SWADHIN TANEJA, BEN LEVITAN, ANDREW RUTENBERG, Dalhousie University, NS, Canada — The peptidoglycan (PG) cell wall along with MreB proteins are major determinants of shape in rod-shaped bacteria. However the mechanism guiding the growth of this elastic network of cross-linked PG (sacculus) that maintains the integrity and shape of the rod-shaped cell remains elusive. We propose that the known anisotropic elasticity and anisotropic loading, due to the shape and turgor pressure, of the sacculus is sufficient to direct small gaps in the sacculus to elongate around the cell, and that subsequent repair leads to longitudinal growth without radial growth. We computationally show in our anisotropically stressed anisotropic elasticity model small gaps can extend stably in the circumferential direction for the known elasticity of the sacculus. We suggest that MreB patches that normally propagate circumferentially [1], are associated with these gaps and are steered with this common mechanism. This basic picture is unchanged in Gram positive and Gram negative bacteria. We also show that small changes of elastic properties can in fact lead to bi-stable propagation of gaps, both longitudinal and circumferential, that can explain the bi-stability in patch movement observed in $\Delta mbl \Delta mreb$ mutants.

3:18PM W45.00005 Modeling of storage-based heterocyst commitment and patterning in cyanobacteria

AIDAN BROWN, ANDREW RUTENBERG, Dalhousie University, Halifax, Nova Scotia, Canada — When deprived of fixed nitrogen, filamentous cyanobacteria differentiate nitrogen-fixing heterocyst cells in a regular, one-dimensional pattern. Many genes have been identified that contribute to heterocyst selection, but the selection process is still not well understood. By including fixed-nitrogen storage in a computational model of nitrogen dynamics, growth, and heterocyst differentiation with lateral inhibition along the filament we can explain the stochastic timing of heterocyst commitment. Notably, the only stochastic element of our model is growth rate randomness sufficient to achieve a natural population structure of cell lengths. Our computational model qualitatively reproduces many measurements associated with heterocyst differentiation including both initial and steady state heterocyst patterns. Our model shows that a fixed storage percentage, together with variability in cell length, can produce a strong implicit cell cycle effect on heterocyst commitment which favors the commitment of shorter cells.

3:30PM W45.00006 Low-temperature STM studies of electronic properties of microbial nanowires[1]

KATHY WALSH, SANELA LAMPA-PASTIRK, JOSHUA VEAZEY, GEMMA REGUERA, STUART TESSMER, Michigan State University — *Geobacter sulfurreducens* expresses pili that act as electrically conductive nanowires. These microbial nanowires transport metabolically generated electrons outside the cell body to electron acceptors in the organism's environment. We have performed scanning tunneling microscopy and spectroscopy on these pili in an endeavor to elucidate the mechanism of conductivity. In particular, we will discuss spectroscopy curves acquired at a temperature of 77 K.

3:42PM W45.00007 Direct observation and quantification of extracellular long-range electron flow in anaerobic bacteria[1] , NIKHIL MALVANKAR, SIBEL YALCIN, MADELINE VARGAS, MARK TUOMINEN, DEREK LOVLEY, University of Massachusetts, Amherst — Some anaerobic microorganisms are capable of transporting electrons outside their cell to distant electron acceptors such as metals, minerals or partner species. Previous studies have focused primarily on transport over short distances (< 1 μm) via diffusion of molecular intermediates, or alternatively via tunneling or thermally-activated hopping across biomolecules. However, we have found that *Geobacter sulfurreducens* can transport electrons over long distances (> 10 μm) using pili filaments that show organic metal-like conductivity [1]. Pili also enable direct exchange of electrons among syntrophic *Geobacter* co-cultures [2]. In order to establish the physical principles underlying this remarkable electron transport, we have employed a novel scanning probe microscopy-based method to perform quantitative measurements of electron flow at a single cell level under physiological conditions. Using this nanoscopic approach, we have directly observed the propagation and distribution of injected electrons in individual native bacterial extracellular proteins. Our direct measurements demonstrate unambiguously for the first time that the pili of *G. sulfurreducens* are a novel class of electronically functional proteins that can sustain electron flow in a surprising manner that has not been observed previously in any other natural protein.

3:54PM W45.00008 Biofilm formation and surface exploration behavior of P. aeruginosa[1] , BERNARD BECKERMAN, Northwestern University, KUN ZHAO, GERARD WONG, University of California at Los Angeles, ERIK LUIJTEN, Northwestern University — Despite extensive studies, the early stages of biofilm formation are not fully understood. Recent work on the opportunistic pathogen Pseudomonas aeruginosa has shown that these bacteria deposit the exopolysaccharide Psl as they move across a surface, which in turn attracts repeat visits of bacteria to the sites of deposition. Using a massively parallel cell-tracking algorithm combined with fluorescent Psl staining and computer simulations, we show that this behavior results in a surface visit distribution that can be approximated by a power law. The steepness of this Zipf's Law is a measure of the hierarchical nature of bacterial surface visits, and is (among other parameters) a function of both Psl secretion rate and sensitivity of the bacteria to Psl. We characterize the bacterial distributions using various computational techniques to quantitatively analyze the effect of Psl on microcolony organization and to identify the key stages of microcolony growth.

4:06PM W45.00009 Pel promotes symmetric, short-ranged surface attachment in P. aeruginosa , B. J. COOLEY, TRAVIS THATCHER, University of Texas at Austin, SARA HASHMI, Yale University, GUILLAUME L'HER, University of Texas at Austin, AHMED TOUHAMI, DANIELE PROVENZANO, University of Texas at Brownsville, VERNITA GORDON, University of Texas at Austin — Bacterial biofilms are surface mounted, multicellular communities of interacting bacteria that are often associated with chronic infections that resist antibiotics and damage host tissue. Bacteria in a biofilm are bound in a matrix of polymeric materials that adhere the bacteria to the surface, give the system spatial structure, and cluster the bacteria near each other. The opportunistic human pathogen *Pseudomonas aeruginosa* is widely studied as a model biofilm-forming organism. The polymeric matrix of *P. aeruginosa* strain PAO1 biofilms is dominated by two bacteria-produced extracellular polymers, Pel and Psl. We use both optical and atomic force microscopy to examine the roles of these polymers in very early biofilm development, in the hours after initial surface attachment. In agreement with other researchers, we find that Psl mediates strong attachment to a glass surface. Unexpectedly, we find that Pel promotes symmetric attachment, in the form of the rod-shaped bacteria lying flat on the surface, independently of permanent attachment to the surface. Further, the presence of Pel makes adhesion forces more short-ranged than they are with Psl alone. We suggest that these effects may result through synergistic interactions of Pel and Psl in the polymeric matrix.

4:18PM W45.00010 Surface-attachment sequence in Vibrio Cholerae , ANDREW UTADA, Bioengineering Dept, UCLA, MAXSIM GIBIANSKY, Bioengineering Department, UCLA, GERARD WONG, Bioengineering Dept, Chem. and Biochem. Dept, CNSI, UCLA — Vibrio cholerae is a gram-negative bacterium that causes the human disease cholera. It is found natively in brackish costal waters in temperate climates, where it attaches to the surfaces of a variety of different aquatic life. V. cholerae has a single polar flagellum making it highly motile, as well as a number of different pili types, enabling it to attach to both biotic and abiotic surfaces. Using in-house built tracking software we track all surface-attaching bacteria from high-speed movies to examine the early-time attachment profile of v. cholerae onto a smooth glass surface. Similar to previous work,[1] we observe right-handed circular swimming trajectories near surfaces; however, in addition we see a host of distinct motility mechanisms that enable rapid exploration of the surface before forming a more permanent attachment. Using isogenic mutants we show that the motility mechanisms observed are due to a complex combination of hydrodynamics and pili-surface interactions.

4:30PM W45.00011 Large scale surface migration of *P. aeruginosa* at early stages of biofilm formation , MAXSIM GIBIANSKY, ANDY UTADA, KUN ZHAO, WUJING XIAN, GERARD WONG, University of California, Los Angeles — *Pseudomonas aeruginosa* is a commonly-studied bacterium which can form biofilms, surface-bound aggregates which display increased resistance to various forms of stress, including a greatly enhanced antibiotic resistance. In the early stages of biofilm formation, free-swimming planktonic cells attach to the surface and form microcolonies, expressing a variety of adhesins and transitioning from reversible to irreversible attachment. By using particle tracking algorithms, we can in principle examine the full motility and division history of all cells in a microcolony. Here, we study the effects of the *pel* polysaccharides in microcolony formation by investigating how *pel* impacts the initial stages of biofilm formation by the *P. aeruginosa* PA14 strain. Specifically, we quantify the phenotypic effects of *pel* on initial attachment, microcolony formation, and biofilm morphology.

4:42PM W45.00012 Quantifying the Dynamics of Bacterial Crowd Surfing , ROBERT MOSCARITOLO, University of Guelph, MATT KINLEY, McMaster University, ROBIN WHITE, COREY KELLY, MAXIMILIANO GIULIANI, University of Guelph, LORI BURROWS, McMaster University, JOHN DUTCHER, University of Guelph — Type IV pili (TFP) are thin (several nanometers in diameter) adhesive protein filaments that can be extended and retracted by certain classes of Gram-negative bacteria including *P. aeruginosa* PAO1 [1]. The motion of bacteria on surfaces by TFP is referred to as twitching motility because of its jerky nature, and it leads to complex, collective motion of large numbers of cells [2]. When non-motile mutants of *P. aeruginosa* cells, which do not have pili and therefore cannot twitch, are mixed with motile, wild type cells, we observed the non-motile cells being carried along ("crowd surfing") by the moving wild type cells. Crowd surfing extends to other non-motile species as well as inert particles and can lead to unexpected transport of non-motile, pathogenic bacterial cells, with direct implications for the spread of bacterial infections. We have developed a protocol for tracking and analyzing the trajectories of moving bacterial cells. Using a custom built, temperature and humidity controlled environmental chamber, we characterize the crowd surfing phenomenon under different environmental conditions. [1] Burrows, L.L. (2005) Mol. Microbiol. 57(4): 878-888. [2] Semmler, A.B., Whitchurch, C.B., Mattick, J.S. (1999). Microbiology 145: 2863-2873.

4:54PM W45.00013 The effect of flagellar motor-rotor complexes on twitching motility in *P. aeruginosa* , KUN ZHAO, ANDREW UTADA, MAXSIM GIBIANSKY, WUJING XIAN, GERARD WONG, University of California, Los Angeles — *P. aeruginosa* is an opportunistic bacterium responsible for a broad range of biofilm infections. In order for biofilms to form, *P. aeruginosa* uses different types of surface motility. In the current understanding, flagella are used for swarming motility and type IV pili are used for twitching motility. The flagellum also plays important roles in initial surface attachment and in shaping the architectures of mature biofilms. Here we examine how flagella and pili interact during surface motility, by using cell tracking techniques. We show that the pili driven twitching motility of *P. aeruginosa* can be affected by the motor-rotor complexes of the flagellar system.

5:06PM W45.00014 Biofilm streamer formation in a microfluidic porous media mimic , ALOKE KUMAR, Biosciences Division, Oak Ridge National Laboratory, AMIN VALIEI, Department of Chemical and Materials Engineering, University of Alberta, Edmonton, AB, Canada T6G 2V4, PARTHA MUKHERJEE, Department of Mechanical Engineering, Texas A&M University, College Station, TX, USA 77843, YANG LIU, Department of Civil and Environmental Engineering, University of Alberta, Edmonton, AB, Canada T6G 2W2, THOMAS THUNDAT, Department of Chemical and Materials Engineering, University of Alberta, Edmonton, AB, Canada T6G 2V4 — Biofilm formation in porous media is of significant importance in many environmental and industrial processes such as bioremediation, oil recovery, and wastewater treatment. Among different biological and environmental factors, hydrodynamics is considered an important determinant of the dynamics of biofilm formation. In the present study, we fabricated a microfluidic porous media mimic and investigated how fluid flow influences the formation of filamentous structures, known as streamers, between porous media structures. Streamers are viscoelastic materials composed of extracellular polymeric substances (EPS) and bacterial cells, and these filamentous structures are typically tethered at either one of both ends to surfaces. We studied evolution of streamers in different flow rates and identified a tangible link between hydrodynamic conditions and development of these filamentous structures. Our results show that hydrodynamic conditions not only determine the limit of the streamers formation, but also influence both temporal evolution and spatial organization of biofilm streamers.

5:18PM W45.00015 Observation of Spontaneous Circulation in a Confined Bacterial Suspension , HUGO WIOLAND, RAYMOND GOLDSTEIN, DAMTP, University of Cambridge — The individual swimming behavior of many microorganisms is often well described by a run-and-tumble model. However steric and fluid interactions with other cells and boundaries can strongly affect this behavior. At high concentrations, rod-like bacteria are known to exhibit self-organization reminiscent of nematic liquid crytal ordering, except with polar alignment. Depending on the experimental conditions different large scale patterns can arise such as vortices, jets, plumes and swarms. We use the model organism *Bacillus subtilis* to study the effect of a quasi-2D confinement on their large scale organization. Bacteria are concentrated in flattened drops surrounded by oil. Using fluorescent microsphere tracers and particle image velocimetry, we measure the flow of the cells and of the suspending fluid inside and outside of the drop. For drop diameters ranging from 10 to 100 μm and 20 μm in height, the suspension displays spontaneous circulation in the form of a single vortex, which, for the largest drops, significantly exceeds the size of swirls in the unconfined system. Moreover we observe a striking backward flow close to the boundary. We compare these results with a theoretical analysis to gain insights into the assembly and stability of such patterns.

Session W46 GIMS: Focus Session: Advances in Scanned Probe Microscopy III: Novel Approaches and Ultrasensitive Detection Hilton Baltimore Holiday Ballroom 5 - Eric Hudson, Pennsylvania State University

2:30PM W46.00001 Probing single molecules with the STM in the frequency and time domains , HIKARI KIMURA, Department of Physics and Astronomy, University of California, Irvine, WEICAI CAO, Department of Chemical Engineering and Materials Science, University of California, Irvine, CALVIN PATEL, Department of Physics and Astronomy, University of California, Irvine, WILSON HO, Department of Physics and Astronomy and Department of Chemistry, University of California, Irvine — We have constructed a scanning tunneling microscope (STM) and combined it with a tunable femtosecond laser (210 nm to 1040 nm) to probe single molecules with simultaneous spatial and temporal resolutions. Employing the RF lock-in amplifier to measure the laser-induced tunneling current that is directly synchronized with the high repetition rate of the laser ($\sim$80 MHz), time resolved measurement of single molecules with atomic scale resolution can be achieved by varying the time delay between pairs of laser pulses in the two-pulse correlation or two-color pump-probe configuration. A femtosecond laser system with widely tunable wavelength enables resonant excitation of single molecules that are partially decoupled electronically from the underlying metallic substrate by a thin oxide or additionally atomic or molecular layers. The experimental arrangement allows measurement of molecular lifetimes by two-photon photoemission spectroscopy and microscopy.

2:42PM W46.00002 High Resolution Single Molecule Vibrational Spectroscopy with the STM , CHEN XU, CHILUN JIANG, YANNING ZHANG, RUQIAN WU, WILSON HO, Department of Physics and Astronomy, University of California, Irvine — Inelastic electron tunneling spectroscopy (IETS) with the scanning tunneling microscope (STM) has been regarded as the ultimate tool to identify and characterize single molecules adsorbed on solid surfaces with atomic spatial resolution. With the improvement of energy resolution obtained at $\sim$ 600 mK, STM-IETS is able to resolve the lowest vibrational energies and reveal subtle interactions between the molecule and its environment which were previously not possible at higher temperatures. Here we demonstrate the capability of sub-Kelvin STM on detecting the influence of the tip as well as the anisotropy of the reconstructed Au(110) surface on the low energy hindered vibrational motions of single adsorbed CO molecule. Single molecule vibrational spectroscopy at $\sim$ 600 mK with atomic scale spatial resolution opens new possibilities to probe molecular interactions with high spectral sub-THz resolution.

2:54PM W46.00003 Measuring infrared absorption of molecular adsorbates at the submonolayer level by scanning tunneling microscopy-based IR spectroscopy (IR-STM) , IVAN V. PECHENEZHSKIY, GIANG D. NGUYEN, XIAOPING HONG, Department of Physics, University of California at Berkeley, Berkeley, California 94720, JEREMY E. P. DAHL, Stanford Institute for Materials and Energy Science, Stanford University, Stanford, California 94305, FENG WANG, MICHAEL F. CROMMIE, Department of Physics, University of California at Berkeley, Berkeley, California 94720 — Here we present a simple, effective technique whereby a scanning tunneling microscope (STM) can achieve vibrational spectroscopy of molecular adsorbates at the submonolayer level through the use of a tunable infrared (IR) laser source. By using the STM as a detector to probe the IR molecular response, the technique takes advantage of the high spectral resolution inherent to IR measurements while avoiding the typical difficulties related to optical detection. This technique also allows sub-nm scale spatial mapping of surface structure under the same experimental conditions that the STM-IR absorption spectra are acquired (sub-nm spatial resolution for specific IR spectral features has not yet been achieved). Using this technique we have obtained IR absorption spectra of higher diamondoid molecules, specifically [121]tetramantane and [123]tetramantane, deposited on a Au(111) surface. The significant differences between the IR-STM spectra obtained for these two molecular isomers show the power of this new technique to differentiate chemical structures.

3:06PM W46.00004 Imaging the Electron-Phonon Interaction on the Atomic Scale[1]

, IGOR ALTFEDER, Air Force Research Laboratory, KONSTANTIN MATVEEV, Argonne National Laboratory, ANDREY VOEVODIN, Air Force Research Laboratory — New STM-based spectroscopic imaging technique, direct real-space imaging of electron-phonon interaction parameter λ, was demonstrated using the combination of STM and inelastic electron tunneling spectroscopy (IETS) for thin Pb islands epitaxially grown on 7x7 reconstructed Si(111). We found that λ increases when the electron scattering at the Pb/Si(111) interface is diffuse and decreases when the electron scattering becomes specular. We show that the effect is driven by transverse redistribution of the electron density inside a quantum well. Reference: Igor Altfeder, K. A. Matveev, A. A. Voevodin, "Imaging the Electron-Phonon Interaction on the Atomic Scale", Physical Review Letters 109, 166402 (2012).

3:18PM W46.00005 Vibrational and electronic properties of small molecules on metal surfaces

, YANNING ZHANG, CHEN XU, CHI-LUN JIANG, WILSON HO, RUQIAN WU, Department of Physics and Astronomy, University of California, Irvine, CA 92697 — Research of manipulating chemical bonds in a single molecule has been extremely active in recent years. Using a newly built milli-Kelvin scanning tunneling microscope, we can now resolve vibrational spectroscopic features down to a few tenths meV. Synergistic density functional calculations allow correct interpretation for each vibrational mode and provide links between experimental observations to the change of individual chemical bonds. In particular, we explored the effect of tunneling gap distance on different vibrational energies, by moving the tip toward the molecules, so as to shed some light for selective bond dissociation and formation. Here we discuss our results of the atomic structure, vibrational and electronic properties of several small molecules such as CO on the anisotropic Au(110) surface and C2H2 on the Cu(001) square lattice. Calculated vibrational frequencies, using the generalized gradient approximation or the non-local van der Waals density functional, are in good agreement with experimental results. **Acknowledgement.** Work was supported by the National Science Foundation under CHE-0802913 and computing time at XSEDE.

3:30PM W46.00006 Design and Implementation of a 4K Cryocooler-Based Scanning Tunneling Microscope[1]

, RAMYA VISHNUBHOTLA, NEAL HARRINGTON, BILL DUSCH, CARRIE GENG, RIJU BANNERJEE, LAVISH PABBI, ERIC W. HUDSON, Pennsylvania State University — Low temperature, ultra-high vacuum scanning tunneling microscopes (STMs) have proved to be excellent tools for the study of electronic properties of complex materials. Unfortunately, with the continuing increase in liquid helium prices, already a dominant cost for operating these systems, their use is becoming exceedingly expensive. Here we describe the design and implementation of a STM cooled by a Cryomech PT407 Remote Motor Cryorefrigerator, allowing us to reach helium temperatures using a closed thermodynamic cycle with zero cryogen waste. Unfortunately, this refrigeration technique is not ultra-high vacuum (UHV) compatible and introduces vibrations. To tackle these problems, we separately house the cryocooler in a high-vacuum (HV) chamber. This provides both a UHV environment for the STM and mechanical isolation to minimize vibrations reaching the instrument. However, it makes for more challenging thermal connections. This last difficulty we solve by introducing a novel coaxial thermal feedthrough between the HV and UHV chambers.

3:42PM W46.00007 Spin dynamics of atoms and magnetic nanostructures on surfaces

, ANDREAS HEINRICH, IBM Research — Scanning tunneling microscopy is a powerful tool for studying the electronic and magnetic properties of magnetic nanostructures on surfaces. Over the last decade, inelastic tunneling spectroscopy has been used to probe discrete energy levels of quantum spin systems. These states can often be described as solutions of simple spin Hamiltonians. In spin excitation spectroscopy, a spin system is kicked from the ground into excited spin states at discrete energy increments. In this talk we will focus on the dynamics of quantum spin systems on surfaces. STM can measure tunnel currents in the range of pico amps with millisecond time resolution. This time resolution is well matched to observing transition between spin states of artificial magnetic nanostructures on surfaces that can be built and measured with STM. We will highlight an example of extended, artificial antiferromagnets on a Cu2N surface (Science 2012). Smaller magnetic clusters relax much faster but their dynamics can be measured with pump probe techniques. A pump voltage pulse drives the spin system into excited states and a subsequent probe pulse measures the resulting population of spin states. An exponential decay back to the ground state is observed when averaging over many pump-probe cycles (Science 2010). We will show results down to nanosecond time resolution with an ultimate limit set by modern electronics at about 100 pico seconds. Individual atoms on Cu2N relax their spin states even faster. Hence, another technique is employed to determine spin relaxation times: small tunnel currents always leave the spin system in the ground state while high currents can create non-equilibrium distributions of spin states. This approach relies on some modeling but allows time domain measurements down to about 1 pico second (Nature Physics 2010). Transition metal atoms on metal surfaces relax even faster, on time scales of about 100 femtoseconds. This fast relaxation manifests itself as a measurable lifetime broadening of spin excitation spectra. Combining these approaches allows measurements of spin relaxation times over about 16 orders of magnitude for spins on surfaces – while maintaining the atomic scale spatial resolution of STM!

4:18PM W46.00008 A versatile variable field module for Asylum Cypher scanning probe system[1]

, HONGXUE LIU, RYAN COMES, JIWEI LU, STUART WOLF, Department of Materials Science and Engineering, University of Virginia, Charlottesville, VA 22904, JIM HODGSON, MAARTEN RUTGERS, Asylum Research, Santa Barbara, CA 93117 — Atomic force microscopy (AFM) has become one of the most widely used techniques for measuring and manipulating various characteristics of materials at the nanoscale. However, there are very limited option for the characterization of field dependence properties. In this work, we demonstrate a versatile variable field module (VFM) with magnetic field up to 1800 Oe for the Asylum Research Cypher system. The magnetic field is changed by adjusting the distance between a rare earth magnet and the AFM probe. A built-in Hall sensor makes it possible to perform in-situ measurements of the field. Rotating the magnet makes it possible to do angular field dependent measurements. The capability of the VFM system is demonstrated by degaussing a floppy disk media with increasing magnetic field. The written bits are erased at about 800 Oe. Angular dependence measurements clearly show the evolution of magnetic domain structures. A completely reversible magnetic force microscopy (MFM) phase contrast is observed when the magnetic field is rotated by 180°. Further demonstration of successful magnetic switching of $CoFe_2O_4$ pillars in $CoFe_2O_4$-$BiFeO_3$ nanocomposites will be presented and field dependent MFM and piezoresponse force microscopy (PFM) will be discussed.

[1]The work at University of Virginia was supported by DARPA under contract no. HR-0011-10-1-0072.

4:30PM W46.00009 Magnetoelectric Force Microscopy for visualizing cross-coupled domains[1]

, YANAN GENG, WEIDA WU, Department of Physics and Astronomy, Rutgers University, Piscataway, NJ 08854 — Intensive studies have been focused on magnetoelectric (ME) effect ever since Dzyaloshinskii and Astrov's seminal works on linear ME effect in Cr_2O_3. The measurements of the components of ME tensor are of great importance in technical applications and in fundamental science (e.g. determining magnetic point groups). For bulk ME measurements, it is necessary to obtain a single domain state by the ME annealing (i.e. applying magnetic and electric fields simultaneously) of the specimen through its transition temperature. However, the ME domain structure has never been directly observed due to the weakness of the ME effect in most magnetoelectrics. To address this critical issue, we have developed a nanoscale imaging technique, namely, the Magnetoelectric Force Microscopy (MeFM), to directly detect local ME response based on magnetic force microscopy with *in-situ* high voltages. Preliminary results of visualizing ME domains will be presented to demonstrate the feasibility of the MeFM technique.

[1]This work is supported by DOE grant DE-SC0008147.

4:42PM W46.00010 Background-free Piezoresponse Force Microscopy with high sensitivity[1] , WENBO WANG, YANAN GENG, WEIDA WU, Department of Physics and Astronomy, Rutgers University, Piscataway, NJ, 08854 USA — Piezoresponse Force Microscopy (PFM) detects small mechanical deformation of a specimen by applying an AC voltage between a conductive AFM tip (as a top electrode) and the bottom electrode. It is widely used for visualizing ferroelectric domain patterns with high lateral resolution. In nominal or commercial setups, the PFM signal is contaminated by the so-called "system-inherent background" with a complex frequency spectrum which consists of many cross-talk resonances with peak amplitude over 10 pm/V [1]. The presence of the system-inherent background will severely distort the PFM contrast (especially the phase signal) and the domain pattern in PFM images of ferroelectrics with weak piezoelectric response ($<$1 pm/V). Although the system-inherent background can be subtracted out by proper calibration using a non-piezoelectric material (e.g. glass slides), it is highly desirable to eliminate it directly from PFM setup for background-free measurements. Here we demonstrate that the system-inherent background can be eliminated using carefully designed electric wiring of PFM setup. Results of background-free PFM detection with excellent sensitivity($\leq$0.1 pm/V) will be presented.

4:54PM W46.00011 On-line Scanned Probe Microscopy Transparently Integrated with DualBeam SEM/FIB Systems , ANDREY IGNATOV, ANATOLY KOMISSAR, Nanonics Imaging Ltd., AARON LEWIS, Hebrew University of Jerusalem, Dept. of Applied Physics & Benin School of Engineering & Computer Science — A multifunctional scanning probe microscope (SPM) will be described that transparently integrates with a DualBeam SEM/FIB System. This is done without perturbing any of the capabilities of the Dual Beam in terms of detectors, gas injectors, analyzers etc while allowing for a completely exposed probe tip to be imaged online even with immersion objectives at working distances as short as 4 mm. In addition, the completely free motion of the rotation axis of the stage is maintained with the probe tip at the eucentric point, this makes it possible to orient the sample in any direction on any structure The X and Y scan range of the atomic force microscopic (AFM) imaging achieves 35 microns with rough motion over 10 millimeters. This permits the SPM to tilt into position perpendicular to the SEM or FIB or under an angle for rapid and accurate placement of the probe tip at or on structures such as biopolymeric materials that are nanometric in X, Y and Z extent. Thus, not only can a structure's nanometric height be accurately profiled but this can be accomplished with the on-line excellence of SEM for X, Y metrology. Furthermore, electron and ion beam sensitive samples can be imaged and characterized by AFM at high resolution.

5:06PM W46.00012 Massively Multiplexed Cantilever-free Scanning Probe Lithography , KEITH A. BROWN, DANIEL J. EICHELSDOERFER, Northwestern University Department of Chemistry and International Institute for Nanotechnology, WOOYOUNG SHIM, Northwestern University Department of Materials Science and Engineering, RADHA BOYA, ABRIN L. SCHMUCKER, GUOLIANG LIU, Northwestern University Department of Chemistry and International Institute for Nanotechnology, CHAD A. MIRKIN, Northwestern University Department of Chemistry, Department of Materials Science and Engineering, and International Institute for Nanotechnology — Cantilever-free scanning probe lithography has emerged as a low-cost technique for rapidly patterning nanoscale materials. In this architecture, an array of probes is fabricated on a soft backing layer that provides mechanical compliance to each probe while an underlying hard surface maintains the structural integrity of the array. One drawback of this technique is that each probe in the array acts simultaneously and thus generates a copy of the same pattern. Here, we discuss recent efforts to incorporate heaters into these probe arrays so that when a given heater is activated, the thermal expansion of the elastomer actuates a single tip. We find thermal actuation to be powerful enough to actuate individual tips over 4 μm with minimal crosstalk, fast enough to actuate on relevant time scales (20 ms), and scalable by virtue of being electrically addressable. Furthermore, tuning the individual heaters allows for variability in the arrays to be compensated for precisely, resulting in high quality nanopatterning. The addition of tunable actuators transforms cantilever-free scanning probe lithography into a technique capable of true desktop nanofabrication.

5:18PM W46.00013 Tuning the Spring Constant of Cantilever-free Probe Arrays , DANIEL J. EICHELSDOERFER, KEITH A. BROWN, RADHA BOYA, Northwestern University Department of Chemistry and International Institute for Nanotechnology, WOOYOUNG SHIM, Northwestern University Department of Materials Science and Engineering, CHAD A. MIRKIN, Northwestern University Department of Chemistry, Department of Materials Science and Engineering and International Institute for Nanotechnology — The versatility of atomic force microscope (AFM) based techniques such as scanning probe lithography is due in part to the utilization of a cantilever that can be fabricated to match a desired application. In contrast, cantilever-free scanning probe lithography utilizes a low cost array of probes on a compliant backing layer that allows for high throughput nanofabrication but lacks the tailorability afforded by the cantilever in traditional AFM. Here, we present a method to measure and tune the spring constant of probes in a cantilever-free array by adjusting the mechanical properties of the underlying elastomeric layer. Using this technique, we are able to fabricate large-area silicon probe arrays with spring constants that can be tuned in the range from 7 to 150 N/m. This technique offers an advantage in that the spring constant depends linearly on the geometry of the probe, which is in contrast to traditional cantilever-based lithography where the spring constant varies as the cube of the beam width and thickness. To illustrate the benefit of utilizing a probe array with a lower spring constant, we pattern a block copolymer on a delicate 50 nm thick silicon nitride window.

5:30PM W46.00014 Debye screening length of electrolytic solutions from capacitive force measurements using atomic force microscopy[1] , BHARAT KUMAR, SCOTT R. CRITTENDEN, Department of Physics and Astronomy, University of South Carolina, Columbia, SC 29208 — We present a method to obtain the Debye screening length of a dilute electrolytic solution by measuring the capacitve force using atomic force microscopy (AFM). A small AC bias voltage of frequency ω was applied between an AFM cantilever and conducting substrate in an electrolytic solution and the resulting capacitive force between them was measured from the cantilever oscillations. The 2ω component of the oscillating force was used to obtain the capacitance gradient between the AFM cantilever tip and substrate as a function of tip-sample distance z. An analytic expression relating tip-sample distance z and capacitance gradient between AFM tip and conducting substrate in an electrolytic solution was derived using the solution of the linearized Poisson-Boltzmann equation. We find that the analytic expression fits well with the experimental data for dilute KCl-water solutions. The fit parameters were further used to calculate the Debye screening length of the electrolytic solution.

Session W47 DBIO: Invited Session: The Spread of Cancer and the Tumor Microenvironment

Hilton Baltimore Holiday Ballroom 6 - Herb Levine, Rice University

2:30PM W47.00001 Modeling invasion of brain tissue by glioblastoma cells: ECM alignment and motility , L.M. SANDER, Physics and Complex Systems, University of Michigan — A key stage in the development of highly malignant brain tumors (Glioblastoma Multiforme) is invasion of normal brain tissue by motile cells moving through a crowded, complex environment. Evidence from *in vitro* experiments suggests the cell motion is accompanied by considerable deformation and alignment of the extra-cellular matrix (ECM) of the brain. In the case of breast cancer, alignment effects of this sort have been seen *in vivo*. We have modeled features of this system including stress confinement in the non-linear elasticity of the ECM and contact guidance of the cell motion.

3:06PM W47.00002 The interplay between invasion and proliferation in tumor cell navigation[1] , ESHEL BEN-JACOB[2], Rice University and Tel Aviv University — Tumor cells can employ different cellular and molecular modes of invasion. The two main phenotypic mechanisms are: 1. *Amoeboid* (or "path finder") cells that can squeeze through small gaps in the ECM (extracellular matrix). 2. *Mesenchymal* (or "path generator") cells that are more rigid and can decompose the ECM to pass through. In addition there is interplay between energy directed to more rapid motility vs. energy used for proliferation. Understanding the relative contributions of these distinct mechanisms and the balance between motility and proliferation to the efficiency of metastatic cancer migration is fundamental to the therapeutic targeting of cancer. We present a conceptual and modeling framework for the analysis and assessment of the success rate, time-to-target, and survival probability of amoeboid vs. mesenchymal modes. Similarly, we contrast invasion with and without proliferation. We treat the complex ECM geometry as a maze and employ semi-realistic modeling of cell motility. Our approach includes metabolic and timing degrees of freedom. The theoretical studies were compared with experimental efforts of cell navigation in specially designed microfluidic devices.

3:42PM W47.00003 The Interplay between Signaling and Metabolism in Breast Cancer Cell Motility and Metastasis , ILAN TSARFATY, Department of Clinical Microbiology and Immunology, Sackler School of Medicine, Tel Aviv University — The initiation and growth of tumor metastases require tumor cells go through a transition between collective-to-individual cell migration. Understanding the molecular, cellular and physical mechanisms of these different migration modes is limited. We focus on the tumor cell migration induced by Hepatocyte Growth Factor / Scatter Factor (HGF/SF) - Met-signaling, a master regulator of cell motility in normal and malignant processes. Met has been implicated in tumorigenesis and metastasis and several Met targeting agents have been introduced into the clinic, and are currently in all phases of clinical trials Our analysis demonstrates that Met signaling dramatically alter the morpho-kinetic dynamics of collective migration of tumor cells. It induce a "wave" of increasing velocities that propagates back from the leading edge, increases cells' orientation and cooperation capabilities. In parallel Met signaling induces amoeboid cell motility that increased cell individuality. The decision making regarding the motility mode is dependent on the extent of activation of unique signal and metabolic cues. We present a combination of molecular imaging, conceptual and modeling framework for the analysis and assessment of the collective mesenchymal to epithelial versus amoeboid motility. Combined together our analysis can contribute to the understanding of metastasis and personalizing anti Met targeted therapy.

4:18PM W47.00004 The biology of tumor cell invasion in the brain and its therapy , E ANTONIO CHIOCCA, Harvard Medical School — No abstract available.

4:54PM W47.00005 The interplay between cell motility and tissue architecture[1] , KANDICE TANNER, Center for cancer research, National Cancer Institure, NIH — Glandular tissue form arboreal networks comprised of acini and tubes. Loss of structure is concomitant with the in vivo pathologic state. *In vitro* models have been shown to recapitulate the functional units of the mammary gland and other organs. Despite our much improved understanding gleaned from both in vitro and in vivo interrogation, the mechanisms by which cells are able to achieve the correct tissue organization remain elusive. How do single mammary epithelial cells form polarized acini when cultured in a surrogate basement membrane gel but not on 2D surfaces? Simply put, how does a cell know which way is up? Why do malignant breast cells show a differential response in that they form non-polarized aggregates? Recently, it was determined that non-malignant cells undergo multiple rotations to establish acini while tumor cells are randomly motile during tumor formation. Can it be that a tumor cell has simply lost its way.

Session Y1 DCMP: Invited Session: New Perspectives on Kondo Systems Ballroom I - David Goldhaber-Gordon, Stanford University

8:00AM Y1.00001 Frustration & Order in Kondo Lattice Systems , MEIGAN ARONSON, Stony Brook University — No abstract available.

8:36AM Y1.00002 Visualizing heavy fermions emerging in a quantum critical Kondo lattice[1] , PEGOR AYNAJIAN, Princeton University — In solids containing elements with f orbitals, the interaction between f-electron spins and those of itinerant electrons leads to the development of low-energy fermionic excitations with a heavy effective mass. These excitations are fundamental to the appearance of unconventional superconductivity and non-Fermi-liquid behavior observed in actinide- and lanthanide-based compounds. We use spectroscopic mapping with the scanning tunneling microscope to detect the emergence of heavy excitations with lowering of temperature in a prototypical family of cerium-based heavy-fermion compounds. We demonstrate the sensitivity of the tunneling process to the composite nature of these heavy quasiparticles, which arises from quantum entanglement of itinerant conduction and f electrons. Scattering and interference of the composite quasiparticles is used to resolve their energy–momentum structure and to extract their mass enhancement, which develops with decreasing temperature. The lifetime of the emergent heavy quasiparticles reveals signatures of enhanced scattering and their spectral lineshape shows evidence of energy–temperature scaling. These findings demonstrate that proximity to a quantum critical point results in critical damping of the emergent heavy excitation of our Kondo lattice system.

9:12AM Y1.00003 Observation of Majorana-like Behavior at the Quantum Critical Point in a Resonant Level Coupled to a Dissipative Environment[1] , GLEB FINKELSTEIN, Duke University — We investigate tunneling through a resonant level embedded in a dissipative environment, which suppresses tunneling rates at low temperatures. Specifically, the resonant level is formed in a carbon nanotube quantum dot, and the dissipative environment is realized by fabricating resistive leads. For the symmetric coupling of the resonant level to the two leads, we find that the resonant peak reaches the unitary conductance e^2/h despite the presence of dissipative modes. Simultaneously, the width of the resonance tends to zero as a non-trivial power of temperature. We draw a connection between our system and a resonant tunneling in a Luttinger liquid and interpret the observed unitary resonance of vanishing width in terms of a quantum critical point (QCP). We further investigate an exotic state of electronic matter obtained by fine-tuning the system exactly to the QCP and report on several transport scaling laws both near and far from equilibrium. Particularly striking is a quasi-linear non-Fermi liquid scattering rate found at the QCP, interpreted in terms of a model with Majorana modes at the resonant level. Although unlikely to be practical for fault-tolerant quantum computing, our device constitutes a viable alternative to topological superconductors as a platform for studying strong correlation effects within Majorana physics.

9:48AM Y1.00004 Nonequilibrium Kondo model: Real-time RG study of crossover from weak to strong coupling , MIKHAIL PLETYUKHOV, Institute for Theory of Statistical Physics, RWTH Aachen University — We analyze the nonequilibrium Kondo model at finite voltage and temperature by using a new formulation [1] of the real-time renormalization group [2] with the Laplace variable as the flow parameter. We evaluate the energy-dependent spin relaxation rate and nonlinear conductance, and derive an approximate form for the universal line shape for the latter in the whole crossover regime from weak to strong coupling (that is, from high to low energy scales). The results are shown to agree well with exact methods and the numerical renormalization group in equilibrium, Fermi liquid theory, weak-coupling expansions, and recent experiments [3].

10:24AM Y1.00005 Quantum quench of Kondo correlations in optical absorption , ANDREAS WEICHSELBAUM[1], Ludwig Maximilians University — Absorption spectra of individual semiconductor quantum dots tunnel-coupled to a degenerate electron gas in the Kondo regime have recently become accessible to the experiment [1]. The absorption of a single photon leads to an abrupt change in the system Hamiltonian, which can be tailored such that it results in a quantum quench of the Kondo correlations. This is accompanied by a clear signature in the form of an Anderson orthogonality catastrophe, induced by a vanishing overlap between initial and final many-body wave functions and with power-law exponents that can be tuned by an applied magnetic field. We have modeled the experiment in terms of an Anderson impurity model undergoing an optically induced quench, and studied this *Kondo exciton* in detail using both analytical methods and the Numerical Renormalization Group (NRG). Our NRG results reproduce the measured absorption line shapes very well, showing that NRG is ideally suited for the study of Kondo excitons. In summary, the experiments demonstrate that optical measurements on single artificial atoms offer new perspectives on many-body phenomena previously studied using transport spectroscopy only.

Session Y2 DCMP: Invited Session: Magnetism and non-Fermi Liquid in Heavy Fermion Metals

Ballroom II - Piers Coleman, Rutgers University

8:00AM Y2.00001 Dimensionality and quantum criticality in heavy fermion metals[1] , SILKE PASCHEN, Vienna University of Technology — Heavy fermion compounds are at the forefront of research on quantum criticality. This is due to the fact that many of these materials can be tuned to a quantum critical point (QCP) by readily accessible values of the control parameters magnetic field, pressure or substitution/doping. In recent years efforts are being made to classify the different kinds of quantum critical behavior experimentally observed, to test the extent to which heavy fermion quantum criticality is universal. We have identified a cubic heavy fermion material, $Ce_3Pd_{20}Si_6$, as exhibiting a field-induced quantum phase transition as the lower of two consecutive phase transitions is suppressed to zero. This transition is accompanied by an abrupt change of Fermi surface [1], reminiscent of what happens across the field-induced antiferromagnetic to paramagnetic transition in tetragonal $YbRh_2Si_2$ [2]. In $Ce_3Pd_{20}Si_6$, the QCP separates two different ordered phases. In fact, a Kondo destruction QCP [3] has been theoretically predicted to exist in the ordered portion of a global phase diagram for quantum critical heavy fermion compounds [4]. We conclude that dimensionality is an effective way to tune through such a global phase diagram and that the cubic material studied here is situated in the barely explored three-dimensional portion of this phase diagram. We believe that this finding will guide the search for further experimental anchoring points in the global phase diagram, and for a unified theoretical description.

8:36AM Y2.00002 From incommensurate correlations to mesoscopic spin resonance in YbRh2Si2[1] , COLLIN BROHOLM, Institute for Quantum Matter and Department of Physics and Astronomy, Johns Hopkins University — Spin fluctuations are reported near the magnetic field driven quantum critical point in YbRh2Si2 [1]. On cooling, ferromagnetic fluctuations evolve into incommensurate correlations with a characteristic in-plane wave vector of $q_m = (\delta, \delta)$ with $\delta = 0.14 \pm 0.04$ r.l.u. At low temperatures, an in plane magnetic field induces a sharp intra doublet resonant excitation at an energy $g\mu_B\mu_0 H$ with $g = 3.8 \pm 0.2$. The intensity is localized at the zone center and has a width in momentum space indicating precession of spin density extending $\xi = 6 \pm 2$ Å beyond the 4f site.

9:12AM Y2.00003 Critical quasi-particle theory and scaling near a Quantum Critical Point of Heavy Fermion metals , PETER WÖLFLE, ITKM and INT, Karlsruhe Institute of Technology, D-76131 Karlsruhe, Germany — We recently developed a theory of the critical properties of a heavy fermion metal near an antiferromagnetic (AFM) quantum phase transition governed by three-dimensional spin fluctuations. The critical spin fluctuations induce critical behavior of the electron quasi-particles (qp) as seen in a diverging effective mass, leading, e.g., to a diverging specific heat coefficient. This in turn gives rise to a modification of the spin excitation spectrum [1]. We use that the concept of electron quasi-particles is well-defined as long as the qp width is less than their excitation energy, which is still the case in the so-called non-Fermi liquid regime. Impurity scattering [1,2] and/or higher order loop processes in the clean system [3] cause a redistribution of the critical scattering at the hot lines all over the Fermi surface, leading to a weakly momentum dependent critical self-energy. We derive a self-consistent equation for the qp effective mass which allows for two physical solutions: the usual weak coupling spin density wave solution and a strong coupling solution featuring a power law divergence of the effective mass as a function of energy scale. The resulting spin excitation spectrum obeys E/T scaling with dynamical exponent z=4 and correlation length exponent ν =1/3, in excellent agreement with data for $YbRh_2Si_2$ [1,2]. Results of our theory applied to three-dimensional metals featuring quasi-two-dimensional spin fluctuations will be presented with the aim of explaining the observed properties of the AFM quantum critical point of $CeCu_{6-x}Au_x$, in particular the E/T scaling exhibited by inelastic neutron scattering data. In that case we find z=8/3 and ν =3/7 [3]. Finally, the microscopic underpinning of our theory will be addressed, including the issues of qp renormalization, vertex corrections, interaction of bosonic fluctuations in the renormalization group sense, and higher loop corrections [3].

9:48AM Y2.00004 Ferromagnetic quantum criticality in heavy fermion systems[1] , MANUEL BRANDO, Max Planck Institute for Chemical Physics of Solids, Noethnitzer Strasse 40, 01187 Dresden, Germany — Heavy fermion (HF) systems are metals where the weak hybridisation between nearly localized f-electrons and the mobile conduction electrons, i.e. the Kondo effect, leads to a Fermi liquid (FL) ground state with narrow bands and quasiparticles with strongly enhanced effective electronic masses. When the magnetic RKKY interaction becomes comparable to the Kondo interaction, magnetic order can appear, mostly at very low T. The magnetic order can be suppressed by an external parameter, e.g. pressure or magnetic field, inducing a quantum phase transition (QPT) at $T = 0$. If this QPT is continuous, the associated quantum critical point (QCP) is surrounded by a non-FL regime of quantum critical fluctuations where unconventional superconductivity or novel phases of matter may arise [1]. The unambiguous observation of antiferromagnetic (AFM) QCPs in HF systems [2] has led to an increasing number of theoretical and experimental works in order to understand QPTs as deeply as their classical counterpart. Although it has been demonstrated that in antiferromagnets QCPs exist, in ferromagnets there is still no clear evidence. Intensive investigations have shown that metallic ferromagnets are inherently unstable [3,4] and do not exhibit a FM QCP. However, in the recently discovered HF system $YbNi_4P_2$, a quasi-1D ferromagnet with a remarkably-low $T_C = 0.15$ K [5], the T-divecgence in the Grüneisen ratio points to the presence of a FM QCP. I will present a general overview of the state of the art of FM quantum criticality in HF systems, discussing in particular the cases of $YbNi_4P_2$, CeFePO, $CePd_{1-x}Rh_x$ as well as the AFM system $YbRh_2Si_2$ where FM order is induced by chemical pressure.

Session Y3 DCMP DCOMP: Invited Session: New Directions in Fractional Quantum Hall Phenomena Ballroom III - Mansour Shayegan, Princeton University

8:00AM Y3.00001 Local thermometry and compressibility measurements as new probes of strongly correlated states , AMIR YACOBY, Harvard University — Electrons in two dimensions and strong magnetic fields can form an insulating two-dimensional system with conducting one-dimensional channels along the edge. Electron interactions in these systems can have fractionalized charge excitations and chiral edges with independent transport of charge and heat, even in opposite directions. Here, we use a quantum dot as a local thermometer to explore such heat transport along the edge at filling factor one and 2/3 in a GaAs 2DEG. Moreover, using a scanning quantum dot as a local charge sensor allows us to extract the charge of elementary excitations at filling factor 5/2 as well as to observe a delicate sequence of fractional quantum Hall states in suspended graphene.

8:36AM Y3.00002 Quantum Hall Transitions and Quantum Number Fractionalization in Trapped Cold Atom Systems , KUN YANG, Florida State University — Recently there have been experimental attempts to realize quantum Hall physics in trapped cold atom systems, either through rotation or synthetic gauge fields. This can potentially open up a completely new direction in the study of quantum Hall effects. In this talk I will discuss possible quantum phase transitions between integer and fractional quantum Hall states, driven by attractive interactions between fermionic atoms. Such transitions have no counterparts in electronic quantum Hall liquids, but are related to fractionalization transitions studied in other strongly correlated systems. In one of these examples charge fractionalization is associated with the confinement-deconfinement transition of the (2+1D) Z2 gauge theory, which is in the Ising universality class.

9:12AM Y3.00003 Fractional Quantum Hall in the Diluted Magnetic Semiconductor CdMnTe , DIETER WEISS, University of Regensburg, Germany — No abstract available.

9:48AM Y3.00004 Tunable interactions and the fractional quantum Hall effect[1] , ZLATKO PAPIC, Princeton University — We explore several realistic methods of tuning the interactions in two-dimensional electronic systems in high magnetic fields. We argue that these experimental probes can be useful in studying the interplay of topology, quantum geometry and symmetry breaking in the fractional quantum Hall effect (FQHE). In particular, we show that the mixing of subbands and Landau levels in GaAs wide quantum wells breaks the particle-hole symmetry between the Moore-Read Pfaffian state and its particle-hole conjugate, the anti-Pfaffian, in such a way that the latter is unambiguously favored and generically describes the ground state at 5/2 filling [1]. Furthermore, the tilting of the magnetic field, or more generally variation of the band mass tensor, probes the fluctuation of the intrinsic metric degree of freedom of the incompressible fluids, and ultimately induces the crossover to the broken-symmetry and nematic phases in higher Landau levels [2]. Some of these mechanisms also lead to an enhancement of the excitation gap of the non-Abelian states, as observed in recent experiments. Finally, we compare the tuning capabilities in conventional systems with that in multilayer graphene and related materials with Dirac-type carriers where tuning the band structure and dielectric environment provides a simple and direct method to engineer more robust FQHE states and to study quantum transitions between them [3].

10:24AM Y3.00005 Fractional quantum Hall effect in AlAs quantum wells: Role of valley degree of freedom , TAYFUN GOKMEN, IBM T.J. Watson Research Center — When interacting two-dimensional electrons are placed in a large perpendicular magnetic field, to minimize their energy, they capture an even number of flux quanta and create new particles called composite fermions (CFs). These complex electron-flux-bound states offer an elegant explanation for the fractional quantum Hall effect. Thanks to the flux attachment, the effective field vanishes at half-filled Landau levels ($\nu = 1/2$ and $3/2$) and CFs exhibit Fermi-liquid-like properties, similar to their zero-field electron counterparts. Here, we study a two-dimensional electron system in AlAs quantum wells where the electrons occupy two conduction band valleys with anisotropic Fermi contours and strain-tunable occupation. We address a fundamental question whether the anisotropy of the electron effective mass and Fermi surface is transferred to the CFs formed around filling factors $\nu = 1/2$ and $3/2$. Similar to their electron counter parts, CFs also exhibit anisotropic transport, suggesting an anisotropy of CF effective mass and Fermi surface. We also study quantum Hall ferromagnetism for fractional quantum Hall states formed at $\nu = 1/3$ and $5/3$ as a function of valley splitting. Within the framework of the CF theory, electronic fractional filling factors $\nu = 1/3$ and $5/3$ are equivalent to the integer filling factor $p = 1$ of CFs. Reminiscent of the quantum Hall ferromagnetism observed at $\nu = 1$, we report persistent fractional quantum Hall states at filling factors $\nu = 1/3$ and $5/3$ when the two valleys are degenerate. However, the comparison of the energy gaps measured at $\nu = 1/3$ and $5/3$ to the available theory developed for single-valley, two-spin systems reveals that the gaps and their rates of rise with strain are much smaller than predicted.

Friday, March 22, 2013 8:00AM - 11:00AM –

Session Y5 DCMP: Graphene: Transport and Optical Phenomena: Heterostructures 301 - Sufei Shi, University of California, Berkeley

8:00AM Y5.00001 Plasmons and Coulomb drag in Dirac/Schroedinger hybrid electron systems[1] , ALESSANDRO PRINCIPI, MATTEO CARREGA, NEST, Istituto Nanoscienze-CNR and Scuola Normale Superiore, I-56126 Pisa, Italy, REZA ASGARI, School of Physics, Institute for Research in Fundamental Sciences (IPM), Tehran 19395-5531, Iran, VITTORIO PELLEGRINI, MARCO POLINI, NEST, Istituto Nanoscienze-CNR and Scuola Normale Superiore, I-56126 Pisa, Italy — We show that the plasmon spectrum of an ordinary two-dimensional electron gas (2DEG) hosted in a GaAs heterostructure is significantly modified when a graphene sheet is placed on the surface of the semiconductor in close proximity to the 2DEG. Long-range Coulomb interactions between massive electrons and massless Dirac fermions lead to a new set of optical and acoustic intra-subband plasmons. Here we compute the dispersion of these coupled modes within the Random Phase Approximation, providing analytical expressions in the long-wavelength limit that shed light on their dependence on the Dirac velocity and Dirac-fermion density. We also evaluate the resistivity in a Coulomb-drag transport setup. These Dirac/Schroedinger hybrid electron systems are experimentally feasible and open new research opportunities for fundamental studies of electron-electron interaction effects in two spatial dimensions.

[1]Work in Pisa was supported by MIUR through the program "FIRB - Futuro in Ricerca 2010." Grant no. RBFR10M5BT ("Plasmons and terahertz devices in graphene").

8:12AM Y5.00002 Enhancement of Coulomb drag in double-layer graphene structures by plasmons and dielectric background inhomogeneity , SAMVEL M. BADALYAN, FRANCOIS M. PEETERS, Department of Physics, University of Antwerp, Groenenborgerlaan 171, B-2020 Antwerpen, Belgium — The drag of massless fermions in graphene double-layer structures has been investigated over a wide range of temperatures and interlayer separations. We have shown [1] that the inhomogeneity of the dielectric background in such graphene structures, for experimentally relevant parameters, results in a significant enhancement of the drag resistivity. At intermediate temperatures the dynamical screening via plasmon-mediated drag enhances the drag resistivity and results in an upturn in its behavior at large interlayer separations. In a range of interlayer separations, corresponding to the crossover from strong to weak coupling of graphene layers, we find that the decrease of the drag resistivity with interlayer spacing is approximately quadratic. This dependence weakens below this range of interlayer spacing while for larger separations we find a cubic (quartic) dependence at intermediate (low) temperatures.

[1] S. M. Badalyan and F. Peeters, Phys. Rev. B **86**, 121405(R) (2012).

8:24AM Y5.00003 Energy-driven drag in Graphene , JUSTIN SONG, Harvard University/MIT, LEONID LEVITOV, MIT — When solid surfaces slide against each other they experience friction which can be enhanced by inserting molasses between them or reduced by using a lubricant. In the same way, two spatially isolated conducting layers that are placed in close proximity with each other feel friction because the long-ranged Coulomb interaction allows electrons in adjacent layers to "rub shoulders at a distance." Recent measurements of Coulomb drag in Graphene by Gorbachev and co-workers from Manchester (doi:10.1038/nphys2441) have found that it is dramatically enhanced near the Dirac point, in stark contradiction with earlier theories predicting vanishing drag. We argue that a new kind of drag develops when heat transport in the two layers becomes strongly coupled due to efficient energy transfer between the layers. As a result, spatial charge inhomogeneity couples the motion of the electron liquid with heat transport through it, damping motion of electron flow in one layer by heat dissipation in the other. Interestingly, and somewhat paradoxically, this leads to strong drag without momentum transfer between layers. We predict distinct experimental signatures and discuss its magnetic field dependence.

8:36AM Y5.00004 Hydrodynamical Modes and New Transport Phenomena in Graphene: Nonlocality and Anomalous Drag , LEONID LEVITOV, MIT — The semimetal band structure of graphene givs rise to an unusually strong coupling between electrical currents and charge-neutral currents. This coupling leads to new transport phenomena mediated by neutral modes. This talk will highlight two examples connected with ongoing experiments. One is giant nonlocality observed in electric measurements.[1] This effect was explained by spin transport made possible by novel spin-Hall response near the Dirac point.[2] Another example is anomalous drag observed at charge neutrality which was attributed to the effects mediated by energy transfer in graphene heterostructures.[3,4] Drag measurements thus afford a unique probe of energy transfer at the nanoscale, a fundamental process which is not easily amenable to more conventional techniques such as calorimetry, and is key for the physics of strong interactions that occur near neutrality.

8:48AM Y5.00005 Insulating behavior at the neutrality point in dual-gated single-layer graphene , FRANCOIS AMET, JAMES WILLIAMS, DAVID GOLDHABER-GORDON, Stanford University — The conductivity at the neutrality point in single-layer graphene is known to saturate on the order of e^2/h due to disorder-induced density fluctuations. In this study, we report contrasting results using dual-gated graphene devices with a boron nitride back-gate dielectric and a suspended top-gate, allowing for carrier mobilities over 100 000 cm^2/Vs. As the temperature is lowered, the peak resistivity at the charge-neutrality point unexpectedly diverges with a power-law behavior and becomes as high as several megohms per square. As a transverse magnetic field is applied, our device remains insulating and directly transitions to the ?=0 quantum Hall state. We discuss possible origins for this insulating behavior.

9:00AM Y5.00006 Broken Symmetry Quantum Hall states in Dual Gated ABA Trilayer Graphene , YONGJIN LEE, University of California Riverside, JAIRO VELASCO JR., University of California Berkeley, DAVID TRAN, University of California Riverside, FAN ZHANG, University of Pennsylvania, WENZHONG BAO, LEI JING, KEVIN MYHRO, University of California Riverside, DMITRY SMIRNOV, National High Magnetic Field Laboratory, JEANIE LAU, University of California Riverside — We perform low temperature transport measurements on dual-gated suspended trilayer graphene in the quantum Hall (QH) regime. We observe QH plateaus at filling factors ν =-8, -2, 2, 6, and 10, in agreement with the full-parameter tight binding calculations. In high magnetic fields, oddinteger plateaus are also resolved, indicating almost complete lifting of the 12-fold degeneracy of the lowest Landau levels (LL). Under an out-of-plane electric field E$\perp$. We observe degeneracy breaking and transitions between QH plateaus. Interestingly, depending on its direction, E$\perp$selectively breaks the LL degeneracies in the electron-doped or hole-doped regimes.

9:12AM Y5.00007 Comparison of mobility at the top and bottom surfaces of multilayer graphene placed on SiO_2 substrate , AKINOBU KANDA, YOUSUKE NUKUI, HIKARI TOMORI, HIDENORI GOTO, YOUITI OOTUKA, University of Tsukuba — It is known that charged impurities attached to the surface of graphene films are the main source of deteriorating mobility in graphene flakes obtained by the mechanical exfoliation. There are several origins for charged impurities: charges in the substrate, to which the bottom surface of the graphene films faces, the adsorbed molecules and contaminations due to chemicals (resist residues and so on) mainly attached to the top surface of graphene. This paper aims to evaluate the influence of the charged impurities on the top and bottom surfaces separately. For this purpose, we used dual-gated multilayer graphene with a contactless top gate. We developed a method of estimating the mobility of the top and bottom surfaces of multilayer graphene (MLG), from the top- and bottom-gate voltage dependence of the conductivity. We find that in thick MLG, mobility of the top surface is more than three times larger than that of the bottom surface. This indicates that the influence of the SiO_2 substrate on the mobility is stronger than that of adsorbates and contaminations on the top surface of the MLG.

9:24AM Y5.00008 Electric charge and potential distribution in twisted multilayer graphene[1] , NATALYA ZIMBOVSKAYA, University of Puerto Rico-Humacao, EUGENE MELE, University of Pennsylvania — The specifics of charge screening and electrostatic potential spatial distribution in rotationally faulted multilayered graphene films with decoupled layers placed in between charged substrates is theoretically analyzed. The analysis is carried out using a nonlinear Thomas -Fermi approach. It is shown that by varying the areal charge densities on the substrates and/or the thickness of the graphene pack one may tune the screening length in the graphene pack. When the charge densities on the substrates are weak, the screening length is of the same order as the pack thickness, which agrees with semimetallic properties of graphene. When the amount of the donated charge is sufficiently large the screening length reduces indicating the transition to a metallic-like behavior of the graphene layers. The transition is shown to turn on rather quickly, and in occurs when the charge on the substrates/external electric field reaches a certain crossover magnitude. The possibilities for experimental observation of the predicted transition are discussed.

9:36AM Y5.00009 Tunable van Hove Singularities and Optical Absorption of Twisted Bilayer Graphene , YUFENG LIANG, LI YANG, Washington University in St. Louis — We perform the first-principles GW-Bethe-Salpeter Equation (BSE) simulation to study the optical absorption spectra of isolated twisted bilayer graphene (TBLG). The twisting generates new van Hove singularities (VHS), and these VHSs and corresponding optical absorption peaks can be tuned in a wide range by the twist angle. Enhanced electron-electron and electron-hole interactions are shown to be important to understand both optical absorption peak positions and their lineshapes. With these many-electron effects included, our calculation satisfactorily explains recent experimental measurements.

9:48AM Y5.00010 Gate tunable quantum transport in double layer graphene heterostructures[1] , KOSTYANTYN KECHEDZHI, EUYHEON HWANG, SANKAR DAS SARMA, CMTC, Department of Physics, University of Maryland College Park — Motivated by the recently observed highly resistive state in double layer graphene heterostructures [1] we consider a system of two layers of graphene, "studied" and "control," separated by an insulating layer. We theoretically analyze the effect of additional screening provided by Dirac electrons in the "control" graphene layer on the transport characteristics of the "studied" graphene layer. We find that in a typical device geometry fabricated on top of SiO2 substrate [1] the suppression of charge inhomogeneity is less efficient than initially expected and is limited by about a factor of 2. We also analyze the effect of additional screening on the quantum correction to the conductivity of the "studied" layer in this system in the metallic regime. We find that "control" layer screening is very efficient at suppressing electron-electron interactions in the "studied" layer which results in improved coherence and a novel gate tunable quantum correction to conductivity. The results of this work are summarized in [2].

