time-lapse images as input and makes least-squares estimates for the cell-edge tensions and cell-internal pressures needed to drive observed changes in cell shape. VFM has previously been used to estimate the cell-level forces that drive invagination during Drosophila gastrulation. Doing so required time-lapse images containing entire cross-sections of the embryo. Here, we extend video force microscopy to in-plane images of epithelia – including examples in which the images cover only a small region of a larger epithelium. This extension requires imposition of constraints on the average cell-internal pressure and the average stress external to the observed patch. We will demonstrate successful estimation of forces in exact models, as well as anomalous cases that prevent successful force estimation. We will then show applications of this technique for inferring the forces driving Drosophila germband retraction and wound healing.

12:03PM G44.00005 Substrate properties affect collective cell motion , ADRIAN PEGORARO, MING GUO, ALLEN EHRLICHER, DAVID WEITZ, Harvard University — When cells move collectively, cooperative motion, which is characterized by long range correlations in cell movement, is necessary for migration. This collective cell motion is influenced by cell-cell interactions as well as by cell-substrate coupling. Furthermore, on soft substrates it is possible for cells to mechanically couple over long distances through the substrate itself. By changing the properties of the substrate, it is possible to decouple some of these contributions and better understand the role they play in collective cell motion. We vary both the substrate stiffness and adhesion protein concentration and find changes in the collective cell motion of the cells despite only small differences in total cell density and average cell size in the confluent layers. We test these changes on polyacrylamide and PDMS substrates as well as on structured substrates made of PDMS posts that prevent mechanical coupling through the substrate while still allowing stiffness to be varied.

12:15PM G44.00006 Modeling Excitable Systems Coupled Through External Medium , JAVAD NOORBAKHSH, PANKAJ MEHTA, Boston University — Excitable systems are stable dynamical systems in which any input beyond a threshold results in a significant output. This behavior is ubiquitous in nature and is seen in biological systems such as Dictyostelium discoideum amoeba and neurons to oscillatory chemical reactions. In this work we will focus on transition to oscillation in populations of excitable systems coupled through an external medium and will study their synchronization. We will describe a mechanism to tune the frequency of oscillations using an external input and will study the effects of stochasticity and inhomogeneity on the collective behavior of the system. Furthermore we will include diffusion into the dynamics of the external medium and will study formation of spatial patterns, their characteristics and their robustness to different factors.

12:27PM G44.00007 Volumetric Measurements of Amnioserosa Cells in Developing Drosophila , DAVID MASHBURN, AROSHAN JAYASINGHE, SHANE HUTSON, Vanderbilt University — The behavior of cells in tissue in developing Drosophila melanogaster has become increasingly clearer over the past few decades, in large part due to advances in imaging techniques, genetic markers, predictive modeling, and micromanipulation (notably laser microsurgery). We now know apical contractions in amnioserosa cells are a significant factor in large scale processes like germ band retraction and dorsal closure. Also, laser microsurgery induces cellular recoil that strongly mimics a 2D elastic sheet. Still, what we know about these processes comes entirely from the apical surface where the standard fluorescent markers like cadherin are located, but many open questions exist concerning the remaining "dark" portion of cells. Does cell volume remain constant during contraction or do cells leak? Also, what shape changes do cells undergo? Do they bulge, wedge, contract prismatically, or something else? By using a marker that labels the entire membrane of amnioserosa cells (Resille, 117) and adapting our watershed segmentation routines for 4D datasets, we have been able to quantify the entire volumetric region of cells in tissue through time and compare changes in apical area and volume. Preliminary results suggest a fairly constant volume over the course of a contraction cycle.

12:39PM G44.00008 The mechanics of retinal detachment[1] , TOM CHOU, UCLA, MICHAEL SIEGEL, NJIT — We present a model of the mechanical and fluid forces associated with exudative retinal detachments where the retinal photoreceptor cells separate typically from the underlying retinal pigment epithelium (RPE). By computing the total fluid volume flow arising from transretinal, vascular, and retinal pigment epithelium (RPE) pump currents, we determine the conditions under which the subretinal fluid pressure exceeds the maximum yield stress holding the retina and RPE together, giving rise to an irreversible, extended retinal delamination. We also investigate localized, blister-like retinal detachments by balancing mechanical tension in the retina with both the retina-RPE adhesion energy and the hydraulic pressure jump across the retina. For detachments induced by traction forces, we find a critical radius beyond which the blister is unstable to growth. Growth of a detached blister can also be driven by inflamed tissue within which *e.g.*, the hydraulic conductivities of the retina or choroid increase, the RPE pumps fail, or the adhesion properties change. We determine the parameter regimes in which the blister either becomes unstable to growth, remains stable and finite-sized, or shrinks, allowing possible healing.

12:51PM G44.00009 Direct micro-mechanical measurements on *C. elegans* , MATILDA BACKHOLM, Department of Physics & Astronomy and the Brockhouse Institute for Materials Research, McMaster University, Hamilton, Canada, WILLIAM S. RYU, Department of Physics, University of Toronto, Toronto, Canada, KARI DALNOKI-VERESS, Department of Physics & Astronomy and the Brockhouse Institute for Materials Research, McMaster University, Hamilton, Canada — The millimeter-sized nematode *Caenorhabditis elegans* provides an excellent biophysical system for both static and dynamic biomechanical studies. The undulatory motion exhibited by this model organism as it crawls or swims through a medium is ubiquitous in nature at scales from microns to meters. A successful description of this form of locomotion requires knowledge of the material properties of the crawler, as well as its force output as it moves. Here we present an experimental technique with which the material properties and dynamics of *C. elegans* can be directly probed. By using the deflection of a flexible micropipette, the bending stiffness of *C. elegans* has been measured at all stages of its life cycle, as well as along the body of the adult worm. The mechanical properties of the worm are modelled as a viscoelastic material which provides new insights into its material properties. The forces exerted by the worm during undulatory motion are also discussed. Direct experimental characterization of this model organism provides guidance for theoretical treatments of undulatory locomotion in general.

1:03PM G44.00010 Emission of sound from the mammalian inner ear[1] , TOBIAS REICHENBACH, ALEKSANDRA STEFANOVIC, The Rockefeller University, FUMIAKI NIN, Niigata University, A.J. HUDSPETH, The Rockefeller University — The mammalian inner ear, or cochlea, not only acts as a detector of sound but can also produce tones itself. These otoacoustic emissions are a striking manifestation of the mechanical active process that sensitizes the cochlea and sharpens its frequency discrimination. It remains uncertain how these signals propagate back to the middle ear, from which they are emitted as sound. Although reverse propagation might occur through waves on the cochlear basilar membrane, experiments suggest the existence of a second component in otoacoustic emissions. We have combined theoretical and experimental studies to show that mechanical signals can also be transmitted by waves on Reissner's membrane, a second elastic structure within the cochea [1]. We have developed a theoretical description of wave propagation on the parallel Reissner's and basilar membranes and its role in the emission of distortion products. By scanning laser interferometry we have measured traveling waves on Reissner's membrane in the gerbil, guinea pig, and chinchilla. The results accord with the theory and thus support a role for Reissner's membrane in otoacoustic emission.

1:15PM G44.00011 Biofilms suck: how bacteria beat the diffusion limit , THOMAS ANGELINI, WENBO ZHANG, STEVEN ZEHNDER, JOLIE BREAUX, University of Florida — Multicellular behavior in bacterial biofilms is intimately tied to the production of an extracellular polysaccharide (EPS) matrix that encases the cells and provides physical integrity to the colony as a whole. Recent work in *Bacillus subtilis* biofilms shows that a sudden increase in EPS production generates osmotic stresses that cause the biofilm to expand. Moreover, EPS production is triggered by a nutrient depletion gradient that develops in the biofilm due to diffusive mass transport limitations. These polymer physics based biofilm behaviors suggest that EPS production may have evolved in biofilms to beat the diffusion limit of nutrient transport into the colony, though no direct observation of nutrient transport has been observed previously. Here we measure the rate of nutrient transport into *b. subtilis* biofilms and find that when EPS production is up-regulated, the polymer sucks fluid into the colony with a characteristic time dependence like that of pressure driven flow. Preliminary data and analysis will be presented.

1:27PM G44.00012 Inhomogeneous DNA replication kinetics is associated with immune system response[1] , JOHN BECHHOEFER, MICHEL G. GAUTHIER[2], Dept of Physics, Simon Fraser University, Burnaby, BC, Canada, PAOLO NORIO, Department of Medicine, Albert Einstein College of Medicine, Bronx, NY — In eukaryotic organisms, DNA replication is initiated at "origins," launching "forks" that spread bidirectionally to replicate the genome. The distribution and firing rate of these origins and the fork progression velocity form the "replication program." Previous models of DNA replication in eukaryotes have assumed firing rates and replication fork velocities to be homogeneous across the genome. But large variations in origin activity and fork velocity do occur. Here, we generalize our replication model to allow for arbitrary spatial variation of initiation rates and fork velocities in a given region of the genome. We derive and solve rate equations for the forks and replication probability, to obtain the mean-field replication program. After testing the model on simulations, we analyze the changes in replication program that occur during B cell development in the mouse. B cells play a major role in the adaptive immune system by producing the antibodies. We show that the process of cell differentiation is associated with a change in replication program, where the zones of high origin initiation rates located in the immunoglobulin heavy-chain locus shift their position as the locus prepares to undergo the recombination events responsible for generating antibody specificity.

1:39PM G44.00013 Effects of Viscosity on the Gravi-kinesis Responses of Swimming *Paramecia* Studied Using Manetic Force Buoyancy Variation , ILYONG JUNG, JAMES M. VALLES, Brown University — Previous studies have shown that *paramecia* exhibit negative gravi-kinesis. They exert a stronger propulsive force when swimming up than when swimming down. This behavior is very surprising since it suggests they sense their tiny apparent weight of only $\sim$ 80pN. In an effort to understand the mechanism of this sensing, we are testing how the viscosity of the swimming medium influences their gravi-kinetic response. We employ the technique of magnetic force buoyancy variation to simulate different effective gravity levels on swimming *Paramecia*. We are analyzing their swimming response employing a phenomenological model that relates the parameters describing their helical trajectories to the beating of their cilia.

1:51PM G44.00014 Fundamental role of bistability in optimal homeostatic control , GUANYU WANG, George Washington University — Bistability is a fundamental phenomenon in nature and has a number of fine properties. However, these properties are consequences of bistability at the physiological level, which do not explain why it had to emerge during evolution. Using optimal homeostasis as the first principle and Pontryagin's Maximum Principle as the optimization approach, I find that bistability emerges as an indispensable control mechanism. Because the mathematical model is general and the result is independent of parameters, it is likely that most biological systems use bistability to control homeostasis. Glucose homeostasis represents a good example. It turns out that bistability is the only solution to a dilemma in glucose homeostasis: high insulin efficiency is required for rapid plasma glucose clearance, whereas an insulin sparing state is required to guarantee the brain's safety during fasting. This new perspective can illuminate studies on the twin epidemics of obesity and diabetes and the corresponding intervening strategies. For example, overnutrition and sedentary lifestyle may represent sudden environmental changes that cause the lose of optimality, which may contribute to the marked rise of obesity and diabetes in our generation.

2:03PM G44.00015 Time-Dependent Kinematics of Complex Human Structures , SAAMI J. SHAIBANI, Independent Modeling, Algorithms & Analytical Studies (IMAAS) — The human body can be arranged in numerous geometrical configurations, including many interesting scenarios from the sport of gymnastics. One particularly challenging analytical example among these is the forward flip with maximum separation from the ground at the apex of the flight. The temporal aspects of this move involve the evaluation of multiple different positions during the trajectory, which adds significantly to the effort required. When a forward flip was executed during a football game [1], ready access to the recording [2] of this allowed a detailed kinematic examination to be performed. Careful application of highly intricate protocols [3] produces results which are consistent with similar athletic environments. The emphasis in this research is to transcend standard approaches elsewhere, which are severely limited to generic athletes and/or generic circumstances. Pedagogical benefits of the rigorous methodology adopted here are explored beyond what was introduced in a recent related study [4].

Session G45 DBIO DPOLY DCP: Focus Session: Physics of Protein Aggregation Hilton Baltimore Holiday Ballroom 4 - Daniel Cox, UC Davis

11:15AM G45.00001 Single Molecule Visualization of Protein-DNA Complexes: Watching Machines at Work , STEPHEN KOWALCZYKOWSKI, Univesity of California, Davis — We can now watch individual proteins acting on single molecules of DNA. Such imaging provides unprecedented interrogation of fundamental biophysical processes. Visualization is achieved through the application of two complementary procedures. In one, single DNA molecules are attached to a polystyrene bead and are then captured by an optical trap. The DNA, a worm-like coil, is extended either by the force of solution flow in a micro-fabricated channel, or by capturing the opposite DNA end in a second optical trap. In the second procedure, DNA is attached by one end to a glass surface. The coiled DNA is elongated either by continuous solution flow or by subsequently tethering the opposite end to the surface. Protein action is visualized by fluorescent reporters: fluorescent dyes that bind double-stranded DNA (dsDNA), fluorescent biosensors for single-stranded DNA (ssDNA), or fluorescently-tagged proteins. Individual molecules are imaged using either epifluorescence microscopy or total internal reflection fluorescence (TIRF) microscopy. Using these approaches, we imaged the search for DNA sequence homology conducted by the RecA-ssDNA filament. The manner by which RecA protein finds a single homologous sequence in the genome had remained undefined for almost 30 years. Single-molecule imaging revealed that the search occurs through a mechanism termed "intersegmental contact sampling," in which the randomly coiled structure of DNA is essential for reiterative sampling of DNA sequence identity: an example of parallel processing. In addition, the assembly of RecA filaments on single molecules of single-stranded DNA was visualized. Filament assembly requires nucleation of a protein dimer on DNA, and subsequent growth occurs via monomer addition. Furthermore, we discovered a class of proteins that catalyzed both nucleation and growth of filaments, revealing how the cell controls assembly of this protein-DNA complex.

11:51AM G45.00002 Hydrogen Bonding Motifs in MutSaphla and their response to binding damaged DNA , LACRA NEGUREANU, FREDDIE SALSBURY, Wake Forest University — Over the past decade, there has been a growing interest in studying the binding of damaged DNA to the MutSalpha protein complex. This protein complex, the Msh2/Msh6 complex in humans, is the initial complex that binds mismatched DNA and other DNA defects that occur during replication. This complex has also been shown to bind at least some types of damaged DNA. As a result of this interest, multiple studies have contrasted the interactions of MutSalpha with its normal mismatched substrate and with the interactions of MutsSalpha to DNA damaged by the chemotherapeutic cisplatin. To complement these studies, we examined the interaction between MutSalpha and DNA damaged by carboplatin via all-atom molecular dynamics simulations. These simulations provide evidence for different hydrogen bonding interactions at the protein/DNA and protein/protein interface. The hydrogen bonding motifs found are broadly similar to those found in binding to the adduct from cis-platin, but have distinct differences. These subtle differences may play a role in the way the different damages are signaled by MutS.

12:03PM G45.00003 Parallel Verlet Neighbor List Algorithm for GPU-Optimized MD Simulations , SAMUEL CHO, Departments of Physics and Computer Science, Wake Forest University — How biomolecules fold and assemble into well-defined structures that correspond to cellular functions is a fundamental problem in biophysics. Molecular dynamics (MD) simulations provide a molecular-resolution physical description of the folding and assembly processes, but the computational demands of the algorithms restrict the size and the timescales one can simulate. In a recent study, we introduced a parallel neighbor list algorithm that was specifically optimized for MD simulations on GPUs. We now analyze the performance of our MD simulation code that incorporates the algorithm, and we observe that the force calculations and the evaluation of the neighbor list and pair lists constitute a majority of the overall execution time. The overall speedup of the GPU-optimized MD simulations as compared to the CPU-optimized version is N-dependent and $\sim$ 30x for the full 70s ribosome (10,219 beads). The pair and neighbor list evaluations have performance speedups of $\sim$ 25x and $\sim$ 55x, respectively. We then make direct comparisons with the performance of our MD simulation code with that of the SOP model implemented in the simulation code of HOOMD, a leading general particle dynamics simulation package that is specifically optimized for GPUs.

12:15PM G45.00004 Coarse-grained Simulations of Protein-Protein Association: Energy Landscape on a Globe , SICHUN YANG, Case Western Reserve University — Understanding how proteins interact and associate into large functional complexes is critical in revealing the molecular basis of virtually every biological process in a living cell. Here, a theoretical simulation pipeline using coarse-grained (CG) models with an efficient sampling method is presented from the studies of protein-protein association. A concept of "energy globe" is introduced and implemented via the projection of simulation data onto a three-dimensional globe specifying protein-protein orientations and interacting energies. This energy-globe approach has the key advantage of locating and identifying multiple stable conformations that are physically accessible on the energy landscape. Tests on several well-studied protein-protein complexes show that the crystal-like conformation is favorable on the energy landscape even if the landscape is relatively rugged with metastable conformations. Recent applications to CG simulations of nuclear hormone receptors, whose experimental structure are still lacking, have predicted multiple favorable conformations on their corresponding landscapes, thereby providing insight into the cross-talk mechanisms of functional domains in the hormone signaling.

12:27PM G45.00005 Snyder-Robinson Syndrome: Rescuing the Disease-Causing Effect of G56S mutant by Small Molecule Binding[1] , ZHE ZHANG, Clemson University, VIRGINIE MARTINY, DAVID LAGORCE, Université Paris Diderot, EMIL ALEXOV, Clemson University, MARIA MITEVA, Université Paris Diderot, CLEMSON UNIVERSITY TEAM, UNIVERSITÉ PARIS DIDEROT TEAM — Snyder-Robinson Syndrome (SRS) is an X-linked mental retardation disorder, which is caused by defects in a particular gene coding for the spermine synthase (SMS) protein. Among the missense mutations known to be disease-causing is the G56S, which is positioned at the interface of the SMS homo-dimer. Previous computational and experimental investigations have shown that G56S mutation destabilizes the homo-dimer and thus greatly reduces the SMS enzymatic activity. In this study, we explore the possibility of mitigating the effect of G56S mutation by binding small molecules to suitable pockets around the mutation site. It is done by combined efforts of molecular dynamics simulations and in silico screening. The binding of selected molecules was calculated to fully compensate the effect of the mutation and rescue the wild type dimer affinity.

12:39PM G45.00006 Aggregation of concentrated monoclonal antibody solutions studied by rheology and neutron scattering[1] , MARIA MONICA CASTELLANOS, Department of Materials Science and Engineering, Pennsylvania State University, University Park, PA, 16802, JAI PATHAK, Formulation Sciences Department, Drug Delivery Group, MedImmune, Gaithersburg, MD, 20878, RALPH COLBY, Department of Materials Science and Engineering, Pennsylvania State University, University Park, PA, 16802 — Protein solutions are studied using rheology and scattering techniques to investigate aggregation. Here we present a monoclonal antibody (mAb) that aggregates after incubation at 40 °C (below its unfolding temperature), with a decrease in monomer purity of 6% in 10 days. The mAb solution contains surfactant and behaves as a Newtonian fluid when reconstituted into solution from the lyophilized form (before incubation at 40 °C). In contrast, mAb solutions incubated at 40 °C for 1 month exhibit shear yielding in torsional bulk rheometers. Interfacial rheology reveals that interfacial properties are controlled by the surfactant, producing a negligible surface contribution to the bulk yield stress. These results provide evidence that protein aggregates formed in the bulk are responsible for the yield stress. Small-angle neutron scattering (SANS) measurements show an increase in intensity at low wavevectors ($q < 4*10^{-2}$ nm^{-1}) that we attribute to protein aggregation, and is not observed in solutions stored at 4 °C for 3 days before the measurement. This work suggests a correlation between the aggregated state of the protein (stability) and the yield stress from rheology.

12:51PM G45.00007 Enhancing Nucleation rates using Porous Silica[1] , SATHISH AKELLA, SETH FRADEN, Brandeis University — The role of nucleants in promoting protein crystal nucleation is an on-going field of research. Porous silica acts as heterogeneous nucleation centers and enhances nucleation rates. For the protein lysozyme there are multiple polymorphs and we demonstrate that porous silica preferentially increases one of the polymorphs. Preliminary studies are presented in which accurate nucleation rates for the different polymorphs as a function of nucleant concentration are obtained through optical microscopy studies of thousands of crystallization trials in identical water-in-oil emulsion drops produced using microfluidics.

[1]NSF-IDBR

1:03PM G45.00008 Solvent-induced size reduction of self-assembled siRNA/copolymer nanoparticles , WEI QU, Northwestern University, JUAN WU, HAI-QUAN MAO, Johns Hopkins University, ERIK LUIJTEN, Northwestern University — Small interfering RNA (siRNA) therapeutics has a demonstrated potential for treating numerous liver diseases. However, traditional polycation vectors used for siRNA delivery typically produce siRNA-containing particles of large size (> 100 nm), along with high cytotoxicity and low colloidal stability. Inspired by earlier work on nanoparticles for plasmid DNA delivery [1], we graft hydrophilic and biocompatible polyethylene glycol (PEG) blocks to the polycation vector to overcome these limitations. We find that the PEG-grafted polycations result in slightly larger particle size, even though the hydrophilic PEG blocks are expected to hinder the formation of larger aggregates. To explain this observation, we investigate siRNA/copolymer self-assembly via computer simulations of coarse-grained polymer and siRNA models. Our calculations suggest that hydrogen bonding between PEG and the polycation leads to the increased particle size, and that smaller particles can be obtained by inhibiting hydrogen bonding in such system. Subsequent experiments employing solvents of lower polarity indeed lead to particles with smaller size.

1:15PM G45.00009 Using Nanoscale Substrate Curvature to Control the Dimerization of Surface-Bound Proteins , HILARY PAULIN, MARTIN KURYLOWICZ, JOSH MOGYOROS, MAXIMILIANO GIULIANI, JOHN DUTCHER, University of Guelph — The influence of surface geometry on adsorbed proteins offers new possibilities for controlling quaternary structure by manipulating protein-protein interactions at a surface, with applications that are relevant to protein aggregation, fibrillation, ligand binding and surface catalysis. To understand the effect of surface curvature on the structure of surface-bound proteins, we have used a combination of polystyrene (PS) nanoparticles (NPs) and ultrathin PS films to fabricate chemically pure, hydrophobic surfaces that have nanoscale curvature and are stable in aqueous buffer. We have used Single Molecule Force Spectroscopy (SMFS) to measure the detachment contour lengths (L_c) for beta-lactoglobulin (b-LG) and alpha-lactalbumin (a-LA) adsorbed onto neighbouring regions of highly curved and flat PS surfaces, allowing us to compare these values *in situ* on the same sample. In general, we measure peaks in the L_c distributions corresponding to monomers and dimers. As the curvature of the underlying surface is increased, the population of dimers decreases such that only monomers are observed for b-LG adsorbed onto 25 nm dia NPs. These results indicate that surface curvature provides a new method of manipulating protein-protein interactions and controlling the quaternary structure of adsorbed proteins.

1:27PM G45.00010 Coarse-grained Molecular Dynamics Simulation of Calmodulin-target Interactions[1] , PENGZHI ZHANG, Department of Physics, University of Houston, QIAN WANG, Sealy Center for Structural Biology and Molecular Biophysics, University of Texas Medical Branch, SWARNENDU TRIPATHI, MARGARET CHEUNG, Department of Physics, University of Houston — Calmodulin (CaM) is a ubiquitous small protein playing an important role in Ca^{2+} signaling in eukaryotic cells, which can bind and regulate hundreds of target enzymes in the presence of Ca^{2+}. Although the binding process is known to be diffusion controlled, however, due to the flexibility of CaM, methodology that provides molecular insights on target binding and recognition. In this study, Brownian dynamics simulations were used to mimic the process Ca^{2+}-bound CaM binds with two target peptides: CaMKI and CaMKII. Using an experimentally-analogous criterion of number of contacts between targets and a specific residue of CaM to define the encounter complexes and to calculate the association rates, we are able to reveal the molecular reason why CaM-CaMKI has twice the rate of CaM-CaMKII while the numbers of amino acids are similar.

[1]NIH 1R01GM097553-01

1:39PM G45.00011 Linear and Nonlinear Microrheology of Interfacial Protein Layers , DANIEL ALLAN, DANIEL FIRESTER, VICTOR ALLARD, DANIEL REICH, ROBERT LEHENY, Johns Hopkins University — Proteins can adsorb to the air-water interface to form a robust layer. As protein accretes and a layer forms, we monitor the layer's shear rheology employing both passive and active microrheology. Measurements of the linear rheology, using multiple-particle-tracking techniques, show a transition from a viscous to elastic interface with increasing layer age. Active measurements of the nonlinear rheology, in which ferromagnetic nanowires at the interface rotate in response to magnetic torques, show that the protein layers behave quantitatively like a Hershel-Bulkley fluid. We interpret these observations in terms of mechanisms of layer formation and protein interactions at the interface.

1:51PM G45.00012 Contributions of equilibrium and non-equilibrium clusters to viscosity in concentrated protein solutions , PRASAD SARANGAPANI, Drug Delivery and Devices, MedImmune, STEVEN HUDSON, Materials Science and Engineering Division, NIST, JAI PATHAK, Drug Delivery and Devices, MedImmune, KALMAN MIGLER, Materials Science and Engineering Division, NIST — Equilibrium and non-equilibrium clustering are ubiquitous phenomena in soft matter physics and are typically observed in systems ranging from colloidal suspensions to monoclonal antibodies (mAbs). Such phenomena are central to understanding and preventing irreversible aggregation in addition to controlling viscosity challenges related to formulation and drug delivery of protein therapeutics. Curiously, little work has been done in exploring the cluster size dependence of low-shear viscosity and intrinsic viscosity in protein solutions in a controlled manner. In this work, we carefully control cluster size of reversible and irreversible clusters formed by globular proteins or monoclonal antibodies over a concentration range of 2 mg/mL-500 mg/mL and pH from 3-9. We find a marked dependence of low-shear viscosity on cluster size using custom-designed silicon-based microfluidic viscometers. Measurements of cluster sizes using static light scattering reveal a correlation of low shear viscosity as well as intrinsic viscosity with the average cluster size. We model the composition dependence of viscosity for the case of equilibrium and non-equilibrium clusters using an adaptation of a model recently presented by Minton for protein mixtures.

Tuesday, March 19, 2013 11:15AM - 1:39PM –

Session G46 SPS: SPS Undergraduate V

Hilton Baltimore Holiday Ballroom 5 - Kendra Redmond, American Institute of Physics

11:15AM G46.00001 Reverse Micelle Synthesis of Gadolinium Nanoparticles[1] , R.H. FUKUDA, M.M. CASTRO, P.-C. HO, Department of Physics/California State University, Fresno, S. ATTAR, M. GOLDEN, Department of Chemistry/California State University, Fresno, D. MARGOSAN, United States Department of Agriculture - Agriculture Research Service — Nanotechnology is an area of great interest due to its variety of applications such as nano-medicine. The reverse micelle method has been used to synthesize Gd nanoparticles by our research group. Through this method, a surfactant protectively cages particles of Gd in the presence of polar methanol and nonpolar hexane. This method can control particle size by growth temperature and the molar ratio of polar solvent to surfactant. The Gd was reduced from its chloride compound by using sodium borohydride. The final products have been derived either through a method of liquid liquid extraction or filtration. Scanning electron microscopy (SEM) paired with energy dispersive x-ray spectroscopy (EDX) was used to examine the size, shape, and composition of the products. The size and shape were also examined using a Leica light microscope between SEM analyses. We found that liquid liquid extraction does not work in the solvent combination of methanol-hexane due to the instability of the reverse micelles. Additionally, the process of carbon coating SEM samples may have destroyed the reverse micelle structures.

11:27AM G46.00002 Ferromagnetic Nanoparticles for Biomedical Applications , FRANK HOLDER, Rowan University, Dept. of Physics & Astronomy, CRISTINA IFTODE, Rowan University, Dept. of Biological Sciences, TABBETHA DOBBINS, Rowan University, Dept. of Physics & Astronomy — This work examines the cytotoxicity of barium hexaferrite to fibroblast (HEK-293) cells and also the response of barium hexaferrite to magnetic fields. Cytotoxicity is a great way for pharmacies to measure for toxic compounds. Cytotoxicity assays are widely used by the pharmaceutical industry to screen new compounds which may be introduced to the cells. Results show the cytotoxicity of nanoparticles of barium hexaferrite. We chose barium hexaferrite because it is a magnetic material—so it can be driven using an applied magnetic field. This would be useful in biomedical applications where these particles may be added to direct treatment to various parts of the body and across the cell wall membrane by an applied magnetic field.

11:39AM G46.00003 Morphological, Thermal, and Magnetic Analysis of Ball-Milled γ-Fe_2O_3 and Fe_3O_4 Nanoparticles for Biomedical Application , PHILIP BURNHAM, GEORGIA C. PAPAEFTHYMIOU, ARTHUR VIESCAS, Villanova University, Department of Physics, CALVIN LI, Villanova University, Department of Mechanical Engineering, NORMAN DOLLAHON, Villanova University, Department of Biology — Superparamagnetic iron oxide nanoparticles are promising agents for hyperthermia cancer treatment, because, when exposed to an alternating magnetic field, they impart heat to surrounding tissue. A comparison of γ-Fe_2O_3 and Fe_3O_4 nanoparticles for such application is presented. The particles were obtained via surfactant-assisted high energy ball-milling in a hexane/oleic acid carrier-fluid environment. Particles with diameters of 5 to 16 nm were prepared with mass ratios (oleic acid):(γ-Fe_2O_3) of 0:1, 1:5, 1:10 and 1:20, with milling times of 3, 6, 9, and 12 hours. TEM micrographs revealed spherical morphology and the effect of oleic acid shells. Optimal size distributions were obtained for high oleic acid contents. At room temperature, a reduced internal magnetic field $\sim$480 kOe) was recorded via Mössbauer spectroscopy compared to bulk γ-Fe_2O_3 $\sim$500 kOe), due to magnetic relaxation; Fe_3O_4 particles produced similar results. For the γ-Fe_2O_3 and Fe_3O_4 nanoparticles with 20% oleic acid by mass, comparative ZFC/FC magnetization (H_{app} = 200 Oe in temperature range from 2 to 400 K) and hysteresis loops (T = 2 K and 300 K up to H_{app} =6 kOe) were obtained. Thermal transport characteristics were verified by Specific Absorption Rate (SAR) measurements using an AC magnetic field (f =282 kHz). Differences and similarities in behavior will be discussed.

11:51AM G46.00004 Multi-scale Size Distributions of Colloidal Gold Clusters Measured by Ultrasmall Angle X-ray Scattering (USAXS) and Dynamic Light Scattering (DLS) , ASHLI NIEVES, Rowan University, JAN ILAVSKY, Advanced Photon Source, Argonne National Laboratory, TABBETHA DOBBINS, Rowan University — Gold colloids are of interest as: (1) catalysts for energy conversion and (2) absorption agents for laser photothermal therapy. This research examines the agglomerate sizes (using DLS) and primary particle sizes (using USAXS) for gold nanoparticles synthesized by trisodium citrate reduction of gold chloroauric acid (HAuCl4). USAXS data was collected at the Advanced Photon Source, beamline 15ID-D. Model fitting of the data show primary particle sizes of 7nm to 14nm formed. DLS results show these particles to aggregate into a bimodal set of clusters centered on approximately 20nm and approximately 200nm. Preliminary results aimed at effectively breaking apart these aggregates are presented.

12:03PM G46.00005 Dynamical properties of colloids immersed in a uniform electric field at high densities

, MATTHEW WOZNIAK[1], MANUEL VALERA[2], ATHULA HERAT[3], Department of Physics & Pre-Engineering, Slippery Rock University
— In light of the recent interest in the control of colloidal systems, we have explored specific properties of electrically interacting colloidal particles. We explored the structural and dynamical characteristics of mono-disperse systems of colloidal particles that are affected by dipole-dipole interactions while immersed in a uniform electric field and compared with the outcomes that could occur if different sizes of particles are mixed. We used molecular dynamics simulations to study the systems. We present results for the diffusion coefficient and other dynamical properties in the high density regime.

[1]Matthew is a senior Computational Physics student at Slippery Rock University, interested in computational solutions to problems of random systems.
[2]Dr. Manuel Valera is an Assistant Professor of Physics & Pre-Engineering. He has been interested in electrically interacting colloidal systems, particularly their transitions to the glassy state and related properties.
[3]Dr. Athula Herat is an Assistant Professor of Physics & Pre-Engineering. He teaches Computational Physics, among other courses, has assisted with the coding associated with this experiment.

12:15PM G46.00006 Synthesis and Characterization of Mg-doped ZnO Nanorods for Biomedical Applications

, H. GEMAR, N.C. DAS, A. WANEKAYA, R. DELONG, K. GHOSH, Missouri State University
— Nanomaterials research has become a major attraction in the field of advanced materials research in the area of Physics, Chemistry, and Materials Science. Bio-compatible and chemically stable metal nanoparticles have biomedical applications that includes drug delivery, cell and DNA separation, gene cloning, magnetic resonance imaging (MRI). This research is aimed at the fabrication and characterization of Mg-doped ZnO nanorods. Hydrothermal synthesis of undoped ZnO and Mg-doped ZnO nanorods is carried out using aqueous solutions of $Zn(NO_3)_2$.$6H_2O$, $MgSO_4$, and using NH_4OH as hydrolytic catalyst. Nanomaterials of different sizes and shapes were synthesized by varying the process parameters such as molarity (0.15M, 0.3M, 0.5M) and pH (8-11) of the precursors, growth temperature (130°C), and annealing time during the hydrothermal Process. Structural, morphological, and optical properties are studied using various techniques such as XRD, SEM, UV-vis and PL spectroscopy. Detailed structural, and optical properties will be discussed in this presentation. This work is partially supported by National Cancer Institute (1 R15 CA139390-01).

12:27PM G46.00007 Study of Thermal Conductivity of Si Nanowires with micro-Raman Spectroscopy[1]

, BINGQING LI, Department of Physics, Bryn Mawr College, KATHRYN F. MURPHY, DANIEL S. GIANOLA, Department of Materials Science and Engineering, University of Pennsylvania, X.M. CHENG, Department of Physics, Bryn Mawr College
— Nanowires have played an increasingly important role in thermoelectric technology due to their high figure of merit ZT resulting from the reduced thermal conductivity, K, and good electrical conductivity. In this work, we report the measurement of K of individual silicon nanowires (SiNWs) by mapping Raman temperature profiles along the testing nanowires using a microelectromechanical system (MEMS) device and a micro-Raman system with a 530 nm laser beam. Thermal conductivity was measured as a function of uniaxial tensile stress applied to the SiNWs, which was varied from 0 to 1.2 GPa. The measured K results for the unstrained nanowires agree well with the predictions based on diffuse phonon boundary scattering. The dependence of SiNWs' thermal conductivity on engineering stress can provide significant information for nanowires fabrication.

[1]The work at University of Pennsylvania is supported by the Department of Energy, Basic Energy Sciences, through an Early Career Award (DE-SC0008135). The work at Bryn Mawr College is supported by NSF Career Award (DMR- 1053854).

12:39PM G46.00008 Characterization of Carbon Nanotubes Synthesized Using Chemical Vapor Deposition[1]

, ANDREW ZEIDELL, SHAWN HUSTON, Appalachian State University, NATHANAEL COX, BRIAN LANDI, Rochester Institute of Technology, TONYA COFFEY, PHILLIP RUSSELL, BRAD CONRAD, Appalachian State University
— Carbon Nanotubes were synthesized using a Chemical Vapor Deposition system with precursor Cyclopentadienyliron Dicarbonyl Dimer and were systematically characterized over a variety of growth conditions using several methods. Scanning Electron Microscopy (SEM) was used to investigate catalyst contamination, tube diameters, growth morphologies, and material alignment. Transmission Electron Microscopy (TEM) was employed to quantify nanotube wall crystallinity and sidewall defects. Raman Spectroscopy was used in conjunction with Thermo-Gravimetric analysis to ascertain the purity levels of each sample. Results are discussed in terms of related precursors and are used to evaluate the efficacy of the precursor and material quality.

12:51PM G46.00009 Bi2Te3 Nanostructure Synthesis on Multiple Substrates[1]

, NICHA APICHITSOPA, JEROME T. MLACK, NINA MARKOVIC, Johns Hopkins University
— The chalcogenide Bi2Te3 is a known and widely used thermoelectric material that has received renewed experimental interest due to the recent discovery of its topologically protected surface states. Nanodevices of this material are particularly interesting because of their high surface-to-volume ratio, which enhances surface-related transport properties by minimizing bulk contributions. Many synthesis processes for Bi2Te3 have been reported, such as as Au-catalyzed vapor-liquid-solid mechanism (VLS) and lithographically patterned galvanic displacement (LPGD). The VLS mechanism is much simpler than the highly-controlled LPGD; however, remnant of Au catalyst on the nanostructures can alter their electronic structure, resulting in modification of TI surface. We report the synthesis of Bi2Te3 nanostructures by VLS mechanism without using Au catalyst, which improves the quality of the nanostructures.

[1]This work was supported in part by National Science Foundation under DMR-1106167 and DGE-1232825.

1:03PM G46.00010 SAM surface domains of 1-mercaptoundecanoic acid and 1-dodecanethiol mixtures on Au(111) investigated via polarized probes[1]

, ROSE PASQUALE, Lock Haven University, RESHANI SENEVIRATHNE, Don's Food Products Inc, INDRAJITH SENEVIRATHNE, Lock Haven University
— SAM (Self Assembled Monolayer) surfaces with –COOH terminus is bio active and therefore has many bioengineering applications. However complex devices patterned on surfaces require a deeper understanding of the surface domain architecture of SAMs with multi component mixtures of thiols. Varying concentration mixed solutions of 1-mercaptoundecanoic acid (hydrophilic -COOH end) and 1-dodecanethiol (hydrophobic –R), dissolved in 200 proof Ethanol with total 5mM concentration were prepared. These solutions were used in developing SAMs on clean flat Au(111) on mica. Resulting SAMs surfaces were investigated with regular and custom built positively and negatively polarized AFM (Atomic Force Microcopy) probes via contact, non contact and lateral force mode AFM with topography and phase imaging. Domains of distinct thiols were identified as selective self assembly on step edges and terraces. Surface roughness, corrugation and morphology at each domain were estimated. Total RMS surface roughness is estimated at $\sim$ 2.44nm for SAMs with 75% 1-mercaptoundecanoic acid while for SAMs with 25% 1-mercaptoundecanoic acid it is estimated at $\sim$ 2.68nm.

1:15PM G46.00011 Characterization of Nanophosphors for Solid State Lighting Devices Grown by Microwave Plasma Assisted Deposition Process , JEDIDIAH MCCOY, Morningside College, MAREK MERLAK, SARATH WITANACHCHI, University of South Florida — Increasingly, greenhouse farming and urban agriculture are being looked at as a more efficient and more cost effective way to grow produce. Currently the lights used in greenhouses rely on light sources that emit a broad spectrum of light. However, only light at wavelengths around 460 nm (blue) and 670 nm (red) are absorbed by most plants for photosynthesis. Solid state lighting devices can be engineered to produce light to match the needs of the plant while reducing the energy cost. An investigation into the photoluminescence properties of the nanophosphor La_2O_3 doped with Bi was done in an effort to produce a phosphor emitting in blue wavelengths. The La_2O_3:Bi coatings were grown using a microwave plasma growth process. Microwave power and chamber pressure were varied to find the optimum synthesis conditions. Power was varied from 100Watts to 900Watts and chamber pressure was varied from 30Torr to 60Torr. The process utilized O_2 and CO_2 plasma. The nanophosphors were investigated by X-ray diffraction, electron microscopy, and photoluminescent spectroscopy. Photoluminescence was shown to be higher from samples synthesized in a CO_2 plasma.

1:27PM G46.00012 Slip, Slide, or Roll? , MIKE TESTA, None — Using an atomic force microscope the research project, "Slip, Slide, or Roll?" investigates rolling and sliding friction on the nanoscale. The findings of this study may be used to develop improved mechanical lubricants and surfaces. Friction may seem like a simple idea that is familiar to everyone, yet scientific literature explaining what dictates the translational modes of nanoscale objects is surprisingly lacking. In the macroscopic world spherical objects energetically prefer rolling over sliding, for nanoscale objects this is not necessarily the case. We are testing the hypothesis that size, surface chemistry, and elastic modulus dictate whether spherical nanoscale objects will slide or roll when a lateral force is applied. In order to understand the conditions that cause nanoscale particles to transition between the two translational modes we precisely manipulate these variables and measure their effects.

Session G47 GSNP: Invited Session: Elasticity and Plasticity Outside of Equilibrium: Modeling From Micro to Meso Scales Hilton Baltimore Holiday Ballroom 6 - Zhi Feng Huang, Wayne State University

11:15AM G47.00001 Dislocation dynamics, plasticity and avalanche statistics using the phase-field crystal model[1] , LUIZA ANGHELUTA[2], (1) Physics of Geological Processes, Department of Physics, University of Olso, Norway — The plastic deformation of stressed crystalline materials is characterized by intermittency and scaling behavior. The sudden strain bursts arise from collective interactions between depinned crystal defects such as dislocations. Recent experiments on sheared nanocrystals provide insights into the connection between the crystal plasticity and the mean field theory of the depinning transition, based on the similar power-law statistics of avalanche events. However, a complete theoretical formulation of this connection is still lacking, as are high quality numerical data. Phase field crystal modelling provides an efficient numerical approach to simulating the dynamics of dislocations in plastic flows at finite temperature. Dislocations are naturally created as defects in a periodic ground state that is being sheared, without any ad hoc creation and annihilation rules. These crystal defects interact and annihilate with one another, generating a collective effect of avalanches in the global plastic strain rate. We examine the statistics of plastic avalanches both at finite and zero temperatures, and find good agreement with the predictions of the mean field interface depinning theory. Moreover, we predict universal scaling forms for the extreme statistics of avalanches and universal relations between the power-law exponents of avalanche duration, size and extreme value. These results account for the observed power-law distribution of the maximum amplitudes in acoustic emission experiments of crystal plasticity, but are also broadly applicable to other systems in the mean-field interface depinning universality class, ranging from magnets to earthquakes. The work reported here was performed in collaboration with: Georgios Tsekenis, Michael LeBlanc, Patrick Y Chan, Jon Dantzig, Karin Dahmen, and Nigel Goldenfeld.

11:51AM G47.00002 Connecting grain boundary properties to microstructural evolution in polycrystalline metals[1] , ELIZABETH HOLM, Carnegie Mellon University — Within the last decade, both computational and experimental methods have evolved to the point that large-scale surveys of grain boundary properties have become tractable. Such studies have provided new information and insight about boundary structure, energetics, motion mechanisms, and mobility on a scale that invites application to polycrystalline systems. However, the complex behavior revealed in these studies often generates as many questions as it answers. This presentation will review pertinent computational and experimental studies of grain boundary properties in FCC metals, concentrating on boundary energy and mobility. The goal will be to identify the microstructural signatures of boundary properties in polycrystalline grain boundary networks. Topics will include how boundary energy and mobility trends manifest in real microstructures; the effects of shear coupling on boundary motion in bicrystals and polycrystals; the significance of boundaries that move in a non-thermally-activated manner to low temperature grain growth; and the consequences of the thermal roughening transition on grain stagnation. In each case, individual grain boundary properties couple with the characteristics of the grain boundary network to generate diverse microstructural outcomes.

[1]Supported in part by the US Department of Energy Office of Basic Energy Sciences.

12:27PM G47.00003 Modeling polycrystalline multiferroics materials , KEN ELDER, Oakland University — Multifeorroics are materials that involve the coupling of elasticity, magnetization and polarization. The ability to turn mechanical energy into electric or magnetic energy has been exploited for many years in device applications. More recently there has been a great deal of interest in systems that contain all three properties so that the elastic coupling can be used to control polarization with magnetic fields or magnetization with electric fields. In this talk I would like to discuss the development of a phase field crystal model that incorporates all of the rich physics contained in polycrystalline multiferroic materials. To extend the use of this model to larger length scales an amplitude description will be presented. This description also provides a natural link to traditional continuum field theories of multiferroic materials.

1:03PM G47.00004 Phase-Field Crystal Modeling of Polcrystalline Pattern Evolution in Hard and Soft Matter , ALAIN KARMA, Center for Interdisciplinary Research on Complex Systems, Director, Northeastern University — The phase-field crystal (PFC) model has attracted considerable attention during the past decade for its potential application to model the complex defect-mediated dynamics of hard and soft crystalline materials on diffusive time scales. The model is rooted in earlier models of non-equilibrium pattern formation (Swift-Hohenberg equation), and classical density functional theory that expresses the free-energy of a system as a functional of its density. This talk will discuss progress made to investigate the dynamics for both isolated grain boundaries and complex polycrystalline patterns under the driving forces of boundary curvature and applied stress. The results highlight fundamental differences between polycrystalline pattern evolution in soft matter, including colloid crystals and crystalline non-equilibrium patterns described by the standard PFC dynamics, and crystalline solids described by a reformulation of this dynamics presented in this talk. The results also pave the way for a unified theory of polycrystalline pattern evolution in hard and soft matter.

1:39PM G47.00005 Understanding the Evolution of Microstructure: What is the Role of Molecular Dynamics?[1] , STEPHEN FOILES, Sandia National Laboratories — The microstructure of a material, as characterized for example by grain size, determines a wide range of materials properties such as strength, toughness, and corrosion resistance. Understanding how the microstructure influences properties and how to obtain a desired microstructure are some of the enduring central problems of materials science. This challenge is inherently multi-scale since the fundamental mechanisms by which microstructures change occur at the atomic scale while the network of interfaces is on a scale of microns and up. In this talk, the role of molecular dynamics (MD) simulations in understanding the evolution of microstructure will be examined. The successes and outstanding challenges of using MD simulations to determine the properties of grain boundaries, in particular free energy and mobility, will be described. Further, microstructures with nanoscale grains evolve in times accessible to MD simulation. The insights into grain growth and deformation that can be obtained from such simulations will be described.