10:00AM Y5.00011 Transport properties of monolayer and bilayer graphene supported by hexagonal boron nitride , JING LI, KE ZOU[1], DONALD SEIWELL, JUN ZHU, Department of Physics, Pennsylvania State University — We present transport studies on hexagonal boron nitride (h-BN) supported monolayer and bilayer graphene. Following the method introduced by Dean et al, we first exfoliate thin sheets of h-BN (15-20 nm) to SiO_2/Si substrate then align and transfer exfoliated graphene flakes onto the h-BN sheets. E-beam lithography is used to process the samples into Hall bar devices. We find that current annealing at low temperature can increase the mobility of as-fabricated devices but often introduces large density inhomogeneity at the same time. AFM images of annealed devices reveal the limitations of this technique. In comparison, thermal annealing is much more reliable in improving the sample quality. Bilayer devices annealed in a flow of Ar/H_2 at 450C for 5 hours show high mobility of 30,000 cm^2/Vs at low temperature. We observe high-quality Shubnikov-de Hass (SdH) oscillations and degeneracy-lifted Landau levels in these samples. We extend existing measurements of the electron and hole effective mass in bilayer graphene[1] to lower carrier density regimes and discuss the implications of the results.[1] K. Zou, X. Hong, and J. Zhu, Phys. Rev. B 84, 085408 (2011).

10:12AM Y5.00012 Ground state of double layer graphene heterostructures in the presence of charged impurities[1] , MARTIN RODRIGUEZ-VEGA, JONATHAN FISCHER, ENRICO ROSSI, College of William and Mary — A graphene double layer heterostructure is formed by two sheets of graphene separated by a thin dielectric film. Using the Thomas-Fermi-Dirac theory we have studied the carrier density profile in the presence of charged impurities. In this talk I will present our results for the case of heterostructures formed by two sheets of single-layer-graphene (SLG) and two sheets of bilayer-graphene (BLG). As for isolated layers, we find that the presence of charged impurities induces strong carrier density inhomogeneities, especially at low dopings where the density landscape breaks up in electron-hole puddles. We find that the amplitude of the carrier density inhomogeneities in double layers can be much lower than in isolated layers due to the better screening properties of double layer systems. I will then present results for the case of "hybrid" structures formed by one sheet of SLG and one sheet of BLG.

10:24AM Y5.00013 Electronic and thermoelectric transport in graphene double layer structures with boron nitride spacers , JIUNING HU, TAILUNG WU, JIFA TIAN, YONG CHEN, Purdue University — Recently, much attention has been devoted to electrically isolated graphene-graphene double layers in which interaction-driven novel physics such as exciton condensation are predicted. We have used polyvinyl alcohol (PVA) based carrier films and a micro-manipulator to transfer mechanically exfoliated flakes onto desired locations with accuracy of $\sim$1 μm. We have fabricated graphene/boron nitride (BN)/graphene stacking structures on BN substrates to study their electronic and thermoelectric transport properties. We observed the low temperature mobility of graphene as high as 75000 cm^2/V-s. We have performed Coulomb drag measurements and observed the sign and magnitude dependence of the drag resistivity on the carrier types and densities of both graphene layers, consistent with the previous reports. We also performed thermoelectric transport measurements in such graphene double layer structures, especially in the complementary doped regime (so called excitonic regime) with one layer of electrons and the other layer of holes. Our approach may be useful to probe exciton condensation and other novel physics driven by electron-electron interactions in graphene double layers.

10:36AM Y5.00014 Photo doping effect in graphene/BN heterostructure , LONG JU, JAIRO VELASCO JR., EDWIN HWANG, JONGHWAN KIM, FENG WANG, UC Berkeley — Boron nitride has been demonstrated as an ideal substrate to achieve high mobility in graphene. At the same time We observed strong change of graphene transport properties by shining light on graphene/BN heterostructure. This is attributed to photo doping effect induced by impurity excitation in BN. Optical spectroscopy based on this photo-doping effects enables us to probe impurities in crystalline BN. Such information will be important for potential applications based on graphene/BN heterostructures. The potential of applying similar technique to probe defects in other insulators and semiconductors will also be discussed.

10:48AM Y5.00015 Photon Induced Transport in Graphene-Boron Nitride-Graphene Heterostructures , NITYAN NAIR, NATHANIEL GABOR, QIONG MA, Massachusetts Institute of Technology, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, Japan, WENJING FANG, JING KONG, PABLO JARILLO-HERRERO, Massachusetts Institute of Technology — Monolayer graphene, an atomically thin sheet of hexagonally oriented carbon, is a zero band gap conductor that exhibits strong electron-electron interactions and broadband optical absorption. By combining MLG and hexagonal boron nitride into ultrathin vertical stacks, experiments have demonstrated improved mobility, Coulomb drag, and field-effect tunneling across few-layer boron nitride barriers. Here, we report on the photon-induced transport of charge carriers through a graphene-boron nitride-graphene heterostructure. The dependence of the generated photocurrent on photon energy and interlayer bias voltage is studied. The photocurrent is found to depend strongly on both these parameters, showing several interesting features. We consider several processes that may serve to explain the rich dependence of photoconductance on applied bias voltage and photon energy.

Session Y6 DCMP: Nanotubes and Nanowires (non-carbon): Transport and Optical Phenomena 302 - Jonathan Spanier, Drexel University

8:00AM Y6.00001 Surface Passivation and Orientation Dependence in the Electronic Properties of Silicon Nanowires , KEENAN ZHUO, Georgia Institute of Technology, Atlanta, Georgia, USA, MEI-YIN CHOU, Insitute of Atomic and Molecular Science, Academia Sinica, Taipei, Taiwan and Georgia Institute of Technology, Atlanta, Georgia, USA — Different surface passivation configurations for silicon nanowires (SiNWs) have previously been studied for expanding their technological applications. Of note, methyl (CH_3) passivated SiNWs have enhanced ambient stability, while electronegative atoms/groups such as halogens are useful in band gap engineering and chemical post-processing. Thus far though, fundamental mechanisms for how such passivations alter the electronic properties of SiNWs have not been rigorously scrutinized. In this work, we address this issue through first-principles calculations on CH_3, fluorine (F) and hydrogen (H) passivated [110] and [111] SiNWs. In comparison to H passivation, we explain how CH_3 and F passivations cause significant band gap reductions in [110] SiNWs, through strain and quantum confinement respectively. Furthermore, we discuss how structural differences in [111] SiNWs mitigate these effects, thereby giving the electronic properties of [111] SiNWs greater stability against various surface passivations than those of [110] SiNWs.

8:12AM Y6.00002 Axial Si/Ge hetero-nanowires for tunneling transistors , SON LE, Department of Physics and School of Engineering, Brown University, DANIEL PEREA, Environmental and Molecular Sciences Laboratory, Pacific Northwest National Laboratory, POOYA JANNATY, XU LUO, Department of Physics and School of Engineering, Brown University, SHADI DAYEH, Department of Electrical and Computer Engineering, University of California, ALEXANDER ZASLAVSKY, Department of Physics and School of Engineering, Brown University, THOMAS PICRAUX, Center for Integrated Nanotechnologies, Los Alamos National Laboratory — Modern vapor-liquid-solid (VLS) growth based on alloy catalysts can grow SiGe heteronanowires (hetero-NWs) with controlled axial heterojunction abruptness [1] combined with simultaneous control of material composition (Si and Ge) and doping profile. Previously, we reported on axial in-situ doped Ge NW pn junction tunneling field effect transistors (TFETs) with effective backgate control of the tunneling current [2]. In this presentation, we report on tri-gated p-Ge/i-Si/n-Si axial hetero-NWs TFET with on-state tunneling occuring in the Ge drain section and off-state leakage dominated by the Si junction in the source. The devices have high Ion of 2 uA/um, suppressed ambipolarity, and a sub-threshold slope SS of 140 mV/decade over 4 decades of current with lowest SS of 50 mV/decade. Device operation in the tunneling mode is confirmed by three-dimensional TCAD simulation. In addition, our devices work standard as NW FETs with good Ion/Ioff ratio when the source-drain junction is forward-biased [3]. [1] D. E. Perea et al., Nano Lett 11, 3117 (2011). [2] Son T. Le et al., Appl. Phys. Lett. 96, 262102 (2010). [3] Son T. Le et al., accepted to Nano Lett. (10/2012).

8:24AM Y6.00003 Probing Interface Band Edge Discontinuity in Single Core-shell Nanowire by Photocurrent Spectroscopy , GUANNAN CHEN, Department of Materials Science & Engineering, Drexel University, GUAN SUN, YUJIE DING, Department of Electrical & Computer Engineering, Lehigh University, ILIO MACCOLI, NICO LOVERGINE, Department of Innovation Engineering, University of Salento, Italy, PAOLA PRETE, IMM-CNR, Lecce, Italy, JONATHAN SPANIER, Department of Materials Science & Engineering, Drexel University — Group III-V co-axial core-shell semiconducting nanowire (NW) heterostructures possess unique advantages over their planar counterparts in logic, photovoltaic and light-emitting devices. Dimensional confinement of electronic carriers and interface complexity in NWs are known to produce local electronic potential landscapes along the radial direction that deviate from those along the normal to planar heterojunction interfaces. However, understanding of electronic and optoelectronic carrier transport properties and device characteristics remains lacking without a direct measurement of band alignment in individual NWs. Photocurrent spectroscopy has proven to be effective in investigating the effects of quantum confinement and surface related properties such as bandgaps, surface adsorption/desorption, and polarization anisotropy. Here, we report on, using the GaAs/Al_xGa_{1-x}As core-shell NW system ($x = 0.24$ and 0.33), how photocurrent and photoluminescence spectroscopies can be used together to construct a band diagram of an individual heterostructure NW with high spectral resolution. This approach and results are relevant for the study of tunable hot electron transfer across NW core-shell interfaces.

8:36AM Y6.00004 Capacitance of Nanowire with different cross sections and different materials at different frequencies[1] , ABBAS ARAB, QILIANG LI, Dept. of ECE, George Mason University, GEORGE MASON UNIVERSITY TEAM — During the past half century, feature-size of electronic elements has been reduced dramatically. Semiconductor industry expects this down-scaling to be continued for at least next decade. Among different approaches proposed for reducing the size of electronic elements, is nanowire (NW) based elements such as nanowire field effect transistor (NW-FET). NW approach offers a coaxial gate-dielectric-channel geometry that has advantage of electrostatic control in down-scaling the electronic elements. NWs can be grown in different cross sections depending on the material used as the core of the coaxial structure. Despite so much interest and research on this field, a complete set of study on nanowire capacitance will be very useful for nanoelectronics. In this work, we are going to study different NW structures with different materials and cross sections including: square, triangular, circular and hexagonal in different frequencies. We will study the effect of oxide thickness, oxide material and rotation of cross section, in cases that are not symmetric to rotation, on NW behavior.

8:48AM Y6.00005 ABSTRACT WITHDRAWN –

9:00AM Y6.00006 Discrete random distribution of source dopants in nanowire tunnel transistors (TFETs)[1] , SOMAIA SYLVIA, University of California Riverside, M. ABUL KHAYER, Intel Corporation, KHAIRUL ALAM, East West University, Dhaka, Bangladesh, HONG-HYUN PARK, Samsung Semiconductor Inc., GERHARD KLIMECK, Purdue University, ROGER LAKE, University of California Riverside — InAs and InSb nanowire (NW) tunnel field effect transistors (TFETs) require highly degenerate source doping to support the high electric fields in the tunnel region. For a target on-current of 1 μA, the doping requirement may be as high as 1.5×10^{20} cm^{-3} in a NW with diameter as low as 4 nm. The small size of these devices demand that the dopants near tunneling region be treated discretely. Therefore, the effects resulting from the random distribution of dopant atoms in the source of a TFET are studied for 30 test devices. Comparing with the transfer characteristics of the same device simulated with a continuum doping model, our results show (1) a spread of $I - V$ toward the positive gate voltage axis, (2) the same average threshold voltage, (3) an average 62% reduction in the on current, and (4) a slight degradation of the subthreshold slope. Random fluctuations in both the number and placement of dopants will be discussed. Also, as the channel length is scaled down, direct tunneling through the channel starts limiting the device performance. Therefore, a comparison of materials is also performed, showing their ability to block direct tunneling for sub-10 nm channel FETs and TFETs.

9:12AM Y6.00007 Observation of defect-induced Photoresponse and charge carrier transport in single GeSe2 nanobelt devices[1]

, BABLU MUKHERJEE, ENG SOON TOK, CHORNG HAUR SOW, National University of Singapore — Single crystal GeSe2 nanobelts were grown using chemical vapor deposition techniques. Morphology of the nanostructures was characterized using scanning electron microscopy (SEM), transmission electron microscopy (TEM), X-ray diffractometry (XRD) and Raman spectroscopy. Electronic transport properties, impedance spectroscopy, photoconductive characteristics and temperature-dependent electrical resistivity measurements were carried out on individual GeSe2 nanobelt devices. The photosensitivity of single GeSe2 nanobelt (NB) devices was examined with two different excitation wavelengths of laser beams with photon energies above band gap and at sub-band gap of the NB. A maximum photoconductive gain 10^6 % was achieved at a wavelength of 808 nm. The magnitude of the photocurrent and response time of the individual GeSe2 NB device indicate that the photoresponse could be attributed to the presence of isolated mid band gap defect levels. Temperature dependent photocurrent measurements indicate the rough estimation of the energy levels for the defect states. Localized photostudy shows that the large photoresponse of the device primarily occurs at the metal-NB contact regions.

9:24AM Y6.00008 Finite Element Analysis of lateral charge distribution in ZnO nanowire

, JAVAD USEFIE MAFAHIM, ARKADII KROKHIN, ARUP NEOGI, University of North Texas — The coupling of piezoelectric and semiconducting properties in zinc oxide creates a strain field and charge separation across a nanowire (NW) as a result of an external or internally induced strain. The potential drop along the transverse section of a hexagonal ZnO NW is simulated by the finite element analysis method. The NW is considered to be fixed at one end and laterally deflected at the other with a uniform force on a constant area of cross-section. We numerically simulate the potential drop across a direction transverse to the growth of the NW attached to the substrate. The piezoelectric potentials difference is analyzed as a function of the lateral force, thickness, and aspect ratio of the NW. It is observed that due to a change in the component of the shear force in the transverse direction with respect to the length of the NW, a significant variation of strain in observed in the direction of the lateral force. Our analysis explains previously observed experimental results. It is also shown that the potential difference is influenced by the changing aspect ratio. The charge distribution is also analyzed in a fluid medium with a lateral flow of the liquid. Our results can be used for the design of novel biosensors.

9:36AM Y6.00009 Tailoring electronic properties of SnO_2 nanobelts via thermal annealing

, TIMOTHY KEIPER, JORGE BARREDA, JOON-IL KIM, Department of Physics, Florida State University, JIM P. ZHENG, Electrical and Computer Engineering, FAMU/FSU College of Engineering, PENG XIONG, Department of Physics, Florida State University — Metal oxide semiconductors nanowires are a viable option for the fabrication of transistors with desirable characteristics for nanoelectronic and sensing applications. SnO_2 nanobelts (NBs) have been synthesized using catalyst-free chemical vapor deposition. The growth parameters have been explored, producing NBs as long as millimeters. These NBs have been demonstrated as effective channel-limited gas [1], pH [2] and protein [3] field-effect transistor (FET) sensors. Through modification of O_2 and vacuum thermal annealing conditions, we investigate the control and optimization of the electronic properties of the NBs to achieve desired device characteristics for biosensing applications. A pronounced increase in conductance, up to the order of microsiemens, has been observed in annealed NBs under O_2 environment at elevated temperatures above 600°C. We also examine the properties of the electrical contacts with different metallization and varying NB conductivity. Optimal device characteristics for various sensing applications will be tested and discussed.

9:48AM Y6.00010 Gated nonlocal transport in sketched oxide nanostructures[1]

, SHICHENG LU, GUANGLEI CHENG, JOSHUA P. VEAZEY, PATRICK IRVIN, FENG BI, MENGCHEN HUANG, JEREMY LEVY, University of Pittsburgh, CHUNG-WUNG BARK, SANGWOO RYU, KWANG-HWAN CHO, CHANG-BEOM EOM, University of Wisconsin-Madison — The oxide heterostructure $LaAlO_3/SrTiO_3$ supports a two-dimensional electron liquid (2DEL) with a variety of competing phases including magnetism, superconductivity and weak antilocalization due to Rashba spin-orbit coupling. Further confinement of this 2DEL into quasi-one-dimensional regime can provide insight into the underlying physics of this system and reveal new behavior. Prior magnetotransport experiments on narrow $LaAlO_3/SrTiO_3$ structures created by a conductive atomic force microscope lithography technique have revealed large nonlocal resistances (as large as $10^4\Omega$), with separations between current and voltage that are large compared to the 2D mean-free path. To help understand the origin of this remarkable behavior, we perform electric gating of nanowire structures in order to vary the carrier density and possibly other interactions such as spin-orbit coupling strength.

10:00AM Y6.00011 ABSTRACT WITHDRAWN –

10:12AM Y6.00012 ABSTRACT WITHDRAWN –

10:24AM Y6.00013 Atomic Hydrogen and Oxygen Adsorptions in Single-Walled Zigzag Silicon Nanotubes[1]

, HAOLIANG CHEN, ASOK RAY, University of Texas at Arlington — *Ab initio* calculations have been performed to study the electronic and geometric structure properties of zigzag Si nanotubes. Full geometry and spin optimizations have been performed without any symmetry constraints with an all electron 3-21G* basis set and the B3LYP functional. The largest zigzag silicon nanotube (12, 0) studied has a binding energy per atom of 3.584eV. Atomic hydrogen and oxygen adsorption on (9, 0) and (10, 0) nanotubes have been studied by optimizing the distances of the adatoms from both inside and outside the tube. The adatom can be placed initially in four adsorption sites- parallel bridge, zigzag bridge, hollow, and on-top site. The on-top site is the most preferred site for hydrogen atom adsorbed on (9, 0) with an adsorption energy of 3.0eV and an optimized distance of 1.49Å. For oxygen adsorption on (9, 0), the most preferred site is the zigzag bridge site with an adsorption energy of 5.987eV. For atomic hydrogen adsorption on (10, 0), the most preferred site is also the on-top site with an adsorption energy of 2.974eV and an optimized distance of 1.49 Å. For adsorption of atomic oxygen on (10, 0), the most preferred site is parallel bridge site with an adsorption energy of 6.275eV.

10:36AM Y6.00014 Topological Effect to Surface Plasmon Excitation in Topological Insulator Nanowires

, MINGDA LI, MIT, WENPING CUI, University of Bonn, JU LI, MIT, YIMEI ZHU, LIJUN WU, QINGPING MENG, BNL, WEISHU LIU, ZHIFENG REN, Boston College, FERHAT KATMIS, PENG WEI, JAGADEESH MOODERA, YONG ZHANG, MIT, LI GROUP, MIT TEAM, CFN, BNL COLLABORATION[1], FBML, MIT COLLABORATION[2], CMSE, MIT COLLABORATION[3], REN GROUP, BC COLLABORATION[4] — We present a theoretical investigation of the surface plasmon at the interface between topologically-non-trivial cylindrical core and topological-trivial surrounding material, from the axion electrodynamics and modified constitutive relations. We find that the topological effect lowers the SP energy in any case, while as the diameter of the core becomes smaller, the topological modification to SP energy is reduced. A qualitative picture based on perturbation theory of shifted boundary is given to explain these phenomena, from which we also infer that in order to amplify the topological effect, the difference between the inverse of dielectric constants of two materials must be increased. We also find that when the surrounding material goes magnetic, the magnetism overcomes topological effect, makes the latter seemingly suppressed. What's more, bulk plasmon energy at 17.5 $\pm$ 0.2eV for semiconducting Bi2Se3 nanoparticle is observed from high-resolution Electron Energy Loss Spectrum Image measurements.

Session Y7 DMP: Focus Session: Carbon Nanotubes: Sensor Applications and Gas Absoprtion

303 - Charlie Johnson, University of Pennsylvania

8:00AM Y7.00001 Parts-per-quadrillion Resolution Molecular Sensor Based on Pristine Carbon Nanotubes

, GUGANG CHEN, Honda Research Institute USA, Inc. — Single-walled carbon nanotube (SWNT) is probably the ultimate sensor among nanoscale semiconducting materials since a SWNT consists solely of surface so that every single carbon atom is in direct contact with the environment, allowing optimal interaction with nearby molecules. Ironically the ultrahigh sensitivity of SWNTs is easily compromised by various unintentional contaminants from the device fabrication process as well as the ambient environment. Here we show that applying continuous in situ ultraviolet (UV) light illumination during gas detection could dramatically enhance a SWNT-sensor's performance and for the first time achieve parts-per-quadrillion (PPQ) resolution with detection limit as low as 590 PPQ for nitric oxide detection at room temperature [1]. Gas detections on NO_2 and NH_3 further showed sensitivities 2 to 3 orders of magnitude better than what previously had reported. The much enhanced performance is apparently aroused from the UV light induced sensor surface cleaning. In addition, aiming for practical applications we illustrate how to address gas selectivity by introducing a gate bias.

8:36AM Y7.00002 Carbon nanotube based photon filter for energetic particle detection[1]

, DAVID DEGLAU, STERGIOS PAPADAKIS, ANDREW MONICA, BRUCE ANDREWS, DONALD MITCHELL, Johns Hopkins University Applied Physics Laboratory, REDD/SD COLLABORATION — Energetic particles (EP) ejected from a plasma carry important information about the plasma physics. To study remote plasmas in the heliosphere, space-based sensors must be used. Furthermore, only energetic *neutral* atoms (ENAs) can be analyzed, since charged particle trajectories are curved by the electric and magnetic fields of the heliosphere. Because low power consumption and weight are important for spacecraft, solid-state detectors are used. The challenge with solid-state detectors is their sensitivity to light; in all observational regions of interest, photon counts are several orders of magnitude higher than ENA counts. Current state of the art solid-state detectors use ultra-thin metal or carbon films to block the photons. This sets an energy threshold for the ENAs due to the fact that the ENAs have to penetrate this film. We aim to replace the thin films with carbon nanotube (CNT) mats. The CNT mats have a much lower density while maintaining extremely high photon absorption. Thus the CNT mats will act as an excellent filter for blocking the photons while minimally affecting the ENAs of interest. We will describe the fabrication of the CNT mats and their performance characterization by optical spectroscopy and energetic particle spectroscopy using alpha particles as an ENA simulant.

8:48AM Y7.00003 Recyclable Buckysponges for De-emulsification and Oil-spill cleaning

, MEHMET KARAKAYA, DEEPIKA SAINI, RAMAKRISHNA PODILA, APPARAO M. RAO, Department of Physics and Astronomy, Clemson University, Clemson, SC 29634, RAO'S GROUP TEAM[1] — Here we present a three dimensional, interconnected, carbon nanotube based, spongy material that is capable of efficiently separating oil from water. The buckysponge, as we term it, exhibits superhydrophobicity and oleophilicity. The adopted facile top down approach allows strong control of the porosity and is easily scalable. Due to capillary action combined with its oleophilicity, a buckysponge is capable of selectively absorbing various organic solvents up to 20 times its weight, a value comparable to existing nanosponge materials. This light weight and highly porous material is shown to work with both free and emulsified oil in water. It is not only an ideal candidate for efficient oil removal but also effective in oil recovery. The absorbed oil can be retrieved by reversibly squeezing the buckysponge, or the oil may be burnt to generate heat energy. Notably, the burnt buckysponge shows no damage to its physical structure or its absorptive properties after squeezing or having the oil burnt, and is therefore re-usable.

9:00AM Y7.00004 Effect of adsorbed monolayers on the conductance of single-walled carbon nanotubes[1]

, BORIS DZYUBENKO, HAO-CHUN LEE, OSCAR VILCHES, DAVID COBDEN, Department of Physics, University of Washington — We have studied the effects of adsorbing noble gases He, Ne, Ar, Kr, Xe, and diatomic gases O2, N2 and CO, on the electrical properties of individual suspended single-walled nanotubes, as a function of pressure and temperature. The quantity of gas adsorbed can be determined from the shift in the mechanical resonance frequency of the nanotube. We find that the conductance can be sensitive to small changes in density for all gases and can be measured on a timescale of milliseconds. This opens ways for studying the dynamics of adsorbed atoms/molecules on the surface of a nanotube. For some devices the conductance varies non-monotonically with coverage as a monolayer builds up. The conductance change results at least in part from a very small charge transfer between the adsorbates and nanotube. Measurements below the 2D critical point show sharp features and fluctuations in some devices but not in others. The reason for this is not currently understood. In the nonlinear regime we observe features in the I-V characteristics which occur because electrical currents cause phase transitions on the surface of a nanotube and may lead to stationary nonequilibrium states.

9:12AM Y7.00005 Toward Quantifying the Electrostatic Transduction Mechanism in Carbon Nanotube Biomolecular Sensors , MITCHELL LERNER, NICHOLAS KYBERT, RYAN MENDOZA, JENNIFER DAILEY, A.T. CHARLIE JOHNSON, University of Pennsylvania — Despite the great promise of carbon nanotube field-effect transistors (CNT FETs) for applications in chemical and biochemical detection, a quantitative understanding of sensor responses is lacking. To explore the role of electrostatics in sensor transduction, experiments were conducted with a set of similar compounds designed to adsorb onto the CNT FET via a pyrene linker group and take on a set of known charge states under ambient conditions. Acidic and basic species were observed to induce threshold voltage shifts of opposite sign, consistent with gating of the CNT FET by local charges due to protonation or deprotonation of the pyrene compounds by interfacial water. The magnitude of the gate voltage shift was controlled by the distance between the charged group and the CNT. Additionally, functionalization with an uncharged pyrene compound showed a threshold shift ascribed to its molecular dipole moment. This work illustrates a method for producing CNT FETs with controlled values of the turnoff gate voltage, and more generally, these results will inform the development of quantitative models for the response of CNT FET chemical and biochemical sensors. As an example, the results of an experiment detecting biomarkers of Lyme disease will be discussed in the context of this model.

9:24AM Y7.00006 ABSTRACT WITHDRAWN –

9:36AM Y7.00007 Measurements of adsorbate binding on individual suspended carbon nanotubes[1] , HAO CHUN LEE, BORIS DZYUBENKO, JIM COY, DAVID COBDEN, OSCAR VILCHES, Department of Physics, University of Washington — By measuring the resonance frequency shift and the conductance change of vibrating suspended single-walled nanotubes at controlled temperature and pressure we can accurately detect the adsorption of gases including He, Ar, Kr, Xe, O2, and N2. The binding energy can then be determined from the low-coverage part of the adsorption isotherms. We find that the adsorption isotherms generally resemble those on graphite but with weaker binding energies, allowing access to behavior at lower two-dimensional (2D) chemical potential than on graphite. For He-4 the binding energy is reduced by as much as a factor of two. For Ar the binding energy on all nanotubes measured is in the range 700 - 800 K, about a third less than that on graphite. This enables us to investigate the 2D critical and triple points of Ar. Puzzlingly, we find that the devices fall into two classes: one with monolayer condensation at lower pressures and sharp 2D liquid-vapor transitions, the other with condensation at higher pressures and lacking sharp transitions even well below the 2D critical point. Possible factors that may be involved are finite-size effects, commensurability, absorption on the inside of nanotubes with holes in them, nanotube bundles containing more than one kind of nanotube and having surface grooves, and amorphous carbon or other contaminants on the surface, though no combination of these factors seems to provide a satisfactory explanation.

9:48AM Y7.00008 Study of Carbon Dioxide adsorption on Purified HiPco Nanotubes[1] , SHREE BANJARA, VAIVA KRUNGLEVICIUTE, ALDO MIGONE, Department of Physics Southern Illinois University — We have investigated the adsorption characteristics of carbon dioxide on purified HiPco single-walled carbon nanotubes. We measured four full isotherms (starting from zero CO_2 coverage an ending at the saturated vapor pressure) for temperatures between 150 K and 187 K. While a linear plot of the adsorption isotherms presents initially a relatively broad region of rapid coverage increase with pressure, logarithmic plots of the isotherms are characterized by the absence of any substeps in the data. The equilibration times for each point along the isotherms are much longer than those for other simple adsorbates (e.g., CH_4 or Ar) on the same sorbent. Results for the effective monolayer capacity as well as values for the isosteric heat of adsorption's dependence on sorbent loading will be presented.

[1]This research was supported by NSF through grant # DMR-1006428

10:00AM Y7.00009 Protein coronas of Graphene and Carbon Nanotubes , RAMAKRISHNA PODILA, PU CHUN KE, Department of Physics, Clemson University, Clemson, SC 29634, JARED BROWN, Brody School of Medicine, East Carolina University, Greenville, NC 27834, APPARAO RAO, Department of Physics, Clemson University, Clemson, SC 29634, CLEMSON PHYSICS TEAM, EAST CAROLINA UNIVERSITY TEAM — We explored the effects of protein coating on the optical and vibrational properties of single-walled carbon nanotubes (SWCNTs) and bi- and few layer graphene nanosheets using micro-Raman spectroscopy, UV-visible absorption and electron microscopy. We found that bovine serum albumin (BSA) forms a hard corona on the surfaces of both graphene and SWCNTs. Our results suggest that the BSA hard corona acted as a weak acceptor to facilitate charge transfer from the carbon nanostructures. Notably, we observed that charge transfer occurred only in the case of SWNTs possibly due to their sharp and discrete electronic density of states. On the contrary, we find that graphene did not show a similar charge transfer due to its continuous energy dispersion. Furthermore, the nanostructures induced significant changes in the secondary structure of the BSA by relaxing their external ?-helices. These results are expected to guide controlled nanostructure-biomolecule interactions and prove beneficial in developing benign nanomaterials.

10:12AM Y7.00010 Optimization of a carbon nanotube field emission electron gun for applications in mass spectrometry[1] , ADRIAN SOUTHARD, University Space Research Association, STEPHANIE GETTY, DANIEL GLAVIN, GREGORY HIDROBO, STEVEN FENG, NASA Goddard Space Flight Center, NICHOLAS COSTEN, MUNIZ, CARL KOTECKI, NASA Goddard Space Flight Center — Field emission electron guns composed of carbon nanotube (CNT) pillar arrays make a low power, robust field emission source with turn-on fields as low as 1.8 Volts/μm. Fowler-Nordheim fits to the current-voltage data exhibit field enhancement factors of greater than 1000. Scaling of a carbon nanotube field emission electron gun to an aspect ratio of 2 mm x 40 mm using MEMS fabrication techniques has increased emitted current by two orders of magnitude beyond previous designs up to a current of 0.7 mA. Enhanced sensitivity from a time-of-flight mass spectrometer compatible with such a source was also obtained. Finite difference simulations (SIMION) of emission from CNT pillar arrays indicate that the field enhancement factors measured in the experiments can't be explained by emission from smooth pillars and must be due to emission from CNTs that protrude from the top of the pillar. SIMION simulations also explain why much of the emitted current is absorbed by the extraction grid using the current geometry and provide methods for improving electron beam transmission through the addition of a second grid. Simulations of electron beam focusing also demonstrate how the addition of a second grid could enable better focusing of the electron beam.

10:24AM Y7.00011 Neon and Xenon adsorption on opened carbon nanohorns[1] , CARL ZIEGLER, VAIVA KRUNGLEVICIUTE, ALDO MIGONE, Department of Physics Southern Illinois University, MASAKO YUDASAKA, SUMIO IIJIMA, Japan Science and Technology Corp., NEC Corporation, Tsukuba 305-8501, Japan — Adsorption isotherms were measured for neon adsorbed on opened (oxidized) carbon nanohorn aggregates. The isotherms were performed at eleven different temperatures between 19 to 40 K. Two distinct substeps are present in logarithmic plots of the adsorption data. The two substeps correspond to high and low binding energy sites present in the nanohorn aggregates. The values of the isosteric heat as a function of substrate loading was calculated; it shows features corresponding to the two adsorption isotherm substeps. The results for neon will be compared to those from ongoing measurements for xenon adsorbed on the same sample of open carbon nanohorn aggregates as well as to a previous study of neon on closed carbon nanohorns.

10:36AM Y7.00012 Phase transition of adsorbed noble gas on suspended graphene , ZAIYAO FEI, HAO-CHUN LEE, BORIS DZYUBENKO, SANFENG WU, DAVID COBDEN, Department of physics, University of Washington — Suspended graphene sheets are simultaneously 2D nanomechanical resonators, hosts to massless Dirac electrons, and 2D substrates for adsorption. Adsorption is expected to modulate the mechanical and elctrical properties in a number of ways. We therefore aim to investigate the effects of equilibrium adsorbates on the vibrational resonances and on the conductance. Beginning with noble gases on non-suspended graphene exfoliated on SiO2, for argon we have seen a gradual change in the conductance as a function of vapor pressure at temperatures below the 2D critical point (54 K), indicating gradual formation of a monolayer over a wide chemical potential range (although we have also seen signs of a sharp monolayer phase transition in a least one sample). The mechanism of conductance modulation is a topic of interest. The large broadening of the expected 2D vapor-liquid step is likely to be due to inhomogeneous binding caused by charge disorder, roughness, and other properties of the SiO2 substrate. We are developing pristine suspended graphene devices to eliminate these complications.

Session Y8 DCMP: Electron-electron Interactions and Unconventional Structures 307 - Sumit Mazumdar, University of Arizona

8:00AM Y8.00001 Modeling graphene interactions beyond pairwise additivity[1] , JOHN DOBSON, TIM GOULD, Griffith University — Dispersion (van der Waals) interactions between graphenic systems are commonly modeled by summing energy contributions between pairs of atoms or '"elements". This pairwise assumption is now known to be inaccurate for such highly polarizable, highly anisotropic systems [1-5]. Many-electron correlation theories of RPA type [6] are more accurate, but are computationally intensive. Here we present a relatively simple type of model, based on long-wavelength RPA dielectric function data for stretched bulk graphite, that captures the non-additive physics. [1] J. F. Dobson, A. White, and A. Rubio, Phys. Rev. Lett. 96, 073201 (2006) [2] H. Y. Kim, J. O. Sofo, D. Velegol, M. W. Cole, and A. A. Lucas, J. Chem. Phys. 124, 074504 (2006) [3] A. White and J. F. Dobson, Phys. Rev. 8:12AM Y8.00002 Charge-Carrier Screening in Single-Layer Graphene , DAVID SIEGEL, University of California, Berkeley / Sandia National Laboratories, WILLIAM REGAN, University of California, Berkeley, ALEXEI FEDOROV, Lawrence Berkeley National Laboratory, ALEX ZETTL, ALESSANDRA LANZARA, University of California, Berkeley / Lawrence Berkeley National Laboratory — Unlike normal metals that have a true Fermi surface, the pointlike Fermi surface of undoped graphene allows for long-ranged coulomb interactions to be unscreened by free charges, leading to singular behaviors. Therefore, the introduction of charge to a neutral graphene sheet can have a profound effect on transport properties and device performance. In this talk I will demonstrate the effects of charge-carrier screening of the electron-electron and electron-impurity interactions on the electronic properties of graphene, as we have observed through angle-resolved photoemission spectroscopy (ARPES). These observations help us to understand the basis for the transport properties of graphene, and shed light on the fundamental physics in the vicinity of the Dirac point crossing.

8:24AM Y8.00003 Evidence for strong electron correlations in graphene molecular fragments: Theory and experiments on two-photon absorptions[1] , KARAN ARYANPOUR, Department of Physics, University of Arizona, ADAM ROBERTS, U.S. Army AMRDEC, Redstone Arsenal AL , ARVINDER SANDHU, Department of Physics and Optical Sciences Center, University of Arizona, ALOK SHUKLA, Department of Physics, IIT Bombay, India, SUMIT MAZUMDAR, Department of Physics and Optical Sciences Center, University of Arizona — Historically, the occurrence of the lowest two-photon state below the optical one-photon state in linear polyenes, polyacetylenes and polydiacetylenes provided the strongest evidence for strong electron correlations in these linear π-conjugated systems. We demonstrate similar behavior in several molecular fragments of graphene with D_{6h} symmetry, theoretically and experimentally. Theoretically, we have calculated one versus two-photon absorptions in coronene, two different hexabenzocoronenes and circumcoronene, within the Pariser-Parr-Pople π-electron Hamiltonian using high order configuration interaction. Experimentally, we have performed z-scan measurements using a white light super-continuum source on coronene and hexa-peri-hexabenzocoronene to determine frequency-dependent two-photon absorption coefficients, for comparison to the ground state absorptions. Excellent agreement between experiment and theory in our work gives strong evidence for significant electron correlations between the π-electrons in the graphene molecular fragments. We particularly benchmark high order electron-hole excitations in graphene fragments as a key element behind the agreement between theory and experiment in this work.

8:36AM Y8.00004 Manipulating molecule-substrate exchange interactions via graphene[1] , SUMANTA BHANDARY, OLLE ERIKSSON, BIPLAB SANYAL, Dept. of Physics and Astronomy, Uppsala University, Sweden — Organometallic molecules with a 3d metal center carrying a spin offers many interesting properties, e.g., existence of multiple spin states [1]. A recent interest has been in understanding the magnetic exchange interaction between these organometallic molecules and magnetic substrates both from experiments and theory [2]. In this work, we will show by calculations based on density functional theory how the exchange interaction is mediated via graphene in a geometry containing iron porphyrin(FeP)/graphene/Ni(111). The exchange interaction varies from a ferromagnetic to an antiferromagnetic one depending on the lattice site and type of defect in the graphene lattice along with the switching of spin state of Fe in FeP between S=1 and S=2, which should be detectable by x-ray magnetic circular dichroism experiments. This scenario of complex magnetic couplings with large magnetic moments may offer a unique spintronic logic device.

8:48AM Y8.00005 Giant capacitance of a plane capacitor with a two-dimensional electron gas in a magnetic field , BRIAN SKINNER, BORIS SHKLOVSKII, University of Minnesota — If a clean two-dimensional electron gas (2DEG) with small concentration comprises one (or both) electrodes of a plane capacitor, the resulting capacitance can be larger than the "geometric capacitance" defined by the physical separation between electrodes. Such capacitance enhancement is a hallmark of the positional correlations that arise between electrons within the 2DEG at low electron density. Here we show that in the presence of a strong perpendicular magnetic field, such correlations are enhanced, leading to unusually large capacitance even for systems where the effective Bohr radius is large. The effect is perhaps most dramatic for ultrathin graphene-based capacitors, where strongly-correlated electron states appear at small filling factors, even though in the absence of magnetic field such correlated states are normally precluded by graphene's Dirac-like kinetic energy spectrum.

9:00AM Y8.00006 Electron-electron Interaction and Thermoelectricity in Graphene , FERESHTE GHAHARI, YURI ZUEV, CARLOS FORSYTHE, Physics Department, Columbia University, KENJI WATANABE, TAKASHI TANIGUCHI, Advanced Materials Laboratory, National Institute for Materials Science, Japan, PHILIP KIM, Physics Department, Columbia University — In this presentation, we report thermoelectric power (TEP) measurements on graphene samples deposited on hexagonal boron nitride substrates where drastic suppression of disorder is achieved. Our results show that at high temperatures where the inelastic scattering rate due to electron-electron (e-e) interactions is higher than the disorder induced elastic scattering rate, the measured TEP deviates from the Mott relation, and can be explained by a non-relativistic hydrodynamic flow of electrons. We also investigated TEP in the quantum Hall regime at a high magnetic fields, where we observed symmetry broken integer quantum Hall due to the strong e-e interactions. The field dependence of TEP at these states reveals the important role that exchange interactions play.

9:12AM Y8.00007 Interface Inducing Interesting Effects on Thermal Transport in Graphene Based Systems[1] , HAIYUAN CAO, HONGJUN XIANG, XINGAO GONG, Fudan University — Using nonequilibrium molecular dynamics method (NEMD), we have studied how the interface affecting the thermal conductivity in multilayer graphene nanoribbons and the graphene grain boundaries. In multilayer graphene nanoribbons, the monotonous decrease of the thermal conductivity with the increase of the number of layers can be attributed to the phonon resonance effect of out-of-plane phonon modes. The reduction of thermal conductivity is proportional to the layer size, which is caused by the increase of phonon resonance. The results clearly show the dimensional evolution of thermal conductivity from quasi-one dimension to higher dimensions in graphene nanoribbons. The thermal transport across the asymmetric tilt grain boundary between armchair and zigzag graphene has also been investigated by simulations. We have observed significant temperature drop and ultra-low temperature-dependent thermal boundary resistance. More importantly, we find an unexpected thermal rectification phenomenon. The thermal conductivity and Kapitza conductance is direction-dependent. The effect of thermal rectification could be amplified by increasing the difference of temperature imposed on two sides. Our results show the interface phonon coupling could greatly change the thermal conductivity. Besides that, we have proposed a new promising kind of thermal rectifier and phonon diode based on the asymmetric interface in graphene.

9:24AM Y8.00008 Direct visualization of reversible dynamics in a Si_6 magic cluster in a graphene pore[1] , JAEKWANG LEE, Oak Ridge National Laboratory, WU ZHOU, Vanderbilt University, STEPHEN PENNYCOOK, JUAN-CARLOS IDROBO, Oak Ridge National Laboratory, SOKRATES PANTELIDES, Vanderbilt University — Clusters containing only a handful of atoms have been the subject of extensive theoretical and experimental studies, but direct imaging of their structure and dynamics has not been possible so far, with information provided mainly by theory. We report a direct atomically-resolved observation of a single Si_6 magic cluster trapped in a graphene nanopore. We report a sequence of images that show a reversible, oscillatory, conformational change: one of the Si atoms jumps back and forth between two different positions. Density functional theory shows that the cluster is exploring metastable configurations under the influence of the beam providing direct information on the atomic-scale energy landscape. The capture of a magic cluster in a graphene nanopore suggests the possibility of patterning nanopores and either capturing or assembling atomic clusters with a potential for applications.

9:36AM Y8.00009 ABSTRACT WITHDRAWN –

9:48AM Y8.00010 Brownian Dynamics Simulations of Dispersed Graphene Sheets , YUEYI XU, MICAH GREEN, Department of Chemical Engineering, Texas Tech University — Past simulations of the dynamics of dispersed graphene sheets are limited to static fluids on small timescales, with little attention devoted to flow dynamics. To address this need, we investigated how flow fields affect graphene morphology dynamics using a coarse-grained model; this relatively untouched area is critical given the importance of graphene solution-processing of multifunctional devices and materials. In particular, we developed a Brownian Dynamics (BD) algorithm to study the morphology of sheetlike macromolecules in dilute, flowing solutions. We used a bead-rod lattice to represent the mesoscopic conformation of individual two dimensional sheets. We then analyzed the morphology dynamic modes (stretching, tumbling, crumpling) of these molecules as a function of sheet size, Weissenberg number, and bending stiffness. Our results indicate the model can successfully simulate a range of dynamic modes in a given flow field and yield fundamental insight into the flow processing of graphene sheets.

10:00AM Y8.00011 Temperature-dependent levitation of a graphene flake due to Casimir forces[1] , ANH PHAN, DAVID DROSDOFF, LILIA WOODS, Department of Physics, University of South Florida, Tampa, Florida 33620, USA, IGOR BONDAREV, Physics Department, North Carolina Central, Durham, North Carolina 27707, USA, NGUYEN VIET, Institute of Physics, 10 Daotan, Badinh, Hanoi, Vietnam — We present theoretical investigations of temperature-dependent Casimir interactions of a graphene flake between substrates in a fluid. By properly choosing the materials, we propose that the graphene can be suspended in the fluid due to the balance between the Casimir, buoyancy and gravitational forces. The graphene properties, such as the Dirac-like nature of the carriers and universal optical conductivity, have a profound effect on the Casimir force making it completely thermal at room temperature. Since thermal contributions to the Casimir interaction in most materials are usually small, the graphene system offers a unique opportunity to demonstrate such effects without going to extreme temperatures. We show that the equilibrium position of the suspended flake is temperature dependent. We suggest that this maybe a promising system for observing thermal Casimir effects via levitation.

10:12AM Y8.00012 Properties of field-effect transistors of CVD grown MoS_2 single atomic layers on CVD grown hexagonal Boron Nitride , NIHAR PRADHAN, DANIEL RHODES, QIU ZHANG, National High Magnetic Field Laboratory, Florida State University, Tallahassee, FL, USA, ANA ELIAS, N. LOPEZ, Department of Physics, The Pennsylvania State University, University Park, PA, USA, ZHENG LIU, SINA NAJMEI, JUN LOU, Department of Mechanical Engineering & Materials Science, Rice University, Houston, TX, USA, SAIKAT TALAPATRA, Department of Physics, Southern Illinois University, Carbondale, IL, USA, MAURICIO TERRONES, Department of Physics, The Pennsylvania State University, University Park, PA, USA, PULICKEL AJAYAN, Department of Mechanical Engineering & Materials Science, Rice University, Houston, TX, USA, LUIS BALICAS, National High Magnetic Field Laboratory, Florida State University, Tallahassee, FL, USA — Two dimensional crystalline layered materials such as MoS_2, WS_2, have recently become an intense focus of research activities due to their exceptional electronic and optical properties. A single- or a few atomic layers of these materials show quite promising charge conduction characteristics, such as large mobility or fast on/off switch ratios, which lead to a few recent examples of integrated circuits based on these materials. Here, we will present a comparison among the electronic transport properties of, either mechanically exfoliated or CVD grown MoS_2 under different substrates, i.e. on SiO_2, on exfoliated or on CVD grown h-BN, and suspended. We will also discuss results obtained from back and top gated configurations with different dielectrics.

10:24AM Y8.00013 Nanochannel Device with Embedded Nanopore: a New Approach for Single-Molecule DNA Analysis and Manipulation , YUNING ZHANG, WALTER REISNER, Department of Physics, McGill University — Nanopore and nanochannel based devices are robust methods for biomolecular sensing and single DNA manipulation. Nanopore-based DNA sensing has attractive features that make it a leading candidate as a single-molecule DNA sequencing technology. Nanochannel based extension of DNA, combined with enzymatic or denaturation-based barcoding schemes, is already a powerful approach for genome analysis. We believe that there is revolutionary potential in devices that combine nanochannels with embedded pore detectors. In particular, due to the fast translocation of a DNA molecule through a standard nanopore configuration, there is an unfavorable trade-off between signal and sequence resolution. With a combined nanochannel-nanopore device, based on embedding a pore inside a nanochannel, we can in principle gain independent control over both DNA translocation speed and sensing signal, solving the key draw-back of the standard nanopore configuration. We demonstrate that we can optically detect successful translocation of DNA from the nanochannel out through the nanopore, a possible method to 'select' a given barcode for further analysis. In particular, we show that in equilibrium DNA will not escape through an embedded sub-persistence length nanopore, suggesting that the pore could be used as a nanoscale window through which to interrogate a nanochannel extended DNA molecule. Furthermore, electrical measurements through the nanopore are performed, indicating that DNA sensing is feasible using the nanochannel-nanopore device.

Friday, March 22, 2013 8:00AM - 11:00AM –

Session Y9 GMAG: Invited Session: Spin Mechanics 308 - Sebastian Goennenwein, Bayerische Akademie der Wissenschaften

8:00AM Y9.00001 Autonomous and forced dynamics in a spin-transfer nano-oscillator: Quantitative magnetic-resonance force microscopy[1] , OLIVIER KLEIN, Service de Physique de l'État Condensé (CNRS URA 2464), CEA Saclay, 91191 Gif-sur-Yvette, France — In this talk, we will discuss how magnetic-resonance force microscopy, can provide quantitative measurement of the power emitted by a spin-transfer nano-oscillator, consisting of a normally magnetized Py—Cu—Py circular nanopillar, excited both in the autonomous and forced regimes.[2] From the power behavior in the subcritical region of the autonomous dynamics, one obtains a quantitative measurement of the threshold current and of the noise level. Their field dependence directly yields both the spin torque efficiency acting on the thin layer and the nature of the mode which first auto-oscillates: the lowest energy, spatially most uniform spin-wave mode. We will then demonstrate that the observed spin-wave spectrum in the forced regime critically depends on the method of excitation. While the spatially uniform radio-frequency (RF) magnetic field excites only the axially symmetric modes having azimuthal index $\ell = 0$, the RF current flowing through the nano-pillar, creating a circular RF Oersted field, excites only the modes having azimuthal index $\ell = +1$.[3] It is then demonstrated that in order to phase lock this auto-oscillating mode, the external source must have the same spatial symmetry as the mode profile, i.e., a uniform microwave field must be used rather than a microwave current flowing through the nanopillar.

8:36AM Y9.00002 Magneto-mechanical detection and control of the nanoscale Barkhausen effect[1] , MARK FREEMAN[2], University of Alberta and National Inst. for Nanotechnology, Edmonton, Canada — Developments in nano- and spin mechanics are driving a resurgence of interest in mechanical approaches to magnetometry. Torque methods for measurement of quasi-static magnetization or detection of spin dynamics can very fruitfully be miniaturized for application to individual magnetic nanostructures, and are complementary to magnetic force microscopy and related techniques [1]. We report a complete study of the Barkhausen effect in torsional magnetometry measurements of a micromagnetic disk. The discovery of Barkhausen noise in 1919 [2] provided the first experimental evidence of ferromagnetic domains. Within three decades elegant experiments had been performed on individual domain walls and a firm qualitative understanding had emerged [3]. Quantitative treatments of the effect have relied on statistical analysis [4], due to the collective nature of domain wall pinning by many sites. However, a vortex core effectively localizes the domain wall to the scale of an individual pining site, thereby converting the Barkhausen effect into a quantitative 2D nanoscale probe of local energetics in thin magnetic films [5]. In addition to characterization of the intrinsic disorder in a polycrystalline film, point-like tailoring of the energy landscape through low dose focussed ion beam implantation is demonstrated, and can be exploited to tune the properties of integrated magneto-mechanical devices.

9:12AM Y9.00003 Coherent mechanical control of a single electronic spin , MICHAEL GRINOLDS, Harvard University — Quantum control of spins via electrical, magnetic, and optical means has generated numerous applications in metrology and quantum information technology. In this talk we present an alternative control scheme that uses the mechanical motion of a resonator to coherently control spins. Specifically, by coupling the motion of a magnetically coated mechanical oscillator to a single nitrogen-vacancy (NV) defect in diamond, we demonstrate manipulations of both the amplitude and phase of the NV's electronic spin. Coherent control is achieved by synchronizing NV-addressing optical and microwave manipulations to the driven motion of the coupled mechanical oscillator, which additionally allows for a stroboscopic readout of the resonator's motion. We demonstrate applications of this mechanical spin control to sensitive nanoscale scanning magnetometry and discuss the potential for sensitive motion sensing of nanomechanical resonators.

9:48AM Y9.00004 Laser-induced magnetization switching in ferrimagnetic alloys , ANDREI KIRILYUK, Radboud University Nijmegen — This talk will discuss the recent studies of ultrafast switching of magnetization and the role of angular momentum in this process in ferrimagnetic rare-earth - transition metal alloys, e.g. GdFeCo, where both magnetization and angular momenta are temperature dependent. It has been experimentally demonstrated that the magnetization can be manipulated and even reversed by a single 40 fs laser pulse, without any applied magnetic field [1]. This switching is found to follow a novel reversal pathway [2], that is shown to depend crucially on the net angular momentum, reflecting the balance of the two opposite sublattices [3,4]. In particular, optical excitation of ferrimagnetic GdFeCo on a time-scale pertinent to the characteristic time of the exchange interaction between the rare earth (RE) and transition metal (TM) spins, i.e. on the time scale of tens of femtoseconds, pushes the spin dynamics into a yet unexplored regime, where the two exchange coupled magnetic sublattices demonstrate substantially different dynamics [3]. As a result, the reversal of spins appears to proceed via a novel transient state characterized by a ferromagnetic alignment of the Gd and Fe magnetic moments, despite their ground-state antiferromagnetic coupling [4]. This process is fully modeled by a system of coupled equations for the longitudinal relaxation of the sublattices [5]. The role of light helicity in this process, being a controversial issue for many years, is clarified as well [6].

10:24AM Y9.00005 Spin-current generation arising from mechanical motions[1] , MAMORU MATSUO, Advanced Science Research Center, Japan Atomic Energy Agency — Spin current, the flow of spins, is a key concept in the field of spintronics.[2] To create and control spin currents, magnetic dynamics, electromagnetic fields, and thermal gradient have been used. Recently, the acoustically generated spin current was observed in an insulating ferromagnet.[3] However, the conversion between mechanical motions and the spin current in non-magnetic materials has not been studied so far. In this talk, we will present our recent results on spin-current generation from mechanical motions, including rigid and elastic motions in non-magnetic metals and semiconductors. In a rigidly accelerating body, the spin-orbit interaction (SOI) is modulated by the mechanical motion.[4] The augmented SOI leads to the spin-current generation from both mechanical rotation and vibration. On the other hand, in the presence of the surface acoustic wave (SAW), the elastically driven rotational motion of the lattice couples to electron spins and the spin current is generated in the direction of depth. Dependence of amplitude and frequency of the SAW, the spin diffusion length, and elastic parameters on the spin current will be shown. We will also discuss the enhancement of the SOI and the spin-rotation coupling caused by an interband mixing, using an extended k.p perturbation with the gauge potential due to mechanical rotation.[5]

Session Y10 GIMS: Invited Session: Advances in Actinide Measurement Techniques 309 - Jason Cooley, Los Alamos National Laboratory

8:00AM Y10.00001 Anomalous thermodynamic behavior in actinides , ARKADY SHEKHTER, Pulsed Field Facility, NHMFL, Los Alamos National Laboratory — The thermal expansion of some of the actinides metals are strongly dependent upon doping. Extreme examples involve a change of sign of the thermal expansion coefficient upon few percent Ga doping. In contrast, resonant ultrasound spectroscopy of these doping series reveals very weak dependence of the elastic moduli on Ga content. We suggest that the anomalous thermodynamic behavior in these systems has dynamic rather than static origin.

8:36AM Y10.00002 Multiconfigurational nature of 5f orbitals in uranium and plutonium and their intermetallic compounds[1] , CORWIN BOOTH, Lawrence Berkeley National Laboratory — The structural, electronic, and magnetic properties of U and Pu elements and intermetallics remain poorly understood despite decades of effort, and currently represent an important scientific frontier toward understanding matter. The last decade has seen great progress both due to the discovery of superconductivity in $PuCoGa_5$ and advances in theory that finally can explain fundamental ground state properties in elemental plutonium, such as the phonon dispersion curve, the non-magnetic ground state, and the volume difference between the α and δ phases. A new feature of the recent calculations is the presence not only of intermediate valence of the Pu 5f electrons, but of multiconfigurational ground states, where the different properties of the α and δ phases are primarily governed by the different relative weights of the $5f^4$, $5f^5$, and $5f^6$ electronic configurations. The usual method for measuring multiconfigurational states in the lanthanides is to measure the lanthanide L_{III}-edge x-ray absorption near-edge structure (XANES), a method that is severely limited for the actinides because the spectroscopic features are not well enough separated. Advances in resonant x-ray emission spectroscopy (RXES) have now allowed for spectra with sufficient resolution to resolve individual resonances associated with the various actinide valence states. Utilizing a new spectrometer at the Stanford Synchrotron Radiation Lightsource (SSRL), RXES data have been collected that show, for the first time, spectroscopic signatures of each of these configurations and their relative changes in various uranium and plutonium intermetallic compounds. In combination with conventional XANES spectra on related compounds, these data indicate such states may be ubiquitous in uranium and plutonium intermetallics, providing a new framework toward understanding properties ranging from heavy fermion behavior, superconductivity, and intermediate valence to mechanical and fundamental bonding behavior in these materials.

9:12AM Y10.00003 Observation of ^{239}Pu NMR in PuO_2– A new frontier for the physics and chemistry of plutonium compounds[1] , YASUOKA HIROSHI, Los Alamos National Laboratory — In actinide science, in general, NMR studies have been forced to limit their scope to nuclei associated with ligand atoms. The only exception of direct observation of NMR in actinide nuclei is that of ^{235}U NMR in UO_2. There have been extensive efforts to realize NMR in actinide compounds since the electronic properties of these materials are predominantly governed by the actinide atom itself. We report the first observation of Nuclear Magnetic Resonance (NMR) on the ^{239}Pu nucleus in any material. Our ^{239}Pu NMR measurements were performed on plutonium dioxide, PuO_2, for a wide range of external magnetic field values (Ho=3∼8T) at a temperature of T=4K. By mapping the external field dependence of the measured resonance frequency, we determined the nuclear gyromagnetic ratio to be $^{239}\gamma_n(PuO_2)$ =2.856 ± .001 MHz/T. Assuming a free ion value for the Pu^{4+} hyperfine coupling constant, we estimated a bare value of $^{239}\gamma_n$ =2.29MHz/T for the ^{239}Pu nucleus, hence a nuclear magnetic moment of μ_n =.15μ_N (where μ_N is the nuclear magneton). Our findings put an end to a fifty-year long search for Pu NMR and open potentially a new horizon for the solid state physics, nuclear materials science and complex chemistry in Pu compounds.

9:48AM Y10.00004 An instrument for the investigation of actinides with spin resolved photoelectron spectroscopy and bremsstrahlung isochromat spectroscopy , JAMES TOBIN, Lawrence Livermore National Laboratory — A new system [1] for spin resolved photoelectron spectroscopy [2,3] and bremsstrahlung isochromat spectroscopy [4] has been built and commissioned at Lawrence Livermore National Laboratory for the investigation of the electronic structure of the actinides. Actinide materials are very toxic and radioactive and therefore cannot be brought to most general user facilities for spectroscopic studies. The technical details of the new system and preliminary data obtained therein will be presented and discussed. Lawrence Livermore National Laboratory is operated by Lawrence Livermore National Security, LLC, for the U.S. Department of Energy (DOE), National Nuclear Security Administration under Contract DE-AC52-07NA27344. This work was supported by the U.S. Department of Energy, Office of Basic Energy Science, Division of Materials Sciences and Engineering.

10:24AM Y10.00005 Transuranic Photoemission Using a Unique Light Source[1] , JOHN JOYCE, Los Alamos National Laboratory — There has been a remarkable advance in the understanding of electronic structure for complex materials in recent years. Much of this advance in understanding has been realized through advanced spectroscopy capabilities available at public synchrotron facilities. While the vast majority of materials can take advantage of facilities at public synchrotrons, transuranic materials are excluded from these facilities when multiple containment barriers are incompatible with the chosen spectroscopy. We have developed an advanced spectroscopy capability at Los Alamos for photoemission on transuranic materials including Pu. Using several different variants of photoemission we have explored a wide range of Pu materials which has lead to a significant improvement in our understanding of transuranic electronic structure. Examples of these successes will be given along with details of the unique facility. Using the unique capabilities of our transuranic photoemission system we exploit opportunities in angle-resolved photoemission (ARPES) providing insight into the details of both the energy and crystal momentum for a material. Additional information is obtained using tunable photons which may be used to isolate the 5f electron contribution to the valence electronic structure. Between ARPES and tunable photoemission, one may construct a fairly detailed picture of the bonding and hybridization for transuranic materials. By adding temperature-dependent (10 - 350K) photoemission to the suite of tools, we may cross over phase transition boundaries as well as quantify electron-phonon coupling. We also have the capability for 1.5 and 3 KeV core-level spectroscopy using a monochromatized x-ray source. By combining the above photoemission tools with a variety of surface preparation capabilities including cleaving, laser ablation, and thermal desorption, we have a flexible and capable spectroscopy facility that provides unique insight into the electronic structure of transuranic materials.

Session Y11 DCMP: Glassy and Amorphous Systems, Including Quasicrystals followed by Epitaxial Growth and Structure of Oxides 310 - Punit Boolchand, University of Cinncinatti

8:00AM Y11.00001 Hydrogen microstructure of amorphous silicon via inversion of nuclear magnetic resonance spectra: A moment-based approach , PARTHAPRATIM BISWAS, The University of Southern Mississippi, RAJENDRA TIMILSINA, The University of Tennessee at Knoxville — We present an inverse approach for reconstructing hydrogen microstructure in amorphous silicon (a-Si). The approach consists of generating a prior distribution (of spins) by inverting experimental nuclear magnetic resonance (NMR) data, which is subsequently superimposed on a network of a-Si. The resulting network is then relaxed using a total-energy functional to obtain a stable, low-energy configuration such that the initial spin distribution is minimally disturbed. The efficacy of this approach is demonstrated by generating model configurations that not only have the correct NMR spectra but also satisfy simultaneously the experimental structural, electronic and vibrational properties of hydrogenated amorphous silicon.