H1.00002 A Practical Realization of the Delayed Choice Method with Haunted Quantum Entanglement for Choosing at a Distance an Overall Distribution Exhibiting Either Which-Way Information or Interference , DOUGLAS SNYDER, None — This method extends the idea of Greenberger and YaSin's haunted measurement to entanglement. There is a delayed choice whether or not to keep the entanglement between paired photons where an idler photon provides which way information to a distant signal photon. One can produce a ww distribution or a distribution showing interference in the signal photons at a distance by either keeping the paired idler photons or losing them in many other similar photons. Movable mirrors can either send an idler photon to one of two detectors along the two idler photon paths or instead send the idler photon into two optical microcavities filled with photons similar to the idler photon. The result is two different distributions depending on whether the paired idler photon is lost before the signal photon is detected. Ultrafast switches for single entangled photons can be used instead of mirrors to change the paths for the idler photon while the idler photon is in flight. References to the delayed choice method with haunted quantum entanglement: http://meetings.aps.org/link/BAPS.2012.MAR.K1.303, http://meetings.aps.org/link/BAPS.2011.APR.S1.23, http://meetings.aps.org/link/BAPS.2011.APR.S1.22.

H1.00003 Rarefaction wave propagation and longitudinal sound velocities in shock compressed tantalum to 105 GPa , ROBERT SCHARFF, PAULO RIGG, ROBERT HIXSON, Los Alamos National Laboratory — The purpose of this work is to investigate the bcc to hexagonal structural phase transition recently reported for shock compressed tantalum. Longitudinal sound velocities were obtained using a velocimetry diagnostic to record the shock and rarefaction wave arrival times at the sample/anvil interface in the reverse-ballistic plate impact geometry. This approach allows for the determination of the sound speed as a function of pressure and is sensitive to volume changes associated with phase transition behavior. The authors demonstrate that if elastic – plastic wave interactions are correctly determined, then the high pressure structural phase transition that has been previously reported is notably absent.

H1.00004 Crystal structure and phase stability of tungsten borides[1] , QUAN LI, DAN ZHOU, Department of Physics and High Pressure Science and Engineering Center, University of Nevada, Las Vegas, Nevada 89154, USA, YANMING MA, State Key Laboratory of Superhard Materials, Jilin University, Changchun 130012, China, CHANGFENG CHEN, Department of Physics and High Pressure Science and Engineering Center, University of Nevada, Las Vegas, Nevada 89154, USA — We address the longstanding and controversial issue of ground-state structures of technically important tungsten borides using a first-principles structural search method via a particle-swarm optimization (PSO) algorithm. We have explored a large set of stable chemical compositions (convex hull) and clarified the ground-state structures for a wide range of boron concentrations, including W_2B, W_3B_2, WB, W_2B_3, WB_2, W_2B_5, WB_3, and WB_4. We further assessed relative stability of various tungsten borides and compared the calculated results with previously reported experimental data. The phase diagram predicted by the presented calculations may serve as a useful guide for synthesis of a variety of tungsten borides.

H1.00005 Determination of Equations of State for AlF3 and AlI3: Semi-empirical Modeling of Extreme Condition Halide Chemistry , JOSEPH ZAUG, Lawrence Livermore National Laboratory, ELISSAIOS STAVROU, Carnegie Institute of Washington, Geophysical Laboratory, SORIN BASTEA, JONATHAN CROWHURST, Lawrence Livermore National Laboratory, ALEAXANDER GONCHAROV, Carnegie Institute of Washington, Geophysical Laboratory, SARAH ROBERTS, JONATHAN PLAUE, JEFFREY CARTER, MICHAEL ARMSTRONG, Lawrence Livermore National Laboratory — Pressure dependent angle-dispersive x-ray powder diffraction measurements of alpha-phase aluminum trifluoride (alpha-AlF_3) and separately, aluminum triiodide (AlI_3) were conducted using a diamond-anvil cell. Results at 295 K extend to 50 GPa. The equations of state of AlF_3 and AlI_3 were determined through refinements of collected x-ray patterns. The respective bulk moduli and corresponding pressure derivatives using multiple orders of the Birch-Murngahan, Ff, and Gg EoS models will be discussed. Aluminum trifluoride exhibits no pressure induced structural phase transition while the triiodide data reveal a second-order iso-structural rearrangement: Applied stress transformed a monoclinicly distorted face centered cubic (FCC) structure into a perfect FCC structure. Results from semi-empirical thermochemical computations of energetic materials formulated with fluorine containing reactants will be presented. * This work was performed under the auspices of the U.S. Department of Energy jointly by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.

H1.00006 High-pressure Raman scattering spectrum of $K_{0.74}Fe_{1.67}Se_{1.6}S_{0.4}$, YONGHUI ZHOU[1], LI LI, ZHAORONG YANG, YUPING SUN, Key Laboratory of Materials Physics, Institute of Solid State Physics, Chinese Academy of Sciences, Hefei 230031, China, YUHENG ZHANG[2], High Magnetic Field Laboratory, Chinese Academy of Sciences, Hefei 230031, China, XIAO-JIA CHEN, HO-KWANG MAO, Geophysical Laboratory, Carnegie Institution of Washington, Washington, DC 20015, USA — We perform high-pressure Raman scattering measurements on $K_{0.74}Fe_{1.67}Se_{1.6}S_{0.4}$ single crystal up to 20 GPa at room temperature. Anomalous changes of both the A_g and B_g phonon modes are found at a critical pressure around 5.0 GPa. Above this pressure, all Raman modes exhibit a hardening behavior at higher pressures. The superconducting transition temperature of this compound was observed to decrease with increasing pressure and vanish at the critical pressure. These results suggest that the lattice modification and the associated electronic structure are important to understand the superconductivity in the FeSe-based superconductors.

[2]University of Science and Technology of China, Hefei 230026, China

H1.00007 Pressure tuning of spin-phonon coupling in $ZnCr_2Se_4$ by Raman spectroscopy , XULIANG CHEN, Key Laboratory of Materials Physics, Institute of Solid State Physics, Chinese Academy of Sciences, Hefei 230031, China, XIAO-JIA CHEN, Geophysical Laboratory, Carnegie Institution of Washington, Washington, D. C. 20015, USA, ZHAORONG YANG, YUPING SUN, Key Laboratory of Materials Physics, Institute of Solid State Physics, Chinese Academy of Sciences, Hefei 230031, China, YUHENG ZHANG, High Magnetic Field Laboratory, Chinese Academy of Sciences, Hefei 230031, China, WENGE YANG, HO-KWANG MAO, Geophysical Laboratory, Carnegie Institution of Washington, Washington, D. C. 20015, USA — Raman scattering measurements are performed to investigate the phonon spectra of $ZnCr_2Se_4$ single crystal as functions of pressure and temperature. We find that five characteristic phonon modes vary simultaneously by changing pressure and temperature. With decreasing temperature, the phonon modes show anomalous shifts at $T_{\rm E}$, corresponding to the temperature of negative thermal expansion of lattice. With the application of pressure, in addition to the enhancements of frequency of Raman modes, $T_{\rm E}$ shifts to higher temperature, indicative of strengthening of spin-phonon coupling.

H1.00008 Pressure-induced disappearance of superconductivity across isostructural transition in underdoped $Bi_2Sr_2CaCu_2O_{8+\delta}$, JIAN-BO ZHANG, Department of Physics, South China University of Technology, Guangzhou 510640, China, XIAO-JIA CHEN, Geophysical Laboratory, Carnegie Institution of Washington, Wanshington, DC 20015, USA, LING-YUN TANG, ZHEN-XING QIN, JIANG ZHANG, Department of Physics, South China University of Technology, Guangzhou 510640, China, MIKHAIL EREMETS, Max Planck Institute fr Chemie, Mainz 55020, Germany, JING LIU, Institute of High Energy Physics, Chinese Academy of Science, Beijing 100190, China, JIN-SHENG WEN, ZHI-JUN XU, GENDA GU, Condensed Matter Physics and Materials Science, Brookhaven National Laboratory, Upton, New York 11973, USA, HO-KWANG MAO, Geophysical Laboratory, Carnegie Institution of Washington, Washington, DC 20015, USA — There exist rich phenomena in the underdoped regime of cuprate superconductors. An underdoped $Bi_2Sr_2CaCu_2O_{8+\delta}$ single crystal is chosen to investigate the pressure-driven evolution of the superconducting behavior and structural properties by electrical resistance and synchrotron X-ray diffraction measurements. We find that an isostructural phase transition starts at 16.0 GPa and a structural collapse occurs at around 23.7 GPa. Meanwhile, superconductivity is observed to disappear and superconductor-insulator transition takes place across the phase transition. These results suggest that the Fermi surface topology could undertake some modification at high pressures.

H1.00009 Structural and vibrational properties of $NaFe_{0}.925Co_{0}.075As$ under pressure , LIU-XIANG YANG, XIAO-JIA CHEN, HO-KWANG MAO, Geophysical Laboratory Carnegie Institution of Science, Washington, DC 20015, A.F. WANG, Y.J. YAN, X.G. LUO, X.H. CHEN, Hefei National Laboratory for Physical Science at Microscale and Dept of Physics University of Science and Technology of China, Hefei 230026, China — We perform high-pressure Raman scattering and synchrotron X-ray diffraction measurements on an overdoped $NaFe_{0.925}Co_{0.075}As$ single crystal up to 20 GPa at room temperature. Both phonon spectra and structural parameters exhibit abnormal behaviors at a critical pressure around 3.0GPa. The superconducting transition temperature was observed to have a maximum at the same critical pressure. Pressure-induced modification of the Fermi surface topology is suggested to account for the observed behaviors. These results offer a better understanding on the superconductivity in this system far away the complex of structural and spin density wave phase transitions in the underdoped regime.

H1.00010 Fabrication of microcoined metal foil Rayleigh-Taylor targets , GREG RANDALL, JAMES VECCHIO, PAUL FITZSIMMONS, JACK KNIPPING, DON WALL, MATTHEW VU, EMILIO GIRALDEZ, TANE REMINGTON, BRENT BLUE, MICHAEL FARRELL, ABBAS NIKROO, General Atomics — Rippled metal foils are currently sought for high strain rate material strength studies. For example, the growth of these ripples by the Rayleigh-Taylor instability after a laser-induced ramped compression yields strength behavior at extremely high strain rate. Because metals of interest (iron, tantalum, steel, etc.) typically cannot be diamond turned, we employ a microcoining process to imprint the $\sim$ 5 μm deep by $\sim$ 50 μm long ripples into the metal surface. The process consists of nitriding a steel die, diamond turning the die, and then pressing the die into a polished metal foil of choice (Seugling et al., Proc EUSPEN Int. Conference, 2010). This work details recent process developments, characterization techniques, and important physics for fabrication of these rippled metal targets.

H1.00011 Molecular Simulations of Biological Systems under Extreme Conditions , YUKO OKAMOTO, Nagoya University — I will present the results of generalized-ensemble simulations of proteins under extreme conditions, namely, high pressure, high temperature, etc. Generalized-ensemble algorithms that we employed were pressure simulated tempering (Y. Mori and Y. Okamoto, J. Phys. Soc. Jpn. 79, 074003 (2010)), multicanonical replica-exchange method (Y. Sugita and Y. Okamoto, Chem. Phys. Lett. 329, 261 (2000)), and replica-exchange umbrella sampling (Y. Sugita, A. Kitao, and Y. Okamoto, J. Chem. Phys. 113, 6042 (2000)). We compare the results with those of experiments.

H1.00012 SURFACES, INTERFACES AND THIN FILMS –

H1.00013 Electronic and Structural Properties of the Oxidized Cu(110) Surface , ANTOINE OLENGA, N.G. FAZLEEV, Department of Physics, University of Texas at Arlington — The study of adsorption of oxygen on transition metal surfaces is important for the understanding of oxidation, heterogeneous catalysis, and metal corrosion. In this work we present an ab-initio investigation of stability and associated physical and electronic properties of different adsorption phases of oxygen on Cu(110). Especially, we focus on studies of changes in the work function, surface energy, electronic density, interlayer spacing, density of states, and band structure of the Cu(110) surface with oxygen coverage. We examine the cases of high oxygen coverage of the reconstructed Cu(110) surface when the oxygen atoms occupy on-surface as well as sub-surfaces sites. Calculations of electronic properties from first principles have been also performed for the (110) surface of Cu2O to use for comparison. The first-principles calculations in this work have been performed on the basis of density functional theory and using DMOl3 code. The obtained theoretical results have been compared with available experimental data. This work was supported in part by the National Science Foundation Grant DMR-0907679 and the GAANN grant P200A090284.

H1.00014 Two-dimensional electrons on KTaO3 surfaces , PUMSUK PARK, Texas State Univ, BYOUNGHAK LEE, Texas State Univ/Univ of Texas at Austin — The two-dimensional electron gas systems at the interface of polar/non-polar oxides interfaces, e.g. $LaAlO_3$(LAO)/$SrTiO_3$(STO), have received considerable attention due to interesting phenomena stemming from strong electron-electron interactions. A recent experiment [1] showed that the (001) surface of $KTaO_3$ (KTO) can induce two-dimensional electron gas even without external doping. KTO differs from widely studied STO in that KTO has more than 20 times stronger spin-orbit coupling. We carried out density functional theory calculations of vacuum-cleaved KTO surface structure to study the electronic and spin properties of the two-dimensional electrons. The electric field that arises from the surface polarization makes the conduction electrons near the surface, resulting in an orbital ordering similar to LAO/STO interface. Despite the strong spin-orbit coupling, about 400 meV, our result shows the Rashba spin splitting in this perovskite oxide is much smaller than that of conventional semiconductors, which is a good agreement with the angle-resolved photoemission measurement.[1] P. D. C. King, et al. Phys. Rev. Lett. 108, 117602 (2012).

H1.00015 Electric multipole interactions in an extended BEG model , TERESA BURNS, Coastal Carolina University, JR DENNISON, Utah State University — General 2D dielectric phase diagrams and phase transitions for multipolar molecules adsorbed to a square ionic crystal are presented. The adsorbed molecules are modeled using a dilute spin-one Ising model in the Blume-Emery-Griffiths formalism, using a mean-field approximation. Physical constants such as the electric multipole moments and binding energies are used to uniquely determine the interaction parameters over the full range of physically-relevant values. We find that temperature- and coverage-dependent antiferroelectric to ferroelectric, coverage-dependent ferroelectric up to ferroelectric down, reentrant ferroelectric to ferrielectric, and order-disorder dipole phase transitions can occur. The results are presented as a quasi-continuous set of phase diagrams. Extensions into ferro-electric parameter space are discussed and connections to analytical solutions are explored.

H1.00016 Study of positron annihilation with core electrons at the clean and oxygen covered Ag(001) surface[1] , P. JOGLEKAR, K. SHASTRY, A. OLENGA, N.G. FAZLEEV, A.H. WEISS, Department of Physics, University of Texas at Arlington — In this paper we present measurements of the energy spectrum of electrons emitted as a result of Positron Annihilation Induce Auger Electron Emission from a clean and oxygen covered Ag (100) surface using a series of incident beam energies ranging from 20 eV down to 2 eV. A peak was observed at $\sim$ 40 eV corresponding to the N23VV Auger transition in agreement with previous PAES studies. Experimental results were investigated theoretically by calculations of positron states and annihilation probabilities of surface-trapped positrons with relevant core electrons at the clean and oxygen covered Ag(100) surface. An ab-initio investigation of stability and associated electronic properties of different adsorption phases of oxygen on Ag(100) has been performed on the basis of density functional theory and using DMOl3 code. The computed positron binding energy, positron surface state wave function, and positron annihilation probabilities of surface trapped positrons with relevant core electrons demonstrate their sensitivity to oxygen coverage, elemental content, atomic structure of the topmost layers of surfaces, and charge transfer effects. Theoretical results are compared with experimental data.

H1.00017 Evidence for a Large, Thermal-Activated Characteristic Length Scale in Unstable Homoepitaxial Growth on GaAs(001) , CHUAN-FU LIN, Department of Materials Science and Engineering, University of Maryland, College Park, HUNG-CHIH KAN, Department of Physics, National Chung-Cheng University, Chia-Yi, Taiwan, R.O.C, S. KANAKARAJU, C.J. RICHARDSON, Laboratory for Physical Science, College Park, MD, RAYMOND PHANEUF, Department of Materials Science and Engineering, University of Maryland, College Park, UNIVERSITY OF MARYLAND TEAM, LABORATORY FOR PHYSICAL SCIENCE COLLABORATION, NATIONAL CHUNG-CHENG UNIVERSITY COLLABORATION — We report on observations of unstable growth on GaAs(001) surfaces nanopatterned with grooves of varying length/width aspect ratios. For homoepitaxial growth at temperatures near 500°, we find that ridges build up at the upper long edges of grooves oriented along [110]. No ridges form at the long edges of grooves oriented [110]; instead cusps form at the bottoms of such grooves. Most interestingly, we find that the evolution of ridge heights during growth breaks into two distinct branches, with the separation occurring at a groove length of 7.5 $\pm$ 2.5 μm for growth at 525°, and at a length which is an order of magnitude smaller than this for growth at 460°. These observations indicate the presence of very large, thermally-activated characteristic lengths which governs the evolution of the topography during growth.

H1.00018 Dynamics of STM-Induced Switching of Melamine/Cu(001) based on first-principles calculations , TATSUHIKO OHTO, Department of Chemical System Engineering, The University of Tokyo, IVAN RUNGGER, School of Physics, Trinity College Dublin, KOICHI YAMASHITA, Department of Chemical System Engineering, The University of Tokyo, HISAO NAKAMURA, Nanosystem Research Institute (NRI), AIST, SANVITO STEFANO, School of Physics, Trinity College Dublin — The manipulation or stimulation of molecules using Scanning Tunneling Microscopy (STM) is a technique that recently has deserved deep attention for its potential applications in molecular electronics. The melamine/Cu(001) system was found to show switching behavior in very wide range of applied bias. Although its mechanism was analyzed by a statistic model, the relationship between the switching rate and bias is still far to be fully clarified. In this context, we performed a campaign of exhaustive first-principles calculations to obtain most of the parameters for resonance model; such model is able to predict the switching rate as functions of bias and current. The energy barrier was calculated using the nudged elastic band method, with the aid of recent implementation of current-induced forces into SMEAGOL code, which is based on the nonequilibrium Green's function method with Density Functional Theory. The electron-phonon coupling and then the Inelastic Tunneling Spectroscopy signal are calculated to validate the one-phonon approximation. The spatial distribution of molecular orbitals and their coupling with vibrational modes are very useful to understand the switching behavior.

H1.00019 Straining Nanomembranes via Highly Mismatched Heteroepitaxial Growth[1] , FRANK FLACK, University of Wisconsin-Madison, CHRISTOPH DENEKE, Institute for Integrative Nanosciences, FRANCESCA CAVALLO, MAX LAGALLY, University of Wisconsin-Madison — Semiconductor membranes (NMs) combine the high quality electronic properties of single crystalline material with the increased compliance of a thin sheet. Lately it has been demonstrated that these layers can be used as templates for the growth of self-assembled nanostructures (Ge islands) and the growth is heavily influenced by the compliant substrate. To quantify the interplay between strained growth and compliance, we examine the growth of highly strained InAs on Si NMs. The large lattice mismatch between these two materials causes the substrate to bend due to strain sharing between the film and substrate. Atomic force microscopy of the resulting curved surface shows continuous variation in island density, indicating local modifications of adatom diffusivity and critical film thickness. X-ray diffraction and finite element modeling show that islands near the apex of the bent surface are highly strained and those near the bound edges are fully relaxed. Finally, we present continuum elasticity calculations suggesting that InAs films could grow epitaxially on Si which is not possible on bulk Si.

H1.00020 High-resolution TEM study of Mg-doped Aluminum Nitride Epilayers[1] , BO CAI, MIM NAKARMI, CUNY-Brooklyn College and Graduate Center — Transmission electron microscopy (TEM) has been employed to study the threading dislocations in Mg-doped Aluminum Nitride (AlN) epilayers grown by metal-organic chemical vapor deposition. The Mg-doped AlN epilayer samples were grown on high quality AlN/Sapphire template of AlN thickness $\sim$ 1 μm. Atomic Force Microscopy and X-ray Diffraction were employed to characterize the surface morphology and the crystalline properties respectively. In the AlN template layers, TEM revealed that the dominant threading dislocation is the edge type dislocation with the average dislocation density of screw and edge dislocation in the order of 10^7 and 10^9 cm^{-2} respectively. In this study, we present our investigation of the threading dislocations associated with Mg-doping in AlN by analyzing the plan-view and cross-section view of TEM images taken under two-beam conditions. We will also use high-resolution dark field and bright field TEM images to investigate the origin and nature of the threading dislocations. Implementation of our finding to improve the quality of Mg-doped AlN epilayers will also be discussed.

H1.00021 Short Perfluoroalkane adsorption on MgO (100) and graphite , NATHANIEL BASS, JOHN Z. LARESE, University of Tennessee, Knoxville — There has been recent interest in the adsorption properties of C_2X_6 and C_3X_8 (X=H,F) adsorbates on graphite [1], silica [2] and Mo (100) [3] surfaces. In particular, Bruch has examined the lattice structure for the monolayer solid, as well as, the area per molecule for each adsorbate on the basal plane of graphite [1]. We will present the result of our thermodynamic efforts to quantify these parameters experimentally on the graphite basal plane. Furthermore, we extend our thermodynamic investigation to the adsorption of these fluoroalkanes to the (100) MgO surface. We report on the thermodynamic properties for both systems including enthalpy, entropy, and isosteric heat of adsorption as calculated using an extensive set of volumetric adsorption isotherms. The wetting properties and a phase diagram for a representative C_NF_{2N+2} layered system will also be presented. [1] L. W. Bruch, J. Phys. Chem. C 113, 17399 (2009). [2] G. M. Leuty, A. Abu-Nada, and M. Tsige, J. Phys. Chem. C 116, 14514 (2012). [3] G. M. Leuty and M. Tsige, J. Phys. Chem. B 115, 12694 (2011).

H1.00022 ABSTRACT WITHDRAWN –

H1.00023 Dependence of the electronic transport on the microstructure in annealed Bi thin films

, THANH NHAN BUI, JEAN-PIERRE RASKIN, ELEN/ICTEAM, Universite catholique de Louvain, LOIC MALET, STEPHANE GODET, 4MAT, Universite Libre de Bruxelles, FREDERICO RODRIGUES MARTINS, SEBASTIEN FANIEL, XAVIER GONZE, DAMIEN CABOSART, BENOIT HACKENS, NAPS/IMCN, Universite catholique de Louvain — Bi thin films, with a thickness ranging from 10 to 100 nm, are deposited by electron-beam evaporation on a thermally oxidized Si(100) substrate. The deposition parameters are optimized in order to maximize the grain size of the polycrystalline films. The evolution of the crystal orientation is examined as a function of the deposition and annealing parameters, by electron back scattering diffraction. Low temperature (21 mK - 150 K) magnetoresistance measurements (up to 15 T) on polycrystalline films reveal weak anti-localization, superimposed by the classical magnetoresistance. The analysis of the weak anti-localization allows us to extract quantum transport parameters, such as the phase coherence and the spin orbit coupling time. From the evolution of the broad magnetoresistance background, we infer the evolution of electronic transport parameters: the mobility, the charge carrier concentration and the mean free path. Magneto-transport and ab initio calculations are combined in order to investigate on the controversial existence of the semimetal-semiconductor transition.

H1.00024 Diffusion of carbon oxides in SiO_2 during SiC oxidation[1]

, TORU AKIYAMA, KOHJI NAKAMURA, TOMONORI ITO, Department of Physics Engineering, Mie University, HIROYUKI KAGESHIMA, NTT Basic Research Laboratories, NTT Corporation, MASASHI UEMATSU, Faculty of Science and Technology, Keio University — SiC is a wide-band-gap semiconductor and has an advantage to fabricate electronic devices such as MOSFETs due to the ability to thermally oxidize to SiO_2. Despite many studies conducted on the oxidation of SiC, the kinetics such as diffusion and interface reaction is not fully understood. Here, we focus on the diffusion process during SiC oxidation, and clarify the diffusion mechanism of carbon oxides (CO and CO_2) in SiO_2 by means of density functional calculations. Our calculations demonstrate that the CO without any chemical bonds with host SiO_2 is stabilized while the CO_2 is incorporated between Si-O bonds of SiO_2 to form a carbonate group. The energy of CO_2 is found to be lower than that of CO by 3.7 eV, indicating that the most stable form of carbon oxides in SiO_2 is CO_2. Furthermore, the calculated energy barriers for diffusion of CO and CO_2 are found to be 0.1 and 1.8 eV, respectively. These results thus imply that CO molecules easily react with oxidant such as O_2 to form CO_2 and the outward diffusion of resultant CO_2 is rate-limiting. Indeed, the estimated activation energy for CO_2 diffusion (3.5 eV) reasonably agrees with that for Si-face SiC (3.1 eV) obtained by Deal-Grove model considering product gas out-diffusion.

H1.00025 ABSTRACT WITHDRAWN –

H1.00026 HAXPES analysis of materials for electronics applications

, CONAN WEILAND, National Institute of Standards and Technology, PAT LYSAGHT, SEMATECH, JOSEPH WOICIK, National Institute of Standards and Technology — To continue the scaling of memory and logic devices, new materials must be employed to replace the traditional Si/SiO_2. However, detailed understanding of the chemical and electronic structures of the new materials and interfaces must be achieved for employment. X-ray photoelectron spectroscopy (XPS) is an excellent tool for studying such materials due to its unique ability to probe both the chemical and electronic structure of materials. However, XPS analysis is inherently limited by the short inelastic mean free paths (IMFPs) of the photoelectrons, limiting the probe depth to the near surface region. To overcome this limitation, XPS using hard X-rays (HAXPES) can be used, increasing the probe depth to technology relavent thicknesses. We present recent HAXPES results of materials and interfaces for electronics applications.

H1.00027 Surface Electronic Structure of Gadolinium Nitride

, ZANE GERNHART, CHIN LI CHEUNG, Department of Chemistry, University of Nebraska-Lincoln, Lincoln NE 68588, JUAN COLÓN SANTANA, Department of Physics and Astronomy, University of Nebraska-Lincoln, Lincoln NE 68588, LU WANG, WAI-NING MEI, Department of Physics, University of Nebraska, Omaha, Omaha NE 68182 — In this work, we report our finding of the surface electronic structure of high-quality [100]-textured gadolinium nitride (GdN) thin films made by a chemical vapor deposition method. The demonstrated ability to synthesize high-quality thin films has allowed for a detailed inverse photoelectron spectroscopy (IPES) study to elucidate the surface band structure of GdN. The results of our study indicate that the band gap of the GdN surface is about a few milli-electron volts. These findings agree well with the predictions of a small density of states at the Fermi level and an overlap of bands at the gamma point from our density functional theory calculations for GdN slab models of eleven to twenty layers. Although it is accepted that GdN is ferromagnetic semiconductor, reports on the nature of the electronic structure of GdN have ranged from insulating to semi-metallic. We attribute this lack of agreement in the literature is likely due to a wide variation in the quality of the analyzed samples and the inability to consistently synthesize high-quality GdN films. Hence it is our belief that our in-depth study will provide insight to this promising ferromagnetic material with semiconducting behavior.

H1.00028 Functionally Graded Nickel Matrix Alumina Reinforced Nanocomposites

, AUSTIN YOUNG, STEPHEN FARIAS, ROBERT CAMMARATA, Dept. of Materials Science & Engineering, Johns Hopkins University — Hierarchical structured nanocomposites are of great interest particularly in the fields of defense, aeronautics, and metamaterials. Previous work has demonstrated the ability to create uniform nickel matrices embedded with aluminum oxide nanoparticles via electrodeposition using a rotating disk electrode (RDE) [1]. This process allows for controlled enhancement of yield strength without negatively affecting other properties [2]. The speed of the RDE controls the rate of particle incorporation, and therefore, particle volume fraction. Hierarchical structures can be formed by simply changing the rotation rate during electrodeposition. This allows for controlled variations of composite structure throughout the material. Simply layered and functionally graded hierarchical materials have been produced using this method with structural resolution of the order of single microns. These layered structures produced unique mechanical properties, even exceeding those of uniformly dispersed composites.

H1.00029 Spectroscopic Ellipsometry Measurements of Wurtzite Gallium Nitride Surfaces as a Function of Buffered Oxide Etch Substrate Submersion[1]

, CHESTER SZWEJKOWSKI, COSTEL CONSTANTIN, James Madison University, JOHN DUDA, PATRICK HOPKINS, University of Virginia, OPTICAL STUDIES OF GAN INTERFACES COLLABORATION — Gallium nitride (GaN) is considered the most important semiconductor after the discovery of silicon. Understanding the optical properties of GaN surfaces is imperative in determining the utility and applicability of this class of materials to devices. In this work, we present preliminary results of spectroscopic ellipsometry measurements as a function of surface root mean square (RMS). We used commercially available 5mm x 5mm, one side polished GaN (3-7 μm)/Sapphire (430 μm) substrates that have a wurtzite crystal structure and they are slightly n-type doped. The GaN substrates were cleaned with Acetone (20 min)/Isopropanol(20 min)/DI water (20 min) before they were submerged into Buffered Oxide Etch (BOE) for 10s - 60s steps. This BOE treatment produced RMS values of 1-30 nm as measured with an atomic force microscope. Preliminary qualitative ellipsometric measurements show that the complex refractive index and the complex dielectric function decrease with an increase of RMS. More measurements need to be done in order to provide explicit quantitative results.

H1.00030 High Surface Area Nanoporous Ti02 Coating for Effective Water Condensation.[1]

, MEHMET BURAK KAYNAR, SNTG Lab. Physics Engineering Dept. Hacettepe Uni. Turkey, MARK MCGARITY, Mechanical Engineering Department Villanova University, USA, EMRE YASSITEPE, S. ISMAT SHAH, Department of Materials Science and Engineering, University of Delaware, Newark, DE 19716, United States — A water collection device utilizing nanoparticles has been researched, towards the possible goal of providing water in much needed areas on Earth. Titanium dioxide nanoparticles were spray coated on stainless steel substrates to measure their effect on atmospheric water condensation. A simple thermoelectric cooler, also called a Peltier device, was used to lower the temperature of the coated and uncoated stainless steel substrates to below the dew point temperature of the surrounding air. The thickness of the spray coating was varied to measure its effect on water condensation. This increase in surface area had a direct effect on the amount of water condensed. Compared with bare stainless steel, the TiO2 spray coated stainless steel had a considerably smaller contact angle of H20 droplets. In addition, the super-hydrophilic properties of TiO2 allowed water to flow more easily off the device.

H1.00031 Effects of epitaxial strain on oxygen vacancy ordering in LaCoO3 films[1]

, NEVEN BISKUP[2], U. Complutense Madrid, Spain, VIRAT MEHTA, U. of California Berkeley, USA, STEVEN PENNYCOOK, Oak Ridge national Laboratory, YURI SUZUKI, U. of California Berkeley, USA, MARIA VARELA[3], Oak Ridge national Laboratory, ORNL COLLABORATION, UCB COLLABORATION, UCM COLLABORATION — We report on atomically-resolved Z-contrast imaging and electron-energy-loss spectroscopy of epitaxial LaCoO3 thin films grown on SrTiO3, LaAlO3 and (LaAlO3)(SrTaO3) substrates. Regardless of the sign and magnitude of the epitaxial strain imposed by substrate, the LaCoO3 thin films contain oxygen vacancies to varying degrees. These oxygen vacancies tend to order parallel to the film/substrate interface in LCO films under tensile strain and perpendicular under compressive strain. Oxygen vacancy ordering results in charge ordering (CO) among the Co ions as observed by EELS through analysis of the Co L2,3 intensity ratio. We will discuss the amount of oxygen vacancies, the resulting superstructures and CO in the context of the ferromagnetismobserved in these films.

H1.00032 Epitaxial Growth of Atomically Flat Yttrium Iron Garnet Thin Films on Gadolinium Gallium Garnet by Pulse Laser Deposition[1]

, TAO LIN, CHI TANG, JING SHI, Department of Physics and Astronomy, University of California, Riverside, CA, 92521 — Yttrium iron garnet (YIG) is a ferrimagnetic insulator which is useful for magneto-optical, microwave, and more recently spintronic devices. Pulsed laser deposition (PLD) has emerged as a preferred technique to deposit complex oxide thin films, heterostructures, and superlattices with high quality. Deposition of YIG films using PLD has been reported by several groups. The layer-by-layer growth mode has been achieved with a high laser repetition rate. No details about surface morphology were discussed. Here we report our approach to grow YIG films with thickness ranging from 10 to 100 nm on (110)- and (111)-oriented gadolinium gallium garnet (GGG) substrates. In both orientations, we have successfully grown epitaxial YIG thin films confirmed by the patterns of the reflection high-energy electron diffraction. The magnetic properties are measured by a vibrating sample magnetometer. The in-plane easy-axis coercivity is less than 1 Oe, while the perpendicular saturation field is $\sim$ 2000 Oe. For both orientations, the atomic force microscopy images show that the YIG surface is extremely flat with roughness $\sim$ 0.6Å. Flat terraces are found with the atomic step height in films with both orientations. This work paves the way to engineering anisotropy of the thin films for YIG-based magnetic devices.

[1]This work was supported in part by DMEA and DOE.

H1.00033 Investigation of $CaMnO_3$ Epitaxial Thin Films by High Resolution X-ray Diffraction and Atomic Force Microscopy[1]

, GRACE YONG, TYLER GOEHRINGER, EVAN SCHULZ, E. KEVIN TANYI, DAVID SCHAEFER, RAJESWARI KOLAGANI, Towson University — $CaMnO_3$ is a perovskite material of interest for its catalytic properties. As the surface characteristics are important in determining the catalytic properties of thin films, we are investigating the structural and morphological characteristics of epitaxial films thin films grown by Pulsed Laser Deposition. Film structure and morphology are sensitive to variations in the deposition conditions such as the deposition oxygen pressure. We are characterizing the films using high resolution x-ray diffraction in the reflectivity mode (low angle measurements) and using Atomic Force Microscopy. We will study Kiessig fringes as a function of film growth conditions. The film thickness can be determined from the period of the fringes and roughness can be characterized by the angular range of the fringes. We will compare the surface roughness obtained by x-ray reflectivity with those obtained using AFM (atomic force microscopy).

[1]We acknowledge support from the NSF grant ECCS 1128586 at Towson University.

H1.00034 Observation of growth of Si(111)-7x7 reconstructed surface with simultaneous step flow and nucleation

, SHIN-ICHIRO KOBAYASHI, MASAHI MATSUSHITA, KING ITAYA, School of Engineering, Tohoku University — The structure of Si(111)-7x7 surface (7x7) has been extensively investigated for five decades and established, both experimentally and theoretically, that the reconstructed surface is described by the dimer-adatom-staking fault model. Recently, we succeeded in observing the peculiar 7x7 surface in not only macroscopic area but also atomic level. Images by the leaser confocal microscopy (LCM)[1] provided us the alternative step structure in macroscopic area. By utilizing AFM, the step height almost corresponded to the step for ten layers of atomic step. This indicates that the step bunching by step flow was occurred by current heating to Si substrate. In addition, by investigating the atomic surface by STM in detail, we could find Si clusters or inlands with about 10 nm^2 at the tip of the step as well as confirm the step bunching. The growth of this structure is originated from simultaneous nucleation by unit cell on 7x7 surface due to energy fluctuation and step flow by current heating. Observation of surface in wide range area by SPM and LCM is useful to understand the growth of mechanism of ultra-flat surface in semi-conductive and metallic surfaces. [1] S. Kobayashi et al, Electrochem. Solid-State Lett., 14, H351(2011) .

H1.00035 Epitaxial growth mechanisms of graphene and effects of substrates[1]

, V. ONGUN OZCELIK, SEYMUR CAHANGIROV, SALIM CIRACI, Bilkent University — Graphene growth and energy barrier calculations of defect healing were investigated using ab-initio MD calculations[1]. It was found that there are two mechanisms which play crucial roles in the growth of graphene. First mechanism is the formation of large carbon rings at the edges which eventually collapse to form honeycomb structure with defects. This collapse is found to be initiated by the new coming carbon atoms which replace one of the bonds in the ring, and expands it until the critical size is reached. Second mechanism is the formation of PH defects near the edge and their healing. We have shown that the energy barrier needed to overcome during healing of the PH defects are much lower than that of the SW defects. We have shown that the presence of a BN or Ni substrate have crucial effect on growth. These substrates guide the formation of honeycomb structures from carbon rings and enable the healing of specific defects as growth proceeds. We also studied graphene growth using carbon dimers as building blocks and found that defect formation is less frequent as compared to growth with monomers.

H1.00036 Optical Properties of ZnO/Cu Nanolaminate Materials by Spectroscopic Ellipsometry

, SETH KING, LORALEE BILKE, JOSEPH KRUEGER, ELIZABETH TENNYSON, BENJAMIN OLESON, University of Wisconsin - La Crosse, UNIVERSITY OF WISCONSIN - LA CROSSE DEPARTMENT OF PHYSICS TEAM — Laminate materials in which ZnO and a metal are layered on the naonometer scale show great promise as transparent conducting oxides (TCO) [1,2]. However, for these materials to be employed in TCO applications a complete understanding of their optical properties must be gained. Specifically, the impact of varying the oxide and/or metal layer thickness, and the number of total laminations layers must be explored. In this study we employ UV – Vis spectroscopy and spectroscopic ellipsometry to investigate variations in the index of refraction, transmittance, and the optical bandgap of ZnO/Cu nanolaminates as a function of Cu interlayer thickness. [1] J.S. Cho, S. Baek, and J.C. Lee; SOLAR ENERGY MATERIALS AND SOLAR CELLS, **95**, 7, 1852-1858 (2011) [2] J.G. Lu, X. Bie, Y.P. Wang, L. Gong, and Z.Z. H1.00037 STRONGLY CORRELATED SYSTEMS, INCLUDING QUANTUM FLUIDS AND SOLIDS —

H1.00038 Magnetic and structural properties of $BiFeO_3$ thin films grown epitaxially on $SrTiO_3$/Si substrates[1]

, NIKOLETA THEODOROPOULOU, DANIEL CURRIE, RYAN LAUGHLIN, ROCIO CONTRERAS-GUERERRO, ARUNA DEDIGAMA, WEERASINGHE PRIYANTHA, RAVINDRANATH DROOPAD, Texas State University, PENG GAO, XIAOQING PAN, University of Michigan — The integration of oxides with semiconductors is important for the technological advancement of the next generation electronics. Concomitant ferroelectric and antiferromagnetic (AF) behavior is demonstrated in single crystal $BiFeO_3$ (BFO) films grown on 20 nm $SrTiO_3$ (STO) virtual substrates on Si (100) using MBE. Commensurate STO thin films are grown on Si in an oxide MBE chamber by co-deposition of Sr, Ti and molecular O_2. The STO/Si films are used as a virtual substrate for MBE deposition of BFO without breaking vacuum. The RHEED image of BFO shows a 2-D growth front with a 6-fold surface reconstruction under optimized conditions. Cross-sectional TEM confirms the high crystallinity of the films and shows sharp, atomically flat interfaces. The SADP reveals that BFO grows in a distorted rhombohedral crystal structure. XRD does not show formation of second phases and is consistent with the TEM and SADP results. The BFO films show AF behavior with a Neel temperature that exceeds 350 K and with a residual ferromagnetic behavior that decreases with film thickness. The saturation magnetization for a 20 nm film was 180 emu/cm^3. The ferroelectric behavior of the films was verified using Piezoresponse Force Microscopy.

H1.00039 Hund's coupling and spin-orbit coupling in iridates revisited

, HUA CHEN, GURU KHALSA, ALLAN H. MACDONALD, University of Texas at Austin — In recent years iridates have attracted a lot of interests because of unusual properties due to a combination of strong correlations and strong spin-orbit scattering. The magnetic properties of these materials are often analyzed theoretically by applying the Kugel-Khomskii model and specifically considering the $J = \frac{1}{2}$ subspace decoupled by strong spin-orbit coupling. It is not obvious that such an approach is always valid, however, given that the spin-orbit coupling, on-site correlation energies, intra-atom exchange energies, tetragonal splittings, etc. all have comparable strength. In this work we will revisit the magnetic interactions of these materials combining insights from an examination of the 2-electron multiplet structure of a t_{2g} ion using the Slater theory of atomic structure, and ab initio electronic structure calculations. We will also discuss the the magnetic anisotropy and domain-wall energies of specific iridate materials implied by these magnetic interactions.

H1.00040 Magnetic properties and compositional homogeneity in (Ce,La,Sr)(Ti,Fe)O_3 films

, XUEYIN SUN, PENG JIANG, Harbin Institute of Technology and Massachusetts Institute of Technology, LEI BI, DONG HUN KIM, Massachusetts Institute of Technology, DAMING JIANG, GAOHUI WU, Harbin Institute of Technology, G.F. DIONNE, C.A. ROSS, Massachusetts Institute of Technology — Single crystal films of $Sr(Ti_{1-x}Fe_x)O_3$ are magnetic well above room temperature with up to 0.8 μ_B/Fe and exhibit strong out-of-plane magnetoelastic anisotropy. The properties are governed by the Fe valence states which can be manipulated by substitution on the A-site. Here, ∼150 nm thick films of $(A_ySr_{1-y})(Ti_{0.6}Fe_{0.4})O_3$ where A=La or Ce were grown on $(LaAlO_3)_{0.3}(Sr_2AlTaO_6)_{0.7}$ substrates by pulsed laser deposition. The La and Ce raised the saturation moment but lowered the optical transparency as the average Fe valence decreased. Theoptical band gap widened and the Fermi level moved toward the vacuum level with increased Ce or La content. The composition distribution in a film with 30% Ce was analyzed by high angle annular dark-field scanning transmission electron microscopy (HAADF-STEM).The film showed columnar growth with homogeneous distribution of Ce, Fe, Ti and O, precluding the possibility of clustering or phase separation.

H1.00041 Fluorination of epitaxial oxides: Creating ferrite and nickelate oxyfluoride films[1]

, STEVEN MAY, EUN JU MOON, Drexel University, YUJUN XIE, Argonne National Laboratory, DAVID KEAVNEY, JUSTIN GOEBEL, ERIC LAIRD, CHRISTOPHER LI, Drexel University — In ABO_3 perovskites, the physical properties are directly coupled to the nominal valence state of the B-site cation. In epitaxial thin films, the dominant strategy to control B-site valence is through the selection of a di- or trivalent cation on the A-site. However, this approach is limited, particularly when electron doping on the B-site is desired. Here we report a simple method for realizing oxyfluoride films, where the substitution of F for O is expected to reduce the B-site valence, providing a new means to tune electronic, optical and magnetic properties in thin films. Fluorination is achieved by spin coating an oxygen deficient film with poly(vinylidene fluoride). The film/polymer bilayer is then annealed, promoting the diffusion of F into the film. We have used this method to synthesize $SrFeO_{3-\delta}F_\delta$ and $LaNiO_{3-\delta}F_\delta$ (δ ? 0.5) films, as confirmed by x-ray photoemission spectroscopy and x-ray absorption spectroscopy.

[1]This work is supported by the U. S. Army Research Office under grant number W911NF-12-1-0132. Work at the Advanced Photon Source is supported by the U.S. Department of Energy (DOE), Office of Basic Energy Sciences under contract DE-AC02-06CH11357.

H1.00042 Coexistence of Ferromagnetism and Ferroelectric Polarization in Epitaxial $NiTiO_3$ thin films with the $LiNbO_3$-Type Structure , TAMAS VARGA, EMSL, TIMOTHY DROUBAY, PNNL, MARK BOWDEN, EMSL, SCOTT CHAMBERS, PNNL, ROBERT COLBY, BERND KABIUS, EDOARDO APRA, WILLIAM SHELTON, VAITHIYALINGAM SHUTTHANANDAN, EMSL — In a search for new multiferroic materials where the direction of magnetization can be switched by an applied electric field, we have looked for materials in which polarization and magnetization are strongly coupled. Recent theory calculations predicted that the family of compounds $MTiO_3$ (M = Mn, Fe, Ni), in a certain polymorphic structure (acentric *R3c*), are promising candidates where a polar lattice distortion can induce weak ferromagnetism (WFM). Guided by these insights, the *R3c* phase of $NiTiO_3$ has been prepared in epitaxial thin film form. The synthesis of these $NiTiO_3$ films, their full structural characterization, physical property measurements along with first-principles DFT calculations to predict the desired $NiTiO_3$ structure, its stability, and the effect electronic structure on the ferroic properties are presented. Optical SHG imaging of the $NiTiO_3$ films indicates a polar lattice. Temperature-dependent magnetization measurements suggest a Neel transition consistent with the *R3c* structure. Our field-dependent magnetization results show a residual magnetism below the Neel temperature suggesting the presence of a ferromagnetic moment induced by the polar lattice distortion. These results validate theory predictions about the coexistence of WFM and ferroelectric polarization in $MTiO_3$ compounds with the *R3c* structure.

H1.00043 Trapping of three-dimensional Holstein polarons by various impurities[1] , HADI EBRAHIMNEJAD, MONA BERCIU, University of British Columbia, MONA BERCIU'S TEAM — We study the bound states of a three-dimensional Holstein polaron near various kinds of single impurities, using the momentum-average approximation. We show that the electron-phonon coupling renormalizes the impurity potential into a strongly retarded effective potential, which describes essential physics ignored by "instantaneous" approximations. The accuracy of our method is gauged by comparison with results from diagrammatic Monte Carlo for the case of an impurity that modifies the on-site energy of the electron. We also discuss impurities that modify the local strength of the electron-phonon coupling as well as isotope substitutions that change both the electron-phonon coupling and the phonon frequency. For the latter, we recover a threshold value of the electron-phonon coupling below which, no matter how strong the impurity is, polaron can not be trapped.

H1.00044 Electrical transport properties of $BaTiO_3/LaAlO_3/SrTiO_3$ heterostructure , THACH NGO, LKHAGVASUREEN BAASANDORJ, University of Science and Technology, Korea Research Institute of Standards and Science, JONGHYUN SONG, Chungnam National University, JINHEE KIM, Korea Research Institute of Standards and Science — Strongly correlated materials with incompletely filled d- of f-electron shells exhibit unusual electronic and magnetic properties, which cannot be effectively explained in terms of non-interacting electron model, and hence hold the promise of novel electronic applications. Here we report the tunneling measurement across $BaTiO_3/LaAlO_3/SrTiO_3$ heterostructure revealing the metal-insulator transition (MIT), at low temperatures, modulated by varying $BaTiO_3$ (BTO) layer thickness. Accordingly, we observed an Ohmic behavior at temperatures $>$ 200 K for all BTO thicknesses, this can be understood with thermoionic emission mechanism, and a clear rectification at low temperatures. The direct tunneling lends a good explanation for the structures with thin BTO layer ($<$ 8 unit cells) and the critical thickness for Zener tunneling contribution is 20 unit cells of BTO. The MIT was clearly observed in the structure with 18 unit cells of BTO.