8:12AM Y11.00002 Antiferromagnetic order in the Cd_6R (R = rare earth) quasicrystal approximants[1] , ALAN GOLDMAN, MIN GYU KIM, Ames Laboratory and Iowa State University, GUILLAUME BEUTIER, SIMaP, UMR 5266 CNRS Grenoble-INP UJF, ANDREAS KREYSSIG, Ames Laboratory and Iowa State University, TAKANOBU HIROTO, TSUNETOMO YAMADA, Tokyo University of Science, JONG WOO KIM, Argonne National Laboratory, MARC DE BOISSIEU, SIMaP, UMR 5266 CNRS Grenoble-INP UJF, RYUJI TAMURA, Tokyo University of Science — Many theoretical treatments of spins on aperiodic lattices support the notion of long-range antiferromagnetic order. However, to date, there has been no experimental confirmation of long-range magnetic order in quasicrystalline systems. The absence of long-range magnetic order extends to crystalline approximant phases of the icosahedral structures as well. Surprisingly, the 1/1 approximant to the Cd-Mg-R icosahedral phases, Cd_6R, appears to be an exception to the rule. Here, we report on the results of x-ray resonant magnetic scattering measurements on Cd_6R approximants which show that long range antiferromagnetic order is, indeed, realized. For R = Tb and Ho, viewing the structure as a body-centered cubic packing of Tsai clusters, we find that the R ions associated with the icosahedral cluster at the corner of the unit cell are antiferromagnetically correlated with the R ions associated with the icosahedral cluster at the body-center of the unit cell.

8:24AM Y11.00003 Fragility, slow homogenization and Intermediate Phase in the $Si_xGe_xTe_{100-2x}$ ternary[1] , K. GUNASEKERA, P. BOOLCHAND, University of Cincinnati, S. MAMEDOV, Horiba Jobin Yvon Inc. — Small sized (0.5g) melts were synthesized by reacting pure elements in 5mm ID quartz tubes at 950C, and examined after 1 week and then 2 weeks of reaction. Bulk glass formation is realized in 6%<x<16% range with Tg(x) increasing linearly in 6%<x<12% range, and decreasing thereafter (x>12%). The enthalpy of relaxation at Tg shows a flat bottomed minimum in 7.5%<x<9.0% range with the term increasing sharply at x>9% and at x<7.5%. We identify the 7.5%<x<9.0% range with the Intermediate Phase. Fragility(m) of melts were established in complex Cp measurements, and show a global minimum (m<30) in the IP range, and a value of m=26 at x=8.5%. The slow homogenization of Telluride melts results from the *strong* character of IP melts. Raman scattering, excited using low power density of 785nm radiation, shows evidence of a broad mode near 160cm^{-1} (characteristic of a-Te chains) and a narrower one near 127cm^{-1} (group IV crosslinking units). The scattering strength of the 127cm^{-1} mode increases at the expense of the 160cm^{-1} mode as x increases. The nature of structure evolution with glass composition will be commented upon.

[1]Supported by NSF grant DMR 08-53957

8:36AM Y11.00004 Slow kinetics of melt homogenization and strong nature of intermediate phase melts in chalcogenides[1] , P. BOOLCHAND, K. GUNASEKERA, University of Cincinnati, S. BHOSLE, IM Flash Technologies — The strong-fragile classification of melts is manifested in the T-dependence of viscosity. Strong (fragile) melts possess a T-independent (dependent) activation energy of viscosity leading to an Arrhenian (non-Arrhenian) behavior reflecting the robust (weak) nature of network structure. We have now measured [1] complex C_p of binary Ge_xSe_{100-x} glasses as a function of x, and find that in dry and homogeneous melts, fragility (m(x)) shows a global minimum ($m < 20$) in the Intermediate Phase (IP) compositions ($19.5\% < x < 26\%$) but increases rapidly outside the IP. These findings have a direct bearing on synthesis of non-stoichiometric melt compositions at elevated temperatures in which IP melt compositions serve as a bottleneck [1] to homogenize [2] batches globally. The physical properties of dry and homogeneous glasses differ significantly from their inhomogeneous counterparts, and have led, in general, to differences in results reported by various groups.

8:48AM Y11.00005 Fragility and slow kinetics of melt homogenization in the As-Se binary[1] , SRIRAM RAVINDREN, KAPILA GUNASEKERA, PUNIT BOOLCHAND, University of Cincinnati — Two gram sized As_xSe_{100-x} batches at various As content x were synthesized using pure Se and As_2Se_3 as starting materials that were reacted at 700^{o}C. Such melts typically took 3-12 days to homogenize, as monitored in punctuated, off-line FT-Raman line profiling[2] experiments. We have now undertaken mDSC experiments as a function of modulation frequency to establish the compositional dependence of complex C_p(x), and deduce the variation of fragility m(x). We find the fragility to be rather low, $m < 20$, across the $22\% < x < 38\%$ range, and to rapidly increase at $x < 22\%$ to acquire a value of 43 near $x = 3\%$. We show that the slow melt homogenization is a direct consequence of the "strong" character of melts that serves as a bottleneck in melt-mixing at high temperatures. Once homogenized, physical properties of glasses, such as density, glass transition temperature T_g(x), the Intermediate phase, and variation of enthalpy of relaxation at T_g(x) differ significantly from their inhomogeneous counterparts.

9:00AM Y11.00006 Quantitative description of orientational order in non-graphitic carbons , ENSHI XU, VINCENT CRESPI, Department of Physics, Penn State University — The key factor that determines the ability to graphtize of a non-graphitic material is believed to be the level of orientational disorder which indicates how well the elemental structures are aligned. To characterize the disorder, we have developed a correlation function with multiple variable dependencies, such as radial distance and zenith angle. Through the characteristic parameter of the function, the ability to graphitize can be determined given the structure of a carbon material. The model is applied to a set of non-graphitic structures, which is generated systematically in non-conventional methods that emphasize to represent the orientational order of the carbon material rather than to match the radial distribution function.

9:12AM Y11.00007 Localization and percolation in random elastic networks , JACOB KRICH, University of Ottawa, ARIEL AMIR, Harvard University, VINCENZO VITELLI, Leiden University, YUVAL OREG, YOSEPH IMRY, Weizmann Institute of Science — We consider a minimal model for a disordered phonon system that shows rich behavior in the localization properties of the phonons. We use a percolation analysis to argue for a localization/delocalization transition of the phonon modes and predict the speed of sound in the delocalized region, with comparison to numerics. We show that in contrast to the behavior in electronic systems (cf. Anderson localization), the transition exists for arbitrarily large disorder, albeit with an exponentially small critical frequency. The structure of the modes reflects a divergent percolation length that arises from the disorder in the springs without being explicitly present in the definition of our model. We calculate the critical frequency as a function of density and test the prediction numerically using a recursive Green function method. We further explore the existence of delocalized states in the two-dimensional version of this model.

9:24AM Y11.00008 Stoichiometric SrTiO3 Films via High Pressure Oxygen Sputter Deposition[1] , PALAK AMBWANI, BHARAT JALAN, CHRIS LEIGHTON, Department of Chemical Engineering and Materials Science, University of Minnesota, USA — Defect management in epilayers of semiconducting complex oxides such as $SrTiO_3$ is a topic of considerable contemporary interest. Recent work has shown that sufficiently precise control over stoichiometry and defects in $SrTiO_3$ enables facile$n$-type doping, record high mobilities, and even simultaneous observation of quantum oscillations and superconductivity. Such progress has typically been made using techniques such as oxygen/LASER MBE or high-temperature PLD. In this work we demonstrate, via homoepitaxy on $SrTiO_3$(001), that RF high pressure oxygen sputtering from a ceramic target is similarly capable of growth of high-quality, stoichiometric $SrTiO_3$ films. We show that optimization of the deposition temperature (above 750 °C) and oxygen pressure (above 2.5 mBar) leads to the deposition of films indistinguishable from the substrate via grazing incidence and wide-angle x-ray scattering. The importance of a pre-treatment of the substrates in oxygen above 900 °C is emphasized. The defect density/stoichiometry was further probed via the transport properties of vacuum annealed samples with controlled O vacancy density. Finally, we also demonstrate that the stoichiometry and defect density of films deposited under non-optimal conditions can be remarkably improved via post-deposition heat treatment.

[1]Work supported by NSF DMR and NSF MRSEC.

9:36AM Y11.00009 Time-resolved *in-situ* X-ray Study of Homoepitaxial $SrTiO_3$ Growth Using Reactive Molecular-Beam Epitaxy , I.C. TUNG, Advanced Photon Source, Argonne National Laboratory; Department of Materials Science and Engineering, Northwestern University, Z.L. LUO, Materials Science Division, Argonne National Laboratory; National Synchrotron Radiation Laboratory, University of Science and Technology of China, J.H. LEE, H. HONG, Advanced Photon Source, Argonne National Laboratory, S.H. CHANG, J.A. EASTMAN, Materials Science Division, Argonne National Laboratory, M.J. BEDZYK, Department of Materials Science and Engineering, Northwestern University, J.W. FREELAND, Advanced Photon Source, Argonne National Laboratory, D.D. FONG, Materials Science Division, Argonne National Laboratory — Functional materials based on complex oxides in thin film form offer new and exciting strategies for meeting many energy challenges. Unfortunately, synthesis of such oxide films can be a major challenge even when utilizing reactive molecular-beam epitaxy (MBE). To understand the fundamental physics of complex oxide thin film growth, we have developed the world's first reactive MBE system with *in-situ* synchrotron x-ray scattering capability at the Advanced Photon Source (APS). Here we present the results of *in-situ* surface x-ray scattering measurements taken during homoepitaxial growth of $SrTiO_3$ on (001) $SrTiO_3$ substrates. We compare the shuttered growth technique with codeposition to understand the nature of the distinctly different approaches. Work at the APS, Argonne is supported by the U.S. Department of Energy, Office of Science, and Office of Basic Energy Sciences, under Contract No. DE-AC02-06CH11357.

9:48AM Y11.00010 STM Studies of Sub-monolayer SrO and $LaAlO_3$ Film Growth on $SrTiO_3$(001) Substrate Surfaces , TAKEO OHSAWA, KATSUYA IWAYA, RYOTA SHIMIZU, SUSUMU SHIRAKI, TARO HITOSUGI, Advanced Institute for Materials Research (WPI-AIMR), Tohoku University. — We report atomic-scale observations of initial growth of sub-monolayer SrO and $LaAlO_3$ (LAO) films on the atomically-ordered $(\sqrt{13}\times\sqrt{13})$-*R*33.7° $SrTiO_3$ (STO) (001) substrate surfaces using scanning tunneling microscopy/spectroscopy (STM/STS). We found that the growth processes depend strongly on the film compositions and the investigations unveil complex chemistry of thin-film oxides. These findings will provide microscopic insights into the understanding of transport properties at the LAO/STO interface, which is known to exhibit conducting and insulating behavior depending on the termination structures of STO substrates, namely, whether "TiO_2-" or "SrO-terminated" surfaces, respectively. Controlling the interface structure genuinely with atomic precision will eventually lead to the creation of exotic electronic phenomena and functionalities at the complex oxide interfaces.

10:00AM Y11.00011 In-situ Surface X-ray Diffraction Study of Ruddlesden-Popper Series Thin Film Growth , JUNE HYUK LEE, SEO HYOUNG CHANG, ZHENLIN LUO, Argonne National Laboratory, I-CHENG TUNG, Northwestern University, MILIND MALSHE, JULIUS JELLINEK, JEFF EASTMAN, HAWOONG HONG, DILLON FONG, FREELAND JOHN, Argonne National Laboratory — The layered Ruddlesden-Popper phases of $A_{n+1}B_nO_{3n+1}$, such as Sr_2TiO_4 and La_2NiO_4, have attracted much attention as potential materials for solid-oxide fuel cell cathodes and thermoelectrics. To understand the fundamentals of this class of layered oxide thin films, we studied the growth of (001)-oriented Sr_2TiO_4 and La_2NiO_4 on $SrTiO_3$ substrates by using oxide molecular beam epitaxy with in-situ surface x-ray diffraction. For Sr_2TiO_4, the synthesis of the double SrO layer followed by TiO_2 dynamically reconstructs back into the $SrTiO_3$ phase, which demonstrates that during thin film deposition other pathways under growth conditions can give rise to new structural arrangements. In contrast with Sr_2TiO_4, the growth of La_2NiO_4 involves the stacking of polar LaO^+ and NiO_2^- layers. This raises the question of how polarity mismatch at the interface with the $SrTiO_3$ substrate will influence the growth process. A detail comparison of these two cases will be discussed. Work at the Advanced Photon Source, Argonne is supported by the U.S. Department of Energy, Office of Science, and Office of Basic Energy Sciences, under Contract No. DE-AC02-06CH11357.

10:12AM Y11.00012 Atomic Resolution and First Principles Study of the Electronic Structure at $SrTiO_3$/GaAs Hetero-interfaces , QIAO QIAO, ROBERT KLIE, SERDAR OGUT, University of Illinois at Chicago, RAVI DROOPAD, ROCIO CONTRERAS-GUERRERO, Texas State University — We examined ultra-thin $SrTiO_3$ films deposited on As-terminated GaAs (001) using molecular beam epitaxy under various O_2 partial pressures. Atomic-resolution Z-contrast images of different $SrTiO_3$ films were obtained using the aberration-corrected JEOL JEM-ARM200CF operated at 80 kV. Using atomic-column resolved EELS, our analysis of the Ti and O near-edge fine structure reveals different bonding configurations at the interface resulting from different growth methods. These results strongly suggest that a Ti pre-layer deposition alleviates the oxidation of the substrate and consequently the Fermi level pinning at the interface, as reported before. We also examined $BaTiO_3$ thin films grown on GaAs (001) with an ultrathin $SrTiO_3$ buffer layer. Interfacial charge distribution related to the polarization of $BaTiO_3$ thin film will be studied using atomic-resolution Z-contrast images, annular bright field images and EELS. Using first-principles DFT calculations, we analyze the formation energies of Ti-related impurity defects in different GaAs surface reconstructions to help interpret the electron microscopy experiments.

10:24AM Y11.00013 Temperature-driven irreversible phase transition of Sr template for epitaxial $SrTiO_3$ growth on vicinal Si (001) , KRISTY KORMONDY, AGHAM POSADAS, ALEXANDER DEMKOV, University of Texas at Austin — Strontium titanate (STO) grown epitaxially on silicon has been an area of interest both for its own properties as a high-k dielectric and its capacity to act as a substrate for other crystalline oxides. In this study, we investigate STO growth on a 4° miscut Si (001) surface with double atomic steps to enhance our understanding of submonolayer Sr deposition and STO growth. It is well-known that a half-ML of Sr on the Si surface is a necessary prerequisite for crystalline growth; however, detailed study of reflection high-energy electron diffraction (RHEED) pattern during Sr deposition at various substrate temperatures reveals two distinct surface reconstructions at half-ML coverage. At temperatures below 350°C, the 2x1 pattern is nearly identical to that of clean Si, but as the temperature is increased, we see the irreversible appearance of a 2x spot parallel to the step edge while the 2x spot perpendicular to the step edge dims. We also find that crystalline STO can be grown on both of these high- and low-temperature templates, with identical RHEED and band alignment as determined by XPS, showing that this previously unexplored low-temperature template can provide an alternative route for STO growth on Si.

10:36AM Y11.00014 Correlation effects on the different crystal structures of AO2 (A=Na, K, and Ba) , MINJAE KIM, CHANG-JONG KANG, B.I. MIN, Pohang University of Science and Technology (POSTECH) — In alkali superoxide (A=Na, and K), the structural phase transition from high symmetry to low symmetry structures occurs upon cooling. On the other hand, in BaO_2 peroxide, the crystal structure is always the high symmetry tetragonal structure of KO_2, independent of temperature. To resolve these different crystal structures of AO_2 (A=Na, K, and Ba), we have calculated phonon dispersions of AO_2, assuming the high symmetry tetragonal structure of KO_2 with first-principle band structure method in the generalized gradient approximation (GGA) incorporating the Coulomb interaction U (GGA+U). From softened phonon modes, we have shown that, in KO_2 and NaO_2, the degeneracy of the incomplete pi anti-bonding level is lifted with the symmetry lowering such as Jahn-Teller effect with help of Coulomb correlation U. In contrast, in BaO_2, the pi anti-bonding level of the peroxide is completely filled without degeneracy. Thus, U is not effective on the phonon structure so that the structural instability does not occur in BaO_2.

10:48AM Y11.00015 Fragility, Intermediate Phase and Polaronic conductivity in heavy metal oxides[1] , SHIBALIK CHAKRABORTY, KAPILA GUNASEKERA, PUNIT BOOLCHAND, University of Cincinnati, MOHAMMED MALKI, Polytech'Orléans, MATTHIEU MICOULAUT, UPMC-University Paris 6 — The $(B_2O_3)_5(TeO_2)_{95-x}(V_2O_5)_x$ ternary forms bulk glasses over a wide range of compositions, 18% $< x <$ 35%. Complex $C_p(x)$ measurements as a function of modulation frequency reveal that melt fragility (m) show a global minimum ($m = 52(2)$) in the 23% $< x <$ 26% range with $m > 65$ outside that window. These results suggest more stable network structure in the window than outside it. The fragility window coincides with a global minimum of the non-reversing enthalpy of relaxation at T_g, the reversibility window (23% $< x <$ 27%), a behavior also found in chalcogenide glasses. Conductivity (σ) data show three regimes of variation; a low σ at $x <$ 23%, a plateau in 23% $< x <$ 27%, and an exponential increase at $x >$ 27%. The reduced activation energy for conductivity at $x >$ 27% is consistent with increased polaronic mobility as the network becomes flexible. These findings show glasses at $x <$ 23% are *stressed-rigid*, in 23% $< x <$ 27% range in the *Intermediate Phase*, and at $x >$ 27% to be *flexible*.

Friday, March 22, 2013 8:00AM - 11:00AM –

Session Y12 DMP GERA FIAP: Focus Session: Themoelectrics Nanomaterials II 314 - Austin Minnich, CalTech

8:00AM Y12.00001 High Temperature Thermal Conductivity from First Principles , CHRISTIAN CARBOGNO, Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin, RAMPI RAMPRASAD, Chemical, Materials & Biomolecular Engineering, University of Connecticut, Storrs, MATTHIAS SCHEFFLER, Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin — In spite of significant research efforts, a first principles determination of the thermal conductivity at high temperatures has remained elusive. Under such conditions, techniques that rely on the harmonic approximation are no longer valid, while standard non-equilibrium molecular dynamics methods require huge temperature gradients that lead to deviations from Fourier's law. The Green-Kubo method [1], which does not suffer from these shortcomings, involves the assessment of the thermal conductivity from the auto-correlation of the heat flux in equilibrium. In classical MD, the heat flux is computed from the energetic contributions of the individual atoms; we show that the Green-Kubo approach can be reformulated in terms of the energy and stress densities [2], which are directly accessible in DFT calculations. This approach leads to a unique definition of the heat flux that does not rely on any partitioning scheme for the total energy. We critically discuss the computational cost, the accuracy, and the applicability of this approach by investigating the thermal conductivity for oxides and semiconductors with low thermal conductivities.

8:12AM Y12.00002 Nonlinear thermoelectric transport in mesoscopic systems , JONATHAN MEAIR, PHILIPPE JACQUOD, University of Arizona — We construct a scattering theory of weakly nonlinear thermoelectric transport through mesoscopic conductors. To preserve gauge invariance interaction induced potentials within the conductor must be self-consistently determined. We describe how to do this and apply our theory to calculating the leading nonlinear contribution to both electrical and heat currents. We present sum rules for our nonlinear response coefficients that must hold for current conservation and gauge invariance to be satisfied. We illustrate the method by investigating the thermoelectric response of a quantum point contact and a resonant tunneling barrier.

8:24AM Y12.00003 Monte Carlo Simulations of Mode Dependent Phonon Transport in Nanostructured Thermoelectric Materials[1] , TAKUMA HORI, The University of Tokyo, JUNICHIRO SHIOMI, The University of Tokyo, PRESTO Japan Science and Technology Agency — Nanostructuring are efficient process to lower the lattice thermal conductivity and thus enhance thermoelectric performance of semiconducting materials. Here, detailed knowledge of phonon transport properties in the nanostructures is needed for prediction of performance and/or optimization of structures. The approach to solve the linearized phonon Boltzmann transport equations stochastically by Monte Carlo method has been demonstrated to be useful to obtain phonon transport properties in mesoscale and complex structures. In this study, we have performed the Monte Carlo simulations to investigate phonon transport properties in nanostructured thermoelectric materials. With the mode-dependent bulk phonon transport properties obtained by first-principles-based calculations, the Monte Carlo simulations are performed to investigate the influence of nanostructure length-scales on the mode-dependent lattice thermal conductivity and its sensitivity to interfacial phonon transmission.

8:36AM Y12.00004 Ab initio thermal transport properties of nanostructures from density functional perturbation theory. , THUSHARI JAYASEKERA, Southern Illinois University, Carbondale, IL, ARRIGO CALZOLARI, Istituto Nanoscienze, CNR-NANO S3 Center I-41125, Modena Italy, KI WOOK KIM, North Carolina State University, Raleigh, NC, MARCO BUONGIORNO NARDELLI, University of North Texas, Denton, TX — We present a comprehensive first principles study of the thermal transport properties of low-dimensional nanostructures such as polymers and nanowires. An approach is introduced where the phonon quantum conductance is computed from the combination of accurate plane-wave density functional theory electronic structure calculations, the evaluation of interatomic force constants through density functional perturbation theory for lattice dynamics and the calculation of phonon transport properties by a real space Green's function method based on the Landauer formalism. This approach is computationally very efficient, can be straight-forwardly implemented as a post-processing step in a standard electronic-structure calculation (Quantum ESPRESSO and WanT in the present implementation), and allows us to directly link the thermal transport properties of a device to the coupling, dimensionality, and atomistic structure of the system. It provides invaluable insight into the mechanisms that govern the heat flow at the nanoscale and pave the way to the fundamental understanding of phonon engineering in nanostructures.

8:48AM Y12.00005 Designing Graphene-based Thermoelectric materials with Chemical Functionalization , JEONG YUN KIM, JEFFREY GROSSMAN, Massachusetts Institute of Technology — Graphene has been explored as a thermoelectric (TE) material recently due to its superior mobility and ambipolar nature. However, the extremely high thermal conductivity (κ) and only moderate Seebeck coefficient (S) make a graphene monolayer a highly inefficient TE material. Graphene superlattices made with chemical functionalization offer the possibility of tuning both the thermal and electronic properties via nano-patterning of the graphene surface. In this work, we investigate the effects of chemical functionalization on the thermoelectric transport properties of graphene using classical and quantum mechanical calculations. Our calculations show that chemical functionalization can control the power factor by changing the width of the pure graphene region and functionalization configuration, as well as κ depending on the functional groups and functionalization coverage. These results suggest that chemical functionalization could be an efficient route to designing graphene-based TE materials.

9:00AM Y12.00006 Power-efficiency trade-off due to density of states (DOS) distortion in a molecular thermoelectric system , PRIYANKA DESOUZA, Department of Energy Science and Engineering, IIT Bombay, Powai, Mumbai-400076, India, BHASKARAN MURALIDHARAN, Department of Electrical Engineering, IIT Bombay, Powai, Mumbai-400076, India — The issue of how a distortion in the electronic DOS affects nanoscale thermoelectric performance is addressed within an "electrical engineering" perspective. This view point is based on the direct evaluation of the overall efficiency and power from device current-voltage characteristics and gives a more complete picture of the thermoelectric performance in comparison to the traditional "figure of merit" based material science approach. We use representative examples from molecular conduction to study the trade-off between maximum efficiency and the maximum power generated within the set up. The trade-off is maximum for the well known example of a sharply resonant molecular level which represents the ultimate distortion in the electronic density of states. As the distortion is reduced via contact induced broadening, we obtain a smaller trade-off between maximum power and efficiency. We then present the effects of self consistent charging, contact induced asymmetry and the HOMO-LUMO gap on the thermoelectric performance. In all cases we compare our non-equilibrium calculations with zT calculations, and our results depict that zT is not the sole metric for the assessment of nanoscale thermoelectric performance.

9:12AM Y12.00007 Solvothermal synthesis and thermoelectric property of undoped and indium doped lead telluride nanoparticles[1] , KAMAL KADEL, WENZHI LI, Florida International University — Undoped and indium (In) doped lead telluride (PbTe) nanostructures were synthesized via solvothermal/hydrothermal route. The crystallinity of the as-prepared un-doped and In-doped PbTe sample were examined by X-ray diffraction (XRD) which indicated the formation of face centered single phase cubic PbTe. Lattice constant calculation from XRD pattern revealed the formation of un-doped and In-doped PbTe crystals with almost similar size. Scanning electron microscopy (SEM) and transmission electron microscopy (TEM) examinations indicated that undoped and In-doped PbTe nanostructures were mostly cubically shaped and highly crystalline. The effect of the synthesis temperature on the structure and morphology of undoped PbTe was also investigated; it was found that the particle size increased with the synthesis temperature. Thermoelectric property of as-synthesized lead telluride sample was also investigated.

9:24AM Y12.00008 Temporal evolution of Seebeck coefficient in an ac driven strongly correlated quantum dot[1] , ALI IHSAN GOKER, Bilecik University, ELIF GEDIK, Eskisehir Osmangazi University — We study the response of the thermopower of a quantum dot in the Kondo regime to sinusoidal displacement of the dot energy level via a gate voltage using time dependent non-crossing approximation and linear response Onsager relations. Instantaneous thermopower begins to exhibit complex fluctuations when the driving amplitude is increased at constant driving frequency. We also find that the time averaged thermopower decreases steadily until it saturates at constant driving amplitude as a function of inverse driving frequency. On the other hand, time averaged thermopower is found to be quite sensitive to ambient temperature at all driving frequencies for large driving amplitudes. We discuss the underlying microscopic mechanism for these peculiarities based on the behaviour of the dot density of states.

9:36AM Y12.00009 Thermopower Measurements of Highly Conducting Single-Molecule Devices , JONATHAN R. WIDAWSKY, WENBO CHEN, HECTOR VAZQUEZ, TAEKYEONG KIM, MARK S. HYBERTSEN, RONALD BRESLOW, LATHA VENKATARAMAN, Columbia University and CFN, Brookhaven National Laboratory — We measure the conductance (G) and thermopower (S) of highly conducting single-molecule junctions with Au electrodes. The junctions are formed and measured using a scanning tunneling microscope-based break-junction technique. The target molecules are synthesized with $SnMe_3$ terminations that cleave off *in situ*, allowing for the formation of direct Au-C covalent bonds to the electrodes[1,2]. We compare the conductance and thermopower for two families of molecules: pi-conjugated polyphenyls, which have a high conductance and thermopower, and sigma-bonded alkyl systems, where we observe a significant thermopower despite the low conductance. For these measurements, we use the most probable thermopower to determine a power factor, GS^2, for each molecular junction studied. Our results show that the molecular thermopower increases systematically and non-linearly with molecular length and also that the power factor is exceptionally large for the case of the biphenyl. 9:48AM Y12.00010 Operating Characteristics of a Microfabricated Phonon Spectrometer , RICHARD ROBINSON, JARED HERTZBERG, OBAFEMI OTELAJA, MAHMUT AKSIT, Department of Materials Science and Engineering, Cornell University — Phonon scattering exhibits a strong influence on the thermal properties of nanostructures. By promoting phonon scattering at surfaces and interfaces, a nanostructured thermoelectric material may achieve reduced thermal conductivity and enhanced thermoelectric efficiency. While phonons over a wide frequency range contribute to energy transport, thermal conductivity measurements capture only their combined effect. However, a window into phonon transport in nanostructures at specific frequencies could provide unique information and also serve as a crucial test platform for phonon transport theories. To this end, we have constructed a microfabricated phonon spectrometer. At a temperature of 0.3K, a superconducting tunnel junction locally generates non-thermal distributions of phonons and transmits them through adjacent silicon micro- and nanostructures.[1] We employ modulation techniques to select narrow frequency bands of phonons at frequencies up to hundreds of GHz. This prototype phonon spectrometer achieves phonon frequency resolution as low as ~10 GHz, more than an order of magnitude lower than comparable thermal methods. We describe the other key parameters of this technique: spatial resolution, frequency range, dynamic range, signal-to-noise ratio and calibration methods. This work was supported in part by the National Science Foundation under Agreement No. DMR-1149036.

10:00AM Y12.00011 Nonlinear thermoelectric response of quantum dots , STEFAN KIRCHNER, FARZANEH ZAMANI, Max Planck Institute for Physics of Complex Systems, ENRIQUE MUNOZ, Pontificia Universidad Catolica de Chile, LUKAS MERKER, THEO COSTI, Forschungszentrum Juelich GmbH — The thermoelectric transport properties of nanostructured devices continue to attract attention from theorists and experimentalist alike as the spatial confinement allows for a controlled approach to transport properties of correlated matter. Most of the existing work, however, focuses on thermoelectric transport in the linear regime despite the fact that the nonlinear conductance of correlated quantum dots has been studied in some detail throughout the last decade. To go beyond the linear response regime, we use a recently developed scheme [1], to address the low-energy behavior near the strong-coupling fixed point at finite bias voltage and finite temperature drop at the quantum dot. We test the reliability of the method against the numerical renormalization group [2] and determine the charge, energy, and heat current through the nanostructure. This allows us to determine the nonlinear transport coefficients, the entropy production, and the fate of the Wiedemann-Franz law in the non-thermal steady-state [3].

10:12AM Y12.00012 Atomistic quantum thermal conductance profile of hybrid interfaces , JEEVAKA WEERASINGHE, Department of Physics, University of North Texas, Denton, TX 76203, ARRIGO CALZOLARI, Instituto Nanoscienze CNR-NANO S3 Center, I-41125 Modena, Italy, MARCO BUONGIORNO NARDELLI, Department of Physics and Department of Chemistry, University of North Texas, Denton, TX 76203 — Atomistic structure at interfaces has been shown to play a critical role in quantum thermal conductance across nanoscale interfaces. In general, current models derive phonon transmission probabilities from bulk material properties. However, they do not account for the effect of atomic scale interfacial structure on thermal conductance. Here we use an ab initio approach that we have recently developed to investigate the correlation between interfacial atomic structure and quantum thermal conductance. In particular, we will discuss the electronic structure and thermal conductances in systems with hybrid metal/self-assembled monolayer (SAM) interfaces with varying chemistry in order to elucidate the role of metal-organic bonds in the thermal properties of complex assemblies. Our methodology integrates the accurate self-consistent minimization of the ground state electronic structure via first-principles density functional theory based calculations, the determination of interatomic force constants via density functional perturbation theory, and the calculation of the quantum conductance using a real space Green's function formalism based on the Landauer approach.

10:24AM Y12.00013 Studies of Thermal Conductivity in Hybrid Organic-Inorganic Nanocrystal Arrays , WEE-LIAT ONG, Carnegie Mellon University, SARA RUPICH, DMITRI TALAPIN, University of Chicago, ALAN MCGAUGHEY, JONATHAN MALEN, Carnegie Mellon University — The thermal conductivity of nanocrystal arrays (NCAs) is studied and found to be tunable through the nanocrystal diameter, and chemistry - a conclusion that is supported by our Molecular Dynamics simulation. Nanocrystal arrays self-assemble from colloidal molecule-coated nanocrystals into close-packed 3D films. It has been suggested that their electronic and thermal transport properties can be decoupled, enabling a resolution to the conflicting needs of various thermal management and solid-state energy conversion applications (e.g. high figures of merit materials for thermoelectric, high-efficiency photovoltaic materials). Although the electronic transport in NCAs has been studied extensively, little is known about their thermal transport. We herein report both experimental measurements and modeling performed to elucidate the thermal transport mechanisms in NCAs. Various factors including the geometry and chemical compositions of the NCAs will be presented. Simulation results showed good agreement with the observed experimental trends, providing a complementary computational approach for elucidating and optimizing NCA thermal properties.

10:36AM Y12.00014 Probing tunable thermal properties of organic hetero-junctions , SHUBHADITYA MAJUMDAR, SCOTT N. SCHIFFRES, JONATHAN A. MALEN, ALAN J.H. MCGAUGHEY, Carnegie Mellon University — The ability to tune physical properties of new organic-inorganic heterojunctions is essential for their popularity in the fields of molecular electronics and energy-generation devices. Intimate associations between the organic and inorganic components at the nano-scale level lead these materials to possess unique transport properties. Here, we probe the thermal conductance of self-assembled monolayer (SAM) junctions using both computational and experimental methods. SAM junctions are ordered, periodic arrays of a single layer of organic molecules chemically bonded to two inorganic substrates. Molecular dynamics simulations are performed on the SAM junctions to study the effect of physical parameters on the junction thermal conductance. These include atomic masses of leads, junction temperature, molecular chain length, and surface coverage. Another important aspect is the contribution of the stiff C-H bonds to thermal transport, an analysis of which is also presented. Lattice dynamics calculations are employed to study the effect of molecular vibrations on the thermal coupling between the leads. The SAM junctions are prepared in the laboratory through a combination of solution immersion and transfer printing techniques. Frequency domain thermo-reflectance (FDTR) – a laser-based non-contact measurement scheme to probe the thermal properties of thin films, is employed to study the samples. A comparison between the results obtained from these studies is thus presented.

10:48AM Y12.00015 Seebeck Coefficient of Manganese Oxide Nanoparticles as a Function of Ohmic Resistance[1] , NICHOLAS FRANCIS, MORGAN HEDDEN, COSTEL CONSTANTIN, James Madison University — Due to the ever increasing energy demand and growing global concern over the environmental impact of CO_2 emissions, there is an urging need to seek solutions to transit from fossil fuels to sustainable energy. Thermoelectric (TE) materials show great promise for converting waste heat energy into electricity. TE systems have many unique advantages such as silent operationality, time reliability, and dimensional scalability. Most recently, researchers Song et al. [1] found that MnO_2 nanoparticles show a giant Seebeck coefficient of S = 20 mV/K, which is100 times higher than bismuth telluride, one of the best TE materials. Song et al.[1] concluded the paper claiming that the giant S is related to the surface density of the electronic states (DOS). However, they provided very little information about the S as a function of Ohmic resistance [R] for different nano particle sizes which can give information about the DOS. Our preliminary results show that there is a sudden increase of S from 0.33-0.63 mV/K as R increases from 80-110 Ohms. This transition has never been seen before and it can give clues as to the existence of the Giant S observed in this material.

Friday, March 22, 2013 8:00AM - 11:00AM –

Session Y13 DCMP: Topological Insulators: Thin Films and Interfaces 315 - Fazel Fallah Tafti, Universite de Sherbrooke

8:00AM Y13.00001 An Infrared Study of Bi2Se3 Thin Films , KIRK POST, BRIAN CHAPLER, University of California - San Diego, LIANG HE, XUFENG KOU, University of California - Los Angeles, ALEX SCHAFGANS, None, KANG WANG, University of California - Los Angeles, DMITRI BASOV, University of California - San Diego — The experimental observation of surface states present in Bi_2Se_3 has been limited by self-doping via selenium vacancies. We have explored this issue by probing the electronic structure of Bi_2Se_3 using a combination of variable angle spectroscopic ellipsometry (VASE) and Fourier transform infrared spectroscopy (FTIR). Specifically, we have measured Bi_2Se_3 thin films grown on Si (111) substrates, ranging from 15 to 99 quintuple layers (QL) thick. These results show that both the carrier density and the energy gap are inversely related to the thickness. Surprisingly, the energy gap in all but the 15QL samples was smaller than the bulk band gap. Furthermore, the energy gap varied by over 100 meV between the 15QL and 99QL sample. The features that we observed are consistent with a modified picture of the band structure of Bi_2Se_3 that includes an impurity band below the conduction band and a Fermi level that is inversely related to the thickness.

8:12AM Y13.00002 Impact of growth conditions on the MBE-grown topological insulator Bi_2Se_3 thin films[1] , Y. LIU, Y.Y. LI, S. RAJPUT, M. WEINERT, L. LI, University of Wisconsin, Milwaukee — Recently, molecular beam epitaxy (MBE) has been successfully applied to prepare atomically flat topological insulator thin films that exhibit helical Dirac states. In this work, we systematically investigate the effects of substrate temperature and Bi/Se flux ratio on the morphology and properties of Bi_2Se_3 thin films grown on graphene/SiC(0001) by MBE. Under optimal growth conditions, *in situ* scanning tunneling microscopy indicates spiral growth [1], characterized by atomically smooth terraces 10 to 50 nm in width, separated by steps that are one quintuple-layer in height. *Ex situ* Raman spectroscopy reveals two characteristic peaks at 130 and 171 cm^{-1}, corresponding to the in-plane E_g^2 and out-of-plane A_{1g}^2 vibrational modes, respectively. The close resemblance of the positions and line shapes of both these peaks to those of bulk Bi_2Se_3 attest to the high quality of the film. These results and the impact of growth spirals on the properties of the topologically protected Dirac surface states of Bi_2Se_3 will be presented at the meeting.

8:24AM Y13.00003 Epitaxial Growth of Topological Insulators on Hexagonal Boron Nitride , CHRISTOPHER GUTIERREZ, WOO CHANG CHUNG, CHOCKALINGAM SUBBAIAH, Columbia University, MATTHEW BRAHLEK, SEONGSHIK OH, Rutgers University, ABHAY PASUPATHY, Columbia University — Topological insulators (TIs) have attracted much attention for exhibiting exotic, topologically-protected surface states consisting of massless Dirac fermions. Investigations on thin film TIs have primarily relied on those either grown by MBE or by mechanical exfoliation onto suitable target substrates. Taking a cue from the graphene community, hexagonal boron nitride (hBN) has proven to be an excellent insulating substrate since it is atomically flat with no surface dangling bonds. In this talk I will report on recent transport and scanning probe measurements on epitaxial thin films of bismuth selenide TI grown by MBE on hBN/SiOx.

8:36AM Y13.00004 Gate-tunable supercurrent in S-TI-S structures[1] , VLADIMIR ORLYANCHIK, MARTIN STEHNO, CHRISTOPHER NUGROHO, DALE VAN HARLINGEN, University of Illinois at Urbana-Champaign, MATTHEW BRAHLEK, NAMRATA BANSAL, NIKESH KOIRALA, SEONGSHIK OH, Rutgers, the State University of New Jersey — Theoretical proposals for observation of the zero energy excitations (Majorana modes) involve coupling between the surface states of 3-D topological insulators (TI) and s-wave superconductors (SC). A prerequisite for such experiments is a highly tunable topological surface which is decoupled from bulk charge carriers and non-topological surface states. Here we report on measurements performed using high-quality MBE-grown thin films of Bi2Se3 patterned to create planar Josephson devices with Nb leads and a metallic top gate. We present the dependence of the conductance and proximity-induced supercurrent on the junction geometry, temperature, and the gate voltage. By analyzing the gate voltage dependence, we deduce that there are contributions to the supercurrent from two channels - topological surface states and a topologically-trivial surface accumulation layer.

[1]Supported by Microsoft Station-Q program.

8:48AM Y13.00005 Terahertz dynamics of gated thin films of the topological insulator Bi_2Se_3[1] , ANDREAS STIER, JAMES NEILSON, LIANG WU, Department of Physics and Astronomy, Johns Hopkins University, NAMRATA BANSAL, MATTHEW BRAHLEK, SEAN OH, Department of Physics and Astronomy, Rutgers, the State University of New Jersey, N. PETER ARMITAGE, Department of Physics and Astronomy, Johns Hopkins University — Topological insulators are a newly discovered class of materials, which in principle exhibit bulk insulating behavior and conducting surface channels with a Dirac like dispersion relation. Real materials, however, suffer from large residual bulk conductance due to donor defect sites. This places the chemical potential in the bulk bands. Ionic liquid gating techniques are capable of moving the chemical potential into the bulk band gap, making the exotic transport characteristics predicted for the surface states accessible. Here, we present terahertz time domain spectroscopy of gated thin films of the topological insulator Bi_2Se_3 utilizing an ionic liquid gel as a top gate. The evolution of the Drude like conductivity features as a function of gate bias show a sharp decrease in the scattering rate which we interpret as the chemical potential moving from the conduction band into the surface states. We also discuss efforts to optically observe potential axionic terms in the action governing Maxwell's equations for this material class, which are reflected in a discontinuous evolution of the Faraday rotation.

[1]This work was funded by the Gordon and Betty Moore foundation.

9:00AM Y13.00006 Scanning tunneling spectroscopic (STS) studies of magnetically doped MBE-grown topological insulators (TIs)[1] , HAO CHU, MARCUS TEAGUE, CHIEN-CHANG CHEN, NICHOLAS WOODWARD, NAI-CHANG YEH, California Institute of Technology, XUFENG KOU, LIANG HE, MURONG LANG, KANG LONG WANG, UCLA, CALTECH COLLABORATION, UCLA COLLABORATION — We conduct STS studies on MBE-grown heterostructures of non-magnetic TI (Bi_2Se_3) with a range of thicknesses (d = 1, 3, 5, 7 quintuple layers, QL) on top of 7-QL magnetically doped TI (Cr-doped Bi_2Se_3). For d = 1 and 3-QL, a spatially homogeneous magnetism-induced surface gap (as large as about 150 meV for d = 1-QL) is observed at 77 K, whereas gapless Dirac spectra are found for d = 5 and 7-QL, suggesting that the effective magnetic length for Cr-doped Bi_2Se_3 is approximately 4 $\sim$ 5-QL. These findings are further corroborated by ARPES and bulk electrical transport measurements. The magnetism-induced surface gap differs from those found in pure Bi_2Se_3 and $(Bi_{0.5}Sb_{0.5})_2Te_3$ films of thicknesses smaller than 6-QL, because the latter are due to overlaps of wave functions between the surface and interface layers, which lead to Rashba-like spin-orbit splitting and spin-preserving quasiparticle interference wave-vectors. In contrast, STS studies of TIs with magnetism-induced surface gap do not yield any quasiparticle interferences for energies within the bulk Bi_2Se_3 gap. Finally, comparative STS studies of pure and magnetically doped TIs in high magnetic fields will be discussed.

[1]This work was supported by DARPA.

9:12AM Y13.00007 Thickness-Independent Transport Channels in Topological Insulator Bi2Se3 Thin Films , NAMRATA BANSAL, Rutgers University, YONG-SEUNG KIM, Sejong University, MATTHEW BRAHLEK, ELIAV EDREY, NIKESH KOIRALA, SEONGSHIK OH[1], Rutgers University — With high quality Bi2Se3 thin films grown on Al2O3(0001), we report thickness-independent transport properties over wide thickness ranges. Low temperature conductance remained nominally constant as the sample thickness changed from 256 to $\sim$8QL (where QL refers to quintuple layer, 1QL$\approx$1nm). Two surface channels with very different behaviors were identified. The sheet carrier density of one channel remained constant at $\sim 3\times10^{13}$ cm^{-2} down to 2QL, while the other, which exhibited quantum oscillations, remained constant at $\sim 8\times10^{12}$ cm^{-2} only down to $\sim$8QL. The weak antilocalization effect also exhibited similar thickness independence. These two channels are most consistent with the topological surface states and the surface accumulation layers, respectively. We will also discuss surface signatures present in Bi2Se3 thin films grown on Si(111) and amorphous SiO2.

[1]Correspondence should be addressed to ohsean@physics.rutgers.edu

9:24AM Y13.00008 An abrupt change in transport dynamics across the topological phase transition in the $(Bi_{1-x}In_x)_2Se_3$ and ultra-thin Bi2$_2$Se$_3$ systems , LIANG WU, ROLANDO VALDES AGUILAR, ANDREAS V. STIER, LUCAS S. BILBRO, YUVAL LUBASHEVSKY, N. PETER ARMITAGE, The Institute for Quantum Matter, Department of Physics and Astronomy, The Johns Hopkins University, Baltimore, MD 21218 USA, MATTHEW BRAHLEK, NAMRATA BANSAL, SEAN OH, Department of Physics and Astronomy, Rutgers the State University of New Jersey. Piscataway, NJ 08854 — We have utilized time-domain terahertz (THz) spectroscopy to investigate the low frequency optical conductivity in $(Bi_{1-x}In_x)_2Se_3$ through its topological phase transition from the pure ($x = 0$) compound to the topologically trivial strongly insulating material ($x > 0.25$). The thickness independent Drude peak shows only minor broadening at low In substitutions. However, above $x \sim 0.05$ we observe a sudden collapse in the transport lifetime. This substitution level closely coincides with a maximum in the mid-infrared (MIR) absorption coefficient which can be identified with the substitution level where the band gap closes, the band structure inverts, and hence the topological class changes. We therefore associate the collapse in the transport lifetime with the loss of topological protection of surface states as the system enters the topologically trivial phase. Topological phase transition driven by reducing film thickness is also investigated. Similar collapse in the transport lifetime is observed in the ultra-thin limit.

9:36AM Y13.00009 Fabrication and transport measurements of stacked double layer topological insulator devices , TAI-LUNG WU, Department of Physics and Birck Nanotechnology Center, Purdue University, West Lafayette, IN 47907, JIUNING HU, School of Electrical and Computer Engineering, Purdue University, West Lafayette, IN 47907, JIFA TIAN, Department of Physics and Birck Nanotechnology Center, Purdue University, West Lafayette, IN 47907, IRENEUSZ MITKOWSKI, Department of Physics, Purdue University, West Lafayette, IN, 47907, YONG P. CHEN, Department of Physics and Birck Nanotechnology Center, Purdue University, West Lafayette, IN 47907 — A double-layer structure, consisting of two separated two-dimensional electron systems close in proximity, has been an interesting system to study novel ground states and transport properties driven by electron-electron interaction, e.g. Coulomb drag, exciton condensation, and counterflow superfluidity. Recently, topological insulators (TI), such as Bi_2Se_3 and Bi_2Te_3, have attracted much attention due to their exotic topologically protected spin-helical and Dirac-particle surface states. Motivated by a recently proposed "topological exciton condensate" that may be formed in two interacting TI surfaces, we have fabricated stacking double-layer TI structures and studied their electrical transport properties. Using a polyvinyl alcohol (PVA) based support film and micro-manipulator, double layer TI structures (Bi_2Se_3/boron nitride/Bi_2Se_3) were fabricated with exfoliated Bi_2Se_3 separated by thin boron nitride flakes ($\sim$ 20 nm). We will present results from transport measurements including mutual-gated electrical field effect, Coulomb drag ,and counterflow conductivity.

9:48AM Y13.00010 Angle-resolved photoemission spectroscopy study of the magnetic doped topological insulator ultra-thin film $Bi_2Fe_xSe_3$[1] , YI ZHANG, LBL/SIMES, BO ZHOU, Stanford/Oxford, YULIN CHEN, Oxford, SUNG-KWAN MO, ZAHID HUSSAIN, LBL, ZHI-XUN SHEN, SIMES/Stanford — Topological insulator is a new type of quantum matter with gapped bulk states coexisting with a gapless surface state (SS) that is protected by time reversal symmetry and robust against non-magnetic impurities. Researches have shown that there exist two routes to open a gap in the SS: doping with magnetic impurities and the coupling of SS on opposite surfaces in ultra-thin films. In order to study the mixing of these two types of gap-opening, we prepared ultra-thin $Bi_2Fe_xSe_3$ films, grown by molecular beam epitaxy, with different Fe concentration and thickness. Size of the gap and its development with Fe concentration and film thickness as well as its momentum dependence have been systematically characterized by in-situ angle resolved photoemission spectroscopy using synchrotron light source.

10:00AM Y13.00011 Tunneling tuned spin modulations in ultrathin topological insulator films[1] , MADHAB NEUPANE, S.-Y. XU, N. ALIDOUST, I. BELOPOLSKI, CHANG LIU, Department of Physics, Princeton University, D.M. ZHANG, A. RICHARDELLA, Department of Physics, Penn State University, J. SANCHEZ-BARRIGA, D. MARCHENKO, A. VARYKHALOV, O. RADER, BESSY II, Germany, M. LEANDERSSON, T. BALASUBRAMANIAN, MAX-Lab, Sweden, L.A. WRAY, ALS, LBNL, T.-R. CHANG, National Tsing Hua University, Taiwan, H.-T. JENG, National Tsing Hua University and Academia Sinica, Taiwan, H. LIN, A. BANSIL, Department of Physics, Northeastern University, N. SAMARTH, Department of Physics, Penn State University, M.Z. HASAN, Department of Physics, Princeton University — Understanding the spin behavior of boundary modes in ultrathin topological insulator films is critically essential for the design and fabrication of functional nano-devices. We report tunneling-dependent evolution of spin configuration in topological insulator thin films across the metal-to-insulator transition. We observe that for a given film thickness of the prototype topological insulator Bi_2Se_3 ultrathin films, the spin polarization is large for larger wave-vectors or for momenta far from the center of the surface Brillouin zone. In addition, the polarization is observed to decrease significantly with enhanced tunneling realized systematically in thin insulating films. We present theoretical model calculations that qualitatively capture the delicate relationship between quantum tunneling and Fermi surface spin polarization.

10:12AM Y13.00012 Study of proximity effect in superconductor - topological insulator heterostructures by scanning SQUID microscope , ILYA SOCHNIKOV, ANDREW J. BESTWICK, JAMES R. WILLIAMS, THOMAS M. LIPPMAN, ANDREW S. BLEICH, JAMES G. ANALYTIS, IAN R. FISHER, DAVID GOLDHABER-GORDON, JOHN R. KIRTLEY, KATHRYN A. MOLER, Stanford University — A proximity induced superconducting state in topological insulators is potentially an enabling condition for exotic forms of superconductivity that may support Majorana fermions in some geometries. Initial studies of induced superconductivity in topological insulators have relied on transport measurements. We present a different contactless characterization approach based on a scanning SQUID microscope. We characterized Al superconducting rings with Josephson junctions made of Bi_2Se_3, long Al/Bi_2Se_3/Al Josephson junctions, and Bi_2Se_3/Al dots. We observe both induced proximity and inverse proximity effects in these heterostructures. Each of the structures provides unique information about the proximity effect, such as the critical current, the magnetic field penetration depth, and the critical temperatures of the induced superconducting state. These measured parameters allow the determination of limits on contributions from the surface and the bulk to the proximity effects in the topological insulator Bi_2Se_3.

10:24AM Y13.00013 Local Magnetic Imaging of Proximity Effect-Induced Superconductivity at the Bi_2Se_3-Nb Interface , PHILIP KRATZ, JOHN KIRTLEY, ILYA SOCHNIKOV, PHILLIP WU, ERIC SPANTON, KRISTIE KOSKI, YI CUI, ROBERT HAMMOND, MALCOLM BEASLEY, KATHRYN MOLER, Stanford University, USA — The interface between a topological insulator (TI) and an s-wave superconductor (SC) is predicted to host Majorana bound states analogous to vortices in a spinless p_x+ip_y superconductor. For 3D TIs coupled to s-wave superconductors, the winding of the superconducting vortices can counteract the TI pi-Berry's phase, resulting in zero-energy Majorana fermion excitations at the interface. Transport measurements of Bi_2Se_3 and Bi_2Te_3 superconducting junctions have shown Josephson junction effects[1,3,4] and established the existence of a supercurrent that is tunable with gate voltage [2], but the relative contributions of the bulk and bound states to the supercurrent is not well-understood. We report on measurements of the local superfluid density at the interface between Bi_2Se_3 nanoplatelets and Nb using a scanning SQUID microscope and quartz tuning fork sensor for simultaneous AFM characterization. We demonstrate that the local penetration depth measurements have increased accuracy and provide an experimentally tractable method for studying proximity effect-induced superconductivity at the SC-TI interface, which is a precursor for observation of the elusive Majorana fermion in Bi_2Se_3 and other 3D TIs.

[1] arXiv:1209.5830 (2012). [2] Nat. Comm. **2** (2011). [3] Nat. Mat. **11**, 421 (2012). [4] Phys. Rev. Lett. **109**, 056803 (2012). [5] Phys. Rev. B **84**, 165120 (2011).

10:36AM Y13.00014 Dirac cone shift and potential fluctuations in a passivated In_2Se_3/Bi_2Se_3 topological interface state[1] , GREGORY S. JENKINS, A.B. SUSHKOV, D.C. SCHMADEL, M.-H. KIM, H.D. DREW, Department of Physics, University of Maryland at College Park, G. KOBLMUELLER, M. BICHLER, Walter Schottky Institut and Physik Department, Technische Universitat Munchen, N. BANSAL, M. BRAHLEK, S. OH, Department of Physics and Astronomy, The State University of New Jersey, Piscataway — The topological interface state of Bi_2Se_3 capped with In_2Se_3 is measured by gated THz cyclotron resonance. An observed shift of 70 meV in the position of the Dirac point towards mid-gap due to the physical properties of the trivial insulator In_2Se_3 on Bi_2Se_3 opens new possibilities in tailoring Dirac cone properties in topological insulators. Modulating and sweeping a semi-transparant gate while probing at terahertz frequencies in magnetic field enables characterization of the burried In_2Se_3/Bi_2Se_3 topological interface state, even in the presence of significant bulk conductivity. Near the Dirac point, the mobility is 3500 $cm^2/V{\cdot}s$ with potential fluctuations of 60 meV. The scattering rate shows a precipitous drop with Fermi energy indicating decoupling of the surface states from bulk states. At Fermi energies above the conduction band edge, a plateau is observed in the real part of the Faraday angle that is 80 times flatter than the step size expected from a single Landau Level, quantized in units of the fine structure constant.

10:48AM Y13.00015 Massive Dirac surface states in topological insulator/magnetic insulator heterostructures[1] , WEIDONG LUO, Shanghai Jiao Tong University, XIAO-LIANG QI, Stanford University — We study the behavior of topological surface states in heterostructures formed by a topological insulator (TI) and a magnetic insulator (MI). Several MIs with compatible magnetic structure and relatively good lattice matching with TIs are identified, and the best candidate material is found to be MnSe, an anti-ferromagnetic insulator. We perform first-principles calculation in Bi_2Se_3/MnSe superlattices and obtain the surface state bandstructure. The magnetic exchange coupling with MnSe induces a gap of 54 meV at the surface states. In addition we tune the distance between Mn ions and TI surface to study the distance dependence of the exchange coupling. Finally, we study the band bending effect at the Bi_2Se_3/MnSe interface, and propose possible solutions to avoid band bending.

Session Y14 DMP FIAP GMAG: Focus Session: Thermal and Magnon Spin Currents 316 - Gabriel Chaves-O'Flynn, New Jersey Institute of Technology

8:00AM Y14.00001 GMAG PhD Dissertation Research Award: The Planar Nernst and Seebeck Effects in Ferromagnetic Metal Films with In-Plane Thermal Gradients , AZURE AVERY, University of Denver — Recently, the spin Seebeck effect (SSE) has attracted a great deal of attention as one possible source of pure spin currents. In response to a thermal gradient (∇T), the SSE is thought to produce a pure spin current detectable by measuring a transverse voltage (V_T) generated by the inverse spin Hall effect. However, recent work on spin-dependent transport in thin film nanostructures supported by bulk substrates suggests that early SSE experiments may have been strongly affected by unintended ∇T through the supporting substrates. They may also have been affected by thermoelectric effects generated from planar thermal gradients such as transverse thermopower, also known as the planar Nernst effect (PNE), in which a V_T develops in response to a ∇T applied in the plane of a film with in-plane magnetization. In this talk, we present the first results from experiments designed to probe the SSE and related effects such as the PNE and longitudinal thermopower in 20 nm thick nickel and permalloy thin films deposited on suspended Si-N platforms. In our experiments, the background thermal conduction of the 500 nm thick platforms is at least 1000x smaller than the bulk substrates used previous experiments, thus confining ∇T to the plane of the film. The results exhibit the $\sin\theta\cos\theta$ angular dependence predicted by the PNE, where θ is the angle between film magnetization and thermal gradient, rather than the $\cos\theta$ dependence expected from SSE predictions. We demonstrate that the magnetic field dependence of the PNE, anisotropic magnetoresistance, and longitudinal thermopower (α) is generated by spin-dependent scattering and present results confirming the Onsager reciprocity between α and the Peltier coefficient. Finally, we present an upper limit for the SSE coefficient in our experiment that is at least an order of magnitude smaller than previously reported by experiments conducted using bulk substrates. I would like to thank my collaborators Barry L. Zink and Matthew R. Pufall and gratefully acknowledge support from the NSF CAREER Grant No. DMR-0847796.

8:36AM Y14.00002 Spin-Seebeck effect in amorphous ferromagnetic alloys[1] , HYUNGYU JIN, Department of Mechanical and Aerospace Engineering, The Ohio State University, Columbus, OH, ZIHAO YANG, ROBERTO MYERS, Department of Electrical and Computer Engineering, The Ohio State University, Columbus, OH, JOSEPH HEREMANS, Department of Mechanical and Aerospace Engineering, The Ohio State University, Columbus, OH — Since its first discovery in 2008 [1], continuous research on spin-Seebeck effect (SSE) has established a theory for the driving mechanisms of SSE: in the presence of a thermal gradient, the spin waves (magnons) present in ferromagnets are brought out of thermal equilibrium. It is suspected that their return to thermal equilibrium is what launches a spin flux, which then is converted into a voltage in a separate material by strong spin-orbit interactions. While it is proven that substrate phonons affect the spin-Seebeck signals [2], another possible mechanism that can drive magnons out of equilibrium can be magnon thermal conductivity. Here, to isolate the magnon and phonon contributions, we investigate the relation between SSE and magnon thermal conductivity in amorphous ferromagnetic alloys (Metglas). Because Metglas has high Curie temperature, yet mostly localized phonon modes, the magnon contribution to SSE is expected to be larger than in crystalline ferromagnets. Experimental SSE data as well as magneto-thermal conductivity data will be presented.

8:48AM Y14.00003 Intrinsic Spin Seebeck Effect in Gold , DANRU QU, The Johns Hopkins University, SSU-YEN HUANG, The Johns Hopkins University, National Tsing Hua University, JUN HU, RUQIAN WU, University of California, Irvine, CHIA-LING CHIEN, The Johns Hopkins University — In Spin Seebeck Effect (SSE), a pure spin current can be generated by a temperature gradient (∇T) and detected by the inverse spin Hall effect usually by Pt. Due to the propensity of out-of-plane ∇_zT through substrate, the SSE in the transverse configuration with an in-plane ∇_xT has been shown contaminated by the anomalous Nernst effect.[1] The SSE in the longitudinal configuration with ∇_zT suffers from the magnetic proximity effect (MPE) of Pt in contact with a ferromagnetic material thus also contaminated.[2] In this work, we demonstrate that Au does not exhibit MPE and reveals the intrinsic SSE. In contrast to Pt/YIG, Au/YIG shows no anomalous Hall signals, very weak inverse MR, and non-monotonic thickness dependence of spin thermal voltage, thus very weak if any MPE. Our results place an upper limit to the intrinsic SSE of 0.1μV/K at the Au thickness of 8nm, two orders of magnitude smaller than that in Pt/YIG. Spin-polarized density-functional calculations also show a sizable Pt but a negligible Au magnetic moment in contact with YIG, in agreement with experiments.

9:00AM Y14.00004 Electrical measurements of nonlinear magnetization dynamics[1] , CAN-MING HU, YONGSHEN GUI, LIHUI BAI, PAUL HYDE, Department of Physics and Astronomy, University of Manitoba, Winnipeg, Canada R3T 2N2, UNIVERSITY OF MANITOBA TEAM — A new approach to measure precisely nonlinear magnetization dynamics is demonstrated by using spin dynamos in combination with sensitive electrical probing techniques. The directly measured intrinsic foldover effect of ferromagnetic resonance in Py unravels a 50-year-old mystery of ferromagnetic metals. Pivotal importance of nonlinear ferromagnetic damping is uncovered via its distinct dependence on the frequency, amplitude, and initial conditions. The experimental results are in excellent agreement with a phenomenological model, which revises the pioneer theoretical work of Anderson and Suhl for nonlinear magnetization dynamics. New evidence for electrically detected pure spin pumping in the nonlinear dynamic regime will be briefly discussed. For more information and references, please check our group website at: http://www.physics.umanitoba.ca/˜hu/.

9:12AM Y14.00005 Irreversible thermodynamics of transport and relaxation of magnetic moments with applications for spin caloritronics , SYLVAIN BRECHET, EPFL — Spin caloritronics is mainly focused on studying the effects of a temperature gradient on the time evolution of the local spin average of a classical system. In many experimental situations, the system can be treated as a classical continuum with magnetisation on the scale of interest where the quantum fluctuations average out and the underlying microscopic structure is smoothed out. Here, we establish a clear classical formalism describing the thermodynamics of a matter continuum with magnetic moments interacting with external electromagnetic fields. Taking into account the chemical nature of the current densities – such as the current density of magnetic moments – and stress tensors leads to three types of dissipation terms: scalars, vectors and pseudo-vectors. The scalar terms account for the chemical reactivities, the vectorial terms account for the transport and pseudo-vectorial terms account for the relaxation. The vectorial phenomenological relations establish notably the Spin Seebeck effect first observed by Uchida and Saitoh. The pseudo-vectorial phenomenological relations establish in particular the Landau-Lifschitz relaxation of the magnetisation.

9:48AM Y14.00006 Spin wave mode coexistence: A consequence of the Oersted field induced asymmetric energy landscape , RANDY DUMAS, EZIO IACOCCA, Univ. of Gothenburg, STEFANO BONETTI, Stanford Institute for Energy and Materials Science , SOHRAB SANI, MAJID MOHSENI, ANDERS EKLUND, JOHAN PERSSON, Royal Institute of Technology (KTH), OLLE HEINONEN, Argonne National Laboratory, JOHAN AKERMAN, Univ. of Gothenburg — The emerging field of magnonics relies on the systematic generation, manipulation, and detection of spin waves (SWs). Nanocontact spin torque oscillators (NC-STOs) provide an ideal platform to study spin transfer torque induced SW emission [1,2]. In analogy to two species competing for the same food supply it has been argued that only one SW mode can survive in the steady state [3]. However, as evidenced in many experiments clear signatures of mode-hopping are often observed [1,4]. We present a third possibility, namely that under the correct experimental conditions, mode coexistence can be realized. Micromagnetic simulations reveal that the SW modes are spatially separated under the NC. Mode coexistence is facilitated by the local field asymmetries induced by the spatially inhomogeneous Oersted field in the vicinity of the NC and further promoted by SW localization. Finally, both simulation and experiment reveal a weak low frequency signal exactly at the difference of the mode frequencies, consistent with inter-modulation of two coexistent modes. [1] S. Bonetti, et al., PRL 105, 217204 (2010). [2] M. Madami, et al., Nature Nanotechnol. 6, 635 (2011). [3] F. M. de Aguiar, et al., PRB 75, 132404 (2007). [4] P. K. Muduli, et al., PRL 108, 207203 (2012).

10:00AM Y14.00007 Controlling spin-wave propagation with Oersted fields[1] , K. VOGT, B. HILLEBRANDS, Technische Universitaet Kaiserslautern, H. SCHULTHEISS, J.E. PEARSON, F.Y. FRADIN, S.D. BADER, A. HOFFMANN, Argonne National Laboratory — The goal of magnon spintronics is to utilize the coherent propagation of spin waves for low-power data processing. Spin waves carry angular momentum and can transport spin information over distances much larger than the spin diffusion length of metals. However, in thin magnetic films the highly anisotropic dispersion relation leads to strong changes in the spin-wave energy for different angles between their propagation direction and the magnetization orientation. Consequently, spin waves only travel along a straight path if the magnetization direction is fixed by a global external magnetic field. We demonstrate that locally rotating magnetic fields generated via electric current pulses allow to vary the propagation direction of spin waves. Using spatially resolved Brillouin light scattering microscopy the propagation behavior was directly verified.[2] We have modeled the current generated magnetic fields with a finite element code and calculated the magnetic response using micro magnetic simulations.

10:12AM Y14.00008 Mapping microwave fields using the spin Hall effect[1] , VINCENT VLAMINCK, Materials Science Division, Argonne National Laboratory, HELMUT SCHULTHEISS, JOHN PEARSON, FRANK FRADIN, SAMUEL BADER[2], AXEL HOFFMANN, Argonne National Laboratory — We present measurements of the spatial variation of the spin pumping - inverse spin Hall effect in a palladium/permalloy bilayer via a coplanar waveguide ferromagnetic resonance (CPW-FMR) broadband technique. We show that the inverse spin Hall signal is both inhomogeneous and asymmetric with respect to both the position along the CPW and the excitation port. These frequency dependent asymmetries in the measured voltage are most likely due to an impedance mismatch at the contact points and the asymmetry between the two ends of the CPW. Based on this observation we show how the inverse spin Hall effect can be used as a sensitive probe for mapping the microwave magnetic field distribution in the FMR frequency range. This work emphasizes the importance of characterizing the microwave field homogeneity in every experiment with extended samples.

10:24AM Y14.00009 Probing the Influence of Thermal Spin Torque on Magnetic Tunnel Junction Switching , TIMOTHY PHUNG, AAKASH PUSHP, CHARLES RETTNER, BRIAN HUGHES, SEE-HUN YANG, STUART PARKIN, IBM Almaden Research Center — It has been established in the past few years that heat flow within a ferromagnet can induce a spin current and an associated voltage. This so called Spin Seebeck effect, initially reported in ferromagnetic metals, has also been observed in magnetic semiconductors, magnetic insulators as well as in strongly spin orbit coupled systems. An open question has been whether heat induced spin currents can be used in switching a magnetic tunnel junction (MTJ) via thermal spin torque (TST). In order to answer this question, we investigate the MTJ switching with TST induced by sharp temperature gradients on the order of 1-10 K/nm. We will describe our experimental setup and present data that show the various roles that temperature plays on the saturation magnetization of the material and on the induced spin currents that influence MTJ switching.

10:36AM Y14.00010 Temperature gradient assisted spin transport in nonlocal lateral spin valves , SAIDUR RAHMAN BAKAUL, SHAOJIE HU, TAKASHI KIMURA, Kyushu University — The advent of non-local spin transport devices (NSTD) provide further possibility for nano spin-electronic devices as these are capable of generating electronic charge-free and non-dissipative pure spin current. The most imperative and primary issue associated with these generic spintronic devices is finding the ways to enhance the amplitude of pure spin current and the simplest way to do that is increasing the excitation charge current density. The bottleneck for this method is the Joule heating, which reduces the pure spin current. However, recent discoveries of spintronic versions of the thermoelectric effects, such as spin-dependent Seebeck and Peltier effects convincingly imply that, in a properly designed device, the thermal gradient may provide aiding impact for pure spin current. In this work we have experimentally studied the multi terminal NSTDs and observed room temperature enhancement of the spin signal at high bias current. The magnitude of the spin signal is asymmetric with respect to the DC bias polarity. We discuss about the role of different thermoelectric effects on the observed spin signal enhancement. These results are important as it may open the road to tackle the Joule heating induced degradation of spin signal in NSTDs.

Friday, March 22, 2013 8:00AM - 11:00AM –

Session Y15 GMAG DMP: Focus Session: Kagome Materials and Experiments 317 - Young Lee, Massachusetts Institute of Technology

8:00AM Y15.00001 Detection of low energy spin loop excitations in rare earth kagomé systems , MICHAEL HOCH, SANHITA GHOSH, SAITI DATTA, HAIDONG ZHOU, National High Magnetic Field Laboratory, FSU, CHRISTOPHER WIEBE, University of Winnipeg, Canada, STEPHEN HILL, Florida State University, NHMFL — Collective spin excitation spectra in frustrated antiferromagnets have been detected using high field electron magnetic resonance (EMR). At low temperatures the langasite kagomé systems $R_3Ga_5SiO_{14}$(R = Pr and Nd) exhibit short range spin correlation effects. Neutron scattering has shown that these systems do not exhibit long-range magnetic order at temperatures down to 30 mK. Field-sweep EMR measurements made on single crystals of $Pr_3Ga_5SiO_{14}$ and $Nd_3Ga_5SiO_{14}$ in the temperature range 1.3 - 20 K, and in fields up to 22 T, give a series of absorption peaks which are quite different to conventional EMR spectra. The resonances are interpreted using a model which involves spin-wave excitations in short range antiferromagnetically correlated spin loops or clusters.

8:12AM Y15.00002 Oxygen Defect Structure in the Geometrically Frustrated Kagomé System $YBaCo_4O_{7+\delta}$: Impact on Structure and Magnetic Properties[1] , S. AVCI, Bursa Technical University and Argonne National Laboratory, O. CHMAISSEM, Northern Illinois University and Argonne National Laboratory, H. ZHENG, Argonne National Laboratory, A. HUQ, Oak Ridge National Laboratory, P. MANUEL, ISIS, Rutherford Laboratory, UK, J. F. MITCHELL, Argonne National Laboratory — The RBaCo4O7 family "R-114"(where R = rare earth, Y or Ca) have been a model system due to their high oxygen affinity, significant electrochemical properties and geometric frustration, in which face-sharing tetrahedra of Co ions link to form trigonal bipyramids on a Kagomé lattice. Here we report quantitative thermogravimetric analysis (TGA), *in-situ* x-ray diffraction (XRD), high resolution synchrotron x-ray and neutron diffraction data characterizing the oxygen uptake/release phenomenon and its impacts on structure and magnetic properties of $YBaCo_4O_{7+\delta}$. We show that $YBaCo_4O_{7+\delta}$ reaches an equilibrium state with $\delta \sim$0.1 when heated slightly above 350 ^{o}C. When heated slightly below 350 ^{o}C, it absorbs significantly more oxygen ($\delta = 1 \sim$1.1) and shows the orthorhombic *Pbc*2_1 symmetry previously reported [O. Chmaissem et al. J. Solid State Chem. 181, 664 (2008)]. We also detected the existence of a miscibility gap that separates the $\delta = 0$ and $\delta =$0.1 phases. In samples $\delta \geq 0.1$, excess oxygen suppresses the structural transition however, there are strong short range magnetic correlations below 100 K despite the preserved Kagomé structure.

[1]Work was supported by the US DOE, BES under Contract No. DE-AC02-06CH11357

8:24AM Y15.00003 Neutron Scattering Studies of a Flat Mode in an S=$\frac{1}{2}$ Kagome Ferromagnet[1] , ROBIN CHISNELL, DANNA FREEDMAN, MIT, JOEL HELTON, DEEPAK SINGH, NIST Center for Neutron Research, CHRIS STOCK, FRANZ DEMMEL, ROBERT BEWLEY, ISIS Facility - Rutherford Appleton Laboratory, DANIEL NOCERA, YOUNG LEE, MIT — Systems with flat bands provide macroscopic degeneracy that allows for the emergence of interesting strongly correlated phenomena such as the fractional quantum Hall effect. Hopping models on geometrically frustrated lattices with spin-orbit interactions predict the existence of flat, topologically nontrivial bands. Experimental realizations of these systems have proved challenging, as the flat band is often distorted by additional interactions. Cu(1,3-bdc) is a hybrid organometallic compound featuring S=$\frac{1}{2}$ Cu^{2+} ions on a kagome lattice. The magnetic moments order ferromagnetically below T=1.8K. We present neutron scattering measurements of Cu(1,3-bdc) and note the emergence of a flat magnon band in the ordered phase. The presence of a small Dzaloshinsky-Moriya interaction along with an applied magnetic field perpendicular to the kagome plane creates a gap between the flat band and lower energy dispersive band.

8:36AM Y15.00004 Kapellasite: a kagome quantum spin liquid with competing interactions , EDWIN KERMARREC, Laboratoire de Physique des Solides, Universite Paris Sud — In recent years, the search for an experimental quantum spin liquid in two dimensions has attracted much interest in the community. Magnetic frustration and quantum fluctuations are believed to be key ingredients to stabilize such a spin liquid ground state in 2D. The $S = \frac{1}{2}$ kagome lattice combines these two ingredients. Among the materials available with this geometry, herbertsmithite has proven to be a very promising candidate. There, the antiferromagnetic nearest neighbor coupling J_1 is dominant. In this talk, I will explore the effect of frustration generated by competing interactions on the quantum kagome lattice, based on experiments performed on kapellasite $Cu_3Zn(OH)_6Cl_2$, a polymorph to herbertsmithite. The system Hamiltonian, determined from a fit of a high-temperature series expansion to magnetic susceptibility and specific heat data, points to competing interactions with a ferromagnetic nearest neighbor exchange J_1 and an "across-hexagon" antiferromagnetic one J_d, with a ratio $|J_d/J_1| \simeq 0.85$. Local probes (μSR, ^{35}Cl-NMR) and inelastic neutron scattering (INS) experiments evidence a gapless spin-liquid state down to 20 mK, showing unusual dynamic short-range correlations characteristic of a 12 spin sublattices antiferromagnetic state called Cuboc2. We further investigate the spin dynamics at different timescales by NMR, μSR and INS measurements and discuss our results within the context of theoretical calculations using the Schwinger-Boson mean field approach.

9:12AM Y15.00005 Signature of a Spin Liquid State in the Low-Frequency Optical Conductivity of the S = 1/2 Kagome Antiferromagnet Herbertsmithite , DANIEL PILON, TIANHENG HAN, JOSHUA LUI, MIT, DAVID SHREKENHAMER, Boston College, ALEX FRENZEL, MIT, Harvard University, WILLIAM PADILLA, Boston College, YOUNG LEE, NUH GEDIK, MIT — Herbertsmithite ($ZnCu_3(OH)_6Cl_2$) is an antiferromagnetic Mott insulator composed of a planar kagome arrangement of S = 1/2 copper atoms separated by nonmagnetic zinc atoms. It has recently emerged as one of the best candidates for exhibiting a quantum spin liquid state, showing no magnetic order down to 50 mK despite an exchange energy of 200 K. Here we report a signature of a spin liquid state in the terahertz optical conductivity of Herbertsmithite, measured via Terahertz Time-Domain Spectroscopy. A power-law dependence on frequency with exponent $\sim$ 1.4 is observed in the in-plane conductivity at low frequency, which increases in magnitude as temperature is decreased. This contribution to the conductivity is notably absent in the out-of-plane direction. Theory has predicted that the existence of a Dirac spin liquid with a gauge field serving to couple the spin and charge degrees of freedom would give rise to a power-law conductivity with exponent $\sim$ 2 inside the Mott gap. We discuss this prediction as well as other possible sources of the observed behavior.

9:24AM Y15.00006 Thermodynamic analysis of a kagome spin liquid candidate , TIANHENG HAN, University of Chicago, CRAIG BONNOIT, ROBIN CHISNELL, MIT, JOEL HELTON, NCNR NIST, YASU TAKANO, University of Florida, YOUNG LEE, MIT — Herbertsmithite $ZnCu_3(OH)_6Cl_2$–one of the most promising quantum spin liquid candidates–presents a promising system for studies of frustrated magnetism on an S=1/2 kagomé lattice. Following our recent success in crystal growth, specific heat has been measured at dilution fridge temperatures up to 18 T on a single crystal sample which gives further information on the low temperature phase. Additional analysis of the thermodynamic measurements on single crystal samples lends further hints on the intrinsic spin liquid physics.

9:36AM Y15.00007 High field magnetic studies of S=1/2 Kagome lattice single crystalline Herbertsmithite , T. ASABA, GANG LI, BEN J. LAWSON, F. YU, Z. XIANG, P. CAI, C. TINSMAN, University of Michigan, TIANHENG HAN, YOUNG LEE, MIT, LU LI, University of Michigan — Herbertsmithite $ZnCu_3(OH)_6Cl_2$ is a promising system to study frustrated magnetism on S=1/2 kagome lattice. A continuum of spinon excitations has been revealed by recent neutron scattering measurements on single crystals. Interesting questions arise on the fate of this spinon excitation under intense external magnetic field. We report field-driven transitions in the high field magnetization of single crystalline $ZnCu_3(OH)_6Cl_2$. These transitions appear below 1 K, and the transition field values are almost independent of the magnetic field orientation. We further discuss methods to separate the magnetic contribution from the impurity to repeal the intrinsic response of the kagome lattice.

9:48AM Y15.00008 Fermion mediated state selection in the Kagome lattice and antiferromagnetism in FeCrAs[1] , PATRICK J. O'BRIEN, Binghamton University, SHIVAM GHOSH, Cornell University, MICHAEL J. LAWLER, Binghamton University, Cornell University, CHRISTOPHER L. HENLEY, Cornell University — We study classical spins on a kagome lattice with weak Hund's coupling J_H to hopping electrons. For each filling, the effective RKKY interactions at all distances are extracted both by fits of the total electronic energy to a database of random spin configurations, as well as second order perturbation theory in J_H. We apply this to model the Cr antiferromagnetic order found below 125K in FeCrAs [2], in which one Cr d band split by the crystal field plays the role of the itinerant fermions; the observed $\sqrt{3} \times \sqrt{3}$ type order is indeed, close to half filling, the optimum state according to our model (out of the commonly considered alternatives) . In contrast, the limit of strong J_H favors the cuboc1[1] state over the $\sqrt{3} \times \sqrt{3}$ state[3], giving a bound on the possible value of the J_H in FeCrAs. Additionally, for weak J_H, cuboc1[1] is selected instead of $\sqrt{3} \times \sqrt{3}$ close to 5/12 filling. The complete phase diagram as a function of filling can be found using Monte Carlo (MC) minimization with the RKKY Hamiltonian. [1] Messio et al PRB 83, 184401 (2011) [2] W. 10:00AM Y15.00009 Double Exchange, Berry fluxes, and fermion mediated state selection in frustrated lattices[1] , SHIVAM GHOSH, CHRISTOPHER L. HENLEY, Cornell University — We consider a Kagome or Pyrochlore magnet with local moments (treated as classical) as well as noninteracting electrons with hopping t at metallic filling, in the "Double Exchange" (DE) limit of infinitely strong Hund's rule coupling J_H. Whereas a DE-dominated model always has a ferromagnetic ground state, we make the problem nontrivial by including a dominant separate antiferromagnetic exchange $J >> t$, so the DE is a perturbation selecting within the highly degenerate ground states of J [1]. We derive this in two stages (i) spin directions define a set of Berry fluxes for each loop in the lattice (ii) we fit an effective Hamiltonian in terms of these fluxes. The same method can be applied to the energy landscape of competing spin-liquid-like states within large-N mean field theories. Depending on filling, the stable state on the Kagome is coplanar or the non-coplanar "cuboc1" [2] phase.

10:12AM Y15.00010 Neutron scattering study of the dimerized spin 1/2 AFM kagome lattice in $Rb_2Cu_3SnF_{12}$, YANG ZHAO, University of Maryland, College Park / NIST NCNR, K. MATAN, Mahidol University, Thailand, Y. NAMBU, T. J. SATO, Tohoku University, Japan, Y. FUKUMOTO, Tokyo University of Science, Japan, T. ONO, Osaka Prefecture University, Japan, H. TANAKA, Tokyo Institute of Technology, Japan, C. BROHOLM, Johns Hopkins University / NIST NCNR, A. PODLESNYAK, G. EHLERS, SNS — The deformed AFM kagome lattice $Rb_2Cu_3SnF_{12}$ is the first realization of 'pinwheel' valence bond solid (VBS) ground state system [1]. Using inelastic neutron scattering technique, we mapped out the spin excitation spectrum up to 12 meV. The singlet to triplet transition is split by a substantial Dzyaloshinskii-Moriya (DM) interaction, with the energy gap at 2.4 meV ($S_z = \pm 1$) and 6.9 meV ($S_z = 0$), respectively. While both excitations are non-dispersive to within 1.0 meV for wave vectors, q_z, perpendicular to the kagome like plane, the intensity varies differently with q_z for the two modes. This difference can be explained by the different polarization factor for $S_z = \pm 1$ and $S_z = 0$ excitations. Under a magnetic field along the c-axis, the low energy gap persist near 1 meV for the fields between 9 T and 15 T. Our findings emphasize the important role of DM interaction in this material.

10:24AM Y15.00011 Electronic structure of the kagome lattice $Cu_4(OH)_6FBr$, KATERYNA FOYEVTSOVA, FRANCESC SALVAT-PUJOL, HARALD O. JESCHKE, ROSER VALENTI, Institut für Theoretische Physik, Goethe-Universität Frankfurt, Max-von-Laue-Strasse 1, 60438 Frankfurt/Main, Germany, JOHN SCHLUETER, Materials Science Division, Argonne National Laboratory, Argonne, Illinois 60439, USA — We investigate the electronic and magnetic properties of $Cu_4(OH)_6FBr$ in the framework of ab initio density functional theory calculations and model considerations. This system, similarly to the well known Herbertsmithite $ZnCu_3(OH)_6Cl_2$, consists of stacked layers of Cu^{2+} ions arranged in a Kagome pattern. We will discuss in terms of microscopic models the resemblances and differences between these two systems.

10:36AM Y15.00012 Spin configurations in the frustrated spin system $YBaCo_4O_7$ by ^{59}Co NMR[1] , SHAOJIE YUAN, MICHAEL HOCH, PHILIP KUHNS, TIGLET BESARA, JEFF WHALEN, National High Magnetic Field Laboratory, FSU, THEO SIEGRIST, Florida State University, NHMFL, ARNEIL REYES, National High Magnetic Field Laboratory, FSU, JIM BROOKS, Florida State University, NHMFL, H. ZHENG, JOHN MITCHELL, Argonne National Laboratory, Argonne — The frustrated spin system $YBaCo_4O_7$ has both kagomé and triangular planes of cobalt ions alternating with each other. The cobalt spins in the triangular layers order antiferromagnetically below the Néel temperature at 106 K. The configurations of the cobalt spins have been studied by both neutron scattering[2] and zero applied field ^{59}Co NMR. While the triangular spin orientations are in agreement for the two approaches, this is not the case for the kagomé layers. The present in-field sample rotation NMR experiments confirm our previous finding that the triangular spins are aligned perpendicular to the [110] crystallographic direction and provide strong evidence that the spins in the kagomé layers are orthogonal those in the triangular layers in what may be described as an internal-field-induced spin-flop configuration.

10:48AM Y15.00013 NIR Optical Studies of the Warped-Kagome Frustrated Magnet Neodymium Langasite[1]

, CHRISTOPHER FERRI, Physics Department, University of California, Merced, CHRIS WEIBE, Department of Chemistry, The University of Winnipeg, SAYANTANI GHOSH, Physics Department, University of California, Merced — We investigate the anti-ferromagnetic-to-spin liquid phase transition of Neodymium (Nd) Langasite, a warped Kagome lattice, using static fluorescence spectroscopy as a function of temperature. Nd3+ is excited at 808 nm and the fluorescence of the ground state to first excited transition is measured, the spectrum of which is a multiplet centered on 890 nm. We measure this spectrum at temperatures ranging between room temperature (295K) and 5K. The individual transitions comprising the spectrum are then fit by Lorentzians to determine the center wavelength (λ_c) of each transition. Plots of λ_c versus temperature show zeros in the first derivative near 52 K, the Neel temperature, and second derivative near 33K, the anti-ferromagentic-to-spin liquid transition temperature. We attribute this to the phase transitions affecting the Zeeman energy of these levels.

8:00AM Y16.00001 Dynamics of Thermal Effects in the Spin-Wave Theory of Quantum Antiferromagnets

, ANGEL RIVAS, MIGUEL A. MARTIN-DELGADO, Universidad Complutense de Madrid — The main propose of this work [1] is to study the dynamics of quantum antiferromagnets due to the interaction with a thermal environment. To this end we resort to the spin wave theory which has become by now an standard and reference tool in order to have a good approximate description of quantum antiferromagnetic systems in appropriate dimensions. We derive a master equation that allows us to study non-equilibrium dynamics due to the thermal bosons in the environment, and give closed analytic form for the magnon decay rates. Moreover, we show that these ones turn out to be closely related to form factors, which are experimentally accessible by means of neutron and Raman scattering. Furthermore, we compute the time-evolution of the staggered magnetization showing that, for moderate temperatures, the magnetic order is not spoilt even if the coupling is fully isotropic. As far as we know, this is a fundamental aspect of spin wave theory that has remained unexplored. We expect this presentation may be interesting for a broad audience as it is at the crossroads of strongly correlated systems and the physics of quantum open systems, that is so much rooted in quantum information theory.

8:12AM Y16.00002 Relevance of Deconfined-Criticality Action in the Light of the J-Q Spin Model[1]

, YUAN HUANG, KUN CHEN, YOUJIN DENG, Department of Physics, University of Massachusetts, Amherst; University of Science and Technology of China, ANATOLY KUKLOV, Department of Engineering Science and Physics, The College of Staten Island, City University of New York, NIKOLAY PROKOFEV, BORIS SVISTUNOV, Department of Physics, University of Massachusetts, Amherst; Russian Research Center "Kurchatov Institute" — We perform large scale Monte Carlo simulations to study critical flows of 2D spin-1/2 J-Q model and 3D SU(2) symmetric discrete NCCP^1 model, a.k.a. deconfined-critical-point (DCP) action. The flows of the J-Q model and the DCP action collapse in a significantly large region of system sizes (up to L$\sim 60-80$), implying that the DCP theory (in general) and the discrete NCCP^1 model (in particular) correctly capture mesoscopic physics of the competition between the antiferromagnetic and valence-bond orders in quantum spin systems. At larger sizes we observe significant deviations between the two flows which both demonstrate strong violations of scale invariance. Furthermore, while the Neel state is perfectly space-time symmetric, the competing phase shows significant deviations from this symmetry. Possible scenarios are outlined.

[1]NSF PHY-1005543

8:24AM Y16.00003 Condensation transitions in critical spin chains

, VILLE LAHTINEN, University of Amsterdam, TERESIA MÅNSSON, Royal Institute of Technology (KTH), Stockholm, JUHA SUORSA, Nordita, Royal Institute of Technology (KTH), Stockholm, EDDY ARDONNE, Stockholm University — We show that two well known one-dimensional spin chains, namely the XY spin chain and the transverse field Ising model with only next-nearest neighbor interactions, can be related at their critical points via an exact mapping. For periodic boundary conditions, the two chains only differ by a boundary term, which accounts for the differences in the critical behavior. We argue that the boundary term induces a "condensation transition," which is closely related to condensation transitions between gapped two-dimensional topological phases.

8:36AM Y16.00004 Oxygen vacancy driven structural and orbital reconstruction on $SrTiO_3$ surface and subsurface

, CHANDRIMA MITRA, CHUNGWEI LIN, ALEXANDER A. DEMKOV, University of Texas at Austin — The role played by oxygen vacancies in bringing about important structural and electronic changes on oxide surfaces and interfaces have been a subject of intense scientific study. From two-dimensional electronic conductivity to the formation of magnetic states, oxygen vacancies have been suggested to be responsible for introducing a variety of interesting physical effects in bulk oxides and their surfaces. In this work, we employ Density Functional theory to perform first principles calculations of oxygen vacancy defects on $SrTiO_3$ surface and subsurface. In a defect free $SrTiO_3$ surface, the surface Ti atoms have conduction bands whose lower end comprises of split t_{2g} states (lower lying degenerate d_{xz} and d_{yz} states and the upper lying d_{xy} state). The upper conduction bands consist of split e_g states where the d_z^2 orbital is shifted lower in energy with respect to the $d_{x^2-y^2}$ orbital. In the presence of an oxygen vacancy, orbitals reorder and the Ti d_z^2 orbitals, (which also hybridizes itself with Ti *4s* state and the neighboring oxygen p states) gets pushed down and occupied leading to the formation of a defect state. Formation energies of oxygen vacancies on the surface and subsurface of $SrTiO_3$ will be presented and the possibility of vacancy induced magnetic states on $SrTiO_3$ surface will be discussed.

8:48AM Y16.00005 A classification scheme of oxide sulfides to guide the design of new hole-conducting transparent materials[1]

, GIANCARLO TRIMARCHI, KANBER LAM, ARTHUR FREEMAN, KENNETH POEPPELMEIER, Northwestern U., Evanston, IL, ALEX ZUNGER, U. of Colorado, Boulder, CO — The addition of S to transition metal oxides has been contemplated as a way to overcome the limitations of pure oxides by producing a hybridized O-S band with lighter hole mass and narrower gap. Here, we show that O-S mixing could lead either to a continuous band broadening and an upward shift of the valence bands ("band amalgamation" scenario) or to the formation of S-localized states deep in the band gap of the host oxide above the O band ("band pinning" scenario). We survey the La-based oxide sulfides by first-principles methods and we observe the following types of VBM wavefunction in relation to the coordination of the O and S atoms: (i) O and S segregate into separate molecular units; the VBM is preferentially localized on the S units (e.g., LaOCuS). (ii) O and S segregate into separate molecular units; the VBM is delocalized on both O and S units (e.g., $(LaO)_2SnS_3$). (iii) O and S are spatially mixed in the lattice; the VBM is preferentially localized on S (e.g., $LaGaOS_2$). (iv) O and S are spatially mixed in the lattice; the VBM is delocalized on both S and O (e.g., $LaCrOS_2$). Thus, selecting the type of anion coordination is a posible route to tune the hole conductivity in oxide sulfides.

9:00AM Y16.00006 Second Order Effective Theory of Bloch Electrons in Electromagnetic Fields , YANG GAO, SHENGYUAN YANG, QIAN NIU, UT Austin — In the first order effective theory of Bloch electrons in electromagnetic fields, the Berry curvature is introduced to yield an anomalous velocity term, which results in profound modification of the phase space density of states. Here we derive the second order single band effective theory, finding that the semiclassical dynamics of physical variables still follows the same structure as before, but with additional field corrections in the Berry curvature and band energy. We also discuss applications of our theory and its extension to multiple band case.

9:12AM Y16.00007 Efficient simulation of infinite tree tensor network states on the Bethe lattice[1] , WEI LI, JAN VON DELFT, Physics Department, Arnold Sommerfeld Center for Theoretical Physics, and Center for NanoScience, Ludwig-Maximilians-Universität, 80333 Munich, Germ, TAO XIANG, Institute of Physics, Chinese Academy of Sciences, P.O. Box 603, Beijing 100190, China — We show that the simple update approach proposed by Jiang et al [H.C. Jiang, Z.Y. Weng, and T. Xiang, Phys. Rev. Lett. **101**, 090603 (2008)] is an efficient and accurate method for determining the infinite tree tensor network states on the Bethe lattice. Ground state properties of the quantum transverse Ising model and the Heisenberg XXZ model on the Bethe lattice are studied. The transverse Ising model is found to undergo a second-order quantum phase transition with a diverging magnetic susceptibility but a finite correlation length which is upper-bounded by $1/\ln(q-1)$ even at the transition point (q is the coordinate number of the Bethe lattice). An intuitive explanation on this peculiar "critical" phenomenon is given. The XXZ model on the Bethe lattice undergoes a first-order quantum phase transition at the isotropic point. Furthermore, the simple update scheme is found to be related with the Bethe approximation. Finally, by applying the simple update to various tree tensor clusters, we can obtain rather nice and scalable approximations for two-dimensional lattices.

9:24AM Y16.00008 A Monte Carlo Approach to Modeling Thermal Decay in Perpendicular Recording Media[1] , TIM FAL, JASON MERCER, MARTIN LEBLANC, JOHN WHITEHEAD, MARTIN PLUMER, Memorial University of Newfoundland, JOHANNES VAN EK, Western Digital Corporation — A procedure is developed to study the evolution of high anisotropy magnetic recording media due to thermally activated grain reversal [1]. Single-domain grains evolve by passing through a sequence of relatively long-lived metastable states punctuated by abrupt reversals. Solutions to the rate equations are obtained using a stochastic integration procedure that calculates the time between successive reversals. Transition rates are formulated from the Arrhenius-Neel expression in terms of the material parameters, the temperature and the applied field. The method is applied to study the rate dependence of finite temperature MH loops and the thermal degradation of a recorded bit pattern in perpendicular recording media. A significant advantage of the method is its ability to extend simulations over time intervals many orders of magnitude greater than is feasible using standard micromagnetics with relatively modest computational effort.

9:36AM Y16.00009 Numerical simulation of 2D ferromagnetic films with perpendicular magnetic anisotropy using a hexagonal lattice and a long range RKKY interaction potential , ZACHARY HOWARD, MICHAEL S. PIERCE, Rochester Institute of Technology — A numerical φ^4 model combined with a RKKY potential was used to simulate 2-D ferromagnetic domains. A small random field component was added to allow for a controlled amount of disorder to be introduced into the system. A hexagonal lattice allows for more realistic domains patterns than a square lattice due to the higher density of lattice sites compared to the conventional square lattice. We find that appropriate regions of parameter space produce realistic domain patterns, major hysteresis loops, and reversal curves. For parameters that produce regions of rapid nucleation and growth we observe reversal curves that can extend outside the major hysteresis loops, due to highly frustrated domain configurations as recently observed by Ref. [1]. We also observe a significant region of exponential dependence of the domain spacing upon the interaction potential. Future work will include increasing the random field contribution to determine if the dependence of the domains and hysteresis loops upon disorder matches experimental systems [2].

9:48AM Y16.00010 Inhomogeneous phases of repulsive fermions in cubic lattices , JIE XU, SIMONE CHIESA, SHIWEI ZHANG, College of William and Mary — We present a fully self-consistent mean-field study of the inhomogeneous phases in the three-dimensional Hubbard model as the density deviates from half-filling. As the interaction U increases at fixed density, there is a transition from a uniform Fermi liquid to an inhomogeneous metallic phase characterized by a spin density wave along the [001] direction. Upon further increase of U the system undergoes a discontinuous transition to an insulating phase with a spin density wave along the [111] direction. We determine the evolution of the modulation wavelength of the spin density wave as a function of U and density, and discuss signature in the momentum distribution that are relevant to optical lattice experiments. Crossover from two- to three-dimensions is also studied.

10:00AM Y16.00011 Theoretical Scanning Probe Images of the (001) Surfaces of MnO and NiO , MIHAIL GRANOVSKIJ, ANDREAS SCHRÖN, FRIEDHELM BECHSTEDT, Institut für Festkörpertheorie und -optik, Friedrich-Schiller-Universität Jena, Max-Wien-Platz 1, 07743 Jena, Germany — In the paramagnetic state the ground-state crystal structure of the $3d$ transition metal oxides (TMOs) MnO and NiO is given by an ideal rock-salt (rs) structure. Below their respective Néel temperature, however, it is characterized by the formation of an antiferromagentic ordering AFM2 which is acompanied by a rhombohedral distortion along the [111] direction. The intersection of the thermally swichable magnetic ordering AFM2 with the crystal surfaces makes TMO surfaces ideal benchmark materials for the investigation of recent magnetic scanning probe techinques such as spin-polarized scanning tunneling microscopy (SP-STM) and magnetic exchange force microscopy (MExFM). We present a density functional theory (DFT) study of the (001) surfaces of MnO and NiO inculding an on-site interaction U. Different theoretical approaches for the description of magnetic scanning probe techniques are employed. the magnetic tip is modelled by a single Fe or 5-Fe-atom pyramid. For NiO, the calculated scanning probe images explain the spin contrast and the corrugation found experimentally. For MnO, the calculated images represent interesting predictions which differ from that of NiO.

10:12AM Y16.00012 Calculated magnetic structure of mobile defects in Fe[1] , DON NICHOLSON, KH. ODBADRAKH, GERMAN SAMOLYUK, G. MALCOLM STOCKS, Oak Ridge National Lab — Mobile defects such as dislocations and crowdions respond to gradients of strain, temperature, concentration, and applied field, thereby, determining a material's viability in particular applications. In Fe, defects affect the magnetic state of the surrounding atoms. We discuss the defect-induced changes in magnetic moment magnitude and orientation, magnetic anisotropy and magnetic interactions. These quantities are calculated (density functional theory (DFT)) for defect models ranging in size from a few hundred to a few thousand. Comparisons are made between different DFT methods. The importance of magnetism to the response of defects to gradients is discussed.

[1]This work was supported by the Center for Defect Physics, an Energy Frontier Research Center funded by the US Department of Energy, Office of Science, Office of Basic Energy Sciences.

10:24AM Y16.00013 Iron impurities in gold and silver: Comparison of magnetoresistance data to numerical renormalization group calculations exploiting non-Abelian symmetries , MARKUS HANL, ANDREAS WEICHSELBAUM, Arnold Sommerfeld Center, LMU Munich, THEO COSTI, Institut für Festkörperforschung, Forschungszentrum Jülich, CHRISTOPHER BÄUERLE, Institut Neel-CNRS and Universite Joseph Fourier, JAN VON DELFT, Arnold Sommerfeld Center, LMU Munich — We consider iron impurities in the noble metals gold and silver and compare experimental data for the resistivity and decoherence rate to numerical renormalization group results for a fully screened n-channel, spin $S = n/2$ Kondo model. Our code exploits non-abelian symmetries, which increases the efficiency by orders of magnitude compared to plain abelian NRG. To be specific, the symmetries used were U(1) for charge conservation, U(1) for spin conservation in the presence of magnetic field and the SU(3) channel symmetry. Compared to previous work [1] on this subject, we show superior numerical data for both quantities at finite temperature and extend our analysis to the resistivity at finite magnetic field. We show that our results are converged and that all examined quantities can be described consistently with a single value of T_K. The excellent agreement between experiment and theory for $n = 3$ shows that both systems are described by a spin-3/2 three-channel Kondo model. [1] T. Costi et al. Phys. Rev. Lett. **102**, 056802 (2009).

10:36AM Y16.00014 Magnetic vortices induced by a moving tip[1] , MARTIN P. MAGIERA, ALFRED HUCHT, DIETRICH E. WOLF, Faculty of Physics, University of Duisburg-Essen, 47048 Duisburg, Germany — A two-dimensional easy-plane ferromagnetic substrate interacting with a dipolar tip which is magnetized perpendicular with respect to the easy plane is studied numerically by solving the Landau-Lifshitz Gilbert equation [Europhys. Lett. **100**, 27004 (2012)]. Due to the symmetry of the dipolar field of the tip, in addition to the collinear structure a magnetic vortex structure becomes stable. It is robust against excitations caused by the motion of the tip. The moved vortex structure shows an increased energy dissipation compared to the collinear structure. We show that for high excitations the system may perform a transition between the two states. The influence of domain walls, which may also induce this transition, is examined.

Session Y17 DMP GMAG: Focus Session: Magnetic Metal Insulator Transitions 319 - Eduardo Granado, Universidade Estadual de Campinas (Brazil)

8:00AM Y17.00001 Magnetically driven metal-insulator transition in NaOsO3[1] , STUART CALDER, Oak Ridge National Laboratory — The metal-insulator transition (MIT) is one of the most dramatic manifestations of electron correlations in materials, enjoying interest both for its fundamental nature and technological application. Various mechanisms producing MITs have been extensively considered over the years, including the Mott (electron localization via Coulomb repulsion), Anderson (localization via disorder) and Peierls (localization via distortion of a periodic one-dimensional lattice). One additional route to a MIT proposed by Slater in 1951, in which long-range magnetic order in a three dimensional system drives the MIT, has received relatively little attention, particularly from an experimental viewpoint. Using neutron and x-ray scattering we have shown that the MIT in $NaOsO_3$ is coincident with the onset of long-range commensurate magnetic order at 410 K. Whilst candidate materials have been suggested, our experimental methodology allows the first definitive demonstration of the long predicted Slater MIT. We discuss our results in light of recent work on other 5d systems that contrastingly have been predicted to host a Mott spin-orbit insulating state.

8:36AM Y17.00002 Metal-insulator transition in pyrochlore Eu2Ir2O7 studied by infrared spectroscopy[1] , ANDREI SUSHKOV, DENNIS DREW, CNAM and MRSEC, Department of Physics, University of Maryland, USA, JUN ISHIKAWA, SATORU NAKATSUJI, Institute for Solid State Physics, University of Tokyo, Japan, XUAN LUO, POSTECH, Korea, SANG-WOOK CHEONG, RCEM, Rutgers University, USA — The large family of pyrochlores with formula $A_2B_2C_7$ attracted a lot of early attention due to strong geometric magnetic frustration. Recent band structure calculations predict that the iridate pyrochlores $A_2Ir_2O_7$ may have nontrivial topological states. We will report the results of an infrared spectroscopic study of the metal-insulator transition in $Eu_2Ir_2O_7$ single crystal and $Y_2Ir_2O_7$ polycrystal. We will report the broad band IR reflection as a function of temperature for an overview of the M-I transition and the low frequency transmission which is more sensitive for detection of a 10 meV gap[1] and other possible excitations. We will discuss possible implications of the semimetal Weyl states. [1] J.J. Ishikawa et al., Phys. Rev. B 85, 245109 (2012).

[1]Work supported in part by NSF-MRSEC grant DMR-0520471

8:48AM Y17.00003 Tuning $J_{eff} = 1/2$ Insulating State via Electron Doping and Pressure in Double-Layered Iridates[1] , L. LI, Center for Advanced Materials, University of Kentucky, P.P. KONG, C.Q. JIN, Institute of Physics, Chinese Academy of Sciences, T.F. QI, O.B. KORNETA, Center for Advanced Materials, University of Kentucky, S.J. YUAN, Department of Physics, Shanghai University, G. CAO, Center for Advanced Materials, University of Kentucky — $Sr_3Ir_2O_7$ exhibits a novel J_{eff}=1/2 insulating state featuring a splitting between J_{eff}=1/2 and 3/2 bands due to spin-orbit interaction. We report that a metal-insulator transition can be induced by either dilute electron (La^{3+}) doping for Sr^{2+} ions in $Sr_3Ir_2O_7$ or via application of high pressure. The following constitutes the central findings of our recent study of single-crystal $Sr_3Ir_2O_7$ and $(Sr_{1-x}La_x)_3Ir_2O_7$: (1) application of high hydrostatic pressure P results in a drastic drop in the electrical resistivity by four orders of magnitude at a critical pressure, P_C = 13.2 GPa, suggesting a significantly reduced splitting between J_{eff}=1/2 and 3/2 bands, but further increasing P up to 35 GPa produces no fully metallic state at low temperatures; (2) however, slight doping of La^{3+} ions for Sr^{2+} ions in $Sr_3Ir_2O_7$ readily induces a robust metallic state that follows no Fermi liquid behavior; and (3) the magnetic ordering temperature is significantly suppressed from 285 K for x=0 but remains finite for $(Sr_{0.94}La_{0.06})_3Ir_2O_7$ where the metallic state occurs. The results will be discussed along with comparisons drawn with Sr_2IrO_4, a prototype of the $J_{eff} = 1/2$ insulator.

9:00AM Y17.00004 Exploring the Unusual Physical Properties near the Metal-Insulator Transition of $RNiO_3$, LUKE G. MARSHALL, JINGUANG CHENG, JIANSHI ZHOU, Texas Materials Institute, University of Texas at Austin, MARÍA JESÚS MARTÍNEZ-LOPE, JOSÉ ANTONIO ALONSO, Instituto de Ciencias de Materiales de Madrid, Consejo Superior de Investigaciones Cientificas, JOHN B. GOODENOUGH, Texas Materials Institute, University of Texas at Austin — Understanding the physical properties at the crossover from localized to itinerant electronic behavior in the transition-metal perovskite-related oxides remains a challenging problem of solid-state physics. This problem can manifest in mixed-valent compounds at this crossover to produce unusual properties such as high-T_c superconductivity in the cuprates and colossal magnetoresistance in the manganites. $RNiO_3$ (R=lanthanide) perovskites are single-valent compounds where the π-band is filled and the σ-band is $\frac{1}{4}$ filled. The electron bandwidth can be tuned by substituting different rare earth cations at the A site, so that the system provides a unique opportunity to study this crossover more simply. While the phase diagram for this compound is well known, magnetic rare earth ions prevent the study of the evolution from Pauli to Curie-Weiss paramagnetism. To account for this, we have used high-pressure synthesis to create a series of $RNiO_3$ samples (R=La, Y, Lu) and studied their magnetic and transport properties. We have also shown that the localized to itinerant crossover can also be explored by substituting Ga^{3+} for Ni^{3+} in $LaNi_{1-x}Ga_xO_3$.

9:12AM Y17.00005 ABSTRACT WITHDRAWN –

9:24AM Y17.00006 Multi-orbital Mott Transition and High T_c Ferromagnetism in Strongly Correlated Oxides[1] , MOHIT RANDERIA, ONUR ERTEN, O. NGANBA MEETEI, NANDINI TRIVEDI, PATRICK WOODWARD, The Ohio State Universitry — Amongst all perovskites with a net magnetic moment, Sr_2CrOsO_6 (SCOO) [1] has the highest $T_c = 725$K. We model this as a multi-orbital Hubbard model with different Coulomb U's and Hund's coupling J_H's on the Cr and Os sites along with spin-orbit coupling (SOC) λ_{so} on Os. Using a slave-rotor approach, we find a new Mott criterion [2] $\left(\tilde{U}_{\rm Cr}\tilde{U}_{\rm Os}\right)^{1/2} > 2.5W$, where W is the bandwidth and $\tilde{U}$'s are the effective charge gaps including the effects of U, J_H and λ_{so}. Using this result, we argue that SCCO is a Mott insulator. Next, we show that the orbital moment on Os is quenched. The effective spin Hamiltonian for $S = 3/2$ moments has Cr-Os and Os-Os antiferromagnetic superexchange interactions that are frustrated. Using a variational approach and Monte Carlo simulations, we show that the system has a canted ground state with a net moment at $T = 0$, a non-monotonic magnetization $M(T)$ and a high T_c. Our results [2] are in excellent agreement with available data [1] and we predict the magnetic $S(\mathbf{q})$ that will test our theory. [1] Y. Krockenberger *et al.*, Phys Rev. 9:36AM Y17.00007 Resonant Ultrasound studies of spin- and orbital ordering transitions in RVO_3[1] , M. KOEHLER, Dept. Materials Science and Engineering, The University of Tennessee, J.-Q. YAN, Dept. Materials Science and Engineering, The University of Tennessee and Materials Science and Technology Division, Oak Ridge National Laboratory, Y. REN, X-ray Science Division, Argonne National Laboratory, B.C. SALES, Materials Science and Technology Division, Oak Ridge National Laboratory, D. MANDRUS, Dept. Materials Science and Engineering, The University of Tennessee and Materials Science and Technology Division, Oak Ridge National Laboratory, V. KEPPENS, Dept. Materials Science and Engineering, The University of Tennessee — RVO_3 perovskites (R = rare earth) have been shown to undergo multiple spin and orbital transitions due to the Jahn-Teller active V^{3+} electrons. We have initiated a study of the elastic response of RVO_3, (R = Dy, Gd, Ce) as well as $Y_{1-x}La_xVO_3$ (x = 0.05, 0.3, 1) using resonant ultrasound spectroscopy. The temperature-dependence of the elastic response is dominated by the ordering transitions, with transition temperatures that change with the size of the rare earth. For $CeVO_3$ and $LaVO_3$, two transitions are observed, separated by 17K and 2K, respectively. $DyVO_3$ and $Y_{0.95}La_{0.05}VO_3$ show three transitions below 220K while $GdVO_3$ only shows one. The full elastic tensor of $Y_0.7La_{0.3}VO_3$ has also been determined from 300K to 50K, yielding the temperature dependence of the 9 orthorhombic elastic moduli.

9:48AM Y17.00008 Strong electronic correlations and spin-orbit coupling in layered ruthenates[1] , FRANK LECHERMANN, MALTE BEHRMANN, CHRISTOPH PIEFKE, I. Institute for Theoretical Physics, University of Hamburg, Germany — The combination of the local-density approximation to density functional theory with explicit many-body approaches has proven to be a powerful tool to investigate the problem of strong electronic correlations on a realistic level. Notably in quasi-twodimensional materials the interaction between the effective dimensionality and the symmetry of the underlying crystal structure with the competition between the localized and the itinerant character of electrons is indeed giving rise to highly interesting physical phenomena, especially within the family of transition-metal oxides. Here we want to focus on the intriguing interplay between rotational-invariant local Coulomb interactions and spin-orbit coupling for the case of the layered strontium ruthenates within the $Sr_{n+1}Ru_nO_{3n+1}$ Ruddlesden-Popper series. Novel results based on a generic realistic modelling of the correlated electronic structure for the n=1,2 members of this family of compounds will be discussed [1]. In this respect, also the intriguing metamagnetic behavior of $Sr_3Ru_2O_7$ will be addressed.

10:00AM Y17.00009 Pressure study of nematicity and quantum criticality in $Sr_3Ru_2O_7$ for a in-plane field , DAN SUN, WENLONG WU, Department of Physics, University of Toronto, SANTIAGO A. GRIGERA, Scottish Universities Physics Alliance, School of Physics and Astronomy, University of St. Andrews, ROBIN S. PERRY, Center for Science at Extreme Conditions, School of Physics, University of Edinburgh, ANDY P. MACKENZIE, Scottish Universities Physics Alliance, School of Physics and Astronomy, University of St. Andrews; Canadian Institute for Advanced Research, STEPHEN R. JULIAN, Department of Physics, University of Toronto; Canadian Institute for Advanced Research — We study the relationship between the nematic phase of $Sr_3Ru_2O_7$ and quantum criticality. At ambient pressure, the nematic phase appears to be associated with a metamagnetic quantum critical end point (QCEP) when the applied magnetic field is near the c-axis. We show, however, that this metamagnetic transition does not produce the same nematic signatures when the QCEP is reached by hydrostatic pressure with the field applied in the ab-plane. Moreover, a distinct nematic phase, that is seen for field applied in the ab-plane close to, but not right at, a metamagnetic anomaly, persists with minimal change to the highest applied pressure, 16.55 kbar. Taken together our results suggest that quantum criticality may not be necessary for the formation of a nematic phase.

10:12AM Y17.00010 Far-infrared optical properties and the metal-insulator transition in Ti-doped $Ca_3(Ru_{1-x}Ti_x)_2O_7$ (x=0.03) , D. TALBAYEV, Tulane University, T. STANISLAVCHUK, A. SIRENKO, New Jersey Institute of Technology, JIN PENG, Z.Q. MAO, Tulane University — The discovery of the intriguing phase diagram of $Ca_3(Ru_{1-x}Ti_x)_2O_7$ is the new and exciting development in correlated electron ruthenates, as Ti doping drastically changes the material's ground state properties. The undoped $Ca_3Ru_2O_7$ is metallic at high temperature and undergoes an antiferromagnetic transition at 56 K that is followed by a metal-insulator transition at 48 K driven by the opening of a charge density wave gap. A quasi-2D metallic state develops below 30 K. At 5% Ti doping, the metal-insulator transition temperature is T_{MI} =80 K, below which the material is a Mott insulator. By contrast, a weakly localized electronic state is observed at intermediate dopings (2-4% Ti) together with antiferromagnetic long range order. In the undoped $Ca_3Ru_2O_7$, the metal-insulator transition at 48 K is accompanied by the development of a charge gap below 200 cm^{-1}. At low temperatures, a small Drude peak develops below 50 cm-1, resulting from small non-nested metallic pockets of the Fermi surface. We report a far-infrared spectroscopic ellipsometry study of $Ca_3(Ru_{1-x}Ti_x)_2O_7$ (x=0.03) at U4IR beamline of NSLS-BNL. Our data indicate that the low-temperature gap in optical conductivity opens at 1000 cm^{-1}, a dramatically different value from the one in the undoped compound. We relate our observations to the effects of Ti doping - the induced changes in carrier itinerancy and the modified double-exchange and superexchange interactions in the material.

10:24AM Y17.00011 Optical Polarization Microscopy of the Electron Nematic Phase in $Sr_3Ru_2O_7$, COLIN HEIKES, Cornell University, S. GHOSH, S. N. Bose National Centre for Basic Sciences, D. MACNEILL, Cornell University, R. PERRY, J.F. MERCURE, St. Andrews University, E.A. KIM, Cornell University, A. MACKENZIE, St. Andrews University, D.C. RALPH, Cornell University — We report the implementation of a fiber-based optical microscope, capable of operating at temperatures below 100 mK and in magnetic fields in excess of 9 Tesla, with sub-micron spatial resolution. This microscope is integrated into the bore of a dilution refrigerator with an optical fiber coupling light to an external optical table. Bench-top optical elements allow for polarization analysis of the reflected light from a surface and thus the detection of magnetic or other polarization-sensitive properties of matter at low temperature and high fields. As a first application of the instrument, we are studying the proposed electron nematic phase of the n=2 Ruddlesden-Popper material $Sr_3Ru_2O_7$, which exhibits a low-temperature phase transition in the form of an in-plane conduction anisotropy. We report initial results from polarization analysis and polarization microscopy with sample temperatures below 150 mK and applied magnetic fields from 0 T to 9 T.

10:36AM Y17.00012 Effect of disorder on quantum phase transition in $(Sr_{1-x}Ca_x)_3Ru_2O_7$, Z. QU, J. PENG, T.J. LIU, D. FOBES, Tulane University, V. DOBROSAVLJEVIC, Florida State University, L. SPINU, Retired, Z.Q. MAO, Tulane University — $(Sr_{1-x}Ca_x)_3Ru_2O_7$ is characterized by complex magnetic states, spanning from anantiferromagnetic state over an unusual heavy-mass nearly ferromagnetic (NFM) state to an itinerant metamagnetic state. The NFM state, which occurs in the $0.4 > x > 0.08$ range, freezes into a cluster spin glass phase at low temperatures [1]. A quantum phase transition (QPT) occurs as the spin freezing temperature T_f is suppressed to zero K near x =0.08. In this talk, we will report a novel quantum phase observed near the QPT [2]. The isothermal magnetization $M(H)$ and the temperature dependence of electronic specific heat $Ce(T)$ of this phaseexhibit anomalous power-law singularities and are controlled by a single exponent. Moreover, the magnetization $M(T,H)$ of this phase is found to follow a phenomenological scaling law of $M(H,T) \propto H^{\alpha} f(H/T^{\delta})$. These observations indicate the slow dynamics in rare regions arising from the effect of disorder on the QPT.

10:48AM Y17.00013 Field-induced magnetic phase transitions in Ti-doped Ca3Ru2O7 bilayer ruthenates , M. ZHU, Department of Physics and Astronomy, Michigan State University, J. PENG, Z.Q. MAO, Department of Physics and Engineering Physics, Tulane University, K. PROKES, S. MATAS, Helmholtz Zentrum Berlin, D-14109 Berlin, Germany, T. HONG, Quantum Condensed Matter Division, Oak Ridge National Laboratory, X. KE, Department of Physics and Astronomy, Michigan State University — Bilayer ruthenate $Ca_3Ru_2O_7$ shows strong magnetic instability that depends sensitively on chemical doping and magnetic fields. Previously we have shown that [1] Ti doping induces Mott insulating ground state with a G-type antiferromagnetic (AFM) structure where nearest-neighbor spins align antiferromagnetically, a feature dramatically distinct from the metallic ground state with an AFM-b structure where the ferromagnetically aligned spins (pointing along the b-axis) within the bilayer are coupled antiferromagnetically along the c-axis. Here we report magnetic phases of the Ti-doped $Ca_3Ru_2O_7$ in a magnetic field revealed via neutron diffraction study. In sharp contrast to pure $Ca_3Ru_2O_7$ [2], below the metal-insulator transition we find a field-induced magnetic phase transition from G-type AFM to AFM-a with spins projected along the a-axis. Concomitantly, a sharp change in lattice parameters is observed, suggesting strong magnetoelastic coupling. The effect of such a field-induced phase transition on the magnetotransport property in the Ti-doped $Ca_3Ru_2O_7$ will be discussed as well. [1] X. Ke et al., Phys. Rev. B **84**, 201102 (R) (2011). Session Y18 GMAG DMP FIAP: Focus Session: Spin-Dependent Phenomena in Semiconductors - Quantum Dots 320 - Avadh B. Saxena, Los Alamos National Laboratory

8:00AM Y18.00001 Unconventional Nodal Wavefunctions in Quantum Dots[1] , JEONGSU LEE, University at Buffalo-SUNY, KAREL VÝBORNÝ, University at Buffalo-SUNY; Institute of Physics ASCR, IGOR ŽUTIĆ, JONG HAN, University at Buffalo-SUNY — In a single band model such as one electron in a box, it is well known that the ground state wavefunction has no node maximizing its spatial symmetry. However, the ordering of eigenstates in a multiband system e.g., p-doped semiconductor quantum dots (QDs) can be very different due to spin-orbit interaction, symmetry of the underlying lattice and geometry of the confinement. Such unconventional ordering of states has appeared in the literature [1, 2] but it is often ignored or merely considered a shortcoming of $k \cdot p$ model [3]. We investigate spatial structure of hole envelope-wavefunctions in QDs with a focus on its symmetry. Our calculation shows a counter-intuitive ordering of eigenstates where a single hole "ground-state" has a node at the center. For simplicity, we start with a 2D QD tight-binding model and extend the discussion to 3D QD tight-binding and $k \cdot p$ models. We also discuss experimental implications of the wavefunction ordering described above. [1] K. Výborný et al., PRB **85**, 155312 (2012) [2] A. Bagga et al., PRB **71**, 115327 (2005); P. 8:12AM Y18.00002 Spin Wigner molecules in quantum dots[1] , IGOR ZUTIC, RAFAL OSZWALDOWSKI, University at Buffalo, PETER STANO, Slovak Academy of Sciences and University of Basel, A. G. PETUKHOV, South Dakota School of Mines and Technology — The interplay of confinement and Coulomb interactions in quantum dots can lead to strongly correlated phases differing qualitatively from the Fermi liquid behavior. While in three dimensions the correlation-induced Wigner crystal is elusive and expected only in the limit of an extremely low carrier density, its nanoscale analog, the Wigner molecule, has been observed in quantum dots at much higher densities [1]. We explore how the presence of magnetic impurities in quantum dots can provide additional opportunities to study correlation effects and the resulting ordering in carrier and impurity spins [2]. By employing exact diagonalization we reveal that seemingly simple two-carrier quantum dots lead to a rich phase diagram [2,3]. We propose experiments to verify our predictions; in particular, we discuss interband optical transitions as a function of temperature and magnetic field. [1] C. Ellenberger et al., Phys. Rev. 8:24AM Y18.00003 Spin polarized current through a quantum shuttle[1] , JORGE VILLAVICENCIO, Facultad de Ciencias - UABC, Ensenada, Mexico, IRENE MALDONADO, None, ERNESTO COTA, Centro de Nanociencias y Nanotecnologia - UNAM, Ensenada, Mexico, GLORIA PLATERO, Instituto de Ciencia de Materiales de Madrid - CSIC, Madrid, Spain — We study spin current through a vibrating triple quantum dot system in a linear arrangement, as a function of detuning across the device, in the presence of a magnetic field, taking into account non-spin-conserving tunneling processes induced by spin-orbit interaction (SOI). Using the density matrix master equation approach, we calculate the current and polarization for both the static and dynamic cases. In the former case the central dot is at rest, while in the latter it is oscillating (triple quantum dot shuttle, TQDS). In both cases, we find new resonances in the current with a definite spin polarization, for both symmetric and asymmetric Zeeman splitting. These resonances are shown to correspond to anticrossings in the energy spectrum reflecting coupling between states due to SOI. For the asymmetric TQDS we obtain a spin filter behavior in the weak coupling regime.

8:36AM Y18.00004 Nonmagnetic spin current generation as nonequilibrium Kondo effect in a spin-orbit nano interferometer[1] , NOBUHIKO TANIGUCHI, University of Tsukuba — We investigate electric generation of spin-dependent transport through a single-level quantum dot embedded in a ring by help of the Rashba spin-orbit coupling[2]. Although it is known for some time that applying finite bias to this type of the spin-orbit interferometer induces finite spin polarization on the dot[3], the mechanism of driving such spin polarization to flow has not fully been understood. For instance, in spite of finite spin polarization on a noninteracting single-level dot, no spin current is found to appear. We show theoretically that it is possible to generate electrically large spin-dependent current through an interacting single-level dot, as a combined effect of the Kondo effect and finite bias as well as the Rashba spin-orbit interaction. In contrast to earlier work[4], we argue the emergent spin-dependent transport in the present model is viewed as a new type of nonequilibrium Kondo effect; it appears in the middle of the Kondo valley and is suppressed by bias voltage larger than the Kondo energy properly renormalized by the Rashba spin-orbit coupling.

8:48AM Y18.00005 The Optimization of Magnetic Ordering in Quantum Dots[1] , JAMES PIENTKA, RAFAL OSZWALDOWSKI, IGOR ZUTIC, JONG HAN, SUNY at Buffalo, ANDRE PETUKHOV, South Dakota School of Mines and Technology — Lately, there have been several theoretical studies that demonstrate how carrier-mediated magnetic ordering is influenced by multiple occupancies in quantum dots (QD) [1,2]. Experimentally, multiple-occupancy can be reached by high photo-excitation intensity. It was observed in type-II QDs that magnetic polaron (MP) formation persists at large temperatures [3]. We show that varying QD occupancy has important consequences, including thermally enhanced magnetic ordering in QDs [4]. We extend our method to take into account the formation of magnetic bipolarons (MBP) [1,2]. We show that a standard mean-field treatment of MBP leads to unphysical phase transitions, removed when fluctuations are taken into account. Finally, we demonstrate that for a single MP, the shrinking of the carrier wave function due to the exchange with magnetic impurities is a small effect. [1] R. Oszwaldowski, I. Zutic, and A. G. 9:00AM Y18.00006 Single-electron transport in a magnetic quantum-dot molecule , JAVIER ROMERO, EDUARDO MUCCIOLO, University of Central Florida — We study single-electron transport in a magnetic quantum-dot molecule by using a stationary rate equation approach. In the molecule, two quantum dots play the roles of magnetic ions and are connected to each other through a third quantum dot which plays the role of a nonmagnetic ion. The magnetic quantum dots are coupled to ideal metallic leads and a back gate voltage is applied to the molecule, forming a field-effect transistor setup. A hopping Hamiltonian, which includes on-site repulsion and magnetic anisotropies, is employed to describe this molecule, resulting in an energy spectrum similar to that of single molecule magnets in the giant spin approximation. An external, in-plane magnetic field is then used to drive the molecule to a diabolical point, where states with maximum total spin with opposite directions are degenerated. Both linear and nonlinear transport are evaluated near the diabolical point, showing features that can be attributed to Berry-phase interference of spin tunneling paths.