H1.00045 Effect of the substitution of Y, Nd, Sm and Eu for La in $La_{1.4}Ca_{1.6}Mn_2O_7$ on its structural and magneto-electrical properties at constant chemical pressure[1] , CABIR TERZIOGLU, SEVGI POLAT ALTINTAS, Department of Physics, Faculty of Arts and Sciences, Abant Izzet Baysal University, 14280 Bolu, Turkey — A systematic study of the electrical and magnetic transport properties of the layered manganite $(La_{1-y}R_y)_{2-2x}Ca_{1+2x}Mn_2O_7$ (R=Y, Nd, Sm, Eu and x=0.3) is presented. The average A-site ionic radius $< r_A >$ is kept constant at 1.327 Å and the role of the magnetic moment of rare earth ion has been studied by characterizing physical properties of the layered manganites. These materials were prepared by solid state reaction route and were characterized comparatively by X-ray diffraction (XRD), AC susceptibility and electrical resistivity measurements. The electrical resistivity in the entire temperature range is found to fit well with the phenomenological percolation model, which is based upon the phase segregation of ferromagnetic clusters and paramagnetic insulating regions.

[1]This work is financially supported by the Abant Izzet Baysal University Scientific Research Projects Unit under contract number 2011.03.02.417.

H1.00046 Structural and magneto-electrical properties of fluorine doped $La_{0.7}Ca_{0.3}MnO_3$ perovskite manganites[1] , SEVGI POLAT ALTINTAS, Department of Physics, Faculty of Arts and Sciences, Abant Izzet Baysal University, 14280 Bolu, Turkey, NABIL MAHAMDIOUA, LEND, Université de Jijel, B. P 98 Jijel 18000, Algeria, CABIR TERZIOGLU, Department of Physics, Faculty of Arts and Sciences, Abant Izzet Baysal University, 14280 Bolu, Turkey, ABDERREZAK AMIRA, LEND, Université de Jijel, B. P 98 Jijel 18000, Algeria — The role of fluorine doping for oxygen in $La_{0.7}Ca_{0.3}MnO_yF_x$ (x=0.0, 0.2, 0.4, 0.6) system has been investigated by means of X-ray diffraction, resistivity and susceptibility measurements. The oxygen content of the samples was determined by a redox back titration method and the Rietveld refinement was used to characterize structurally the manganites. The metal-insulator transition temperature T_{MI} of all samples is found to increase by fluorine doping. In order to understand the conduction mechanism, the phenomenological percolation approach which depends on the phase segregation of ferromagnetic clusters and paramagnetic insulating regions was used.

[1]This work is financially supported by the Abant Izzet Baysal UniversityScientific Research Projects Unit under contract number 2011.03.02.417.

H1.00047 Two metal-insulator transitions in Iridates , T. DAS, Los Alamos Natl. Lab. — The experimental discovery of metal-insulator transition (MIT) in clean Iridates came as a surprise since electron-electron correlation is known to be weaker than the effective bandwidth of the extended 5d electrons of Iridium ion. Numerous studies indicate that the strong spin-orbit coupling in this system is responsible for the insulating behavior. Theories of MIT include strong coupling spin-liquid, Mott physics or weak-coupling Slater-type spin-ordering. Here we show that there exists another MIT in the spin-orbit density wave channel, which wither coexists with the spin-ordering insulator or phase separated in the parameter space of chemical potential, Coulomb interaction and spin-orbit coupling strength. The results are compared with various experimental data which support this proposal. [1] T. Das, Phys. Rev. Letts. (2012). Work is supported by US DOE.

H1.00048 Vortex lattice disorder and the stability of nucleated topological liquids , VILLE LAHTINEN, University of Amsterdam, ANDREAS LUDWIG, University of California, Santa Barbara, SIMON TREBST, University of Cologne — When interacting non-Abelian anyons are arranged on a regular lattice, such as an Abrikosov lattice in a topological superconductor or a Wigner crystal in a fractional quantum Hall liquid, it has been shown that a new topological state is nucleated. Studying Majorana mode binding vortex lattices in Kitaev's honeycomb model, we show that the nucleated phases are stable with respect to both moderate vortex dimerization and local random disorder. In the limit of strong disorder, the first will recover the parent topological state, while the latter will drive the system into a gapless thermal metal state.

H1.00049 Quantum order-by-disorder in an extended Shastry-Sutherland model , KEOLA WIERSCHEM, PINAKI SENGUPTA, Nanyang Technological University — We show two examples of quantum order-by-disorder processes in an extended Shastry-Sutherland model. This model incorporates uniaxial exchange anisotropy along with additional next-nearest-neighbor bonds not present in the canonical Shastry and Sutherland model. Moreover, the transverse component of exchange is ferromagnetic, while the longitudinal component remains antiferromagnetic. This guarantees the model to be free of the quantum Monte Carlo sign problem, and we thereby explore two regions of the phase diagram that display the order-by-disorder phenomenon. In the first instance, we show that quantum fluctuations can turn a highly degenerate solid phase into a supersolid phase with higher degrees of diagonal order than the solid phase. In the second instance, the highly degenerate states along a phase boundary are lifted by quantum fluctuations and replaced by a striped solid phase.

H1.00050 Indication of an internal field along the basal plane below the hidden order temperature in URu_2Si_2 from ^{29}Si-NMR in a random powder sample[1] , EDITH SOTO[2], OSCAR BERNAL, Department of Physics and Astronomy, California State University, Los Angeles, CA 90032 — We present a study of the lineshape of ^{29}Si NMR spectra in hidden-order URu_2Si_2 for relatively low applied fields (1 and 2 T) and temperatures from 5 to 300 K. The random-powder pattern we obtained changes considerably at the transition temperature (17.5 K). Fitting the spectra to a powder pattern of axial symmetry (for which one can define the parameters: $h_{||}$ and $h_{\perp}$ to locate the position of the spectral feature that corresponds to the orientation of the applied field parallel and perpendicular to the c-axis respectively) allows us to address the question of whether changes on the parameters imply an internal field throughout the sample. From these data we have been able to conclude that there is indeed a shift in the position of the line in the perpendicular geometry. The change in frequency units is between 3 and 4 kHz, which correspond to a field of about 4 G, just as we found previously for a single crystal. This is not the case for the parallel geometry, for which the strong T dependence of the paramagnetic broadening and shift precludes us from making a similar conclusion.

H1.00051 Electronic Tuning in $CeCoIn_5$, K. GOFRYK, F. RONNING, J.-X. ZHU, M.N. OU, P.H. TOBASH, X. LU, E.D. BAUER, J.D. THOMPSON, Los Alamos National Lab., S.S. STOYKO, A. MAR, Department of Chemistry, University of Alberta, Canada, T. PARK, Sungkyunkwan University, South Korea, Z. FISK, University of California, Irvine — We report a globally reversible effect of electronic tuning on the magnetic phase diagram in $CeCoIn_5$ driven by electron (Pt and Sn) and hole (Cd, Hg) doping. Consequently, we are able to extract the superconducting pair breaking component for hole and electron dopants with pressure and codoping studies, respectively. We find that these nominally nonmagnetic dopants have a remarkably weak pair breaking effect for a d-wave superconductor. The pair breaking is weaker for hole dopants, which induce magnetic moments, than for electron dopants. Furthermore, both Pt and Sn doping have a similar effect on superconductivity despite being on different dopant sites, arguing against the notion that superconductivity lives predominantly in the $CeIn_3$ planes of these materials. In addition, we shed qualitative understanding on the doping dependence with density functional theory calculations.

H1.00052 Torsion Pendulum energy dissipation due to ^{3}He in aerogel. Dissipation signature of the A-phase , NIKOLAY ZHELEV, ROBERT BENNETT, Cornell University, JOHANNES POLLANEN, California Institute of Technology, ERIC SMITH, Cornell University, WILLIAM HALPERIN, Northwestern University, JEEVAK PARPIA, Cornell University — A torsion pendulum excited at acoustic frequencies was used to measure the dissipation Q^{-1} and period shift of ^{3}He confined in a 98% open aerogel, compressed by 10% along the axial direction. Data was taken in the range between 100mK and T_c, as well as below T_c for a series of pressures. After accounting for bulk and empty cell contributions, Q^{-1} is seen to be pressure and temperature independent in the normal state. The dissipation is larger than expected, which can be accounted for either by invoking a very long frictional relaxation time or by taking into account the internal friction in the aerogel that is affected by mass loading of ^{3}He. In contrast, the dissipation in the superfluid state depends strongly on temperature and pressure. The A phase (observed on cooling) shows a higher dissipation than the B phase (observed on warming); the excess dissipation is greater at high pressures.

H1.00053 A Study of the Superfluid Transition in Helium Films Adsorbed to a Rough CaF_2 Surface Over a Large Temperature Range , MARTY SCHWARZ, LAURA WADLEIGH, DWIGHT LUHMAN, Carleton College — Rough two-dimensional substrates, such as thermally deposited CaF_2, have been shown to modify the experimental signatures of the superfluid transition in adsorbed thin helium films. Previous experiments have investigated a series of increasingly rough surfaces over a limited temperature range and found that the features at the superfluid transition become less defined as substrate roughness is increased. In this work we use a single rough CaF_2 substrate and study the superfluid transition in adsorbed helium films over a wide range of temperatures. Our results show that as the transition temperature increases the abrupt jump in superfluid density at the transition become less distinct. The changing characteristics of the transition on a single CaF_2 substrate with temperature suggest that the reduced observability of the transition on rough substrates cannot be explained entirely by simple surface geometry effects, such as tortuosity.

H1.00054 Single-Photon-Sensitive Superconducting TES Sensors for EUV Photons in Superfluid Helium , FAUSTIN CARTER, SCOTT HERTEL, DANIEL PROBER, DANIEL MCKINSEY, Yale University — Incident radiation can excite superfluid helium into a diatomic He2* excimer, which decays through the emission of a 15 eV photon. Such excimers have been used as tracers to measure the superfluid's quantum turbulence, thanks partly to the long half-life of the He2* triplet state ($\sim$13 seconds). However, the efficient detection of these excimers remains a challenge. This work presents two different detector designs capable of in-situ detection of the He2* excimers either directly, or by collecting the 15 eV emission upon decay. Both detectors are based on the superconducting transition edge sensor. One is designed to operate near 2 K, while the other is designed for $\sim$100 mK operation in a dilution refrigerator. We will discuss operating characteristics of both, and present preliminary data from the 2 K detector.

H1.00055 INSULATORS AND DIELECTRICS –

H1.00056 Band alignment in $Ge/GeO_x/HfO_2/TiO_2$ heterojunctions as measured by hard x-ray photoelectron spectroscopy , ABDUL RUMAIZ, NSLS, Brookhaven National Laboratory, JOSEPH WOICIK, CONAN WEILAND, National Institute of Standards and Technology, Q. XIE, Department of Solid State Science, Ghent University, PETER SIDDONS, NSLS, Brookhaven National Laboratory, CHRISTOPHE DETAVERNIER, Department of Solid State Science, Ghent University — Hafnium based high-k materials have been widely studied to replaced SiO_2 as a gate insulator in field effect transistors. Apart from offering low equivalent oxide thickness, they also offer a favorable band offset with Si. The development in the field of high-k dielectrics has also reduced the significance of Si/SiO_2 interface, thus opening new possibilities with high mobility semiconductors such as Ge. It is well known that the leakage current of a gate stack is dependent on the dielectric constant and the tunnel barrier height. Based on the current scaling trend, an oxide with k $\sim$ 40 would be ideal. Among the widely studied oxides TiO_2 is known to have a very high dielectric constant. However the poor conduction band offsets with both Si and Ge, makes it completely impractical as a gate oxide material. The problem of poor conduction band offset has been addressed by introducing a suitable interlayer with higher conduction band offset. In our work we investigate the interlayer thickness dependence of band alignment in a germanium based bilayer metal-oxide-semiconductor sandwich with an amorphous HfO_2 and TiO_2 high k gate dielectric using hard x-ray photoelectron spectroscopy. We see a strong evidence of intermixing at Hf-Ge interface and a deviation from bulk offset for ultra thin HfO_2.

H1.00057 Strain controlled ferroelectric switching time of $BiFeO_3$ capacitors , ER-JIA GUO, ANDREAS HERKLOTZ, KATHRIN DOERR, Institute of Physics, MLU-Halle Wittenburg, Germany, MAX-PLANK INSTITUTE OF MICROSTUCTURE IN HALLE COLLABORATION — Recent advances in the epitaxial growth of complex oxide thin films made an artificial control of the strain states of ferroelectric (FE) films possible However, it is quite difficult to separate the intrinsic strain effects on FE switching from those effects resulting from the variable microstructures and defects. For this reason, the switching kinetics which is particularly sensitive to defects has not yet been investigated in controlled strain states. In this paper, we investigated the strain-dependent switching of $BiFeO_3$ capacitors grown on piezoelectric PMN-PT substrates at various temperatures. The FE switching exhibits good agreement with the KAI model. The strain-induced relative change of the switching time is different in the low and high electric field regions, showing a crossover from slowing down at low fields to acceleration of the switching at high fields under $\sim$0.1% of reversible compressive strain. We attribute this behavior to the difference between the dynamics of domain-wall propagation in the creep and depinning regimes. As the temperature decreases, a tenfold strain-induced enhancement of the switching time was observed as a result of reduced thermal activation and the strain-induced rise of the pinning potential. This work will advance the fundamental understanding of the domain switching processes. The huge sensitivity of the switching time bears a strong potential for the optimization of FE devices.

H1.00058 Domain formation and dielectric response in $PbTiO_3$: A first-principles free energy landscape analysis , ANIL KUMAR, KARIN RABE, Dept of Physics and Astronomy, Rutgers University, UMESH V. WAGHMARE, Jawaharlal Nehru Centre for Advanced Scientific Research, Bangalore, India — We determine the relative thermodynamic stability of competing homogeneously and inhomogeneously ordered ferroelectric phases of $PbTiO_3$ using its free energy landscape, obtained from a newly developed method based on a combination of constrained polarization molecular dynamics simulations with a first-principles effective Hamiltonian and thermodynamic integration. While we find that the tetragonal structure is thermodynamical ly most stable at temperatures below the ferroelectric transition temperature ($T_0 = 660K$), free energy of an "orthorhombic-like" 90° domain phase relative to the tetragonal phase almost vanishes at $T = 540K$, and remains small at all temperatures below T_0. In contrast to $BaTiO_3$, 90° domain walls are an order of magnitude lower in energy than 180° domain walls. We show that the computed dielectric response of the "orthorhombic-like" phase includes contributions from domain walls, and thus is significantly larger than that of the unifor mly polarized tetragonal phase of $PbTiO_3$.

H1.00059 ABSTRACT WITHDRAWN –

H1.00060 Probing laser induced space charge fields with Engineered Defects[1] , HOSANNA ODHNER, Bryn Mawr College, GREG STONE, Pennsylvania State University, VOLKMAR DIEROLF, Lehigh University — We report on the ability to measure the buildup of space charge fields in ferroelectric materials with engineered defects, such as optically active rare earth ions. Analysis of the erbium emission reveals several changes in the intensity, frequency, and width of several peaks that occur on different time scales. Also, these changes are sensitive to the intrinsic defect concentration and the addition of extrinsic defects. Comparatively the magnitude of the spectral shifts for the different erbium peaks in erbium peaks are similar to those seen for an applied external electric field across the z-axis of the crystal. Also, several new peaks appear in the erbium emission demonstrating the ability to probe simultaneous changes in defect complexes.

[1]Supported by NSF-DMR 1008075.

H1.00061 Structure and Properties of Hexagonal R_xMnO_{3+d}[1] , TREVOR TYSON, TIAN YU, Department of Physics, New Jersey Institute of Technology, Newark, NJ 07102, CATHERINE DUBOURDIEU, INL, CNRS - Ecole Centrale de Lyon, Ecole Centrale de Lyon, 36 ave Guy de Collongue, 69134 Ecully — Films of hexagonal Multiferroic RxMnO3+d (R=Dy and Er) have been prepared. Local atomic and electronic structure measurements have been utilized to probe the variation of properties of samples. The defect levels obtained, x $\sim$ 0.6 to x $\sim$ 1.2, correspond to systems with defect (voids) on the R sites and then the Mn sites. The spectroscopic studies are complemented by electronic structure calculations to predict the magnetic and electrical polarization properties as a function of defect level

[1]This work is supported by DOE Grant DE-FG02-07ER46402.

H1.00062 How Magnesium Substitution Changes the Magnetostrictive Properties of Cobalt Ferrite , DAVID C. JILES, Department of Electrical and Computer engineering, Iowa State University, CAJETAN NLEBEDIM, Ames Laboratory, US DOE, Iowa State University, RAVI HADIMANI, Department of Electrical and Computer engineering, Iowa State University, RUSLAN PROZOROV, Department of Physics and Astronomy, Iowa State University — Materials based on cobalt ferrite are promising for magnetostrictive applications. Significant research effort has been invested towards understanding the effects of substituting different cations into the spinel crystal lattice of cobalt ferrite on its magnetostrictive properties. Al and Mg are the two cations that occupy the tetrahedral and octahedral sites of the spinel ($MgAl_2O_4$) from which cobalt ferrite derives its crystal structure. In our previous study, compared with other cation substituted cobalt ferrite studies, Al substitution resulted in the best compromise in magnetostriction and strain sensitivity. In this study, we present the effects of substituting Mg for Fe in cobalt ferrite. It was found that Mg substitution resulted in a near-linear decrease in magnetization of the samples. Remarkably, both magnetostriction and strain sensitivity showed a similar dependence on Mg substitution. This trend is unlike previous observations in which both properties show opposite dependence on cation substitution at lower concentrations of the substituted cations.

H1.00063 $EuTiO_3$: a possible multiferroic material, structural, magnetic and dynamical characterization , ZURAB GUGUCHIA, HUGO KELLER, Physik-Institut der Universität Zürich, JUERGEN KOEHLER, ANNETTE BUSSMANN-HOLDER, Max-Planck-Institute for Solid State Research, STUTTGART COLLABORATION, ZUERICH COLLABORATION — Structural analogies between $SrTiO_3$ and $EuTiO_3$ suggest that other similarities exist, namely an oxygen octahedral rotational instability. This has been tested experimentally as well as theoretically by specific heat measurements [1], X-ray powder diffraction [2], EPR and μSR experiments [3], within the polarizability model and by ab initio calculations [4,5]. Earlier evidence for strong spin phonon coupling in $EuTiO_3$ [6] has been further explored for the high temperature instability at T_S and is reflected in the magnetic field dependence of T_S [7].

H1.00064 Non-saturating Magneto-resistance up to 60 Tesla in Topological Insulator Bi2Te3 Thin Films

, SHIXIONG ZHANG, Center for Integrated Nanotechnologies, Los Alamos National Laboratory, ROSS D. MCDONALD, ARKADY SHEKHTER, National High Magnetic Field Laboratory, Los Alamos National Laboratory, ZHENXING BI, Center for Integrated Nanotechnologies, Los Alamos National Laboratory, YAN LI, National High Magnetic Field Laboratory, Los Alamos National Laboratory, QUANXI JIA, S.T. PICRAUX, Center for Integrated Nanotechnologies, Los Alamos National Laboratory — We report magneto-transport studies of topological insulator Bi2Te3 thin films grown by pulsed laser deposition. A non-saturating linear-like magneto-resistance (MR) was observed at low temperatures in the magnetic field range from a few Tesla up to 60 Tesla. Due to the large Fermi Surface, the magnetic field is not high enough to quantize all the surface Dirac Fermions into the lowest Landau level, which rules out the possibility of 'quantum linear magnetoresistance'. We have further shown that the Linear MR may be associated with the weak antilocalization effect at high fields and can be described by the Hikami-Larkin-Nagaoka analysis providing the elastic scattering time is longer than the spin-orbit scattering time.

H1.00065 Growth of topological insulators on Si(111)-(7×7) surfaces by molecular beam epitaxy[1]

, ANUPAM ROY, SUSHANT SONDE, SAMARESH GUCHHAIT, SANJAY BANERJEE, Microelectronics Research Center, The University of Texas at Austin — Following the theoretical prediction about Bi_2X_3 (X=Se, Te) being a topological insulator (TI) because of strong spin-orbit interactions, interest has grown in integrating these materials with Si technology for potential future devices. In this work, we will be presenting the epitaxial TI structures grown by molecular beam epitaxy (MBE) by codepositing high purity Bi and Se or Te onto the clean Si(111)-(7×7) substrates under ultra-high vacuum (base pressure better than 1×10^{-10} mbar). In-situ studies show sharp streaky reflection high-energy electron diffraction (RHEED) patterns. Scanning tunneling microscopy (STM) studies show the growth of Bi_2Se_3 islands along the terraces. High resolution STM studies show hexagonal atomic structure of Bi_2Se_3. For Bi_2Te_3, STM shows that the growth follows a layer-by-layer mode with the height difference being same as the quintuple layer height of Bi2Te3. Spectroscopy studies of the grown film to confirm the chemical stoichiometry will also be presented.

[1]SWAN-NRI

H1.00066 Phonon Dispersion, Electronic Structure and Photocatalytic Properties of Rutile TiO_2 doped with X-doped (X=N, B and Pt)

, SANJEEV K. GUPTA, Department of Physics, Michigan Technological University, Houghton, Michigan 49931, USA, PRAFULLA K. JHA, Department of Physics, Maharaja Krishnakumarsinhji Bhavnagar University, Bhavnagar-364001, India, IGOR LUKAČEVIĆ, Department of Physics, University J. J. Strossmayer, Osijek, Croatia — First principles calculations were performed on the electronic, vibrational and Raman spectra of substitutional N, B and Pt-doped rutile titanium dioxide (TiO_2), within the density functional theory (DFT), using the plane-wave pseudopotential method as implemented in the ABINIT package. Of all the photocatalytic materials TiO_2 has been shown as the most useful one, with the most efficient photoactivity, the highest stability and the lowest cost. Moreover, it is safe for humans and the environment. The development of new types of photocatalytic cells is driven by the need for clean and sustainable energy. In this respect best doped materials are considered as a promising route for departing from the traditional photocatalytic cells. The physical insight provided by computational modeling may help in developing improved photocatalytic devices. To this end it is important to obtain an accurate description of the electronic structure and phonon dynamics, including the fundamental gaps and level alignment at the doped-TiO_2 interface.

H1.00067 Structural, electronic, and optical properties of $Ba_{1-x}Zn_xO$[1]

, ZEYAD A. ALAHMED, HAMAD A. ALBRITHEN, AHMED M. EL-NAGGAR, Department of Physics and Astronomy, King Saud University, Riyadh 11451, Saudi Arabia — We have investigated structural, electronic and optical properties of $Ba_{1-x}Zn_xO$ alloy in the range of ($0 \leq x \leq 1$) in the zinc-blende phase. The all-electron full potential linearized augmented plane wave (FP-LAPW) method implemented in WIEN2k code was utilized in these calculations. Structural optimization of $Ba_{1-x}Zn_xO$ alloy for the compositions x = 0, 0.25, 0.50, 0.75, and 1.0 was carried out by minimizing the total energies as functions of the unit cell volume. The calculated equilibrium lattice constant a and bulk modulus B for both binary BaO and ZnO compounds are found to be (a =6.04Å, B=45.51GPa for BaO) and (a =4.689Å, B=113.84GPa for ZnO), in good agreement with the values reported by different groups. We have observed a nonlinear behavior of the lattice constant a as varying the composition x. The electronic structure and the band gap of different composition x are calculated using different types of exchange–correlation potentials. Additionally, we will present the electron charge density distribution for different crystallographic planes of the unit cell. Also, we will demonstrate the effects of variation of compositions x on the optical properties such as the complex dielectric function and refractive index of the alloy.

H1.00068 The Image Potential for Spherical Conductors and Dielectrics

, GODFREY GUMBS, Hunter College of the CUNY, ANTONIOS BALASSIS, Fordham University, ANDRII IUROV, Hunter College of the CUNY, PAULA FEKETE, United States Military Academy — We calculate the image potential for spherical conductors and dielectrics, such as fullerene buckyballs. Our calculations show that these structures can support electronic states which may be localized at some distance away from the surface. These "spherical image states" exist within extended surface potentials formed by the competition between the attractive image force, the external electron and its image charge in the spherical shell, and the repulsive centrifugal force arising from the angular motion. The effective potential leads to extended stable states away from the surface of the spherical shell. At low temperatures, this results in long lifetimes for the image states. We expect that spherical image states with binding energies of a few meV. The bound states may be formed with the aid of radiative recombination.

H1.00069 Competing Mechanisms for Temperature-Dependant Electron Relaxation in Disordered SiO_2 Layers Under Electron Irradiation[1]

, JR DENNISON, GREGORY WILSON, AMBERLY E. JENSEN, USU Materials Physics Group, RYAN HOFFMANN, Air Force Research Laboratory, Kirtland Air Force Base — High energy electrons incident on highly disordered insulating materials undergo quasielastic collisions that imparts both charge and energy to the material; this can excite multiple intrinsic electrons from valence band or low level trap states into the extended states of the conduction band. These excited electrons provide a significant conduction mechanism in insulators under the influence of applied fields, but quickly thermalize to shallow localized trap states just below the conduction band edge that are associated with structural (physical) or compositional (chemical) defects. Electrons in these shallow trap states can: (i) remain in these shallow trap states; (ii) be thermally re-excited into the conduction band, leading to thermally assisted charge transport, termed radiation induced conductivity (RIC); (iii) decay into deep traps well within the band gap, often emitting a photon which is termed cathodoluminescence; or (iv) decay to low level valence band or trap states through radiative or non-radiative processes. Simple theory based on thermally-assisted hopping conductivity and disordered band theory is used to link diverse temperature-dependant measurements to the transition mechanisms for electrons in the shallow states.

H1.00070 Study of Insulator-Metal transition of VO_2 thin films with ultrafast optical pulses[1] , ELIZABETH RADUE, LEI WANG, The College of William and Mary, EVAN CRISMAN, Department of Physics, The College of William and Mary, RUSSELL WINCHESKI, NASA-Langley Research Center, S. KITTIWATANAKUL, J. LU, S.A. WOLF, Department of Physics, University of Virginia, ROSA LUKASZEW, IRINA NOVIKOVA, The College of William and Mary — VO_2 has been a popular material to study in the past few decades as it has a reversible insulator-metal transition (IMT) when heated past 340K or stimulated with an ultrafast optical pulse. The resistance and optical properties change by several orders of magnitude, making it an attractive candidate for low loss plasmonic devices, ultrafast switches, or smart windows. We study the dynamics of the transition of VO_2 thin films on different substrates with femtosecond pulses in a pump-probe experiment in order to better understand the mechanisms behind the transition. We have measured the IMT at several different temperatures to investigate any change in the dynamics of the transition. We also study the Raman spectroscopy of VO_2 thin films heated through the transition. The effects of the different substrates on the transition of the VO_2 thin film will be discussed.

[1]This work is financed by NSF, DMR-1006013: Plasmon Resonances and Metal Insulator Transitions in Highly Correlated Thin Film Systems. We also acknowledge support from the NRI/SRC sponsored ViNC center and the Commonwealth of Virginia through the Virginia

H1.00071 Direct Determination of Electric Current in Born-Oppenheimer Molecular Dynamics[1] , TAO SUN, RENATA M. WENTZCOVITCH, Department of Chemical Engineering and Materials Science, University of Minnesota — We introduce a new approach to calculate directly the electric current in Born-Oppenheimer molecular dynamics. In this approach the electric current is computed from the adiabatic variations of the Kohn-Sham eigenstates between consecutive time steps. This conceptually straightforward method is fairly efficient and can be easily implemented into existing electronic structure programs. We test the method in two representative systems: liquid D_2O and crystalline MgO. The polarization change and the electric current density computed from the present approach are in excellent agreement with those from the Berry phase method and explicit density functional perturbation theory calculations of Born-effective charges.

[1]Supported by NSF Grants EAR-1047626 and EAR-0810272.

H1.00072 Radio-frequency tunnel-junction shot noise thermometry and its application to the study of thermal properties at low temperature , JUNG HWAN PARK, DONG-GWANG HA, WOON SONG, YONUK CHONG, Korea Research Institute of Standards and Science, Daejeon 305-340 — We developed a radio-frequency broadband measurement setup for shot noise thermometry in the temperature range from 0.1 K to 300 K. The noise power from a metallic tunnel junction was measured at 1 GHz with a bandwidth of 400 MHz. Very small noise signal from the tunnel junction was amplified by a cryogenic HEMT amplifier. The signal was then amplified by a room temperature amplifiers followed by a diode detector that converts the noise power into voltage output. Broadband measurement technique enables a fast measurement of RF signal. The shot noise thermometer directly measures the electron temperature and our measurement uncertainty is less than 3% in the sub-Kelvin range. Because of the small size of the tunnel junction, local measurement of the temperature on a device is possible. Since we measure the electron temperature directly, we can apply this technique to the study of thermal properties at low temperature.We suggest a method of measuring electron temperature before and after a thermal process in a chip at low temperature, which will help understanding of the thermal properties of electron-phonon system at low temperature.

H1.00073 Improved Atonic Mechanics Calculations and New Milieu , ALFRED PHILLIPS JR., Source Institute — We have devised a way for improving the accuracy of electron energy level calculations done in what we named Atonic mechanics. The more accurate calculations resulted from a new way of modeling magnetic effects. Prior to the improvement, the Atonic mechanic energy level calculation were about as accurate as conventional quantum mechanics for simple atoms. We have also created a more general milieu in which we can model the particle's motion.

H1.00074 Investigation of Proton Dynamics in a $(CH_3)_4NCdCl_3$ Single Crystal by using ^1H Nuclear Magnetic Resonance Measurements , MOOHEE LEE, JUNG SEOK SIM, KIHYEOK KANG, HO HYOUN KIM, Department of Physics, Konkuk University, Seoul 143-701, South Korea, AE RAN KIM, Department of Science Education, Jeonju University, Jeonju 560-759, South Korea — $(CH_3)_4NCdCl_3$(TMCC) is reported to exhibit two first-order structural phase transitions. The crystal has a hexagonal structure in phase I at room temperature and then changes to a monoclinic one in phase II below 118 K. Finally a ferro-elastic monoclinic phase III appears below 104 K. The a- and c-axes of TMMC were found by using X-ray diffraction at room temperature. ^{1}H NMR measurements of spectrum, spin-lattice relaxation time T_1 and rotating-frame relaxation time $T_{1\rho}$ were performed at 4.8 T parallel or perpendicular to the c-axis from 300 K down to 65 K. The spectrum shows no significant changes at both transition temperatures. T_1 and $T_{1\rho}$ monotonically decrease at low temperature and then show an abrupt decrease around 110 K. As the temperature decreases further, T_1 shows a minimum at 100 K and becomes longer whereas $T_{1\rho}$ continuously decreases. From these data, the proton dynamical behavior is analyzed and identified.

H1.00075 Temperature Dependence of ^{7}Li NMR Spectra in a $Li_2KRb(SO_4)_2$ Single Crystal , MOOHEE LEE, HO HYOUN KIM, KIHYEOK KANG, JUNG SEOK SIM, Department of Physics, Konkuk University, Seoul 143-701, South Korea, AE RAN LIM, Department of Science Education, Jeonju University, Jeonju 560-759, South Korea — $Li_2KRb(SO_4)_2$ is a mixed crystal of $LiKSO_4$and $LiRbSO_4$. $LiKSO_4$ has a hexagonal symmetry at room temperature and undergoes four phase transitions at low temperature. On the other hand, $LiRbSO_4$ is pare-electric with a monoclinic symmetry at room temperature and then shows a phase transition above 400 K. In order to understand the microscopic details of structural phase transitions in the single crystal of $Li_2KRb(SO_4)_2$, we have measured the temperature dependence of ^{7}Li NMR spectrum at 8 T from 300 K down to 100 K. The ^{7}Li NMR spectrum shows three resonance peaks, which is a typical shape from three nuclear Zeeman level splitting for the nuclear spin of I=3/2 with nuclear-quadruple interaction. The spectrum shows a different shape for 8T parallel and perpendicular to the c-axis. As temperature decreases, the spectrum shows no significant change whereas the ^{7}Li nuclear quadrupole frequency increases monotonically.

H1.00076 Quantum criticality in Kondo quantum dot coupled to helical edge states of interacting 2D topological insulators[1] , CHUNG-HOU CHUNG, SALMAN SILOTRI, Department of Electrophysics, National Chiao-Tung University, HsinChu, Taiwan, R.O.C. — We investigate theoretically the quantum phase transition (QPT) between the one-channel Kondo (1CK) and two-channel Kondo (2CK) fixed points in a quantum dot coupled to helical edge states of interacting 2D topological insulators (2DTI) with Luttinger parameter $0 < K < 1$[1]. For $K < 1$, the strong coupling 2CK fixed point of the model was argued to be stable for infinitesimally weak tunnelings between dot and the 2DTI based on a simple scaling dimensional analysis[2]. We re-examine this model beyond the scaling dimension analysis via a 1-loop renormalization group (RG) approach combined with bosonization and re-fermionization techniques near weak-coupling and strong-coupling (2CK) fixed points. We find for $K \to 1^-$ that the 2CK fixed point can be unstable towards the 1CK fixed point and the system may undergo a quantum phase transition between 1CK and 2CK fixed points. The QPT in our model comes as a result of the combined Kondo and the helical Luttinger physics in 2DTI, and it serves as the first example of the 1CK-2CK QPT accessible by the controlled RG approach. We extract quantum critical and crossover behaviors. [1] C.-H. Chung and S. Silotri, arXiv:1201.5610. [2] K.T. Law, C.Y. Sheng, Patrick A. Lee, and T.K. Ng, Phys. Rev. B **81**, 041305(R) (2010).

[1]We acknowledge the support from the NSC grants No.98-2112-M-009-010-MY3, No.101-2628- M-009-001-MY3, the MOE-ATU program, the CTS of NCTU, the NCTS of Taiwan, R.O.C..

H1.00077 The fate of Z_2 topological insulator in optical lattices with disorder , AHAD KHALEGHI ARDABILI, Koç University PhD student, TEKIN DERELI, Professor of Physics KoçUniversity, ÖZGÜR MÜSTECAPLOLU, Assistant Professor, Department of Physics Koç University — Topological insulator is considered to be very robust against any perturbation which Doesn't break time-reversal invariant and there are now many proposal about creating such systems in cold atom area which one can have very good control for tuning it. Here we investigate the effect of disorder in the TI Z_2 system proposed in B. Beri and N. R. Cooper PRL 107, 145301 (2011) We show that under a strong disorder the system undergoes a topological phase transition.

H1.00078 Persistent currents in a Kane-Mele graphene ring with armchair edges , MING-CHE CHANG, National Taiwan Normal University, BOR-LUEN HUANG, Academia Sinica, CHUNG-YU MOU, National Tsing Hua Univeristy — A graphene nano-ribbon with armchair edges is known to have no edge state. However, if the nano-ribbon is in the quantum spin Hall (QSH) state, then there must be helical edge states. By folding a graphene ribbon to a ring and threading it by a magnetic flux, we study the persistent charge and spin currents in the tight-binding limit. It is found that, for a broad ribbon, the edge spin current approaches a finite value independent of the radius of the ring. For a narrow ribbon, inter-edge coupling between the edge states could open the Dirac gap and reduce the overall persistent currents. Furthermore, by enhancing the Rashba coupling, we find that the persistent spin current gradually reduces to zero at a critical value, beyond which the graphene is no longer a QSH insulator.

H1.00079 Electronic properties at an interface between Mott-insulator and topological-insulator , SUGURU UEDA, NORIO KAWAKAMI, Kyoto University, MANFRED SIGRIST, ETH Zürich — We investigated the correlated heterostructure of two-dimensional topological and Mott insulator with the inhomogeneous dynamical- mean-field theory combined with Lanczos exact diagonalization method. We focus on the proximity effects driven by the topological helical edge-state. It is elucidated that the edge state penetrates into the Mott insulator and induces a strongly renormalized in-gap state with helical energy spectrum We also address how the in-gap state is affected by the coupling between the Mott and topological insulators, and find the enhanced renormalization-effect caused by the band reconstruction at the interface.

H1.00080 Quantum Network Models and Topological Insulators , MONICA PATE, LIANG FU, Massachusetts Institute of Technology — We develop quantum network models for Anderson localization on the surface of weak topological insulators and topological crystalline insulators. These models represent systems in which delocalized helical electrons travel along contours that separate topologically distinct states. We perform numerical studies on random network systems to study the localization-delocalization transition in these materials.

H1.00081 Three-dimensional Fermi surface in $Cu_xBi_2Se_3$, GANG LI, TOMOYA ASABA, FAN YU, BENJAMIN LAWSON, ZIJI XIANG, COLIN TINSMAN, ADAM BERKLEY, Physics Dept., Univ. of Michigan, YEW SAN HOR, Physis Dept., Missouri S&T, LU LI, Physics Dept., Univ. of Michigan — To study the evolution of bulk electronic structure by copper doping in Bi_2Se_3, highly sensitive torque magnetometry measurements are carried out on a series of single crystals of different doping levels. By employing magnetic field up to 31 Tesla, we are able to observe de Hass-van Alphen oscillations from Field perpendicular to the basal plain (H$\|$c) up to the parallel configuration (H$\perp$c), and confirm the three-dimensional nature of the Fermi surface in the doped compounds. The quantum oscillation frequency varies and the Cu concentration changes. The anisotropy of the effective mass and the Fermi velocity will be also discussed.

H1.00082 Nearly flat Andreev bound states in superconductor-topological insulator hybrid structures , MAHMOUD LABABIDI, ERHAI ZHAO, George Mason University — Exotic excitations arise at the interface between a three-dimensional topological insulator (TI) and superconductors. For example, Majorana fermions with a linear dispersion $E \sim k$ exist in a short π Josephson junction on the TI surface. We show that in these systems, the Andreev bound state spectrum becomes nearly flat at zero energy when the chemical potential is sufficiently away from the Dirac point. The flat dispersion is well approximated by $E \sim k^N$, where N scales with the chemical potential. A similar evolution from linear to flat dispersion also occurs for the subgap spectrum of a periodic superconducting proximity structure, such as a TI surface in contact with a stripe superconductor.

H1.00083 Turning topological insulators 'insulating' using irradiation with swift particle beams , LUKAS ZHAO, HAIMING DENG, City College of New york, M. KONCZYKOWSKI, Ecole Polytechnique - Palaiseau, A. HRUBAN, Institute of Electronic Materials Technology - Warsaw, LIA KRUSIN-ELBAUM, City College of New york, CCNY TEAM, ECOLE POLYTECHNIQUE TEAM — To understand the transport and quantum electronic behaviors of the topological Dirac surface states, it is essential to develop techniques that will unambiguously separate surface physics from that of the bulk. In the approaches taken thus far, such as nanostructured materials synthesis, doping, or compositional tuning, the complete elimination of the bulk conduction still remains a challenge. Here we present a different approach that uses swift particle beams to introduce controlled disorder into a bulk of topological insulators (TIs) thereby increasing bulk resistivity by orders of magnitude. The process creates Frenkel pairs, with charged vacancies stable up to room temperature. We report the results of irradiation of TIs Bi_2Te_3 and Sb_2Te_3 – both *p*-type in as-grown state – with 2.5 MeV electrons performed at liquid hydrogen temperature (20 K). The longitudinal resistivity ρ_{xx} monitored *in-situ* as a function of particle fluence ϕ displays a maximum at which the hole (*p*-type) conduction appears compensated; beyond ϕ_{max} a conversion to *n*-type is obtained. The effect of this 'compensation' on the surface states of the irradiated TIs probed in electric-field gated structures will be discussed.

H1.00084 Polarization modulated diode effect in a ferroelectric tunnel capacitor with semiconducting $BiFeO_3$ barrier[1] , GUOLEI LIU, SHUMIN HE, SHISHOU KANG, YANXUE CHEN, SHISHEN YAN, LIANGMO MEI, School of Physics and State Key Laboratory of Crystal Materials, Shandong University — Polarization modulated diode effect was investigated in a ferroelectric tunnel capacitor with semiconducting $BiFeO_3$ barrier, which was grown on a conductive Nb-$SrTiO_3$(001) substrate by oxygen plasma assisted molecular beam epitaxy. Switchable diode effect with a good rectifying property and large bipolar resistance switching observed. The on/off resistance ratio is larger than two orders of magnitude. The tunneling resistance was found to be dominated by the Schottky contact forming at $BiFeO_3$/Nb-$SrTiO_3$ interface, in the regime of Fowler-Nordheim tunneling across the Schottky-like barrier. The switchable diode effect was attributed to the Schottky barrier variations upon polarization reversal. The width variation of depletion layer was estimated about 8nm, which is comparable with the 25nm-thick $BiFeO_3$ barrier.

H1.00085 UNDERGRADUATE RESEARCH SOCIETY / SOCIETY OF PHYSICS STUDENTS ABSTRACTS –

H1.00086 Magnetic Behavior of Nanostructured Mn0.23TaS2 Near Ferromagnetic Transition[1]

, COREY COOLING, PAUL SHAND, K.R. BOYLE, TIM KIDD, LAURA STRAUSS, University of Northern Iowa — We have investigated the ferromagnetic transition for tantalum disulfide intercalated with 23% manganese. The material was grown in the form of nanotube/nanowire structures with diameters ranging from 30nm to several hundred nanometers. These nanotube structures give the material a high anisotropy. The material was studied through Curie-Weiss analysis, dc magnetization, and ac susceptibility measurements. The ferromagnetic transition for $Mn_{0.23}TaS_2$ occurs around 85K and varies with the applied dc magnetic field. The ferromagnetic transition is characterized by a peak in the ac susceptibility. Analysis of the susceptibility peaks revealed atypically high critical exponent values when compared to other disordered ferromagnetic systems. The large exponents may be due to the existence of two transitions in close proximity. The first transition (at a higher temperature) is to a ferromagnetic state; the second is to a disordered magnetic state. Arrott-Noakes plotting provided further justification of a multicritical transition. Further work includes taking measurements on a bulk crystalline sample of similar concentration and comparing its properties to those of the nanostructured sample.

H1.00087 Estimating the Distance and Metallicity of an RR Lyrae Star

, SHOUVIK BHATTACHARYA, APS — Minnesota State University Moorhead has a working observatory and recently renovated named the Paul P Feder Observatory at the Buffalo River State Park in the Northwest Minnesota. The observatory is equipped with a 16" Cassegrain reflecting telescope, an Apogee Alta CCD camera, two research grade computers and the SBIG SGS Spectrograph, which was installed in the observatory facility in fall 2012. The student researcher used the facility and made photometric and spectroscopic observations of the RR Lyrae stars. The distance of the RR Lyrae star was estimated by analyzing the photometric data, extracting information about period and measured quantify brightness from the observed science images. High resolution spectroscopy was performed on the same star and its applicability to metallicity estimation will be reported.

H1.00088 Do the Dark Matter Halos of Dwarf Galaxies share a Universal Core Radius?

, LIYANG YU, CASET R. WATSON, Millikin University — Recent observations suggest that dark-matter-dominated Milky Way dwarf satellite galaxies contain a universal mass of $\sim 10^7$ $M_\odot$ within their innermost 300 pc. Additional observations suggest a universal, core dark matter (DM) surface density ($\mu_0 = r_0\rho_0$) for galaxies at all observed mass and luminosity scales. We demonstrate that the combination of these two results implies the existence of a universal DM halo core radius (r_0) for dwarf galaxies. To test this prediction, we compare the results of our calculations to existing dwarf galaxy data for Burkert and NFW DM density profiles.

H1.00089 Does the Observed Phase Space Density of Dwarf Galaxies Indicate a Consistent Value for the Mass of the Dark Matter Particle?

, JOSEPH CHEENEY, CASEY WATSON, Millikin University — Recent studies have suggested that the phase space densities (Q) of Milky Way dwarf satellite galaxies imply a keV-scale dark matter particle mass. To go beyond this order-of-magnitude estimate, we examine trends in the phase space density data and consider their implications for the relationship between the primordial Q (Q_P), which depends directly on the dark matter particle mass, and the presently observed values of Q (Q_0). We then determine whether the application of a consistent Q_P-Q_0 relationship to the Q_0 data yields a consistent and more well-defined value of the dark matter particle mass.

H1.00090 Probability Current in Hydrogen with Spin-Orbit Interaction

, WILLIAM HODGE, Davidson College, SAM MIGIRDITCH, None, WILLIAM KERR, Wake Forest University — The spin-orbit interaction is a coupling between a particle's spin and its motion. The Hamiltonian for a spin-$1/2$ particle which includes this coupling is

$$\mathcal{H} = \frac{\mathbf{p}^2}{2m} + V(\mathbf{x}) + \frac{\nabla V(\mathbf{x}) \times \mathbf{p}}{2m^2c^2} \cdot \mathbf{S}. \tag{2}$$

To describe the flow of probability in this system, we derive the continuity equation, which takes the usual form. In this case, however, we find the probability current density $\mathbf{j}(\mathbf{x}, t)$ to be the sum of two terms. The first term is the one obtained by most quantum mechanics textbooks during their derivation of the continuity equation. The second term,

$$\mathbf{j}_s(\mathbf{x}, t) = \frac{1}{2m^2c^2} \sum_{\sigma,\sigma'=\uparrow,\downarrow} \left[\psi^*(\mathbf{x}, \sigma, t)\langle\sigma|\mathbf{S}|\sigma'\rangle\psi(\mathbf{x}, \sigma', t)\right] \times \nabla V(\mathbf{x}), \tag{3}$$

arises due to the inclusion of the spin-orbit term in the Hamiltonian and is small compared to the first. Using a perturbative treatment, we calculate $\mathbf{j}(\mathbf{x}, t)$ for hydrogenlike atoms; for states with $\ell = 0$, we find that $\mathbf{j}(\mathbf{x}, t) = \mathbf{j}_s(\mathbf{x}, t)$.