9:12AM Y18.00007 Optical control and coherence of electron or hole spins in coupled quantum dots

, SAMUEL CARTER, Naval Research Laboratory — The spin of an electron or hole in an InAs quantum dot is an attractive qubit because it combines the advantages of a semiconductor platform with the power of ultrafast optical coherent control techniques. In the last few years, basic quantum operations such as initialization, rotation, and readout have become possible using single spins, but now improvements in spin coherence and demonstrations of multi-qubit systems are needed. In this work, we combine advances in the design and growth of coupled quantum dots with optical coherent control techniques to demonstrate ultrafast manipulation and coherence improvements for one or two interacting electron [1] or hole [2] spins in a coupled pair of InAs dots. For each of these spin systems, we use a sequence of picosecond and nanosecond pulses to initialize, manipulate, and measure the coherent spin dynamics. These dynamics include precession about a magnetic field and also entangling dynamics from the exchange interaction for coupled spins. For a single electron spin, precession dephases after only a few nanoseconds due to the hyperfine interaction with nuclear spins. For hole spins, we measure a dephasing time an order of magnitude longer due to a weaker hyperfine interaction. Coupled electron and hole spins are essential for multi-qubit systems, and they can also be used to decrease sensitivity to the environment. In these systems, we typically measure the coherent dynamics of the singlet-triplet states (m_s =0), which are much less sensitive to the nuclear environment. At present, dephasing is due to fluctuations in the electrical environment. With careful sample design, we can make these systems much less sensitive to electrical fluctuations, giving a powerful combination of long coherence times and ultrafast gates. Finally, we demonstrate that these spin qubits can be incorporated into a photonic crystal cavity and manipulated with optical pulses, a major step toward a quantum interface between photons and these spin qubits.

9:48AM Y18.00008 Dephasing and relaxation of central hole spins by nuclear spin baths in InGaAs quantum dots: role of nuclear quadrupolar coupling[1]

, YAN LI, N.A. SINITSYN, A. SAXENA, D.L. SMITH, Los Alamos National Lab, D. REUTER, A.D. WIECK, Ruhr-Universitat Bochum, D.R. YAKOVLEV, B. MANFRED, University of Dortmund, S.A. CROOKER, Los Alamos National Lab — Single electron or hole spins in III-V semiconductor quantum dots (QDs) are promising candidates for solid-state qubits. Their coherence properties are typically governed by the hyperfine coupling between these "central" electronic spins and the dense surrounding bath of lattice nuclear spins. Theoretically this is a challenging problem due to its many-body and strongly-correlated nature. Here we measure the spin dynamics of holes in InGaAs quantum dots by detecting their intrinsic, random spin fluctuations while in thermal equilibrium, which reveals the spin correlation time scales τ_h and the functional form of bath-induced spin relaxation. In zero magnetic field, τ_h is very long ($\sim$400 ns) and decays exponentially, in marked contrast with recent theories. τ_h increases to $\sim$5 μs in small (100 G) longitudinal fields, and the spin dynamics evolve to a very slow $\sim$1/ln(t) decay [1]. We model the influence of nuclear quadrupolar coupling on spin dynamics in these strained QDs for both electrons and holes [2], and find a good agreement with experimental data when the quadrupolar coupling exceeds the hyperfine coupling strength. [1] Yan Li, N. Sinitsyn, et al., PRL 108, 186603 (2012). [2] N. Sinitsyn, Yan Li, et al., PRL 109, 166605 (2012).

10:00AM Y18.00009 Quadrupolar spectra of nuclear spins in strained InGaAs quantum dots[1]

, CEYHUN BULUTAY, Bilkent University — Self-assembled quantum dots (QDs) are born out of lattice mismatched ingredients where strain plays an indispensable role. Through the electric quadrupolar coupling strain affects the nuclear spins. To guide upcoming single-QD nuclear magnetic resonance (NMR) as well as dynamic nuclear spin polarization experiments, a computational atomistic insight to the strain and quadrupolar field distributions will be presented. Among our findings, a high aspect ratio of the QD geometry enhances the quadrupolar interaction; inclined interfaces introduce biaxiality and the tilting of the major quadrupolar principal axis away from the growth axis; the alloy mixing of gallium into the QD enhances both of these features while reducing the quadrupolar energy. NMR spectra in Faraday and Voigt geometries are computed, unraveling in the first place the extend of inhomogeneous broadening and the appearance of the normally-forbidden transitions. Moreover, from the main extend of the NMR spectra the alloy mole fraction of a single QD can be inferred. In the presence of an external magnetic field, the borderlines between the quadrupolar and Zeeman regimes are extracted as 1.5 T for In and 1.1 T for As nuclei.

10:12AM Y18.00010 Integrability-based analysis of the hyperfine interaction induced decoherence in quantum dots

, ALEXANDRE FARIBAULT, DIRK SCHURICHT, RWTH Aachen — Using the Algebraic Bethe Ansatz in conjunction with a simple Monte Carlo sampling technique, we study the problem of the decoherence of a central spin coupled to a nuclear spin bath. We describe in detail the full crossover from strong to weak external magnetic field field, a limit where a large non-decaying coherence factor is found. This feature is explained by Bose-Einstein-condensate-like physics which also allows us to argue that the corresponding zero frequency peak would not be broadened by statistical or ensemble averaging.

10:24AM Y18.00011 Dynamics of carrier populations and localized spins during magnetic-polaron formation in quantum dots[1]

, BIPLOB BARMAN, RAFAL OSZWALDOWSKI, LARS SCHWEIDENBACK, ANDREAS RUSS, JOSEPH MURPHY, ALEXANDER CARTWRIGHT, IGOR ZUTIC, BRUCE MCCOMBE, ATHOS PETROU, SUNY Buffalo, WU-CHING CHOU, WEN CHUNG FAN, National Chiao Tung University, IAN SELLERS, University of Oklahoma, ANDRE PETUKHOV, South Dakota School of Mines & Technology — We have extended our previous investigation of time evolution of PL from (Zn,Mn)Te/ZnSe quantum dots in a magnetic field B [1]. PL studies at T =5 K in these type-II dots reveal formation of magnetic polarons (MP). We find their formation time τ_{MP} to be 0.5 ns, which varies little with B. The circular polarization P of the emission shows a surprising behavior. For all fields, the characteristic time τ_P is longer than τ_{MP}. Furthermore, τ_P decreases from 10 ns to 1.9 ns as B increases from 1 to 4 tesla. We attribute this effect to a low-B bottleneck in the σ_+ recombination channel, due to the almost equal populations of the spin $\pm 1/2$ electrons participating in the interband transitions. In contrast, the $\pm 3/2$ holes in the (Zn,Mn)Te QDs, are affected mostly by the effective field due to exchange interaction between hole and Mn spins around it. This effective field is much larger than B.

10:36AM Y18.00012 Room temperature spin decoherence and dephasing in CdSe nanocrystal quantum dots[1] , AHMAD KHASTEHDEL FUMANI, Department of Physics, Case Western Reserve University, REZA SHARGHI-MOSHTAGHIN, Department of Materials Science and Engineering, Case Western Reserve University, JESSE BEREZOVSKY, Department of Physics, Case Western Reserve University — We combine transmission electron microscopy (TEM) and Faraday-rotation-based spin measurements to reveal the connection between coherent electron spin dynamics and the shape and size distribution of an ensemble of nanocrystal quantum dots. Optically pumped spins in CdSe nanocrystal quantum dots provide a platform for studying coherent dynamics and decoherence of spins of charge carriers in a complex, room-temperature environment. In a transverse magnetic field, decay of the ensemble spin signal is often ascribed to inhomogeneous dephasing caused by the distribution of nanocrystal sizes across the ensemble. In this work, we measure the size and shape distribution of an ensemble of nanocrystals using TEM, and compare the resulting calculated spin dynamics to those measured in a time-resolved Faraday rotation experiment. We find that the size inhomogeneity alone is insufficient to explain the measured dephasing times and decay envelopes. We propose an ensemble decoherence mechanism based on the distribution of nanocrystal shapes which can account for both the magnetic field dependence of the dephasing time and the shape of the decay envelope.

10:48AM Y18.00013 A phonon laser using quantum dot spin states , ALEXANDER KHAETSKII, XUEDONG HU, IGOR ZUTIC , University at Buffalo, SUNY — Sound analog of laser (saser) has not yet been realized experimentally, though some steps in this direction have been made recently [1]. As is known, the main reason impeding coherent generation of phonons in solid state is high density of phonon states [2]. We suggest a particular realization of saser, which consists of an ensemble of quantum dots and uses the Zeeman-split spin levels of the ground orbital state in the quantum dot. We develop a complete set of saser equations taking into account the Coulomb blockade conditions for a quantum dot, and evaluate all the parameters such as the threshold, output power and efficiency of the device. Supported by NSF-ECCS and US ONR, NSF PIF,and US ARO. [1]. R.P. Beardsley et al., PRL **104,** 085501 (2010). [2]. J. Chen and J.B. Khurgin, IEEE Journal of Quantum Electronics, **39**, 600 (2003) .

Friday, March 22, 2013 8:00AM - 11:00AM –

Session Y19 DCMP: Charge Density Wave Order 321 - David Hawthorn, University of Waterloo

8:00AM Y19.00001 Specific heat studies of the chiral phase transition in charge ordered 1T-$TiSe_2$, XU LUO, Material Science Division, Argonne National Laboratory, Argonne, IL60439, J.-P. CASTELLAN, Karlsruhe Institute of Technology, D-76021, Karlsruhe, Germany, S. ROSENKRANZ, R. OSBORN, Q. LI, Material Science Division, Argonne National Laboratory, Argonne, IL60439, G. KARAPETROV, Department of Physics, Drexel University, Philadelphia, PA 19104, J.P.C. RUFF, CHESS, Cornell University, Ithaca, NY 14853, U. WELP, Material Science Division, Argonne National Laboratory, Argonne, IL60439, J. VAN WEZEL, H.H. Willis Physics Laboratory, University of Bristol, BS8 1TL, UK — We use high-resolution steady-state ac-micro-calorimetry to investigate the transition of 1T-$TiSe_2$ into the charge-ordered state. A mean-field like step of $\sim$ 0.4 J/molK in the specific heat C(T) near 193 K signals the transition into the commensurate CDW state. Upon further cooling, C(T) varies linearly in temperature until near 180 K a clear break in the slope of C(T) by 13mJ/molK^2 and possibly a small step indicate a second phase transition. Comparisons with theoretical predictions based on the Ginzburg-Landau free energy, with resistivity measurements, and with x-ray diffraction indicate that, at this transition, the commensurate CDW state changes into a helically ordered state along the crystal c-axis.

8:12AM Y19.00002 Electronic Properties of Cu_xTiSe_2 Single Crystals[1] , PETRA HUSANIKOVA, Drexel University and IEE, Slovak Academy of Sciences, JAN FEDOR, JAN DERER, VLADIMIR CAMBEL, IEE, Slovak Academy of Sciences, GORAN KARAPETROV, Drexel University — We investigate the normal state and superconducting properties of 1T-$TiSe_2$ family of single crystals intercalated with different level of copper content. Magnetoresistance and Hall effect data indicate that 1T-$TiSe_2$ is a compensated narrow band-gap semiconductor or semimetal with small number of electron and hole carriers. We compare the influence of copper intercalant and titanium interstiatials on the temperature evolution of charge density waves via resistivity and Hall effect measurements. Our findings indicate that the origin of the charge density waves in 1T-$TiSe_2$ is due to the combination of exciton and Jahn-Teller mechanisms. At higher copper concentrations we investigate the superconducting properties of Cu_xTiSe_2 in overdoped regime and find that the system is a single-gap strongly type-II superconductor with in-plane Ginzburg-Landau parameter reaching 50.

8:24AM Y19.00003 The effect of dimensionality on the charge-density-wave phase in layered dichalcogenides[1] , DARSHANA WICKRAMARATNE, PRADYUMNA GOLI, ALEXANDER BALANDIN, ROGER LAKE, University of California, Riverside — Transition-metal dichalcogenides exhibit a variety of conducting phases, which includes a charge-density wave state (CDW). Exfoliation of these layered materials allows the effect of dimensionality on the CDW state to be studied. CDW collective states are currently being considered as an alternative state variable for information processing [1]. 2H-$TaSe_2$ and 1T-$TiSe_2$ are examples of layered transition metal dichalcogenides that undergo a CDW transition. Our recent experiments demonstrated an increase in the CDW transition temperature of $TiSe_2$ with a decrease in film thickness [1]. This increase in temperature was attributed to the negative coefficient of the CDW transition temperature-pressure relationship. Here we present a density-functional theory investigation of the CDW instability in bulk, single and few-layer 1T-$TiSe_2$ and other layered dichalcogenide materials. The effect of the film thickness on the atomic structure, electronic structure, electron-phonon coupling and the CDW transition temperature will be discussed for each material.

8:36AM Y19.00004 Charge-Density Wave and Superconducting Dome in $TiSe_2$ from Electron-Phonon Interaction , MATTEO CALANDRA, MAURI FRANCESCO, CNRS and Université P. et M. Curie — At low temperature TiSe2 undergoes a charge-density wave instability. Superconductivity is stabilized either by pressure or by Cu intercalation. We show [1] that the pressure phase diagram of TiSe2 is well described byfirst-principles calculations. At pressures smaller than 4 GPa charge-density wave ordering occurs, in agreement with experiments. At larger pressures the disappearing of the charge-density wave is due to a stiffening of the short-range force constants and not to the variation of nesting with pressure. This suggests a common origin of the charge density waves instability in transition metal dichalcogenides, as also demonstrated in previous works by first principles calculations on bulk and few layers NbSe2 [2]. In TiSe2, the behavior of Tc as a function of pressure is entirely determined by the electron-phonon interaction without need of invoking excitonic mechanisms. Our work demonstrates that phase diagrams with competing orders and a superconducting dome are also obtained in the framework of the electron-phonon interaction.

8:48AM Y19.00005 A quantum phase transition from triangular to stripe charge order in $NbSe_2$[1] , ERIC HUDSON, Pennsylvania State University, ANJAN SOUMYANARAYANAN, M. M. YEE, YANG HE, Harvard University, D. J. RAHN, K. ROSSNAGEL, University of Kiel, JASPER VAN WEZEL, M.R. NORMAN, Argonne National Laboratory, JENNIFER E. HOFFMAN, Harvard University — We use scanning tunneling microscopy to reveal a previously unknown unidirectional (stripe) charge density wave (CDW) smoothly interfacing with the familiar tridirectional (triangular) CDW on the surface of the stoichiometric superconductor $NbSe_2$. Our low temperature measurements rule out thermal fluctuations, and point to local strain as the tuning parameter for this quantum phase transition. We use this discovery, in conjunction with bandstructure calculations, to resolve two longstanding debates about the anomalous spectroscopic gap and the role of Fermi surface nesting in the CDW phase of $NbSe_2$. First, the 15% wavelength difference between the two CDWs demonstrates that Fermi surface nesting plays a minor role in determining the CDW wavevectors in $NbSe_2$. Second, we disentangle a $\Delta \sim$12 meV particle-hole asymmetric CDW gap from a spectrum dominated by collective modes, resolving a longstanding debate regarding anomalous gaps previously observed by STM and ARPES. Our results highlight the importance of local strain in governing phase transitions and competing phenomena, and suggest a new direction of inquiry for resolving similarly longstanding debates in cuprate superconductors and other strongly correlated materials.

9:00AM Y19.00006 Role of impurities in the charge density wave state of transition metal dichalcogenides[1] , JUNICHI OKAMOTO, ANDREW MILLIS, Columbia University — Motivated by recent scanning tunneling microscope (STM) measurements of $NbSe_2$ which revealed the formation of charge density wave (CDW) droplets around impurities even at temperatures of the order of three times the transition temperature [1], we present a theory of impurity-induced CDW formation, and examine its consequences for the thermodynamic phase transition and low temperature ordered phases. Our fits to the STM measurements suggest that the CDW is strongly pinned by impurities, so that a standard theory predicts that even at lowest temperature the material should be in the disordered phase. We present a new theoretical picture explaining how to reconcile the experimental observation of a sharp transition with the strong pinning. [1] S. P. Chockalingam *et al.* (submitted to PNAS)

9:12AM Y19.00007 Electronic Structure and Charge-Density Wave Instabilities in Monolayers of Transition Metal Dichalcogenides[1] , PIERRE DARANCET, Dept of Applied Physics and Applied Mathematics, Columbia University, ANDREW J. MILLIS, Dept of Physics, Columbia University, CHRIS A. MARIANETTI, Dept of Applied Physics and Applied Mathematics, Columbia University — Transition metal dichalcogenides (TMDC) are layered materials displaying a variety of charge-density wave (CDW) instabilities and complex phase diagrams for group IV & V transition metals. Recent progress in mechanical exfoliation and device fabrication now allow for electrical characterization and gating of individual, 3-atom thick layers [1] of TMDCs, providing new probes of the complex many-body interactions arising in these compounds. In this talk, I will present our investigations using density functional and dynamical mean-field theory regarding the electronic structure and electronic correlations arising in distorted monolayers, bilayers, and trilayers of octahedral group V TMDCs. We will examine the importance of doping, crystal fields, and many-body interactions, and their influence on the transport and optical properties of these materials upon distortion. [1] K. S. Novoselov et al., PNAS 102, 10451 (2005) .

9:24AM Y19.00008 Role of Disorder in Atomic Scale Onset of Charge Density Waves , ERICK ANDRADE, CARLOS ARGUELLO, ETHAN ROSENTHAL, SUBBAIAH CHOCKALINGAM, LUIYAN ZHAO, CHRISTOPHER GUTIERREZ, WOO CHUNG, WENCEN JIN, PO-CHUN YEH, Columbia University, TONICA VALLA, Brookhaven National Labs, RAFAEL FERNANDES, Columbia University, SHUANG JIA, Princeton University, RICHARD OSGOOD, ANDREW MILLIS, Columbia University, ROBERT CAVA, Princeton University, ABHAY PASUPATHY, Columbia University — How does strong disorder affect the electronic states of complex electronic materials? This question is of relevance to many quantum materials such as the cuprates and pnictides, where interesting electronic phases like superconductivity only arise in strongly disordered samples. The study of these materials is complicated by the presence of multiple electronic phases, which obscures the interpretation of local spectroscopic measurements. To gain insight into this problem, we study 2H-$NbSe_2$, a relatively simple material with a 2D charge density wave ground state. To tune the disorder in the sample, we use sulfur substitution to go from weak (in pristine $NbSe_2$) to strong disorder (in $NbSe_{2-x}S_x$). We use variable-temperature scanning tunneling microscopy and spectroscopy to visualize the electronic structure in real space. Strong changes in the local electronic spectrum are observed with the introduction of disorder, with a pseudogap appearing in the local density of states. We also observe strong changes in the quasiparticle interference from spectroscopic images. We will discuss the interpretation of quasiparticle interference in the limit of strong disorder, and its relevance to existing measurements in the cuprates and pnictides.

9:36AM Y19.00009 Charge Density Wave Disproportionation in Pd(III)-containing PdTeI , PATRICK COTTINGHAM, JOHN SHECKELTON, DAVID MILLER, JAMES NEILSON, TYREL MCQUEEN, Johns Hopkins University — Exotic electronic properties in strongly correlated materials often emerge from the interplay of structure and charge. In most Pd^{3+}-containing materials, Pd^{3+} statically disproportionates into Pd^{2+} (d^8) and Pd^{4+} (d^6) with square planar and octahedral geometries, respectively. However, high-resolution diffraction data acquired for PdTeI indicate exclusively octahedral coordination of the Pd species within this compound. Temperature-dependent electrical resistivity measurements of this material performed in our lab show a hysteresis between $T_{CDW1} \sim 120$ K and $T_{CDW2} \sim 50$ K, indicative of a first-order phase transition. The most likely origin of this anomaly is the formation of a CDW involving partial, dynamic charge disproportionation of Pd^{3+}. In addition, low-temperature diffraction data show a broadening of Bragg peaks on cooling which is indicative of strain or of disorder concomitant with disproportion. In this presentation the temperature dependencies of the magnetic susceptibility, heat capacity, and electronic properties of PdTeI will be discussed in the context of CDW formation.

9:48AM Y19.00010 Short-range CDW correlations in Co_xNbSe_2 and Mn_xNbSe_2 , J. LEE, Physics Department, Temple University, Philadelphia, PA 19122, R. DI CAPUA, Dipartimento S.pe.S., Universita degli Studi del Molise, Campobasso, and CNR-SPIN, Napoli, Italy, G. KARAPETROV, Physics Department, Drexel University, Philadelphia, PA 19104, T. NISHIZAKI, N. KOBAYASHI, Institute for Materials Research, Tohoku University, Sendai 980-8577, Japan, M. IAVARONE, Physics Department, Temple University, Philadelphia, PA 19122 — Scanning tunneling microscopy and transport measurements were performed on $NbSe_2$ and Co- and Mn-intercalated $NbSe_2$ single crystals, to address the effect of disorder induced on the CDW structure by the effect of intercalation. We find that the CDW transition at T_{CDW}=33 K in the pure compound is accompanied by a small anomaly in resistivity, a strong non linearity of the Hall effect, with a sign reversal occurring at CDW transition, and high magnetoresistance in agreement with previous reports. The system remains metallic below the CDW transition. Upon increase of disorder the anomaly in resistivity moves at a lower temperature and eventually disappears for higher doping levels. By increasing the disorder also the magnetoresistance decreases and the Hall effect does not show any sign reversal. STM measurements on a pure sample reveal that CDW phase is long-range ordered below T_{CDW}. For doped samples short range CDW correlations dominate a large part of the phase diagram.

10:00AM Y19.00011 Optical Excitation Spectrum in Ni- and Cu-doped $ZrTe_3$, CHIARA MIRRI, ADAM DUSZA, LEONARDO DEGIORGI, Solid State Physics Laboratory, ETH Zurich, CH-8093 Zurich, Switzerland, CEDOMIR PETROVIC, Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory, Upton NY 11973, USA, BROOKHAVEN NATIONAL LABORATORY COLLABORATION — We report on an optical study performed on Cu_xZrTe_3 and Ni_xZrTe_3 single crystals. $ZrTe_3$ was previously found to display a BCS-like CDW-gap opening in the optical spectra along the direction orthogonal to the Zr-chains and to undergo a filamentary superconducting transition below a T_c of about 2 K. The intercalation by Cu and Ni between the $ZrTe_3$ layers partially fills the CDW gap and induces bulk superconductivity coexisting with the CDW state below T_c. Here we show the effect of Ni and Cu intercalation on the reflectivity and optical conductivity above and below the CDW phase-transition temperature. Furthermore, we analyze the optical spectral weight, providing equivalent information in both compounds about the partial gapping of the Fermi surface and the overall redistribution of spectral weight across the CDW phase transition.

10:12AM Y19.00012 Interplay between electron-electron and electron-lattice interactions in the RTe3 compounds[1] , ALEXANDER KEMPER, Lawrence Berkeley National Laboratory, H.-M. EITER, M. LAVAGNINI, R. HACKL, Walther Meissner Institut, Bayerische Akademie der Wissenschaften, E.A. NOWADNICK, T.P. DEVEREAUX, J.-H. CHU, J.G. ANALYTIS, I.R. FISHER, Stanford Institute for Materials and Energy Sciences, SLAC National Accelerator Laboratory, L. DEGIORGI, Laboratorium für Festkörperphysik, ETH - Zürich — Charge and spin density waves, periodic modulations of the electron and magnetization densities, respectively, are among the most abundant and non-trivial low-temperature ordered phases in condensed matter. The ordering direction is widely believed to result from the Fermi surface topology. However, several recent studies indicate that this common view needs to be supplemented. Here, we show how an enhanced electron-lattice interaction can contribute to or even determine the selection of the ordering vector in the model charge density wave (CDW) system ErTe3. We show how the electron-phonon coupling in the vicinity of band degeneracy points is strongly enhanced, leading to a CDW direction that is different from that determined by first-principles calculations. This combination of electron-electron and electron-lattice interactions may be generally relevant for driving phase transitions in other broken-symmetry ground states.

[1]The authors acknowledge support from the US DOE, the DFG and the Swiss National Foundation for Scientific Research.

10:24AM Y19.00013 Charge density wave formation in multi-band systems , RUDI HACKL, HANS-MARTIN EITER, MICHELA LAVAGNINI, Walther Meissner Institut, 85748 Garching, Germany, ELIZABETH A. NOWADNICK, ALEXANDER F. KEMPER, THOMAS P. DEVEREAUX, JIUN-HAW CHU, JAMES G. ANALYTIS, IAN R. FISHER, Stanford University, Stanford CA 94305, USA, LEONARDO DEGIORGI, ETH Zurich, 8093 Zurich, Switzerland — Charge and spin density waves are among the most abundant low-temperature ordered phases in condensed matter. The Fermi surface topology is widely believed to determine the ordering direction. However, several recent experimental and theoretical studies show that nesting is only one out of various other driving forces behind these instabilities. We use Raman scattering to demonstrate in which way an enhanced electron-lattice interaction can contribute to or even determine the selection of the ordering vector in the model charge density wave (CDW) system $ErTe_3$ and other rare-earth tri-tellurides. In our joint experimental and theoretical study we exploit the symmetry properties of the electron-photon and electron-phonon coupling vertex and establish a relation between the selection rules of the electronic light scattering spectra and the enhanced electron-phonon coupling in the vicinity of band degeneracy points. The proposal shown here for CDW formation, may be of more general relevance in multi-band systems for driving phase transitions into other broken-symmetry ground states. For example, the iron-based superconductors exhibit a similar phenomenology close to the intersection points of the backfolded electron bands.

10:36AM Y19.00014 Charge-density wave transitions of rare-earth tritellurides investigated by femtosecond electron crystallography[1] , TZONG-RU HAN, ZHENSHENG TAO, SUBHENDRA D. MAHANTI, KISEOK CHANG, CHONG-YU RUAN, Physics and Astronomy Department, Michigan State University, East Lansing, Michigan 48824, USA, CHRISTOS D. MALLIAKAS, MERCOURI G. KANATZIDIS, Department of Chemistry, Northwestern University, Evaston, Illinois 60208, USA, CHONG-YU RUAN TEAM, MERCOURI G. KANATZIDIS TEAM — The electron-phonon mechanism that gives rise to various charge-ordered systems depends on the topology of the Fermi surface that is subjective to the influence of hybridization, nesting, and electron correlation at low dimensions. Rare-earth tritellurides are ideal systems to investigate the two-dimensional charge-density density wave (CDW) formation as both nesting and hybridization are at play to select the unidirectional CDW at different temperatures. Using fs electron crystallography, we investigate the noncooperative suppression of the structural order parameters following ultrafast electronic quenching and correlate electronic and ionic evolutions based on a framework of three-temperature model and nonisotropic fluctuational analysis. We show that a joint consideration of the couplings between the lattice phonons, the CDW collective modes, and the corresponding electronic subsystem is required to account for the various novel structural dynamics features.

10:48AM Y19.00015 1/f noise anomalies in nanoribbons of charge density wave materials , ZHENZHONG SHI, ADAM STABILE, Department of Physics, PETER M. MARLEY, SARBAJIT BANERJEE, Department of Chemistry, GANAPATHY SAMBANDAMURTHY, Department of Physics, University at Buffalo, Buffalo, NY 14260 — Charge density wave (CDW) as an ordered form of matter has attracted attention for many decades. Below a critical temperature (T_P), CDW materials undergo a Peierls transition and enter the CDW ground state, where the energy is minimized by a collectively pinning mechanism. Under a moderate electric field, CDWs can be depinned and they start sliding. An onset of a large broad band noise (BBN) has been observed in bulk CDW materials as a signature of this depinning process. We report low frequency conductance fluctuation (1/f noise) measurements on single nanoribbon devices of single-crystalline $NbSe_3$, across both Peierls transitions. In the CDW state, a non-monotonic behavior in the noise magnitude was observed when approaching the threshold electric field for depinning: while increasing voltage from the zero-bias limit, the magnitude of BBN first decreases before increasing sharply near the threshold voltage. This unusually large BBN magnitude and the non-monotonic behavior below the depinning threshold suggest some inherent instability that could be suppressed by a small bias field, and is clearly different from results from bulk materials. Transport and noise studies from individual nanoribbons of $NbSe_3$, Ta-doped $NbSe_3$ and o-TaS_3 will be presented.

Friday, March 22, 2013 8:00AM - 11:00AM –

Session Y20 DCMP: Focus Session: Electron, Ion, Exciton Transport in Nanostructures: Quantum Dots and Low-dimension Structures 322 - Seungbum Hong, Argonne National Laboratory

8:00AM Y20.00001 Flux-dependent effects in degenerate and symmetric double dot Aharonov-Bohm interferometer with and without interactions[1] , SALIL BEDKIHAL, Chemical Physics Theory Group, University of Toronto, Department of Chemistry, MALAY BANDYOPADHYAY, Department of Physics, Indian Institute of Technology, Bhubaneshwar, DVIRA SEGAL, Chemical Physics Theory Group, University of Toronto, Department of Chemistry — We study the steady-state characteristics and the transient behaviour of the non equilibrium double-dot Aharonov-Bohm interferometer using analytical tools and numerical simulations. Our simple setup includes non-interacting degenerate quantum dots that are coupled to two biased metallic leads at the same strength. A magnetic flux Φ is piercing the set-up perpendicularly. As we tune the degenerate dots energies away from the symmetric point we observe four non trivial magnetic flux control effects: (i) flux dependency of the dots occupation, (ii) magnetic flux induced occupation difference between the dots, at degeneracy, (iii) the effect of "phase-localization" of the dots coherence holds only at symmetric point, while in general both real and imaginary parts are non-zero, and (iv) coherent evolution survives even when the dephasing strength, introduced into our model using Buttiker probe, is large and comparable to the dots energies and the bias voltage. Moreover, not only finite dephasing strength does not destroy the coherence features, it can provide a new type of coherent oscillation. These four phenomena take place when the dot energies are gated, away from the symmetric point,demonstrating the delicate controllability over the dot occupation and coherence.

[1]Authors acknowledge support from NSERC

8:12AM Y20.00002 Optical phonon lasing in transport through semiconductor double quantum dots , RIN OKUYAMA, MIKIO ETO, Faculty of Science and Technology, Keio University, TOBIAS BRANDES, Institut fur Theoretische Physik, Technische Universitat Berlin — We theoretically propose optical phonon lasing for a double quantum dot (DQD) fabricated in a semiconductor substrate. No additional cavity or resonator is required. We show that the DQD couples to only two phonon modes that act as a natural cavity. The pumping to the upper level is realized by an electric current through the DQD under a finite bias. Using the rate equation in the Born-Markov-Secular approximation, we analyze the enhanced phonon emission when the level spacing in the DQD is tuned to the phonon energy. We find the phonon lasing when the pumping rate is much larger than the phonon decay rate, whereas anti-bunching of phonon emission is observed when the pumping rate is smaller. Both effects disappear by an effective thermalization induced by the Franck-Condon effect in a DQD fabricated in a suspended carbon nanotube with strong electron-phonon coupling. [1]
[1] R. Okuyama, M. Eto, and T. Brandes, arXiv:1205.6955 (2012).

8:24AM Y20.00003 Quantum Confined Silicon Clathrate Quantum Dots[1] , MARK LUSK, NICHOLAS BRAWAND, Colorado School of Mines — Silicon (Si) allotropes can be synthesized in such a way that tetrahedrally bonded atoms form cage-like structures with bulk mechanical and opto-electronic properties distinct from those of diamond silicon (dSi). We use DFT, supplemented with many-body Green function analysis, to explore the structural stability of clathrate Si quantum dots (QDs) and to characterize their confinement as a function of crystal symmetry and size. Our results show that that there is a simple relationship between the confinement character of the QDs and the effective mass of the associated bulk crystals. Clathrate QDs and dSiQDs of the same size can exhibit differences of gap energies by as much as 2 eV. This offers the potential of synthesizing Si dots on the order of 1 nm that have optical gaps in the visible range but that do not rely on high-pressure routes such as those explored for the metastable BC8 and R8 phases. These results prompt the question as to how minimal quantum confinement can be in dots composed of Si. More broadly, clathrate QDs can in principle be synthesized for a wide range of semiconductors, and the design space can be further enriched via doping.

8:36AM Y20.00004 Excess current noise in electrically conductive, crack-free, nanopatterned films of semiconductor nanocrystals , TAMAR MENTZEL, University of California at Berkeley, NIRAT RAY, DARCY WANGER, MOUNGI BAWENDI, MARC KASTNER, MIT — We present the first electrical measurements of semiconductor nanocrystal films that have nanoscale dimensions and are crack-free. These films make it possible to study the electrical properties intrinsic to the nanocrystals unimpeded by defects such as cracking and clustering that typically exist in larger-scale films. The films' dimensions are as small as 30 nm and are positioned on a surface with 30 nm precision. The electrical conductivity of the crack-free nanoscale films is 180 times higher than that of drop-cast, microscopic films made of the same type of nanocrystal. In the nanoscopic patterns, we find excess noise in the current that is thermally activated. This noise is unusual in that it is of a comparable order of magnitude to the average current, and both the average current and the noise fluctuate by several orders of magnitude in time. The noise increases with an applied field and with a gate. The inability to explain these effects by commonly known origins of electrical noise suggests that we are observing a novel effect in the nanocrystals.

8:48AM Y20.00005 Energy spectrometry of electrons ejected from dynamic quantum dots driven up a potential slope by a surface acoustic wave , CHRISTOPHER FORD, MATTHEW BENESH, SEOK-KYUN SON, University of Cambridge, MASAYA KATAOKA, NPL, UK, CRISPIN BARNES, ROBERT MCNEIL[1], JON GRIFFITHS, GEB JONES, IAN FARRER, DAVID RITCHIE, University of Cambridge — Surface acoustic waves (SAWs) in a GaAs/AlGaAs heterostructure generate an electrostatic wave which propagates at the sound velocity. This potential wave is capable of collecting electrons from a 2D electron gas (2DEG) and transporting them through a depleted channel. The SAW minima form a continuous series of dynamic quantum dots, each transporting a controllable number of electrons along the channel. The confinement of the electrons in each dot increases as the potential rises along the channel, ejecting electrons one-by-one back into the 2DEG above the Fermi energy. These electrons can travel several microns before thermalising. We measure their energy spectrum using a variable potential barrier upstream as the channel is squeezed by split gates, and correlate this with the SAW-driven current along the channel.

9:00AM Y20.00006 Measurement of Valley Kondo Effect in a Si/SiGe Quantum Dot[1] , MINGYUN YUAN, ZHEN YANG, CHUNYANG TANG, A.J. RIMBERG, Department of Physics and Astronomy, Dartmouth College, R. JOYNT, D.E. SAVAGE, M.G. LAGALLY, M.A. ERIKSSON, University of Wisconsin-Madison — The Kondo effect in Si/SiGe QDs can be enriched by the valley degree of freedom in Si. We have observed resonances showing temperature dependence characteristic of the Kondo effect in two consecutive Coulomb diamonds. These resonances exhibit unusual magnetic field dependence that we interpret as arising from Kondo screening of the valley degree of freedom. In one diamond two Kondo peaks due to screening of the valley index exist at zero magnetic field, revealing a zero-field valley splitting of $\Delta \approx 0.28$ meV. In a non-zero magnetic field the peaks broaden and coalesce due to Zeeman splitting. In the other diamond, a single resonance at zero bias persists without Zeeman splitting for non-zero magnetic field, a phenomenon characteristic of valley non-conservation in tunneling.

9:12AM Y20.00007 The impact of finite-area inhomogeneities on resistive and Hall measurement , DANIEL KOON, St. Lawrence University — I derive an iterative expression for the electric potential in an otherwise homogeneous thin specimen as the result of a finite-area inhomogeneity in either the direct conductance, the Hall conductance, or both. This expression extends to the finite-area regime the calculation of the effect of such inhomogeneities on the measurement error in the sheet resistance and Hall sheet resistance. I then test these results on the exactly-solvable case of a circular inhomogeneity equally distant from the four electrodes of either a square four-point-probe array on an infinitely large conducting specimen or a circular van der Pauw specimen with symmetrically-placed electrodes.

9:24AM Y20.00008 Quasibound States and Evidence for a Spin 1 Kondo Effect in Asymmetric Quantum Point Contacts[1] , HAO ZHANG, Duke University, PHILLIP WU, Stanford University, ALBERT CHANG, Duke University — Linear conductance below $2e^2/h$ shows resonance peaks in highly asymmetric quantum point contacts (QPCs). As the channel length increases, the number of peaks also increases. At the same time, differential conductance exhibits zero bias anomalies (ZBAs) in correspondence with every other peak in the linear conductance. This even odd effect, observable in the longer channels, is consistent with the formation of quasi-localized states within the QPC. In rare cases, triple peaks are observed, indicating the formation of a spin one Kondo effect when the electron filling number is even. Changing the gate voltage tunes this spin triplet to a singlet which exhibits no ZBA. The triple-peak provides the first evidence suggestive of a spin singlet triplet transition in a QPC, and the presence of a ferromagnetic spin interaction between electrons.

9:36AM Y20.00009 Enhancement of the excition emission in ZnO nanowires[1] , ANDREW EPPS[2], JAMIE NOWALK[3], MARIAN TZOLOV[4], Lock Haven University — The ZnO nanowires were grown by the chemical vapor transport method using a thin gold film as a catalyst. Their light emission in the visible and near UV spectral range was excited by continuous wave and pulsed UV light and by electrons within an SEM. The emission spectrum consists typically of the exciton emission band and a band in the green spectral range related to structural defects. We have followed the evolution of the ratio between the exciton and green band between our samples. The highly localized excitation by the electron beam allowed the profiling of the emission spectrum across the thickness of nanowire samples. We demonstrate that the tips of the nanowires show substantially higher exciton emission. Depth of excitation was varied independently by the electron accelerating voltage. The results have been interpreted within a model accounting for the surface effects and associated band banding at the surface.

9:48AM Y20.00010 BEC-BCS crossover of a dipolariton condensate in a semiconductor microcavity , JUNG-JUNG SU, E. L. Ginzton Lab., Stanford Univ.; Dept. of Electrophys. Natl. Chiao Tung Univ., Taiwan, NA YOUNG KIM, E. L. Ginzton Lab., Stanford Univ, YOSHIHISA YAMAMOTO, E. L. Ginzton Lab., Stanford Univ; Natl. Inst. of Informatics, Japan, ALLAN H. MACDONALD, Dept. of Phys., Univ. of Texas at Austin — We study the electron-tunnel-coupling condensation of dipolar exciton-polariton (dipolariton) at the BEC-BCS crossover. An exciton-polariton (EP) is an extremely light bosonic quasiparticle composed of excitons and photons and can condense a temperatures as high as room temperature. Electron tunneling between nearby quantum wells can coupled spatially direct and indirect excitons and therefore also the corresponding exciton-polaritons; the indirect EPs in particular carry the interesting dipolar nature. We use a fermionic mean-field theory to examine the influence of this coupling on EP condensates from the dilute BEC to the dense BCS limits. A wide variety of distinct states are found, including mixed direct and indirect EP condensates, and metallic condensates, depending on particle-densities and on the relative positions of the quantum well states in different wells. Possible experimental manifestations of these phenomena will be discussed.

10:00AM Y20.00011 Strain-controlled band engineering and Self-doping in Ultrathin LaNiO3 films , X. LIU, E.J. MOON, Department of Physics, University of Arkansas, Fayetteville, Arkansas 72701, J.M. RONDINELLI, Department of Materials Science and Engineering, Drexel University, Philadelphia, Pennsylvania 19104, N. PRASAI, Department of Physics, University of Miami, Coral Gables, Florida 33124, B.A. GRAY, M. KAREEV, J. CHAKHALIAN, Department of Physics, University of Arkansas, Fayetteville, Arkansas 72701, J.L. COHN, Department of Physics, University of Miami, Coral Gables, Florida 33124 — We discover a unique self-doping carrier transition by strain-induced in $LaNiO_3$ ultra thin film. Transport properties evolving from compressive to tensile strains are similar to those of different hole-doping superconducting cuprates. DFT calculations show the changes in low-energy electronic band structure account for the charge transfer between O p and Ni d states. The results indicate that ultrathin films can be used to change the carrier concentration transition metal oxides without resorting to chemical substitution.

10:12AM Y20.00012 Monte Carlo simulations of electron transport for electron beam-induced deposition of nanostructures , FRANCESC SALVAT-PUJOL, HARALD O. JESCHKE, ROSER VALENTI, Institut für Theoretische Physik, Goethe-Unversität Frankfurt, Max-von-Laue-Str. 1, 60438 Frankfurt, Germany — Tungsten hexacarbonyl, $W(CO)_6$, is a particularly interesting precursor molecule for electron beam-induced deposition of nanoparticles, since it yields deposits whose electronic properties can be tuned from metallic to insulating. However, the growth of tungsten nanostructures poses experimental difficulties: the metal content of the nanostructure is variable. Furthermore, fluctuations in the tungsten content of the deposits seem to trigger the growth of the nanostructure. Monte Carlo simulations of electron transport have been carried out with the radiation-transport code Penelope in order to study the charge and energy deposition of the electron beam in the deposit and in the substrate. These simulations allow us to examine the conditions under which nanostructure growth takes place and to highlight the relevant parameters in the process.

10:24AM Y20.00013 Monte Carlo simulations of neon versus helium ion beam induced deposition, sputtering and etching , RAJENDRA TIMILSINA, DARYL SMITH, The Unviersity of Tennesse at Knoxville, Tennessee, PHILIP RACK, The Unviersity of Tennesse at Knoxville, Tennessee and Center for Nanophase Materials Sciences Oak Ridge National Laboratory, Oak Ridge, — The ion beam induced nanoscale synthesis of PtCx (where x $\sim$ 5) using the trimethyl (methylcyclopentadienyl)platinum(IV) ($MeCpPt^{IV}Me_3$) precursor is investigated by performing Monte Carlo simulations of helium and neon ions. The helium beam leads to more lateral growth relative to the neon beam because of its larger interaction volume. The lateral growth of the nanopillars is dominated by molecules deposited via secondary electrons in the both simulations. Notably, the helium pillars are dominated by SE-I electrons whereas the neon pillars by SE-II electrons. Using a low precursor residence time of 70μs resulting in an equilibrium coverage of $\sim$ 4%, the neon simulation has a lower deposition efficiency (3.5%) compared to that of the helium simulation (6.5%). At larger residence time (10ms) and consequently larger equilibrium coverage (85%) the deposition efficiencies of helium and neon increased to 49% and 21%, respectively; which is dominated by increased lateral growth rates leading to broader pillars. The nanoscale growth is further studied by varying the ion beam diameter at 10 ms precursor residence time. The study shows that total SE yield decreases with increasing beam diameters for the both ion types. However, the helium has the larger SE yield as compared to that of neon in the both low and high precursor residence time, and thus pillars are wider in all the simulations studied.

10:36AM Y20.00014 Electron field emission from freestanding Diamond nanomembranes and Application to time-of-flight mass spectrometry , HYUNSEOK KIM, University of Wisconsin, Madison, JONGHOO PARK, Kyungpook National University, Daegu, Korea, HYUNCHEOL SHIN, ROBERT H. BLICK, University of Wisconsin, Madison — We introduce a prototype of a freestanding diamond nanomembrane for large protein detection in time-of-flight mass spectrometry. Doped diamond as a material for mass spectroscopy is extremely interesting due to its mechanical and electrical properties. The freestanding diamond nanomembranes we are able to fabricate have lateral extensions of $400\,\mu m \times 400\,\mu m$ with a thickness of 100nm. We employ optical lithography and a Buffered Oxide Etch (BOE) of SiO_2 followed by anisotropic etching of the substrate silicon using TMAH solution and finally removing SiO_2. The electron field emission from the surface of the membrane is traced in the *IV* characteristics at room temperature. The membrane is then applied for detection of the large ionized proteins using time-of-flight mass spectrometry. Ion detection is demonstrated in our nanomembrane MALDI-TOF analysis of Insulin (5,735 Da). That is when the ions with a large kinetic energy bombard the nanomembrane, their energy is thermalized upon impact into phonons. The phonons give a thermal energy to the electrons with the membrane, which are then excited to higher energetic states. Given an extraction voltage this leads to electron field emission from the membrane which we labeled phonon-assisted field emission (PAFE). In other words, the MALDI mass spectra are obtained by exploiting ballistic phonon propagation and quasi-diffusive phonon propagation.

10:48AM Y20.00015 A Density Functional Study of the Redox Properties of H2TPP Porphyrin[1] , DAYLA MORRISON, Physics Department, University of Texas at Arlington, Arlington, Texas, ROBERT THOMAS, Optical Radiation Bioeffects Branch, Bioeffects Division, Air Force Research Laboratory, Fort Sam Houston, Texas, ASOK RAY, Physics Department, University of Texas at Arlington, Arlington, Texas — Properties of the ground state of free base meso-tetraphenylporphyrin (H2TPP) have been calculated with various charges using the B3LYP functional and the 6-31+G basis set. The porphyrin skeleton was rippled and saddled and the meso-phenyl rings were twisted to yield the C_{2h}, C_{2v}, D_2, D_{2h} planar and D_{2h} non-planar symmetries and the structures optimized. The ground state structure was found to be of C_{2v} symmetry although the C_{2h}, D_2 and D_{2h} non-planar structures were basically degenerate, a conclusion not supported by experimental data. The C_{2v} structure indicated a nonzero net dipole moment for all levels of charge studied. Increase in negative charge increased the distortion of the H2TPP structure. The Raman spectra was calculated and compared with experimental data.[2] In addition, the results were used to select the most likely binding configuration among a set of solutions yielded by computational docking algorithms. Calculations using higher basis sets will also be presented.

Session Y21 FIAP: Semiconductors: Thermodynamic & Transport Properties (Theory) 323 - Chris Palmstrom, University of California, Santa Barbara

8:00AM Y21.00001 Thermal transport in the two-dimensional disordered electron gas , GEORG SCHWIETE, Dahlem Center for Complex Quantum Systems, Freie Universität Berlin, ALEXANDER FINKELSTEIN, Texas A&M University, College Station, Texas, and The Weizmann Institute of Science, Rehovot, Israel — We develop a theory of thermal transport in the two-dimensional disordered electron gas at low temperatures. Our approach is based on the calculation of the heat density correlation function. To this end we subject the Keldysh nonlinear sigma model in the presence of source fields to a renormalization group analysis. Special care is taken to additionally account for scattering processes with a very small frequency transfer.

8:12AM Y21.00002 Electronic properties of near-surface InAs heterostructures , BORZOYEH SHOJAEI, Materials Department, University of California at Santa Barbara, JAVAD SHABANI, California Nanosystems Institute, University of California at Santa Barbara, BRIAN SCHULTZ, Department of Electrical and Computer Engineering, University of California at Santa Barbara, CHRIS PALMSTROM, Department of Electrical and Computer Engineering and Materials Department, University of California at Santa Barbara — The interest in low-dimensional narrow gap semiconductors with large spin orbit and high electron mobility has recently surged because of novel proposals on the realization of Majorana modes in such materials. To induce the proximity effect in the semiconductor by coupling to a superconductor, and to tune parameters of the system to realize Majorana excitations the electron channel has to form at or near the interface with the superconductor. In this work we have systematically studied near surface InAs heterostructures grown by molecular beam epitaxy (MBE). We have measured magnetotransport properties in these structures and compared them to theoretical values. We also discuss the in-situ growth of s-wave superconductors on InAs heterostructures and the proximity effect.

8:24AM Y21.00003 Impact of Silicon Nitride Passivation Thickness on AlGaN \GaN Transport Properties and Device Performance , HELEN JACKSON, JAMES PETROSKY, ROBERT HENGEHOLD, Air Force Institute of Technology, ZHAOQIANG FANG, Wright State University Semiconductor Research Center — Silicon nitride passivation (Si_3N_4) on AlGaN\GaN heterojunction devices can improve performance by reducing electron traps at the surface. In this study, the effects of passivation layer thickness were investigated at various thicknesses (0, 20, 50 and 120 nanometers) on bare epilayer AlGaN\GaN structures with either an AlN nucleation layer or a GaN cap. Hall system measurements were used to observe changes in carrier concentration and mobility as a function silicon nitride thickness. Mobility changes were measured and carrier scattering mechanisms are analyzed both with and without Si_3 N_4. Capacitance voltage measurements were done to give information about the surface donor states and the Si_3N_4 charge at the interface. A monatomic decrease in saturation capacitance with increasing Si_3N_4 thickness was observed. Gate current measurements were done to examine the effect of Si_3N_4 on the gate leakage current and thus device performance.

8:36AM Y21.00004 Anomalous Mobility Enhancement via PPC of a GaAs/AlGaAs 2DEG[1] , YUN SUK EO, STEVEN WOLGAST, ÇAĞLIYAN KURDAK, Randall Laboratory of Physics, University of Michigan, LOREN PFEIFFER, KEN WEST, Department of Electrical Engineering, Princeton University — We report the unusual transport behavior of a two-dimensional electron gas (2DEG) in a δ-doped $GaAs/Al_xGa_{1-x}As$ heterostructure. Typically, the carrier density can be varied with a gate voltage or via the persistent photoconductivity (PPC) effect. The relationship between carrier density and mobility has often been expressed with the empirical relation $\mu \sim n^{\alpha}$, where α contains scattering mechanism information and typically ranges between 1 and 2. Here, we study the carrier density and mobility using gating techniques and the PPC effect with infrared and white light in small incremental exposures. At 4.2K, we find that the addition of a gate structure greatly reduces the achievable mobility. For PPC, we find that after white exposures, α can become unusually large. At 0.3 K, we observe an unusual decrease in carrier density, accompanied by an enhancement in mobility ($\alpha < 0$) after repeated exposures of light. When the mobility is further enhanced by PPC, the 2DEG exhibits parallel conduction in its doping layer, and the transport becomes no longer controllable. However, the drifting mobility and carrier density eventually settle to reproducible values that are independent of the light increment history or other initial conditions.

[1]The project was supported by NSF grant #DMR-1006500, and in part by the Gorden and Betty Moore Foundation, the NSF MRSEC program #DMR-0819860, and the NSF-funded Lurie Nanofabrication Facility.

8:48AM Y21.00005 Parallel Magnetic Field Effect in the Insulating Phase of 2D Metal-Insulator Transition in p-GaAs with High r_s , RICHARD L.J. QIU, XUAN P.A. GAO, Department of Physics, Case Western Reserve University, LOREN N. PFEIFFER, KEN W. WEST, Department of Electrical Engineering, Princeton University — We present magnetotransport measurements on the insulating side of the 2D metal-insulator transition in p-type GaAs quantum wells with 10 nm width (critical density $p_c \sim 0.8*10^{10}/cm^2$, $r_s \sim 36$). Before entering the disorder dominated regime ($p^* < p < p_c$) ($p^* \sim 0.5*10^{10}/cm^2$), the conductance of the insulating phase follows a power-law like temperature dependence that is different from the well known thermally activated or variable range hopping behavior for insulators. In this unconventional insulating regime, a strong in-plane magnetic field ($B_{||} > B_c \sim$ 1-2 Tesla) drives the insulating phase into a "normal" insulating state which shows the variable range hopping behavior with Coulomb gap. Moreover, with the presence of a strong in-plane magnetic field in the hopping transport regime, large negative magnetoresistance (ρ can decrease by a factor of 5) is observed when increasing the $B_\perp$ component. The authors thank the NSF (DMR-0906415, DMR-0819860) and the Gordon and Betty Moore Foundation for funding support.

9:00AM Y21.00006 Temperature dependence of TCR and 1/f Noise in p-type a-Si:H[1] , VINCE LOPES, ERIC HANSON, KIRAN SHRESTHA, CHRIS LITTLER, ATHANASIOS SYLLAIOS, University of North Texas Department of Physics — The amorphous semiconductor a-Si:H is used for infrared detection applications. Key figures of merit are the temperature coefficient of resistance (TCR) and 1/f noise. We report on the temperature dependence of the electrical resistivity and noise of devices fabricated on as grown boron-doped p-type a-Si:H. The 1/f noise was found to be proportional to the bias voltage and inversely proportional to the square root of the device area. As a result, it can be described by Hooge's empirical expression. However, the 1/f noise was found to be constant in the temperature range investigated, even though the resistance changes by a factor of 2.5. We conclude that the carrier concentration is nearly constant in the temperature range studied; thus, the resistance change is due to the temperature dependence of the hole mobility. This interpretation is consistent with temperature dependent hole mobility measurements of others and suggest that the TCR for p-type a-Si:H material near room temperature is determined by changes in the hole mobility.

9:12AM Y21.00007 Fabrication, electrical characterization and scanning gate microscopy of Schottky silicon nanowire devices , SORIN MELINTE, ANDRA IORDANESCU, CONSTANTIN DUTU, DENIS FLANDRE, ELEN/ICTM, Universite catholique de Louvain, Belgium, SEBASTIEN FANIEL, FREDERICO MARTINS, BENOIT HACKENS, NAPS/IMCN, Universite catholique de Louvain, Belgium, ICTM TEAM, IMCN TEAM — We report the fabrication and the electrical characterization of Schottky silicon nanowire field effect transistors. Our devices are built with a top down approach on silicon-on-insulator wafers with (100) crystallographic orientation and 10 - 25 Ω.cm resistivity of the silicon top layer. The transistor's channel is assured by silicon nanowires patterned by electron beam lithography and wet etching. The nanowires have nominal cross sections down to 30×30 nm^2. For example, platinum-silicon Schottky contacts are made by physical deposition of a platinum layer followed by an annealing at 500°C for 2 minutes in a N_2 atmosphere. The devices are characterized at various temperatures by current-voltage measurements and scanning gate microscopy techniques. Varying the dimensionality and geometry of the contacts, the nature of metal-semiconductor junctions and the substrate strain, we get new insights into the influence of trapped charges at the $Si - SiO_2$ interface on transport through SiO_2-enclosed nanowires, at the nanometer scale.

9:24AM Y21.00008 Investigation of two-dimensional electron systems at low density on hydrogen-terminated silicon (111) surface , BINHUI HU, TOMASZ M. KOTT, B. E. KANE, University of Maryland — Two-dimensional electron systems (2DESs) on hydrogen-terminated Si(111) surfaces show very high quality. The peak electron mobility of 325,000 cm^2/Vs can be reached at T=90 mK and 2D electron density $n_{2d} = 4.15 \times 10^{11}$ cm^{-2} , and the device shows the fractional quantum hall effect[1]. 2DESs on H-Si(111) at lower densities may exhibit new physics, because both valley degeneracy and effective mass lead to a large Wigner–Seitz radius r_s at accessible densities. In these devices, phosphorus ion implantation is used to defined the contacts to the 2DESs[2]. The contacts themselves work at low temperature. However, at lower 2D electron density ($< 2 \times 10^{11}$ cm^{-2}) and low temperature (<1 K), the contact resistance to the 2DESs shows strong temperature dependence. This makes accurate Hall measurements difficult in this region. We have systematically investigated the contact resistance at different electron densities and temperatures. Different ion implantation annealing parameters are adjusted to mitigate the issue. Possible measurement technique is also explored to overcome the problem. [1] Tomasz M. Kott, Binhui Hu, S. H. Brown, and B. E. Kane, arXiv:1210.2386 (2012) [2] K. Eng, R. N. McFarland, and B. E. Kane, Appl. Phys. Lett. 87, 052106 (2005)

9:36AM Y21.00009 Electrical Properties of p-Ge and p-GeSn materials grown on n-Si substrates , THOMAS R. HARRIS, YUNG KEE YEO, Department of Engineering Physics, Air Force Institute of Technology, Wright-Patterson AFB, OH 45433-7765, USA, MEE-YI RYU, Department of Physics, Kangwon National University, Kangwon-Do 200-701, Korea, RICHARD BEELER, JOHN KOUVETAKIS, Department of Chemistry and Biochemistry, Arizona State University, Tempe, Arizona 85287-1504, USA — The electrical properties of *p*-Ge and *p*-$Ge_{1-y}Sn_y$ (y=0.06-0.1%) grown on *n* -Si substrate were investigated through temperature-dependent Hall-effect measurements. It was found that there exists a degenerate parallel conducting layer in $Ge_{1-y}Sn_y$/Si as well as a second, deeper acceptor in addition to a shallow acceptor. Additionally, a conductivity type conversion from *p* to *n* was observed between 370 and 440 K for these samples. The parallel conducting layer dominates the electrical properties of the $Ge_{1-y}Sn_y$ layer below 50 K, and also significantly affects those properties at higher temperatures. The conductivity type conversion and causes of the degenerate conduction layer will be discussed.

9:48AM Y21.00010 ABSTRACT HAS BEEN MOVED TO H1.00346 —

10:00AM Y21.00011 Theoretical and experimental study of kinetics of photoexcited carriers in wide band gap semiconductors , SARA SHISHEHCHI, Boston University, SERGEY RUDIN, GREGORY GARRETT, MICHAEL WRABACK, U.S. Army Research Laboratory, ENRICO BELLOTTI, Boston University — We present a theoretical and experimental study of the subpicosecond kinetics of photo-excited carriers in the wide band gap semiconductors GaN and ZnO. In the theoretical model, interaction with a photo-excitation laser pulse is treated coherently and a generalized Monte Carlo simulation is used to account for scattering and dephasing. The scattering mechanisms included are carrier interactions with polar optical phonons and acoustic phonons, and carrier-carrier Coulomb interactions. For comparison, experimental time-resolved photoluminescence studies on GaN and ZnO samples are performed over a range of temperatures and excitation powers.

10:12AM Y21.00012 Electrical Resisitivity in Metals and Metallic Alloys from First Principles , ALEXANDER SLEPKO, The University of Texas at Austin; Intel Corporation, Santa Clara, California, USA, SADASIVAN SHANKAR, JUSTIN WEBER, Intel Corporation, Santa Clara, California, USA, ALEXANDER DEMKOV, The University of Texas at Austin — We have developed a method for estimation of resistivity of metals and their alloys based on ab initio methods. The formalism is based on quantifying electron phonon interactions using Boltzmann-based electronic transport and plane wave-based density functional theory for electronic structure and phonon frequencies. We explicitly take into account long wave length scattering, energy band dispersion and interaction between impurities, often omitted in previous approaches. Given the detailed nature of our formalism, we will explain deviations from the most-used Matthiessen's Rule. We have tested our technique on Al, Cu, and Al-doping in Copper. Our resisitivity values compare very well with experimental data at room temperature; Al 2.75 $\mu\Omega$ cm (experimental, 2.83 $\mu\Omega$ cm), Cu 1.81 $\mu\Omega$ cm (experimental, 1.66 $\mu\Omega$ cm). We were also able to estimate the drops in conductivity of Cu due to alloying with Al for a wide range of composition (from dilute to concentrated alloys) which are consistent with the experiments. Given the general nature of our formalism, we believe that it is extendable to nanostructures.

10:24AM Y21.00013 Ab-initio calculations of the lattice thermal conductivity from an exact solution of the Boltzmann-Peierls equation , LAURENT CHAPUT, Institut Jean Lamour — In this work we present *ab-initio* calculations of the lattice thermal conductivity and related quantities for several semiconductors of interest in energy transport and thermoelectricity. Excellent agreements with experiments are found. A new method is proposed to obtain a numerically exact and fast solution to the Boltzmann-Peierls equation. This is made possible using the symmetry of the systems and open the way to the theoretical design of new materials. The collision kernel of the equation is constructed using an efficient parallelization of the code over the irreducible triplets of phonon wavevectors involved in the different possible collisions. These irreducible triplets are the equivalent of the irreducible part of the Brillouin zone for single particle quantities. Therefore a formulation of the self energy and collision kernel based on their use drastically reduce the computational time.

10:36AM Y21.00014 Nonlinear strain generation in ultrafast laser excited semiconductors , ERIC LANDAHL[1], DePaul University, SOOHEYONG LEE, Korean Research Institute of Standards and Science, G. JACKSON WILLIAMS[2], DePaul University, DONALD WALKO, Argonne National Laboratory — We have investigated the laser fluence dependence of the lattice response of Indium Antimonide and Gallium Arsenide crystals to ultrafast laser absorption using time-resolved x-ray diffraction. In both materials, slow thermal cooling follows an initial acoustic strain impulse. For Indium Antimonide, where the laser photon energy is significantly above the band gap, we find that both acoustic and thermal lattice expansions increase linearly with increasing laser fluence. The band gap and photon energy are much closer in Gallium Arsenide, where we find that while the thermal response remains linear with laser fluence, the magnitude of the acoustic impulse is highly nonlinear, exhibiting an initial saturation and recovery far below the laser damage threshold limit. Several hypotheses have been put forward of different nonlinear processes that could lead to this behavior. To place additional constraints on these models, we have recorded high-resolution diffraction lineshapes which can be directly compared to semiconductor strain models incorporating the transport of sound, heat, and charge.