H1.00091 The Angular Momentum Flux in the Scalar Self-Force Problem

, SAMUEL CUPP, Austin Peay State University, PETER DIENER, Louisiana State University — The scalar self-force problem consists of a scalar point charge orbiting a supermassive black hole. The object is small enough that the perturbation of space-time due to its mass is inconsequential, and the only forces are gravity and the self-force. The self-force is a force on the inspiraling particle that results from the back-scattering of the object's own field off of curved space-time. I derived an accurate calculation of the angular momentum flux for the scalar self-force problem and implemented it into a preexisting (3 spatial +1 time) dimensional code. We then compared our results to very precise frequency domain calculations. The angular momentum flux calculations yield results that converge to the actual value of 0.0124682173 M. However, the calculations currently converge at about .7 order, and the reasons for this extremely slow convergence is currently unknown.

H1.00092 Development of Embedded Atom Potential for Aluminum for Simulation of Materials at extreme conditions[1]

, CHANCE BROWN, East Tennessee State University, BRIAN DEMASKE, VASILY ZHAKHOVSKY, IVAN OLEYNIK, University of South Florida — An embedded atom potential (EAM) potential for aluminum was developed by fitting a wide range of zero-temperature stress tensor components calculated using density functional theory (DFT). The theoretical stress tensor components were calculated for isotropic compressions as well as uniaxial deformations along three principal crystal axes. A number of experimental properties were included within the fitting database to ensure the accuracy of the potential near equilibrium conditions. Out of many candidate potentials, the one that most closely reproduced the experimental melting point and shock Hugoniot data was selected as the final potential. This potential gives a good description of aluminum under extreme pressures and temperatures, making it well-suited for atomistic simulations of laser-matter interactions and shock compression.

H1.00093 Symmetries of Four Harmonically-Trapped Particles in One Dimension

, BRIAN WEINSTEIN, NATHAN HARSHMAN, JESSICA USCINSKI, American University — We present a method for solving trapped, interacting, four-body systems in a one-dimensional harmonic trap. By expressing the particle coordinates in Jacobi spherical coordinates, we discover the underlying O_h symmetry, i.e. tetrahedral symmetry with parity inversion. This symmetry provides an alternate method for describing particle configurations and clustering, and it simplifies numerical calculations of the energy eigenstates of the system for tunable interactions.

H1.00094 Spin Noise Spectroscopy and Some Design Constraints on Spintronics Devices[1] , AMINA BELKADI, A.F. ISAKOVIC, Khalifa University - KUSTAR — Spin noise spectra are obtained on GaAs samples with the standard setup. The spin spectral characteristics are studied in comparison with the spin transport efficiency for diodes fabricated on the same samples. It is shown that spectral characteristics of spin noise, such as FWHM and Q-factor are related to the spin transfer efficiency. Temperature and magnetic field dependence of the spin noise spectra are studied in the context of spin relaxation mechanisms. We also performed spin noise correlations analysis with respect to the volume effects motivated by the need to understand the design constraints on spintronics devices due to spin noise effects.

[1]This work was supported by KU-IRF Level1 grant and, in part by US DOE through BNL.

H1.00095 Modeling Plasma Formation in a Micro-gap at Microwave Frequency , ARTHUR BOWMAN, Wayne State University , STEPHEN REMILLARD, Hope College — In the presence of a strong electric field, gas molecules become ionized, forming a plasma. The study of this dielectric breakdown at microwave frequency has important applications in improving the operation of radio frequency (RF) devices, where the high electric fields present in small gaps can easily ionize gases like air. A cone and tuner resonant structure was used to induce breakdown of diatomic Nitrogen in adjustable micro-gaps ranging from 13 to 1,156 μm. The electric field for plasma formation exhibited strong pressure dependence in the larger gap sizes, as predicted by previous theoretical and experimental work. Pressure is proportional to the frequency of collision between electrons and molecules, which increases with pressure when the gap is large, but levels off in the micro-gap region. A separate model of the breakdown electric field based on the characteristic diffusion length of the plasma also fit the data poorly for these smaller gap sizes. This may be explained by a hypothesis that dielectric breakdown at and below the 100 μm gap size occurs outside the gap, an argument that is supported by the observation of very high breakdown threshold electric fields in this region. Optical emissions revealed that vibrational and rotational molecular transitions of the first positive electronic system are suppressed in micro-gaps, indicating that transitions into the molecular ground state do not occur in micro-gap plasmas. Acknowledgements: National Science Foundation under NSF-REU Grant No. PHY/DMR-1004811, the Provost's Office of Hope College, and the Hope College Division of Natural and Applied Sciences.

H1.00096 Modeling Q-switched Laser Dynamics by State Space Methods , LAMEKA BOOKER, IKECHUKWU UME, MAKHIN THITSA, Old Dominion University — Q-switched lasers are prevalent in applications that require high intensity laser in ultra-short pulses. In a solid state laser Q-switching regime, the laser rate equations are a set of nonlinear coupled differential equations involving photon flux ϕ_a, instantaneous population inversion density n_s, and the absorption center density n_a. In this paper, the Q-switched laser is modeled by a system theoretic approach called state space method, where the three physical quantities: ϕ_a, n_a, and n_s are defined as the state variables of the system, the modulation function of the cavity losses, $\alpha(t)$ as the input function, and the laser output power as the output function of the system. First the system is Taylor linearized and the linearized system is simulated by MATLAB Simulink software. The full nonlinear system is also simulated in Simulink. The contribution to the output from the nonlinear components of the system is obtained from the difference between the outputs of the two models.

H1.00097 All-optical quasi-phase matching of frequency doubling using counterpropagating light[1] , RACHEL MYER, ALLISON PENFIELD, ETIENNE GAGNON, AMY LYTLE, Franklin & Marshall College — Nonlinear optical frequency conversion is a useful method for creating coherent light sources with unique capabilities. The main challenge for conversion efficiency of processes like frequency doubling is the chromatic dispersion of the nonlinear medium. Successful techniques for correcting the phase mismatch between the different frequencies are often limited by the type of nonlinear medium that may be used. An all-optical method of quasi-phase matching using counterpropagating light has recently been demonstrated for high-order harmonic generation, an extreme nonlinear process. Sequences of counterpropagating pulses are used to interfere with the harmonic generation process periodically, correcting the phase mismatch and boosting efficiency. We report progress on an experimental investigation of the effect of counterpropagating light on the more commonly used low-order nonlinear optical processes. We present data showing the effects of a single counterpropagating pulse on the efficiency of frequency doubling of a Ti:sapphire ultrafast laser oscillator in beta-Barium Borate.

[1]This work is supported by the Hackman Summer Scholars program at Franklin & Marshall College, and a CCSA grant (#21084) from the Research Corporation for Science Advancement.

H1.00098 Optical up-conversion in Er^{3+}:Y_2O_3 nanoparticles through spectral masking of broadband pump light[1] , LAUREN TULCHINSKY, AMY LYTLE, ETIENNE GAGNON, KEN KREBS, Franklin & Marshall College, ELIZA JONATHAN, ANN SILVERSMITH, Hamilton College — Up-conversion photoluminescence (UC-PL) has been extensively studied for potential use in up-conversion lasers, IR to visible detectors, and high efficiency lighting applications. Here we report experimental results exploring the excited state absorption process behind the UC-PL of Er^{3+} : Y_2O_3 nanoparticles under shaped-pulse laser excitation. By beginning with a broadband laser pulse and then spectrally shaping it to remove either the high or low energy part of the excitation, we examine the full width of the double resonance between the ground-to-excited state absorption and the excited state absorption of the impurity ions. We propose a model for the manifolds of the electronic energy states that treats each Stark level as a Gaussian of fixed width and then superimposes a Boltzmann distribution for the thermalized population of the levels. This simple model fits the experimental data well at room temperature, but begins to show expected differences at 78 K.

[1]This work is supported by the Hackman Summer Scholars program at Franklin & Marshall College.

H1.00099 Time-resolved Terahertz spectroscopy using a Ti:Sapphire laser oscillator , PRADOSH KHAREL, WASSAM WAQUAR, ETIENNE GAGNON, Franklin and Marshall College — In time-resolved terahertz spectroscopy, electromagnetic radiation in the frequency range 0.3 - 3 THz (corresponding to wavelengths of 0.1 - 1.0 mm) is used to probe the dynamic properties of charge carriers within materials. When a sample material is excited using an ultrafast optical laser pulse, the terahertz probe that passes through the sample a time later reveals the subsequent behavior of the charge carriers in the sample. Real-time mapping of the dynamics can then be achieved through a pump-probe delay experiment. To date, most time-resolved terahertz spectroscopy has relied on high-power laser systems in order both to excite the sample as well as to generate the probing terahertz radiation. Here, we investigate the feasibility of adapting this technology to a relatively less expensive Ti:sapphire laser oscillator. We present preliminary data and discuss challenges going forward.

H1.00100 Construction and Characterization of a Nanosecond Nd:YAG Laser Pumped Distributed Feedback Dye Laser Generating Picosecond Pulses[1]

, TIMOTHY CLARK[2], CHRIS WECKERLY[3], LASZLO UJJ[4], Department of Physics, SSE, University of West Florida — We have constructed a Distributed Feedback Dye Laser (DFDL) using interferometric pumping. DFDL works according to the dynamic modulation of the gain medium creating short pulses. Shortening of the pulses, stability, and dynamic range of the DFDL were investigated. Pulses were measured with the help of a photodiode with a 30 picosecond response time. Traces were recorded with a Tektronics DSA73304D (33GHz) digital serial analyser. The gain medium contains an ethanol solution of Rhodamine 590 dye and DODCI saturable absorber. Increasing the concentration of DODCI saturable absorber resulted in significant pulse shortening (150 to 54 picoseconds). Single pulse generation was achieved when the power of the pump laser was adjusted 10 percent above the laser threshold. The central wavelength of the laser pulses was 587 nm. The mathematical modeling, optical layout of the DFDL, and the results of the temporal and spectral characterization of the laser are presented on the poster. The development of the DFDL will lead to an extensive investigation of short pulse dye lasers for educational purposes and for applications in nonlinear spectroscopy.

H1.00101 Characterizing the Effect of Surface Hydrophobicity on the Depletion Layer

, ERIN BROWN, SHANNON PETERSEN, JESSICA JEROSKI, ARIEL STATMAN, ADELE POYNOR, Allegheny College — When water is forced into contact with an extended hydrophobic surface, a uniform region of reduced density forms along the interface. We seek to identify both a qualitative and a quantitative relationship between the hydrophobicity of a surface and the characteristics of the corresponding depletion layer, specifically its thickness and density. We determine these qualities using surface plasmon resonance spectroscopy (SPR). We produce surfaces of different hydrophobicities through the formation of self-assembled monolayers of organothiols on gold-plated slides. Self-assembled monolayers (SAMs) of 1-octadecanethiol are used to produce surfaces with high hydrophobicity, as the terminal methyl group is highly nonpolar, while 11-mercapto-1-undecanol is used to produce surfaces with minimal hydrophobicity, as the terminal hydroxyl group is hydrophilic. Surfaces of intermediate hydrophobicity are fabricated using mixed SAMs of 1-octadecanethiol and 11-mercapto-1-undecanol. We measure surface hydrophobicity for the resulting SAM-coated slides by their contact angle with water droplets. In order to ensure an unchanging hydrophobicity throughout SPR trials, we analyze the stability of the surfaces to through repeated testing of contact angle variability over time and after extended submersion both in water and in ethanol.

H1.00102 Computer Automated Contact Angle Measurement for Surface Plasmon Resonance

, ARIEL STATMAN, ADELE POYNOR, Allegheny College — When water meets an extended hydrophobic surface, an ultra-thin, low density depletion layer is expected at the interface. Exactly how the depletion layer changes with change in hydrophobicity is still an open question. When studying the interaction between water and a hydrophobic surface, we need to be able to test the hydrophobicity of a self-assembled monolayer, and its stability over time. To do this, we take a series of images over time and determine whether the contact angle changes.

H1.00103 Synthesis and characterization of iron platinum magnetic nanoparticles with controlled morphology and size[1]

, TRINIDY COMBS, Oberlin College, HAFSA KHURSHID, HARIHARAN SRIKANTH, University of South Florida — We report the synthesis and characterization of monodispersed iron-platinum nanoparticles by the thermal decomposition of organometallic compounds. First, platinum (Pt) seeds were synthesized at 100C, followed by the addition of iron pentacarbonyl via injection method in the presence of oleic acid and oleylamine surfactants. An immediate injection after the decomposition of Pt acetylacetonate made alloy nanoparticles of Pt nanoparticles, whereas its injection after a prolonged period of time formed mixed particles of iron oxide and Pt. Particle shape was tuned from spherical to cubic by varying molar ratios of oleic acid to oleylamine during the reaction. The particles' size was controlled by varying the injection temperature of the iron precursor. XRD was used to confirm the crystallographic phases of the samples. Particle size and shape were investigated using TEM. Magnetic properties indicated that as-synthesized FePt nanoparticles are superparamagnetic with a blocking temperature of 64 K for 7 nm and shifted to 29 K for 3 nm.

H1.00104 Structure and dynamics of Au/Fe nano-structures: results of molecular dynamics simulation

, TIMOTHY FINDLING, AHLAM AL-RAWI, Department of Physics, University of Central Florida — Gold-plated iron nanostructures have chemical, optical, magnetic, and biomedical applications owing to the unique properties of the iron-gold combination. However, relatively little is known about the atomistic surface composition of these alloys. We have studied the structure and dynamics of Au/Fe nano-alloys using molecular dynamics simulations with an embedded-atom interaction potential [1]. We will present analyses of the structural composition as Au atoms are deposited on Fe facets, leading to locally optimal crystal structures for this alloy, as a function of composition and substrate temperature. We will also present a complete analysis of the stability of the resulting structures by calculating the vibrational density of state using velocity autocorrelation. The vibrational entropic contributions to the free energy of the Fe atoms and Au atoms in their vicinities will be evaluated as a function of the local surface geometry. The net outcome of this study is prediction of viable Au/Fe nanostructures.

H1.00105 Iron-Platinum Nanoparticles Dispersible in Aqueous Solutions[1]

, JASON HUYNH, University of Delaware, ANGSHUMAN PAL, HAFSA KHURSHID, None, GEORGE HADJIPANAYIS, University of Delaware — In this work, we have used a low temperature method that reduces $Pt(acac)_2$ and thermally decomposes $Fe(CO)_5$ in the presence of oleic acid (OA) and oleyl amine (OY) to fabricate monodispersed fcc FePt nanoparticles [1]. Adjusting the parameters, such as injection temperature and heating rate, could control the size and shape, respectively. The nanoparticles made for this study had a cubic shape and an average diameter of 5.3 nm. The particles were found to be superparamagnetic at room temperature with low coercivity. The aim of this project was to disperse nanoparticles in aqueous solutions. The surfactants (OA/OY) were then exchanged with tetramethylammonium hydroxide (TMAOH) to allow water phase transfer [2]. After the transformation, the FePt nanoparticles were dispersed in 20 mL of a 0.01-wt % TMAOH solution. The structural and magnetic properties were maintained as shown by X-Ray Diffraction and Vibrating Sample Magnetometer data. From these findings, the FePt nanoparticles are being modified for higher coercivity for potential use in hyperthermia studies. [1] L. Colak and G. C. Hadjipanayis, Nanotechnology 20 (2009) 485602. H1.00106 Study of Hydrogen flame annealed Au thin-film surface morphology, integrity and film quality on various substrate surfaces[1]

, MICHAEL SCHELL, INDRAJITH SENEVIRATHNE, Lock Haven University — Au thin-films have many applications in both industry and proof of concept investigations in device engineering. Typical Au depositions on substrate give rise to Stanski-Krastanov (SK) like growth while Frank-van der Merwe (FM) mode like growth is desired in many molecular self assembly and other engineering applications. Au films are magnetron sputter deposited at 100mtorr at low deposition rates ($\sim$ 1ML/min) on cleaved/fresh mica, glass microscopy slides and Si surfaces. Samples are hydrogen flame annealed to facilitate surface diffusion with minimal film contamination. Resulting Au surfaces were investigated and compared against purchased Au(111) on mica (standard) surface. Regular and custom built hydrophilic and hydrophobic AFM (Atomic Force Microcopy) probes were used in contact, and non contact AFM with topography and phase imaging to access the contamination and surface defects. Surface integrity, roughness, corrugation and morphology on Au surfaces were estimated.

H1.00107 Structural Properties of Gold Thin Films Deposited on Technologically Important Substrates by Magnetron Sputtering[1]

, CALEB GLASER, MICHAEL SCHELL, MARIAN TZOLOV, INDRAJITH SENEVIRATHNE, MONIRUZZAMAN SYED, Lock Haven University of Pennsylvania — Gold (Au) thin films offer a wide range of applications and may be used for memory storage, energy harvesting, nanosensors, optics, and biosensing devices. Au thin films are currently being studied more closely since they are highly conductive and yet not easily oxidized. Therefore, it is necessary to understand the growth mechanisms of film on various substrates. The structural properties of gold thin films also play an important role on the film quality, which may affect its' optical properties and the sensing capability of the device. In this study, Gold (Au) thin films were deposited on glass (SiO2), silicon (100) and other substrates at room temperature (RT) in an argon (Ar) gas environment as a function of deposition time. The structural properties and surface morphology of the Au thin film has been studied using an Atomic Force Microscope (AFM), Scanning Electron Microscope (SEM), Energy Dispersive X-Ray Spectrometry (EDX), and X-Ray Diffraction (XRD) measurements. The deposition rate was found to be decreased monotonically as deposition time increased for the films on glass substrates. The effect of the annealing temperature on the structural properties of the Au film deposited on the aforementioned substrates will also be discussed in this study.

H1.00108 Characterization of Electrodeposited Nanoporous Ni and NiCu Films[1]

, KYLA KOBOSKI, JENNIFER HAMPTON, Hope College — Nanoporous thin films are interesting candidates to catalyze certain reactions because of their large surface areas. This project focuses on the deposition of Ni and NiCu thin films on a Au substrate and further explores the catalysis of the hydrogen evolution reaction (HER). Depositions are created using controlled potential electrolysis. Samples are then dealloyed using linear sweep voltammetry. Before and after the dealloying, all the samples are characterized using multiple techniques. Electrochemical capacitance measurements allow comparisons of sample roughness. HER measurements characterize the reactivity of the sample with respect to the specific catalytic reaction. The Tafel equation is fit to the data to obtain information about the kinetics of the HER of the samples. Other methods for characterizing the samples include scanning electron microscopy (SEM) and energy dispersive spectroscopy (EDS). The use of SEM allows images to be taken of the deposition to determine the change in the structure pre- and post- dealloy of the sample. EDS allows the elemental composition of the deposition to be determined before and after the dealloy stage.

[1]This material is based upon work supported by the National Science Foundation under RUI Grant DMR-1104725, MRI Grant CHE-1126462, MRI Grant CHE-0959282, and ARI grant PHY-0963317.

H1.00109 Electrodeposition and Characterization of Nickel, Iron, Copper Thin Films and the Creation of Nanoporous Structures[1]

, JONATHAN YARRANTON, JENNIFER HAMPTON, Hope College — There has been much research in creating nanoporous platinum or gold thin films for catalysis, but there has not been as much work done with other, less noble metals. This research explored the deposition of nickel, iron, and copper ternary alloys using controlled potential electrolysis (CPE) and the selective removal of the copper with DC potential amperometry (DCPA) and linear sweep voltammetry (LSV) to create nanoporous structures. These structures have the advantage of increased surface area creating more efficient catalysts. All films were characterized before and after dealloying using scanning electron microscopy (SEM) and energy dispersive x-ray spectroscopy (EDS) for composition. The roughness of each of the films was characterized by the capacitance of the film, with higher capacitances indicating a higher electrochemical surface area.

[1]This material is based upon work supported by the National Science Foundation under RUI Grant DMR-1104725, MRI Grant CHE-0959282, and ARI grant PHY-0963317.

H1.00110 Effect of Carrier Doping on Nonlinearity of High Temperature Superconducting Thin Films

, MICHAEL BISCHAK, JINU THOMAS, STEPHEN REMILLARD, Hope College — The nonlinearity of superconductors if found to depend on the sample's location on the phase diagram, and hence on the carrier doping. The doping level was tuned by annealing $Tl_2Ba_2CaCu_2O_{8-x}$ thin films in a reducing nitrogen atmosphere at temperatures ranging from 250°C to 400°C. Nonlinear microwave surface impedance of $Tl_2Ba_2CaCu_2O_{8-x}$ wafers in a 5.6 GHz sapphire dielectric resonator reveal dependence on carrier doping x, with fluxon hysteresis contributing more significantly in under-doped films (x greater than 0.1) at all temperatures and in more optimally doped films at high reduced temperature. With the critical temperature being used as the indicator of carrier density, it was found that under-doped samples have larger fluxon hysteresis losses as indicated by a one-to-one variation of surface reactance with surface resistance. This work was supported by the National Science Foundation under grants 1206149 and 1004811, and by the Research Corporation for Science Advancement.

H1.00111 Ionic self-assembly of thin films: analytical and experimental results

, VINCENT KIM, WILL BANKS, ANDREW SEREDINSKI, BRIAN SIMPSON, DAN MAZILU, IRINA MAZILU, Washington and Lee University — Our work is motivated by the manufacturing process of self-assembled antireflective coatings using silica and titania nanoparticles. The properties of these coatings depend on the surface coverage of the substrate. During the manufacturing process, it is highly desirable to know the analytical relationship between the index of refraction and the particle density of the surface. We use a class of cooperative sequential adsorption models on a Cayley tree to model the self-assembly mechanism. Using the empty interval method, and generalizing results known from reaction–diffusion processes on Cayley trees, we calculate the time-dependent surface coverage. We compare our model to the experimental results obtained in the thin film lab.

H1.00112 Analytical study of cooperative sequential adsorption models on Cayley trees and their applications to drug encapsulation of nanoparticles

, ANDREW SEREDINSKI, VINCENT KIM, BRIAN SIMPSON, WILLIAM BANKS, IRINA MAZILU, DAN MAZILU, Washington and Lee University — We present a class of cooperative sequential adsorption models on a Cayley tree with constant and variable attachment rates and their possible applications for drug encapsulation of nanoparticles. Using the empty interval method, and generalizing results known from reaction–diffusion processes on Cayley trees, we calculate a variety of quantities such as time-dependent surface coverage and time-dependent probabilities of certain particle configurations.

H1.00113 Elucidating the Equilibrium States of C60 molecules on Ag(111)

, STEPHANIE SU, RENEE DIEHL, Penn State University, KATARIINA PUSSI, Lappeenranta University of Technology, Finland, HEEKEUN SHIN, HSIN-I LI, Penn State University, LAURA SERKOVIC, AJAY SHUKLA, VINCENT FOURNEE, JULIAN LEDIEU, Institut Jean Lamour, France, LINLIN WANG, Ames Lab, KRISTIN MARINO, MICHAEL SNYDER, Penn State University — The properties of C_{60} on surfaces depend strongly on their local geometries, but until recently there were few quantitative studies for these structures. The interactions of C_{60} molecules on Ag(111) surface produce an interesting structural complexity that manifests as a competition between two geometrical states. We studied the most stable $(2\sqrt{3}\times2\sqrt{3})R30^{o}$ phase of C_{60} on Ag(111) by using STM, LEED, and DFT. This phase consists of molecules in two different geometrical states - one sitting on a C-C bond on the top site and one sitting on a hex face on a vacancy. By measuring the dynamical equilibrium behavior of the system, we obtained detailed information on the energetics of two states.

H1.00114 Fluorescent Quantum-Sized Carbon Dots Isolated in an rf Paul Trap[1]

, ANDREW FARR, College of Charleston, CURTIS ALLEN, RUSSELL HILLEKE[2], ROBERT CLARK[3], The Citadel, the Military College of South Carolina — Quantum-sized carbon particles, known as carbon dots, exhibit strong wavelength- and size-dependent photoluminescence that makes them attractive candidates for many applications in nanoscale electronics and as biological markers. It has been shown that carbon dots become luminescent upon surface passivation with organic molecules; however, this property has never been verified outside of a chemical solution. To understand the mechanisms which underlie the photoluminescence, we are building an experiment to isolate single carbon dots in vacuum in an rf Paul trap and perform laser-induced fluorescence spectroscopy upon them. We report progress toward this goal, including the design and implementation of a custom electrospray ionization system.

H1.00115 CVD graphene growth and transfer techniques for the fabrication of micromechanical resonators

, DANIEL J. LOSOWYJ, ISAAC R. STORCH, THOMAS J. MCCUNE, Laboratory of Atomic and Solid State Physics, Cornell University, PAUL L. MCEUEN, Laboratory of Atomic and Solid State Physics, Kavli Institute at Cornell for Nanoscale Science, Cornell University — Graphene's superlative mechanical strength, electrical mobility, low mass, and large surface area make it a prime candidate for use in micromechanical resonators [1,2], which have potential applications in mass and force sensing [3], radio frequency signal processing, and optomechanics [4]. Our resonators use graphene grown by chemical vapor deposition (CVD) and have excellent mechanical performance, but their electrical performance is comparatively worse than that of exfoliated graphene devices. We attribute these limitations to contamination from copper oxidation during the growth and solvents used in the transfer process. To remedy this, we have performed CVD growths on copper foils with long anneal times, confirming with Raman spectroscopy and SEM that the graphene is single layer and high quality. We have also found that graphene suspended on a substrate can survive high temperature air annealing, provided that the temperature ramp is gradual. Improving the electrical performance of these novel devices will facilitate their use in a variety of new experiments and applications. [1] J. S. Bunch *et al.*, Science (2007) [2] A. H1.00116 Effects of Recombination Processes on the Nonlinearity of Semiconductor Optical Amplifiers

, IKECHUKWU UME, LAMEKA BOOKER, MAKHIN THITSA, Old Dominion University, ECE OLD DOMINION UNIVERSITY TEAM — An optical signal traveling along the fiber often loses its strength and needs to be rejuvenated. Optical amplifiers perform amplification directly on the optical signal without optical-to-electrical and electrical-to-optical conversion. Especially, semiconductor optical amplifiers (SOA's), which use a semiconductor material as the laser gain medium could be integrated into monolithic photonic circuits. Therefore, SOA's are being considered as the building blocks of future all-optical networks. Since linear amplification of the signal is strongly desired for SOA's in many applications, it is important to determine the degree of nonlinearity in practical SOAs. In this paper the effects of recombination processes, namely: linear recombination, bimolecular recombination and Auger recombination on the nonlinearity of the SOA are investigated by using the Volterra series model.

H1.00117 Relationship between shallow donors and H impurities in In_2O_3 from their behavior upon annealing[1]

, KIRBY SMITHE, University of Tulsa, WEIKAI YIN, MICHAEL STAVOLA, Lehigh University, LYNN BOATNER, Oak Ridge National Lab — Indium oxide is a transparent conducting oxide used widely in modern electronics [1]. Theory predicts that interstitial H and H trapped by an oxygen vacancy act as shallow donors [2]. We have introduced H into In_2O_3 single crystals to produce O-H centers and also the broad IR absorption arising from free carriers. To investigate the relationship between the O-H centers and the shallow donors that are introduced by H, we have studied the annealing behavior of the O-H local vibrational modes and the free-carrier absorption by IR spectroscopy to determine how these spectral features are correlated. [1] M. McCluskey *et al.*, J. Mater. Res. **27**, 2190 (2012) [2] S. Limpijumnong *et al.*, Phys. Rev. B **80**, 193202 (2009).

H1.00118 Characterization of Nickel-Zinc Electrodeposition[1]

, KEVIN TKACZ[2], JENNIFER HAMPTON, Hope College — Nanoporous nickel serves as an interesting catalytic material due to its large surface area and therefore high reactivity. The purpose of this project is to develop a method for producing thin films of nanoporous nickel. This is done by the electrodeposition of a nickel-zinc alloy followed by the selective removal of zinc. A series of primarily sulfate baths were used for deposition in an attempt to produce samples ideal for selective removal of zinc. Deposition variables examined include metal concentration in the solution, ratio of metals in solution, deposition potential and solution pH. Depositions were characterized with scanning electron microscopy (SEM) and energy dispersive x-ray spectroscopy (EDS). Linear sweep voltammetry was also used to characterize the dealloying process. It was determined that increasing the nickel concentration in solution also increased the concentration in the deposit. Uniform depositions with low nickel concentration were successfully made although attempts to increase the nickel concentration adversely affected the deposition quality.

[1]This material is based upon work supported by the National Science Foundation under REU Grant PHY/DMR-1104811, RUI Grant DMR-1104725, MRI Grant CHE-1126462, MRI Grant CHE-0959282, and ARI grant PHY-0963317.

H1.00119 Ionic self-assembly of silica nanoparticles: time-dependence of surface coverage

, KATY WILSON, BRIAN SIMPSON, VINCENT KIM, ANDREW SEREDINSKI, WILL BANKS, DAN MAZILU, IRINA MAZILU, Washington and Lee University — We investigate the deposition by ionic self-assembly of alternating silica nanoparticle and poly(allyamine hydrochloride) layers. The optical properties of these coatings depend on the surface coverage of the substrate. We report experimental data for the surface coverage of the substrate as a function of dipping time. We model this process using a cooperative sequential adsorption model on a Cayley tree. We compare the analytical and experimental results and discuss possible generalizations of the model.

H1.00120 Growth of Zinc Oxide Nanobelts , JAMIE NOWALK, Lock Haven University — Zinc Oxide is a unique material that has a variety of applications in optoelectronics due to its piezoelectric, optical, and semiconducting properties. The carbothermal reduction of zinc oxide is a common technique used in chemical vapor deposition of nanostructures via the vapor transport mechanism. In this research project, the supply of zinc atom was successfully decoupled from the delivery of the oxidant, molecular oxygen. We have grown various forms of ZnO nanostructures at varying temperatures in a three-zone furnace. The reactions took place at a constant pressure of 200 torr on silicon substrates, each coated with a thin film of gold catalyst. Two-dimensional nano-ribbons were observed to grow best at higher temperatures between 800-1000 C, with the thinnest belts (30 nm) at 800 C. At 1000 C, the belts appear to taper off, resulting in shorter structures. One-dimensional wire growth was predominantly observed at 600 C. We compare our results with previously published syntheses of ZnO nanobelts.

H1.00121 Low-energy electron diffraction study of the surface of $SrTiO_3(001)$, ADAM BELL, KRISTIN MARINO, RENEE DIEHL, Department of Physics, Penn State University, University Park, PA 16802 — Oxide materials having the perovskite structure have many intriguing physical properties, such as high-temperature superconductivity, colossal magnetoresistance, and ferroelectricity. These properties make them good candidates for applications such as hard drive read heads or random access memory. Although fabrication of such devices involves growing thin films, the characterization of the surface structures of perovskite materials has been slow. This is partly because they often have complex or unstable structures that can be difficult to prepare and maintain and partly because the electron or ion beams common in surface techniques can charge the surface and perturb the incident and scattered beams This is particularly true of low-energy electron diffraction (LEED), the primary technique for determining the surface structures In this study, we have developed new methods to reduce the exposure of the insulating surface to electrons in a LEED experiment. These include using low incident beam currents, pulsing the electron beam and image enhancement techniques. We will carry out a LEED characterization of the $SrTiO_3$(001) surface structure, which has been the subject of some controversy concerning the terminating structure.[1]

[1]R. Herger et al., Phys. Rev. B 76, 195435 (2007).

H1.00122 Growth and Characterization of Mn-doped NaFeAs , NICKOLAS LUTTRELL, SCOTT CARR, YU SONG, CHENGLIN ZHANG, PENGCHENG DAI, University of Tennessee, UNIVERSITY OF TENNESSEE CONDENSED MATTER PHYSICS TEAM — We grew multiple dopings of Mn-doped NaFe As with the goal of observing a shift in the Tc from the NaFeAs parent compound as well as any structural transitions. A VSM was used to characterize the magnetic response of the samples. Results indicate slight Mn doping does not kill superconductivity immediately. We will make a direct comparison with Mn-doped BaFe2As2.

H1.00123 NISXW study of Si adsorbed on an Al-Co-Ni quasicrystal , NICK STANISHA, Penn State University, ANINDITA CHAUDHURI, University of Warwick, JULIAN LEDIEU, Institut Jean Lamour, CNRS, Ecole des Mines, Nancy Universite, HSIN LI, STEPHANIE SU, ANDREAS MAYER, Penn State University, KEVIN LOVELOCK, ROBERT JONES, University of Nottingham, LISA WEARING, University of Liverpool, DAVID WOODRUFF, University of Warwick, RENEE DIEHL, Penn State University — The normal incidence standing x-ray wavefield (NISXW) technique has never before been applied to the determination of adsorption structures on quasicrystals, even though it is quite clear that, under the right conditions, x-ray standing waves do exist in quasicrystals. This omission may be due to a misconception that the relationship between the phase of the standing waves and the atoms at a quasicrystal surface is arbitrary. We have performed a NISXW experiment for the adsorption of Si atoms on the nominally 10-fold surface of the decagonal Al-Co-Ni quasicrystal. NISXW spectra were obtained for a Si coverage of about 0.3, for two different angles of incidence: normal to the 10-fold surface, and at an angle of about 60○ from the surface normal. These angles correspond to two strong x-ray reflections of the quasicrystal. The intensity of the Si 1s photoemission signal was measured in order to determine the location of the Si atoms.order to accurately model the 5-fold symmetry of the surface, our analysis employed a 200 Å x 200 Å x 8 Å structure model for the quasicrystal. The results indicate that the Si atoms have an average height of 1.80 Å above the surface, and are arranged in 6-atom pentagonal clusters centered at points of 5-fold symmetry. This study demonstrates the feasibility for using NISXW as a structural tool for adsorbed atoms or molecules on quasicrystal surfaces.

H1.00124 Magnetic Properties of Quasi-One-Dimensional Ca_3LiRuO_6 and $CaFe_4As_3$, DONOVAN MYERS, AMAR KARKI, RONGYING JIN, Department of Physics and Astronomy, Louisiana State University, Baton Rouge, Louisiana 70803, USA — Needle-like Ca_3LiRuO_6 and $CaFe_4As_3$ single crystals were grown using the flux method. While the structure of Ca_3LiRuO_6 is characterized by one-dimensional chains of alternating face-sharing LiO_6 trigonal prisms and RuO_6 octahedra along the c axis, $CaFe_4As_3$ consists of edge-sharing $FeAs_4$ tetrahedra ribbons along the b axis. Despite the one-dimensional nature, magnetization measurements reveal evidence of long-range magnetic ordering: Ca_3LiRuO_6 orders ferromagnetically below $T_C = 120$ K and $CaFe_4As_3$ undergoes two successive antiferromagnetic transitions at $T_{N1} = 90$ K and $T_{N2} = 26$ K. Possible magnetic interactions will be discussed.

H1.00125 Exploring the variability of ion heating at reconnection events in MST[1] , M.S. CARTOLANO, D. CRAIG, Wheaton College, D.J. DEN HARTOG, S.T.A. KUMAR, M.D. NORNBERG, University of Wisconsin-Madison — The variability of ion heating for individual reconnection events in the Madison Symmetric Torus (MST) is correlated with key plasma parameters to give insight into the process of ion heating. Magnetic reconnection is a process that converts energy stored in the magnetic field in the plasma into ion thermal energy. The change in impurity ion temperature during several thousand reconnection events was analyzed for standard plasmas in MST. These changes in the ion temperature were then correlated with various plasma parameters to try to understand the variations in the amount of heating. As expected, the change in ion temperature correlates strongly with the change in magnetic energy. Magnetic fluctuations in MST are thought to be responsible for driving reconnection, and larger amounts of ion heating do correspond to larger increases in the amplitudes of these magnetic fluctuations during an event. The strongest correlation is with the rate of change in the amplitude of magnetic fluctuations that are resonant in the edge of the plasma. Other anomalous behavior appears during reconnection, such as dynamo activity and electron thermal transport. When these activities are stronger, the amount of ion heating is stronger. Finally, a toroidal asymmetry to the ion heating is examined.

H1.00126 Phase Dynamics in a Two-Plaquette Josephson Junction Array , ZIJIE POH, Ohio Wesleyan University, MA'AYAN DAGAN, Oberlin College, JEANETTE VELDMAN, Central College, BRAD TREES, Ohio Wesleyan University — We study numerically and analytically the phase dynamics of two coupled plaquettes of Josephson junctions shunted by another junction. A plaquette is a square with a junction on each side. This geometry is motivated by single crystal Bismuth Strontium Calcium Copper Oxide (BSCCO), a layered high-T_c superconductor consisting of hundred or thousands of intrinsic Josephoson junctions. The coupled plaquettes of our analysis are a simple model for two neighboring BSCCO crystals. We look for evidence of both frequency and phase synchronization in the dynamic (oscillating) junctions of the plaquettes. We find numerical evidence that intra-plaquette synchronization can be obtained even with weak coupling between the junctions in a plaquette and without the shunting junction. However, the shunting junction is crucial for synchronization between the junctions in neighboring plaquettes (inter-plaquette synchronization). Analytically, we use perturbation theory and a multiple time-scale analysis to predict the combinations of junction parameters for which phase synchronization appears in the array. By this analytical approach, we successfully capture the intra-plaquette synchronization behavior. The analytic study of inter-plaquette synchronization is still in progress.

H1.00127 Measuring the off axis magnetic field within a Helmholtz Coil , EDWARD PLUHAR, ERIC MARTELL, Millikin University — Helmholtz coils are used because they produce nearly uniform magnetic fields on-axis. Prior research, namely Graf's thin coil experiment [The Physics Teacher, pp. 360 (2012)], has accurately measured the axial magnetic field produced by a thin coil; however, the magnetic field off-axis is known to be significantly more complicated and cannot be calculated analytically. In this research, I have numerically determined the magnetic field off-axis in the region between the two coils and compared those calculations with measured values. I then determined the effect the deviation from uniformity has on the behavior of a charged particle moving through this region, such as in the well-known electron charge-to-mass ratio experiment.

H1.00128 Assessing the Reliability of Quantitative Imaging of Sm-153 , HANNAH PONEK, Point Loma Nazarene University and Johns Hopkins University, MICHELLE CHEN, Point Loma Nazarene University, ERIC FREY, Johns Hopkins University — Samarium-153 is used for palliation of and recently has been investigated for therapy for bone metastases. Patient specific dosing of Sm-153 is based on quantitative single-photon emission computed tomography (SPECT) and knowing the accuracy and precision of image-based estimates of the in vivo activity distribution. Physical phantom studies are useful for estimating these in simple objects, but do not model realistic activity distributions. We are using realistic Monte Carlo simulations combined with a realistic digital phantom modeling human anatomy to assess the accuracy and precision of Sm-153 SPECT. Preliminary data indicates that we can simulate projection images and reconstruct them with compensation for various physical image degrading factors, such as attenuation and scatter in the body as well as non-idealities in the imaging system, to provide realistic SPECT images.

H1.00129 Mechanical Properties of Chicken Embryo Somites to Analyze Cell Migration during Somitegenesis , SARIT ZHUKOVSKY, Fischell Department of Bioengineering, LISA TANEYHILL, CHYONG WU, Department of Animal and Avian Sciences, HELIM ARANDA-ESPINOZA, Fischell Department of Bioengineering — Somites develop as round segments on the sides of the neural tube and are responsible for the development of the vertebrae and other structures. Using Atomic Force Microscopy and Micropipette techniques, we were able to apply a known force to obtain data about the differences in the mechanical properties of the somites. Using contact mode in AFM, we obtained graphs that relate distance travelled by the cantilever versus deflection of the sample. We then used Matlab to analyze the data and find the material properties of the somites. We measured the Young's modulus of the anterior and posterior parts of the somites to be around 2 ± 0.8 kPa, but further data is needed to finalize our conclusion. Finding the mechanical properties of the posterior and anterior parts of the somites helped us to mimic those mechanical properties on polyacrylamide gels with different stiffness to determine the physiological functions of the somites and predict any mechanical abnormalities that might affect the migration of stem cells. By observing the major steps of migration, we were able to better understand how cell migration orchestrates embryonic morphogenesis with respect to their known mechanical properties.

H1.00130 Mechanisms of stability of electrospun polypeptide fibers[1] , ALINA GITNIK, University of Texas at Austin, DHAN B. KHADKA, MICHAEL C. CROSS, NICOLE K. LE, DONALD T. HAYNIE, University of South Florida — Electrospun nano- and microfibers made of biodegradable and absorbable polymers are of great interest in biomedical engineering for tissue engineering, wound healing and other purposes. We have investigated physical properties of fibers made of the synthetic organic polymer co-poly(L-glutamic acid_4, L-tyrosine_1) (PLEY). This water-soluble polypeptide has a net negative charge at neutral pH. Dehydrated fibers are crosslinked with a diimide reagent dissolved in ethanol, giving a maximum average number of crosslinks of 1 per polymer molecule. Fiber integrity has been assessed in an aqueous medium at pH 2, 7 and 12, before and after crosslinking. Non-crosslinked fibers dissolved rapidly at all pH values, on a timescale of seconds to minutes. Crosslinked fibers dissolved completely at pH 12, but not at pH 2 or pH 7, the rate depending on the concentration of crosslinking reagent and therefore the density of crosslinks. Dissolution at pH 12 is attributable to ionization of the tyrosine side chain, which has a nominal pK_a of 10.4, an increase in electrostatic repulsion between side chains and the migration of counterions into the fiber. Fibers crosslinked in 50 mM EDC buckled on a timescale of minutes at pH 12 and dissolved shortly thereafter.

H1.00131 SAM surface domains of 11-Mercapto-1-undecanol and 1-dodecanethiol mixtures on Au(111) investigated via hydrophilic and hydrophobic probes[1] , INDRAJITH SENEVIRATHNE, MACKENZIE MAURER, Lock Haven University, RESHANI SENEVIRATHNE, Don's Food Products Inc. — SAM (Self Assembled Monolayer) surfaces may lead to many potential applications from polymer based electronics to sensor engineering. These devices may require a deeper understanding of the surface domain architecture of SAMs with multi component mixtures of thiols. Varying concentration mixed solutions of 11-Mercapto-1-undecanol (hydrophilic -OH end) and 1-dodecanethiol (hydrophobic –R), dissolved in 200 proof Ethanol with total 5mM concentration were prepared. These solutions were used in developing SAMs on clean flat Au(111) on mica. Resulting SAMs surfaces were investigated with regular and custom built hydrophobic and hydrophilic AFM (Atomic Force Microcopy) probes via contact, non contact and lateral force mode AFM with topography and phase imaging. Domains of distinct thiols were identified as selective self assembly on step edges and terraces. Surface roughness, corrugation and morphology at each domain were estimated. Total RMS surface roughness was estimated at $\sim$ 3.1nm for SAMs from unmixed (100%) 11-Mercapto-1-undecanol with increasing RMS surface roughness estimates for SAMs from mixtures with increasing concentrations of dodecanethiol.

[1]LHU Nanotechnology Program, PASSHE FPDC (LOU # 2010-LHU-03).

H1.00132 Study of SAM surface morphology, integrity and film quality on various Au surfaces[1] , JOHN MURPHY, INDRAJITH SENEVIRATHNE, Lock Haven University — SAM (Self Assembled Monolayer) surfaces have many possible applications from polymer based electronics to sensor engineering. Common substrate architecture for such systems happens to be Au(111) on mica. Au on layered mica lacks mechanical resilience towards engineering applications. Solutions of 1-dodecanethiol (hydrophobic –R), dissolved in 200 proof Ethanol with 5mM concentration were prepared. These solutions were used in developing SAMs on purchased, clean flat Au(111) on mica (standard), Au sputter deposited on mica, Hydrogen flame annealed Au layers on glass, and Hydrogen flame annealed Au layers on mica. Resulting SAM surfaces were investigated with regular and custom built hydrophilic and hydrophobic AFM (Atomic Force Microcopy) probes via contact, and non contact AFM with topography and phase imaging. Surface integrity, roughness, corrugation and morphology on SAM surfaces were estimated. Preliminary data indicated total RMS surface roughness at $\sim$ 2.8nm for SAMs on typical gold surfaces on mica purchased (standard) while varying RMS surface roughness estimates on subsequent surfaces with flame annealed samples showing similar RMS surface roughness.

[1]LHU Nanotechnology Program, PASSHE FPDC (LOU # 2010-LHU-03).

H1.00133 SAM surface domains of 6-Amino-1-hexanethiol hydrochloride and 1-dodecanethiol mixtures on Au(111) investigated via hydrophilic and hydrophobic probes[1]

, ALBERT FOSTER, Lock Haven University, RESHANI SENEVIRATHNE, Don's Food Products Inc, INDRAJITH SENEVIRATHNE, Lock Haven University — Amine terminated SAM (Self Assembled Monolayer) surfaces have shown to be bioactive. Hence similar systems can be exploited towards bioengineering applications. However a deeper understanding of the surface domain architecture of SAMs with multi component mixtures of such thiols is need. Varying concentration mixed solutions of 6-Amino-1-hexanethiol hydrochloride (hydrophilic –NH2 end) and 1-dodecanethiol (hydrophobic –R), dissolved in 200 proof Ethanol with total 5mM concentration were prepared. These solutions were used in developing SAMs on clean flat Au(111) on mica. Resulting SAMs surfaces were investigated with regular and custom built hydrophilic and hydrophobic AFM (Atomic Force Microcopy) probes via contact, non contact and lateral force mode AFM with topography and phase imaging. Domains of distinct thiols were identified as selective self assembly on step edges and terraces. Surface roughness, corrugation and morphology at each domain were estimated. Total RMS surface roughness was estimated at $\sim$ 3.75nm for SAMs from unmixed (100%) 6-Amino-1-hexanethiol hydrochloride with increasing RMS surface roughness estimates for SAMs from mixtures with increasing concentrations of dodecanethiol.

[1]LHU Nanotechnology Program, PASSHE FPDC (LOU # 2010-LHU-03).

H1.00134 $p-n$ junction diodes fabricated from isolated electrospun fibers of (P(NDI2ODT2)) and an inorganic p-doped semiconductor[1]

, ALEXANDER ROSADO, NICHOLAS PINTO, University of Puerto Rico - Humacao — A simple method to fabricate, under ambient conditions and within seconds, $p-n$ diodes using an individual electrospun poly{[N , N′-bis(2-octyldodecyl)-naphthalene-1,4,5,8-bis(dicarboximide)-2,6-diyl]-alt-5,5′-(2,2′-bithiophene)}-(P(NDI2ODT2)) fiber and a commercially available p-doped Si/SiO_2 substrate is presented. Band bending at the fiber/Si^+ interface leads to asymmetric I-V characteristic curves resembling that of a diode. The diode turn-on voltage was in the range $\sim$1V and was unaffected via UV light irradiation. The rectification ratio however could be tuned reversibly thereby making this device multifunctional. In addition to being a rectifier, the advantage of our design is the complete exposure of the rectifying junction to the surrounding environment. This has the advantage of making them attractive candidates in the potential fabrication of low power, sensitive and rapid response photo-sensors.

H1.00135 Polymer Films with Enhanced Light Emission[1]

, ADAM THOMAS, ZAC BARCIKOWSKI, MARIAN TZOLOV, Lock Haven University of Pennsylvania — Organic and polymer emitting diode degradation and efficiency are the main problem for industry in commercializing them as a product. This research focused on improving the efficiency of these devices with the main goal of tuning the emission spectrum of certain polymers to emit white light. By layering two polymers during the spin coating process of the device, the photoluminescence (PL) of the particular device was enhanced depending on the polymers we placed down and in particular order. This enhancement however did not occur when the same set of polymers that improved PL were mixed together in solution and then spin coated onto the device. The double layer structures with improved PL were evaluated using PL emission, excitation and optical absorption spectroscopy tests to determine how the polymers were interacting with each other. It was found that two polymers in one orientation would improve PL but wouldn't improve PL if the same polymers were spun in reverse order. As well as the second layer of polymer did not emit its own color but enhanced the under lying polymer layer.

[1]I Adam Thomas would like to thank the NSF for their financial support that allowed me to do this research.

H1.00136 Direct Piezoelectricity of Soft Composite Electrospun Fibers

, MICHAEL VARGA, JASON MORVAN, Liquid Crystal Institute, NICK DIORIO, Chemical Physics Interdisciplinary Program, EBRU BUYUKTANIR, Liquid Crystal Institute; Department of Chemistry, Stark State College, JOHN HARDEN, Liquid Crystal Institute, JOHN WEST, Liquid Crystal Institute; Department of Chemistry, ANTAL JAKLI, Chemical Physics Interdisciplinary Program — Recently soft fiber mats electrospun from solutions of Barium Titanate (BT) ferroelectric ceramics particles and poly lactic acid (PLA) were found to have large (d33 1nm/V) converse piezoelectric signals offering a myriad of applications ranging from active implants to smart textiles. Here we report direct piezoelectric measurements (electric signals due to mechanical stress) of the BT/PLA composite fiber mats at various BT concentrations. A testing apparatus was designed and constructed solely for these measurements involving AC stresses provided by a speaker in 10Hz-10kHz frequency range. The piezoelectric constant d33 $\sim$1nC/N was found to be in agreement with the prior converse piezoelectric measurements. The largest signals were obtained with 6% BT/PLA composites, probably because the BT particles at higher concentrations could not be dispersed homogeneously. Importantly the direct piezoelectric signal is large enough to power a small LCD by simply pressing a 0.2mm thick 2 cm2 area mat by a finger. We expect to use these mats in active Braille cells and in liquid crystal writing tablets.

H1.00137 Growth and Characterization of PEDOT:PSS and Carbon Nanotube Composite Structures for Excitonic Solar Cells

, CONSTANCE OWENS, Houston Baptist University, CHAMINDA HETTIARACHCHI, DOMINGO MATEO-FELICIANO, Universtity of South Florida, ROBERT HYDE, SARATH WITANACHCHI, University of South Florida — Harnessing solar energy is one of the most promising ways to tackle today's energy issues. Though solar cells are comprised of many different layers, our focus is on a single layer. The main goal of this study is to create thin film composite structures of poly(3,4-ethylenedioxythiophene) poly(styrenesulfonate) (PEDOT:PSS) and carbon nanotubes (CNT), more specifically with multiple wall carbon nanotubes (MWCNT) by employing a spray method that utilizes Bernoulli's principle. We believe that a spray method will produce a better uniform layer than other methods that are utilized for creating thin films. Uniformity within a thin film is of the upmost importance because as uniformity is improved, many properties are enhanced. PEDOT:PSS was mixed separately with both dimethylformamide (DMF) and water. By the Dektak 3030ST, a profilometer device, it was discovered that the PEDOT:PSS containing DMF dispersed better than the PEDOT:PSS mixed with water, thus creating a more uniform film. Also it is well known that CNTs possess many excellent properties that can make them very useful in the field of solar technology. In this study we also combine MWCNTs into our thin films to see how they affect thickness, transparency and conductivity by using the Lambda 950, a UV/VIS spectrometer, and a four point probe.

H1.00138 Electrical characterization of polymer solar cells

, CHRISTOPHER GREEN, ZANE COHICK, MARIAN TZOLOV, Lock Haven University of Pennsylvania — Polymer solar cell devices were fabricated using a mixture of the polymer PCPDTBT, PCBM, and 1,8-diiodooctane. The films were spin coated on ITO patterned substrates and covered with a hole injection layer. The film drying was performed at varied annealing temperatures and times. These devices were characterized utilizing current-voltage characteristics and the fill factor was determined. Devices were tested under dark and bright conditions using a xenon lamp. The current-voltage characteristics were modeled with an equivalent circuit yielding values for the shunt and series resistances. The variations in performance due to the changes in annealing temperatures and drying times were studied. Impedance spectroscopy was used to determine the dielectric constant of the active film.

H1.00139 Photocurrent spectroscopy and structural studies of polymer solar cells , ZANE COHICK, CHRISTOPHER GREEN, MARIAN TZOLOV, Lock Haven University — Polymer solar cells devices of the polymer mixture PCPDTBT:PCBM and 1,8-dioodooctane were created employing varied annealing temperatures and drying times. We used SEM and EDX to image the cross-section of the active layers and to identify separate phases. The short circuit photocurrent spectrum of the devices was measured and compared with the absorption spectrum of composite films and individual polymer films. The thicknesses of the solar cells were measured with a profilometer. Studies of the internal electric fields were performed using electroabsorption.

H1.00140 Performance analysis of an inexpensive Direct Imaging Transmission Ion Microscope , PATRICK BARNES, ARTHUR PALLONE[1], Norwich University — A direct imaging transmission ion microscope (DITIM) is built from a modified webcam and a commercially available polonium-210 antistatic device mounted on an optics rail. The performance of the DITIM in radiographic mode is analyzed in terms of the line spread function (*LSF*) and modulation transfer function (*MTF*) for an opaque edge. Limitations of, potential uses for, and suggested improvements to the DITIM are also discussed.

H1.00141 Testing the Accuracy of a Projectile Motion Apparatus , BRET HENDERSON, ERIC MARTELL, Millikin University — The purpose of this research is to predict where a ball would land given initial velocity, angular velocity, and atmospheric conditions. A spinning spherical object flying through air is affected by gravity, quadratic drag forces, and the Magnus force. Mathematica was used to numerically solve predictions for the equations of motion. These predictions were compared with experimental data gathered by launching tennis balls, baseballs, and/or soccer balls from a machine we designed to propel the balls with a pre-determined initial velocity and initial angular velocity.

H1.00142 Building and Testing a Superconductivity Measurement Platform for a Helium Cryostat[1] , HEATH ROSE, JOSHUA OSTRANDER, JIM WU, ROBERTO RAMOS, Indiana Wesleyan University — Superconductivity experiments using Josephson junctions are an excellent environment to study quantum mechanics and materials science. A standard electrical transport technique uses filtered four wire measurement of these superconducting devices. We report our experience as undergraduates in a liberal arts college in building and testing an experimental platform anchored on the cold-finger of a helium cryostat and designed for performing differential conductance measurements in Josephson junctions. To filter out RF, we design, build and test cryogenic filters using ceramic capacitors and inductors and thermocoax cables. We also use fixed attenuators for thermal anchoring and use miniature connectors to connect wires and coax to a sample box. We report on progress in our diagnostic measurements as well as low-temperature tunneling experiments to probe the structure of the energy gap in both single- and multi-gapped superconductors.

H1.00143 Dielectric Relaxation in Liquid Crystals 4'-Octyl-4-Cyanobiphenyl (8-CB) and C-16 Flourescent Dipyrrinone , CHLOE RENFROE, ANDREIY KONDRAT'YEV, CALEB MORTON, Undergraduate, PREEYAL GUPTA, Pensacola High School, AARON WADE, CHANDRA PRAYAGA, MICHEAL HUGGINS, Faculty Advisor, AMY RENAUD, REBECCA CHANDLER, Undergraduate — This paper reports the study of the dielectric relaxation time of the liquid crystal 4'-octyl-4-cyanobiphenyl (8-CB) in the smetic, nematic, and isotropic phases. The time constant of the decay was studied using a 10 mV square wave input signal. Large changes in the relaxation time were observed near the phase transitions. 8-CB was injected int a commercially available liquid crystal capacitor cell to act as a dielectric. The cell was housed in a temperature controlled environment constructed in the lab and an RC circuit was assembled using the 8-CB capacitor. The temperature of the capacitor was varied over the range 25°C to 43°C, covering all three phases. The sample was held at each temperature with a precision of 1mK using a temperature controller before measuring the voltage across the resistor with a digital oscilloscope. The input resistance (50Ω) of the oscilloscope was the resistance in the RC circuit. The recorded data was fitted to an exponential decay. These results give insight into the behavior of the time constant in the different phases and near the phase transitions. This method is used to study the dielectric relaxation of the new liquid crystal C-16 fluorescent dipyrrinone, synthesized in the Department of Chemistry, University of West Florida.

H1.00144 Fabrication of a Liquid Crystal Capacitor Cell using Spin-Coating , LOGAN TATE, TABATHA DUCHARME, CHANDRA PRAYAGA, AARON WADE, University of West Florida, Physics, MICHAEL HUGGINS, REBECCA CHANDLER, AMY RENAUD, University of West Florida, Chemistry — This paper presents our work to fabricate and characterize a liquid crystal capacitor cell using novel liquid crystals. These LCs are not in their isotropic phase at room temperature and require the capacitor cells to be fabricated around them. This was done using spin coating where the samples were dissolved in Toluene, Anisole, or C_4CL. Next, the liquid crystals were spin-coated on either an ITO coated glass slide or a separate silicon wafer. This spin coating process was done in two stages where the first stage started at a slow speed to begin spreading the sample, and then during the second stage the spin coater ramped to a higher rpm to thin the sample while removing excess material. M-Line spectroscopy was used to determine the films thickness of the silicon substrate sample. To make the capacitor cell, a second ITO coated slide was placed on top of the first and the edges sealed with epoxy. Wires were soldered to the bus bars and the samples were mounted in a temperature controlled environment constructed in the lab and an RC circuit was assembled using the LC capacitor. Initial dielectric measurements were taken at room temperature to ensure the integrity of the cell.

H1.00145 Compound droplet generation with viscoelastic interfaces , MAXWELL COLLYARD, St. Olaf College, GREG RANDALL, BRENT BLUE, General Atomics — Compound droplets, or droplets-within-droplets, are traditionally key components in many applications ranging from the food and drug industries to inertial fusion targets. A microfluidic double T-junction can be used to create compound droplets, but each T-junction material typically must be carefully chosen so that the generated droplet does not spread on the walls. By introducing protein into the water shell and by heating simple off-the-shelf T-junctions to 70°C, we were able to prepare oil-in-water-in-oil (O/W/O) droplets that were prevented from spreading on the channel walls. The stability is due to a thin, strong viscoelastic gel that forms on the oil/water interfaces. This is a path forward to mass fabrication of robust compound droplets since the proteins greatly stabilize the droplets near walls. Furthermore, these interfaces are less prone to deformation and useful for creation of uniform-walled shells using high electric fields.

H1.00146 Dynamic Deformation of Theatrical Flats , JAMIAHUS WALTON, ERIC MARTELL, Millikin University, VERDA BETH MARTELL, University of Illinois at Urbana Champaign — In theatre, flats are used as walls and background scenery. During construction, flats are often built on the ground and then "walked up," where a group of stagehands manually lift one end while another anchors the other end in place. When flats are very large, they can deform during this process. Stiffeners are used to decrease the amount of deformation in the flat. The purpose of this research is to determine the strain along the flat during the process of raising it up with and without stiffeners. We will also explore the effect of the person anchoring the pivot edge of the flat and discuss the safety concerns this presents. This research is part of the Physics of Theatre Project, an interdisciplinary collaboration designed to improve safety, reduce costs, and increase knowledge of physics principles within the technical theatre community.

H1.00147 Using IOLab to correct student misunderstandings of Newton's Third Law , NIKKI TIPSWORD, ERIC MARTELL, Millikin University — The Force Concept Inventory (FCI) is used at schools across the country as a tool to measure student conceptual understanding of Newtonian physics. One of the weaknesses commonly identified is in applications of Newton's Third Law. In this project, we are utilizing a recently-developed wireless data acquisition system, the IOLab, to attempt to rectify student misunderstandings regarding the Third Law. The subjects for this research came from calculus and algebra-based introductory physics courses. An assessment of the effectiveness of this teaching tool as well as a comparison between the two courses will be included.

H1.00148 Using the Weather Research & Forecasting Model (NACR) to Model the Atmosphere over the North Eastern United States and Investigate the Effects of Land Use on the Atmosphere , JOSEPH TROUT, TIFFANY LUTES, Richard Stockton College of NJ — In this pilot project, the Weather Research & Forecasting Model (WRF) from the National Center for Atmospheric Research was used to investigate the effects of land use on the weather and climate. New Jersey, especially New Jersey coastlines and NJ pine barrens have seen a rapid amount of development in a very short period. In this project, the WRF model is initialized with real. Observations and simulations are compared over areas of different land use.

H1.00149 What does the Observed, Universal Dark Matter Surface Density of Galaxies tell us about Halo Substructure? , CHRIS PELIKAN, CASEY WATSON, Millikin University — Recent observations suggest a universal, core dark matter (DM) surface density ($\mu_0 = \rho_0 r_0$) for galaxies at all observed mass and luminosity scales. We show that this result emerges naturally if the gravitational field at the core radius of a DM halo is spherically symmetric. This result is independent of the scale of the DM halo core being considered as well as the assumed DM density profile. If a spherically symmetric gravitational field is the correct interpretation of the universal value of μ_0, it implies that no dark matter substructure can exist, even within the largest core radius for which the universal μ_0 relation holds, lest it spoil the symmetry – except in the highly contrived scenario that substructure is symmetrically distributed in the cores of DM halos at all scales for which the universal μ_0 relation is observed. Ignoring this extremely unlikely special case, the symmetry condition translates into an upper bound on the mass of the dark matter particle. Our result, which favors lower mass candidates, is consistent with the findings of several other recent studies.

H1.00150 Zeta Potential Measurements of Glyoxalated Polyacrylamide (GPAM) Resins , SUMIT LIBI, APSANA SHRESTHA, DAVID NORWOOD, Southeastern louisiana University, STEVEN BOONE, Bercen Inc. — We will describe the use of a NICOMP 380 ZLS light scattering instrument (Particle Sizing Systems) to measure the zeta potential of glyoxalated polyacrylamide (GPAM) resins used in the paper industry. These experiments are part of a broader study of GPAM molecule properties (molecular weight, RMS radius, contour and persistence length) intended to understand differences in performance between various GPAM resins (specifically, differences in drainage performance during paper processing and wet/dry strength of paper). Additionally, zeta potential measurements help to understand the long term stability of these resins. Data and results obtained from the experiment will be presented.

H1.00151 Magnetization reversal of patterned disks with perpendicular magnetic anisotropy , ZHUYUN XIAO, XIAO WANG, X.M. CHENG, Department of Physics, Bryn Mawr College, YAOHUA LIU, SUZANNE G.E. TE VELTHUIS, Materials Science Division, Argonne National Laboratory, DANIEL ROSENMANN, RALU DIVAN, Center for Nanoscale Materials, Argonne National Laboratory — Magnetic vortex dynamics in magnetic disks have been extensively studied. However, spin dynamics in magnetic disks with perpendicular magnetic anisotropy (PMA) still remain to be fully understood. Magnetic configurations in disks with strong PMA are more complicated than magnetic vortices, resulting in novel spin dynamics with potential applications. In this work, we study the magnetization reversal of Co/Pd multilayered disks with PMA. Magnetic disks (3-8 microns in diameter) with the structure of [Co (0.3 nm)/Pd (0.5 nm)]$_5$/Co(0.3nm) were patterned on Si substrates via direct laser writing lithography, electron beam evaporation, and lift-off methods. A Kerr microscope was used to image magnetization reversal processes at various bias fields. The imaging results revealed a nucleation dominated magnetization reversal process with the growth of dendritic domains. The coercivity of the disks is significantly bigger than that of thin films with the same structure. Quantitative analysis of the real time Kerr imaging results shed light on the magnetization reversal mechanism of the patterned disks with PMA. Work at Bryn Mawr is supported by NSF under Grant No. 1053854. Work at Argonne National Laboratory and use of the Center for Nanoscale Materials was supported by the U. S. Department of Energy, Office of Science, Office of Basic Energy Sciences, under Contract No. DE-AC02-06CH11357.

H1.00152 Apparent Sphere to Elongated particle transition of Elastin-Like Polypeptide Thermoreversible micelles , KAITLIN VANDEMARK, ALI GHOORCHIAN, NOLAN HOLLAND, KIRIL STRELETZKY, Cleveland State University — Biosynthesized polymers can be designed to assemble into environmentally responsive nanoparticles. Such a system consisting of an oligomerization domain connecting three elastin-like polypeptide (ELP) chains has been developed. These polypeptides reversibly transition from aqueous soluble polymers to amphiphiles when the temperature is raised above the ELP transition temperature. As amphiphiles these can assemble into micelles under appropriate solution conditions. A particular system has been designed to reversibly form micelles at a neutral pH. However, the shape and size of micelles was found to depend strongly on salt concentration. We used polarized and depolarized dynamic light scattering to study temperature-driven formation of micelles of various geometries under different solvent conditions. We also monitored the sphere-to-elongated particle transition of the ELP micelles with addition of salt. The apparent dimensions, shape, and dynamics of micelles strongly depend on salt concentration, with two distinct salt regimes and a broad transition region observed. At low salt concentration (0-15 mM), largely spherical micelles were found with a hydrodynamic radius of 10-15 nm. At intermediate salt concentration (15-35 mM) the transition from spherical to elongated micelles is observed. At high salt concentrations (above 35 mM), the micelles again reach a stable structure consisting of highly anisotropic particles with an aspect ratio of higher than 10.

H1.00153 Complex Refractive Index Structures in a Holographic Photopolymer Optimized for Optofluidic Devices , BENJAMIN CERJAN, ANDREW PETERSON, MARTHA-ELIZABETH BAYLOR, Carleton College — We present complex refractive index features in a thiol-ene / methacrylate-based holographic photopolymer. Our photopolymer can fabricate coplanar optical features and fluid channels using three optical exposures. Previously with this material, we have fabricated linear multi-mode waveguides and 90-degree crossings of an optical waveguide and integrated fluidic channel. We now are using a simple photolithography system at 405 nm to create more interesting index structures. In this poster we present demonstrations of a variety of index structures (e.g., single mode waveguides, diffraction gratings, etc.) and explore the limitations of fabricating these structures.

H1.00154 APPLICATIONS (IT, MEDICAL/BIO, PHOTONICS, ETC.) –

H1.00155 Vacuum-Assisted Self-Assembly of Polymer Derived Siliconoxycarbide-Graphene Composite as Li-ion Battery Anode , LAMUEL DAVID, GURPREET SINGH, Kansas State University — Exfoliated graphene oxide (GO) and polysiloxane were blended and pyrolyzed to synthesize freestanding SiOC-graphene composite papers ($\sim$ 10 μm thick). The structural and chemical characterization of the composite prepared with varying ceramic concentrations was carried out using electron microscopy, XRD, XPS and FT-infrared spectroscopy. High resolution microscopy images shows layer by layer stacking of GO sheets and an increase in interlayer spacing was observed by X-ray analysis. FTIR peaks at 3400 cm-1 (O-H), 1720 cm-1 (C=O), 1600 cm-1 (graphene), 3056 cm-1 (Si-CH=CH2) and 1034 cm-1 (Si-O-Si) confirmed the successful functionalization of SiOC with GO. Thermo-gravimetric analysis showed enhanced thermodynamic stability of the composite paper up to at least 700 °C in flowing air. The SiOC/Graphene composite paper anodes showed stable electrochemical capacity of approx. 500 mAh/g which was twice that of free standing graphene anodes. The average coulombic efficiency (second cycle onwards) was observed to be approx. 97%.

H1.00156 Robust signatures in the current-voltage characteristics of DNA molecules oriented between two graphene nanoribbon electrodes , CARLOS PAEZ, Instituto de Fisica Gleb Wataghin, Universidade Estadual de Campinas, Brazil, PETER SCHULZ, Faculdade de Ciências Aplicadas, Universidade Estadual de Campinas, Brazil, RUDOLF ROEMER, NEIL WILSON, Department of Physics, University of Warwick, United Kingdom — In this work we numerically calculate the electric current through three kinds of DNA sequences (telomeric, λ-DNA, and p53-DNA) described by different heuristic models. A bias voltage is applied between two zig-zag edged graphene contacts attached to the DNA segments, while a gate terminal modulates the conductance of the molecule. The calculation of current is performed by integrating the transmission function (calculated using the lattice Green's function) over the range of energies allowed by the chemical potentials. We show that a telomeric DNA sequence, when treated as a quantum wire in the fully coherent low-temperature regime, works as an excellent semiconductor. Clear steps are apparent in the current-voltage curves of telomeric sequences and are present independent of lengths and sequence initialisation at the contacts. The current-voltage curves suggest the existence of stepped structures independent of length and sequencing initialisation at the contacts. We also find that the molecule-electrode coupling can drastically influence the magnitude of the current. The difference between telomeric DNA and other DNA, such as λ-DNA and DNA for the tumour suppressor p53, is particularly visible in the length dependence of the current.

H1.00157 Interfacial energy level adjustment for ZnO/polymer electronics using triethoxysilane-based monolayers , THOMAS E. FURTAK, T.M. BRENNER, G. CHEN, R.T. COLLINS, Colorado School of Mines, D.C. OLSON, NREL — Because of its large band gap and large ionization energy, together with its relatively large mobility and benign environmental character, ZnO is being increasingly employed in hybrid organic/inorganic electronics. It is commonly necessary to tailor the interfaces in these devices to optimize performance through surface treatment of the ZnO. Traditional molecular oxide modifiers, such as thiols and organic acids, etch ZnO, making it difficult to work with very thin ZnO films or nanostructures. To avoid etching we have developed a ZnO functionalization strategy based on siloxane-based molecular layers. We used this method to create monolayers on ZnO sol-gel films having variable average dipole character by mixing two molecules with different molecular dipoles. Samples were analyzed with IR spectroscopy and Kelvin probe measurements prior to being incorporated as the cathode in bulk heterojunction photovoltaic devices. We observed continuous tuning of the work function of treated ZnO over a range of 0.5 eV that is correlated with the composition of the monolayer. The open-circuit voltage of the devices was linearly proportional to the composition, although the magnitude of the change was much smaller than the change in work function.—Sponsored by NSF through DMR-0907409.

H1.00158 Microwave pump-probe transmission x-ray microscopy for magnetization dynamics imaging[1] , STEFANO BONETTI, ROOPALI KUKREJA, Stanford University, HENDRIK OHLDAG, SLAC National Accelerator Laboratory, RICHARD HOUANCHE, University at Albany, JUDE PINTO, JOSEF FRISCH, JO STOHR, HERMANN DURR, SLAC National Accelerator Laboratory — The development of scanning transmission x-ray microscopy at synchrotron lightsources has seen a rapid development in recent years. The possibility of combined elemental specificity, nanometer resolution, magnetic sensitivity and even time-resolved capabilities, have made this imaging technique relevant for a large number of investigations in condensed matter physics. We further built up on these recent achievements by developing a new microwave "pump-probe" technique, where the "pump" is a continuous microwave source, precisely synchronized with the frequency of the synchrotron pulses, the "probe". Combined with the availability of low-alpha operation at Stanford Synchrotron Radiation Lightsource, that provides x-ray pulses as short as 10-15 ps FWHM, our instrument is capable of creating direct images of dynamical phenomena in the 5-10 GHz range, with 40 nm resolution, at x-ray energies in the 500-1000 eV range. When used together with circularly polarized x-rays, the above capabilities can be used in magnetism. In particular, they can be combined to study magnetic phenomena at microwave frequencies, such as spin waves or magnetization switching. Preliminary results on the imaging of spin waves emitted by spin transfer torque in nano-contacts will be discussed.

H1.00159 Effective Mass and g-factor of 2D Electrons in a HgTe Quantum Well from THz Photoresponse[1] , MEHDI PAKMEHR, A.V. STIER, H.D. ZHANG, University at Buffalo, C. BRUENE, H. BUHMANN, L. MOLENKAMP, University of Wuerzburg, B.D. MCCOMBE, University at Buffalo — There is current interest in HgTe because of its interesting "inverted" band structure and large spin-orbit interaction, and because it is a topological insulator under quantum confinement, Well-widths close to that at which the band structure goes from the "inverted" to the normal structure are of particular interest. We have used photoresponse excited by several lines from an optically pumped THz laser and magnetotransport measurements to determine the cyclotron effective mass and g-factor of 2D electrons in the gamma_6 conduction band of a high quality HgTe quantum well (n_s = 1.55 x 10^{12} cm^{-2}; 6 nm well) at low temperatures. One of the two samples studied was gated, which allowed density to be varied by over 30%. We find m*=0.039m_e and g = -18 at the highest density from fits to the PR with the field normal to the plane of the QW, and separately from CR transmission measurements and tilted field experiments. We will also discuss electron spin resonance measurements near filling factors 7 and 9.

[1]Supported in part by NSF DMR 1008138

H1.00160 Temperature-Dependent Multi-Polarization Switching in VCSELs , YU-FONG CHEN, PEI-HOU CHIN, CHENG HSU, SHAHAM QUADIR, YUEH-CHEN LI, YU-HENG WU, TSU-CHIANG YEN, National Sun Yat-sen University Department of Physics, NATIONAL SUN YAT-SEN UNIVERSITY DEPARTMENT OF PHYSICS TEAM — The multi-polarization switching (MPS) in vertical-cavity surface-emitting lasers (VCSELs) at constant temperature was investigated. The experiment was performed by triangular modulation signal at 100 Hz under 10 °C and 7 °C. The results show that the number of polarization switching (PS) was varied from single PS to five PSs and seven PSs at 10 °C and 7 °C, respectively. It also observed that the variation of PS in VCSEL was sensitive to the increasing and decreasing process of temperature. Rich results concluded that the substrate temperature play an significant role in MPS.

H1.00161 Simulation of polarization switching of Vertical-Cavity Surface-Emitting Lasers at constant current

, PEI-HOU CHIN, WANG-CHUANG KUO, SHAHAM QUADIR, YU-HENG WU, TSU-CHIANG YEN, Department of Physics National Sun Yat-sen University — The polarization switching (PS) in Vertical-Cavity Surface-Emitting Lasers (VCSELs) at constant bias current was investigated by numerical simulation in this research. The simulation was performed by Linear Current Gain model. The PS with a delay time at constant bias current was observed in the experiment which was performed by quasi-step current. The simulation results show that the PS delay time depends on the constant bias current and these results are matching well with experimental results. These results contribute to the understanding of the mechanism of VCSEL's polarization switching.

H1.00162 Analysis of Multi-Polarization Switching in Vertical-Cavity Surface-Emitting Lasers Using Multi-peak gain model

, CHUAN HSU, YU-FONG CHEN, PEI-HOU CHIN, SHAHAM QUADIR, YUEH-CHEN LI, YU-HENG WU, TSU-CHIANG YEN, Department of physics, National Sun Yat-sen University — This research investigated the mulit-polarization switching (MPS) in vertical-cavity surface-emitting lasers (VCSELs) at constant temperature by simple multi-peak gain model.In experimental results, the phenomenon of the polarization switching (PS) in the VCSEL were arduous to definite quantitative analysis. A simple multi-peak gain model which included the temperature effect and current effect was established to match the MPS in the VCSEL. Simulation results match the experimental results well and shoe that the variation of temperature is a affecting factor of MPS. Therefore, the simple multi-peak gain model contributed a good understanding of multi-polarization switching in VCSELs.

H1.00163 ABSTRACT WITHDRAWN –

H1.00164 Critical Slowing Down of Relaxation Time in VCSEL's Polarization Switching

, YUEH-CHEN LI, WANG-CHUANG KUO, YU-HENG WU, TSU-CHIANG YEN, Department of Physics, National Sun Yat-sen University — This study investigates the polarization switching (PS) of vertical-cavity surface-emitting lasers (VCSELs) approaching to criticality. The dynamical bifurcation of VCSEL's PS (VPS) which was researched in earlier investigations essentially differs from the static cases typically presented in thermodynamics. Therefore, a VCSEL is driven by quasi-increasing step current and quasi-decreasing step current instead of alternating current in this study. The results show a critical slowing down nearing PS, a power law and scaling law of the relaxation time which are the characteristics of second order phase transition. This investigation has potential for connecting the phase transition characteristics of VPS and quantum phase transitions (QPTs).

H1.00165 Surface temperature measurement by optical self-interference of laser beam at the edge of a thermally sensitive thin film

, PHUONG ANH DO, MOHAMED TOUABIA, ALAIN HACHE, Universite de Moncton — Measurement of surface temperature is problematic when the thermal mass of the probe (e.g. thermocouple or thermometer) is large relative to that of the sampled volume (e.g. thin film). With the goal of reducing thermal mass error, we developed a method using thermal probes in the form of thin films with materials exhibiting large physical and optical changes with temperature. Using chitosan, a polymer, as test material, we show that thermal expansion and refractive index changes in the film are detectable optically with a laser beam. When half of the Gaussian-shaped beam travels through the edge of the film and half of it does not, self-interference in the form of a fringe pattern is observed in the far field. With the fringe displacement correlated to phase variations and temperature changes, the calibration can be used to probe surface temperature on other samples. With the laser beam focused to 50 μm and chitosan films as thin as 100 nm, the method is adequate to measure temperature in the near vicinity of the surface. We provide a theory and numerical simulations to determine the ideal experimental conditions and parameters.

H1.00166 Effect of doping on performance of IR quantum dot photodetector

, GUILLAUME THOMAIN, VLADIMIR MITIN, VICTOR POGREBNYAK, ANDREI SERGEEV, University at Buffalo — We investigated the influence of the dopant position and dopant concentration on performance of InAs/$Al_{.22}Ga_{.78}$As quantum dot infrared photodetectors. We designed and fabricated three types of the QDIP with a InAs-dot sheet concentration of 1.04x10^{11} cm^{-2}, which differ only in the position and density of a Si-dopant. In the first one, the dopant with a density of 5.4x$10^{11}cm^{-2}$ was placed directly into the QD layer; in the second, the same amount of the dopant was placed in the middle of the $Al_{.22}Ga_{.78}$As spacer between the QD layer in such a way that it was sandwich between the two undoped $Al_{.22}Ga_{.78}$As layers facing QD layers on both sides; in the third type, position of the dopant was the same as in the second device, but its concentration was 1.5 greater. The spectral, electrical, and temperature characterization of these devices demonstrated that device 3 had the largest responsivity and detectivity at 3.7 μm comparable with the best quantum well and MCT detectors. The experimental characterization along with simulations allowed us to analyze and explained the enhanced photoresponse of device 3.

H1.00167 Toward terahertz heterodyne detection with superconducting Josephson junctions

, N. BERGEAL, M. MALNOU, C. FEUILLET-PALMA, A. LUO, T. WOLF, J. LESUEUR, ESPCI ParisTech, C. ULYSSE, LPN Marcoussis, P. FEBVRE, LAHC Université de Savoie — The terahertz region of the electromagnetic spectrum [0.3-10THz] has, so far, not been exploited fully due to the lack of suitable sources and detectors. Indeed, THz frequency lies between the frequency range of traditional electronics and photonics where the existing technology cannot be simply extended. SIS Niobium tunnel junctions that are currently used as mixing element in heterodyne receivers are intrinsically limited in frequency by the energy gap of Nb and operate only at low temperature (4.2K). An alternative to these devices consists of using High-Tc superconducting receivers. Over the past years, we have developed a new approach based on ion irradiation to make Josephson nano-junctions and SQUIDs with YBCO thin films [1,2]. In this talk, we will present a study of the high-frequency mixing properties of such junctions up to 400 GHz [3]. Conversion gain has been measured at frequencies spanning the range below and above the characteristic frequency fc = (2e/h)IcRn of the junctions. The transition between two distinct mixing regimes has been clearly evidenced, in good agreement with the prediction of the three ports model.

H1.00168 An Actively Shielded 1.5T MgB_2 MRI Magnet Design[1]

, MICHAEL MARTENS, TANVIR BAIG, MIHAI CARA, ROBERT BROWN, Case Western Reserve University, DAVID DOLL, MICHAEL TOMSIC, Hyper Tech Research Inc. — Superconducting magnets for MRI are often constructed with NbTi wire cooled below 4.2K using liquid helium. As helium costs have more than tripled in the last decade, there is a need for a cryogen-free conduction-cooled alternative. A key reason for pursuing MgB_2 superconductor wire in the design of MRI magnets is its superior critical current compared to NbTi over a temperature range of 10-15K. We present a 1.5T whole body actively shielded main magnet design assuming second-generation multifilament MgB_2 wire using an improved functional approach. The design exhibits 4 pairs of primary bundles and 1 pair of shielding bundles with an inner (outer) diameter of 1.1 (1.89)m and a length of 1.54m. The imaging volume is 45cm with a maximum of 9ppm inhomogeneity. The wire dimension is assumed to be 1mm^2 and the wire current is 135A. The maximum field on a wire is found to be 4.1T well below the critical field value of approximately 6T at 10K for the second-generation wire. The 5-Gauss footprint for the new magnet is found to be 2.7 (3.7)m in the radial (axial) direction. The maximum hoop stress and axial force on a bundle, respectively, are 82.9MPa and 2680.2kN. Trade-offs for the reduction of any given parameter are analyzed.

H1.00169 Magnetic rotor flux observer of induction motors with fast convergence and less transient oscillation , CHANG-WOO PARK, JUNG-HOON HWANG, Korea Electronics Technology Institute — This paper presents an observer design for the estimation of magnetic rotor flux of induction motors. We characterize the class of MIMO induction motor systems that consists of the linear observable and the nonlinear part with a block triangular structure. The similarity transformation that plays an important role in proving the convergence of the proposed observer is generalized to the systems. Since the gain of the proposed observer minimizes a nonlinear part of the system to suppress for the stability of the error dynamics, it improves the transient performance of the high gain observer. Moreover, by using the generalized similarity transformation, it is shown that under some observability and boundedness conditions, the proposed observer guarantees the global exponential convergence to zero of the estimation error. Since the proposed scheme minimizes the nonlinearity of an induction motor system, it improves the transient performance of the observer and guarantees the global exponential convergence to zero of the estimation error. The estimation results of magnetic rotor fluxes through experiments are shown and it is presented that the proposed magnetic flux observer exhibits less transient oscillation and faster convergence time than the general observer.

H1.00170 Energy Minimizers in Thin Ferromagnetic Nanorings with Four-Fold In-Plane Anisotropy[1] , GABRIEL CHAVES, CYRILL MURATOV, New Jersey Institute of Technology — We present results obtained from micromagnetic simulations of thin ferromagnetic nanorings. We investigate annuli made of materials with non-negligible cubic anisotropy. In thin films the crystalline anisotropy favors magnetizations lying in the film plain along $\pm\hat{\mathbf{x}}$ or $\pm\hat{\mathbf{y}}$ directions. The magnetostatic energy separates into boundary and bulk terms. Our previous work provided a classification of remanent states based on the above contributions to the energy [1]. There are three regimes with distinct features of the remanent states depending on the dominant energy term. The magnetization configurations present four distinct domains. Different remanent states coexist in each of these regimes and they are characterized by the behavior of the domain walls spanning the annulus. Here, we compute the energies for these metastable states in a variety of ring dimensions and material parameters. In particular, we attempt to locate the ground state as a function of ring dimensions. This information is of importance for the design of magnetic storage devices based on configurations presenting 2π domain walls [2]. [1] G.D. Chaves-O'Flynn, C. Muratov. Submitted. IEEE Trans. Mag. H1.00171 Development magnet for portable MRI device: Investigate skin cancer , NURCAN DOGAN, Gebze Institute of Technology — Nuclear magnetic resonance (NMR) is well known from diagnostic medical imaging and analytical chemical spectroscopy. The sample is brought into the laboratory to be investigated with radio-waves inside stationary magnets. This paper describes a new approach useful to reduce the gradient strength of the magnetic field. Despite of the recent progress in magnet design, homogeneity of permenant magnet is still very limited. Fortunately for medical applications usually there is need in high-field homogeneity to obtain the high-resolution spectra that provide the detailed chemical shift and coupling-constant. In this work we discuss various permanent magnet design-without cooling system- for magnetic imaging. The magnet used for the present application consists of two units. The main unit is built from static magnet blocks and generates the main magnetic field. The second one is the shim unit. It consists of smaller movable magnets used to correct in a controlled manner the magnetic field generated by the main unit. By combining the two units, magnetic fields with defined spatial dependence can be generated with high accuracy. The performance of the magnet in terms of resolution and sensitivity is first evaluated and compared with conventional other magnets of higher gradient strength using phantoms of known geometry and relaxation times. After integration of magnet with spectrometer, Our new system is used to profile the structures of healty and unhealthy (cancer) human skins in vivo. To understand the contrast between the different skin type, the distribution of relaxation times T1 is spatially investigated.

H1.00172 Human umbilical vein endothelial cell interaction with phospholipid polymer nanofibers coated by micro-patterned diamond-like carbon (DLC) , SOKI YOSHIDA, Department of Mechanical Engineering, Keio University, TERUMITSU HASEBE, Department of Radiology, Tokai University Hachioji Hospital, TETSUYA SUZUKI, ATSUSHI HOTTA, Department of Mechanical Engineering, Keio University — Blood-contacting medical devices should possess the surface properties with the following two important characteristics: The first is the anti-thrombogenicity of the material surface and the second is the re-endothelialization over the device surface after long-term implantation, because endothelial cells have excellent anticoagulant properties in blood vessels. To develop highly hemocompatible materials that could promote surface endothelialization, we investigated biocompatible polymers coated with thin diamond-like carbon (DLC) film. In this research, we examined the viability of human umbilical vein endothelial cells (HUVECs) for hydrophilic 2-methacryloyloxyethyl phosphorylcholine (MPC) fibers with DLC coatings, both of which were known to be anti-thrombogenic. DLC was synthesized on MPC by varying the ratio of covered area by patterned DLC. HUVECs were seeded on DLC-coated MPC for 6 days. The results indicated that the MPC surface with DLC did not disturb HUVEC proliferation in 6 days of culture. Additionally, we are currently making strong efforts to fabricate MPC fibers with bFGF which is an important growth factor involved in cell proliferation. MPC containing bFGF with DLC coatings could be extensively utilized for blood-contacting medical devices.

H1.00173 Theoretical Investigation of the Electronic Interaction between Au and TiO2 Nanosystems[1] , ANDREW RICE, West Virginia Unversity — The focus of this research is to theoretically study the underlying mechanisms of the enhanced catalytic properties presented by the oxide supported gold nanoparticles. Extensive studies have established that the interaction between the gold nanoparticles and the oxide substrates plays an important role in enhancing the catalytic performance. Several factors, such as geometry, electronic coupling and the charge transfer occurring between Au and TiO2 need to be considered in order to understand the interaction between Au and TiO2. One issue that will be discussed in this study is the bonding character between the Au/ TiO2 nanosystems. Experimentally, geometries on this subject have been researched. However, there is no clear picture of how the Au nanoparticles bonding to TiO2 surfcace in terms of the preference locations along certain orientation of TiO2 (anatase in our study). Using computational approaches, we are aiming to understand the bonding characters and the electronic properties of Au/ TiO2 nanosystems. The spherical shape of Au13 has been established. As for the TiO2 substrate, we considered three anatase nanoparticles with both (101) and (001) surface existence. Along with size increasing, the (001) surface tends to be the dominate surface of TiO2 nanoparticle. The reason we designed the TiO2 nanoparticle in this manner is that we are interested in the preferable locations of Au nanoclusters anchoring to TiO2. In our study, we found Au13 on all three TiO2 substrates showed geometric deformation.

H1.00174 Temperature Dependence of the Single-Photon Sensitivity of a Quantum Dot, Optically Gated, Field-Effect Transistor , ANDREW PRUDHOM, ERIC GANSEN, Physics Department, University of Wisconsin-La Crosse, MARY ROWE, Optoelectronics Division, National Institute of Standards and Technology, Boulder, SEAN HARRINGTON, JOHN NEHLS, Physics Department, University of Wisconsin-La Crosse, SHELLEY ETZEL, SAE WOO NAM, RICHARD MIRIN, Optoelectronics Division, National Institute of Standards and Technology, Boulder — The potential advantages that quantum communications and computing have over their conventional counterparts have seeded a growing interest in transmitting and processing information with individual photons. However, if these technologies are ever to reach their full potential, improved single-photon detectors will have to be developed. Here, I present a systematic study of the temperature dependence of the electrical noise in a quantum dot, optically gated, field-effect transistor (QDOGFET) and detail how the noise influences the sensitivity of this novel single-photon detector. Previous studies have shown that when cooled to 4K, QDOGFET's exhibit single-photon sensitivity and photon-number resolving capabilities; however, there has been no systematic study of how operating temperature affects their performance. Here, we measure the noise spectra of a device for a range of sample temperatures between 7K and 60K. We use the noise data to determine the signal-to-noise ratio of the optical response of the device for various temperatures and detection rates. Our analysis indicates that QDOGFET's can operate over a broad range of temperatures, where increased operating temperature can be traded for decreased sensitivity.

H1.00175 Nanocomposite materials for radiation detection , SUNIL SAHI, University of Texas at Arlington — Colloidal quantum dots (CdTe, CdSe, and ZnO) have attracted tremendous interest in wide range of application from biological imaging, biosensing, solar cells to optoelectronic devices. However very few published reports on the radiation detection based on colloidal quantum dots. Quantum dots based nanocomposite materials could be a promising material for radiation detection because of their short luminescence life time and high quantum efficiencies as a consequence of quantum size confinement. However stopping power of most quantum dots is low and their scintillation luminescence is very weak. The combination of high stopping power of inorganic scintillator (CeF_3LaF_3: Ce, YAG:Ce) and high efficiency of quantum dot could potentially lead to a new class of scintillator. We have studied the nanocomposite of inorganic scintillator and quantum dot based on energy transfer principle and investigate the scintillation properties of nanocomposite scintillator.

H1.00178 Why a magnetized quantum wire can act as an optical amplifier , M.S. KUSHWAHA, Rice University — Essentially, we embark on the device aspects of the intersubband collective (magnetoroton) excitations in a quantum wire characterized by a confining harmonic potential and subjected to a perpendicular magnetic field. The computation of the gain coefficient suggests a significant application: the electronic device based on such magnetoroton modes can act as an optical amplifier.

H1.00179 Process simulation of carbon-based nanostructures in next-generation semiconductor integrated elements , YASUNARI ZEMPO, Hosei University, TAKAHISA OHNO, National Institute for Materials Science (NIMS) — The trend in semiconductor devices leads us to develop new materials such as CNT and graphene from the point of high electric conductivity, new CMOS channel and interconnect, and low-voltage operation. To realize the carbon-based nano device, we have established HPCI carbon-based nano structure material consortium with industries, universities and institutions, aiming for R&D of nano electric fabrication. Our research is oriented to process simulations of nano structure manufacturing for optimal process design, property analyses for comprehensive assessment of the device applications, and providing industry-friendly environment that combines first principles and other methods (semi-empirical and classical). To promote device manufacturing with the help of HPCI (K computer), PHASE is our key software for electronic structure calculations based on DFT using plane wave base, which is not only wide applicable to various materials, and involves analytical tools for dielectric response, vibrational analysis, STM simulation, etc. but also compatible to wide range of platforms from note PC to SC, with well optimized parallel computation. Some of applications will be presented together with the scalability on K computer such as SiC defects, graphene growth, and conductivity analysis

H1.00180 BIOLOGICAL PHYSICS —

H1.00181 A More Practical Sort of Interstellar Travel? , ROBERT JONES, Emporia State University — Various radio messages have been beamed toward nearby stellar systems. I contributed to one a couple years ago. (My contribution was a warning to anyone who got the message. I warned of humankind's rather imperfect value system.) But perhaps we should send the complete digital description of the human genome. Or perhaps those of various humans. Along with this would be an attempt to explain what the message is. One might hope that the recipients could then construct human beings at their end from atoms available there. Perhaps spaceships aren't needed. And perhaps a larger fraction of the space budget should be spent on seti. As a hedge against global catastrophe we should begin to send such signals now.

H1.00182 Stochastic discrete-state simulation of cell population growth in different environments

, MERZU K. BELETE, University of Houston & MD Anderson Cancer Center, RHYS M. ADMAS, GABOR BALAZSI, MD Anderson Cancer Center — Living cells possess low copies of many molecular components like DNA and proteins which cause stochastic fluctuations in gene expression. Gene expression affects cell phenotypes as a function of the environment.[1] Among all encoded phenotypes, fitness measures how well the organism survives in its environment. A number of experimental gene expression measurements confirmed that gene expression is a determinant factor for cellular fitness in various environments[2]. Yet, gene expression is a stochastic process better described by its probability distribution rather than its first moment. For bimodal gene expression, the individual cell gene expression is quite different from population average gene expression and it involves stochastic transitions between cellular states. Therefore, cell fitness is noisy and fluctuates randomly according to noisy gene expression. To address fitness in noise, we develop a stochastic model accounting different environments (combinations of drug and inducer). We found that the population fitness is nontrivial dependence on drug and inducer in agreement with our lab.[3]

H1.00183 Simulations of single-molecule pulling experiments: equilibrium and non-equilibrium free-energy landscape trajectories

, ERIC COPENHAVER, JUTTA LUETTMER-STRATHMANN, Department of Physics, University of Akron — The response of a single molecule to an applied force is important for many biological processes. This response is often investigated via single-molecule pulling experiments, where a tension force is applied to the opposite ends of a biological chain molecule. In equilibrium conditions, the system follows a trajectory that may be predicted from the free-energy landscape. In non-equilibrium experiments, the pulling force varies too rapidly for the chain to explore all available configurations resulting in a deviation from the equilibrium trajectory. To gain a better understanding of the relationship between equilibrium and non-equilibrium processes, we investigate the effect of the pulling speed on the system's trajectory with two types of computer simulations of single-molecule experiments. We perform Wang-Landau simulations to determine the energy landscape and Langevin dynamics simulations to probe the dynamic response of the same bead-spring model of a biopolymer. After verifying that both simulation methods yield consistent equilibrium results, we study the effect of the pulling protocol on the free-energy landscape trajectories. The goal of this project is to devise an effective dynamic field that recreates the non-equilibrium pathway under equilibrium conditions.