10:48AM Y21.00015 Topological scattering of an electron gas by edge dislocations , KOUSHIK VISWANATHAN, SRINIVASAN CHANDRASEKAR, Purdue University — A theory of electron scattering by the strain field surrounding an edge dislocation in a linear isotropic medium is presented. When considered on a continuum scale, edge dislocations are topological defects — the underlying elastic medium can no longer be described as a Euclidean manifold, but instead must be mapped to a Riemann–Cartan manifold with nontrivial torsion. An electron gas placed in such a background has additional covariant terms in the Hamiltonian. These act alongside the usual deformation potential arising from the shift in the conduction band minima due to the dislocation strain field. When considered as perturbations, these additional terms scatter electrons from one planewave state to another. For a group of parallel, randomly distributed edge dislocations, it is shown, through an iterative evaluation of the Boltzmann equation, that the contribution of these terms to the electrical resistivity of cold-worked Cu is larger than that of the deformation potential and the resulting specific dislocation resistivity is very close to the experimentally established value. The corresponding effect in the presence of grain boundaries (edge dislocation walls) is discussed and the application of these general results to transport in semiconductors is also presented.

Friday, March 22, 2013 8:00AM - 11:00AM –

Session Y22 DCMP: Quantum Solids - He4 324 - Matthias Graf, Los Alamos National Laboratory

8:00AM Y22.00001 Dissipative superfluid mass flux through solid ^{4}He[1] , YEGOR VEKHOV, ROBERT HALLOCK, Dept. of Physics, Univ. of Mass. Amherst — The thermo-mechanical effect in superfluid helium is used to create a chemical potential difference, $\Delta\mu$, across a liquid or solid ^{4}He sample and induce a mass flux. With an improved technique, measurements of the mass flux, F, through a solid-filled sample cell at several fixed helium sample temperatures, T, have been done as a function of $\Delta\mu$. And, measurements of F (in the range $100 < T < 550$ mK) have been done as a function of temperature for several fixed values of $\Delta\mu$. The temperature dependence of the flow through solid helium above 100 mK is confirmed to show a reduction of the flux with increasing temperature, while for liquid helium there is no marked temperature dependence in the temperature range studied. The dependence of F on $\Delta\mu$ documents in some detail the dissipative nature of the flow for the case of a solid helium- filled sample cell. In the case of solid helium we observe $F \sim \Delta\mu^b$ with $b \approx 0.3$, which is consistent with expectations for 1D superfluidity. The relationship between this work and the various torsional oscillator NCRI results is not clear. We may be exploring different phenomena.

8:12AM Y22.00002 Exact Solution for Vortex Dynamics in Temperature Quenches of Two-Dimensional Superfluids[1] , ANDREW FORRESTER, HAN-CHING CHU, GARY WILLIAMS, UCLA — An exact analytic solution for the dynamics of vortex pairs is obtained for rapid temperature quenches of a superfluid film starting from the line of critical points below the critical temperature T_{KT}. An approximate solution for quenches at and above above T_{KT} provides insights into the origin of logarithmic transients in the vortex decay, and are in general agreement with recent simulations of the quenched XY model. These results confirm that there is no "creation" of vortices whose density increases with the quench rate as predicted by the Kibble-Zurek theory, but only monotonic decay of the thermal vortices already present at the initial temperature. The problem in the Kibble-Zurek argument is the artificial restriction to measuring the vortex density only at the "freezeout" sampling time, which increases with the quench time. But since the the pairs continually decay, of course this will always result in lower vortex densities for a longer quench time and hence a later sampling time. But in fact the vortex densities can be measured at all times, and it then becomes quite clear that the instantaneous superfluid quench has the lowest vortex density at all times of any quench rate, since it most rapidly gets to the lowest temperature.

8:24AM Y22.00003 Elasticity, Plasticity and Supersolidity in Solid Helium[1] , JOHN BEAMISH, University of Alberta, ARIEL HAZIOT, ANDREW FEFFERMAN, XAVIER ROJAS, SEBASTIEN BALIBAR, Laboratoire de Physique Statistique de l'ENS — The frequency of a torsional oscillator containing solid helium depends on the helium's elastic properties, as well as its inertia. Mobile dislocations reduce the helium's shear modulus, but they are pinned at low temperatures. The resulting increase in shear stiffness raises the TO frequency and can mimic mass decoupling in a supersolid. The size of this elastic effect depends on the geometry of the oscillator and on the magnitude of the modulus changes. We recently showed that the elastic effect can be large enough to explain the apparent mass decoupling in some oscillators whose torsion rods have a central hole to admit the helium, suggesting that the apparent supersolidity is an artifact due to elastic changes. We have observed extremely large modulus changes in high quality single crystals. We were able to identify the dislocations responsible for the elastic changes and to show that they were arranged in a network with very large pinning lengths. The large modulus changes reflect the dislocations' extremely high mobility at low temperatures, which produces a "giant plasticity" in this quantum crystal.

8:36AM Y22.00004 The giant plasticity in ^{4}He crystals , ARIEL HAZIOT, ANDREW FEFFERMAN, XAVIER ROJAS, Ecole Normale Superieure, JOHN BEAMISH, University of Alberta, SEBASTIEN BALIBAR, Ecole Normale Superieure — We have applied very small shear stresses (down to 1 nanobar) to oriented single ^{4}He crystals, and directly measured their response as a function of temperature (from 15 mK to 1 K), orientation, crystal quality, ^{3}He concentration, frequency and shear stress magnitude. For particular orientations, we have found a giant plasticity that is reversible, associated with the elastic coefficient c_{44} which nearly vanishes around 200 mK. Other elastic coefficients show no measurable anomaly. The strong reduction of c_{44} (80% in high quality crystals with no impurities) shows that dislocations glide in the basal plane of the hexagonal structure with no dissipation. This plasticity disappears as soon as traces of ^{3}He impurities bind to the dislocations (at low T) or if their motion is damped by collisions with thermal phonons (at higher T). It has no equivalent in classical crystals.

8:48AM Y22.00005 Dislocation densities and lengths in solid ^{4}He from elastic measurements[1] , ANDREW FEFFERMAN, ARIEL HAZIOT, Laboratoire de Physique Statistique de l'ENS, JOHN BEAMISH, University of Alberta, SEBASTIEN BALIBAR, Laboratoire de Physique Statistique de l'ENS — Elastic measurements on solid ^{4}He show large softening of the shear modulus due to motion of dislocations, behavior which has been described as quantum plasticity. Dislocation networks may also be responsible for the unusual behavior seen at low temperatures in torsional oscillator and flow experiments. However, existing estimates of dislocation densities in helium crystals vary by many orders of magnitude. By measuring the temperature and frequency dependence of the elastic dissipation, we have determined dislocation densities and network lengths in both single crystals and polycrystals of ^{4}He. The dislocation lengths are much longer than previous estimates, meaning that they are less connected than previously thought. Even in polycrystals, we find no evidence for the large densities of well-connected dislocations which would be needed to explain mass decoupling in torsional oscillators in terms of superfluidity in a dislocation network.

9:00AM Y22.00006 Solid ^{4}He probed by both torsional oscillator and ultrasound[1] , HARRY KOJIMA, Rutgers University, IZUMI IWASA, Kanagawa University, JOHN GOODKIND, UCSD — The interpretation of observed anomalous increases in the frequencies of torsional oscillators (TO) containing solid ^{4}He confined in Vycor nanopores as evidence for emergence of a supersolid phase has been met recently by conflicting experiments. Yet questions remain on the origin of the observed TO anomalies in bulk solid ^{4}He samples. To search for the origin, we are carrying out simultaneous measurements of 10 MHz longitudinal ultrasound and TOs (250 $\sim$ 1100 Hz) on identical solid ^{4}He samples. Temperature dependence of velocity and attenuation of ultrasound and that of amplitude and frequency of TO are measured. At the temperatures, where TO anomalies occur, anomalies in sound velocity and attenuation also appear. When solid ^{4}He is doped with 20 ppm ^{3}He, the tempeature of TO anomaly tracks that of ultrasound. Interpretation of these observations in terms of the motion of dislocation lines will be presented.

9:12AM Y22.00007 Excitations of Amorphous Solid Helium , JACQUES BOSSY, Institut Néel, CNRS-UJF, BP 166, 38042 Grenoble Cedex 9, France, JACQUES OLLIVIER, Institut Laue-Langevin, BP 156, 38042 Grenoble, France, HELMUT SCHOBER, Institut Laue-Langevin, BP 156, 38042 Grenoble, France, Universite Joseph Fourier, UFR de Physique, F38041 Grenoble Cedex 9, France, HENRY R. GLYDE, Department of Physics and Astronomy, University of Delaware — We present neutron scattering measurements of the dynamic structure factor, $S(Q,\omega)$, of amorphous solid helium confined in 47 Å pore diameter MCM-41 at pressure 48.6 bar. At low temperature, $T = 0.05$ K, we observe $S(Q,\omega)$ of the confined quantum amorphous solid plus the bulk polycrystalline solid between the MCM-41 powder grains. No liquid-like phonon-roton modes, other sharply defined modes at low energy ($\omega <$ 1.0 meV) or modes unique to a quantum amorphous solid that might suggest superflow are observed. Rather the $S(Q,\omega)$ of confined amorphous and bulk polycrystalline solid appear to be very similar. At higher temperature ($T > 1$ K), the amorphous solid in the MCM-41 pores melts to a liquid which has a broad $S(Q,\omega)$ peaked near $\omega \simeq 0$ characteristic of normal liquid ^{4}He under pressure. Expressions for the $S(Q,\omega)$ of amorphous and polycrystalline solid helium are presented and compared. In previous measurements of liquid ^{4}He confined in MCM-41 at lower pressure the intensity in the liquid roton mode decreases with increasing pressure until the roton vanishes at the solidification pressure (38 bars), consistent with no roton in the solid observed here

9:24AM Y22.00008 Plasticity and dislocation-induced anomalous softening of solid helium under DC shea , IRENE BEYERLEIN, CAIZHI ZHOU, Los Alamos National Laboratory, JUNG-JUNG SU, Stanford University, MATTHIAS GRAF, CHARLES REICHHARDT, ALEXANDER BALATSKY, Los Alamos National Laboratory — The classical motion of gliding dislocation lines in slip planes of crystalline solid helium leads to plastic deformation even at temperatures far below the melting temperature and strongly affects elastic properties. In this work we propose that the gliding of dislocations and plasticity may be the origin of many observed elastic anomalies in solid He-4, which have been argued to be connected to supersolidity. We present and propose a dislocation motion model that describes the stress-strain τ–ε curves and work-hardening rate $\tau/\mathrm{d}\varepsilon$ of a DC shear experiment to be performed at constant strain rate in solid helium. The calculated $\tau/\mathrm{d}\varepsilon$ exhibits strong softening with increasing temperature owing to the motion of dislocations, which mimics anomalous softening of the elastic shear modulus μ. In the same low-temperature region the classical motion of dislocations causes dissipation with a prominent peak [1] [1] C. Zhou et al., Philos. Mag. Lett. 92 (2012) 608

9:36AM Y22.00009 Simultaneous measurements of the torsional oscillator and shear modulus of solid 4He diluted with various 3He concentration[1] , JAEHO SHIN, WONSUK CHOI, JAEWON CHOI, SEONG JANG, Center for Supersolid & Quantum Matter Research and Department of Physics, KAIST, Daejeon 305-701, Republic of Korea, KEIYA SHIRAHAMA, Department of Physics, Keio University, Yokohama 223-8522, Japan, EUNSEONG KIM, Center for Supersolid & Quantum Matter Research and Department of Physics, KAIST, Daejeon 305-701, Republic of Korea — In 2004, Kim and Chan observed the non-classical rotational inertia (NCRI) of solid helium-4 by using a torsional oscillator (TO). Below 200mK, the resonance period of solid helium dropped, which was originally interpreted as the mass decoupling of the fraction of solid helium. Recently, anomalous increase in the shear modulus of solid helium was found and showed striking similarity in temperature, frequency, 3He concentration, and drive dependence to those of the NCRI [2]. To understand the connection between the NCRI and the shear modulus anomaly, we simultaneously measure the change in the resonance frequency and the stiffness of solid helium below 200mK. The torsion cell contains a pair of the concentric piezoelectric transducers (PZT) which defines an annular channel for the simultaneous measurements. We will report the interference between the motion of the TO at resonance and AC motion of the PZT in solid 4He with different 3He concentration.

9:48AM Y22.00010 ^{4}He adsorption on α-graphyne[1] , YONGKYUNG KWON, HOONKYUNG LEE, Konkuk University, Seoul, KOREA, DAVID M. CEPERLEY, University of Illinois at Urbana-Champaign, IL61801, U.S.A. — Path-integral Monte Carlo calculations have been performed to study ^{4}He adsorption on a single α-graphyne sheet that is a hexagonal network of sp- and sp^2-bonded carbon atoms. Using the ^{4}He-substrate interaction described by a pairwise sum of the helium-carbon inter-atomic potentials, we have found that each hexagon of a graphyne can accomodate one ^{4}He atom at its in-plane center. The first layer of ^{4}He atoms adsorbed on this ^{4}He-attached graphyne sheet with a composite of C_8He_1, exhibits various quantum phases depending on the helium coverage. It is found to be in a Mott insulating state at a coverage of 0.0706 Å^{-2} with three ^{4}He atoms occupying each unit cell while the helium atoms form a commensurate triangular solid at 0.0941 Å^{-2}. With the introduction of Ising pseudospins for two degenerate configurations of three ^{4}He atoms in a hexagonal cell, the transition from the Mott insulator to the triangular solid can be interpreted as a ferromagnetic transition. In addition we find stable formation of zero-point vacancies in the commensurate triangular solid and their roles in possible realization of supersolidity are under investigation

10:00AM Y22.00011 Pursuit of the Elusive Supersolid[1] , XIAO MI, JOHN D. REPPY, Cornell University — The excitement following the initial report of supersolid behavior for ^{4}He embedded in porous Vycor glass has been tempered by the realization that many of the early supersolid observations were contaminated by effects arising from an anomaly in the elastic properties of solid ^{4}He. In an attempt to separate dynamic elastic effects from a true supersolid signal, we employed a torsional oscillator with two eigen frequencies to study the ^{4}He-Vycor system. We found that frequency dependent elastic signals can entirely account for the observed period shift signals. Although, we conclude that supersolid does not exist for the ^{4}He-Vycor case, the question of its presence in bulk samples remains open. In our current experiments we apply the two-frequency test to bulk samples of solid ^{4}He. Again we find a frequency dependent contribution arising from elastic effects. However, in some cases we also find a small frequency independent contribution, which may indicate the existence of a remnant supersolid phase. Given the history of this subject such results must be treated with caution.

10:12AM Y22.00012 An Ordered State of Dislocations in Solid Helium , HANS JOCHEN LAUTER, Oak Ridge National Laboratory, ECKHARD KROTSCHECK, University at Buffalo-SUNY, EFIM KATS, Landau Institute for Theoretical Physics, KENNETH HERWIG, ANDREY PODLESNYAK, DIALLO SOULEYMANE, Oak Ridge National Laboratory, GLYDE HENRY, University of Delaware, ANDREII SAVICI, Oak Ridge National Laboratory — An ordered state of dislocations, see e.g. [1], is disclosed from neutron inelastic scattering data taken from solid helium at 40mK and a pressure of about 30bar. A characteristic feature is the phonon gap at the origin of about 0.15 meV, which reveals the non-equilibrium state of stressed helium created by rapid cooling with the blocked-capillary method. Energy gain scattering starts to appear at a temperature of 0.5 K that underlines the non-equilibrium state of stressed helium and the non-applicability of the detailed balance. The increasing thermal occupation of phonon-states observed as increasing intensity in energy gain scattering builds to a phase transition close to 1.4K. The creation of a helium single crystal with hcp-structure in thermal equilibrium [2] is observed at this temperature. This phase transition is in agreement with the vanishing quasi two-dimensional superfluid helium in solid helium confined in aerogel around 1.3K [3]. The event of the "supersolid" transition around 100mK is not observed in the two neutron scattering experiments.

10:24AM Y22.00013 Stability limit of a metastable state of hcp solid helium-4 , FABIEN SOURIS, JULES GRUCKER, JACQUES DUPONT-ROC, PHILIPPE JACQUIER, Laboratoire Kastler Brossel, ENS/CNRS/Universite Paris 6, 24 rue Lhomond, Paris 75005, France, ATOMES DANS MONOCRISTAUX TEAM — Solid helium has the unique feature of having an horizontal melting curve in the P,T plane. This offers novel opportunities to study the stability limits of a metastable solid, by using the pressure as a control parameter of the metastability. The metastable state is obtained by focusing a 1 MHz ultrasonic sound wave inside an helium-4 crystal. Around 4 bar below the melting pressure, the metastable crystal becomes unstable. Different configurations with one or two ultrasonic emitters have been used and lead to the same stability limit. This happens at much lower depression than predicted by nucleation theory or by quantum Monte Carlo simulations. Repeated experiments show that the instability initially appears as a small defect (~ 0.2 mm) located at the maximum isotropic strain. Further studies are performed to understand the underlying mechanism of the instability. Possible scenarios accounting for this unexpected observation are discussed.

10:36AM Y22.00014 Path-Integral Monte Carlo Simulations of Ideal Strength and Peierls Stress in HCP 4He , EDGAR JOSUÉ LANDINEZ BORDA, MAURICE DE KONING, Instituto de Física Gleb Wataghin, Universidade Estadual de Campinas, UNICAMP — The ideal strength of a crystal is defined as the stress required to induce plastic deformation in a defect-free crystal. It is a theoretical upper bound to the strength of real crystals. The Peierls stress, on the other hand, is the minimum stress required to move a lattice dislocation and produce defect-mediated deformation. Here we present results for both quantities in HCP 4He as obtained from a series of Path-integral Monte Carlo simulations and discuss them in terms of its deformation behavior.

10:48AM Y22.00015 Superfluid transition in a correlated dislocation network[1] , HANNES MEIER, MATS WALLIN, KTH, Stockholm, Sweden, STEPHEN TEITEL, University of Rochester — The search for a supersolid state in He-4 solids has motivated theoretical investigations of 3D connected superfluid dislocation networks. It has usually been assumed that a 3DXY universality class controls the superfluid transition in such systems since the random distance between intersections of the dislocation lines carrying superfluidity appears as uncorrelated disorder which is irrelevant at the 3DXY transition. We consider the possibility that the random disorder instead has long range correlations, and investigate several different models of correlated defects. Analytic arguments and extensive Monte Carlo simulations demonstrate new disordered universality classes for the superfluid transition with a smooth temperature dependence at the transition of the superfluid density and heat capacity.

Session Y23 FIAP: Semiconductors: Thermodynamic & Optical Properties I 325 - Andre Sushkov, University of Maryland

8:00AM Y23.00001 Temperature Dependence of Band Gaps in Semiconductors: Electron-Phonon Interaction , J.S. BHOSALE, A.K. RAMDAS, Purdue University, West Lafayette, IN, USA, A. BURGER, Fisk University, Nashville, TN, USA, A. MUÑOZ, Universidad de La Laguna, Tenerife, Spain, A.H. ROMERO, Max Planck Institut, Halle, Germany, M. CARDONA, R. LAUCK, R.K. KREMER, Max Planck Institut, Stuttgart, Germany — A theoretical investigation with *ab initio* techniques of the electron-phonon interaction of semiconductors with chalcopyrite structure and its comparison with modulated reflectivity experiments yield a striking difference between those with ($AgGaS_2$) and without ($ZnSnAs_2$) d electrons in their valence bands. The former exhibit a non-monotonic temperature dependence of the band gaps whose origin is not yet fully understood. The analysis of this temperature dependence with the Bose-Einstein oscillator model[1] involving two oscillator terms having weights of opposite signs, provides an excellent agreement with the experimental data and correlates well with the characteristic peaks in the phonon density of states associated with the acoustical phonon modes. This work underscores the need for theoretical understanding of the electron-phonon interaction involving d electrons, particularly in *ab initio* investigations.

8:12AM Y23.00002 ABSTRACT WITHDRAWN –

8:24AM Y23.00003 The Franz-Keldysh effect revisited: Electroabsorption in GaAs including interband coupling and excitonic effects , FEDERICO DUQUE-GOMEZ, J.E. SIPE, Department of Physics, University of Toronto — We show numerical results for the linear optical absorption of bulk GaAs in the presence of a homogeneous dc electric field. Our approach, based on gauge-invariant nonequilibrium Green functions [1], is suitable for including many-body effects and using realistic band models. We calculate the time evolution of the interband polarization driven by an optical pulse and derive the absorption coefficient from it. The interband effects of the dc field are captured in a matrix transform in the band indices, which satisfies a differential equation solved efficiently in a separate numerical calculation. For the present calculation we have used a 14-band $\mathbf{k}\cdot\mathbf{p}$ model and treated excitonic effects at a Hartree-Fock level. Previous calculations in the independent particle approximation have shown interesting effects of the band structure and the importance of the interband coupling.[2] We describe the effect of including the Coulomb interaction, which is especially relevant in low temperature and low field experiments. 8:36AM Y23.00004 Photoreflectance and Strain Relaxation Studies of Semipolar InGaN , GRACE METCALFE, NATHANIEL WOODWARD, HONGEN SHEN, MICHAEL WRABACK, U.S. Army Research Laboratory, PO SHAN HSU, JAMES SPECK, University of California, Santa Barbara — Recently, there has been a surge of interest in semipolar nitride material for quantum well devices to reduce or eliminate the quantum confined stark effect due to the strong internal polarization. Studies on the effect of the strain relaxation in semipolar nitrides are critical to the successful development and operation of long wavelength devices such as LEDs and LDs. In general, the wavefunctions associated with the A, B, and C exciton transitions in wurtzite material are mixed for crystal orientations other than c-plane. Therefore, the polarization and energy of these exciton interband transitions within wurtzite nitrides also depend on the strain and crystal orientation. In this paper, we present the effects of partial strain relaxation on the optical properties of a thickness series of semipolar (11-22) and (20-21) InGaN compressively strained to GaN using polarization-dependent photoreflectance (PR) measurements. We observe that the absolute energy of the exciton transition parallel to the c-axis is greater than that perpendicular to the c-axis, and the energy separation between them increases with strain relaxation. Our PR data compares well with strain relaxation measurements taken using X-ray diffraction, as well as with our calculations.

8:48AM Y23.00005 X-ray induced optical transparency and x-ray/optical photon interactions in GaAs[1] , STEPHEN DURBIN, Department of Physics, Purdue University, TIM GRABER, ROB HENNING, Center for Advanced Radiation Sources, University of Chicago — An intense x-ray synchrotron pulse transforms a thin crystal of GaAs from being opaque to transparency in picoseconds for probe photon energies near the band gap energy. X-ray absorption and subsequent de-excitation processes pump a high density of electrons from the valence band into the conduction band, causing Pauli blocking of the band gap photons and hence their transmission through the bulk of the specimen. Although the GaAs photocarrier lifetime is less than 300 ps, the transmission decay time constant was as large as 2000 ps when the laser intensity was increased, an effect that can be partially understood in terms of photobleaching and the depth of x-ray absorption. Finally, the excess transmission of band gap photons due to high laser intensity could be suppressed by the onset of the x-ray pulse, evidence for x-ray quenching of laser hole burning. These effects are manifestations of x-ray/optical photon interactions mediated by their conduction band excitations in GaAs.

9:00AM Y23.00006 Exciton absorption of entangled photons in semiconductor quantum wells[1] , FERNEY RODRIGUEZ, DAVID GUZMAN, LUIS SALAZAR, LUIS QUIROGA, Universidad de los Andes, CONDENSED MATTER PHYSICS GROUP TEAM — The dependence of the excitonic two-photon absorption on the quantum correlations (entanglement) of exciting biphotons by a semiconductor quantum well is studied. We show that entangled photon absorption can display very unusual features depending on space-time-polarization biphoton parameters and absorber density of states for both bound exciton states as well as for unbound electron-hole pairs. We report on the connection between biphoton entanglement, as quantified by the Schmidt number, and absorption by a semiconductor quantum well. Comparison between frequency-anti-correlated, unentangled and frequency-correlated biphoton absorption is addressed. We found that exciton oscillator strengths are highly increased when photons arrive almost simultaneously in an entangled state. Two-photon-absorption becomes a highly sensitive probe of photon quantum correlations when narrow semiconductor quantum wells are used as two-photon absorbers.

9:12AM Y23.00007 Localized-delocalized transitions in GaAsN , KIRSTIN ALBERI, BRIAN FLUEGEL, National Renewable Energy Laboratory, SCOTT CROOKER, National High Magnetic Field Laboratory, Los Alamos, DANIEL BEATON, AARON PTAK, ANGELO MASCARENHAS, National Renewable Energy Laboratory — Dilute nitride semiconductors are promising materials for high efficiency multijunction solar cells and light emitting diodes, yet they exhibit an unusual evolution of their optical and electronic properties as they transition from an impurity-doped semiconductor into an alloy upon the addition of N. For example, a significant change in the photoluminescence spectrum of GaAsN is accompanied by a rapid increase in the broadening parameters of the E_0 and E_1 critical point transitions in electromodulated reflectance spectra as the N concentration is increased from 0.12% N to 0.32% N. We demonstrate that these changes result from the percolation of localized N cluster states bound below the conduction band into fully extended superclusters and the emergence of a mobility edge. Furthermore, photoluminescence studies show that we are able to reverse this localized to delocalized transition through the application of high magnetic fields to 57 tesla. These experimental results provide new insight into the percolation behavior of isoelectronic cluster states in semiconductor alloys.

9:24AM Y23.00008 A Tunable Terahertz Detector Based On Self Assembled Plasmonic Structure on a GaAs 2DEG , CHEJIN BAE, DEEPU GEORGE, ROHIT SINGH, ANDREA MARKELZ, SUNY Buffalo, DEPARTMENT OF PHYSICS, UNIVERSITY AT BUFFALO, THE STATE UNIVERSITY OF NEW YORK TEAM — To improve detector sensitivity, tunability and remove polarization dependence, we develop the gated grid plasmonic structure on 2DEG by using nanosphere self-assembly lithography. The measured transmission clearly is not following Drude response, but rather has three sharp resonances corresponding fundamental, 3rd, and 5th harmonics of plasmon resonance respectively. Measurements at 80K show a large transmission change of 25%. We also confirmed a magneto plasmon dispersion of this device. In this paper we will discuss the radiative damping effect which affects enhanced absorption at the higher harmonics mode relative to fundamental [1] and inductive grid resonance of this self-assembled plasmonic structure by demonstrating an angular dependence of transmission due to 2D plasmon[2]. 9:36AM Y23.00009 Electron-hole sound: Observation of coherent acoustic plasmons in photoexcited GaAs , PRASHANT PADMANABHAN, STEVE YOUNG, MEREDITH HENSTRIDGE, SISHIR BHOWMICK, PALLAB BHATTACHARYA, ROBERTO MERLIN, The University of Michigan — Three-dimensional multi-component plasmas involving species with very different masses are expected to show a new branch of charge density fluctuations with a frequency dispersion that is linear with respect to the wave vector [1]. Not to be confused with similarly named modes of metallic surfaces [2], these bulk excitations are known as *acoustic plasmons*. In the past, they have been identified in some gas plasmas [3] and, notably, also in electron-hole plasmas in GaAs via spontaneous Raman scattering [4]. Here, we present the first observation of *coherent* acoustic plasmons in photoexcited GaAs. We utilize an ultrafast double pump-probe scheme to probe, in the time domain, the oscillations in the sample reflectivity associated with these modes. Results agree well with theoretical calculations based on the random phase approximation. The data also suggests that the coherent acoustic oscillation is driven by the interaction with modes resulting from the coupling between the longitudinal-optical-phonons and the conventional optical plasmons of the electrons. Pinczuk, J. Shah, and P. A. Wolff, Phys. Rev. Lett. 47, 1487 (1981).

9:48AM Y23.00010 Polarization and Interface Effects on THz Emission from c-plane InGaN/GaN Heterostructures , NATHANIEL WOODWARD, CHAD GALLINAT, RYAN ENCK, GRACE METCALFE, HONGEN SHEN, MICHAEL WRABACK, U.S. Army Research Laboratory — Nitride semiconductors have strong piezoelectric and spontaneous polarizations, which, when terminated at a heterointerface, create a large internal electric field. This field enables transport-based THz radiation with intensities comparable to that from conventional contactless semiconductor surface emitters such as InAs. We observed THz emission from 200-nm thick c-plane InGaN coherently strained to various doped GaN substrates due to photocarrier acceleration toward the surface in the field resulting from the polarization charge at the InGaN/GaN interface. We compare THz emission from the samples pumped from the substrate side as well as the epilayer side such that diffusive and polarization field-induced transport were in the same and opposite directions, respectively. When pumped from the substrate side, we observed several spectral features that did not appear when pumping the InGaN surface. These features may be attributed to effects from the InGaN/GaN heterointerface.

10:00AM Y23.00011 Helicity-dependent photocurrent in a (110) GaAs quantum well stack , D.C. SCHMADEL, M.-H. KIM, A.B. SUSHKOV, G.S. JENKINS, Department of Physics, University of Maryland (Physics-UMD), J.D. KORALEK, Lawrence Berkeley National Lab (LBNL), J.E. MOORE, J. ORENSTEIN, University of California Berkeley, and LBNL, YUZO OHNO, HIDEO OHNO, Research Institute of Electrical Communication, Tohoku University, Japan, H.D. DREW, Physics-UMD — There have been many reports on the circular photogalvanic effect (CPGE) in GaAs quantum wells. A recent theoretical study suggests that the CPGE can be governed by a quantum confinement-induced Berry phase effect that depends only on the quantum-well width and crystal orientation (J.E. Moore, Phys. Rev. Lett. 2010). We have measured the photocurrent in a (110)-oriented GaAs quantum well stack under illumination of circularly polarized THz radiation. We will report measurements of the helicity-driven photocurrent as a function of frequency, polarization, angle of incident, and temperature, and compare with theoretical predictions of the Berry phase contribution.

10:12AM Y23.00012 Direct-Indirect Crossover in $Ga_xIn_{1-x}P$ Alloys , ANGELO MASCARENHAS, KIRSTIN ALBERI, BRIAN FLUEGEL, National Renewable Energy Laboratory — Advances in metamorphic growth of high quality $Ga_xIn_{1-x}P$ ($x > 0.5$) on GaAs substrates have improved the practicality of using these alloys in visible light emitting diodes and lasers. The wavelength range over which these materials are efficient light emitters is determined by the direct-indirect crossover energy, yet considerable discrepancies still remain in the literature regarding the precise crossover composition, x_C. We revisit this topic and present new experimental results that precisely pinpoint the crossover composition without extrapolation of the direct and indirect bandgap trends. Observation of concurrent yet distinct direct and indirect transitions in the 2 K time integrated and time resolved photoluminescence spectra of disordered $Ga_{0.719}In_{0.281}P$ films places the crossover very near the composition $x_C = 0.71$. This revised value is critical for facilitating realistic engineering of $Ga_xIn_{1-x}P$ alloys for light emitting and photovoltaic applications.

10:24AM Y23.00013 Temperature Dependent Dielectric Functions of MBE-grown GaMnAs Thin Films , F.C. PEIRIS, Z.J. WEBER, N. MANDEL, T. SCULLY, Kenyon College, X. LIU, J.K. FURDYNA, University of Notre Dame — Spectroscopic ellipsometry was used to measure the dielectric functions of a series of $Ga_{1-x}Mn_xAs$ samples from 20 K to 300 K. Initially, by modeling the ellipsometric data in the transparent region, the film thickness and the index of refraction of $Ga_{1-x}Mn_xAs$ alloys were obtained. Extending the analysis into the absorption region, the dielectric function for the entire spectral range between 0.6 eV and 6.5 eV was determined. Monitoring the temperature dependence of the critical points, corresponding to electronic transitions in the Brillouin zone, we deduced the electron-phonon coupling parameters using Bose-Einstein occupation distributions. In comparison to GaAs, we find that the ternary alloy $Ga_{1-x}Mn_xAs$ shows a slight enhancement in its electron-phonon coupling.

10:36AM Y23.00014 Enhanced THz emission from stacked $+c$-plane InGaN/GaN heterostructures grown by plasma-assisted molecular beam epitaxy , CHAD GALLINAT, NATHANIEL WOODWARD, RYAN ENCK, GRACE METCALFE, HONGEN SHEN, MICHAEL WRABACK, US Army Research Laboratory — We have previously demonstrated THz emission in a single, fully-strained 200 nm InGaN layer grown on GaN. This emission was due to the acceleration of electrons toward the surface in the piezoelectric polarization charge-induced electric field. We observed a reduction in the THz emission from a fully relaxed InGaN layer where the piezoelectric polarization was removed. In order to increase the InGaN layer thickness to maximize the absorption of the excitation pulse, we introduced GaN spacers to limit strain relaxation. We observed an increase in THz emission strength from samples with three stacks of coherently strained 100 nm/10 nm InGaN/GaN layers over the emission from single layer structures. We explored the balance of In alloy content, InGaN layer thickness and InGaN layer strain to maximize the piezoelectric polarization for enhanced THz emission.

10:48AM Y23.00015 Optical spectroscopies of materials from orbital-dependent approximations , ISMAILA DABO, Ecole des Ponts ParisTech, ANDREA FERRETTI, CNR Istituto Nanoscienze, MATTEO COCOCCIONI, University of Minnesota, NICOLA MARZARI, Ecole Polytechnique Federale de Lausanne — Electronic-structure calculations based upon density-functional theory (DFT) have been fruitful in diverse areas of materials science. Despite their exceptional success and widespread use, a range of spectroscopic properties fall beyond the scope of existing DFT approximations. Failures of DFT calculations in describing electronic and optical phenomena take root in the lack of piecewise linearity of approximate functionals. This known deficiency reverberates negatively on the spectroscopic description of systems involving fractionally occupied or spatially delocalized electronic states, such as donor-acceptor organic heterojunctions and heavy-metal organometallic complexes. In this talk, I will present a class of orbital-dependent density-functional theory (OD-DFT) methods that are derived from a multidensity formulation of the electronic-structure problem and that restore the piecewise linearity of the total energy via Koopmans' theorem. Such OD-DFT electronic-structure approximations are apt at describing full orbital spectra within a few tenths of an electron-volt relative to experimental photoemission spectroscopies and with the additional benefit of providing appreciably improved total energies for molecular systems with fractional occupations.

Session Y24 DCOMP: Focus Session: Advances in Fermionic Simulatons 326 -

8:00AM Y24.00001 Determinantal Quantum Monte Carlo simulations of fermions in optical lattices[1] , THEREZA PAIVA, Universidade Federal do Rio de Janeiro — The ability to cool fermions in optical lattices to ultra cold temperatures has led to an interdisciplinary area of research, that has attracted a lot of attention in recent years. An interesting development in this area is the possibility to realize models for strongly correlated fermions in the laboratory, such as the fermionic Hubbard Model. Determinantal Quantum Monte Carlo simulations have proven to be an important tool in the study of fermionic atoms. Nonetheless, it is important to compare the results and efficiency of different methods. Here comparisons with Numerical Linked Cluster Expansion and Dynamical Mean Field Theory data for double occupation and short range correlations, both relevant to current optical lattice experiments, will be presented and discussed. Another topic relevant in the context of optical lattice experiments is the study of metal insulator transitions. Indeed, the Mott insulating phase has been realized and observed in two-flavor mixtures of fermionic atoms loaded on optical lattices, being characterized both by the double occupation and the compressibility. An interesting point that has been addressed in the literature over the years is whether the same fermion-fermion interaction, responsible for the Mott insulating state, could drive an insulating system metallic. Here we show that, when fermions are loaded in optical lattices with spatially varying interactions a correlation induced Mott insulator to metal transition can take place. The spatial modulation of the interactions was recently demonstrated and opens the possibility for the experimental realization of such exotic phases.

8:36AM Y24.00002 Quantum Monte Carlo Calculations of Entanglement[1] , NORM TUBMAN, JEREMY MCMINIS, University of Illinois Urbana-Champaign — Spatial entanglement properties have become increasingly important in physics which includes studies in diverse fields such as condensed matter physics, astrophysics, and quantum computation. One of the important outstanding problems in the field of entanglement is to understand the effect of many body interactions. Recent advances in quantum Monte Carlo have facilitated such studies over a range of Hamiltonians that were previously inaccessible by other techniques. We apply these techniques to interacting molecular and condensed matter systems and discuss the effect interactions have on entanglement properties.

8:48AM Y24.00003 Excited state calculations in solids by auxiliary-field quantum Monte Carlo[1] , FENGJIE MA, SHIWEI ZHANG, HENRY KRAKAUER, College of William and Mary — We present an approach for ab initio many-body calculations of excited states in solids. Using auxiliary-field quantum Monte Carlo [2], we introduce an orthogonalization constraint with virtual orbitals to prevent collapse of the stochastic Slater determinants in the imaginary-time propagation. Trial wave functions from density-functional calculations are used for the constraints, and detailed band structures can be calculated. Results for standard semiconductors are in good agreement with GW calculations and with experiment. For the challenging ZnO, we obtain a fundamental band gap of 3.30(16) eV, consistent within the range of experimental measurements [3]. Applications to other systems are currently underway.

9:00AM Y24.00004 Bold Diagrammatic Monte Carlo for Fermionic and Fermionized Systems[1]

, BORIS SVISTUNOV, University of Massachusetts, Amherst — In three different fermionic cases—repulsive Hubbard model, resonant fermions, and fermionized spins-1/2 (on triangular lattice)—we observe the phenomenon of sign blessing: Feynman diagrammatic series features finite convergence radius despite factorial growth of the number of diagrams with diagram order. Bold diagrammatic Monte Carlo technique allows us to sample millions of skeleton Feynman diagrams. With the universal fermionization trick we can fermionize essentially any (bosonic, spin, mixed, etc.) lattice system. The combination of fermionization and Bold diagrammatic Monte Carlo yields a universal first-principle approach to strongly correlated lattice systems, provided the sign blessing is a generic fermionic phenomenon.

9:36AM Y24.00005 Path Integral Quantum Monte Carlo Benchmarks for Molecules and Plasmas[1]

, JOHN SHUMWAY, Arizona State University — Path integral quantum Monte Carlo is used to simulate hot dense plasmas and other systems where quantum and thermal fluctuations are important. The fixed node approximation—ubiquitous in ab initio ground state Quantum Monte Carlo—is more complicated at finite temperatures, with many unanswered questions. In this talk I discuss the current state of fermionic path integral quantum Monte Carlo, with an emphasis on molecular systems where good benchmark data exists. We look at two ways of formulating the fixed node constraint and strategies for constructing finite-temperature nodal surfaces. We compare different the free energies of different nodal choices by sampling an ensemble of nodal models within a Monte Carlo simulation. We also present data on imaginary-time correlation fluctuations, which can be surprisingly accurate for molecular vibrations and polarizabilty.

9:48AM Y24.00006 Quantum Monte Carlo simulations of complex Hamiltonians[1]

, VALERY ROUSSEAU, KALANI HETTIARACHCHILAGE, KA-MING TAM, JUANA MORENO, MARK JARRELL, Louisiana State University — In the last two decades there have been tremendous advances in boson Quantum Monte Carlo methods, which allow for solving more and more complex Hamiltonians. In particular, it is now possible to simulate Hamiltonians that include terms that couple an arbitrary number of sites and/or particles, such as six-site ring-exchange terms. These ring-exchange interactions are crucial for the study of quantum fluctuations on highly frustrated systems. We illustrate how the Stochastic Green Function algorithm with Global Space-Time Update can easily simulate such complex systems, and present some results for a highly non-trivial model of bosons in a pyrochlore crystal with six-site ring-exchange terms.

10:00AM Y24.00007 Quasi-adiabatic Quantum Monte Carlo algorithm for non-equilibrium quantum phase transitions[1]

, CHENG-WEI LIU, ANDERS W. SANDVIK, ANATOLI POLKOVNIKOV, Department of Physics, Boston University — We investigate a new quantum Monte Carlo algorithm for studying static and dynamic properties of quantum phase transitions. The method, called the quasi-adiabatic quantum Monte Carlo algorithm, is based on evolution with a changing Hamiltonian to derive information pertinent to a quantum quench according to an arbitrary protocol. We demonstrate the method with results for 1D and 2D transverse-field Ising models, showing finite-size and finite-velocity scaling according to a generalization of the Kibble-Zurek mechanism. We explore ways to extract critical points and critical exponents to high precision.

10:12AM Y24.00008 Ground state phases in the half-filled staggered π-flux Hubbard model on square lattices[1]

, CHIA-CHEN CHANG, RICHARD T. SCALETTAR, Department of Physics, University of California, Davis — Ground state phase diagram of the half-filled staggered π-flux Hubbard model on a square lattice are studied by means of constrained-path quantum Monte Carlo method. Charge and spin excitation gaps and magnetic order are calculated as a function of interaction strength U/t. Within our numerical scheme, it is found that the ground state phase is a semi-metal at $U/t < 5.6$, and a Mott insulator with long-range antiferromagnetic order at $U/t > 6.6$. In the window $5.6 < U/t < 6.6$, the system is an insulator in which both magnetic and dimer orders are absent. Spin excitation in the intermediate phase appears to be gapless, and the measured equal-time spin-spin correlation function shows a power-law dependence of relative distance. Our data suggests that the paramagnetic insulating intermediate phase might be a possible place to look for the putative algebraic spin liquid.

10:24AM Y24.00009 Momentum-dependent pseudogaps in the half-filled two-dimensional Hubbard model

, NILS BLUEMER, DANIEL ROST, ELENA GORELIK, Institute of Physics, Johannes Gutenberg University, Mainz, Germany, FAKHER ASSAAD, Institute of Theoretical Physics and Astrophysics, Julius Maximilian University, Würzburg, Germany — We compute unbiased spectral functions of the two-dimensional Hubbard model by extrapolating Green functions, obtained from determinantal quantum Monte Carlo simulations, to the thermodynamic and continuous time limits. Our results clearly resolve the pseudogap at weak to intermediate coupling, originating from a momentum selective opening of the charge gap. A characteristic pseudogap temperature T^*, determined consistently from the spectra and from the momentum dependence of the imaginary-time Green functions, is found to match the dynamical mean-field critical temperature, below which antiferromagnetic fluctuations become dominant. Our results identify a regime where pseudogap physics is within reach of experiments with cold fermions on optical lattices.

D. Rost, E. V. Gorelik, F. Assaad, N. Blümer, Phys. Rev. B **86**, 155109 (2012).

10:36AM Y24.00010 Series Expansion for the Green's Function of the Infinite-U Hubbard Model

, EHSAN KHATAMI, University of California, Santa Cruz / Georgetown University, EDWARD PEREPELITSKY, B. SRIRAM SHASTRY, University of California, Santa Cruz, MARCOS RIGOL, Pennsylvania State University — We implement computationally a strong-coupling expansion for the dynamical single-particle Green's function of the infinite-U Hubbard model up to the eighth order in the hopping, within the formalism introduced by Metzner [1]. We obtain analytical expressions for the finite Matsubara frequency Green's functions and the Dyson self energy in the momentum space at all densities in the thermodynamic limit. The results match those obtained up to the fourth order by means of another method devised by us. Furthermore, we employ Pade approximations and various numerical re-summation techniques to extend the region of convergence to lower temperatures.

Session Y25 DCOMP: Focus Session: Novel Theories and Methods in Computational Physics

327 - Rajamani Narayanan, Florida International University

8:00AM Y25.00001 Beyond standard model physics using lattice techniques , ARI HIETANEN, CP3-Origins, University of Southern Denmark — I will review the recent results of beyond standard model lattice calculations. The focus is on the models of dynamical electroweak symmetry breaking, Technicolor, and dark matter. A lot of effort has been devoted to finding out which models are conformal and which exhibit a chiral symmetry breaking. Lately also phenomenologically interesting observables, like mass anomalous dimension, glueball spectrum, and a contribution to scalar meson mass, have been calculated. I will briefly comment about the implications of these calculations to the phenomenology.

8:36AM Y25.00002 Conformal and near-conformal field theories , ANNA HASENFRATZ[1], University of Colorado Boulder — Non-Abelian gauge fermion systems could be chirally broken and confining or conformal, depending on the number of fermions and their representation. Models near the conformal boundary are important as they could be relevant in describing physics beyond the Standard Model. These models are strongly coupled and require non-perturbative investigations. Lattice techniques that were developed for QCD studies can be used to simulate these systems but there is growing evidence that new observables, new approaches are needed to study the properties of conformal or near conformal models. In this talk I will briefly summarize the most promising models and describe some standard and some promising new methods to study their properties.

[1]Department of Physics

9:12AM Y25.00003 Gradient corrections to finite-temperature exchange-correlation functionals[1] , TRAVIS SJOSTROM, JAMES DUFTY, University of Florida — In principle, the only approximation in Kohn-Sham DFT is for the exchange-correlation (XC) energy. As such, about 40 years of development for the zero-temperature XC density functional has resulted in a ladder of functionals from simple LDA (based on essentially exact QMC results) to orbital-dependent functionals including virtuals. The non-zero temperature situation is different. To date, a handful of $T \neq 0$ K XC functionals have been introduced based on approximate electron gas calculations or interpolations. Except for a finite-T gradient expansion of X, all are local density approximations. Here we present calculations for the XC energy of the electron gas in the dielectric formalism, specifically with approximate local field corrections (LFC). Analysis of the LCF is used to evaluate the first term of the gradient expansion of the XC energy in the slowly varying limit. The resulting gradient expansion finite temperature XC functional will be presented and possible generalized gradient approximations will be considered.

9:24AM Y25.00004 High-Throughput Investigation of Delafossite materials[1] , BARRY HAYCOCK, M. KYLEE UNDERWOOD, Department of Physics, West Virginia University, WV26506, United States, JONATHAN LEKSE, CHRISTOPHER MATRANGA, The National Energy Technology Laboratory, Pittsburgh, PA 15236, United States, JAMES P. LEWIS, Department of Physics, West Virginia University, WV26506, United States — We present the application of high-throughput calculations to the intriguing problem of the forbidden optical transition in the $CuGa_{1-x}Fe_xO_2$ delafossites, which is prototypical of many delafossite systems. When 5% or more of the Ga sites are replaced with Fe, there is a sudden shift to an optical band gap of 1.5eV from 2.5eV. Using high-throughput calculations and data mining techniques, we show the most likely positional configurations for x = 0.00 through x = 0.10 of the Fe atoms relative to one another. Implications of this result and applications of the techniques used are discussed, including the development of candidate materials via high-throughput analysis of constituent search-space.

[1]Funded by the National Science Foundation through NSF DMR 09-03225 and a subcontract from NETL (URS RES) for Work Activity 0004000.6.600.007.002.420.000.005 ARRA ICMI Project.

9:36AM Y25.00005 Classical representation of quantum systems at equilibrium[1] , SANDIPAN DUTTA, JAMES DUFTY, University of Florida — A classical system has been constructed that reproduces the thermodynamics of a quantum system at equilibrium.The classical system has an effective temperature, local chemical potential, and pair interaction that are defined by requiring equivalence of the pressure, density and pair correlation functions for the classical and quantum systems. The thermodynamic parameters of the classical system are determined such that the ideal gas and weak coupling RPA limits are preserved. The pair correlations predicted from this model are in excellent agreement with Diffusion Monte Carlo results at $T = 0$ and with the finite-temperature results from the Perrot-Dharmawardana model [1]. Systems in harmonic confinement have also been studied to look into the quantum effects on shell formation. [1] M. W. C. Dharma-wardana and F. Perrot, Phys. Rev. Lett. 84, 959 (2000).

[1]US DOE Grant DE-SC0002139.

9:48AM Y25.00006 Phase Diagram and Isentropic Curves for Ferromagnetic and Antiferromagnetic Transverse Ising Model on a Triangular Lattice , VLADIMIR IGLOVIKOV, Physics Department, University of California, Davis, USA, JAAN OITMAA, School of Physics, The University of New South Wales, Sydney, Australia, RAJIV SINGH, RICHARD SCALETTAR, Physics Department, University of California, Davis, USA — We study both the ferromagnetic and anti-ferromagnetic Ising model on a triangular lattice with a transverse magnetic field. Quantum Monte Carlo simulations and series expansions techniques are employed to determine the isentropes and phase diagrams for the system. Quantum Phase Transitions in the transverse field Ising model have recently been observed experimentally for linear chains and for small clusters with long range interactions. They are currently under investigation for triangular lattices.

10:00AM Y25.00007 Critical behavior of the XY model on fractal lattices , MICHELLE PRZEDBORSKI, BOZIDAR MITROVIC, Brock University — There has been considerable interest in determining whether the universality hypothesis extends to systems which are of non-integer dimension or to systems which are scale invariant (fractals). Specifically, research into these types of systems is concerned with determining the relevance of topological properties to their critical phenomena. We have performed Monte Carlo simulations for the XY model on three fractal lattices with different topological properties: the Sierpinski pyramid, Menger sponge, and Sierpinski carpet (which underwent unusual Berezinskii-Kosterlitz-Thouless transition). We will discuss the details of our results and show that while some properties, such as the order of ramification, are important in determining the critical behavior of these structures, the fractal dimension is not.

10:12AM Y25.00008 Strong curvature effects in wave problems , MORTEN WILLATZEN, Technical University of Denmark, Kgs. Lyngby, Denmark, ANDERS PORS, University of Southern Denmark, Snderborg, Denmark, JENS GRAVESEN, Technical University of Denmark, Kgs. Lyngby, Denmark — Linear-in-curvature contributions to wave-problem eigenvalues in quantum mechanics and acoustics are evaluated analytically using differential geometry methods and perturbation theory. It is demonstrated that in the case of Neumann boundary conditions, relevant for electromagnetic and acoustic problems, linear-in-curvature contributions are nonvanishing if the geometry supports eigenstates that do not satisfy parity. If Dirichlet boundary conditions apply, however, linear-in-curvature vanish identically. We continue to compute analytically eigenvalue changes for a toroidal angular-sector geometry in the case of both Dirichlet and Neumann boundary conditions. Eigenstate and eigenvalue results are finally verified qualitatively and quantitatively against Comsol finite element model results.

10:24AM Y25.00009 ABSTRACT WITHDRAWN –

10:36AM Y25.00010 Computing the response functions of topological insulators with non-commutative geometry[1] , EMIL PRODAN, Department of Physics, Yeshiva University, New York, NY 10016 — For periodic systems, the correlation functions take closed-form expression involving integrations and derivations of ordinary functions defined over the Brillouin torus (Bloch-Floquet calculus). The non-commutative geometry provides an analog of the Bloch-Floquet calculus for aperiodic systems under magnetic fields, and this formalism was used in the past to derive closed-form expressions for Kubo-formula, orbital electric and magnetic polarization and much more, for strongly disordered systems under magnetic fields. In this talk I will describe how these non-commutative formulas can be evaluated on a computer, enabling us to investigate the response coefficients of strongly disordered topological with unprecedented precision and efficiency.

[1]This research was supported by the U.S. NSF grants DMS-1066045 and DMR-1056168.

10:48AM Y25.00011 Disordered Floquet Topological Insulators , PARAJ BHATTACHARJEE, NETANEL LINDNER, GIL REFAEL, California Institute of Technology — We study the problem of localization in the recently proposed two-dimensional Floquet topological insulators in semiconductor quantum wells. We compute the single particle Green's function for the system using a real-time simulation. The phase diagram obtained indicates that at weak disorder the system remains delocalized. The edge-states are protected and only destroyed when the disorder closes the gap in the Floquet spectrum. The system localizes only at disorder strength which is much larger than the gap in the Floquet spectrum, long after this gap has been closed due to disorder. Analytically we compare these results with the results obtained using disorder averaged Floquet Green's functions in the Born approximation.

Friday, March 22, 2013 8:00AM - 11:00AM –

Session Y28 GSNP: Rods & Buckling 336 - Basile Audoly, University Paris 6

8:00AM Y28.00001 Three-dimensional Curling of Pre-strained Elastomeric Strips: From Hemi-helix to Helix , JIA LIU, JIANGSHUI HUANG, TIANXIANG SU, KATIA BERTOLDI, DAVID CLARKE, Harvard University — A variety of three dimensional curls can be produced by a simple generic process consisting of pre-straining one elastomeric strip, joining it to another and then releasing the bi-strip. In thin strips we observe the formation of hemi-helices, which consists of multiple, alternating helical sections of half wavelength in opposite chiralities, separated by perversions. By contrast, helical shapes with uniform handedness are found when the cross-section is wide and flat. Finally, in the transition region between helices and hemi-helices not only the geometry effects but also boundary conditions as well as dynamic effects severely contributes. The phase separation of hemi-helical and helical structures has similarities with coiled polymer molecules and plant tendrils.

8:12AM Y28.00002 A rod theory for pleated elastic strips , BASILE AUDOLY, Universtity Paris 6 and CNRS, MARCELO DIAS, Brown University — We consider the equilibrium shapes of a thin, annular strip cut out in a sheet of paper: when such a strip is folded along its circular centerline, it has been observed to buckle out-of-plane (Dias et al., PRL, 2012). We derive an equivalent Kirchhoff rod model for the folded strip. A nonlinear effective constitutive law capturing the underlying geometrical constraints is derived. In this rod model, the opening mode of the ridge appears as an internal degree of freedom. The buckling of the strip is shown to be equivalent to the buckling of a circular ring having two frozen curvatures. Another type of instability is pointed out, whereby the centerline remains planar but the ridge angle is modulated.

8:24AM Y28.00003 Buckling of a Flexible Strip Sliding on a Frictional Base , ALEXANDRE HUYNEN, University of Liege, JULIEN MARCK, University of Minnesota, VINCENT DENOËL, University of Liege, EMMANUEL DETOURNAY, University of Minnesota — The main motivation for this contribution is the buckling of a drillstring sliding on the bottom of the horizontal section of borehole. The open questions that remain today are related to the determination of the onset of instability, and to the conditions under which different modes of constrained buckling occur. In this presentation, we are concerned by a two-dimensional version of this problem; namely, the sliding of a flexible strip being fed inside a conduit. The ribbon, which has a flexural rigidity EI and a weight per unit length w, is treated as an inextensible elastica of negligible thickness. The contact between the ribbon and the wall of the conduit is characterized by a friction coefficient μ. First, we report the result of a stability analysis that aims at determining the critical inserted length of the ribbon $\ell_*(\mu)$ (scaled by the characteristic length $\lambda = (EI/w)^{1/3}$) at which there is separation between the strip and the conduit bottom, as well as the buckling mode. Next, the relationship between the feeding force F and the inserted length ℓ after bifurcation is computed. Finally, the results of a "kitchen table" experiment involving a strip of silicon rubber being pushed on a plank are reported and compared with predictions.

8:36AM Y28.00004 Better Contact Through Twist? The skew-dependence of inter-filament adhesion , LUIS CAJAMARCA, GREGORY GRASON, University of Massachusetts Amherst — Adhesive interactions between flexible filaments maximizes their contact, though the geometry of optimal contact is far from obvious. We address a simple question: how does inter-filament twist vary the adhesive energy? We investigate two models for adhesive interactions for filaments: a Lennard-Jones potential (LJP), and a model consisting of opposite interactions, screened electrostatic repulsion and depletion attraction (SED). In both potentials the interaction energy decreases for large twist. However, for small twist the SED potential is metastable whereas the LJP is not. We understand this effect by looking at how distances between patches of area on the surface change with twist. Patches further away come into closer contact as twist increases, effectively increasing the repulsion energy. This in turn pushes the filaments away and the net result is to favor a locally parallel orientation. Finally, we predict how the geometric minima of the interaction energy varies with inter-filament spacing for the LJP, where we observe two regions dominated by geometry: threads regime, where the filaments are very thin and interactions are long-range, and contact regime, where the filaments are very thick tubes and interactions become short-range compared to tube diameter.

8:48AM Y28.00005 Buckling of an elastic wire inside an elastic matrix , TIANXIANG SU, JIA LIU, Harvard University, DENIS TERWAGNE, MIT, KATIA BERTOLDI, Harvard University, PEDRO REIS, MIT — Using both experiment and dynamic simulation results, we will discuss in this talk how a compressed elastic wire embedded within an elastic matrix buckles into two dimensional (2D) planar shape and then three dimensional (3D) helical shape. We will show that the transitions from the initial 1D to 2D and then 3D configurations can be tuned by and are highly sensitively to the supporting matrix stiffness. This property may be useful for future photonic and piezoelectric devices. Analytic buckling and post-buckling analysis will also be presented to rationalize our results.

9:00AM Y28.00006 Buckling of a thin rod under cylindrical constraint , JAY MILLER, MIT, TIANXIANG SU, Harvard University, NATHAN WICKS, JAHIR PABON, Schlumberger-Doll Research, KATIA BERTOLDI, Harvard University, PEDRO REIS, MIT — We investigate the buckling and post-buckling behavior of a thin elastic rod, under cylindrical constraint, with distributed loading. Our precision model experiments consist of injecting a custom-fabricated rod into a transparent glass pipe. Under imposed velocity (leading to frictional axial loading), a portion of the initially straight rod first buckles into a sinusoidal mode and eventually undergoes a secondary instability into a helical configuration. The buckling and post-buckling behavior is found to be highly dependent on the system's geometry, namely the injected rod length and the aspect ratio of the rod to pipe diameter, as well as material parameters. We quantify the critical loads for this sequence of instabilities, contrast our results with numerical experiments and rationalize the observed behavior through scaling arguments.

9:12AM Y28.00007 Statistical properties of an elastic rod dynamically confined in 2D , FREDERIC LECHENAULT, MOKHTAR ADDA-BEDIA, LPS, Ecole Normale Supérieure — We investigate the statistical properties and stationary states of an elastic rod dynamically confined in a Hele-Shaw cell. As the confined length is increased, we observe a transition from an ordered spiral-like pattern to a disordered, rearranging pack of loops. In the disordered phase, we decipher the trajectories of the rod from its geometric configurations, and report correlation between curvilinear and spatial energy distributions. Moreover, we establish the relationship between the number of loops and the confined length, yielding insights into the loop occupation number and the overall rigidity of the system.

9:24AM Y28.00008 Loops, Wrinkles and Scrolls in Twisted Ribbons , JULIEN CHOPIN, ARSHAD KUDROLLI, Clark University — We explore experimentally the stable and metastable configurations of an elastic ribbon under mixed twist and tension. A ribbon is a slender and thin elastic material with an extremely narrow cross section which exhibits features of rods and plates: it can coil and form loops but wrinkles and stress localization can also been seen yielding a surprisingly rich variety of shapes. Using the twist angle and the tension as control parameters, the various configurations obtained can be rationalized in a phase diagram. Using x-ray tomography, we are able to reconstruct the 3D shape of the ribbon which can then be precisely characterized by measuring locally the mean and Gaussian curvature. Guided by our experimental data, we will present a simple model for the bifurcations observed. Finally, implications for the fabrication of structured rods and yarns with novel mechanical and transport properties will be discussed.

9:36AM Y28.00009 Explicit solutions for the buckling of an imperfect strut on a nonlinear foundation , ROMAIN LAGRANGE, MIT, DANIEL AVERBUCH, IFPEN, IFPEN TEAM — We perform a theoretical and numerical study of the buckling of an imperfect finite strut on a nonlinear elastic Winkler type foundation. The imperfection is introduced by considering an initially deformed shape which is a sine function with an half wavelength. The length of the strut is chosen such that the first buckling mode is excited and the restoring force is either a bi-linear or an exponential profile. Considering these two profiles, we show (exact piecewise solution theory, explicit Galerkin method, numerical resolution) that the system is subcritical, imperfection sensitive and the deflection is an amplification of the default. For small imperfection sizes, the equilibrium paths hit a limit point which is asymptotic to the Euler load for a critical imperfection amplitude. This critical amplitude is determined analytically and does not depend on the choice of the restoring force. The decrease of the maximum value of the axial force supported by the beam as a function of the imperfection magnitude is determined. We show that the leading term of the development has a different exponent than in subcritical buckling of elastic systems, and that the exponent values depend on the regularization.

9:48AM Y28.00010 On the tensorial nature of chirality , EFI EFRATI, WILLIAM IRVINE, University of Chicago — Chirality occupies a central role in fields ranging from biological self assembly to the design of optical meta-materials. The definition of chirality, as given by lord Kelvin in 1893, associates handedness with the lack of mirror symmetry. However, the quantification of chirality based on this definition has proven to be an elusive task. The difficulty in quantifying chirality is contrasted by the ease with which one determines the handedness of objects with a well defined axis such as screws and helices. In this talk I will present table-top demonstrations that show that a single object can simultaneously be left handed and right handed when considered from different directions. The orientation dependence of handedness motivates a tensorial quantification of chirality relating directions to rotations. I will give an explicit example of such a tensorial measure of chirality for embedded surfaces, and show how the tensorial nature of chirality can be probed in experiments and exploited as a design principle.