H1.00185 An Integrated Method for Quantification and Analysis of Motility in C. Elegans

, FRANK VAN BUSSEL, AMAR PATEL, Texas Technical University, Department of Mechanical Engineering, VENKAT PADMANABHAN, Indian Institute of Technology, Kharagpur, KHAN ZEINA, SIVA VANAPALLI, Texas Technical University, Department of Chemical Engineering, JERZY BLAWZDZIEWICZ, Texas Technical University, Department of Mechanical Engineering — Though the nematode C. Elegans is a model organism in many areas of biology, its most readily observed behaviors, crawling and swimming, have yet to be thoroughly described. The outcome of detailed studies, for example, on the relation of neural control to chemotaxis, or the effects of gene suppression as manifested in the behavior of mutant strains, depends upon the acquisition of detailed trajectory data over nontrivial time and length scales. Here we present a methodology for processing, quantifying, and analyzing nematode motion data both in terms of their shape over short time scales and their trajectories over long time scales. This method is based on a succinct representation of shape/trajectory information using piecewise-harmonic functions in curvature space, first described in [1]. The representation parameters are obtained through automated image processing techniques. Using this method we are able to analyze large amounts of nematode data relatively quickly, making it applicable to detailed worm-motion studies. References: 1. Padmanabhan V, Khan ZS, Solomon DE, Armstrong A, Rumbaugh KP, et al. (2012) Locomotion of C. elegans: A Piecewise-Harmonic Curvature Representation of Nematode Behavior. H1.00186 The Effect of Plasma on Tail Regeneration of Tadpoles *Xenopus Laevis*[1]

, JOYCE JUNE, CHIMA AMADI, JAISHRI MENON, KEVIN MARTUS, William Paterson University — Healthy wounds require a balanced combination of nutrients and growth factors for healing and tissue regeneration. Nitric oxide, (NO), is also crucial in wound healing processes and linked with production of several cytokines, interaction with other free radicals and influence on microcirculation. Hypothesize is that exposure to plasma will affect wound healing and tail regeneration in tadpoles *Xenopus laevis* and plasma induced endogenous NO production may have an important role to play at the cellular level. Tail amputation was immediately followed by exposure of the wound to the helium plasma. For histological features, blastema (growing regenerate) was fixed in 4% neutral buffer formalin for paraffin sections. *In situ* staining for NO was carried out 5 days post amputation. The rate of the regenerating tail was proportional to the plasma exposure time at the expense of metamorphic rate. Histological features show that the tadpoles exposed to the plasma had a higher level of cellular proliferation and microvasculature in blastema. *In situ* staining for NO indicated its increased endogenous production compared to the control. These findings suggest that accelerated wound healing and tail regeneration following exposure to the plasma may be due to its direct effect on cell proliferation and increased NO production which may be involved in microvascularization.

H1.00187 Effect of substrate mechanical properties on T cell activation

, KING LAM HUI, ARPITA UPADHYAYA, Department of Physics, University of Maryland, College Park, MD — T cell activation is a key process in cell-mediated immunity, and engagement of T cell receptors by peptides on antigen presenting cells leads to activation of signaling cascades as well as cytoskeletal reorganization and large scale membrane deformations. While significant advances have been made in understanding the biochemical signaling pathways, the effects imposed by the physical environment and the role of mechanical forces on cell activation are not well understood. In this study, we have used anti-CD3 coated elastic polyacrylamide gels as stimulatory substrates to enable the spreading of Jurkat T cells and the measurement of cellular traction forces. We have investigated the effect of substrate stiffness on the dynamics of T cell spreading and cellular force generation. We found that T cells display more active and sustained edge dynamics on softer gels and that they exert increased traction stresses with increasing gel stiffness. A dynamic actin cytoskeleton was required to maintain the forces generated during activation, as inferred from small molecule inhibition experiments. Our results indicate an important role for physical properties of the antigen presenting cell as well as cytoskeleton-driven forces in signaling activation.

H1.00188 Physical controls on matrix mineralization[1]

, JINHUI TAO, MIKE NIELSEN, JIM DE YOREO, Lawrence Berkeley National Laboratory — During biomineral formation, protein matrices impose order on nucleating mineral phases. While many studies have examined the structural relationships between mineral and matrix, few have explored the energetics. To address this gap we use *in situ* TEM and AFM to investigate calcium phosphate nucleation and growth in collagen and amelogenin matrices. *In situ* TEM results indicate that, in the absence of calcium, amelogenin nanospheres are loose aggregates of oligomers, while in the presence of calcium phosphate solution, can form chain-like structures and become mineralized with an amorphous phase before the appearance of crystalline phases. Results on collagen reveal the evolution of nucleation pathways from direct to indirect with increasing supersaturation and analysis of nucleation rates using classical theory demonstrates a reduction in interfacial energy due to matrix-mineral interactions. However, the calculated thermodynamic barriers are in contradiction to the observed pathways and well in excess of sensible values. We present a model based on cluster aggregation within the classical context that reconciles experiment and theory.

[1]Authors would like to acknowledge grant no. DK61673 from the National Institutes of Health. Theoretical analysis was supported by Office of Science, Office of Basic Energy Sciences of the U.S. Department of Energy under Contract no. DE-AC02-05CH1123.

H1.00189 X-ray absorption Studies of Zinc species in *Centella asiatica*[1]

, SUNIL DEHIPAWALA, TAK CHEUNG, CLAYTON HOGAN, YAO AGOUDAVI, Queensborough Community College, SUMUDU DEHIPAWALA, SUNY at Stony Brook — Zinc is a very important mineral present in a variety of vegetables. It is an essential element in cellular metabolism and several bodily functions. We used X-ray fluorescence, and X-ray Absorption near Edge structure(XANES) to study the amount of zinc present in several leafy vegetables as well as its chemical environment within the plant. Main absorption edge position of XANES is sensitive to the oxidation state of zinc and is useful when comparing the type of zinc present in different vegetables to the standard zinc present in supplements. Normalized main edge height is proportional to the amount of zinc present in the sample. Several leafy greens were used in this study, such as *Spinacia oleracea*, *Basella alba*, *Brassica oleracea*, *Cardiospermum halicacabum* and *Centella asiatica*. All of these plant leaves contained approximately the same amount of zinc in the leaf portion of the plant and a slightly lower amount in the stems, except *Centella asiatica*. Both leaves and stems of the plant *Centella asiatica* contained nearly two times the zinc compared to other plants. Further investigation of zinc's chemical environment within *Centella asiatica* could lead to a much more efficient dietary consumption of zinc.

H1.00190 A Minimal Model of the E. Coli Bacterium in Exponential Phase Growth[1]

, ARIJIT MAITRA, KEN DILL, Stony Brook University — We study the fundamental process of exponential cell growth in the E. Coli bacterium under conditions of extracellular glucose limitations using a minimalistic reaction framework by accounting for energy metabolism and protein synthesis. The cell model has three nodes: ATP, the ribosomal and the non-ribosomal proteins. Their interdependencies and dynamics are wrapped in a system of ordinary differential equations. The formulations of their interactive fluxes capture the essence of cellular physiology under conditions of growth. We solve the model numerically for different glucose concentrations, and, where possible, explore the cell states analytically under steady state conditions. We verify the model predictions with available experimental data. The model lets us quantify the coupling between energy generation and biomass growth. An implication of this model is that it provides a layout to compute the fitness landscape in terms of the parameters of the cells, such as the protein translation rates, to make hypotheses about possible routes for cellular evolution under glucose limitation.

H1.00191 DNA translocation through a nanopore in a single layered doped semiconductor membrane[1]

, INING A. JOU, DMITRIY V. MELNIKOV, CHRISTOPHER R. MCKINNEY, MARIA E. GRACHEVA, Clarkson University — We have recently developed a computational model that allows us to study the influence a semiconductor membrane has on a DNA molecule translocating through a nanopore in this membrane. Our model incorporates both the self-consistent Poisson-Nernst-Planck simulations for the electric potential of a solid state membrane immersed in an electrolyte solution together with the Brownian Dynamics of the biomolecule. We study how the applied electrolyte bias, the semiconductor membrane bias and the semiconductor material type (n-Si or p-Si) affect the translocation dynamics of a single-stranded DNA moving through a nanopore in a single layered semiconductor membrane. Our results show that the type of semiconductor material has a prominent effect on the biomolecule's translocation time, with DNA exhibiting much longer translocation times through the p-type membrane than through the n-type at the same electrolyte and membrane potentials. In addition, we find the optimal combination for membrane/electrolyte system's parameters to achieve longest translocation time and largest DNA extension. With our single layered electrically tunable membranes, the DNA translocation time can be manipulated to have an order of magnitude increase.

H1.00192 In-Situ Creation of Solid State Nanopores

, KYLE BRIGGS, HAROLD KWOK, VINCENT TABARD-COSSA, University of Ottawa — Recent advances in nanopore technology have demonstrated that they are a powerful tool for single biomolecule analysis, and great progress has been made toward the promise of nanopore-based DNA sequencing devices. A limiting factor in solid-state nanopore science is the complexity, throughput and cost of current fabrication methods, based on focused ion or election beam drilling, which require sophisticated equipment and highly trained personnel. Our laboratory at the University of Ottawa has demonstrated a simple and extremely low cost method to fabricate individual nanopores on thin solid-state membranes. By controlling an applied voltage across the membrane in aqueous salt solution, we are able to routinely create sub-5nm pores in dielectric membranes. In addition, the method can easily be extended to tune nanopore size with sub-nm precision. We will describe the fabrication method in detail, and present the effects of electric field strength, membrane material, solution salt composition, concentration and pH on the pore creation time and size distribution. These results allow us to elucidate the physical mechanisms responsible for nanopore formation.

H1.00193 Dual mechanisms of DNA sequencing based on tunnelling between nitrogen-doped carbon nanotube electrodes

, HAN SEUL KIM, YONG-HOON KIM, KAIST Graduate School of EEWS — The DNA sequencing approach based on the combination of nanopores and electron tunnelling has seen considerable advances in recent years, and particularly carbon nanomaterials have emerged as promising candidates to replace metal electrodes. Carrying out extensive first-principles calculations, we here show that two distinct DNA sequencing mechanisms can be achieved with different configurations of a single-type nitrogen-doped capped carbon nanotube (CNT) that has significantly enhanced transmission and chemical sensitivity over its pristine counterpart. With a small CNT-CNT gap size that induces face-on nucleobase configurations, we obtain a typical conductance ordering where the largest signal is induced from guanine due to its highest occupied molecular orbital energetic position higher than those of other bases. On the other hand, for a large CNT-CNT gap size that accommodates edge-on nucleobase configurations, we extract a completely different conductance ordering in which thymine results in the largest signal. We find that the latter novel nucleobase sensing mechanism originates from the nature of chemical connectivity between nitrogen-doped CNT caps and nucleobase functional groups that include the thymine methyl group. This work thus demonstrates the feasibility of a tunnelling-based dual-mode approach toward whole genome sequencing applications, detection of DNA base modifications, and single-molecule sensing in general.

H1.00194 Charged Nanoparticle Translocation through Solid-State Nanopores , SANTOSHI NANDIVADA, RYAN ROLLINGS, NATHAN WALSH, JIALI LI, University of Arkansas at Fayetteville — Solid-state nanopores are widely used for detection of biomolecules and small particles by measuring the pore resistance change when the molecules or particles are electrophoretically driven through. Using the same principle, in this study we look at the translocation of different size, around 10 nm in diameter, negatively charged nanoparticles through nanopores fabricated by combining ion beams and electron beams. We measure the relationship between the current blockage signal caused by pore resistance change with nanoparticle size and nanopore geometry. We also estimate the magnitude and duration of current blockage signal theoretically by relating the change in the resistance of the nanopore to the geometry of the pore and the particle. Preliminary results obtained from experiment and numerical simulation using finite element analysis software (Multiphysisc,COMSOL Inc) will be presented.

H1.00195 High Temperature Baking as a Means of Controlling Solid-state Nanopore Fabrication and Stability , NATHAN WALSH, DENIS TITA, SANTOSHI NANDIVADA, RYAN ROLLINGS, JIALI LI, University of Arkansas — Solid-state nanopores have been of interest in single biomolecule analysis due to their ability to be tunable in dimension and robust nature. The ability to withstand wide variations in temperature, salt, denaturing agent, and pH while maintaining pore stability has made it a promising technology in detecting biomolecules at the single molecule level. One of the current methods for fabricating these solid-state nanopores uses a low energy ion beam, $\sim$ 3 keV, incident on a 100nm diameter hole in a silicon nitride membrane to close it to a smaller diameter. Because of individual variability in between samples, the time taken for pore closure can vary from a matter of seconds to a few hours. Because the error in the measured final diameter of the nanopore is proportional to the closure rate, this causes a wide variability in final nanopore diameter. In addition, the variations in stability and electrical noise level of these nanopores at experimental solution condition have also been observed. Here we use a tube furnace to investigate adventitious carbon and its effects on the closure rate. We also use the tube furnace to bake the silicon nitride nanopores after fabrication and investigate the effects on the stability of the pore and electrical noise in solution.

H1.00196 Cell mobility after endocytosis of carbon nanotubes , MASSOOMA PIRBHAI, THOMAS FLORES, SABRINA JEDLICKA, SLAVA V. ROTKIN, Lehigh University — Directed cell movement plays a crucial role in cellular behaviors such as neuronal cell division, cell migration, and cell differentiation. There is evidence in preclinical in vivo studies that small fields have successfully been used to enhance regrowth of damages spinal cord axons but with a small success rate. Fortunately, the evolution of functional biomaterials and nanotechnology may provide promising solutions for enhancing the application of electric fields in guiding neuron migration and neurogenesis within the central nervous system. In this work, we studied how endocytosis and subsequent retention of carbon nanotubes affects the mobility of cells under the influence of an electric field, including the directed cell movement.

H1.00197 Whole Protein Native Fitness Potentials , ESHEL FARAGGI, Research and Information Systems, LLC; IUPUI Biochem. and Mol. Bio. Dept.; NCH/OSU Battelle Center for Mathematical Medicine, ANDRZEJ KLOCZKOWSKI, Battelle Center for Mathematical Medicine, NCH/OSU, Columbus, Ohio, USA — Protein structure prediction can be separated into two tasks: sample the configuration space of the protein chain, and assign a fitness between these hypothetical models and the native structure of the protein. One of the more promising developments in this area is that of knowledge based energy functions. However, standard approaches using pair-wise interactions have shown shortcomings demonstrated by the superiority of multi-body-potentials. These shortcomings are due to residue pair-wise interaction being dependent on other residues along the chain. We developed a method that uses whole protein information filtered through machine learners to score protein models based on their likeness to native structures. For all models we calculated parameters associated with the distance to the solvent and with distances between residues. These parameters, in addition to energy estimates obtained by using a four-body-potential, DFIRE, and RWPlus were used as training for machine learners to predict the fitness of the models. Testing on CASP 9 targets showed that our method is superior to DFIRE, RWPlus, and the four-body potential, which are considered standards in the field.

H1.00198 Directional Mechanosensing in Myosin VI , YUBO YANG, RIINA TEHVER, Denison University — Myosin is a family of versatile motor proteins that perform various tasks, such as organelle transport, anchoring and cell deformation. Although the general mechanism of the motors has been fairly well established, details on dynamic aspects like force response of the motor, and force propagation are yet to be fully understood. In this poster, we present the response of the ATP binding region to force exerted on the tail domain in order to test the proposed tension-dependent gating mechanism of myosin VI processive motion. We employed the Self-Organized Polymer model in a computer simulation to explore the effect. Current results show that the ATP binding domain of myosin VI indeed exhibits tension dependence – both structurally and dynamically.

H1.00199 Aggregation of model amyloid insulin protein in crowding environments and under ac-electric fields , ZHONGLI ZHENG, BENXIN JING, University of Notre Dame, BRIAN MURRAY, MIRCO SORCI, GEORGES BELFORT, Rensselaer Polytechnic Institute, Y. ELAINE ZHU, University of Notre Dame — In vitro experiments have been widely used to characterize the misfolding/unfolding pathway characteristic of amylodogenic proteins. Conversion from natively folded amyloidogenic proteins to oligomers via nucleation is the accepted path to fibril formation upon heating over a certain lag time period. In this work, we investigate the effect of crowing environment and external electric fields on the pathway and kinetics of insulin, a well-established amyloid model protein by single fluorescence spectroscopy and imaging. With added co-solutes, such as glycerol and polyvinylpyrrolidone (PVP), to mimic the cellular crowding environments, we have observed that the lag time can be significantly prolonged. The lag time increases with increasing co-solute concentration, yet showing little dependence on solution viscosity. Conversely, applied ac-electric fields can considerably shorten the lag timewhen a critical ac-voltage is exceeded. The strong dependence of lag time on ac-frequency over a narrow range of 500 Hz-5 kHz indicates the effect of ac-electroosmosis on the diffusion controlled process of insulin nucleation. Yet, no conformational structure is detected with insulin under applied ac-fields, suggesting the equivalence of ac-polarization to the conventional thermal activation process for insulin aggregation. These finding suggest that at least the aggregation kinetics of insulin can be altered by local solution condition or external stimuli, which gives new insight to the treatment of amyloid related diseases.

H1.00200 Conformational dynamics of amyloid proteins at the aqueous interface[1] , MATTHEW ARMBRUSTER, NATHAN HORST, BRENDY AOKI, SAAD MALIK, PATRICIA SOTO, Creighton University — Amyloid proteins is a class of proteins that exhibit distinct monomeric and oligomeric conformational states hallmark of deleterious neurological diseases for which there are not yet cures. Our goal is to examine the extent of which the aqueous/membrane interface modulates the folding energy landscape of amyloid proteins. To this end, we probe the dynamic conformational ensemble of amyloids (monomer prion protein and Alzheimer's Ab protofilaments) interacting with model bilayers. We will present the results of our coarse grain molecular modeling study in terms of the existence of preferential binding spots of the amyloid to the bilayer and the response of the bilayer to the interaction with the amyloid.

H1.00201 Multiple attachments, heterogeneous binding and the high force tail in protein-protein binding force histograms , ANWESHA SARKAR, EDWARD KRAMKOWSKI, Wayne State University, ESSA MAYYAS, Henry Ford Hospital, PETER M. HOFFMANN, Wayne State University — Atomic Force Microscopy (AFM) is a useful tool in measuring protein-protein interactions. However, a "clean" interpretation of the obtained data is not always easy. For instance, rupture force histograms generally do not fit simple theories. In particular, there is a high force tail that is not accounted for. This tail has variously been attributed to multiple binding (even though obvious multiple ruptures are excluded from analysis) or heterogeneity in the binding geometry. Here, we present a combined approach to answer the question of how much of the high force tail can be attributed to either cause. We used surfaces with well-controlled densities of active sites (biotin) to control multiple attachments with a functionalized tip (avidin). We found that the presence of multiple attachments, while significant, accounts for only a fraction of the events in the high force tail of the distribution. We also performed Monte Carlo simulations to match experimental results with theoretical expectations, confirming the importance of possible bond heterogeneity in these types of measurements.

H1.00202 Study of the Agglomeration of 5 to 25nm Gold Nanoparticles as a Function of Viscosity and Ionic Concentration , ADAM STEFANKIEWICZ, TABBETHA DOBBINS, Rowan University — Gold nanoparticles (AuNPs) attached to carcinoma cells and treated with light irradiation are able to convert the light into heat energy, thus killing those cells. In order to get the particles to the affected area, they may be entered into the circulatory system where the environment is highly viscous and comprised of high salt concentrations. This study examines the aggregation behavior of gold nanoparticles under those conditions. Surface charge creates coulombic repulsion between particles. Likewise, highly viscous solutions will prevent aggregation by limiting the rate of transport of gold through the solution. This study examines the aggregation behavior of gold nanopartilces as a function of viscosity (varied using polyethylene glycol). The study also examines the role of excess ions in the solution (varied using 5-Bromo-4-chloro-3-indolyl phosphate disodium salt). The aggregation phenomena was explored using dynamic light scattering for particle size analysis. Early results are presented here.

H1.00203 Investigation of HT1080 tumor growth dynamics and ECM invasion in 3D , OSMAN N. YOGURTCU, Department of Mechanical Engineering, Johns Hopkins University, ANGELA M. JIMENEZ VALENCIA, MENG-HORNG LEE, Department of Chemical and Biomolecular Engineering, Johns Hopkins University, SEAN X. SUN, Department of Mechanical Engineering, Johns Hopkins University, DENIS WIRTZ, Department of Chemical and Biomolecular Engineering, Johns Hopkins University — Tumors are complex arrangements of tissues made up of several components, including dense masses of cancer cells and re-organized extracellular matrix (ECM). Recent studies have revealed the crucial role that extracellular matrix components have on single cancer cell behavior, but how the interaction of ECM components affects the growth dynamics of an entire tumor is not fully understood. Here, we use human derived fibrosarcoma cell (HT1080) aggregates in combination with live cell imaging, cryo-stat sectioning, immunostaining, and confocal imaging to study changes in cell aggregate size, proliferation, and spatial distribution within 3 dimensional (3D) matrices. We compare our experimental observations with a coupled partial differential equations based mathematical model to predict cell aggregate growth and cell density distribution and determine how cell interactions play a significant role in this dynamic growth. Using this model, we investigate the distinct contributions from cell migration, proliferation, cell-matrix interactions, and matrix remodeling to the aggregate dynamics.

H1.00204 Stochastic transcriptional activity results in precise RNA distribution profiles of-Drosophilagap genes , MIKHAIL TIKHONOV[1], Joseph Henry Laboratories of Physics, Princeton University, SHAWN LITTLE[2], Howard Hughes Medical Institute, Department of Molecular Biology, Princeton University, THOMAS GREGOR, Joseph Henry Laboratories of Physics, Lewis-Sigler Institute for Integrative Genomics, Princeton University — How can biological systems reliably achieve a precise and reproducible response if they are constructed of noisy components? Using a novel single-molecule precision method in fixed Drosophila embryos we simultaneously measure the RNA distribution profiles and the transcriptional activity of individual nuclei in absolute units. We show that these RNA profiles of early patterning genes are precise at 8% in absolute units, while the instantaneous activity of any one transcription site has an intrinsic noise exceeding 45%. Thus the remarkable precision of Drosophila patterning system is already achieved at the RNA level and requires neither transcriptional feedback nor special mechanisms to reduce transcription noise. Instead, noise is filtered using straightforward spatiotemporal averaging. We further show that in regions where patterning genes are maximally expressed, they are all produced at the same absolute rate. This universality across gap genes suggests that the observed RNA production rate and noise are independent of promoter details and are inherent to transcription in Drosophila.

H1.00205 Diblock organization of individual nucleoporin amino acid sequence determines overall structure and function of the nuclear pore complex , DAVID ANDO, University of California, Merced, YONG WOON KIM, Korea Advanced Institute for Science and Technology, ROYA ZANDI, University of California, Riverside, ED LAU, Lawrence Livermore National Laboratory, MICHAEL COLVIN, University of California, Merced, MICHAEL REXACH, University of California, Santa Cruz, AJAY GOPINATHAN, University of California, Merced — The transport of cargo across the nuclear membrane is highly selective and accomplished by a poorly understood mechanism involving hundreds of nucleoporins within the nuclear pore complex (NPC). Currently, there is no clear picture of the overall structure formed by this collection of proteins within the pore, primarily due to their disordered nature. We perform coarse grained simulations of both individual nucleoporins and grafted rings of nups mimicking the $in\ vivo$ geometry and supplement this with polymer brush modeling. Our results indicate that different regions or "blocks" of an individual NPC protein can have distinctly different forms of disorder and properties and that this appears to be a conserved feature. Furthermore, this block structure at the individual protein level is critical to the formation of a unique higher-order polymer brush architecture. Our results indicate that there exist transitions between distinct brush morphologies (open and closed states of the gate), which can be triggered by the presence of cargo with specific surface properties. The resulting transport mechanism, that we propose, is fundamentally different from existing models and points to a novel form of gated transport in operation within the NPC.

H1.00206 Identification of low frequency intramolecular vibrational modes in crystalline adenosine via high pressure Raman spectroscopy , SCOTT LEE, University of Toledo, A. ANDERSON, University of Waterloo — DNA is predicted to have an internal vibrational mode, below about 100 cm^{-1}, involving stretching motions of the hydrogen bonds between the basepairs. This mode is potentially important for mediating strand separation, an integral part of transcription and replication. Experiments are performed on ordered fibers and films containing many DNA molecules, while theoretical calculations are performed on single molecules. In addition to internal vibrations, solid samples also have external vibrations in which molecules within the unit cell vibrate against each other, meaning that the measured vibrational spectra will have both internal and external vibrations. Since these external vibrations are not calculated in theoretical calculations, the comparison between observed and calculated spectra is difficult. However, the restoring forces associated with the external modes are due to the long-range interactions between the neighboring molecules. Such modes are strongly affected by the application of high pressure. Internal modes are associated with much shorter ranged restoring forces, and are not affected so strongly by high pressure. Thus, high pressure experiments can determine whether the observed modes are internal or external in character. Here we report our high-pressure Raman studies of crystalline adenosine to reveal the nature of all the low-frequency vibrational modes.

H1.00207 Raman spectroscopic determination of the hydrogen bond length for the water of hydration of DNA

, N.J. TAO, Arizona State University, SCOTT LEE, University of Toledo, ALLAN RUPPRECHT, University of Stockholm — Raman spectroscopy is used to probe the nature of the hydrogen bonds which hold the water of hydration to DNA. The $\sim$ 3450 cm^{-1} molecular O-H stretching mode shows that the first 6 water molecules per base pair of the primary hydration shell are very strongly bound to the DNA. The observed shift in the peak position of this mode permits a determination of the length of the hydrogen bonds for these water molecules. These hydrogen bonds appear to be about 0.3 Å shorter than the hydrogen bonds in bulk water. The linewidth of this mode shows no significant changes above water contents of about 15 water molecules per base pair. This technique of using a vibrational spectroscopy to obtain structural information about the hydration shells of DNA could be used to study the hydration shells of other biomolecules.

H1.00208 Stem Cell Physics. Multiple-Laser-Beam Treatment of Parkinson's Disease[1]

, V. ALEXANDER STEFAN, Institute for Advanced Physics Studies, Stefan University, La Jolla, California 92037 — A novel method for the treatment of Parkinson's disease is proposed. Pluripotent stem cells are laser cultured, using ultrashort wavelength, (around 0.1 micron-ultraviolet radiation-with intensities of a few mW/cm^2), multiple laser beams.[2] The multiple-energy laser photons[3] interact with the neuron DNA molecules to be cloned. The laser created dopaminergic substantia nigra neurons can be, (theoretically), laser transplanted, (a higher focusing precision as compared to a syringe method), into the striatum or substantia nigra regions of the brain, or both.

H1.00209 Real-time autocorrelator for fluorescence correlation spectroscopy based on graphical-processor-unit architecture: method, implementation, and comparative studies[1]

, NICHOLAS LARACUENTE, CARL GROSSMAN, Swarthmore College — We developed an algorithm and software to calculate autocorrelation functions from real-time photon-counting data using the fast, parallel capabilities of graphical processor units (GPUs). Recent developments in hardware and software have allowed for general purpose computing with inexpensive GPU hardware. These devices are more suited for emulating hardware autocorrelators than traditional CPU-based software applications by emphasizing parallel throughput over sequential speed. Incoming data are binned in a standard multi-tau scheme with configurable points-per-bin size and are mapped into a GPU memory pattern to reduce time-expensive memory access. Applications include dynamic light scattering (DLS) and fluorescence correlation spectroscopy (FCS) experiments. We ran the software on a 64-core graphics pci card in a 3.2 GHz Intel i5 CPU based computer running Linux. FCS measurements were made on Alexa-546 and Texas Red dyes in a standard buffer (PBS). Software correlations were compared to hardware correlator measurements on the same signals.

[1]Supported by HHMI and Swarthmore College

H1.00210 Monte-Carlo Simulations of Drug Delivery on Biofilms[1]

, ALPER BULDUM, ANDREW SIMPSON, Department of Physics, The University of Akron, Akron, OH — The focus of this work is on biofilms that grow in the lungs of cystic fibrosis (CF) patients. A discrete model which describes the nutrient and biomass as discrete particles is created. Diffusion of the nutrient, consumption of the nutrient by microbial particles, and growth and decay of microbial particles are simulated using stochastic processes. Our model extends the complexity of the biofilm system by including the conversion and reversion of living bacteria into a hibernated state, known as persister bacteria. Another new contribution is the inclusion of antimicrobial in two forms: an aqueous solution and encapsulated in biodegradable nanoparticles. The bacteria population growth and spatial variation of drugs and their effectiveness are investigated in this work.

[1]Supported by NIH

H1.00211 Physical mode of bacteria and virus coevolution

, PU HAN, LIANG REN NIESTEMSKI, MICHAEL DEEM, Rice University — Single-cell hosts such as bacteria or archaea possess an adaptive, heritable immune system that protects them from viral invasion. This system, known as the CRISPR-Cas system, allows the host to recognize and incorporate short foreign DNA or RNA sequences from viruses or plasmids. The sequences form what are called "spacers" in the CRISPR. Spacers in the CRISPR loci provide a record of the host and predator coevolution history. We develop a physical model to study the dynamics of this coevolution due to immune pressure. Hosts and viruses reproduce, die, and evolve due to viral infection pressure, host immune pressure, and mutation. We will discuss the differing effects of point mutation and recombination on CRISPR evolution. We will also discuss the effect of different spacer deletion mechanisms. We will describe population structure of hosts and viruses, how spacer diversity depends on position within CRISPR, and match of the CRISPR spacers to the virus population.

H1.00212 A Molecular Dynamics Investigation of the Physical-Chemical Properties of Calicivirus Capsid Protein Adsorption to Fomites

, DAVID PEELER, SILVINA MATYSIAK, Fischell Department of Bioengineering, University of Maryland, College Park — Any inanimate object with an exposed surface bears the possibility of hosting a virus and may therefore be labeled a fomite. This research hopes to distinguish which chemical-physical differences in fomite surface and virus capsid protein characteristics cause variations in virus adsorption through an alignment of in silico molecular dynamics simulations with in vitro measurements. The impact of surface chemistry on the adsorption of the human norovirus (HNV)-surrogate calicivirus capsid protein 2MS2 has been simulated for monomer and trimer structures and is reported in terms of protein-self assembled monolayer (SAM) binding free energy. The coarse-grained MARTINI forcefield was used to maximize spatial and temporal resolution while minimizing computational load. Future work will investigate the FCVF5 and SMSVS4 calicivirus trimers and will extend beyond hydrophobic and hydrophilic SAM surface chemistry to charged SAM surfaces in varying ionic concentrations. These results will be confirmed by quartz crystal microbalance experiments conducted by Dr. Wigginton at the University of Michigan. This should provide a novel method for predicting the transferability of viruses that cannot be studied in vitro such as dangerous foodborne and nosocomially-acquired viruses like HNV.

H1.00213 Physics - The Difference between Life and Death: III. Great Height , SAAMI J. SHAIBANI, Independent Modeling, Algorithms & Analytical Studies (IMAAS) — Although calculation of the maximum survivable height from which a human can fall is problematic, it is reasonable to opine that the probability of non-fatality in a descent of some 500 feet from the roof of a building is exceptionally low. When two brothers simultaneously experienced such an event, one lived and the other did not [1]. (Note: A nominally similar fall by another male also resulted in survival [2].) The general methodology for resolving such diverse outcomes is explained in other work [3,4], which provides some background for this study. Differentiation between the two subject adult males was limited by a lack of sufficient specificity in available data; however, it is still possible to consider the relevant physics principles and thereby examine the issues involved. Injury mechanisms are discussed and comparisons with other traumatic environments are made. The latter are included because their everyday nature provides a helpful illustration for learning.

H1.00214 Bone strength and athletic ability in hominids: *Ardipithecus ramidus* to *Homo sapiens* , S.A. LEE, University of Toledo — The ability of the femur to resist bending stresses is determined by its midlength cross-sectional geometry, its length and the elastic properties of the mineral part of the bone. The animal's athletic ability, determined by a "bone strength index," is limited by this femoral bending strength in relation to the loads on the femur. This analysis is applied to the fossil record for *Homo sapiens, Homo neanderthalensis, Homo erectus, Homo habilis, Australopithecus afarensis* and *Ardipithecus ramidus*. Evidence that the femoral bone strength index of modern *Homo sapiens* has weakened over the last 50,000 years is found.

H1.00215 Modeling Light-Dependent Biofilm Morphology , CHASE KERNAN, JEAN HUANG, REBECCA CHRISTIANSON, Franklin W. Olin College of Engineering — Bacterial aggregates on submerged substrates can produce complex biofilm morphologies that are subject to environmental and metabolic factors. We develop a reductionistic cellular automata model of these structures with the intent of guiding experimentation and explaining prior results. We focus on reproducing the columnar and "mushroom" phases of aerobic *R. palustris* and light-sensitive anaerobic *R. palustris*, respectively. This light sensitivity requires the novel inclusion of a characteristic light penetration depth in addition to surface tension and media penetration parameters. We quantitatively divide this parameter space into roughly four morphological phases—columnar, mushroom, uniform, and irregular—by examining the resultant convexity defect distribution, horizontal correlation, and coverage as a function of height. Finally, we both validate experimental evidence of these phases and suggest new parameter regimes to investigate empirically.

H1.00216 Vision below threshold: why it can be beneficial to waste photons , MORITZ KREYSING, Department of Physics, LMU Munich, Germany, KRISTIAN FRANZE, Department of Physiology, Development and Neuroscience, Cambridge University, UK, MIKE FRANCKE, ANDREAS REICHENBACH, Paul Flechsig Institute, University of Leipzig, Germany, JOCHEN GUCK, Biotechnology Center, TU Dresden, Germany — Vision at low light intensities relies on photoreceptors being able to detect individual photons. As an accepted rule, the light sensitive portions of vertebrate rods and cones, namely outer segments, increase in volume the darker the animals' habitat gets in order to enhance the probability to capture incident photons. Consequently, the biggest outer segments are found in fish living in the deep sea. A peculiar exception to this rule are the eyes of some deep sea fish, as well as fish living in highly turbid rivers. In their retinas relatively short outer segments are bundled into spatially isolated groups, clearly not meant to maximize the probability of photon absorption. Based on a detailed morphological and optical study of multilayer light-collectors surrounding these segments [1], we argue that under extreme conditions in which quantum noise, i.e. the rate of spontaneous photo-pigment activation, becomes comparable to the rate of photon arrival, visual sensitivity cannot be achieved by large outer segments anymore. Instead the retinal focusing of light on very small receptors is the only way to lower the visual threshold further, or to see at near IR wavelengths, even though this means partial photon loss. H1.00217 Bioinspired quantum heat engines , DMITRI VORONINE, Texas A&M University, KONSTANTIN DORFMAN, SHAUL MUKAMEL, University of California, Irvine, MARLAN SCULLY, Texas A&M University — Quantum mechanics and thermodynamics have deep connections which govern the behavior of laser and photocell quantum heat engines (QHEs). We describe QHEs inspired by photosynthesis that operate under the natural conditions of incoherent excitation by sunlight. We investigate parameter regimes where large electric current yield enhancement and/or population oscillations are observed and identify noise-induced quantum coherence as the common origin of these effects. Quantum coherence plays a role in enhancing energy and charge transfer efficiencies and holds promise for improving the design and boosting the efficiencies of light-harvesting devices. A broad range of parameter regimes provides flexibility in designs and materials.

H1.00218 PHYSICS EDUCATION –

H1.00219 The Meaning of the Temperature , GREGORIO RUIZ-CHAVARRIA, Universidad Autonoma Chapingo — While the concept of temperature is routinely used in daily life, its meaning is very confusing for the vast majority of ordinary humans. The main reason of this study is to provide a discussion about this concept in order to try to clarify its meaning. In most of the high school and college courses handled this concept saying that the temperature is a fraction of the average kinetic energy of the molecules that make up the body. Using this definition of temperature, a thermometer should then measuring the kinetic energy of the system under study, which does not. Then present a discussion about the meaning of temperature, analyzing which is the operating principle of some thermometers, leading the discussion in terms of the balance between two systems and we see that the interpretation of temperature as a fraction of the average kinetic energy, is an interpretation only at this level.

H1.00220 Indiana Wesleyan University SPS Physics Outreach to Rural Middle School and High School Students[1] , JOSHUA OSTRANDER, HEATH ROSE, ROBERT BURCHELL, ROBERTO RAMOS, Indiana Wesleyan University — The Society of Physics Students chapter at Indiana Wesleyan University is unusual in that it has no physics major, only physics minors. Yet while just over a year old, IWU-SPS has been active in performing physics outreach to middle school and high school students, and the rural community of Grant County. Our year-old SPS chapter consists of majors from Chemistry, Nursing, Biology, Exercise Science, Computer Science, Psychology, Pastoral Studies, and Science Education, who share a common interest in physics and service to the community. IWU currently has a physics minor and is currently working to build a physics major program. Despite the intrinsic challenges, our multi-disciplinary group has been successful at using physics demonstration equipment and hands-on activities and their universal appeal to raise the interest in physics in Grant County. We report our experience, challenges, and successes with physics outreach. We describe in detail our two-pronged approach: raising the level of physics appreciation among the IWU student community and among pre-college students in a rural community of Indiana.

[1]Acknowledgements: We acknowledge the support of the Society of Physics Students through a Marsh White Outreach Award and a Blake Lilly Prize.

H1.00221 Investigation of Nematode Diversity using Scanning Electron Microscopy and Fluorescent Microscopy[1]

, TAYLOR SEACOR, CARINA HOWELL, Lock Haven University — Nematode worms account for the vast majority of the animals in the biosphere. They are colossally important to global public health as parasites, and to agriculture both as pests and as beneficial inhabitants of healthy soil. Amphid neurons are the anterior chemosensory neurons in nematodes, mediating critical behaviors including chemotaxis and mating. We are examining the cellular morphology and external anatomy of amphid neurons, using fluorescence microscopy and scanning electron microscopy, respectively, of a wide range of soil nematodes isolated in the wild. We use both classical systematics (e.g. diagnostic keys) and molecular markers (e.g. ribosomal RNA) to classify these wild isolates. Our ultimate aim is to build a detailed anatomical database in order to dissect genetic pathways of neuronal development and function across phylogeny and ecology.

H1.00222 On-Ramp: Improving students' understanding of lock-in amplifiers[1]

, SETH DEVORE, CHANDRALEKHA SINGH, JEREMY LEVY, University of Pittsburgh — A lock-in amplifier is a powerful and versatile instrument which is used frequently in condensed matter physics research. However, many students struggle with the basics of a lock-in amplifier and they have difficulty in interpreting the data obtained with this device in diverse applications. To improve students' understanding, we are developing an "On-Ramp" tutorial based on physics education research which makes use of a computer simulation of a lock-in amplifier. During the development of the tutorial we interviewed several faculty members and graduate students. The tutorial is based on a field-tested approach in which students realize their difficulties after predicting the outcome of experiments that use a lock-in amplifier; students can check their predictions using simulations. The tutorial then guides students toward a coherent understanding of the basics of a lock-in amplifier. This poster will discuss the development and assessment process.

H1.00223 Improving Performance through Motivation: Teaching Biology Pre-Med Students Physics

, ELENA GREGG, Oral Roberts University — Several major factors which affect students' learning are assessed (curricula, different teaching approaches, assessment methods, engagement, and motivation). Direct connection between motivation, attitudes, self-confidence and achievement was established. It was demonstrated that improvement of motivation and self-confidence among students (particularly females, minorities and low achievers) is essential. Effectiveness of different instructional methods and motivational approaches was analyzed and evaluated in algebra-based Physics course for Biology pre-med undergraduate students.

H1.00224 Using In-class Group Exercises to Enhance Lectures and Provide Introductory Physics Students an Opportunity to Perfect Problem Solving Skills through Interactions with Fellow Students

, JOSEPH TROUT, JARED BLAND, Richard Stockton College of NJ — In this pilot project, one hour of lecture time was replaced with one hour of in-class assignments, which groups of students collaborated on. These in-class assignments consisted of problems or projects selected for the calculus-based introductory physics students The first problem was at a level of difficulty that the majority of the students could complete with a small to moderate amount of difficulty. Each successive problem was increasingly more difficult, the last problem being having a level of difficulty that was beyond the capabilities of the majority of the students and required some instructor intervention. The students were free to choose their own groups. Students were encouraged to interact and help each other understand. The success of the in-class exercises were measured using pre-tests and post-tests. The pre-test and post-test were completed by each student independently. Statistics were also compiled on each student's attendance record and the amount of time spent reading and studying, as reported by the student. Statistics were also completed on the student responses when asked if they had sufficient time to complete the pre-test and post-test and if they would have completed the test with the correct answers if they had more time. The pre-tests and post-tests were not used in the computation of the grades of the students.

H1.00225 Improving Science Teacher Preparation through the APS PhysTEC and NSF Noyce Programs[1]

, TASHA WILLIAMS, MICHEAL E. TYLER, ANDREA VAN DUZOR, MEL SABELLA, Chicago State University — Central to the recruitment of students into science teaching at a school like CSU, is a focus on the professional nature of teaching. The purpose of this focus is twofold: it serves to change student perceptions about teaching and it prepares students to become teachers who value continued professional development and value the science education research literature. The Noyce and PhysTEC programs at CSU place the professional nature of teaching front and center by involving students in education research projects, paid internships, attendance at conferences, and participation in a new Teacher Immersion Institute and a Science Education Journal Reading Class. This poster will focus on specific components of our teacher preparation program that were developed through these two programs. In addition we will describe how these new components provide students with diverse experiences in the teaching of science to students in the urban school district.

H1.00226 GENERAL —

H1.00227 Resources for startup and growing businesses in the science and engineering sectors[1]

, JOSEPH SABOL[2], Chemical Consultant — The American Chemical Society provides resources for members involved in forming startup and growing small businesses in the chemical and related sectors. In particular, the ACS Division of Small Chemical Businesses SCHB provides member benefits, informative programming at national and regional meetings, and networking opportunities for entrepreneurs. SCHB member benefits include listing in a directory of members' products and services, discounted expo booth rental at ACS national meetings, sponsorship to attend ACS leadership development courses, volunteer opportunities to shape and direct SCHB's operations, multiple social networking platforms, and professional networking opportunities with like-minded and similarly situated small business principals. SCHB's mission is "To aid in the formation, development and growth of small chemical businesses." SCHB collaborates with other units in ACS, including local sections, the Chemical Entrepreneurship Council, the Division of Business Development & Management, Entrepreneurial Initiative, and Career Services. SCHB helps chemists gain skills to translate research into commercially successful products; build strong, growing companies that create jobs; and collaborate with professionals outside the chemical community.

H1.00228 The 2014 Gordon Research Conference: Physics Research & Education: The Complex Intersection of Biology and Physics , MEL SABELLA, Chicago State University, MATTHEW LANG, Vanderbilt University — The field of biological physics and the physics education of biology and medically oriented students have experienced tremendous growth in recent years. New findings, applications, and technologies in biological and medical physics are having far reaching consequences that affect and influence the science community, the education of future scientists and health-care workers, and the general population. As a result leaders in Physics Education Research have begun to focus their attention on the specific needs of students in the biological sciences, the different ways physicists and biologists view the nature of science and the interactions of scientists in these disciplines. In this poster we highlight some of these findings and pose questions for discussion. The Complex Intersection of Biology and Physics will be the topic of the next Gordon Research Conference on Physics Research and Education to be held in June 2014. The exact date and location are still to be determined.

H1.00229 A Descriptive Approach to the Geometric Phase , MATTHEW RAVE, JEFF LAWSON, Western Carolina University — Geometric phase in a dynamical system can be visualized as the interplay between two characteristic periods of a closed orbit which go in and out of "synch." We present several intuitive examples of such systems that are suitable for physics instruction. We then examine the details of a simple mechanical system on a torus to illustrate two specific approaches to determining the geometric phase: direct computation from the equations of motion, and the use of conservation laws. The elegance and simplicity of the latter approach can be explained by observing invariants under an action of the planar rotation group on the torus. We conclude by describing (in brief) how this approach extrapolates to the general method of reduction by symmetry.

H1.00230 Spiral Galaxy Central Bulge Tangential Speed of Revolution Curves , LAURENCE TAFF[1], Taff and No Associates — The objective was to, for the first time in a century, scientifically analyze the "rotation curves" (sic) of the central bulges of scores of spiral galaxies. I commenced with a methodological, rational, geometrical, arithmetic, and statistical examination—none of them carried through before—of the radial velocity data. The requirement for such a thorough treatment is the paucity of data typically available for the central bulge: fewer than 10 observations and frequently only five. The most must be made of these. A consequence of this logical handling is the discovery of a unique model for the central bulge volume mass density resting on the positive slope, linear, rise of its tangential speed of revolution curve and hence—for the first time—a reliable mass estimate. The deduction comes from a known physics-based, mathematically valid, derivation (not assertion). It rests on the full (not partial) equations of motion plus Poisson's equation. Following that is a prediction for the gravitational potential energy and thence the gravitational force. From this comes a forecast for the tangential speed of revolution curve. It was analyzed in a fashion identical to that of the data thereby closing the circle and demonstrating internal self-consistency. This is a hallmark of a scientific method-informed approach to an experimental problem. Multiple plots of the relevant quantities and measures of goodness of fit will be shown.

H1.00234 Undergraduate Physics Education at Radcliffe and Harvard 1895-1953 , JOANNA BEHRMAN, Harvard University — The effort to get more women to continue in physics is ongoing and many hypotheses exist as to why the gender ratio lags more in physics than in other fields. A historical investigation can offer insights to the origin of this persistent problem. Radcliffe College offered to female students an education supposedly equivalent to that offered to male students at Harvard. I track physics classes at Radcliffe and Harvard from Radcliffe's charter year to the year the physics classes fully merged. Data on instructors, enrollment, and later employment offers insights to trends in physics education over time and how the genders were affected differently even when multiple variables are isolated across the two single-gender groups.