10:00AM Y28.00011 Mechanics and Dynamics of Snapping Beams , ANUPAM PANDEY, Virginia Tech, DEREK MOULTON, DOMINIC VELLA, Oxford University, DOUGLAS HOLMES, Virginia Tech — Snap-buckling is an elastic instability that causes a rapid transition between two states separated by a finite distance. These rapid instabilities occur naturally in plants like the Bunchberry dogwood and the Venus flytrap, yet the dynamics of this phenomenon remain poorly understood. In this talk we discuss the statics and dynamics of the point load snap through of an arch. During deformation, the arch transitions from a symmetric to an asymmetric mode at a critical load and then snap-buckles at a critical indentation height. We will demonstrate that this critical force and displacement for stability loss varies nonlinearly with the amount of initial compression applied to the flat beam, and the dynamics of the snapping arch have an instability growth-rate dictated by the speed of sound within the material.

10:12AM Y28.00012 Effect of aspect ratio on the stress response of frictional elastic rod assemblies , VIKRANT YADAV, ARSHAD KUDROLLI, Clark University — We discuss the effect of aspect ratio on the response of a random assembly of frictional elastic rods under repeated top loading stress-strain cycles. Random assemblies of rods of different aspect ratios were created by rain deposition of particles. Considerable hysteresis is observed over the first few cycles, but the response starts to approach a more reversible path with each cycle. The assembly was scanned after each cycle using a 3D X-ray computer aided tomography instrument to determine position, orientation, and contacts of each constituent particle. We show that rods of small aspect ratio pack tend to have small compression under the same stress as compared to rods of higher aspect ratio because they pack more densely, and thus have larger Young's modulus. By tracking motion of constituent rods over subsequent cycles we observed that larger number of rearrangements take place in the bulk away from boundaries. The mean distance over which a particle moves to rearrange also decreases with each cycle. The mean numbers of contacts were also evaluated and were found to increase rapidly with small changes in volume fraction.

10:24AM Y28.00013 Thin film buckling : a relation between adhesion and morphology , ETIENNE BARTHEL, JEAN-YVON FAOU, SERGEY GRACHEV, CNRS/Saint-Gobain, GUILLAUME PARRY, Simap CNRS/UJF/INP Grenoble — When thin films with low adhesion are compressively stressed, they may buckle. These buckles exhibit interesting morphologies such as the well known telephone cord. However our understanding of this form of buckling is limited because it couples the large displacement nonlinearities of plates with the subtleties of mixed-mode adhesion. Here we investigate the morphology of the thin film buckles as a function of mode mixity by a combination of experiments and simulations. We first exhibit a linear relation between the period of the telephone cord buckles and a characteristic parameter of the mixed mode adhesion. Furthermore we evidence a rich set of new buckle morphologies through experiments, and demonstrate that these morphologies can be reproduced in the simulations. We also show that we can rationalize the transitions between morphologies through a phase diagram. This excellent agreement between experimental results and numerical predictions further validates the simulation method we have developped recently.

10:36AM Y28.00014 Use of magnetic micro-cantilevers to study the dynamics of 3D engineered smooth muscle constructs[1] , ALAN LIU, RUOGANG ZHAO, CRAIG COPELAND, Johns Hopkins University, CHRISTOPHER CHEN, University of Pennsylvania, DANIEL REICH, Johns Hopkins University — The normal and pathological response of arterial tissue to mechanical stimulus sheds important light on such conditions as atherosclerosis and hypertension. While most previous methods of determining the biomechanical properties of arteries have relied on excised tissue, we have devised a system that enables the growth and in situ application of forces to arrays of stable suspended microtissues consisting of arterial smooth muscle cells (SMCs). Briefly, this magnetic microtissue tester system consists of arrays of pairs of elastomeric magnetically actuated micro-cantilevers between which SMC-infused 3D collagen gels self-assemble and remodel into aligned microtissue constructs. These devices allow us to simultaneously apply force and track stress-strain relationships of multiple microtissues per substrate. We have studied the dilatory capacity and subsequent response of the tissues and find that the resulting stress-strain curves show viscoelastic behavior as well as a linear dynamic recovery. These results provide a foundation for elucidating the mechanical behavior of this novel model system as well as further experiments that simulate pathological conditions.

10:48AM Y28.00015 Pattern formation by deposition of a thin elastic rod on a moving substrate , MOHAMMAD KHALID JAWED, Massachusetts Institute of Technology, FANG DA, EITAN GRINSPUN, Columbia University, PEDRO REIS, Massachusetts Institute of Technology — We report on the formation of coiling patterns when a thin elastic rod is deposited onto a moving solid boundary. We combine precision model experiments with cutting-edge computational mechanics tools ported from the computer graphics community. In our experiments, we deposit elastomeric rods onto a conveyor belt. Our numerical tool simulates the experimental scenario by implementing a discrete notion of bending and twist of the thin rod, based on discrete differential geometry, exhibiting excellent performance and robustness. The synergy between experiments and numerics, and the excellent agreement between the two, allows us to identify the key physical ingredients of the process, explore the phase diagram of the system, quantify the influence of the control parameters and rationalize the underlying mechanical instabilities. The gained predictive understanding of this geometrically-nonlinear pattern formation process has potential applications ranging from the micron-scale (coiling of carbon nanotubes) to the kilometer-scale (laying down of transoceanic undersea cables).

Session Y29 GSNP: Complex Networks and Their Applications I 337 - Greg Morrison, Harvard University

8:00AM Y29.00001 Phase transition and Self-Organized Criticality in the Brain , MARZIEH ZARE, University of North Texas, MALGORZATA TURALSKA, Duke University, PAOLO GRIGOLINI, University of North Texas — Empirical evidence for a scale free distribution of avalanche sizes in the brain as a manifestation of self-organized criticality (SOC) suggests that the brain operates near criticality. Simulations in the literature also show the optimal function of the brain at criticality. However, due to the lack of sufficient set of conditions in the SOC hypothesis for the classification of a system, there is no clear connection between the phase transition and SOC. Here we study a set of cooperative neurons in a two-dimensional regular network. Using a leaky integrate-and-fire model, we analyze the temporal complexity and find a phase transition from Poisson to periodic process for a specific value of the cooperation parameter. We also evaluate the efficiency of information transfer between two networks and find the maximum at the same critical value. To study the connection between phase transition and SOC, we measure the avalanche size distribution at the critical point. Our results show no evidence on scaling to the popular inverse power law of 1.5 in size, while we observe this scaling in the supercritical regime. Overall, based on these results, we propose that an epileptic brain can generate power law scaling while a healthy brain works in an intermediate regime.

8:12AM Y29.00002 An application of a measure for organization of complex networks , GEORGI GEORGIEV, MICHAEL DALY, Assumption College — In order to measure self-organization in complex networks a quantitative measure for organization is necessary. This will allow us to measure their degree of organization and rate of self-organization. We apply as a measure for quantity of organization the inverse of the average sum of physical actions of all elements in a system per unit motion multiplied by the Planck's constant, using the principle of least action. The meaning of quantity of organization here is the inverse of average number of quanta of action per one node crossing of an element of the system. We apply this measure to the central processing unit (CPU) of computers. The organization for several generations of CPUs shows a double exponential rate of change of organization with time. The exact functional dependence has, S-shaped structure, suggesting some of the mechanisms of self-organization. We also study the dependence of organization on the number of transistors. This method helps us explain the mechanism of increase of organization through quantity accumulation and constraint and curvature minimization with an attractor, the least average sum of actions of all elements and for all motions. This approach can help to describe, quantify, measure, manage, design and predict future behavior of complex systems to achieve the highest rates of self-organization to improve their quality.

8:24AM Y29.00003 Phase Transitions in the Quadratic Contact Process on Complex Networks , CHRIS VARGHESE, RICK DURRETT, Duke University — The quadratic contact process (QCP) is a natural extension of the well studied linear contact process where a single infected (1) individual can infect a susceptible (0) neighbor and infected individuals are allowed to recover ($1 \to 0$). In the QCP, a combination of two 1's is required to effect a $0 \to 1$ change. We extend the study of the QCP, which so far has been limited to lattices, to complex networks as a model for the change in a population via sexual reproduction and death. We define two versions of the QCP – vertex centered (VQCP) and edge centered (EQCP) with birth events $1-0-1 \to 1-1-1$ and $1-1-0 \to 1-1-1$ respectively, where '$-$' represents an edge. We investigate the effects of network topology by considering the QCP on regular, Erdős-Rényi and power law random graphs. We perform mean field calculations as well as simulations to find the steady state fraction of occupied vertices as a function of the birth rate. We find that on the homogeneous graphs (regular and Erdős-Rényi) there is a discontinuous phase transition with a region of bistability, whereas on the heavy tailed power law graph, the transition is continuous. The critical birth rate is found to be positive in the former but zero in the latter.

8:36AM Y29.00004 Two-dimensional classical XY model by HOTRG , JI-FENG YU, ZHIYUAN XIE, TAO XIANG, None — Two-dimensional (2D) classical XY model has a special phase transition, the so-called Kosterlitz-Thouless (KT) transition. Below the transtion temperature, the system has quasi long range order with all spins aligned, and the correlation function decays as power law, while the other unordered phase is exponential. Large size system study by numerical simulation is necessary, but pratically difficult.In this work, we applied a newly well-developed method: high-order tensor renormalization group (HOTRG) to investigate this model. This method is verified by 2D Ising model, and thoretially, it can deal with infinite system size. Some thermodynamic quantities such as entropy, specific heat and magnetic susceptibility etc., are computed, which may be used to find Fisher's zero of the partition function, and then to characterize the transition.

8:48AM Y29.00005 Optimal Phase Oscillatory Network[1] , ROSANGELA FOLLMANN, Polytechnic school of University of Sao Paulo — Important topics as preventive detection of epidemics, collective self-organization, information flow and systemic robustness in clusters are typical examples of processes that can be studied in the context of the theory of complex networks. It is an emerging theory in a field, which has recently attracted much interest, involving the synchronization of dynamical systems associated to nodes, or vertices, of the network. Studies have shown that synchronization in oscillatory networks depends not only on the individual dynamics of each element, but also on the combination of the topology of the connections as well as on the properties of the interactions of these elements. Moreover, the response of the network to small damages, caused at strategic points, can enhance the global performance of the whole network. In this presentation we explore an optimal phase oscillatory network altered by an additional term in the coupling function. The application to associative-memory network shows improvement on the correct information retrieval as well as increase of the storage capacity. The inclusion of some small deviations on the nodes, when solutions are attracted to a false state, results in additional enhancement of the performance of the associative-memory network.

9:00AM Y29.00006 The Dynamics of Network Coupled Phase Oscillators: An Ensemble Approach[1] , GILAD BARLEV, THOMAS ANTONSEN, EDWARD OTT, University of Maryland, College Park — We consider the dynamics of phase oscillators that interact through a coupling network. We further consider an ensemble of such systems where, for each ensemble member, the set of oscillator frequencies is randomly chosen according to a given distribution function. We then seek a statistical description of the dynamics of this ensemble. This approach allows us to apply the ansatz of Ott and Antonsen to the marginal distribution of the ensemble of states at each node. This results in a reduced set of ordinary differential equations determining these marginal distribution functions. The new set facilitates the analysis of network dynamics in several ways: (i) the time evolution of the reduced system of equations is smoother, and thus numerical solutions can be obtained much faster; (ii) the new set of equations can be used to obtaining analytical result; and (iii) for a certain type of network, a reduction to a low dimensional description of the entire network dynamics is possible. We illustrate our approach with numerical experiments on a network version of the classic Kuramoto problem, with both unimodal and bimodal frequency distributions. In the bimodal case, the dynamics are characterized by bifurcations and hysteresis involving a variety of steady and periodic attractors.

9:12AM Y29.00007 Core percolation on complex networks , YANG-YU LIU, Northeastern University; Dana-Farber Cancer Institute, ENDRE CSÓKA, Eotvos Lorand University, HAIJUN ZHOU, Chinese Academy of Sciences, MÁRTON PÓSFAI, Northeastern University; Budapest University of Technology and Economics; Eotvos Lorand University — As a fundamental structural transition in complex networks, core percolation is related to a wide range of important problems, including combinatorial optimizations and network controllability. Yet, previous theoretical studies of core percolation have been focusing on the classical Erdős-Rényi random networks with Poisson degree distribution, which are quite unlike many real-world networks with scale-free or fat-tailed degree distributions. Here we show that core percolation can be analytically studied for complex networks with arbitrary degree distributions. We derive the condition for core percolation and find that purely scale-free networks have no core for any degree exponents. We show that for undirected networks if core percolation occurs then it is always continuous while for directed networks it becomes discontinuous (and hybrid) if the in- and out-degree distributions differ. We also find that core percolations on undirected and directed networks have completely different critical exponents associated with their critical singularities. Finally, we apply our theory to real-world directed networks and find, surprisingly, that they often have much larger core sizes as compared to random models.

9:24AM Y29.00008 Devil's Staircases, Crackling Noise and Phase Transitions in Percolation , JAN NAGLER, Max Planck Inst. for Dynamics and Self-Organization, Goettingen, Germany — We identify and study certain phenomena in percolation that can subvert predictability and controllability in networked systems. We establish devil's staircase phase transitions, non-self-averaging, and power-law fluctuations in percolation. We provide exact conditions for percolation that exhibits multiple discontinuous jumps in the order parameter where the position and magnitude of the jumps are randomly distributed - characteristic of crackling noise. The framework can be linked to magnetic effects and fragmentation processes.

9:36AM Y29.00009 Explosive percolation transitions in Euclidean space , YOUNG SUL CHO, SUNGMIN HWANG, Seoul National University, HANS JÜRGEN HERRMANN, Eidgenössische Technische Hochschule Zürich, BYUNGNAM KAHNG, Seoul National University — Since the explosive percolation transition was discovered in a random graph model in the Achlioptas process, whether the explosive percolation transition is indeed discontinuous or continuous has been controversial. Even though extensive studies have been focused on the mean-field behavior of the type of the explosive percolation transition, only a few studies are carried out in Euclidean space, Here, we show that depending on a parameter we introduce, the explosive percolation transition can be either discontinuous or continuous transition in Euclidean space, and is reduced to be continuous in the mean-field limit, which can be shown using an analytic approach.

9:48AM Y29.00010 Effective spectral dimension in heterogeneous networks , SUNGMIN HWANG, Department of Physics and Astronomy, Seoul National University, DEOK-SUN LEE, Department of Natural Medical Sciences and Department of Physics, BYUNGNAM KAHNG, Department of Physics and Astronomy, Seoul National University — Random walks(RWs) approach is the simplest but the most fundamental method which encapsulates essential properties of diffusive dynamic process. Here, we study the two basic quantities, the return to origin probability and the first passage time distribution of random walks on scale-free networks. The behaviors of those quantities as a function of time typically depend on the spectral dimension d_s in disordered fractal systems. However, we show that in scale-free networks, due to the heterogeneity of connectivities of each node in scale-free networks, those quantities display a crossover decay behavior from $\sim t^{-d_s^{(\mathrm{hub})}/2}$ in early time regime to $\sim t^{-d_s/2}$ in later time regime, where $d_s^{(\mathrm{hub})} \to 0$ as the degree exponent λ approaches 2. This result implies that a random walker can be trapped effectively at the hub when $\lambda \to 2$. Next, we discuss the origin of the $d_s^{(\mathrm{hub})}$ by applying the renormalization group transformation to deterministic hierarchical networks.

10:00AM Y29.00011 Natural emergence of clusters and bursts in network evolution , JAMES BAGROW, DIRK BROCKMANN, Northwestern University — Network models with *preferential attachment*, where new nodes are injected into the network and form links with existing nodes proportional to their current connectivity, have been well studied for some time. Extensions have been introduced where nodes attach proportional to arbitrary fitness functions. However, in these models attaching to a node increases the ability of that node to gain more links in the future. We study network growth where nodes attach proportional to the clustering coefficients, or local densities of triangles, of existing nodes. Attaching to a node typically lowers its clustering coefficient, in contrast to preferential attachment or rich-get-richer models. This simple modification naturally leads to a variety of rich phenomena, including non-poissonian bursty dynamics, community formation, aging and renewal. This shows that complex network structure can be modeled without artificially imposing multiple dynamical mechanisms.

10:12AM Y29.00012 Walking and searching in time-varying networks , NICOLA PERRA, ANDREA BARONCHELLI, DELIA MOCANU, BRUNO GONCALVES, Northeastern University, ROMUALDO PASTOR-SATORRAS, UPC, ALESSANDRO VESPIGNANI, Northeastern University — The random walk process lies underneath the description of a large number or real world phenomena. Here we provide a general framework for the study of random walk processes in time varying networks in the regime of time-scale mixing; i.e. when the network connectivity pattern and the random walk process dynamics are unfolding on the same time scale. We consider a model for time varying networks created from the activity potential of the nodes, and derive solutions of the asymptotic behavior of random walks and the mean first passage time in undirected and directed networks. Our findings show striking differences with respect to the well known results obtained in quenched and annealed networks, emphasizing the effects of dynamical connectivity patterns in the definition of proper strategies for search, retrieval and diffusion processes in time-varying networks.

10:24AM Y29.00013 Measuring importance in complex networks , GREG MORRISON, LEVI DUDTE, L. MAHADEVAN, Harvard School of Engineering and Applied Sciences — A variety of centrality measures can be defined on a network to determine the global 'importance' of a node i. However, the inhomogeneity of complex networks implies that not all nodes j will consider i equally important. In this talk, we use a linearized form of the Generalized Erdos numbers [Morrison and Mahadevan EPL 93 40002 (2011)] to define a pairwise measure of the importance of a node i from the perspective of node j which incorporates the global network topology. This localized importance can be used to define a global measure of centrality that is consistent with other well-known centrality measures. We illustrate the use of the localized importance in both artificial and real-world networks with a complex global topology.

10:36AM Y29.00014 Sequential detection of temporal communities in evolving networks by estrangement confinement[1] , SAMEET SREENIVASAN, Rensselaer Polytechnic Institute, VIKAS KAWADIA, Raytheon BBN Technologies — Temporal communities are the result of a consistent partitioning of nodes across multiple snapshots of an evolving network, and they provide insights into how dense clusters in a network emerge, combine, split and decay over time. Reliable detection of temporal communities requires finding a good community partition in a given snapshot while simultaneously ensuring that it bears some similarity to the partition(s) found in the previous snapshot(s). This is a particularly difficult task given the extreme sensitivity of community structure yielded by current methods to changes in the network structure. Motivated by the inertia of inter-node relationships, we present a new measure of partition distance called estrangement, and show that constraining estrangement enables the detection of meaningful temporal communities at various degrees of temporal smoothness in diverse real-world datasets. Estrangement confinement consequently provides a principled approach to uncovering temporal communities in evolving networks. (V. Kawadia and S. Sreenivasan, http://arxiv.org/abs/1203.5126)

10:48AM Y29.00015 Bimodality in Network Control , TAO JIA, YANG-YU LIU, MARTON POSFAI, Center for Complex Network Research and Department of Physics, Northeastern University, JEAN-JACQUES SLOTINE, Non-linear Systems Laboratory, Massachusetts Institute of Technology, ALBERT-LASZLO BARABASI, Center for Complex Network Research and Department of Physics, Northeastern University — Controlling complex systems is a fundamental challenge of network science. Recent tools enable us to identify the minimum driver nodes, from which we can control a system. They also indicate a multiplicity of minimum driver node sets (MDS's): multiple combinations of the same number of nodes can achieve control over the system. This multiplicity allows us to classify individual nodes as critical if they are involved in all control configurations, intermittent if they occasionally act as driver nodes and redundant if they do not play any role in control. We develop computational and analytical framework analyzing nodes in each category in both model and real networks. We find that networks with identical degree distribution can be in two distinct control modes, "centralized" or "distributed", with drastic change on the role of each node in maintaining the controllability and orders of magnitude difference in the number of MDS's. In analyzing both model and real networks, we find that the two modes can be inferred directly from the network's degree distribution. Finally we show that the two control modes can be switched by small structural perturbations, leading to potential applications of control theory in real systems.

Session Y30 GSNP: Jamming & Shearing 338 - Ted Brzinski, University of Pennsylvania

8:00AM Y30.00001 Plastic Deformation of Semicrystalline Polyethylene under Extension, Compression, and Shear using Molecular Dynamics Simulation , JUN MO KIM, Massachusetts Institute of Technology, REBECCA LOCKER, ExxonMobil Research and Engineering Co., GREGORY RUTLEDGE, Massachusetts Institute of Technology — Molecular dynamics simulation has been performed to investigate the plastic deformation of semicrystalline polyethylene under various modes of deformation, such as extension, compression and shear. Many mechanical and structural properties of semicrystalline polyethylene are examined and compared with previous study [Lee and Rutledge, Macrmol. 44, 3096 (2011)]. Under tensile deformation, we observed crystallographic slip at low strains ($e_3 < 0.08$) regardless of deformation rate. However, two different yield mechanisms were monitored as a function of deformation rate at intermediate strains ($e_3 < 0.25$). At high strains ($e_3 > 0.25$), melting and recrystallization were observed for slow deformation ($5\times10^6 s^{-1}$) whereas cavitations were monitored for fast deformation ($5\times10^7 s^{-1}$). Under compressive deformation, stress-strain curve shows very similar behavior to tensile deformation at low strain, and crystallographic slip plays an important role for mechanical response of semicrystalline polyethylene. Under shear deformation, the chains tend to stretch and align into the shear direction. We also calculated stiffness constants for shear deformation and compared these to results of previous study [In't Veld et al. Macromol. 39, 439 (2006)]. Interestingly, semicyrstalline polyethylene shows typical transient behavior of Newtonian fluids under shear deformation, which we compare to various constitutive models, such as the Upper-Convected Maxwell (UCM) and Giesekus models.

8:12AM Y30.00002 Size Segregation in Sheared Jammed Colloids[1] , ARMSTRONG MBI, DANIEL BLAIR, Georgetown University Department of Physics and Institute of Soft Matter and Metrology — It is well known that granular materials can spontaneously size segregate when continuously driven. However, in jammed colloidal suspensions, this phenomenon is not well understood. Colloidal dispersions provide a unique system to study the structure and dynamics of jammed matter. In this talk, we present results of size segregation of a continuously sheared binary colloidal suspension well above point J. Our colloidal system is comprised of indexed-matched bi-disperse silica particles with diameters $a = \{2.3\mu m$ and $3.2\mu m\}$ and at $\phi \approx 61\%$, well above the colloidal glass transition. We apply a highly controlled shear at a constant shear rate through the use of a rheometer. By coupling our rheometer with a high-speed laser scanning confocal microscope, we directly image the structure and flow profiles of the suspension as it un-jams. We observe migration of the small and large species; large particles move to the top while the small particles move toward the bottom conserving the total volume fraction in all regions. Moreover, we find that an associating feature of segregation is a sustained shear band. Our results are consistent with a recently proposed void filling and squeeze expulsion mechanism.

[1]Funding is provided by NSF DMR #0847490.

8:24AM Y30.00003 Reversible and irreversible deformation in hard-sphere colloidal glasses , KATHARINE JENSEN, Harvard University, NOBUTOMO NAKAMURA, Osaka University, Harvard University, DAVID WEITZ, FRANS SPAEPEN, Harvard University — Colloidal glass provides a unique experimental system with which to study the structure, defects, and dynamics of amorphous materials. We report experiments on 1.55-μm-diameter, hard-sphere silica colloidal glasses under conditions of uniform shear. We deform the samples to maximum strains ranging from 0.5% to 10% at various strain rates, and then reverse the deformation so that the net bulk strain is zero at the end of the experiment. We use confocal microscopy to follow the 3D, real-time trajectories of roughly 50,000 particles over the course of an experiment. In this way, we probe the elastic, anelastic, and plastic response of the system, with particular emphasis on the specific, local mechanisms of deformation. We directly observe yield as the onset of local, irreversible deformation. In both sheared and unsheared (quiescent) samples, we observe thermally-activated clusters of particles that behave as Eshelby inclusions, undergoing highly localized plastic strain that couples elastically to the surrounding material. We identify and characterize these regions as they develop in the glass, with particular focus on density-related properties including the Voronoi volume and free volume.

8:36AM Y30.00004 Shearbanding in Amorphous Solids and Interacting Eshelby Singularities , H.G.E. HENTSCHEL, Emory University, Atlanta, GA, RATUL DASGUPTA, ITAMAR PROCACCIA, Weizmann Institute, Rehovot, Israel — We will describe recent work in which it was found that the fundamental shear-localizing instability of amorphous solids under external strain, which eventually results in a shear band and failure, consists of a highly correlated line of Eshelby quadrupoles all having the same orientation and some density ρ. We describe how the energy $E(\rho, \gamma)$ associated with such highly correlated structures as a function of the density ρ and the external strain γ can be calculated. We then show that when the strain γ is smaller than some characteristic yield stress γ_y the minimum energy solution is attained for $\rho = 0$ (i.e. isolated localized plastic events). While for $\gamma \geq \gamma_y$ there is a bifurcation allowing a finite density of quadrupoles. We finally suggest how the universal Johnson-Samwer $T^{2/3}$ temperature reduction of the yield stress in metallic glasses can be accounted for by such ideas.

8:48AM Y30.00005 Compression of granular pillars with constant width at top and bottom , YUKA TAKEHARA, JENNIFER RIESER, University of Pennsylvania, JERRY GOLLUB, Haverford College, DOUGLAS DURIAN, University of Pennsylvania — Granular media display both elastic and plastic behavior, including the formation of shear bands under extreme loading. In this study, we performed two-dimensional granular pillar compression experiments and tracked of grain- and macro- scale flows via video imaging and force measurement. Especially we focus on the condition that the top and bottom widths of the granular pillars are constrained to avoid free expansion along the contact edge. This causes more energy to be stored elastically deep inside of the pillars, which gives rise to a different kind of shear banding than for free top/bottom widths. Furthermore we tried several series of experiments with different elastic/frictional particles and also ordered/disordered systems. We demonstrate how the micro properties and packing structure contribute to the formation of shear band to discuss the mechanical failure in disordered packing.

9:00AM Y30.00006 The Chaotic Dynamics of Jamming[1] , DAVID A. EGOLF, Department of Physics, Georgetown University, EDWARD J. BANIGAN, Dept. of Physics and Astronomy, Univ. of Pennsylvania, MATTHEW K. ILLICH, DERICK J. STACE-NAUGHTON, Department of Physics, Georgetown University — Despite the appearance of simplicity, much of the behavior of granular materials remains mysterious. One intriguing puzzle is the dynamical mechanism underlying the "jamming" transition, in which disordered grains become rigid at high density. By applying nonlinear dynamical techniques to simulated 2D shear cells, we reveal the mechanisms of jamming and find they conflict with the prevailing picture of growing cooperative regions. Additionally, at the density corresponding to random close packing, we find a dynamical transition from chaotic to non-chaotic states accompanied by diverging dynamical length and time scales. Furthermore, we find that the dominant cooperative dynamical modes are strongly correlated with particle rearrangements and become increasingly unstable before stress jumps, providing a way to predict the times and locations of these earthquake-like stress-release events.

9:12AM Y30.00007 Shear Transformation Zone theory parameters from molecular dynamics and experiment[1] , ADAM R. HINKLE, PENGFEI GUAN, MICHAEL L. FALK, Johns Hopkins University — Shear Transformation Zone (STZ) theory provides a continuum framework to describe the deformation of amorphous systems. However, as a phenomenological theory it relies upon parameters which must be determined for a specific material system. We present current progress towards a set of theoretical and computational methodologies for determining the parameters of STZ theory. We investigate two distinct systems, a copper-zirconium lamellar nanocomposite, and a simple yield stress fluid (YSF), where both systems are loaded in simple shear. We show that the molecular dynamics simulations of the nanocomposite system and experimental measurements of the YSF can be used to provide the initial conditions of the dynamical fields as well as the essential STZ parameters.

[1]National Science Foundation Award #0808704

9:24AM Y30.00008 Heterogeneous relaxation dynamics in amorphous materials under cyclic loading , NIKOLAI PRIEZJEV, Michigan State University — Molecular dynamics simulations are performed to investigate heterogeneous dynamics in amorphous glassy materials under oscillatory shear strain. We consider three-dimensional binary Lennard-Jones mixture well below the glass transition temperature. The structural relaxation and dynamic heterogeneity are quantified by means of the self-overlap order parameter and the four-point correlation function. We found that at small strain amplitudes, the mean square displacement develops an extended sub-diffusive plateau followed by the diffusive regime; whereas at larger amplitudes only the diffusive regime is present. At intermediate time and length scales, the dynamic susceptibility exhibits a pronounced peak, whose magnitude increases at larger strain amplitudes, indicating progressively larger size of dynamically correlated regions. The analysis of particle hopping dynamics reveals that the periodic deformation generates a heterogeneous temporal response characterized by intermittent bursts of large particle displacements. The role of dynamical facilitation in the formation of clusters of mobile particles is discussed.

9:36AM Y30.00009 Shear deformation of naocrystal-metallic glass composites: A computational analysis , PENGFEI GUAN, MICHAEL L. FALK, Johns Hopkins University — Due to the shear strain localization, the limited ductility becomes the major drawback for the application of metallic glass materials, and the introducing of crystalline phase has been regarded as the effective method for improving the ductility of these materials. Here, we systematically investigate the nanocrystal-metallic glass composites by using Molecular Dynamic (MD) simulations. The three–dimension (3D) atomic configurations with different crystalline grain sizes and factions are constructed based on the ZrCu EAM potential. The phase diagram based on the crystalline grain size-fraction is established between single nanocrystal phase and amorphous phase. The mechanical responses of these materials are investigated by applying the shear deformation, and the relationships between the mechanical properties and atomic structure information (crystalline fraction, grain size ?) are established.

9:48AM Y30.00010 Criticality of non-colloidal suspensions under periodic shear[1] , EMMANOUELA FILIPPIDI, DAVID PINE, Center for Soft Matter Research, NYU — Suspensions of non-colloidal particles under slow periodic strain undergo a dynamical phase transition: they can either relax to an absorbing configuration in which particles are not displaced after every cycle or can reach a stationary fluctuating state. We correlate microscopic particle motion with macroscopic rheology and explain the existence of the critical transition experimentally by comparing particles of different surface roughness and by varying the volume fraction towards jamming. Particle roughness is implicated in the transition to reversibility, as smoother particles push the critical strain to higher values. Theoretically, we attempt to construct quasi-particles that encompass the strain-induced particle interactions and discover that geometry is not sufficient to understand suspension irreversibility under strain.

10:00AM Y30.00011 Temperature-equivalent of strain rate for the yield stress of amorphous solids , PENGHUI CAO, XI LIN, HAROLD S. PARK, Department of Mechanical Engineering, Boston University — We couple the recently developed self-learning metabasin escape (SLME) algorithm with continuous shear deformations to probe the yield stress as a function of temperature for a binary Lennard-Jones amorphous solid. At room temperature and laboratory strain rates, the activation volume associated with yield is less than 10 atoms, while the yield stress is found to be as sensitive to a 1.5%Tg increase in temperature as it is to a one order of magnitude decrease in strain rate. Our SLME results suggest a transition in yield mechanism for temperatures lower than about 0.54Tg that is not captured by extrapolating high strain rate molecular dynamics simulations to laboratory strain rates.

10:12AM Y30.00012 Identifying Defects in Disordered and Ordered Solids , SVEN WIJTMANS, LISA MANNING, Syracuse University — Characterizing defects in solids is an important step to developing continuum equations for failure in materials. Defects in crystalline solids (i.e. dislocations) are easy to characterize, but in disordered solids the lack of crystalline order makes it difficult to identify where particle rearrangements are likely to occur. Here we describe simulations of quasi-statically sheared athermal jammed packings of bidisperse discs in 2D. We perform energy minimization at each step using a combination of conjugate gradient and line search algorithms. By analyzing localized excitations in low-frequency vibrational modes, one can identify flow defects in disordered solids. We have developed tools to carefully match these flow defects to corresponding plastic events, and we analyze how the properties of defects change across packings ranging from disordered to completely ordered. This will allow us to understand the fundamental connections between dislocations and flow defect dynamics in solids.

10:24AM Y30.00013 Atomic-scale flow defect population in Cu-Zr metallic glass[1] , SYLVAIN PATINET, PENGFEI GUAN, ADAM HINKLE, MICHAEL FALK[2], Department of Materials Science and Engineering, Johns Hopkins University, Baltimore, Maryland 21218, USA — We adapt the method developed by Manninget al.[PRL 107, 108302 (2011)] to characterize the flow defects population of a Cu-Zr metallic glass modeled using embedded atom method potentials. We investigate how the statistics of Shear Transformation Zones (STZs) change as a function of system size and quench rate during glass formation. We also consider the evolution of the STZ population during mechanical loading. On the basis of this analysis, we relate our results with predictions of the STZ theory of amorphous plasticity to consider the history dependence implicit in the strain-stress response of the metallic glass.

10:36AM Y30.00014 Viscous rheology of soft particles near jamming , ERIK WOLDHUIS, Leiden University, BRIAN TIGHE, Delft University, MARTIN VAN HECKE, Leiden University — We investigate the effect of changing the exact nature of the viscous interaction in simulations of sheared soft, viscous, repulsive disks, which are considered to be a good model for foams and emulsions. We determine the way in which the power-law exponent of the rheological curve, in other words the shear-thinning or shear-thickening part, depends on the microscopic viscous interaction around the jamming density. We attempt to find a model that describes and predicts this dependence.

Session Y31 DPOLY: Phase Behavior of Copolymers 339 - Chris Ellison, University of Texas at Austin

8:00AM Y31.00001 Phase Behavior of All-Hydrocarbon "Diblock-Random" Copolymers , BRYAN BECKINGHAM, RICHARD REGISTER, Princeton University — "Block-random" copolymers (A_xB_{1-x})-(A_yB_{1-y}), where each of the two blocks is a random copolymer of monomers A and B, present a convenient and useful variation on the typical block copolymer architecture, as the interblock interactions and physical properties can be tuned continuously through the random block's composition. The ability to tune the effective interaction parameter between the blocks continuously, allows for the order-disorder transition temperature (T_{ODT}) to be tuned independently of molecular weight using only two monomers. This flexibility makes block-random copolymers a versatile platform for the exploration of polymer phase behavior and structure-property relationships. Here, we present the phase behavior of hydrogenated derivatives of various lamellae-forming diblock-random copolymers where one block is a styrene/isoprene (SrI) random copolymer. Using small-angle x-ray scattering, we investigate a series of isoprene hydrogenated hI-SrI with varying styrene content, determine order-disorder transition temperatures and compare the observed phase behavior to that of more typical S-hI block copolymers via mean-field theory. Additionally, diblock-random copolymers, 50 wt. % styrene in the SrI block, are synthesized with polyisoprene, polybutadiene or polystyrene blocks and we examine the phase behavior of both their hydrogenated derivatives, prepared with catalysts which either leave the S units intact or saturate them to vinylcyclohexane.

8:12AM Y31.00002 Self-consistent field theory for directed self-assembly in non-cylindrical confinement , TATSUHIRO IWAMA, Asahi Kasei E-Materials Co., University of California Santa Barbara, NABIL LAACHI, BONGKEUN KIM, KRIS DELANEY, GLENN FREDRICKSON, University of California Santa Barbara — We use self-consistent field theory to study the directed self-assembly (DSA) of diblock copolymers under non-cylindrical pore confinement such as oval, rectangular or the like. Our goal is to understand whether block copolymers can rectify non-cylindrical holes with reduced critical dimension in both minor direction and major direction of the non-cylindrical prepatterns. We explore a wide range of prepattern shapes, polymer characteristics to optimize DSA non-cylindrical holes. We also discover defects of DSA morphologies in the non-cylindrical prepattterns.

8:24AM Y31.00003 Phase behavior of binary blends of asymmetric diblock copolymers: Bulk and thin films , ADETUNJI ONIKOYI, EDWARD KRAMER, UCSB — Experimental and theoretical investigations of the phase behavior of binary blends of block copolymers in bulk state have been published, yet there is little work on the effects of confinement of such blends to thin films. We investigate the phase behavior of blends of two poly(styrene-b-2vinylpyridine) diblock copolymers; one sphere forming (BCP1, with $f_{P2VP} = 0.12$, N=538) and the other cylinder forming (BCP2, with f_{P2VP} =0.25, N=355). SAXS, TEM and SFM are used to characterize the microstructures formed as a function of temperature, blend compositions and film thickness. Results show that increased surface-induced free energy penalties in thin films lead to a significant change in phase behavior when compared to similar samples in bulk. Order disorder temperatures (ODT), mixing regimes and overall microstructure are strongly affected by the dominant contributions of the surface to the overall free energy of the system. Furthermore, for a regime (with BCP1 blend composition $\sim$ 0.4-0.6) of expected mixed phases of 2D hexagonal spheres and parallel cylinders in thin films, we are able to selectively stabilize 2D hexagonal sphere phases rather than the cylindrical phase by appropriate choice of confinement size and geometry.

8:36AM Y31.00004 Identifying the ODT in simulations of diblock copolymers using thermodynamic integration with a flexible simulation cell , PAVANI MEDAPURAM, JENS GLASER, DAVID MORSE, University of Minnesota — The order-disorder transition (ODT) has been precisely identified in several simulation models by using a thermodynamic integration procedure introduced by Mueller and Daoulas (*J. Chem. Phys.*, 128, 024903, 2008). We have applied the method to constant pressure simulations with a flexible tetragonal simulation unit cell to avoid incommensurability effects. The transition is found to be surprisingly weakly first order, even for very short chains, in agreement with recent experiment results on short, strongly-incompatible diblocks. Precise values for the value of χ N at the transition are obtained by combining this free energy method with a fit of the disordered state scattering data to the renormalized one-loop theory, which is found to give an excellent fit for several different models over a wide range of molecular weights. Results from different chain lengths and models are compared to test the degree of universality of the ODT, and to test the accuracy of the Fredrickson-Helfand theory predictions for the ODT.

8:48AM Y31.00005 Identifying the ODT in simulations of diblock copolymers using metadynamics , JENS GLASER, DAVID MORSE, Dept. of Chemical Engineering and Materials Science, University of Minnesota — We propose a novel approach based on the structure factor as an order parameter and metadynamics as a free-energy technique to precisely locate the order-disorder transition in melts of symmetric diblock copolymers, which is flucutation-induced first-order. We are able to directly measure the height of the free energy barrier separating the disordered and the ordered phase. We quantify finite size effects on the free energy minima and barrier.

9:00AM Y31.00006 Rod-Coil Block Copolymer Simulation With SCFT , LEE TRASK, ERIC COCHRAN, Iowa State University — Theoretical and experimental investigations of rod-coil block copolymer systems have made leaps forward recently. Fully 3D computer simulations of rod-coil diblock copolymer systems using self-consistent field theory (SCFT) have become feasible due to advances in theory and computer resources, while a number of experimental papers have illustrated a wide array of phases. These simulations include the use of all spatial and orientational degrees of freedom along with a Maier-Saupe interaction to describe the rod-rod alignment interactions. However, these 3D simulations have not been compared to experimental data. Simulations of moderately segregated poly(alkoxyphenylenevinylene-*b*-isoprene) (PPV-*b*-PI) are performed for a range of characteristic parameters linked to these systems. For different Flory-Huggins parameters, compositions, Maier-Saupe parameters, and geometric asymmetries, phase diagrams are constructed and compared with the phase diagrams previously reported in the literature. Along with phase space information, the domain space scaling relationship of the lamellar phase as a function of molecular weight is compared.

9:12AM Y31.00007 Self-consistent Field Theory Simulations of the Phase Behavior of Tapered Diblock Copolymers , JONATHAN BROWN, LISA HALL, Ohio State University — Phase diagrams of tapered and inverse-tapered diblock copolymers were computed by self-consistent field theory. These copolymers consist of three "blocks": a pure A block, a linear gradient "block" that is either A to B (tapered) or B to A (inverse-tapered), and a pure B block. This composition was approximated using a multi-block model in which the tapered region consisted of alternating A and B blocks of appropriate size to approximate the gradient. Phase diagrams were produced for varying sizes of the tapered region, showing a shift of the ordered phases to higher χN for larger tapered regions (and higher still for inverse-tapered systems), while preserving non-lamellar phases in some cases.

9:24AM Y31.00008 Theory of Chiral Block Copolymer Melts: Mesoscopic Helicity from Inter-Segment Twist , GREGORY GRASON, WEI ZHAO, THOMAS RUSSELL, University of Massachusetts Amherst — We study the effects of chirality at the segment scale on the thermodynamics of block copolymer melts using self consistent field theory. In linear diblock melts where segments of one block prefer a twisted, or cholesteric, texture, we show that melt assembly is critically sensitive to the ratio of random coil size to the preferred pitch of cholesteric twist. For weakly-chiral melts (large pitch), mesophases remain achiral, while below a critical value of pitch, two mesocopically chiral phases are stable: an undulated lamellar phase; and a phase of hexagonally-ordered helices. We show that the non-linear sensitivity of meso-scale chiral order to preferred pitch derives specifically from the geometric and thermodynamic coupling of the helical mesodomain shape to the twisted packing of chiral segments within the core, giving rise to a second-order cylinder-to-helix transition.

9:36AM Y31.00009 Self-assembly of peptoid block copolymers with tunable conformational asymmetry , ADRIANNE ROSALES, University of California, Berkeley, RONALD ZUCKERMANN, Lawrence Berkeley National Laboratory, RACHEL SEGALMAN, University of California, Berkeley — Functional polymers such as conjugated or biological molecules have been shown to have a variety of chain conformations that affect their self-assembly. Polypeptoids are sequence-specific biomimetic polymers for which the statistical segment length can be tuned by the introduction of monomers with bulky, chiral side chains, allowing one to change the polymer conformation independent of chemical structure or molecular weight. Furthermore, sequence specificity enables the precise placement of those chiral monomers along the polymer chain. This work presents a systematic study of block copolymer self-assembly using chiral polypeptoids or their racemic analogs and poly(n-butyl acrylate). For the chiral block copolymers, SAXS measurements reveal that the change in conformational asymmetry increases the morphological domain spacing and decreases the corresponding interfacial area per chain, indicating that the chiral peptoid chains can pack more closely within the domain compared to the racemic peptoid chains. The effect on domain spacing is also probed by changing the position of the chiral monomers with respect to the block copolymer junction. These results lend insight to the design of block copolymers with secondary structure.

9:48AM Y31.00010 Phase coexistence calculations via a unit-cell Gibbs ensemble formalism for melts of reversibly bonded block copolymers , ZOLTAN MESTER, NATHANIEL LYND, GLENN FREDRICKSON, University of California, Santa Barbara — Melts of block copolymer blends can exhibit coexistence between compositionally and morphologically distinct phases. We derived a unit-cell approach for a field theoretic Gibbs ensemble formalism to rapidly map out such coexistence regions. We also developed a canonical ensemble model for the reversible reaction of supramolecular polymers and integrated it into the Gibbs ensemble scheme. This creates a faster method for generating phase diagrams in complex supramolecular systems than the usual grand canonical ensemble method and allows us to specify the system in experimentally accessible volume fractions rather than chemical potentials. The integrated approach is used to calculate phase diagrams for AB diblock copolymers reversibly reacting with B homopolymers to form a new diblocks we term "ABB." For our case, we use a diblock that is sixty percent A monomer and a homopolymer that is the same length as the diblock. In the limits of infinite reaction favorability (large equilibrium constant), the system approaches cases of an ABB diblock-B homopolymer blend when the AB diblock is the limiting reactant and AB diblock-ABB diblock blend when the homopolymer is the limiting reactant. As reaction favorability is decreased, the phase boundaries shift towards higher homopolymer compositions so that sufficient reaction can take place to produce the ABB diblock that has a deciding role stabilizing the observed phases.

10:00AM Y31.00011 Phase behavior of multi-arm star-shaped polystyrene-*block*-poly(methyl methacrylate) copolymer , SANGSHIN JANG, HONG CHUL MOON, DUSIK BAE, JONGHEN KWAK, JIN KON KIM, Pohang University of Science and Technology — We synthesized star-shaped polystyrene-*block*-poly(methyl methacrylate) copolymer (PS-b-PMMA) by utilizing α-cyclodextrin (α-CD) as a core of the star-shaped block copolymer. Eighteen hydroxyl groups on α-CD were transformed to bromine by the reaction with α-bromoisobutyryl bromide. We found that the number of bromine substituted arms per one α-CD was higher than 16, which was determined by nuclear magnetic resonance and Matrix-assisted laser desorption/ionization. We could control molecular weight of block copolymers by changing polymerization times. The block copolymers were characterized by gel permeation chromatography and nuclear magnetic resonance. Phase behaviors of these star-shaped block copolymers were investigated by small angle X-ray scattering and transmission electron microscopy.

10:12AM Y31.00012 Pressure Effect of Various Inert Gases on the Phase Behavior of Polystyrene-*block*-Poly(n-pentyl methacrylate) Copolymer , HONG CHUL MOON, HYE JEONG KIM, Pohang University of Science and Technology, JUNHAN CHO, Dankook University, JIN KON KIM, Pohang University of Science and Technology — We investigated the pressure effect of three inert gases (nitrogen, helium and argon) on the phase behavior of polystyrene-*block*-poly(n-pentylmethacrylate) copolymer (PS-b-PnPMA) showing closed-loop phase behavior and baroplasticity. Helium gas pressure enhanced the miscibility between PS and PnPMA blocks similar to the hydrostatic pressure. Very interestingly, however, with increasing nitrogen and argon gas pressure, the miscibility between the two blocks decreased even though these two are also considered as inert gases. To explain these unexpected results, we measured the amount of gas absorption into each block. The experimentally measured gas absorption results are consistent with the theoretical ones based on the Sanchez-Lacombe theory. The results in this study imply that well-known and widely employed inert gases such as nitrogen and argon could significantly affect the phase behavior of a weakly interacting block copolymer at high pressures.

10:24AM Y31.00013 Micellization behavior of A-b-(B-*alt*-C)$_{\rm n}$ multiblock terpolymers in a selective solvent for one terminal A-block , YU-CHIEH HSU, CHING-I HUANG, Institute of Polymer Science and Engineering, National Taiwan University, Taiwan, WEIHUA LI, FENG QIU, Department of Macromolecular Science, Fudan University, China, AN-CHANG SHI, Department of Physics and Astronomy, McMaster University, Canada — We used self-consistent field theory to investigate the micellization behavior of A-b-(B-*alt*-C)$_{\rm n}$ multiblock terpolymers in the presence of a solvent that is selective to the terminal A-block. In particular, we focused on the effects of $\chi_{\rm BC}$, and $f_{\rm A}$, on the formation of micelles from ABC triblock and A(BC)$_3$ multiblock terpolymers, respectively. We observed a general trend that a segmented packing of B- and C-layers along the axial direction of the micelles is favored than the coaxial packing with the increasing of $\chi_{\rm BC}$ or decreasing of $f_{\rm A}$. The separation of B and C blocks within a micelle leads to the formation of a variety of multicompartment micelle morphologies, such as core-shell-corona spherical micelles, hamburgers, and bump-surface micelles, in the ABC triblock copolymers. In the A(BC)$_3$ multiblock terpolymers, we discovered more fascinating micelles by implementing the SCFT simulation than by the DPD simulation. Besides the BC-segmented worm-like micelles, which have been found in the DPD simulation work, concentric multilayer spheres and vesicles can be formed by the solvent-induced effect when the solvophilic A-block is a majority component.

10:36AM Y31.00014 Micellar Packing in Aqueous Solutions of As-Received and Pure Pluronic Block Copolymers[1] , CHANG RYU, HAN JIN PARK, Rensselaer Polytechnic Institute — Pluronic block copolymers (Pluronics) are produced on a commercial scale to enable wide range of novel applications from emulsification and colloidal stabilization as nonionic surfactants. While the Pluronic block copolymers offer the advantages of being readily available for such applications, it contains non-micellizable low molecular weight (MW) impurities that would interfere with the self-assembly and micellar packing of PEO-PPO-PEO triblock copolymers in aqueous solutions. The impacts of the low MW impurities will be discussed on the micellar packing of Pluronics F108 and F127 solutions, which form BCC and FCC. While as-received Pluronic samples typically contain about 20 wt.% low MW impurities, we were able to reduce the impurity level to less than 2 wt.% using our large scale purification technique. Comparative studies on small angle x-ray scattering (SAXS) experiments on as-received and purified Pluronics solutions revealed that the contents of triblock copolymers in solutions essentially governs the inter-micellar distance of Pluronic cubic structures. A universal relationship between triblock copolymer concentration and SAXS-based domain spacing has been finally discussed.

Friday, March 22, 2013 8:00AM - 10:48AM –

Session Y32 DPOLY: Polymer Nanocomposites III 340 - Jeff Meth, DuPont Chemicals

8:00AM Y32.00001 Layered polymer nanocomposite films of type-specific single wall carbon nanotubes , MATTHEW R. SEMLER, JOHN M. HARRIS, NDSU, JEFFREY A. FAGAN, NIST, ERIK K. HOBBIE, NDSU — Thin networks of single-wall carbon nanotubes (SWCNTs) on elastic polymer substrates show significant promise for applications in flexible electronics, but the modulus and conductivity of such films can degrade significantly under an applied strain. This softening occurs because strong van der Waals interactions between adjoining nanotubes promote coarsening into a preferred parallel alignment under even modest compression. We demonstrate that by capping the nanotube layer with a thin glassy polymer film, the mechanical properties of networks can be substantially improved, which we attribute to the stabilizing influence of excluded-volume interactions.

8:12AM Y32.00002 Influence of Thermal History on Microphase Separation and Morphology of Elastomeric Polyureas[1] , JAMES RUNT, ALICIA CASTAGNA, AUTCHARA PANGON, Department of Materials Science and Eng, Penn State University — Polyureas are versatile elastomers consisting of alternating soft and hard segments. These polymers tend to form a nanophase-segregated morphology consisting of high aspect ratio hard domain ribbons in a low Tg matrix, the details of which are key in tailoring the unique characteristics of this family of materials. In the present work, bulk-polymerized polyureas were synthesized from a modified diphenylmethane diisocyanate and a polytetramethyleneoxide based diamine (1000 g/mol) and annealed at selected elevated temperatures. Various experimental probes (e.g. atomic force microscopy and small-angle X-ray scattering) reveal significant changes in hard domain ordering as a function of thermal history. Time-resolved synchrotron X-ray scattering was also conducted as a function of temperature to augment these findings.

8:24AM Y32.00003 ABSTRACT WITHDRAWN –

8:36AM Y32.00004 Optical characterization of isotactic polypropylene and carbon nanotube composites using spectroscopic ellipsometry , SABYASACHI SARKAR, PARVATHALU KALAKONDA, Worcester Polytechnic Institute, GEORGI GEORGIEV, Assumption College, GERMANO IANNACCHIONE, Worcester Polytechnic Institute — We report the dielectric properties of optically characterized isotactic polypropylene (iPP) and its composites with carbon nanotubes (CNTs) using spectroscopic ellipsometry. Characterization was performed at angles ranging from 50 to 70 degrees and for the spectral range between 300-1000 nm. CNT concentrations varied from 0 to 5 wt% in the iPP/CNT composites investigated. Ellipsometry is a non-invasive and non-destructive technique that enabled us to determine the dielectric properties of the materials investigated. A concentration dependency on CNT wt% was found to exist for both the refractive index and the extinction coefficient for the iPP/CNT composites. At higher concentrations however, this distinction was not very clear, suggesting that saturation levels were reached in the material. We will also discuss our efforts to separate the optical properties of bound CNT from the analyzed nanocomposites.

8:48AM Y32.00005 Temperature dependent photoluminescence from polymer nanocomposites of size-puified silicon quantum dots , AUSTIN R. VANSICKLE, JOSEPH B. MILLER, NDSU, REBECCA J. ANTHONY, UWE R. KORTSHAGEN, University of Minnesota, ERIK K. HOBBIE, NDSU — The photoluminescence (PL) of polydimethylsiloxane (PDMS) nanocomposites of size-purified silicon nanocrystals is measured as a function of temperature and nanoparticle size. The overall behavior is in agreement with the trends imposed by quantum confinement, where the temperature dependence of the nanocrystal bandgap is governed primarily by intrinsic electron-phonon coupling. The response of the PDMS nanocomposites provides a consistent measure of local temperature through intensity and lifetime in a polymer-dispersed morphology suitable for biomedical applications, and we exploit this to fabricate a small-footprint fiber-optic cryothermometer.

9:00AM Y32.00006 Non-Bleaching Photoluminescent Magnetic Nanoparticles , LU ZOU, CHANJOONG KIM, Kent State University, EMAD GIRGIS, WAGDY K. B. KHALIL, National Research Centre, Egypt — We report a new type of photoluminescent magnetic nanoparticles produced by a very simple process. The nanoparticle consists of an ordinary magnetic nanoparticle as core and a non-toxic polymer shell. The biocompatibility is evaluated using in-vivo tests on mice. They are non-bleaching photoluminescent without any addition of fluorophores, such as quantum dots or fluorescent dyes that can be toxic and easily photobleached, respectively. This work provides a low-cost, bio-safe, non-bleaching alternative of conventional fluoroscent magnetic nanoparticles which covers a wide range of applications, from bio-imaging to biomedical diagnostics and therapeutics, such as hyperthermia.

9:12AM Y32.00007 Electrically Percolating Clusters in Sheared Carbon Nanotube Composites , KALMAN MIGLER, DOYOUNG MOON, JAN OBRZUT, JACK DOUGLAS, Materials Science and Engineering Division, NIST, Gaithersburg, MD, THOMAS LAM, RENU SHARMA, ALEX JAMES LIDDLE, Center for Nanoscale Science and Technology, NIST, Gaithersburg, MD — The electrical conductivity of polymer nanotube composites can be dramatically modified by processing flows and subsequent annealing. The mechanism is widely believed to be nanotube structural rearrangements that occur during flow and alter the percolating pathways. We seek to directly visualize these flow-induced three-dimensional percolating clusters through three-dimensional confocal microscopy and image analysis.

9:24AM Y32.00008 Electrical properties of isotactic polypropylene loaded with carbon nanofibers , MIRCEA CHIPARA, The University of Texas Pan American, MAGDALENA L. CIUREA, National Institute of Materials Physics, Romania, KAREN LOZANO, The University of Texas Pan American, GHEORGHE V. ALDICA, National Institute of Materials Physics, Romania, DORINA M. CHIPARA, The University of Texas Pan American, STELIAN POPA, IONEL STAVARACHE, National Institute of Materials Physics, Romania — Nanocomposites have been obtained by dispersing vapor grown carbon nanofibers (VGCNF) within isotactic polypropylene (iPP) via melt mixing. VGCNFs were purified and disentangled before blending with iPP. The mixing was performed by using HAAKE Rheomix, at 180 ^{o}C and 65 rpm for 9 minutes followed by an additional mixing at 90 rpm for 5 minutes (same temperature). The electrical properties of nanocomposites loaded with various amounts of VGCNFs (0%, 1%, 2.5%, 5%, 7.5%, 10%, 15%, and 20% wt.) have been investigated. DC electrical measurements revealed a percolation threshold at about 12 % wt. VGCNFs. The DC electrical characteristics of the nanocomposites located above the percolation threshold were investigated in detail, in a wide temperature range starting from 20 K up to about 750 K. The investigations revealed small changes of the DC conductivity within the glass and melting transition range of the polymeric matrix. The dominant charge transport mechanism below the glass transition temperature as well as between the glass and melting transition temperature is the variable range hopping. Above the melting temperature an Arrhenius like dependence of the DC conductivity was noticed.

9:36AM Y32.00009 Polyaniline-SnO_2 Nanocomposites for Better Sensitivity of NO_X gases at Lower Temperatures , NAVENDU GOSWAMI, Department of Physics and Material Science and Engineering, Jaypee Institute of Information Technology, A-10, Sec. 62, Noida -201307, India, ANJALI SHARMA, MONIKA TOMAR, VINAY GUPTA, Department of Physics and Astrophysics, University of Delhi, New Delhi-110007, India — We demonstrate that the sensor based on Polyaniline (PAni) nanofibers, simply prepared by the interfacial polymerization, has advantages of sensitivity, spatial resolution and rapid time response for NO_2 gas at room temperature. Although PAni is one of the most studied conducting polymers due of its good electrical conductivity, environmental stability and relative easier synthesis, yet due to poor solubility of PAni, it is difficult to form the film adopting conventional methods. Nonetheless, nanomaterials of conjugated polymers are found to exhibit superior performance as compared to conventional materials due to their larger exposed surface area. The objective of this work is to study the PAni doped SnO_2 nanocomposite as novel sensing system and to probe the NOx sensing characteristics of this sensor at room temperature. Here we focus on the effect of doping ratio of sensor material, gas flow time and response time. PAni with different amounts has been stirred with SnO_2 solution to obtain SnO_2/PAni mixture. In present work, sensors with different PAni doping ratio were prepared and characterized so as to ascertain the favorable conditions for higher sensitivity, selectivity and better gas sensing characteristics. The as-grown films characterized employing various techniques and revealed that PAni/SnO_2 nanocomposite show good gas sensitivity at 30-100 $^{\circ}$C.

9:48AM Y32.00010 Self-healing of polymeric materials: The effect of the amount of DCPD confined within microcapsules[1] , DORINA M. CHIPARA, ALMA PEREZ, KAREN LOZANO, IBRAHIM ELAMIN, JAHAZIEL VILLARREAL, ALFONSO SALINAS, MIRCEA CHIPARA, The University of Texas Pan American — The self-healing SH) of polymers is based on the dispersion of a catalyst and of microcapsules filled with monomer within the polymeric matrix. Sufficiently large external stresses will rupture the microcapsule, releasing the monomer which will diffuse through the polymer and eventually will reach a catalyst particle igniting a polymerization reaction. The classical SH system includes first generation Grubbs catalyst and poly-urea formaldehyde microcapsules filled with DCPD. The polymerization reaction is a ring-opening metathesis. The size and the mechanical features of microcapsules are critical in controlling the SH process. Research was focused on the effect of DCPD on the size and thickness of microcapsules. Microscopy was used to determine the size of microcapsules (typically in the range of 10^{-4} m) and the thickness of the microcapsules (ranging between 10^{-6} to 10^{-8} m). Research revealed a thick disordered layer over a thin and more compact wall. Raman spectroscopy confirmed the confinement of DCPD, TGA measurements aimed to a better understanding of the degradation processes in inert atmosphere, and mechanical tests supported the ignition of self-healing properties.

[1]This research has been supported by National Science Foundation under DMR (PREM) grant 0934157.

10:00AM Y32.00011 Engineering Flame Retardant Biodegradable Nanocomposites[1] , SHAN HE, KAI YANG, YICHEN GUO, LINXI ZHANG, SEONGCHAN PACK, SUNY, Stony Brook University, RACHEL DAVIS, Massachusetts Institute of Technology, MENAHEM LEWIN, Polytechnic Institute of New York University, HARALD ADE, Department of Physics, North Carolina State University, CHAD KORACH, SUNY, Stony Brook University, TAKASHI KASHIWAGI, Fire Research Division, National Institute of Standards and Technology, Gaithersburg, MIRIAM RAFAILOVICH, SUNY, Stony Brook University — Cellulose-based PLA/PBAT polymer blends can potentially be a promising class of biodegradable nanocomposites. Adding cellulose fiber reinforcement can improve mechanical properties of biodegradable plastics, but homogeneously dispersing hydrophilic cellulose in the hydrophobic polymer matrix poses a significant challenge. We here show that resorcinol diphenyl phosphates (RDP) can be used to modify the surface energy, not only reducing phase separation between two polymer kinds but also allowing the cellulose particles and the Halloysite clay to be easily dispersed within polymer matrices to achieve synergy effect using melt blending. Here in this study we describe the use of cellulose fiber and Halloysite clay, coated with RDP surfactant, in producing the flame retardant polymer blends of PBAT(Ecoflex) and PLA which can pass the stringent UL-94 V0 test. We also utilized FTIR, SEM and AFM nanoindentation to elucidate the role RDP plays in improving the compatibility of biodegradable polymers, and to determine structure property of chars that resulted in composites that could have optimized mechanical and thermal properties.