H1.00235 New research in Superconductivity , MONA KHORRAMI, Sanofi Groupe Co. — Superconductors are materials that have no resistance to electricity's flow; they are one of the last great frontiers of scientific discovery. The theories that explain superconductor behavior seem to be constantly under review. In 1911 superconductivity was first observed in mercury by Dutch physicist Heike Kamerlingh Onnes When he cooled it to the temperature of liquid helium, 4 degrees Kelvin (-452F, -269C), its resistance suddenly disappeared. It was necessary for Onnes to come within 4 degrees of the coldest temperature that is theoretically attainable to witness the phenomenon of superconductivity. In 1933 German researchers Walther Meissner and Robert Ochsenfeld discovered that a superconducting material will repel a magnetic field. A magnet moving by a conductor induces currents in the conductor, but, in a superconductor the induced currents exactly mirror the field that would have otherwise penetrated the superconducting material - causing the magnet to be repulsed. This phenomenon is known as strong diamagnetism and is today often referred to as the "Meissner effect" (an eponym). Later on the theory developed by American physicists John Bardeen, Leon Cooper, and John Schrieffer together with extensions and refinements of the theory, which followed in the years after 1957, succeeded in explaining in considerable detail the properties of superconductors.

H1.00236 ATOMIC, MOLECULAR AND OPTICAL (AMO) PHYSICS —

H1.00237 Time-reversal-invariant Hofstadter-Hubbard model with ultracold fermions , PETER P. ORTH, Karlsruhe Institute of Technology (KIT), Germany, DANIEL COCKS, Institut fuer Theoretische Physik, Goethe Universitaet, 60438 Frankfurt/Main, Germany, STEPHAN RACHEL, Institute for Theoretical Physics, Dresden University of Technology, 01062 Dresden, Germany, MICHAEL BUCHHOLD, Institut fuer Theoretische Physik, Universitaet Innsbruck, Austria, KARYN LE HUR, [1] Center for Theoretical Physics, Ecole Polytechnique, CNRS, 91128 Palaiseau Cedex, France; [2] Yale University, WALTER HOFSTETTER, Institut fuer Theoretische Physik, Goethe Universitaet, 60438 Frankfurt/Main, Germany — We consider the time-reversal-invariant Hofstadter-Hubbard model which can be realized in cold-atom experiments [1]. In these experiments, an additional staggered potential and an artificial Rashba-type spin-orbit coupling are available. Without interactions, the system exhibits various phases such as topological and normal insulator, metal as well as semi-metal phases with two or even more Dirac cones. Using a combination of real-space dynamical mean-field theory and analytical techniques, we discuss the effect of on-site interactions and determine the corresponding phase diagram. In particular, we investigate the semi-metal to antiferromagnetic insulator transition and the stability of different topological insulator phases in the presence of strong interactions. We compute spectral functions which allow us to study the edge states of the strongly correlated topological phases. [1] Daniel Cocks, Peter P. Orth, Stephan Rachel, Michael Buchhold, Karyn Le Hur, and Walter Hofstetter, arXiv:1204.4171 (2012) (accepted for Phys. Rev. Lett.)

H1.00238 Progress towards generating spin-squeezed sodium Bose-Einstein condensates , JIE JIANG, LICHAO ZHAO, MICAH WEBB, YINGMEI LIU, Department of Physics, Oklahoma State University, Stillwater, OK 74078 — A coherent spin-state is an unentangled state with all spins aligned in the same direction, while the spin degrees of freedom of atoms become entangled in spin-squeezed states. Spin-squeezing has attracted much attention for its potential to improve the sensitivity of spin-resonance measurements. We present the design and construction of a novel apparatus to generate spin-squeezing with sodium Bose-Einstein condensates (BECs) in optical lattices. Spin-squeezing requires an interaction among atoms to suppress spin noise. Different types of interactions in BECs are exploited in our system: atom-light interaction via a quantum non-demolition measurement, self interactions and elastic collisions controlled by spin-dependent potentials, and spin-exchange collisions. We will also discuss a possibility of using sequences of universal pulses to control loss of entanglement due to decoherence from environmental effects.

H1.00239 ABSTRACT WITHDRAWN —

H1.00240 Route to Observable Fulde-Ferrell-Larkin-Ovchinnikov Phases in 3D Spin-Orbit Coupled Degenerate Fermi Gases , ZHEN ZHENG, Key Laboratory of Quantum Information, University of Science and Technology of China, MING GONG, Department of Physics, the University of Texas at Dallas, XUBO ZOU, Key Laboratory of Quantum Information, University of Science and Technology of China, CHUANWEI ZHANG, Department of Physics, the University of Texas at Dallas, GUANGCAN GUO, Key Laboratory of Quantum Information, University of Science and Technology of China, KEY LABORATORY OF QUANTUM INFORMATION, UNIVERSITY OF SCIENCE AND TECHNOLOGY OF CHINA TEAM, DEPARTMENT OF PHYSICS, THE UNIVERSITY OF TEXAS AT DALLAS TEAM — The Fulde-Ferrell-Larkin-Ovchinnikov (FFLO) phase, a superconducting state with non-zero total momentum Cooper pairs in a large magnetic field, was first predicted about 50 years ago. Recently, the possibility of observing FFLO states using ultracold degenerate Fermi gases has sparked tremendous interest. However, unambiguous experimental evidence for FFLO states is still elusive because of the stringent parameter requirement in experiments. Here, we show that a giant parameter regime for FFLO states can be obtained in 3D degenerate Fermi gases in the presence of spin-orbit coupling and an in-plane Zeeman field, two ingredients that were already developed for cold atoms in recent experiments. The predicted FFLO state is stable against quantum fluctuations due to the 3D geometry, and can be observed with experimentally already achieved temperature, thus opens a new fascinating avenue for exploring FFLO physics in degenerate Fermi gases.

H1.00241 ABSTRACT WITHDRAWN —

H1.00242 Quantum mechanical toolbox to study the dirty crossover in cold atomic gases[1] , B. TANATAR, Department of Physics, Bilkent University, 06800, Ankara, Turkey, AYAN KHAN, Bilkent University, Department of Physics, 06800, Ankara, Turkey, SAURABH BASU, Department of Physics, Indian Institute of Technology-Guwahati, Guwahati, India — We consider an ultracold atomic gas exhibiting the BCS-BEC crossover as the short-range interaction strength (characterized by the scattering length) is increased. In particular, we investigate the dirty crossover (for a disoredered gas) by means of the fidelity susceptibility (FS). Fidelity susceptibility is related to the overlap between the ground states of different phases. The disorder is incorporated in the mean-field formalism through Gaussian fluctuations. We observe a rise of asymmetric nature in the FS with increasing disorder which might be an indication for an impending quantum phase transition (QPT). We analyze our results for the FS and the density of states using the statistical tools such as skewness and kurtosis.

H1.00243 Quench dynamics of interacting impurity boson in boson sea[1] , HUIJIE GUAN, DEEPAK IYER, NATAN ANDREI, Department of Physics and Astronomy, Rutgers University — We use the Yudson Representation to study the quench dynamics of a system consisting of a one dimensional gas of interacting bosons and a mobile impurity boson. We are able to get an exact solution for finite coupling constant and finite time for two particles. To solve for more particles, long time approximation is made to simplify the calculation. We calculate the time evolution of impurity density and noise correlation and compare the results with experimental data.

[1]The work is supported by NSF grant DMR 1006684.

H1.00244 The physics of SU(4) alkaline-earth-atom-based Kondo lattice model at the Toulouse point , SOLOMON F. DUKI, HONG LING, Rowan University — The study of ultracold alkaline-earth atoms has gained significant attention due largely to recent efforts to employ ultracold alkaline-earth atoms as a unique platform to explore quantum computing and many-body physics. For alkaline-earth atoms, there is an almost perfect decoupling of the nuclear spin from the electronic angular momentum in both the ground and the metastable states. This along with the existence of relatively high nuclear spin degrees of freedom makes the cold alkaline-earth atoms an excellent candidate that one can employ to study Kondo effects with higher SU(N) spin degrees of freedom. In this work, we focus on a mixture of two-component fermionic alkaline-earth atoms loaded in external optical lattice potentials and treat it as an cold atom implementation of SU(4) Kondo lattice model. We apply bosonization and canonical transformation to obtain an exactly solvable point (the so-called Toulouse point). We study the physics of the system at the Toulouse point by calculating various correlation functions in the parameter regimes that are experimentally accessible to cold atom experiments. This work is supported by the US National Science Foundation and the US Army Research Office.

H1.00246 Bound states of fermions with short-range interactions in the presence of spin-orbit coupling and Zeeman fields , DOGA MURAT KURKCUOGLU, PhD Student, C. A. R. SA DE MELO, Professor — We discuss the emergence of two-particle bound states of spin-$1/2$ fermions in the presence of Zeeman fields for arbitrary mixtures of Dresselhaus and Rashba spin-orbit couplings, under the assumption that interactions are short-ranged and occur only in the s-wave channel. In this case, we calculate explicitly binding energies and effective masses and analyze their dependence on spin-orbit couplings, Zeeman fields and interactions. Finally, we note that such exact two-body results serve as important benchmarks for the construction of many-particle wavefunctions that recover the few-particle regime in the low density limit.

H1.00247 Fractional topological phase in one-dimensional flat bands with nontrivial topology , HUAIMING GUO, Department of Physics, Beihang University — We show the existence of the fractional topological phase (FTP) in a one-dimensional interacting fermion model using exact diagonalization, in which the noninteracting part has flat bands with nontrivial topology. In the presence of the nearest-neighboring interaction V_1, the FTP at filling factor $\nu = 1/3$ appears. It is characterized by the threefold degeneracy and the quantized total Berry phase of the ground states. The FTP is destroyed by a next-nearest-neighboring interaction V_2, and the phase diagrams in the (V_1, V_2) plane are determined. We also present a physical picture of the phase and discuss its existence in the nearly flat band. Within the picture, we argue that the FTP at other filling factors can be generated by introducing proper interactions. The present study contributes to a systematic understanding of the FTPs and can be realized in cold-atom experiments.

H1.00248 Manipulating Topological Edge Spins in One-Dimensional Optical Lattice[1] , XIONG-JUN LIU, University of Maryland, College Park, ZHENG-XIN LIU, Institute for Advanced Study, Tsinghua University, MENG CHENG, University of Maryland, College Park — We propose to observe and manipulate topological edge spins in 1D optical lattice based on currently available experimental platforms. Coupling the atomic spin states to a laser-induced periodic Zeeman field, the lattice system can be driven into a symmetry protected topological (SPT) phase, which belongs to the chiral unitary (AIII) class protected by particle number conservation and chiral symmetries. In free-fermion case the SPT phase is classified by a Z invariant which reduces to Z_4 with interactions. The zero edge modes of the SPT phase are spin-polarized, with left and right edge spins polarized to opposite directions and forming a topological spin-qubit (TSQ). We demonstrate a novel scheme to manipulate the zero modes and realize single spin control in optical lattice. The manipulation of TSQs has potential applications to quantum computation.

H1.00249 Interference Signatures of Abelian and Non-Abelian Aharonov-Bohm effect on Neutral Atoms in Optical Lattices , MING-XIA HUO, NIE WEI, Centre for Quantum Technologies, National University of Singapore, DAVID A.W. HUTCHINSON, CQT, National University of Singapore; Centre for Quantum Technology, Department of Physics, University of Otago, New Zealand, LEONG CHUAN KWEK, Centre for Quantum Technologies, National University of Singapore; IAS and NIE, Nanyang Technological University — We propose a scheme to generate an effective Abelian U(1) or non-Abelian SU(2) gauge field for cold neutral atoms in a ring- or square-shaped optical lattice by using Laguerre-Gauss lasers. The synthetic field produced is strongly localized, which allows us to study the Aharonov-Bohm effect on the neutral atoms. By preparing a coherent state of atoms initially and allowing them to evolve along two different paths enclosing the generated magnetic field, we obtain interference signatures of the Aharonov-Bohm effect with distinctly different patterns in the detection area for systems exposed to a zero, an Abelian U(1) or a non-Abelian SU(2) gauge field.

H1.00250 Quantum Control of the Spin-Orbit Interaction Using the Autler-Townes Effect , ERGIN AHMED, SONIA INGRAM, TEODORA KIROVA, OMER SALIHOGLU, Temple University, JOHN HUENNEKENS, Lehigh University, JIANBING QI, Penn State University, Berks Campus, YAFEI QUAN, MARJATTA LYYRA, Temple University — The interaction between the spin and the orbital angular momenta (spin-orbit interaction) of the electron in an atom or a molecule often can be neglected or treated as a perturbation. However, when relativistic effects are not negligible, the spin-orbit interaction must be taken into account. It can cause mixing of electronic states of different spin multiplicity, with the degree of mixing dependent on the strength of the spin-orbit interaction as well as the energy separation between the interacting states. It is also well known that, in the presence of strong electromagnetic fields, the energy levels in atoms or molecules experience shifts in their positions due to the Autler-Townes (AT) effect. Thus control of the spin-orbit interaction can be realized by using resonant or nonresonant laser fields as an external control mechanism. We have demonstrated [1] experimentally such control of the spin-orbit interaction using resonant cw optical field. We show that the enhancement of the spin-orbit interaction between a pair of weakly interacting singlet-triplet rovibrational levels, $1^3\Sigma_g^-$(v=1, N =21, f) – $G^1\Pi_g$(v=12, J =21, f), depends on the Rabi frequency (laser power) of the control laser. The increase in the spin-orbit interaction due to the control field is observed as a change in the spin character of the individual components of the perturbed pair.

H1.00251 ABSTRACT WITHDRAWN –

H1.00252 Lithium as a refrigerant for polar molecules , A. KAUSHIK, S.K. TOKUNAGA, R.J. HENDRICKS, E.A. HINDS, M.R. TARBUTT, Imperial College London — Gases of ultracold polar molecules offer exciting new possibilities in many areas, including precision measurements [1], simulations of many-body quantum systems [2], and quantum information processing [3]. We aim to cool polar molecules by sympathetic cooling with ultracold atoms inside a suitable trap [4]. This poster presents our work on the production and transportation of a dense ultracold cloud of lithium for use as a refrigerant in sympathetic cooling. Up to 10^{10} lithium atoms are loaded from a Zeeman slower into a magneto-optical trap. Using a moving magnetic trap the atoms are transported to a separate chamber where they will later be co-trapped with molecules. We present the design of our setup and our recent results on transport. We also explore the possibility of electrically polarizing the lithium so that dipole-dipole interactions become important in the gas.

H1.00253 K-Shell Dielectronic Recombination for Si^{5+} and Ar^{9+} Ions , SHAHIN ABDEL-NABY, Department of Physics, Beni-Suef University, FAYEZ SHAHIN, Department of Physics, Beni-Suef University, Egypt — Dielectroinic recombination (DR) is the dominant electron-ion recombination process for most of the ions found in low density photoionized plasmas and low-to-medium density electron collisionally ionized plasmas. Accurate DR rate coefficients are needed for plasma modeling. We report on K-shell DR cross sections and rate coefficients of Si^{5+} and Ar^{9+} ions. The DR cross sections are calculated in the angular momentum average scheme. The dominant contributions to the DR cross sections and rate coefficients are obtained from the $1s2s^22p^6np$ resonant states. The total DR rates increase as the effective charge of the ions increases and the peaks of these rates are shifted toward higher incident electron energies as the degree of ionization increases.

H1.00254 A spin-flip Zeeman slower controlled by a fast feedback circuit , LICHAO ZHAO, JIE JIANG, MICAH WEBB, YINGMEI LIU, Department of Physics, Oklahoma State University, Stillwater, OK 74078 — We present an effective setup for a spin-flip Zeeman slower controlled by a fast feedback circuit. Our experimental data demonstrate an efficient method to optimize the Zeeman slower for trapping more alkali atoms in a magneto-optical trap. In addition, we confirm that our feedback circuit can be applied to rapidly and simply control various magnetic fields used for creating atomic Bose-Einstein condensates and for studies related to magnetic Feshbach resonances.

H1.00255 Laser cooling molecules , VALENTINA ZHELYAZKOVA, AKI MATSUSHIMA, Imperial College London — Laser cooling is a simple technique routinely used to cool atoms down to temperatures in the mK range. As the presence of a closed transition is essential for the cooling to work, laser cooling is usually not tractable in molecules due to their complex structure. Molecules can rotate and vibrate and usually only scatter a few photons before they end up in a dark state. In particular, the molecule often changes a vibrational state in the absorption-emission cycle. Recently, a whole class of polar molecules (e.g. CaF, SrF, BaF and TiO) has been shown to possess a highly diagonal Franck-Condon matrix, which makes them viable candidates to be laser cooled. We demonstrate a scheme for laser cooling of a supersonic beam of CaF and SrF radicals. The Franck-Condon factor for the relevant transition makes it possible for the molecules to scatter 10^4 photons with only one or two vibrational repump lasers. We show evidence of longitudinal slowing and cooling in CaF and beam brightening and cooling in SrF.

H1.00256 Spectroscopic Characterization of Thulium doped Potassium Lead Chloride for Potential Applications in Optical Cooling , EI BROWN, HERBERT BROWN, UWE HOMMERICH, Hampton University, ALTHEA BLUIETT, Elizabeth City State University, SUDHIR TRIVEDI, Brimrose Corporation of America — Rare-earth doped solids have experienced increased attention for possible applications in anti-Stokes fluorescence cooling. Solid-state optical refrigeration offer several advantages over current bulky mechanical coolers including compact, lightweight, and vibration free. Most efforts have focused on optical cooling in Yb^{3+} doped solids and cooling down to ~155 K has been demonstrated. In this work, the optical properties of Tm^{3+} doped KPC were evaluated as a potential solid-state material for laser cooling applications. Following 1907 nm excitation, Tm:KPC exhibited infrared emission with a center wavelength of 1806 nm arising from the $^3F_4 \rightarrow {}^3H_6$ transition of Tm^{3+} ions. Under 1907nm pumping conditions, it was estimated that a quantum emission efficiency of at least 95% is required to achieve a net cooling effect in Tm:KPC. Based on temperature dependent decay time studies the emission quantum efficiency of Tm:KPC was estimated to be only ~75%. Employing the energy-gap law, non-radiative decay through multi-phonon relaxation is predicted to be negligibly small in Tm:KPC. Concentration quenching effects and/or energy transfer processes to other defects seems most likely to be responsible for the low quantum efficiency.

H1.00257 Infrared Emission and Upconversion Studies of Er^{3+} Doped in the Low Phonon-Energy Hosts KPb_2Cl_5 and KPb_2Br_5[1] , ALTHEA BLUIETT, Elizabeth City State University, EI EI BROWN, CRAIG HANLEY, UWE HOMMERICH, Hampton University, SUDHIR TRIVEDI, Brimrose Corporation of America — There continues to be interests in Er^{3+} doped materials that can generate efficient emission in the 1.5-1.6 um range for eye-safe laser applications and optical communications. Directly pumping the $^4I_{13/2}$ band of Er^{3+} has been extensively studied in many hosts, such as YAG, however, it is well understood that the excitation of Er^{3+} through this channel automatically generates unwanted upconversion emission, which depletes $^4I_{13/2}$ level of Er^{3+} and moreover produces unwanted heating of the crystal. In this study, cw and pulsed laser excitation of the $^4I_{13/2}$ band of Er^{3+} will be explored as a function of host material (KPb_2Cl_5 and KPb_2Br_5) rare-earth ion concentration, and temperature in the search for the optimum combination of variables to minimize upconversion and concurrently generate more efficient 1.5 μm emission from Er^{3+}.

H1.00258 Progress Towards a Quantum Memory with Telecom-Wavelength Conversion[1] , DANIEL STACK, QUDSIA QURAISHI, IAN GRISSOM, RONALD MEYERS, KEITH DEACON, ARNOLD TUNICK, PATRICIA LEE, US Army Research Laboratory — Fiber-based transmission of quantum information over long distances may be achieved using quantum memory elements and quantum repeater protocols.[2] However, atom-based quantum memories typically involve interactions with light fields outside the telecom window where attenuation in optical fibers is at a minimum. We report on progress towards a quantum memory based on the generation of 780 nm spontaneously emitted single photons by an off-resonant Raman beam interacting with a cold ^{87}Rb ensemble. The single photons are then frequency converted into telecom photons (via four-wave mixing in a cold Rb sample), sent through a 13 km fiber, and then converted back to 780 nm photons (via sum frequency generation in a PPLN crystal). Finally, the atomic state is read out via the interaction of another off-resonant Raman beam with the quantum memory. With such a system it will be possible to realize a long-lived quantum memory that will allow transmission of quantum information over many kilometers with high fidelity, essential for a scalable, long-distance quantum network.

H1.00259 Mimicking interacting relativistic theories with stationary pulses of light , DIMITRIS G. ANGELAKIS, Science Department, Technical University of Crete, Chania, Crete, Greece; Centre for Quantum Technologies, National University of Singapore, MING-XIA HUO, Centre for Quantum Technologies, National University of Singapore, DARRICK CHANG, ICFO, Institute of Photonic Sciences, Barcelona, Spain, LEONG CHUAN KWEK, Centre for Quantum Technologies, National University of Singapore; IAS and NIE, Nanyang Technological University, Singapore, VLADIMIR KOREPIN, C.N. Yang Institute for Theoretical Physics, State University of New York at Stony Brook, NY, USA — Photonic quantum simulations of one dimensional many-body systems have attracted renewed interest lately with works on photon crystallization and Luttinger liquids. In this work we show that the quantum Thirring model for interacting fermions in (1+1) dimension can be realized using stationary polaritons in hollow waveguides filled with atoms. By controlling optical parameters such as one-photon detunings and external laser intensities, the massless and the massive Thirring models are realizable. Coherently mapping the polaritons into propagating photons allows for the direct probing of the relevant correlation functions and scaling behaviours characteristic of the underlying theories in question.

H1.00260 Reduction of Cavity loss and Spontaneous Emission in Cavity QED , WAYNE MANRAKHAN, Delaware State University — An investigation of the entanglement dynamics of two atoms with a quantized cavity field in the presence of dissipation is undertaken. A study of the effects of spontaneous emission and cavity loss in our scheme shows how to reduce the effects of each independently in a bimodal cavity. Our computer numerical simulation results indicate that by choosing proper parameters one can reduce the effects of spontaneous emission and cavity loss.

H1.00261 Non-Equilibrium Quantum Impurity Physics with Hybrid Light-Matter Systems , KARYN LE HUR, Centre de Physique Theorique, Ecole Polytechnique, CNRS, 91128, Palaiseau Cedex, France, MARCO SCHIRO, Princeton Center for Theoretical Science and Department of Physics, Joseph Henry Laboratories, Princeton University, Princeton, NJ 08544, USA — Recent advances in quantum electronics allowed to engineer hybrid nano devices made by coupling on chip a quantum dot to a microwave resonator as well as to electron reservoirs maintained at different bias voltages. These systems realize novel platforms to explore non equilibrium quantum impurity physics with light and matter. Focusing on a simple model of a biased quantum dot coupled to a photon mode we elucidate the signatures of the electronic correlations in the phase of the transmitted microwave signal. In addition we illustrate the effect of the electronic degrees of freedom on the photon field, giving rise to anharmonicity, damping and dissipation, and discuss how to control these effects by means of gate and bias voltages.

H1.00262 A Luttinger liquid of photons and spin-charge separation in hollow-core waveguides , DIMITRIS G. ANGELAKIS, Centre for Quantum Technologies, National University of Singapore; Science Department, Technical University of Crete, Chania, Crete, Greece, MING-XIA HUO, ELICA KYOSEVA, Centre for Quantum Technologies, National University of Singapore, LEONG CHUAN KWEK, Centre for Quantum Technologies, National University of Singapore; IAS and NIE, Nanyang Technological University, Singapore — In this work we show that light-matter excitations (polaritons) generated inside a hollow one-dimensional fiber filled with two types of atoms, can exhibit Luttinger liquid behavior. We explain how to prepare and drive this quantum-optical system to a strongly interacting regime, described by a bosonic two-component Lieb Lininger model. Utilizing the connection between strongly interacting bosonic and fermionic systems, we show how spin-charge separation could be observed by probing the correlations in the polaritons. This is performed by first mapping the polaritons to propagating photon pulses and then measuring the effective photonic spin and charge densities and velocities by analyzing the correlations in the emitted photon spectrum. The necessary regime of interactions is achievable with current quantum optical technology.

H1.00263 Efficient Non-Resonant Absorption in Thin Cylindrical Targets: Experimental Evidence , ANDREY AKHMETELI, LTASolid Inc., Houston, Texas, USA, NIKOLAY KOKODIY, BORIS SAFRONOV, VALERIY BALKASHIN, IVAN PRIZ, Kharkov National University, Kharkov, Ukraine, ALEXANDER TARASEVITCH, University of Duisburg-Essen, Institute of Experimental Physics, Duisburg, Germany — A theoretical possibility of non-resonant, fast, and efficient (up to 40 percent) heating of very thin conducting cylindrical targets by broad electromagnetic beams was predicted in [Akhmeteli, arXiv:physics/0405091 and 0611169] based on rigorous solution of the diffraction problem. The diameter of the cylinder can be orders of magnitude smaller than the wavelength (for the transverse geometry) or the beam waist (for the longitudinal geometry) of the electromagnetic radiation. This can be used for numerous applications, such as pumping of active media of short-wavelength lasers, e.g., through efficient heating of nanotubes with laser radiation. Experimental confirmation of the above results is presented [Akhmeteli, Kokodiy, Safronov, Balkashin, Priz, Tarasevitch, arXiv:1109.1626 and 1208.0066]. Significant (up to 6%) absorption of microwave power focused on a thin fiber (the diameter is three orders of magnitude less than the wavelength) by an ellipsoidal reflector is demonstrated experimentally. For the longitudinal geometry, preliminary experiments provide a qualitative confirmation of significant absorption of the power of a wide CO2 laser beam propagating along a thin wire (the diameter of the wire can be orders of magnitude less than the beam waist width).

H1.00264 ABSTRACT WITHDRAWN –

H1.00265 Spectroscopic methods for calculation of electron density and temperature in laser generated Hydrogen plasma , MOHAMMADREZA REZAEE, Physics and Astronomy Department, The University of Tennessee Knoxville, CHRISTIAN PARIGGER, University of Tennessee Space Institute, Tullahoma, TN — Laser induced plasma spectroscopy has been around for several decades and has generated a lot of interest.Remote analyzing capability makes it favorable in applications where it is difficult to have an experimental probe physically there to do the measurements. One of these applications is in controlled fusion devices like Tokamaks in which Hydrogen and its isotopes are used as fuel. Having accurate knowledge of the plasma density and temperature is a key factor in plasma stability in confined plasma machines. Hydrogen lines are powerful tools in remote plasma diagnostics, and we can infer the plasma density and temperature from their broadening and shift. In a high power nanosecond-pulsed laser generated plasma, which is a transient phase and has a high electron density, Stark broadening is the dominant broadening mechanism and by measuring the FWHM of the broadened Hydrogen Balmer lines we calculated the electron density and temperature. We calculated the electron density by utilizing different available approaches and compared the results. There is difference between the electron density obtained from Stark broadened H_α at initial time after shot in comparison to that obtained from the H_β and H_γ, which is related to the strong self-absorption.

H1.00266 Colliding with the Speed of Light, Using Low-Energy Photon-Photon Collision Study the Nature of Matter and the universe , MEGGIE ZHANG, AISRO — Our research discovered logical inconsistence in physics and mathematics. Through reviewing the entire history of physics and mathematics we gained new understanding about our earlier assumptions, which led to a new interpretation of the wave function and quantum physics. We found the existing experimental data supported a 4-dimensional fractal structure of matter and the universe, we found the formation of wave, matter and the universe through the same process started from a single particle, and the process itself is a fractal that contributed to the diversity of matter. We also found physical evidence supporting a not-continuous fractal space structure. The new understanding also led to a reinterpretation of nuclear collision theories, based on this we succeeded a room-temperature low-energy photon-photon collision (RT-LE-PPC), this method allowed us to observe a topological disconnected fractal structure and succeeded a simulation of the formation of matter and the universe which provided evidences for the nature of light and matter and led to a quantum structure interpretation, and we found the formation of the universe started from two particles. However this work cannot be understood with current physics theories due to the logical problems in the current physics theories.

H1.00267 MEST- avoid next extinction by a space-time effect[1] , DAYONG CAO, Avoid Earth Extinction Association — Sun's companion-dark hole seasonal took its dark comets belt and much dark matter to impact near our earth. And some of them probability hit on our earth. So this model kept and triggered periodic mass extinctions on our earth every 25 to 27 million years. After every impaction, many dark comets with very special tilted orbits were arrested and lurked in solar system. When the dark hole-Tyche goes near the solar system again, they will impact near planets. The Tyche, dark comet and Oort Cloud have their space-time center. Because the space-time are frequency and amplitude square of wave. Because the wave (space-time) can make a field, and gas has more wave and fluctuate. So they like dense gas ball and a dark dense field. They can absorb the space-time and wave. So they are "dark" like the dark matter which can break genetic codes of our lives by a dark space-time effect. So the upcoming next impaction will cause current "biodiversity loss." The dark matter can change dead plants and animals to coal, oil and natural gas which are used as energy, but break our living environment. According to our experiments, which consciousness can use thought waves remotely to change their systemic model between Electron Clouds and electron holes of P-N Junction and can change output voltages of solar cells by a life information technology and a space-time effect, we hope to find a new method to the orbit of the Tyche to avoid next extinction. (see Dayong Cao, BAPS.2011.APR.K1.17 and BAPS.2012.MAR.P33.14)

H1.00268 Pinning quantum phase transition of photons in a hollow-core fiber , MING-XIA HUO, Centre for Quantum Technologies, National University of Singapore, DIMITRIS G. ANGELAKIS, Centre for Quantum Technologies, National University of Singapore; Science Department, Technical University of Crete, Chania, Crete, Greece — The Bose-Hubbard and sine-Gordon models have been extremely successful in describing a range of quantum many body effects and especially quantum phase transitions. We show that a pinning transition for photons could be observed in a hollow-core one-dimensional fiber loaded with a cold atomic gas. Utilizing the strong light confinement in the fiber, a range of different strongly correlated polaritonic and photonic states, corresponding to both strong and weak interactions can be created and probed. We analyze the relevant phase diagram corresponding to the realizable Bose-Hubbard (weak) and sine-Gordon (strong) interacting regimes and conclude by describing the measurement process. The latter consists of mapping the stationary excitations to propagating light pulses whose correlations can be efficiently probed once they exit the fiber using available optical technologies.

H1.00269 Information Theoretic Study of the Confined Harmonic Oscillator in Position, Momentum and Phase-Space , HUMBERTO LAGUNA[1], ROBIN SAGAR[2], Universidad Autonoma Metropolitana Iztapalapa — The confined quantum harmonic oscillator (CHO) is an intermediate model which lies between the particle-in-a-box (PIAB), where the free particle is confined, and the quantum harmonic oscillator (HO) where the particle is not confined but is under the influence of a harmonic potential. Position and momentum space densities, and phase-space Wigner functions, are obtained for this system and analyzed using tools from information theory. Shannon entropies are used to gain insights into the localization of the particle in position, momentum and phase-space. The statistical correlation between the position and momentum of the particle is examined using the Wigner function and its mutual information. The analysis is performed as a function of the quantum number and of the box length, and the calculated quantities are compared to those of the PIAB and HO models. Our interests lie in determining similarities or differences among the different models and if there are regimes where the behavior of the CHO model more closely resembles either that of the PIAB or HO model.

H1.00270 Bimodal Hong-Ou-Mandel Interferometry[1] , DEEPIKA SUNDARRAMAN, THOMAS GILLISS, CODY LEARY, The College of Wooster — We investigate two-photon Hong-Ou-Mandel interference in several interferometric systems, in which each of the two interfering input photons exist in arbitrary linear superpositions of the first-order Hermite-Gaussian modes HG_{10} and HG_{01}. We find that if both input photons are in balanced superpositions of the HG_{10} and HG_{01} modes, the resulting two-photon interference can be engineered to transform these diagonal Hermite-Gaussian inputs into output modes of the Laguerre Gaussian type, which are entangled with respect to both output path and transverse spatial mode. We show that such two-photon interference effects can occur even if the input photons are prepared with *distinguishable* transverse spatial states.

H1.00271 Combinatorial Approach to Studying Metal Enhanced Fluorescence from Quantum Dots , NGUYET LE, TIMOTHY CORRIGAN, Concord University, MICHAEL NORTON, DAVID NEFF, Marshall University — Fluorescence is extensively used in biochemistry for determining the concentration or purity of molecules in a biological environment. In metal-enhanced fluorescence (MEF), the fluorescence molecules separated from a metal surface by several nanometers can be enhanced. The fluorescent enhancement is dependent on the size and spacing of the nanoparticles, as has been shown previously for a number of fluorophore molecules. Fluorescence from quantum dots is of particular interest because the quantum dots do not lose fluorescence ability when exposed to light and they have higher intensity of fluorescence. The purpose of this study is to determine the effect of size and spacing on fluorescence intensity when coupling gold nano-particles with quantum dots. We employ a combinatorial approach, depositing gold particles ranging in diameter from 30 nm to 130 nm with varied spacings onto the substrate, followed by a protein spacer-layer and quantum dots. The fluorescence signal from the metal enhanced quantum dots were determined by confocal microscopy.

H1.00272 QUANTUM INFORMATION, CONCEPTS AND COMPUTATION –

H1.00273 Electron Spin Relaxation due to Charge Noise[1]

, PEIHAO HUANG, XUEDONG HU, University at Buffalo
— It is widely accepted that for a single electron confined in a quantum dot, spin relaxation is dominated by spin-orbit interaction in combination with phonon emission. The effect of charge noise is usually considered to be small in the case of a single electron spin qubit, although it is never actually evaluated in a quantum dot. Here we examine the single-electron spin decoherence due to charge noise, mediated by the spin-orbit interaction. We find that at the lowest order, it is a relaxation channel, with $T_2 = 2T_1$, similar to the case of spin-orbit interaction and phonon scattering. The relaxation rate is linearly proportional to the applied magnetic field, in contrast to the 5th power magnetic field dependence in the phonon case. Our calculated spin relaxation time ranges from ms in GaAs to seconds in Si for 1 T field, making this relaxation channel at low field comparable or even more important than that due to phonon emission. The relaxation rate is inversely proportional to the 4th power of the dot confinement energy, so that increasing the confinement energy is an efficient way to suppress this relaxation channel.

H1.00274 Characterization of rf-SSET in both in-plane and perpendicular magnetic fields[1]

, CHUNYANG TANG, ZHEN YANG, MINGYUN YUAN, A.J. RIMBERG, Dartmouth College, D.E. SAVAGE, M.A. ERIKSSON, University of Wisconsin-Madison, RIMBERG TEAM, ERIKSSON COLLABORATION
— Previous success in coupling an aluminum radio-frequency superconducting single electron transistor (rf-SSET) to quantum dots (QDs) has demonstrated use of the rf-SSET as an ultra-sensitive and fast charge sensor [1]. Since a magnetic field is usually necessary for quantum dot qubit manipulation, it is important to understand the effect of magnetic fields, either in-plane or perpendicular, on the performance of any charge sensor near the QDs. Here we report characterization of rf-SSETs in both in-plane and perpendicular magnetic fields. The rf-SSET works well in an in-plane fields up to 1 Tesla at a temperature of 30 mK. At 0.3K, in a perpendicular field generated by a stripline located 700 nm away, the rf-SSET charge sensitivity even shows improvement for up to 2.1 mA current through the stripline (corresponding roughly to a field of 6 Gauss). H1.00276 Counterfactual Assessment of Decoherence in Quantum Systems

, ONOFRIO RUSSO, New Jersey Institute of Technology, LIANG JIANG, Yale University
— Quantum Zeno effect occurs when the system is observed for unusually short observation times, t, where the probability of the transition between different quantum states is known to be proportional to t^2. This results in a decrease in the probability of transitions between states and the consequent decrease in decoherence. We consider the conditions in which these observations are made counterfactual to assess whether this results in a significant change in decoherence.

H1.00277 Universal set of quantum gates for electron defect spin qubits in diamond and silicon carbide

, DMITRY SOLENOV, SOPHIA E. ECONOMOU, THOMAS L. REINECKE, Naval Research Laboratory, Washington, District of Columbia 20375, USA
— Electron spin qubits based on nitrogen-vacancy centers in diamond and defects in silicon carbide have become a rapidly developing direction in quantum information and computing due to their potential in room temperature quantum computing. While single-qubit manipulations have been proposed and experimentally realized, the design of a realistic deterministic two-qubit entangling gate currently remains an important challenge. We propose fast optically controlled design where a two-qubit gate between spatially separate qubits is mediated by a photonic microcavity mode. The proposed gate scheme is compatible with available single-qubit operations. In addition, our design provides an opportunity to perform individual single qubit operations without the need to spatially resolve the qubits. As a result, for the first time a universal set of deterministic gates is proposed that can be implemented with current experimental capabilities in these systems.

H1.00278 Fabrication and characterization of transmon qubits and rectangular waveguide resonators for circuit quantum electrodynamics

, DONG-GWANG HA, JUNG HWAN PARK, SO-YEON JUN, WOON SONG, YONUK CHONG, Korea Research Institute of Standards and Science, Daejeon 305-340, Korea
— We present our design, fabrication and characterization of superconducting transmon qubits and resonators for circuit quantum electrodynamics (QED). We have made coplanar waveguide resonators and rectangular waveguide resonators. The characteristics of the resonators are well controlled by the design parameters, with the fundamental frequencies in the range of 1 to 8 GHz and the quality factors in the range of 10^2 to 10^6, respectively. We measured the resonator characteristics as a function of temperature. The excitation power dependence of the resonator characteristics was also investigated. For transmon qubits, we fabricated 100 nm-scale $Al/Al_2O_x/Al$ tunnel junctions with e-beam lithography and double angle evaporation. The junctions were characterized at low temperature down to 10 mK. Furthermore, quantum state measurement and manipulation in circuit QED structure will be discussed.

H1.00279 Microwave Spectroscopy of a Josephson Junction Rhombi Chain[1] , MATTHEW BELL, JOSHUA PARAMANANDAM, LEV IOFFE, MICHAEL GERSHENSON, Rutgers University — It has been proposed that Josephson Junction (JJ) Rhombi chains can be used as a superconducting qubit symmetry protected from local noises [1]. We have studied the microwave response of a two-rhombi chain coupled to a lumped-element microwave resonator. The resonance frequency of this circuit was measured as a function of the phase φ across the JJ Rhombi chain. The effective inductance of the JJ Rhombi as a function of φ oscillates with a period $\Delta\varphi{=}\pi$ when the magnetic flux Φ in the Rhombi approaches half a flux quantum. In this regime, microwave spectroscopy of the first excited state of the JJ Rhombi was performed as a function of φ and the gate-controlled charge on the central island of the two-Rhombi chain. The results of the microwave spectroscopy are in agreement with numerical simulations. We also discuss the results of time domain measurements of the Rhombi chain which establishes a baseline for the future coherence time measurements for longer (and, thus, more protected) chains.

H1.00280 New Method for Determining the Quality Factor and Resonance Frequency of Superconducting Micro-resonators from Sonnet Simulation , DAVID WISBEY, ALEXANDER REINISCH, WESLEY GARDNER, JACOB BREWSTER, Saint Louis University, JIANSONG GAO, National Institute of Standards and Technology — Lithographed superconducting microwave resonators (micro-resonators) are useful in a number of important applications including microwave kinetic inductance detectors (MKIDs), as a memory element in quantum information, and readout of qubits and nanomechanical resonators. One of the major tasks in designing these devices is to find the resonance frequency (f_r) and quality factor (Q) for these microwave circuits using EM simulation software such as Sonnet. The traditional method iteratively sweeps and zooms in frequency to fit simulated S_{21} data, which is often time consuming. In this work, we show a new—and much faster—method for determining f_r and Q by adding an internal (virtual) port in the Sonnet model and examining the input impedance through the added port. Accurate f_r and Q values can be retrieved from a single simulation with a wide frequency sweep. This is a robust method that works on many types of resonance circuits and eclipses the speed with which Q is traditionally extracted by eliminating the need for multiple frequency sweeps using Sonnet.

H1.00281 Nonblinking green emission from single H3 color centers in nanodiamonds , JUI-HUNG HSU, National Sun Yat-sen University, WEI-DE SU, KAI-LIN YANG, Kao-Yuan University, YAN-KAI TZENG, HUAN-CHENG CHANG, Academia Sinica — We present a work that investigates the emission properties of single color centers in natural diamond nanoparticles for potential use as single photon sources and photostable biomarkers. Two emitters, H3 and H4, were identified by their sharp zero-phonon lines at 503 nm and 496 nm, respectively, in the photoluminescence spectra. Using a modified Hanbury Brown and Twiss setup, we observed complete photon antibunching for the H3 center. No fluorescence blinking was detected for a single H3 emitter on the ms timescale, indicating weak coupling between the electronic transition 1A1↔1B1 and adjacent metastable states of this nitrogen-vacancy-nitrogen point defect.

H1.00282 Counting statistics and entanglement in a disordered free fermion system with a voltage bias[1] , JOSEPH BURG, GREGORY LEVINE, Hofstra University — The Full Counting Statistics is studied for a disordered one-dimensional system of non-interacting fermions with and without a voltage bias. For two unbiased L site lattices connected at time $t = 0$, the charge variance increases as the natural logarithm of t, following the universal expression $\langle \delta N^2 \rangle \approx \frac{1}{\pi^2} \log t$. Since the static charge variance for a length l region is given by $\langle \delta N^2 \rangle \approx \frac{1}{\pi^2} \log l$, this result reflects the conformal invariance and dynamical exponent $z = 1$ of the disorder-free lattice. With disorder and strongly localized fermions, we have compared our results to a model with a dynamical exponent $z \neq 1$, and also a model for entanglement entropy based upon dynamical scaling at the Infinite Disorder Fixed Point (IDFP). The latter scaling, which predicts $\langle \delta N^2 \rangle \propto \log \log t$, appears to better describe the charge variance of disordered 1-d fermions. When a bias voltage is introduced, the behavior changes dramatically and the charge and variance become proportional to $(\log t)^{1/\psi}$ and $\log t$, respectively. The exponent ψ may be related to the critical exponent characterizing spatial/energy fluctuations at the IDFP.

H1.00283 New indicators of quantum phase transitions in several exactly solvable critical systems , FERDI ALTINTAS, RESUL ERYIGIT, Department of Physics, Abant Izzet Baysal University, Bolu, Turkey — Quantum phase transitions (QPT) are the abrupt changes of the ground state of quantum systems as a consequence of a continous change of a tuning parameter (an external field or an anisotropy parameter). They are solely because of quantum fluctuations and occur at absolute zero temperature. The quantumness measures, such as entanglement and quantum discord (QD), are shown to be promising indicators of QPTs. In this presentation, we will introduce new indicators, such as Bell nonlocality as revealed by the viloation of CHSH inequality and measurement induced disturbance (MID), for characterizing quantum phase transitions in several exactly solvable critical systems, discuss their usefulness in capturing QPTs and compare the performance of these measures with that of the well known QPT-detectors. We have shown that although entanglement, QD and MID can partially indicate the QPTS (mostly model dependent), CHSH-Bell inequality can detect all QPTs of the considered models even when the relevant ground state is uncorrelated.

H1.00284 Reduction of loss in quantum entanglement by temperature increase , JULIO CESAR GONZALEZ HENAO, JOSE ANTONIO ROVERSI, State University of Campinas, Unicamp — In this study we investigate the effect of coupling between a system of two qubits initially prepared in an entangled state and a nonlinear thermal bath. Under these conditions we can find an analytical solution for the system that allows us analyze the effects of temperature. We can also demonstrate that the increases of the thermal reservoir temperature produces a reduction of losses in the entanglement of the two-qubit system.

H1.00286 Fault-tolerent Holonomic Quantum Computation Based on Stabilizer Codes , YI-CONG ZHENG, TODD BRUN, Department of Electrical Engineering, University of Southern California, QIP TEAM — We present an all-geometric scheme for fault-tolerant holonomic quantum computation with stabilizer codes, based on non-Abelian adiabatic holonomies. This scheme implements a universal set of quantum gates by adiabatic deformation of the stabilizer eigenspaces (both the code space and error spaces) through the same closed path in the parameter space, so that each eigenspace obtains the same holonomy. This approach makes fault-tolerant error correction possible. We give examples to show how this scheme works for different stabilizer codes.

H1.00287 Simulation of stochastic quantum systems using polynomial chaos expansions , KEVIN YOUNG, MATTHEW GRACE, Sandia National Laboratories — We present an approach to the simulation of quantum systems driven by classical stochastic processes that is based on the polynomial chaos expansion, a well-known technique in the field of uncertainty quantification. The polynomial chaos expansion represents the system density matrix as a series of orthogonal polynomials in the principle components of the stochastic process and yields a sparsely coupled hierarchy of linear differential equations. We provide practical heuristics for truncating this expansion based on results from time-dependent perturbation theory and demonstrate, via an experimentally relevant one-qubit numerical example, that our technique can be significantly more computationally efficient than Monte Carlo simulation.

H1.00288 Quantum Knowledge Diagrams , DOUGLAS SNYDER, None — The principles behind quantum knowledge can be extracted from the specific empirical implementations so that pictorial elements can be developed representing fundamental concepts of quantum knowledge. With these elements, one can represent quantum knowledge principles underlying specific empirical implementations more simply and in a way that allows for a more direct comparison of quantum knowledge principles underlying various specific empirical implementations. These representations are quantum knowledge diagrams. Basic diagram elements include: 1) a which-way process; 2) a non-which-way process (showing interference); 3) availability, or lack thereof, of the which-way or non which-way information to the environment; 4) particles; 5) entanglement, or lack thereof, of 2 or more particles; 6) delayed choice.

H1.00290 Dynamic Localization of Particle Moving in Solid Film , GENNADIY FILIPPOV, Cheboksary polytechnic unstitute (branch) of the moscow state open university — Calculation of the density matrix (DM) for a projectile during the passage through a solid film have shown progressive diminishing of the projectile's coherence length. For to find a more detail information about the projectile we perform a famous von Newmann's decomposition of DM on "pure" states and find an ambiguity of this approach. The unambiguous decomposition can be obtained if we introduce an additional coherence criterion: each term of the decomposition should conserve the shape of function of coherence. We use the next arguments: i) the function of coherence could be measured; ii) the parts of a wave field found in relation of mutual coherence belong to one particle and couldn't be separated from the particle; iii) the parts of a wave field which dont find in relation of mutual coherence are belong to different particles and couldn't be associated with one particle. With the help of this approach one can find that during the penetration in a film the projectile undergo a significant spatial localization. The localized quasi-stationary state of projectile could conserve the information about the past interaction with environment.

H1.00291 How to slow down light and where relativity theory fails[1] , MEGGIE ZHANG, AISRO — Research found logical errors in mathematics and in physics. After discovered wave-particle duality made an assumption I reinterpreted quantum mechanic and I was able to find new information from existing publications and concluded that photon is not a fundamental particle which has a structure. These work has been presented at several APS meetings and EuNPC2012. During my research I also arrived at the exact same conclusion using Newton's theory of space-time, then found the assumptions that relativity theory made failed logical test and violated basic mathematical logic. And Minkowski space violated Newton's law of motion, Lorenz 4-dimensional transformation was mathematically incomplete. After modifying existing physics theories I designed an experiment to demonstrate where light can be slow down or stop for structural study. Such method were also turn into a continuous room temperature fusion method. However the discoveries involves large amount of complex logical analysis. Physicists are generally not philosophers, therefore to make the discovery fully understood by most physicists is very challenging.

[1]This work is supported by Dr. Kursh at Northeastern University.

H1.00292 Classical Trajectories from Coherent Quantum Oscillations , ALAN M. KADIN, Princeton Junction, NJ 08550 USA — In the conventional Copenhagen interpretation of quantum mechanics, classical behavior arises from microscopic coherent quantum systems only in the presence of decoherence on the macroscopic scale. On the contrary, we derive classical Hamiltonian trajectories for a confined quantum wave directly from coherent phase evolution on the microscopic scale, without decoherence or wavefunction collapse (see also [1]). This suggests that the basis for classical macroscopic physics, including relativity, lies in the microscopic behavior of coherently oscillating quantum fields. An outline of such a theory will be presented, which resolves longstanding paradoxes involving wave-particle duality, quantum entanglement, and the quantum-to-classical transition.

H1.00293 The Physical Origin of the Feynman Path Integral , ARMIN NIKKHAH SHIRAZI, University of Michigan, Ann Arbor — The Feynman path integral is an essential part of our mathematical description of fundamental nature at small scales. However, what it seems to say about the world is very much at odds with our classical intuitions, and exactly why nature requires us to describe her in this way is currently unknown. We will describe here a possibility according to which the path integral may be the spacetime manifestation of objects existing in a lower-dimensional analog of spacetime until they give rise to the emergence of spacetime objects under a process that is currently labeled a "Quantum Measurement." This idea is based on a mathematical distinction which at present does not appear to be widely appreciated

H1.00294 Superconducting Qubit Readout Using Capture-Disperse-Release of Microwave Field , ERIC MLINAR, University of California, Riverside — We analyze a measurement scheme for superconducting qubits via controlled capture, dispersion, and release of a microwave field. The Purcell effect is circumvented by using a tunable coupler to decouple the microwave resonator from the transmission line during dispersive interaction with the qubit. We show that fast and high-fidelity qubit readout can be achieved for nonlinear dispersive qubit-resonator interaction and for sufficiently adiabatic tuning of the qubit frequency. The Jaynes-Cummings nonlinearity results in self-developing quadrature squeezing of the resonator field below the standard quantum limit, leading to a significant decrease in measurement error.

H1.00296 FLUIDS —

H1.00297 Electron Shock Waves with Current behind the Shock Front[1] , MOSTAFA HEMMATI, W.C. CHILDS, H. MORRIS, P. PINKSTON, Arkansas Tech University — Electrical breakdown of a gas in a strong electric field is carried out by a wave with a strong discontinuity at the wave front, and traveling with speed comparable to speed of light. For theoretical investigation of electrical breakdown of a gas, we apply a one-dimensional, steady state, constant velocity, three component fluid model, and assume the electrons to be the main element in propagation of the wave. Our set of electron fluid-dynamical equations consists of the equations of conservation of mass, momentum, and energy plus the Poisson's equation. For breakdown waves with a significant current behind the shock front, in addition to the set of electron fluid dynamical equations, the shock condition on electron temperature need to be modified as well. Considering existence of current behind the shock front, we have derived the shock condition on electron temperature, and for a set of experimentally measured current values, we have been able to integrated the set of electron fluid dynamical equations through the dynamical transition region of the wave. Our results meet the expected conditions at the trailing edge of the wave.

H1.00298 POST-DEADLINE ABSTRACTS —

H1.00299 The dynamic and geometric phase transition in the cellular network of pancreatic islet , XUJING WANG, University of Alabama at Birmingham — The pancreatic islet is a micro-organ that contains several thousands of endocrine cells, majority of which being the insulin releasing β-cells. β-cells are excitable cells, and are coupled to each other through gap junctional channels. Here, using percolation theory, we investigate the role of network structure in determining the dynamics of the β-cell network. We show that the β-cell synchronization depends on network connectivity. More specifically, as the site occupancy is reducing, initially the β-cell synchronization is barely affected, until it reaches around a critical value, where the synchronization exhibit a sudden rapid decline, followed by an slow exponential tail. This critical value coincides with the critical site open probability for percolation transition. The dependence over bond strength is similar, exhibiting critical-behavior like dependence around a certain value of bond strength. These results suggest that the β-cell network undergoes a dynamic phase transition when the network is percolated. We further apply the findings to study diabetes. During the development of diabetes, the β-cell network connectivity decreases. Site occupancy reduces from the reducing β-cell mass, and the bond strength is increasingly impaired from β-cell stress and chronic hyperglycemia. We demonstrate that the network dynamics around the percolation transition explain the disease dynamics around onset, including a long time mystery in diabetes, the honeymoon phenomenon.

H1.00300 Numerical Modeling of Fluorescence Emission Energy Dispersion in Luminescent Solar Concentrator[1] , LANFANG LI, XING SHENG, JOHN ROGERS, RALPH NUZZO, University of Illinois, Urbana — We present a numerical modeling method and the corresponding experimental results, to address fluorescence emission dispersion for applications such as luminescent solar concentrator and light emitting diode color correction. Previously established modeling methods utilized a statistic-thermodynamic theory (Kenard-Stepnov etc.) that required a thorough understanding of the free energy landscape of the fluorophores. Some more recent work used an empirical approximation of the measured emission energy dispersion profile without considering anti-Stokes shifting during absorption and emission. In this work we present a technique for modeling fluorescence absorption and emission that utilizes the experimentally measured spectrum and approximates the observable Frank-Condon vibronic states as a continuum and takes into account thermodynamic energy relaxation by allowing thermal fluctuations. This new approximation method relaxes the requirement for knowledge of the fluorophore system and reduces demand on computing resources while still capturing the essence of physical process. We present simulation results of the energy distribution of emitted photons and compare them with experimental results with good agreement in terms of peak red-shift and intensity attenuation in a luminescent solar concentrator.

H1.00301 Micro Solar Cells with Concentration and Light Trapping Optics[1] , LANFANG LI, ERIC BREUCKNER, CHRISTOPHER CORCORAN, YUAN YAO, LU XU, RALPH NUZZO, University of Illinois, Urbana — Compared with conventional bulk plate semiconductor solar cells, micro solar cells provide opportunity for novel design geometry and provide test bed for light trapping at the device level as well as module level. Surface recombination, however, will have to be addressed properly as the much increased surface area due to the reduced dimension is more prominent in these devices than conventional solar cells. In this poster, we present experimental demonstration of silicon micro solar cells with concentration and light trapping optics. Silicon micro solar cell with optimized surface passivation and doping profile that exhibit high efficiency is demonstrated. Effective incorporation of high quantum yield fluorescent centers in the polymer matrix into which micro solar cell was encapsulated was investigated for luminescent solar concentration application. Micro-cell on a semi-transparent, nanopatterned reflector formed by soft-imprint lithography was investigated for near field effect related solar conversion performance enhancement.

[1]This work is supported by the DOE 'Light-Material Interactions in Energy Conversion' Energy Frontier Research Center under grant DE-SC0001293

H1.00302 Kagome-like Lattice Distortion in the Pyrochlore Material $Hg_2Ru_2O_7$[1]

, JOOST VAN DUIJN, ROCÍO RUIZ-BUSTOS, Universidad de Castilla-La Mancha, AZIZ DAOUD-ALADINE, Rutherford Appleton Laboratory — $Hg_2Ru_2O_7$ is one of the few pyrochlore materials known containing Ru^{5+}. It undergoes a first order metal to Mott insulator transition (MIT) at T= 107 K, below which the susceptibility is significantly reduced and appears to be nearly T independent. While initially it has been suggested that below 107 K the Ru S=3/2 moments are quenched into an antiferromagnetic spin singlet ground-state, similar as to what is observed in $Tl_2Ru_2O_7$, recent muon and polarized neutron diffraction experiments reveal the onset of long-range magnetic ordering below the MIT. In order to shed light on the magnetic interactions that give rise to the observed long-range ordering we have performed high resolution powder neutron diffraction experiments to determine the low temperature structure of $Hg_2Ru_2O_7$. Below the MIT the symmetry is lowered from cubic to monoclinic and the Ru-Ru bonds, which are equal in the pyrochlore phase, become split into short, medium and long bonds. As a result the exchange interactions between the Ru atoms become more two dimensional. The short and medium bonds form layers, which are separated by the long bonds, that run parallel to the monoclinic ab plane. The low temperature structure can best be described as a stacking of Kagome-like layers.

H1.00303 Non-equilibrium dynamics of isolated trapped ion chain

, ZHEXUAN GONG, LUMING DUAN, Department of Physics, University of Michigan — We have studied the dynamics of an isolated trapped ion chain under a non-equilibrium initial state in both motional and internal degrees of freedom. For motional state, we find that the dynamics of temperature distribution is qualitatively different between axial and transverse direction, due to distinctive sound wave propagation. For internal state, we show that by engineering the effective Hamiltonian through laser field, we can get a variety of spin wave dynamics based on the range of effective spin-spin interaction. We also show that these interesting non-equilibrium dynamics can be readily tested with current ion-trap technology.

H1.00304 Direct Measurement of the Pressure Dependence of the Glass Transition Temperature: A Comparison of Methods[1]

, WILLIAM OLIVER III[2], TIMOTHY RANSOM, JAMES COOPER III, University of Arkansas — Two methods for the direct measurement of the pressure dependence of the glass-transition temperature T_g are presented and compared. These methods involve the use of the diamond anvil cell (DAC), and hence, enable the ability to measure $T_g(P)$ to record high pressures of several GPa. Such studies are increasingly relevant as new methods have pushed other high-pressure experimental investigations of glass-forming systems into the same pressure regime. Both methods use careful ruby fluorescence measurements in the DAC as temperature is increased from the glass ($T<T_g$) to the viscous liquid ($T>T_g$). Method 1 observes the disappearance of pressure gradients as the viscous liquid region is entered, whereas method 2 involves observation of slope changes in the P-T curve during temperature ramps. Such slope changes are associated with the significant change in the volume expansion coefficient between the highly viscous, metastable, supercooled liquid state and the solid glassy state. In most cases, the two methods yield good agreement in the $T_g(P)$ curve. Data will be presented for more than one glass-forming system, including the intermediate strength glass-forming system glycerol and the fragile glass former salol.

H1.00305 Plasma assisted selenization for the preparation of CuInGaSe absorbers

, ZHI HUANG, P.F. LUO, Z. CEVHER, Y.H. REN, City University of New York, MATERIAL FABRICATION LAB TEAM — Cu(In,Ga)(S,Se)2 (CIGS) compound has attracted much attention most recently because of their application in high efficient photovoltaic devices. In order to obtain a decent CIGS photovoltaic device, it is very critical to optimize the metallic precursor layers and choose a suitable selenization technique. We demonstrate a plasma assisted selenium cracking method for preparing CIGS semiconductor films using elemental selenium vapor. The two stage selenization process includes the modification of the ionization state of Se species by radio frequency plasma and the deposition of a selenium cap layer above CuInGa metallic precursors. A CIGS absorber layer with improved homogeneity and crystallization is realized after a post annealing process. The result is explained by the enhancement of reaction kinetics between the reduced Se phase and metallic precursor layers.

H1.00306 Transfer of Chirality from Molecule to Phase in Self-assembled Chiral Block Copolymers

, RONG-MING HO, Department of Chemical Engineering, National Tsing Hua University — Here, we report the mechanisms of chiral transfer at various length scales in the self-assembly of enantiomeric chiral block copolymers (BCPs*). We show the evolution of homochirality from molecular chirality into phase chirality in the self-assembly of the BCPs*. The chirality of molecule in the BCP* is identified from circular dichroism (CD) spectra while the handedness of the helical conformation in the BCP* is determined from split-type Cotton effect in vibrational circular dichroism spectra. Microphase separation of the BCP* is exploited to form a helical (H*) phase, and the handedness of helical nanostructure in the BCP* is directly visualized from transmission electron microscopy tomography. As examined by CD and fluorescence experiments, significant induced CD signals and bathochromic shift of achiral perylene moiety as a chemical junction of the BCPs* can be found while the concentration of the BCPs* in toluene solution is higher than critical micelle concentration, suggesting a twisting and shifting mechanism initiating from microphase-separated interface of the BCPs* leading to the formation of the H* phase from self-assembly. The operation of the self-assembly of the BCP* may provide insights into morphological evolution from the molecular level via homochiral evolution, and give the appealing applications such as chiral metamaterials.

H1.00307 Effect of Temperature on Nanophase-segregation and Transport in Polysulfone-Based Anion Exchange Membrane Fuel Cell: Molecular Dynamics Simulation Approach

, KWAN HO KO, KYUNG WON HAN, Georgia Institute of Technology, School of Mechanical Engineering, JI IL CHOI, Georgia Institute of Technology, School of Materials Science and Engineering, YING CHANG, CHULSUNG BAE, Rensselaer Polytechnic Institute, Department of Chemistry and Chemical Biology, SEUNG SOON JANG, Georgia Institute of Technology, School of Materials Science and Engineering, GEORGIA TECH TEAM, RPI TEAM — The effect of temperature on hydrated polysulfone-based anion exchange membrane is studied using molecular dynamics. Various temperature conditions such as 313K, 353 K and 393K with two different water contents (10 wt % and 20 wt %) are simulated. From the viewpoint of structure-property relationship, we scrutinize the change in the nanophase-segregated structure of membrane and transport of anionic charge carrier (hydroxide) as a function of temperature. Since it is well known that the anion transport is less than the proton transport, we attempt to pursue a fundamental understanding of the difference between anion transport and proton transport. For this purpose, we simulate the polysulfone-based proton exchange membrane that has the same molecular structure and molecular weight. By analyzing the pair-correlation of charge carriers, we observe the correlation among hydroxides is much stronger than that among hydroniums. The extent of nanophase-segregation is also analyzed using structure factor profile.

H1.00308 On The Geometric Nature of "Singlet Fission" in Certain Crystalline Conjugated Polymers , NOAH RAHMAN, Department of Chemistry, University of California - Santa Barbara — In recent years, the coherent fission of low-lying singlet electronic excitations in conjugated polymers has attracted interest as a possible way to exceed the Shockley-Queisser limit in organic photovoltaics. Femtosecond spectroscopic and fluorescence measurements of such singlets and the resulting triplets in crystalline anthracene, tetracene and naphthalene reveal curious phenomena associated with certain vibrational modes, such as ultrafast propagation on a timescale inconsistent with conventional intersystem crossing, long-lived electronic coherence, and triplet magnetic anisotropy whose structure is consistent across all three materials. This conflicts with NRG and quantum chemical simulations, which posit isotropic triplets. I explain this by a dynamical Rashba spin-orbit interaction that decays as R^{-6}. This arises from a geometric SU(2) gauge potential generated by a nuclear-motion-induced parametric near-degeneracy of the molecular electronic states. The anisotropy is shown to follow from the work of Affleck and Oshikawa on spin one-half Heisenberg chains. Possible directions for future work are discussed, especially with regard to adiabatic pumping and topological insulators.

H1.00309 Multiple Phase Transition of the Fulde-Ferrel-Larkin-Ovchinnikov States in two-band Superconductors , MASAHIRO TAKAHASHI, Department of Physics, Gakushuin University, TAKESHI MIZUSHIMA, KAZUSHIGE MACHIDA, Department of Physics, Okayama University — The Fulde-Ferrell-Larkin-Ovchinnikov (FFLO) states in the two-band superconductors are studied. FFLO states will be realized in superconductors with high external field or in ultracold atom gases with imbalanced population of the atoms for paring. In this study we focused on superconductors. We take into account the contribution of the 2nd band which has not been considered from the microscopic point of view. We extended the Bogoliubov-de Gennes equation for the multiple-band system and solved numerically with various parameters. As a result, the multiple phase transition from the BCS state to FFLO state, and in addition, between multiple FFLO states. The transition between states are 1st order, where usual BCS to FFLO phase transition is 2nd order.

H1.00310 Spin Polarization Induced by Rashba Field and Electromagnetic Wave , KATSUHISA TAGUCHI, GEN TATARA, Tokyo Metropolitan University — We theoretically show that the spin polarization is induced by the electric field of the electromagnetic wave in the presence of the Rashba spin-orbit interaction in metals. The spin is derived from the correlation function between the spin and electron's density and between the spin and electron's current. The correlation function is calculated by using the thermal Green's function, which includes non-perturbative Rashba spin-orbit interactions. The result shows that the spin is generated by electric field and Rashba fields.

H1.00311 Google in a Quantum Network , GIUSEPPE PAPARO, Universidad Complutense —

H1.00312 Observation of fishtail effects in $BaFe_{2-x}Ni_xAs$ single crystals , YING ZI ZHANG, HI QIAN LUO, NLSC Institute of Physics, and Center for Condensed Matter Physics, Chinese Academy of Sciences — Isothermal magnetization loops were performed to characterize magnetic properties of three small chips of $Bi_{2+x}Sr_{2-x}CuO_{6+\delta}$ single crystals in different temperatures, where x = 0.10, 0.12, 0.14. All of the crystals show anomalous fishtail effects (second peak effects). We found that the second peaks can be described by thermal decoupling modal. The lowest crossover field from the first peak to the second peak is found as low as several Oe. We suggest that the crossover field is related to unbinding the vortex-antivortex pairs and building the vortex interaction from layer to layer.

H1.00313 Phase separation dynamics in polymer blends close to Tg: aging and rejuvenating , GREGOIRE JULIEN, CNRS/Rhodia UMR 5268 — We extend the Percolation of Free Volume Distribution (PFVD) model developed by Long and co-workers to deal with polymer blends dynamics close to the glass transition. The dynamical model incorporates an extension of the Flory Huggins model to the case of compressible blends for calculating the driving forces. Spatial dynamics follows then from an Onsager like description. The model is solved on a 2D lattice corresponding to spatial scales of about a few tens to 100 nm and a resolution corresponding to the scale of dynamical heterogeneities, allowing to study phase separation close to Tg. We study also the reverse process, after the temperature is increased again in the totally miscible range. We observe a temporal asymmetry between the aging and the rejuvenation dynamics: the slow domains melt much faster than the elapsed time required to built them during the separation process and total miscibility is recovered after a much shorter time.

H1.00314 Focused ion beam lithographically patterned growth of vertically aligned ZnO nanorods arrays on GaN , WING LUN CHUNG, HUA SHENG WU, Physics Department, The University of Hong Kong — Ordered ZnO nanorods were synthesized on GaN by using hydrothermal method via silicon dioxide template etched by focused ion beam nanolithography. Due to the nucleation site confinement, the as-grown ZnO nanorods were selectively budding inside the nanopattern. Scanning electron microscope image showed that the as-grown ZnO nanorods were highly ordered and exhibited hexagonal structure. This indicated the GaN substrate retained its crystalline orientation despite the destructive Focused ion beam lithography.

H1.00315 First-Principles Calculations of Structural, Electronic and Optical Properties of $CaTiO_3$ Crystal , SUBÊNIA MEDEIROS, JUSCIANE SILVA, Universidade Federal Rural do Semi-Árido - UFERSA, EUDENILSON ALBUQUERQUE, Universidade Federal do Rio Grande do Norte - UFRN, VALDER FREIRE, Universidade Federal do Ceará - UFC — The structural, electronic, vibrational, and optical properties of perovskite $CaTiO_3$ in the cubic, orthorhombic, and tetragonal phase are calculated in the framework of density functional theory (DFT) with different exchange-correlation potentials by CASTEP package. The calculated band structure shows an indirect band gap of 1.88 eV at the Γ-R points in the Brillouin zone to the cubic structure, a direct band gap of 2.41 eV at the $\Gamma-\Gamma$ points to the orthorhombic structure, and an indirect band gap of 2.31 eV at the MΓ points to the tetragonal phase. I have concluded that the bonding between Ca and TiO_2 is mainly ionic and that the TiO_2 entities bond covalently. Unlike some perovskites the $CaTiO_3$ does not exhibit a ferroelectric phase transition down to 4.2 K. It is still known that the $CaTiO_3$ has a static dielectric constant that extrapolates to a value greater than 300 at zero temperature. Our calculated lattice parameters, elastic constants, optical properties, and vibrational frequencies are found to be in good agreement with the available theoretical and experimental values. The results for the effective mass in the electron and hole carriers are also presented in this work.

H1.00316 Spin torque switching and precession states in a spin Hall effect systems with perpendicularly magnetized ferromagnetic layer[1] , SHU YAN, YAROSLAW BAZALIY, Department of Physics and Astronomy, University of South Carolina — Magnetic switching in spin Hall effect (SHE) systems attracted some recent attention. Those bilayer systems consist of a perpendicularly polarized ferromagnetic (F) layer next to a non-magnetic metallic (N) layer with large SHE. A dc electric current flow along the layers was found to cause magnetic switching. One of the theoretical explanations proposed for this phenomenon is based on the emergence of a spin torque due to the spin polarized current coming from the N-layer into the F-layer. The latter current is produced by the SHE in N-layer. We study the influence of the external magnetic field on the current induced switching. It is shown that depending on the direction of the field the astroid curve describing magnetic switching can experience either a quantitative deformation, or a qualitative change with the emergence of stable precession cycles. These predictions allow us to suggest new test experiments designed to further probe the spin torque theory of SHE switching.

H1.00317 Geometry in Biomimetic Network: Double Gyroid to Pseudo-Single Gyroid in Nanohybrid Materials

, HAN-YU HSUEH, RONG-MING HO, Department of Chemical Engineering, National Tsing Hua University Hsinchu 30013, Taiwan, YU-CHUEH HUNG, YI-CHUN LING, Institute of Photonics Technologies, National Tsing Hua University, Hsinchu 30013, Taiwan, HIROKAZU HASEGAWA, Department of Polymer Chemistry, Graduate School of Engineering, Kyoto University, Nishikyo-ku, Kyoto, 615-8510, Japan — Biological systems have developed delicately arranged micro- and architectures to produce striking optical effects since millions of years ago. Inspired by the textures of butterfly wings with single gyroid (SG) structure, herein, we aim to fabricate biocompatible and robust materials with SG-like structure in nanometer size so as to give new materials with unprecedented optical properties for applications. Biommicking from the biological photonic structures of butterfly wings, a double gyroid (DG) structure in nanometer size is obtained from the self-assembly of polystyrene-b-poly(L-lactide) (PS-PLLA). To acquire robust backbone networks, inorganic networks in polymer matrix are fabricated by using the hydrolyzed PS-PLLA with DG structure as a template for sol-gel reaction. Owing to the soft polymer matrix, two co-continuous inorganic networks embedded in the polymer matrix can be rearranged by thermal annealing at temperature above the glass transition of the polymer. Consequently, the rearrangement of these inorganic networks leads the formation of SG-like structure possessing unique nanohybrids with ordered texture. This unique nanomaterials with SG-like structure is referred as a pseudo-SG (p-SG) nanohybrids.

H1.00318 Overlooked restrictions on Euler angles in quantum computation[1]

, MITSURU HAMADA, Tamagawa University — Let X, Y, Z denote the Pauli matrices. For $\vec{n} = (n_x, n_y, n_z) \in \mathbf{R}^3$ with $n_x^2 + n_y^2 + n_z^2 = 1$ and $\theta \in \mathbf{R}$, put $R_{\vec{n}}(\theta) = \cos(\theta/2)I - i\sin(\theta/2)(n_x X + n_y Y + n_z Z)$. Put $R_y(\theta) = R_{(0,1,0)}(\theta)$ and $R_z(\theta) = R_{(0,0,1)}(\theta)$. Theorem: Assume $\alpha, \gamma, \theta \in \mathbf{R}$, $\vec{n} = (n_x, n_y, n_z) \in \mathbf{R}^3$ and $n_x^2 + n_y^2 + n_z^2 = 1$. Then, there exists some $\beta, \delta \in \mathbf{R}$ satisfying $R_{\vec{n}}(\theta) = e^{i\alpha} R_z(\beta) R_y(\gamma) R_z(\delta)$ if and only if (iff) $e^{i\alpha} = 1$ or -1, and $\sqrt{1 - n_z^2}|\sin(\theta/2)| = |\sin(\gamma/2)|$. Corollary: Assume $\alpha, \gamma \in \mathbf{R}$, $\vec{n} = (n_x, n_y, n_z) \in \mathbf{R}^3$ and $n_x^2 + n_y^2 + n_z^2 = 1$. Then, there exist some $\beta, \delta, \theta \in \mathbf{R}$ such that $e^{i\alpha} R_z(\beta) R_{\vec{n}}(\theta) R_z(\delta) = R_y(\gamma)$ iff $e^{i\alpha} = 1$ or -1, and $|\cos(\gamma/2)| \geq |n_z|$. This corollary shows a widespread fallacy on universal gates in quantum computation. Namely, when $|\cos(\gamma/2)| < |n_z| < 1$, according to a claim often found in textbooks, $R_y(\gamma)$ could be written as $e^{i\alpha} R_z(\beta) R_{\vec{n}}(\theta) R_z(\delta)$ for some $\alpha, \beta, \delta, \theta \in \mathbf{R}$. This is untrue by the corollary.

H1.00319 Fabrication of chalcopyrite light-absorbing layers based on nanoparticle and nanowire networks[1]

, YUHANG REN, PAIFENG LUO, BO GAO, ZEHRA CEVHER, CHIVIN SUN, CUNY, Hunter College — We report on a method of preparing chalcopyrite, CuInGaSe2 (CIGS) light-absorbing layers using low cost air stable ink based on semiconductor nanoparticle and nanowires. The nanoparticles and nanowires are prepared from metal salts such as metal chloride and acetate at room temperature without inert gas protection. A uniform and non-aggregation CIGS precursor layer is fabricated with the formation of nanoparticle and nanowire networks utilizing ultrasonic spaying technique. We obtain a high quality CIGS absorber by cleaning the residue salts and carbon agents at an increased temperature and through selenizing the pretreated CIGS precursors. Our results offer an opportunity for the low-cost deposition of chalcopyrite absorber materials at large scale with high throughput.

H1.00320 ABSTRACT WITHDRAWN –

H1.00321 Quantum dots with light-hole exciton ground state

, BARBARA WITEK, NIKA AKOPIAN, Kavli Institute of Nanoscience, TU Delft, YONGHENG HUO, SANTOSH KUMAR, Institute for Integrative Nanosciences, IFW Dresden, RICARDO CARDENAS, GABRIEL BESTER, Max-Planck-Institute for Solid State Research, Stuttgart, ARMANDO RASTELLI, Institute of Semiconductor and Solid State Physics, Linz, OLIVER SCHMIDT, Institute for Integrative Nanosciences, IFW Dresden, VAL ZWILLER, Kavli Institute of Nanoscience, TU Delft — A light-hole exciton is a quasiparticle formed from a single electron and a single light-hole (LH). This is a fundamental excitation in a semiconductor quantum dot (QD), which could potentially lead to new and simpler schemes in quantum information science and technology, However, it has not been explored so far because the ground state of a hole in a QD has dominant heavy-hole character. Here we develop a novel type of a QD system that allows us to engineer GaAs/ AlGaAs QDs with a light-hole (LH) ground state by embedding them in tensile strained membranes. We fully characterize LH exciton states in polarization resolved μ-photoluminesce in the external magnetic field. LH exciton manifests itself in three orthogonally-polarized bright transitions and a large fine-structure. Further, we determine LH g-factor and observe different diamagnetic coefficients for LH $p_{x,y}$ and p_z orbitals. Finally, we provide a comprehensive theoretical description of all the observed LH exciton properties: fine structure, polarization, oscillator strength and g-factors. Our work paves the way to explore the fundamental properties and potential relevance of LH-excitons in QD for quantum information technologies.

H1.00322 Kinetic Potential Model of the Cloud-to-Drizzle Transition

, ROBERT MCGRAW, YANGANG LIU, EDWARD LUKE, GUNNAR SENUM, Brookhaven National Laboratory — It has been nearly a decade since the kinetic potential theory of drizzle formation in warm clouds was introduced [McGraw and Liu, Phys. Rev. Letts. 90, 018501 (2003)], and much progress in understanding the cloud-drizzle transition, especially regarding the role of turbulence, has been achieved within its framework. This poster will begin with an introduction to the kinetic potential idea, working up to the method it provides for predicting drizzle threshold conditions and rates, and concludes with an analysis this year of DOE/ARM cloud parcel vertical velocity measurements - discussing their implications for assessing turbulence fluctuations in water vapor saturation ratio and cloud droplet size.

H1.00323 Non-Classical Order in Sphere Forming ABAC Tetrablock Copolymers[1]

, JINGWEN ZHANG, ExxonMobil Corporation, SCOTT W. SIDES, Tech-X Research Corporation, FRANK S. BATES, University of Minnesota — AB diblock and ABC triblock copolymers have been studied thoroughly. ABAC tetrablock copolymers, representing the simplest variation from ABC triblock by breaking the molecular symmetry via inserting some of the A block in between B and C blocks, have been studied systematically in this research. The model system is poly(styrene-b-isoprene-b-styrene-b-ethylene oxide) (SISO) tetrablock terpolymers and the resulting morphologies were characterized by nuclear magnetic resonance, gel permeation chromatography, small-angle X-ray scattering, transmission electron microscopy, differential scanning calorimetry and dynamic mechanical spectroscopy. Two novel phases are first discovered in a single component block copolymers: hexagonally ordered spherical phase and tentatively identified dodecagonal quasicrystalline (QC) phase. In particular, the discovery of QC phase bridges the world of soft matters to that of metals. These unusual sets of morphologies will be discussed in the context of segregation under the constraints associated with the tetrablock molecular architecture. Theoretical calculations based on the assumption of Gaussian chain statistics provide valuable insights into the molecular configurations associated with these morphologies.

H1.00324 How does the host population's network structure affect the estimation accuracy of epidemic parameters?

, KENTA YASHIMA, KANA ITO, KAZUYUKI NAKAMURA, Meiji University — When an Infectious disease where to prevail throughout the population, epidemic parameters such as the basic reproduction ratio, initial point of infection etc. are estimated from the time series data of infected population. However, it is unclear how does the structure of host population affects this estimation accuracy. In other words, what kind of city is difficult to estimate its epidemic parameters? To answer this question, epidemic data are simulated by constructing a commuting network with different network structure and running the infection process over this network. From the given time series data for each network structure, we would like to analyzed estimation accuracy of epidemic parameters.

H1.00325 Systematic Construction of Braids for Topological Quantum Computation

, CAITLIN CARNAHAN, Dept. of Computer Science and NHMFL, Florida State Univ., DANIEL ZEUCH, N.E. BONESTEEL, Dept. of Physics and NHMFL, Florida State Univ. — In topological quantum computation, quantum gates are carried out by braiding worldlines of non-Abelian anyons in 2+1 dimensional space-time. The simplest such anyons for which braiding is universal for quantum computation are Fibonacci anyons. Reichardt [1] has shown how to construct nontrivial braids for three Fibonacci anyons which yield 2×2 unitary operations whose off-diagonal matrix elements (in the appropriate basis) can be made arbitrarily small through a simple and efficient iterative procedure. A great advantage of this construction is that it does not require either brute force search or the Solovay-Kitaev method. There is, however, a downside—the phases of the diagonal matrix elements cannot be directly controlled. Despite this, we show that the resulting braids can be used to construct leakage-free entangling two-qubit gates for qubits encoded using four Fibonacci anyons each. We give two explicit constructions—one based on the "functional braid" approach of Hu and Wan [2], and another based on the "effective qubit" approach of Hormozi et al. [3].

H1.00326 Study of polymorphism of Atenolol and Captopril antihypertensives using x-ray powder diffraction and Rietveld refinement[1]

, JULIANA SATO, FABIO FERREIRA, Universidade Federal do ABC (UFABC) — Characterization of bulk drugs has become increasingly important in the pharmaceutical industry. X-ray powder diffractometry is an effective technique for the identification of crystalline solid-phase drugs. The technique is unique, since it combines specificity with a high degree of accuracy for the characterization of pharmaceuticals in solid state and is an especially useful method to describe the possible polymorphic behavior of drugs substances. In this work X-ray diffraction data have been obtained for two well-known antihypertensive drugs currently being administered in tablet form. They include atenolol and captopril. Atenolol and captopril were purchased from drugstore. The characterizations of the atenolol and captopril samples were carried out by FTIR spectroscopy and X-ray powder diffraction (XRPD).

[1]We would like to thank the Brazilian agencies CNPq and FAPESP for their financial support.

H1.00327 Solvation properties of C60 fullerene in water-DMSO mixtures

, CLEITON MACIEL, Universidade Federal do ABC, EUDES FILETI, Universidade Federal de São Paulo — Binary solvent mixtures present important properties that allow their use in wide field of applications. For instance, aqueous solutions of dimethyl sulfoxide have been use in biological systems due to the properties that can reach varying on the concentration of the compounds. Solvation properties in these mixtures have been explored but have never been reported investigations of solvation properties of large non polar solutes in that system. In this work, molecular dynamics simulations were employed to investigate the solvation properties of C60 fullerene immersed in water-DMSO binary mixtures. The role of DMSO as a cosolvent was studied modeling fullerene solutions varying the DMSO molar fraction from 0 to 1.0. Partial structural results showed a dense concentration of DMSO molecules around C60 at low DMSO content solutions. In high DMSO concentrations (~ 0.70) the average number of hydrogen bonds between DMSO and water molecules and the lifetime of these interactions were smaller and higher than poor DMSO solutions, respectively. Additionally, free energy calculations were performed and an increasing hydrophobic behavior of C60 was observed in DMSO rich solutions.

H1.00328 Growth of Graphene by Catalytic Dissociation of Ethylene on CuNi(111)[1]

, PARUL TYAGI, TYLER MOWLL, ZACHARY ROBINSON, CARL VENTRICE, University at Albany-SUNY — Copper foil is one of the most common substrates for growing large area graphene films. The main reason for this is that Cu has a very low carbon solubility, which results in the self-termination of a single layer of graphene when grown using hydrocarbon precursors at low pressure. Our previous results on Cu(111) substrates has found that temperatures of at least 900 °C are needed to form single domain epitaxial films. By using a CuNi alloy, the catalytic activity of the substrate is expected to increase, which will allow the catalytic decomposition of the hydrocarbon precursor at lower temperatures. In this study, the growth of graphene by the catalytic decomposition of ethylene on a 90:10 CuNi(111) substrate was attempted. The growths were done in an ultra-high vacuum system by either heating the substrate to the growth temperature followed by introducing the ethylene precursor or by introducing the ethylene precursor and subsequently heating it to the growth temperature. The growth using the former method results in a two-domain epitaxial graphene overlayer. However, introducing the ethylene before heating the substrate resulted in considerable rotational disorder within the graphene film. This has been attributed to the deposition of carbon atoms on the surface at temperatures too low for the carbon to crystallize into graphene.

H1.00329 Exciton-induced degradation of photocurrent in small-molecule organic solar cells

, XIAORAN TONG, Materials Science and Engineering, University of Michigan, Ann Arbor, NANA WANG[1], Electrical Engineering and Computer Science, University of Michigan, Ann Arbor, MICHAEL SLOOTSKY, Physics, University of Michigan, Ann Arbor, STEPHEN FORREST, MSE, EECS and Physics, University of Michigan, Ann Arbor — The reliability of organic photovoltaic cells (OPVs) has become a focus of research. In this work, the intrinsic degradation mechanism of archetypal subphthalocyanine/fullerene OPVs in the absence of water and oxygen is studied. We focus on the initial burn-in period (<10h) during which there is no significant change in fill factor or open-circuit voltage, suggesting stable interfacial and bulk morphology. In planar OPVs employing C_{60} as the acceptor, the efficiency drop is primarily due to a reduction of photocurrent contributed by C_{60}, as observed in the spectrally-resolved external quantum efficiency (EQE). The current loss occurs after the cell is illuminated in the C_{60} absorption range, regardless of intensity and proportional to the total number of C_{60}-absorbed photons. The degradation over time is modeled as due to an increasing density of exciton-induced quenching sites that hinder exciton diffusion to the donor-acceptor interface. Experimentally, we find this mechanism can be effectively mitigated by employing a mixed donor-acceptor active layer where excitons are rapidly dissociated and the steady-state exciton density is reduced. The trap formation rate and exciton dynamics will be discussed in detail. Degradation of different OPV systems will be compared.

H1.00330 ABSTRACT WITHDRAWN –

H1.00331 Evaluation of the band-gap of Ruddlesden-Popper tantalates , JUAN RAMIREZ DE ARELLANO, SABINA RUIZ CHAVARRIA, Facultad de Ciencias, PABLO DE LA MORA, Facultad de Ciencias, Universidad Naciona Autonoma de Mexico, HOOVER A. VALENCIA, Universidad Tecnológica de Pereira, Colombia, GUSTAVO TAVIZON, Facultad de Quimica, Universidad Naciona Autonoma de Mexico — Tantalum-oxide based laminar compounds are suitable systems to perform water photo splitting reactions since the gap associated to the exciton formation has advantages over other systems. In the Ruddlesden-Popper series of compounds $A'_2[A_{n-1}B_nO_{3n+1}]$, where B=Ta and A=Lanthanide, for n=2 and 3, we have studied the effect of the A= La, Nd and Pr on the gap value, and compare our results to the experimental values for those systems. We also discuss the experimental results of the water intercalated compounds in the water splitting reaction in light of our results on the electronic structure calculations. We have evaluated the band-gap of these compounds with the WIEN2k package using the modified Becke Johnson exchange potential.

H1.00332 Photoionization of Ne IV Fine Structure Levels[1] , SULTANA NAHAR, The Ohio State University — Determination of Ne abundance, particularly in the sun, from the observed ionized neon lines has been a long standing problem. Ne IV-V lines are detected requring accuate data for the atomic processes to carry out the spectral analysis. For precise astrophysical modelling, photoionization cross sections of Ne IV have been calculated for a large number of fine structure levels in the relativistic Breit-Pauli R-matrix method. Resonances due to Rydberg series of auotionizaing states belonging to 19 excited core levels of configurations $2s^22p^2$, $2s2p^3$, and $2p^4$ are resolved with fine energy mesh. Near threshold resonances due to fine structure effects, not allowed in LS coupling, are found. Details of resonant structures and enhanced background due to Seaton resonances will be reported.

H1.00333 Radiosensitization of high-Z compounds by medium-energy 160 kV vs. high-energy 6 MV X-rays for radiation therapy: Theoretical, in vitro and in vivo studies of platinum compounds activating glioma F98 cancer cells , S. LIM, A. PRADHAN, S. NAHAR, M. MONTENEGRO, R. BARTH, R. NAKKULA, C. TURRO, The Ohio State University — Energy dependence of X-ray irradiation of high-Z compounds for enhanced radiosensitization is explored thoeretically and via in vitro and in vivo experiments. The cell killing ability of medium-energy X-rays from 160 kV source are found to be more effective than 6 MV X-rays in activating high-Z contrast agents. Results are presented for a newly synthesized Pt compound, Pyridine Terpyridine Pt(II) Nitrate ([Pt(typ)(py)]) and carboplatin in treating F98 rat glioma. In-vitro results show considerable reduction in cell viability for radiosensitized cells irradiated with a 160 kV irradiator. Cells treated with 6 MV LINAC radiation find little variation with radiation dose. Maximum dose enhancement factors (DEFs) and minimum cancer cell survival fractions correspond to 50-200 keV range, and fall rapidly at higher energies. Theoretical calculations of photoelectric absorption vis-a-vis total scattering demonstrates this energy dependence. However, in vivo studies of rats treated with [Pt(tpy)(py)] had a severe negative neurotoxic response, confirmed by histopathological analysis. But subsequent in vivo studies using carboplatin showed very positive results in the treatment of F98 glioma bearing rats and potential clinical radiation therapy.

H1.00334 The effective field induced by Rashba interaction in ferromagnetic systems , NORIYUKI NAKABAYASHI, GEN TATARA, Tokyo Metropolitan University — The spin motive force is widely used in spintronics. For example, it is demonstrated that domain wall motion is discussed by the spin motive force[1]. The spin mortive force should be devided into the two effective fields: the effective electric and magnetic field. The electric field induced by Rashba interaction is estimated from equation of motion of conduction electron[1,2], while estimating the effective magnetic field in the same way are somewhat difficult. We estimate the effective magnetic field which is estimated by calculating the electric current[3]. The electirc current is calculated in ferromagnetic metals in the presence of Rashba interaction.

H1.00335 Geometry and surface controlled formation of nanoparticle helical ribbons , JONATHAN PHAM, JIMMY LAWRENCE, DONG YUN LEE, GREGORY GRASON, TODD EMRICK, ALFRED CROSBY, University of Massachsuetts Amherst — Helical structures are interesting because of their space efficiency, mechanical tunability and everyday uses in both the synthetic and natural world. In general, the mechanisms governing helix formation are limited to bilayer material systems and chiral molecular structures. However, in a special range of dimensions where surface energy dominates (i.e. high surface to volume ratio), geometry rather than specific materials can drive helical formation of thin asymmetric ribbons. In an evaporative assembly technique called flow coating, based from the commonly observed coffee ring effect, we create nanoparticle ribbons possessing non-rectangular nanoscale cross-sections. When released into a liquid medium of water, interfacial tension between the asymmetric ribbon and water balances with the elastic cost of bending to form helices with a preferred radius of curvature and a minimum pitch. We demonstrate that this is a universal mechanism that can be used with a wide range of materials, such as quantum dots, metallic nanoparticles, or polymers. Nanoparticle helical ribbons display excellent structural integrity with spring-like characteristics and can be extended high strains.

H1.00336 Non-Gaussian statistics and spatially-organized extreme events on experimental fracture surfaces , LAURENT PONSON, CNRS, INSTITUT JEAN LE ROND D'ALEMBERT TEAM — The measurement of an abnormally high roughness exponent $\zeta \simeq 0.80$ on fracture surfaces of a large range of materials has been a long standing open question. Here, we revisit the roughness of cracks in metallic alloys and mortar where this value were reported, and show that this behavior is intimately connected with a non-Guaussian statistics of the height fluctuations of the fracture surfaces. The fat tails observed on the roughness distribution are shown to result from spatially organized domains where the local slope is abnormally large. This network of extreme events is characterized by long-range spatial correlations and power law statistics, and their scale of observations suggest that they are signature of microcracking in the material. Our findings support that damage is the central mechanism at the origin of the universal scaling behavior with $\zeta \simeq 0.80$ and open new perspectives in the quantitative investigation of microscopic failure processes from the analysis of fracture surfaces.

H1.00337 Alignment of Magnetic Nanoparticles in Polymer Films , ECEM YARAR, Department of Chemical Engineering, Yeditepe University, Istanbul, 34755, Turkey, DENIZ RENDE, Department of Materials Science and Engineering, Rensselaer Nanotechnology Center, Rensselaer Polytechnic Institute, Troy, NY 12180, USA, SEYDA BUCAK, Department of Chemical Engineering, Yeditepe University, Istanbul, 34755, Turkey — Polymer nanocomposites are advanced materials, which are obtained by the addition of natural or synthetic nanosized inorganic fillers into the polymeric material. The addition of trace amounts of nanoparticles could enhance the polymer's mechanical, thermal, electrical and optical properties due to their size and high surface area/volume ratio. In this work, magnetite/PMMA nanocomposites were prepared either by randomly dispersing or by aligning magnetite nanoparticles in the matrix using an external magnetic field. Oleic acid coated iron oxide nanoparticles (magnetite) were used as nanofiller. 7-9 nm iron oxide nanoparticles were synthesized by co-precipitation method with different surfactant amounts and at different synthesis temperatures. Superparamagnetic property of bare iron oxides was confirmed by Vibrating Sample Magnetometer (VSM) analysis. Thermogravimetric Analysis (TGA) measurements were used to calculate the surface coverage of the oleic acid on iron nanoparticles, which increases with increasing oleic acid concentration and consistent across synthesis temperature. Dispersion and alignment of nanoparticles through the polymer film were investigated with TEM and SEM. Results showed that magnetic nanoparticles formed under the influence of an external magnetic field were aligned and formed rods consisting of individual nanoparticles.

H1.00338 Disordered Floquet topological insulators

, SHIRIT BARUCH, TAMI PEREG-BARNEA, McGill University — In the presence of an external periodic field some materials become Floquet topological insulators. Introducing disorder into these systems may alter their electronic properties, which may critically affect their applications. We investigate the effects of disorder on Floquet topological insulators using a Green's function formalism. We find that in the presence of disorder, the transport properties of Floquet topological insulators differ from those of standard topological insulators. We further investigate the robustness of the topological phase to disorder.

H1.00339 Method for Reducing the Nano-Cracks on the Surface of the Heterostructure

, GAGIK SHMAVONYAN, OVSANNA ZADOYAN, State Engineering University of Armenia — The sizes of dislocations in the hetero-interface and nano-cracks on the surface of the heterostructure conditioned by lattice mismatch of semiconductors are sometimes close to those of nano-layer structures made up of a few atomic layers. Elimination of such defects becomes important in the elaboration of high quality semiconductor nanostructured optoelectronic devices. So, it is actual to develop new technological processes and elaborate adequate regimes, which will allow decreasing the sizes of defects in the heterointerface from the characteristic sizes of the structure. The method of reducing the dislocations in the heterointerface and nano-cracks on the surface of the heterostructure grown on the substrate is suggested: applying substrates with high crystallographic indices (bent substrate) and then depositing various buffer nano-layers based on compositionally graded films to the bent substrate. By solving the problem of obtaining high-quality hetero-interface and surface through epitaxial technologies it is possible to a) decrease mechanical and thermal strain in the heterointerface, b) obtain relaxed and high-quality nanoheterostructures based on big lattice mismatch.