10:12AM Y32.00012 Designing high hard block Content TPU resins for composite application , ALBERTO SAIANI, The University of Manchester, School of Materials, UK, CHINEMELUM NEDOLISA, The University of Manchester, School of Materials, UK, CHRISTOPHER I. LINDSAY, Huntsman Polyurethanes, Everslaan 45, 3078 Everberg, Belgium, POLYMER AND PEPTIES RESEARCH GROUP TEAM, HUNTSMAN POLYURETHANES TEAM — Thermoplastic Polyurethanes (TPU) are linear block copolymers typically constructed of statistically alternating soft (SS) and hard (HS) segments. Due to their numerous industrial applications these materials have received considerable attention. We have recently investigated the phase behavior and morphology of a set of high hard block content polyurethanes. Using mainly calorimetry, scattering and microscopy techniques we were able to elucidate the origins of all the thermal events observed through differential scanning calorimetry and propose a new morphological model of the structure and the phase behavior of these high hard block content polyurethanes [A. Saiani et al. Macromolecules, 34, 9059-9068 (2001); 37, 1411-1421 (2004); 40, 7252-7262 (2007)]. We have now shown that these new materials can potentially be used as resins for designing fiber based composites and investigated the effect of processing on conditions the final properties of the composites

10:24AM Y32.00013 Structure and Dynamics Characterization of HMDI- and MDI-based Poly(urethane urea) Elastomers via Solid- State NMR , WEIGUO HU, University of Massachusetts Amherst, ALEX HSIEH, B. CHRISTOPHER RINDERSPACHER, TANYA CHANTAWANSRI, U.S. Army Research Laboratory — High performance elastomers have recently gained considerable interest throughout DoD, particularly for their potential in ballistic impact protection and blast mitigation capabilities. Recent simulation results based on coarse-grained modeling have revealed the role of the intermolecular interaction and the flexibility of interface between hard and soft segments on the morphology and mechanical deformation behavior of poly(urethane urea), PUU, elastomers. In this work, we exploit solid-state nuclear magnetic resonance (NMR) techniques to investigate the influence of hard domain size on molecular dynamics by comparing the diisocyanate chemistry (aliphatic 4,4'-dicyclohexylmethane diisocyanate (HMDI) vs. aromatic 4,4'-diphenylmethane diisocyanate (MDI)) in PUU elastomers. Despite identical stoichiometry and soft segment chemical structure, large difference in the molecular dynamics, indicated by the ^{1}H dipolar dephasing time (T_d), is observed. The T_d of HMDI-PUU is shorter and it exhibits higher activation energy, suggesting finer phase mixing. Results from ^{1}H spin echo measurements are also included for comparison.

10:36AM Y32.00014 Thermal Boundary Resistance Across Solid-Fluid Interface[1] , SANGHAMITRA NEOGI, DAVIDE DONADIO, Max-Planck Institute for Polymer Research, Ackermannweg 10, 55128 Mainz - Germany — The recent advances in the field of nanotechnology, specially the advent of nanostractures and nanocomposite materials, have prompted an increased interest in the study of thermal transport across interfaces. When heat flows across an interface, the local temperature presents a discontinuity which is related to the thermal boundary resistance (TBR), also known as the Kapitza resistance. The investigation of Kapitza resistance has important technological applications in the improvement of the thermal performances of composite materials. The current theoretical understanding of TBR is primarily based on the "acoustic mismatch theory" or the "diffusive mismatch model." Both these models consider only the bulk properties of the two materials, with no account being taken of the details of the material properties near the interface. Here, we investigate the thermal transport across a model solid-fluid interface using the technique of reverse non-equilibrium molecular dynamics simulations. The interaction potentials between the particles in our system are governed by the Lennard-Jones potential. We study the influence of pressure on the thermal boundary resistance for a range of mismatched interfaces and compare our results to the existing analytical models.

Session Y33 DMP: Focus Session: Organic Electronics and Photonics - Morphology and Structure I 341 - Penpeng Zhang, Michigan State University

8:00AM Y33.00001 Molecular simulation studies of morphology in blends of conjugated polymers and fullerene derivatives for organic photovoltaic applications , ERIC JANKOWSKI, HILARY MARSH, ARTHI JAYARAMAN, University of Colorado at Boulder — The device efficiency of organic solar cells is dependent on the microstructure of the active layer, which is typically a mixture of conjugated polymer electron donor molecules and fullerene based acceptor molecules. Active layer morphology can be tuned by choosing these acceptor and donor components that self-assemble into thermodynamically stable structures and by choosing processing conditions that facilitate the formation of equilibrium structures or that "trap" the active layer in an optimal metastable configuration. We present the results of molecular dynamics studies of model conjugated polymers and fullerene derivatives performed on GPUs. We show that the ordered structures that are self-assembled from initially disordered configurations depend strongly upon the strength of the attractions between acceptor and donor molecules, the relative amounts of each component, and the architecture of the donor molecules. Further we quantify the relaxation times and suggest processing strategies for obtaining optimal morphologies for charge transport.

8:12AM Y33.00002 Correlation of Fullerene Structure to its Miscibility in P3HT and OPV Function , MARK DADMUN, HUIPENG CHEN, University of Tennessee, JEFF PEET, Konarka — The miscibility of four fullerenes, bis-PCBM, ICBA, Thio-PCBM and $PC_{70}BM$ in poly(3-hexylthiophene) (P3HT) is determined by neutron reflectivity by monitoring the intermixing of P3HT and fullerene bilayers with thermal annealing. The miscibility limit of these fullerenes in P3HT ranges from 11% to 26%, where the bis-adduct fullerenes exhibit a lower miscibility in P3HT than singly functionalized fullerenes. The correlation of miscibility to device performance indicates that sufficient polymer/fullerene miscibility is crucial to rationally optimize organic photovoltaic active layers. Low miscibility of conjugated polymer and fullerene in the amorphous phase decreases the probability of exciton dissociation and enhances the recombination of free charge-carriers. Moreover, the results indicate that the average surface-to-surface distance between fullerenes must be less than approximately of 5-7 Å to minimize charge traps and allow sufficient charge transport in the mixed phase to improve photovoltaic performance.

8:24AM Y33.00003 Mixing-Induced Anisotropic Correlations in Molecular Crystalline Systems: Rationalizing the Behavior of Organic Semiconductor Blends , KATHARINA BROCH, ANTJE AUFDERHEIDE, JIRI NOVAK, ALEXANDER HINDERHOFER, ALEXANDER GERLACH, RUPAK BANERJEE, FRANK SCHREIBER, Institut fuer Angewandte Physik, Universitaet Tuebingen, Germany — Binary mixtures of organic semiconductors (OSCs) have recently become an important field of research, as they find applications in opto-electronic devices [1]. In these systems, the mixing (intermixing vs. phase separation) and ordering behavior is crucial, since it affects the optical and electronic properties. We present a comprehensive study of binary mixtures of the three prototypical OSCs pentacene (PEN), perfluoropentacene (PFP) and diindenoperlyene (DIP) in all possible combinations [1,2]. Using X-ray reflectivity and grazing incidence X-ray diffraction we investigate the stuctural properties of the mixed films as well as their impact on the optical spectra obtained by spectroscopic ellipsometry. For PEN:DIP we find an anisotropic ordering behavior, comparable to that observed in some liquid crystals, which is fundamentally new for OSCs [2]. The influence of sterical compatibility and the strength of the intermolecular interactions on the mixing and ordering behavior in the different blends will be discussed by extending a conventional mean-field model [1]. Finally, we discuss general rules for the targeted preparation of blends of OSCs. [1] A. Hinderhofer and F. Schreiber, Chem. Phys. Chem., 13, 628 (2012); [2] A. Aufderheide et al., Phys. Rev. Lett., 109, 156102 (2012)

8:36AM Y33.00004 Domain compositions in the active layer of low band gap polymer/fullerene solar cells strongly affect device performance[1] , SAMEER VAJJALA KESAVA, Penn State University, ZHUPING FEI, MARTIN HEENEY, Imperial College, London, CHENG WANG, ALEXANDER HEXEMER, Advanced Light Source, LBL, ENRIQUE GOMEZ, Penn State University, ENRIQUE GOMEZ-MARTIN HEENEY COLLABORATION, ENRIQUE GOMEZ-ALEXANDER HEXEMER COLLABORATION — We have characterized the morphology of mixtures of a germole-containing polymer, poly[(4,4'-bis(2-ethylhexyl)dithieno[3,2-b:2',3'-d]germole)-2,6-diyl-alt-(2,1,3-benzothiadiazole)-4,7-diyl] (PGeBTBT), and PCBM using Resonance Soft X-ray Scattering (RSOXS) and Energy-Filtered Transmission Electron Microscopy (EFTEM). PGeBTBT belongs to cyclopentadithiophene-based polymer family with a band gap of 1.5 eV. Analyses of RSOXS data and EFTEM images have shown that the volume fraction of polymer in the fullerene matrix enveloping PGeBTBT fibers ($\sim$10 nm diameter) decreases with increasing overall composition of PCBM. Furthermore, PGeBTBT/PCBM devices demonstrate a correlation between the short circuit current and the purity of the PCBM-rich phase. We hypothesize that the relationship between PCBM domain composition and device performance is related to charge recombination, where increasing the polymer content suppresses charge transport thereby increasing the transit time.

8:48AM Y33.00005 The importance of domain purity for performance in P(NDI2OD-T2)-based all-polymer solar cells revealed by resonant x-ray scattering , HARALD ADE, NCSU, BRIAN COLLINS, NIST, MARCEL SCHUBERT, STEFFEN ROLAND, ROBERT STEYRLUETHNER, University Potsdam, ZHIHUA CHEN, ANTONIO FACCHETTI, Polyera, DIETER NEHER, University Potsdam — The nanostructure of bulk heterojunction organic solar cells has long been recognized as critical to their performance. To date, the primary morphological characteristics under investigation have been the level and nature of crystallinity of the materials. Yet the recent and wide-spread measurement of molecular mixing and diffusion of the electron donor and acceptor materials in amorphous regions has focused attention on the non-crystalline portions in these films as well. Here we investigate both aspects using x-ray diffraction and resonant scattering techniques to measure crystallinity and the domain sizes and purities, respectively, of devices based on P3HT:P(NDI2OD-T2) blends. The repercussions of the nanostructure is revealed in measurements of exciton bandwidth and photoluminescence quenching. We find that through variation of solvent blends and film drying conditions can significantly alter domain size and purity. This results in significant increases in device performance that correlate with increased domain purity and exciton bandwith of the P3HT crystals. This strongly indicates that molecular mixing of these materials is detrimental to performance in harvesting solar energy.

9:00AM Y33.00006 Probing the morphology of novel non-fullerene based bulk heterojunction solar cells , GREGORY SU, TOAN PHO, FRED WUDL, EDWARD KRAMER, MICHAEL CHABINYC, University of California, Santa Barbara — Organic semiconductors are promising for low-cost, large-area electronics such as organic photovoltaics (OPVs). OPVs require an active layer that is an intimate mixture of an electron donor, usually a conjugated polymer, and an electron acceptor, typically a fullerene. While fullerene-based OPVs show high efficiencies, the inability to tune its electronic levels limits the open circuit voltage, so alternative acceptors are desirable. Here, we report on blend films consisting of a polymer donor, poly(3-hexylthiophene) (P3HT), and a novel acceptor, decacyclene triimide (DTI), that display good solar power conversion efficiencies (PCE) as-cast. The PCE of these blends decreases significantly with thermal annealing, unlike P3HT:fullerene blends. NEXAFS spectroscopy and grazing incidence wide angle X-ray scattering suggest the PCE decrease is due to the formation of hexagonally packed DTI columns with an in-plane π-π stacking direction, resulting in poor electron transport out-of-plane. Polarized resonant soft X-ray scattering suggests that the π-π stacking directions are orthogonal at interfaces between DTI and P3HT domains. These results demonstrate the importance of blend morphology in OPV efficiency and key differences between DTI-based and fullerene-based blends.

9:12AM Y33.00007 Tuning polymer/inorganic blend morphology using pyridine terminated poly(3-hexylthiophene)s: Novel ligands for potential OPV applications , W. MICHAEL KOCHEMBA, S. MICHAEL KILBEY II, University of Tennessee, DEANNA L. PICKEL, BOBBY G. SUMPTER, Oak Ridge National Laboratory — End-functional pi-conjugated polymers are promising materials for the improvement of organic electronic devices due to their high hole mobility and ease of processability. Here we describe a "materials by design" approach to create 2- and 3-pyridyl, end-functionalized poly(3-hexylthiophene)s (P3HTs) that possess the capacity to ligate semiconductor quantum dots (SQDs). The replacement of native ligands on the SQD surface by pyridyl-terminated P3HTs provides the opportunity to manipulate the morphology of polymer/inorganic blends created by dispersing the P3HT-ligated SQDs in a P3HT matrix. TEM imaging and small angle x-ray scattering were used to assess the morphological traits of the blends as a function of ligand type, processing condition, and matrix molecular weight, which in general show that the P3HT ligands improve dispersion of the nanoparticles upon thermal annealing.

9:24AM Y33.00008 Determination of the Crystallinity of Semicrystalline Poly(3-hexyl thiophene) by Means of Wide Angle X-Ray Scattering , JENS BALKO, Martin Luther University Halle-Wittenberg, Halle, Germany, RUTH LOHWASSER, MUKUNDAN THELAKKAT, University of Bayreuth, Germany, MICHAEL SOMMER, University of Freiburg, Germany, OVIDIU PASCUI, KAY SAALWAECHTER, THOMAS THURN-ALBRECHT, Martin Luther University Halle-Wittenberg, Germany — Poly(3-hexyl thiophene) (P3HT) is a common polymer semiconductor, often used as material or component in organic field effect transistors or solar cells. The crystallinity of this semicrystalline material is among other parameters governing the electronic mobility. However, at present there is no routine method available to determine an absolute value for the crystallinity, and the values given in the literature e.g. for the enthalpy of melting vary by a factor of three. Wide Angle X-Ray Scattering (WAXS) probes the crystals as well the amorphous parts of the sample. We present an approach for the determination of the crystallinity based on the evaluation of WAXS intensities at low scattering vectors emanating from the amorphous regions. The result is used for a calibration of the melting enthalpy (34 J/g) that can serve as a reference value for more convenient calorimetric techniques and compared to the results of recent NMR investigations. We discuss the crystallinity for a number of chemically well-defined samples, with different molecular weight and a typical commercial sample with broad molecular weight distribution. Despite the high crystallinities of 60 to 80% the crystallites exhibit a large amount of disorder.

9:36AM Y33.00009 Structural and Morphological Analysis of Poly(3-hexylthiophene) at Surfaces and Interfaces[1] , YENENEH YIMER, MESFIN TSIGE, Department of Polymer Science, The University of Akron — The structure and morphology of semiconducting polymers such as Poly(3-hexylthiophene) (P3HT) at surfaces and interfaces have significant influence over the performance of organic solar cell devices. Because charge-carrier generation, transport to and collection at the electrodes depend on the material properties of P3HT - themselves controlled by factors including packing, orientation and environment - analysis of the mechanisms that contribute to efficient charge generation and minimization of recombination is necessary. Using molecular dynamics simulation, we have investigated the structural properties and morphological evolution of P3HT at different surfaces and interfaces. We have also investigated the dependence of those properties on temperature, chain length, and interfacial energies. The morphology of P3HT is correlated to efficient charge transport. Using our analyses, we have attempted to elucidate these correlations, which should help lead to optimization of the morphology of P3HT in devices in the pursuit of increasing the efficiency of polymeric devices.

9:48AM Y33.00010 Conjugated backbone orientation variation in high mobility regioregular PT based copolymers , LOUIS PEREZ, LEI YING , GUILLERMO BAZAN, EDWARD KRAMER , University of California - Santa Barbara — The synthesis of novel solution processable conjugated polymers is an active field of study due to the potential to fabricate low cost, high though-put electronic devices such as organic field effect transistors (OFET). A regioregular copolymer based on cyclopenta[2,1-*b*:3,4-*b*′]dithiophene (CDT) and pyridal[2,1,3]thiadiazole (PT) structural units has been prepared by using polymerization reactions involving reactants specifically designed to avoid random orientation of the asymmetric PT heterocycle. Compared to it's regiorandom counterpart, the regioregular polymer exhibits a two orders of magnitude increase in hole mobility from 0.005 to 0.6 $cm^2\,V^{-1}\,s^{-1}$. A combination of X-ray scattering techniques were employed to quantitatively access the degree of orientation and crystallinity in thin films (15-20 nm) that matched device architecture. We examined the backbone orientation dependence as a function of depth via grazing incidence wide angle X-ray scattering (GIWAXS) and found significant differences in the backbone stacking orientation between the regiorandom and regioregular copolymers. These experiments suggest the backbone regularity leads to significant differences in the structural arrangement and it is another important design criteria to consider in the design of new conjugated copolymers with asymmetric structural units.

10:00AM Y33.00011 Poly(3-hexylthiophene) Brush-Modified Interfaces for Control of Active Layer Morphology and Properties , S. MICHAEL KILBEY, W. MICHAEL KOCHEMBA, University of Tennessee, DEANNA PICKEL, JOSE ALONZO, Oak Ridge National Laboratory — Tailoring the morphology of donor-acceptor blends based on conjugated polymers and fullerenes is an essential part of optimizing the power conversion efficiency of organic photovoltaic (OPV) devices. While a variety of studies have demonstrated the importance of the nanoscale morphology of donor-acceptor blends on efficiency, a clear understanding of the links between morphology, processing, interfacial structure and device-level properties is yet to emerge. Here we turn to well-defined layers of end-tethered poly(3-hexylthiophene) (P3HT) chains as modifiers, or buffer layers, that straddle the inorganic/organic interface and exert control over the morphology of donor-acceptor blends. In addition to improving device performance characteristics, ostensibly due the presence of surface dipoles brought about by confinement, P3HT brushes affect the penetration of the fullerene derivative, 6,6-phenyl-C61-butyric acid methyl ester, PCBM, into the brush as well as the morphology of bilayers and blends of P3HT and PCBM coated atop the brushes. The role of molecular weight, chain grafting density, and thermal aging and light cycling on these behaviors will be highlighted.

10:12AM Y33.00012 Rod-Coil Copolymer as Efficient Compatibilizer for Thermally-Stable Polymer Solar Cell , H.J. KIM, K. PAEK, H. YANG, B.J. KIM, KAIST — Improving the thermal stability of polymer solar cells (PSC) is important for the future application of these devices since any heat generated by solar irradiation could be detrimental to the performance as a result of the relatively low Tg of polymers and the strong immiscibility of components in the active layer. Herein we have developed new type of compatibilizers having two different blocks of conjugated polymer and poly(2-vinyl pyridine)(P2VP). The P2VP and fullerene are mixed together by supramolecular interaction resulting conjugated polymer-P2VP copolymers act as a compatibilizer reducing the interfacial tension between the two dissimilar components of the PSC. Our compatibilizer successfully suppresses the macrophase separation of donor and acceptor blended films made of either singly functionalized PCBM or bisadduct fullerene derivatives. P3HT/o-xylene-C60-bissadduct fullerne(OXCBA) blended device containing 10 vol percent of compatibilizer shows an average efficiency higher than 4.3 percent after 60 h annealing at an elevated temperature of 150'C.

10:24AM Y33.00013 Percolating bulk-heterostructures from neutron reflectometry and small angle scattering data[1] , DANIEL OLDS, PHILLIP DUXBURY, Michigan State University — We present a novel algorithm for efficiently calculating the simulated small angle scattering data of any discretized morphological model of arbitrary scale and resolution, referred to as the distribution function method (DFM). Unlike standard SAS fitting methods, the DFM algorithm allows for the calculation of form factors and structure factors from complex nanoscale morphologies commonly encountered in many modern polymeric and nanoparticle based systems, which have no exact analytical corollary. The computational efficiency of the DFM algorithm suggests it's use in morphological model refinement. We will present a number of simple examples to demonstrate the accuracy and limits of the algorithm, followed by an example of incorporation of the DFM algorithm into reverse Monte Carlo structural refinement of bulk-heterojunction two-phase morphologies, such as those commonly found in organic photovoltaic devices. We will show that morphological features introduced via direct incorporation of experimental neutron reflectometry and SANS data to the models has a direct effect on the results of device simulations.

[1]The authors thank CORE-CM at Michigan State University for it's funding of this research.

10:36AM Y33.00014 In-situ Neutron Scattering Determination of 3D Phase-Morphology Correlations in Fullerene -Polymer Organic Photovoltaic Thin Films[1] , ALAMGIR KARIM, Dept of Polymer Engineering, University of Akron, DAVID BUCKNALL, Materials Science and Engineering, Georgia Institute of Technology, DHARMARAJ RAGHAVAN, Dept of Chemistry, Howard University, BOBBY SUMPTER, CNMS, Oak Ridge National Lab, SCOTT SIDES, Tech-X Corporation — The tunability of the morphology and structure of conjugated polymer-fullerene bulk heterojunctions (BHJs) is being investigated through synthesis of new materials, novel processing strategies and advanced characterization (experimental and computational). We are using this integrated approach to test currently poorly understood fundamental issues in organic photovoltaic (OPV) performance relating to structure-property and very importantly processing relationships. Using model conjugated polymer-fullerene systems, we are investigating how the phase morphology of the BHJs correlate with OPV efficiency. A range of fullerenes is being investigated that include a number of new derivatives that we have synthesized. We are currently investigating the use of surface energy confinement and block copolymer templating to control both phase domain segregation and orientation relative to the film normal to allow us to test morphology-device efficiency hypotheses in OPVs. Using both neutron scattering and computational modeling we have developed important correlations that establish relationships between the polymer-fullerene miscibility, phase domain orientation and interfacial behavior with the corresponding photoelectronic properties.

Friday, March 22, 2013 8:00AM - 11:00AM –

Session Y34 DPOLY: Focus Session: Microfluidics, Nanofluidics Applications 342 - Alberto Fernandez-Nieves, Georgia Institute of Technology

8:00AM Y34.00001 Acoustic Microfluidics for Bioanalytical Application[1] , GABRIEL LOPEZ, Duke University — This talk will present new methods the use of ultrasonic standing waves in microfluidic systems to manipulate microparticles for the purpose of bioassays and bioseparations. We have recently developed multi-node acoustic focusing flow cells that can position particles into many parallel flow streams and have demonstrated the potential of such flow cells in the development of high throughput, parallel flow cytometers. These experiments show the potential for the creation of high throughput flow cytometers in applications requiring high flow rates and rapid detection of rare cells. This talk will also present the development of elastomeric capture microparticles and their use in acoustophoretic separations. We have developed simple methods to form elastomeric particles that are surface functionalized with biomolecular recognition reagents. These compressible particles exhibit negative acoustic contrast in ultrasound when suspended in aqueous media, blood serum or diluted blood. These particles can be continuously separated from cells by flowing them through a microfluidic device that uses an ultrasonic standing wave to align the blood cells, which exhibit positive acoustic contrast, at a node in the acoustic pressure distribution while aligning the negative acoustic contrast elastomeric particles at the antinodes. Laminar flow of the separated particles to downstream collection ports allows for collection of the separated negative contrast particles and cells. Separated elastomeric particles were analyzed via flow cytometry to demonstrate nanomolar detection for prostate specific antigen in aqueous buffer and picomolar detection for IgG in plasma and diluted blood samples. This approach has potential applications in the development of rapid assays that detect the presence of low concentrations of biomarkers (including biomolecules and cells) in a number of biological sample types.

[1]We acknowledge support through the NSF Research Triangle MRSEC.

8:36AM Y34.00002 Electrokinetic device for three-dimensional trapping of single fluorescent emitters , JASON K. KING, BRIAN K. CANFIELD, LLOYD M. DAVIS, University of Tennessee Space Institute — Trapping by use of actively controlled electric fields is a valuable tool for studies of single biological molecules and nanoparticles. Devices have been developed to trap in one and two dimensions, but these rely on physically constraining the molecule along one or more directions. However, behavior of trapped molecules may be perturbed due to high collision rates with walls. Here we report on the development of a three-dimensional (3D) electrokinetic trap to counteract Brownian motion. Two pairs of electrodes arranged in a crossed configuration on separate planes allow generation of an electric field of variable orientation and magnitude. A custom forward-illuminated microscope with astigmatism introduced to the tube lens is used to determine the nanoparticle's 3D position in real time. This device has demonstrated the capability to manipulate and confine single 40 nm fluorescent latex beads in glycerol-water solution. The use of an electron-multiplying CCD camera allows for faster detection rates (>100 Hz) and single-photon sensitivity. Characterization of particle motion and performance analysis of trapping methods is investigated. The use of alternative 3D detection methods is discussed, as well as applications to studies of single biomolecules and nanoparticles.

8:48AM Y34.00003 It may be possible to construct a Chemical Synthesizing Computer based on Capillary Action , RICHARD KRISKE, University of Minnesota — This author had previously proposed that Capillary Action has a Quantum Mechanical Model. This model can be easily constructed by noting that when a photon of the heat wavelength evaporates one molecule of water at the top of a capillary column, a "hole" is transmitted from the top of the column to the roots and into the water reservoir sustaining the capillary tube. This "hole" is a true hole (a true particle) in that it is transmitted as a quantized unit through the capillary tube. The mathematics of this process are the same as used in Quantum Field Theory, with the capillary acting as a perfect spring (like the spring used on a "stack" of dishes). When the external field using a force to pull the water molecule off the stack, an equal and opposite spring force (which is quantized), is transmitted down the column to the reservoir. When the water is not pure, this author proposes that each of the elements in the unpure water act linearly, each with its own quantized spring constant that does not interact with the other quantized spring constants, so it is possible to pull a single electron off the top of the water stack, yet the water in the stack is undisturbed (the reservoir is disturbed). Likewise it is possible to pull a sugar molecule off and balance chemical equations.

9:00AM Y34.00004 ABSTRACT WITHDRAWN –

9:12AM Y34.00005 Integrated optics for Lab-On-Chip , YU GU, Saint Joseph's University, ANDREA CRESPI, Milan Politecnic University, LISA MARIANI, GIANNA VALENTINO, Saint Joseph's University, GIULIO CERULLO, ROBERTO OSELLAME, Milan Politecnic University, SAINT JOSEPH'S UNIVERSITY DEPARTMENT OF PHYSICS, GU LAB TEAM, MILAN POLITENIC UNIVERSITY DEPARTMENT OF PHYSICS, IFN TEAM — The miniaturization of traditional chemical and biochemical functionalities called Lab-On-Chip has many advantageous over existing methods, such as portability, small sample size, multiplexing and simpler automation and standardization. In recent years, the integration of microfluidic and microoptical elements together onto monolithic platforms has led to the new term optofluidics. We present novel optofluidic devices based on integrated waveguides, microfluidic channels and high-index fluids. Such devices have a variety of applications including label-free biochemical sensing and telecommunications.

9:24AM Y34.00006 A microfluidic separation platform using an array of slanted ramps , SUMEDH RISBUD, Johns Hopkins University, JORGE BERNATE, Stanford University, GERMAN DRAZER, Rutgers, The State University Of New Jersey — The separation of the different components of a sample is a crucial step in many micro- and nano-fluidic applications, including the detection of infections, the capture of circulating tumor cells, the isolation of proteins, RNA and DNA, to mention but a few. Vector chromatography, in which different species migrate in different directions in a planar microfluidic device thus achieving spatial as well as temporal resolution, offers the promise of high selectivity along with high throughput. In this work, we present a microfluidic vector chromatography platform consisting of slanted ramps in a microfluidic channel for the separation of suspended particles. We construct these ramps using inclined UV lithography, such that the inclined portion of the ramps is upstream. We show that particles of different size displace laterally to a different extent when driven by a flow field over a slanted ramp. The flow close to the ramp reorients along the ramp, causing the size-dependent deflection of the particles. The cumulative effect of an array of these ramps would cause particles of different size to migrate in different directions, thus allowing their passive and continuous separation.

9:36AM Y34.00007 Size based separation of micro-particles using adhesive ciliated surfaces: Mimicing the behaviour of suspension feeders , ANURAG TRIPATHI, Dept. of Chemical and Petroleum Engineering, University of Pittsburgh, AMITABH BHATTACHARYA, Dept. of Mechanical Engineering, Indian Institute of Technology Bombay, Mumbai, India, ANNA BALAZS, Dept. of Chemical and Petroleum Engineering, University of Pittsburgh — Separation of different size micro-particles in microfluidic devices is important for many biomedical applications. Inspired by the selective intake of small food particles by marine suspension feeders, we propose a novel separation mechanism of micro-particles using active cilia arrays with adhesive tips. By means of Lattice Boltzmann simulations, we show that mixture of two different size particles with size ratio greater than or equal to two can be nearly completely separated by tuning adhesion strength and cilia stiffness. The proposed technique can be used even at low Reynolds number ($\mathrm{Re} \ll 1$) where separation mechanisms based on inertial effects will be of little use. For a given cilia-particle interaction, the balance of hydrodynamic and adhesive forces favors capture of particles below a critical size, which can be predicted by a simple analytical model.

9:48AM Y34.00008 Stiffness Dependent Separation of Cells in a Microfluidic Device , TODD SULCHEK, GONGHAO WANG, WENBIN MAO, ALEXANDER ALEXEEV, Georgia Tech — Abnormal cell mechanical stiffness can point to the development of various diseases including cancers and infections. We report a high-throughput technique for continuous cell separation utilizing variation in cell stiffness. We use a microfluidic channel that is decorated by periodic diagonal ridges to force cells of different stiffness values to follow different trajectories. The ridges within the microfluidic flow channel compress and deform the cells in rapid succession to translate each cell perpendicular to the channel axis in proportion to its stiffness. We report the experimental demonstration of separation as well as computational validation of the mechanism of separation. Atomic force microscopy (AFM) was used to independently measure cell stiffness. By flowing cells through the microfluidic device, we can quickly and efficiently separate mixtures into subpopulations of stiff cells and soft cells. We then summarize how we expect this technology may produce new biomedical diagnostic capabilities.

10:00AM Y34.00009 Process development for perfectly concentric droplets-within-droplets and uniform-walled shells , GREG RANDALL, BRENT BLUE, General Atomics — Compound droplets, or droplets-within-droplets, are currently precursors for shell targets used in intertial fusion experiments. To implode properly, each shell requires a uniform wall thickness, which in turn requires a centered core droplet in the compound droplet precursor. Previously, Bei et al. (2009, 2010) have shown that stationary compound droplets could be centered in a static fluid using an electric field of 0.7 kV/cm at 20 MHz. We present our recent results in developing a continuous microfluidic process to mass fabricate these uniform-walled shells. This includes: using electric fields to center the core of moving compound droplets, inhibiting droplet stretching by using protein emulsifiers, and maintaining a centered core during polymerization. We apply a physical scaling analysis from a fluid mechanics perspective to aid process design.

10:12AM Y34.00010 Optical Nanodozers: A New Tool for Probing Single-Molecule Conformation and Confinement Free Energy in Cavities of Adjustable Nanoscale Dimension , AHMED KHORSHID, WALTER REISNER, McGill University — Experiments probing single-molecule DNA statics and dynamics in nanoconfined systems are typically performed via fluoresence microscopy, yielding access to information regarding molecule conformation but no direct information regarding nanoscale forces. In our experiment we combine two single-molecule manipulation tools, optical trapping and nanoconfinement, to develop a novel assay that can yield information regarding both molecule conformation and forces experienced in confinement. Polystyrene beads are trapped inside 300x300nm silica nanochannels. These beads are then used as "nano-pistons" or "nanodozers," to apply compressive forces to single-molecules confined inside the nanochannels. In particular, a single nanodozer is used to push a DNA molecule against a nanoslit barrier, enabling measurements of force versus molecule compression. By carefully calibrating our trap via assessing Brownian motion of the nanochannel confined bead we are able to obtain a force-compression curve that we are comparing to polymer physics models for a cavity confined chain. In addition, we can determine the force required to drive the polymer across the entropic barrier as the critical force applied when the polymer jumps out of the cavity and over the slit.

10:24AM Y34.00011 DNA in Nanochannels: A Multistage Free Energy Perturbation Approach[1] , YANWEI WANG[2], Soochow University, DOUGLAS R. TREE, KEVIN D. DORFMAN, University of Minnesota-Twin Cities — Nanochannels are ideal platforms for studying the basic physics of confined polymers, using DNA as the model polymer. While the scaling laws for strong (Odijk) and weak (de Gennes) confinement were established decades ago, recent experiments and computer simulations have illuminated the complex physics arising between these limiting cases. To understand fully the transition region between the classical regimes of de Gennes and Odijk, it is necessary to examine the underlying free energy behavior of DNA in nanochannels. This presentation reports our studies on the confinement free energy and other properties of nanochannel-confined DNA by the multistage free energy perturbation (MFEP) technique. Emphases are focused on the methodology, the role of the aspect ratio of the channel on the confinement free energy and the force-extension relation of DNA confined in nanochannels.

10:36AM Y34.00012 Molecular Dynamics Study of Polymer Separation Using a Nanofluidic Staircase , FREDERICK PHELAN JR., CHRISTOPHER FORREY, National Institute of Standards and Technology (NIST) — The diffusive behavior of isolated polymer chains in a nanofluidic staircase has recently been studied experimentally [Strychalski et al., Macromolecules, 45(3), 1602, (2012); Stavis et al., Lab Chip, 12(19), 1174, (2012)] and by simulation [Phelan et al., in preparation, (2012)]. Chains are observed to exhibit spontaneous 1-D biased diffusion from regions of high to low confinement, without the use of external forces, under conditions where the local confinement lies in either the Odijk or de Gennes regimes. The transport mechanism is that of a Brownian motor, where the polymer free energy is used to generate directed transport using thermal fluctuations and the biased structural features of the device. The nanostaircase has potential for a number of applications in polymer measurement science and transport, an important one of which could be separations. To study this, we examine polymer separation in the nanofluidic staircase using the molecular dynamics simulation software LAMMPS. Length based separations of linear polymers as applicable to DNA separations are the main topic of the study, but the effect of more complex architectures such as branching are also examined.

10:48AM Y34.00013 Measuring the confinement free energy of DNA in nanofluidic cavities , ALEXANDER KLOTZ, WALTER REISNER, McGill University — It is possible to dictate the equilibrium conformation of single DNA molecules in nanofluidic systems by creating topographies where confinement varies over scales of nanometers to microns. Much work has been done to elucidate the polymer physics of systems with simple 1D or 2D confinement, but there is little quantitative understanding of behavior in more complex systems. Using single-molecule fluorescence microscopy, we study the equilibrium conformation of single DNA molecules partitioning into a single nanoscale pit etched in a nanoscale slit. In this system the polymer exists in a conformation which is partially occupying the nanopit and partially outside in the slit: the fraction of contour filling the pit is determined by a balance of confinement free energy and self-avoidance. We measure statistical distributions of this filling fraction resulting from fluctuations of contour in and out of the slit. These distributions are measured as a function of slit height and pit width and interpreted in terms of free energy models based on the balance of confinement free energy and self-avoidance. These measurements serve as a unique experimental probe of cavity-like polymer confinement, a system with rich phase behavior that has not been probed experimentally. Together with previous work on the statistics of molecules spanning multiple pits, we can use this system to make measurements of the free energy of confinement and self-avoidance effects in confined systems, essential quantities in the design of nanofluidic devices for DNA manipulation.

Session Y35 DMP: Low TC: 2-D Superconductor-insulator Transition 343 - Greg Boyd, Georgetown University

8:00AM Y35.00001 Strongly disordered s-wave superconductors probed by microwave electrodynamics , E.F.C. DRIESSEN[1], P.C.J.J. COUMOU, R.R. TROMP, P.J. DE VISSER[2], T.M. KLAPWIJK, Kavli Institute of Nanoscience, Delft University of Technology — In contrast to Anderson's theorem, recently evidence has emerged that superconductivity is susceptible to strong disorder and that there is a disorder-induced superconductor-to-insulator transition (SIT). We probe the effects of strong disorder ($8.6 > k_F l > 2.4$, approaching the SIT) in thin films of niobium titanium nitride and titanium nitride by measuring the microwave electrodynamics in coplanar waveguide resonators. The electromagnetic response gradually evolves with disorder, deviating from conventional Mattis-Bardeen theory, for both materials. The result is understood as due to changes in the quasiparticle density of states, as a consequence of the short elastic scattering length. Our observations are consistent with a model that uses an effective pair breaker, which is inversely proportional to the value of $k_F l$.

8:12AM Y35.00002 Berezinsky Kosterlitz Thouless transition in ultrathin NbN films near superconductor-insulator transition , JIE YONG, Department of Physics, Ohio State University, K. IL'IN, M. SIEGEL, Institute of Micro- und Nano-electronic Systems, Karlsruhe Institute of Technology, Germany, THOMAS LEMBERGER, Department of Physics, Ohio State University — We report temperature dependent superfluid densities λ^{-2}(T) in ultrathin NbN films near thickness-tuned superconductor-insulator transition (SIT). Superfluid densities in these films are measured by two-coil mutual inductance apparatus. For thick films, dirty limit BCS theory fits experimental data well and this verifies the correctness of this technique. As films get thinner and closer to SIT, sharp downturns near transition temperatures (T_c), signature of Berezinsky-Kosterlitz-Thouless transition, are observed. This downturn occurs much earlier than what 2-D XY theory predicts. This might due to smaller vortex core energy than expected in 2-D XY model. The superconducting gap, deduced from fitting low temperature λ^{-2}(T), is linear with T_c for most films but remain finite across SIT. This is consistent with the scenario that superconductivity is destroyed by phase fluctuations. Zero temperature sheet superfluid density also shows correlation with T_c, further proving the importance of fluctuations near SIT.

8:24AM Y35.00003 Universal Scaling of the order parameter distribution in strongly disordered superconductors , A. KAMLAPURE, S.C. GANGULI, TIFR, India, G. LEMARIÉ, D. BUCHELI, L. BENFATTO, J. LORENZANA, C. CASTELLANI, Sapienza University, Rome, Italy, G. SEIBOLD, Institut Für Physik, BTU Cottbus, Germany, P. RAYCHAUDHURI, TIFR, India — We present scanning tunneling spectroscopy measurements on strongly disordered s-wave superconductor, NbN, close to Anderson metal insulator transition. At low temperatures all our samples show superconducting spectra with dip close to zero bias and two coherence peaks after correcting with large V shaped background. Although spectra do not show significant variation in the superconducting energy gap but we see large distribution in the coherence peak heights characteristic to the strength of disorder. We take average value of the coherence peak heights on positive and negative bias as a measure of local order parameter S [1]. We observe that maxima of order parameter distribution (OPD) steadily decrease with increasing disorder. On rescaling with the new scaling variable R_S as logarithm of order parameter normalized to its variance, OPD for all the samples collapse into single curve showing universality of the OPD. In addition OPD is in good agreement with the universal Tracy-Widom distribution in finite dimension. We also identify similar scaling relation of the OPD within two prototype fermionic and bosonic models for disordered superconductors showing an excellent agreement between experiment and theory in the current field.

8:36AM Y35.00004 The effects of disorder and temperature on the glassy dynamics of the first-order spin-paramagnetic transition in ultrathin granular Al films[1] , JOSEPH PRESTIGIACOMO, PHILIP ADAMS, Louisiana State University — We report an ongoing experimental study of the effects of disorder and temperature on the glassy dynamics of the first-order spin-paramagnetic transition in ultrathin granular Al films. The disorder of the films is gauged primarily by their proximity to the quantum sheet resistance $R_Q \approx 6.45$ KΩ/sq at temperatures slightly above T_c. In general, thicker films with $R \ll R_Q$ achieve equilibrium almost entirely through avalanches in resistance while thinner films with $R \sim R_Q$ exhibit slow stretched-exponential relaxation with very few detectable avalanches. Preliminary observations indicate that increasing measurement temperatures to near the tricritical point has the effect of speeding up the relaxations, thereby reducing the time constants involved. Similarities between this system and other glassy systems will be discussed.

8:48AM Y35.00005 Transport Behavior of Ultrathin Films with NanoThickness Undulations in the Strongly Localized Regime[1] , J.C. JOY, S.M. HOLLEN, C. ZHAO, Department of Physics, Brown University, G. FERNANDES, J.M. XU, Division of Engineering, Brown University, J.M. VALLES, JR., Department of Physics, Brown University — Recent work on thin films of superconducting material grown on anodized aluminum oxide (AAO) has revealed the existence of a Cooper Pair Insulator (CPI), a state in which superconducting pair correlations survive, but with activated transport dominated by electron pairs. AFM data has revealed that the AAO substrates have a regular undulating structure, which causes films to grow with predictable variations in thickness. These thickness undulations, which have a spatial period greater than the superconducting coherence length, work to localize Cooper pairs in the insulating state. To gain insight into the properties of the normal state of the CPI, we are investigating the transport properties of Copper films grown on AAO substrates. Early data indicate activated transport with activation energies of approximately 20 K in the most insulating films.

9:00AM Y35.00006 Superconductor-Metal-Insulator transition in two dimensional Ta thin Films[1] , SUN-GYU PARK, EUNSEONG KIM, Center for Supersolid and Quantum matter Research, Department of Physics, KAIST, Daejeon 305-701, Korea — Superconductor-insulator transition has been induced by tuning film thickness or magnetic field. Recent electrical transport measurements of MoGe, Bi, Ta thin films revealed an interesting intermediate metallic phase which intervened superconducting and insulating phases at certain range of magnetic field. Especially, Ta thin films show the characteristic IV behavior at each phase and the disorder tuned intermediate metallic phase [Y. Li, C. L. Vicente, and J. Yoon, Physical Review B 81, 020505 (2010)]. This unexpected metallic phase can be interpreted as a consequence of vortex motion or contribution of fermionic quasiparticles. In this presentation, we report the scaling behavior during the transitions in Ta thin film as well as the transport measurements in various phases. Critical exponents v and z are obtained in samples with wide ranges of disorder. These results reveal new universality class appears when disorder exceeds a critical value. Dynamical exponent z of Superconducting sample is found to be 1, which is consistent with theoretical prediction of unity. z in a metallic sample is suddenly increased to be approximately 2.5. This critical exponent is much larger than the value found in other system and theoretical prediction.

9:12AM Y35.00007 Magneto-transport Measurements of Electrostatically Tuned Disordered In2O3 Films near the Superconductor-Insulator Transition[1] , YEONBAE LEE, University of Minnesota, AVIAD FRYDMAN, Bar Ilan University, Israel, ALLEN GOLDMAN, University of Minnesota — We have used an electric double layer transistor configuration employing an ionic liquid to modify the carrier density and resultant properties of disordered In_2O_3 films near the superconductor-insulator (SI) transition. By carrier density modulation up to 7 X 10^{14} carriers-cm^{-2}, we have been able to traverse the SI transition as well as significantly alter the strength and location of the large magnetoresistance peak found in the insulating regime. We have also been able to correlate the magnetic length associated with the largest magnetoresistance peak with a length scale for granularity of the film obtained from a spectral analysis of surface profile data obtained using atomic force microscopy. The latter suggests that film morphology may play an important role in the peak.

9:24AM Y35.00008 AC evidence of a field tuned 2D superconductor-metal transition in a low-disorder InO_x film , WEI LIU, LIDONG PAN, JIAJIA WEN, Johns Hopkins University, MINSOO KIM, SAMBANDAMURTHY GANAPATHY, SUNY Buffalo, PETER ARMITAGE, Johns Hopkins University — Employing microwave spectroscopy, we investigated the field tuned quantum phase transition between the superconducting and the resistive states in a low-disorder amorphous InO_x film in the frequency range of 0.05 to 16 GHz. Our AC measurements are explicitly sensitive to the critical slowing down of the characteristic frequency scales approaching a transition. The relevant frequency scale of superconducting fluctuations approaches zero at a field B_{sm} far below the field B_{cross} where different isotherms of resistance as a function of magnetic field cross each other. The phase stiffness at the lowest frequency vanishes from the superconducting side at B $\approx B_{sm}$, while the high frequency limit extrapolates to zero near B_{cross}. Our data are consistent with a scenario where B_{sm} is the true quantum critical point for a transition from a superconductor to an anomalous metal, while B_{cross} only signifies a crossover to a regime where superconducting correlations make a vanishing contribution to both AC and DC transport measurements in the low-disorder limit.

9:36AM Y35.00009 Observation of the Collapse of the Cooper Pair Phase Coherence Length at a Superconductor to Insulator Transition[1] , JAMES VALLES, Brown University, SHAWNA HOLLEN, The Ohio State University, GUSTAVO FERNANDES, JIMMY XU, Brown University — Experiments on ultrathin amorphous Bi films provided one of the best known examples of a Superconductor to Insulator quantum phase transition (SIT). Nevertheless, controversy persists over whether this thickness tuned SIT is "fermionic" or "bosonic". Early data suggested fermionic with the suppression of the amplitude of the superconductor order parameter creating a weakly-localized, phase incoherent, single electron insulator. However, recent work on other uniformly disordered materials suggests that bosonic physics universally dominates at the SIT to produce insulators of locally phase coherent Cooper pair islands. To address this issue, we used a technique that previously revealed local Cooper pair phase coherence in insulating non-uniformly thick films. We measured the strength of flux periodic magneto-resistance oscillations of ultrathin a-Bi films patterned with a nano-array of holes. The data indicate that the Cooper pair phase coherence length collapses at this SIT. This collapse is inconsistent with the continuous decrease of the phase coherence length expected for a bosonic SIT. It is consistent with the order parameter amplitude disappearing at a fermionic SIT.

9:48AM Y35.00010 Transport of thin superconducting films and multilayer heterostructure made by Atomic layer deposition , THOMAS PROSLIER, JEFFREY KLUG, NICKOLAS GROLL, Argonne National Laboratory, NICHOLAS BECKER, Illinois Institute of Technology, ANDREAS GLATZ, VALERII VINOKUR, MICHAEL PELLIN, Argonne National Laboratory, TATYANA BATURINA, Institute of Semiconductor Physics, JEFFREY ELAM, Argonne National Laboratory, JOHN ZASADZSINKI, Illinois Institute of Technology — We report the use of atomic layer deposition (ALD) to synthesize thin superconducting films and multilayer superconductor-insulator (S-I) heterostructures. The ALD technique applied to superconducting films opens the way for a variety of applications, including improving the performance and decreasing the cost of high energy particle accelerators, superconducting wires for energy storage, and bolometers for radiation detection. Furthermore, the atomic-scale thickness control afforded by ALD enables the study of superconductivity and associated phenomena in homogeneous layers in the ultra-thin film limit. In this respect, we will present results of ALD-grown transition metal-based superconductors, including nitrides, carbides, and silicides of niobium, nitrides of molybdenum and titanium, and $Nb_{1-x}Ti_xN$/AlN-based S-I heterostructures. Transport measurement for various composition and film thicknesses will be presented.

10:00AM Y35.00011 Dynamical conductivity across the superconductor-insulator transition , MASON SWANSON, The Ohio State University, YEN LEE LOH, The University of North Dakota, MOHIT RANDERIA, NANDINI TRIVEDI, The Ohio State University — Thin superconducting films can exhibit a quantum phase transition from a superconductor to an insulator with increasing disorder. While the exact mechanism of the transition is not completely understood, there is strong evidence that it is bosonic in nature in some models and materials, with disorder acting to localize the superconducting pairs [1]. Previous studies of bosonic models of the superconductor-insulator transition (SIT) have focused almost entirely on criticality and dc properties at the transition. We go beyond these studies by calculating the dynamical conductivity of a disordered (2+1)D XY model using quantum Monte Carlo simulations that capture the phase fluctuations driving the SIT. Our results obey standard sum rule constraints for the longitudinal and transverse current correlation functions and show a build-up of integrated spectral weight near the transition. We will discuss the low frequency spectral weight in terms of a possible intermediate bose-metal phase between the superconductor and insulator. [1] K. Bouadim, Y. L. Loh, M. Randeria, and N. Trivedi, *Nat. Phys.* **7**, 884 – 889 (2011). We acknowledge support from the NSF Graduate Research Fellowship Program (MS), NSF DMR-1006532 (MR), and DOE DE-FG02-07ER46423 (NT).

10:12AM Y35.00012 Off-diagonal disorder in two-dimentional attractive Hubbard model: A Bogoliubov-deGennes study , SANJEEV KUMAR, Indian Institute of Science Education and Research (IISER) Mohali, PRABUDDHA CHAKRABORTY, Indian Statistical Institute (ISI) Chennai — We present a detailed computational study of the two-dimensional attractive Hubbard model on a square lattice in the presence of off-diagonal disorder. The focus is on the superconductor to insulator transition, and on the comparison between the effects of diagonal disorder and those of off-diagonal disorder. We decouple the attractive Hubbard model in the pairing channel and make use of the Bogoliubov deGennes methodology to study the resulting model numerically on finite lattices. The work is motivated by recent observation of Anderson localization in optical lattices, and the possibility of tuning the sign of interactions between the atoms [Rev. Mod. Phys. **80**, 885 (2008)]. We find very interesting qualitative differences between the models of diagonal and off-diagonal disorder. The average amplitude of superconducting order parameter and spectral gap are strongly suppressed with off-diagonal disorder. This is in contrast to the case of diagonal disorder, where the spectral gap has a minumum and the amplitude of superconducting order parameter remains finite. We also present systematic lattice-size dependence of results. In addition, we compare the results of binary (discrete), and box (continuous) distributions, for both diagonal and off-diagonal disorder models.

10:24AM Y35.00013 Random-Field Model of a Cooper Pair Insulator , THOMAS PROCTOR, The Graduate Center, CUNY, EUGENE CHUDNOVSKY, DMITRY GARANIN, CUNY Lehman College — The model of a disordered superconducting film with quantum phase fluctuations is mapped on a random-field XY spin model in 2+1 dimensions. Analytical studies within continuum field theory, supported by our recent numerical calculations on discrete lattices, show the onset of the low-temperature Cooper pair insulator phase. The constant external field in the random-field spin model maps on the Josephson coupling between the disordered film and a bulk superconductor. Such a coupling, if sufficiently strong, restores superconductivity in the film. This provides an experimental test for the quantum fluctuation model of a superinsulator.

10:36AM Y35.00014 Collective effects in the two-dimensional Josephson junction array , VALERII VINOKOUR, IVAN SADOVSKYY, ALEXEY GALDA, Materials Science Division, Argonne National Laboratory, Argonne, Illinois 60439, USA — We study collective quantum effects in the two-dimensional Josephson junction arrays (JJA) in the vicinity of the superconductor-insulator transition (SIT). We find the contribution of the quantum coherent phase slips (QCPS) into the formation of thermodynamic properties of the JJA, including critical current, as a function of the magnetic field. We investigate the response of the 2D JJA to the external bias and the contribution from QCPS to this response.

Friday, March 22, 2013 8:00AM - 11:00AM –

Session Y36 DCMP: Novel Superconductors III 344 - N. Peter Armitage, Johns Hopkins University

8:00AM Y36.00001 Spin incommensurability varies linearly with hole content in single-layer Bi2201 cuprate[1] , JOHN TRANQUADA, Brookhaven National Lab, M. ENOKI, M. FUJITA, T. NISHIZAKI, K. YAMADA, Tohoku U., S. IIKUBO, Kyushu Inst. Tech., D.K. SINGH, S. CHANG, NCNR — We have performed inelastic neutron scattering measurements on the single-layer cuprate $Bi_{2+x}Sr_{2-x}CuO_{6+y}$ (Bi2201) with $x = 0.2$, 0.3, 0.4 and 0.5, a doping range that spans the spin-glass (SG) to superconducting (SC) phase boundary [1]. The doping evolution of low energy spin fluctuations ($\lesssim 11$ meV) was found to be characterized by a change of incommensurate modulation wave vector from the tetragonal [110] to [100]/[010] directions, while maintaining a linear relation between the incommensurability and the hole concentration, $\delta \approx p$. In the SC regime, the spectral weight is strongly suppressed below ~ 4 meV. Similarities and differences in the spin correlations between Bi2201 and the prototypical single-layer system $La_{2-x}Sr_xCuO_4$ will be discussed.

8:12AM Y36.00002 Strong coupling behavior of the neutron resonance mode in unconventional superconductors , PATRIK HLOBIL, BORIS NAROZHNY, JOERG SCHMALIAN, Karlsruhe Institute of Technology, INSTITUTE FOR THEORY OF CONDENSED MATTER COLLABORATION — A number of unconventional superconductors are characterized by a resonance mode in the spin excitation spectrum, measured via inelastic neutron scattering, which emerges below the superconducting transition temperature and is sharp as function of momentum and energy. A promising theory for the resonance is based on the analysis of the particle-hole spectrum in the superconducting state and in the presence of antiferromagnetic fluctuations. In this theory, a resonance occurs in case of a sign change of the superconducting gap function for momenta on the Fermi surface that are coupled by the antiferromagnetic ordering vector. So far, the theory was analyzed without including higher order vertex corrections of the particle-hole spectrum. In this work we analyze such vertex correction and show that: i) the qualitative difference in the behavior between a gap that changes sign and that doesn't change sign remains if one includes higher order vertex corrections, ii) vertex corrections are of order unity and cannot be ignored. Thus, while the resonance mode does seem to be a reliable fingerprint for an unconventional, sign-changing order parameter, it is a strong coupling phenomenon and no reliable approach to determine its detailed behavior seems to exist.

8:24AM Y36.00003 Distinct Fe-induced magnetic states in the underdoped and overdoped regimes of $La_{2-x}Sr_xCu_{1-y}Fe_yO_4$ revealed by muon spin relaxation

, KENSUKE SUZUKI, TADASHI ADACHI, YOUICHI TANABE, HIDETAKA SATO, Department of Applied Physics, Tohoku University, RISDY RISDIANA, YASUYUKI ISHII, TAKAO SUZUKI, ISAO WATANABE, Advanced Meson Science Laboratory, Nishina Center for Accelerator-Based Science, RIKEN, YOJI KOIKE, Department of Applied Physics, Tohoku University — Zero-field muon-spin-relaxation measurements have been performed in partially Fe-substituted $La_{2-x}Sr_xCu_{1-y}Fe_yO_4$ in a wide range of hole concentration, to investigate the magnetic state induced by the Fe substitution recently suggested from the neutron-scattering measurements [1]. It has been found that a static magnetic order is formed in 1% Fe-substituted $La_{2-x}Sr_xCu_{1-y}Fe_yO_4$ in a wide range of hole concentration where superconductivity appears in Fe-free $La_{2-x}Sr_xCuO_4$. In the underdoped regime, the Fe-induced magnetic order can be understood in terms of the concept of stripe pinning by Fe. In the overdoped regime, on the other hand, the Fe-induced magnetic order is short-ranged, which is distinct from the stripes. It is plausible that a spin-glass state of Fe spins derived from the RKKY interaction is realized in the overdoped regime. These results suggest a change of the electronic state from the strongly correlated electron state to the Fermi-liquid-like state with hole doping in La-214 high-T_c cuprates [2,3].

8:36AM Y36.00004 Test of Variational Methods for Electronic Structures of Solid State and Molecular Systems by Application to Atomic Systems

, R.H. PINK, University at Albany, SUNY, S.R. BADU, University at Buffalo, SUNY, R.H. SCHEICHER, Uppsala University, T.P. DAS, University at Albany, SUNY — The Linked Cluster Many-Body Perturbation Theory [1,2] uses energies and wave-functions obtained from the one-electron Hartree-Fock equations for the ground state to determine the occupied states' contribution to properties such as magnetic hyperfine interaction. Both the occupied and unoccupied bound and continuum state energies and wave-functions are then used to include many-body effects through perturbation theory. This method has been found to provide excellent agreement between theoretical and experimental values for hyperfine constants for atomic systems [3,4]. Due to their multi-center nature, one cannot solve the Hartree-Fock differential equations by numerical integration methods for solid state and molecular systems, and must instead use variational methods [5,6,7]. We shall present our assessment of the accuracy of the variational procedure by determining the hyperfine constants for the Phosphorous [3] and Lithium [2] atoms. [1] Hugh P. Kelly, Phys. Rev. 144, 39 (1966) [2] E.S. Chang, R.T. Pu and T.P. Das, Phys. Rev. 174, 1 (1968) [3] N.C. Dutta, C. Matsubara, R. T. Pu, and T.P. Das, Phys. Rev. Lett. 21, 1139 (1968) [4] J. Andriessen, K. Raghunathan, S.N. Ray and T.P. Das, Phys Rev. B15, 2533 (1977) [5] C.C.J. Roothaan, Rev. Mod. Phys. 23, 69 (1951) [6] J.E. Rodgers and T.P. Das, Phys. Rev. A8, 2195 (1973) [7] W.J. Hehre, R.F. 8:48AM Y36.00005 Understanding of Nuclear Quadrupole Interaction of ^{19}F* and Binding Mechanism in Solid Fluorine at First-Principles Level

, D.R. MISHRA, M.M. ARYAL, N.P. ADHIKARI, Central Department of Physics, Tribhuvan University, Kirtipur, Kathmandu, Nepal, R.H. PINK, T.P. DAS, Department of Physics, University at Albany, SUNY — We have carried out a theoretical study of the nuclear quadrupole interaction (NQI) parameters of ^{19}F* excited nuclear state in solid fluorine as well as the intermolecular binding of fluorine molecules in the solid. This is in continuation of our investigation [1] of the properties of solid halogens using the first-principles Hartree-Fock (HF) cluster procedure combined with many-body perturbation theory (MBPT), implemented by the Gaussian 03 set of programs. For the NQI parameters, the value of (e^2qQ/h) obtained from our investigation for the ^{19}F* excited nuclear state in solid fluorine is 120.9 MHz, which agrees with the experimental value 127.2 MHz, quoted in [2], within 5% and the asymmetry parameter, η is essentially zero. For obtaining (e^2qQ/h) the value of the quadrupole moment, Q for ^{19}F* is taken from [3] as 0.072×10^{28} m^2. As regards the binding of fluorine molecules in solid fluorine, our quantitative binding energy results show that the binding arises mainly from the van der Waals interaction obtained from intermolecular many-body effects with the one electron HF contribution being weak and repulsive in nature.

9:00AM Y36.00006 Enhanced charge stripe order in superconducting $La_{2-x}Ba_xCuO_4$ in high magnetic fields[1]

, M. HUECKER, Brookhaven National Laboratory, M. V. ZIMMERMANN, Deutsches Elektronen-Synchrotron DESY, Z.J. XU, J.S. WEN, G.D. GU, J.M. TRANQUADA, Brookhaven National Laboratory — There is mounting evidence for a proximity of the superconducting ground state in the cuprates to competing states with static spin and/or charge density modulations. One such competing state is the spin and charge stripe phase in $La_{2-x}Ba_xCuO_4$. By means of high energy (100 keV) x-ray diffraction we have studied the effect of a high magnetic field (H||c) on the charge stripe order in a broad range of doping ($0.095 \leq x \leq 0.155$). We find that the field can significantly enhance the charge stripe order, but only at temperatures and dopings where it coexists with bulk superconductivity at zero field. The field also increases stripe correlations between the planes, which can result in an enhanced frustration of the interlayer Josephson coupling. Close to the famous x=1/8 compound, where zero field stripe order is pronounced and bulk superconductivity is suppressed, charge stripe order is independent of the field. The results imply that static stripe order and three-dimensionally coherent superconductivity are competing ground states.

9:12AM Y36.00007 Lifetime of Skyrmions in Cuprates and Other Layered Materials[1]

, LIUFEI CAI, EUGENE CHUDNOVSKY, DMITRY GARANIN, CUNY Lehman College, CUNY LEHMAN COLLEGE TEAM — Collapse of a skyrmion due to the discreteness of a crystal lattice in isotropic two-dimensional ferro- and antiferromagnets has been studied analytically and by numerical solution of equations of motion for up to 2000×2000 classical spins on a square lattice coupled via Heisenberg exchange interaction. Excellent agreement between analytical and numerical results has been achieved. The lifetime of the skyrmion scales with its initial size, λ_0, as $(\lambda_0/a)^5$ in ferromagnets and as $(\lambda_0/a)^{2.15}$ in antiferromagnets, with a being the lattice parameter. This makes antiferromagnetic skyrmions significantly shorter lived than ferromagnetic skyrmions.

9:24AM Y36.00008 Fractional Flux Quantization in Loops of Unconventional Superconductors

, FLORIAN LODER, ARNO KAMPF, THILO KOPP, Center for Electronic Correlations and Magnetism, University of Augsburg, Germany — The magnetic flux threading a conventional superconducting ring is typically quantized in units of $\Phi_0 = hc/2e$. The factor 2 in the denominator of Φ_0 originates from the existence of two different types of pairing states with minima of the free energy at even and odd multiples of Φ_0. Here we show that spatially modulated pairing states exist with energy minima at fractional flux values, in particular at multiples of $\Phi_0/2$. In such states condensates with different center-of-mass momenta of the Cooper pairs coexist. The proposed mechanism for fractional flux quantization is discussed in the context of cuprate superconductors, where $hc/4e$ flux periodicities as well as uniaxially modulated superconducting states were observed.

9:36AM Y36.00009 Magnetic structures in YBCO single crystals under tilted magnetic fields , VITALII VLASKO-VLASOV, ULRICH WELP, ALEXEI KOSHELEV, WAI KWOK, Argonne National Laboratory — We study magnetic flux distributions in YBCO single crystals remagnetized by magnetic fields of different orientations using the magneto-optic indicator technique. Application of the perpendicular field to the crystals cooled in the in-plane magnetic field, application of the in-plane field to the crystals cooled in the normal magnetic field, and remagnetization by magnetic field tilted to the sample surface result in unusual quasiperiodic vortex structures. These strongly inhomogeneous vortex patterns can be associated with the flux cutting and strong anisotropy of the vortex kink motion depending on the trapped flux and external field orientations. We discuss the effect of resulting inhomogeneous current distributions on the current carrying ability of the YBCO coated conductors. Work supported by the US DoE-BES funded Energy Frontier Research Center and by Department of Energy, Office of Science, Office of Basic Energy Sciences under Contract No. DE-AC02-06CH11357.

9:48AM Y36.00010 Vortex lock-in transition coinciding with the 3D to 2D crossover in $YBa_2Cu_3O_7$, SASKIA BOSMA, STEPHEN WEYENETH, Physics Institute - University of Zurich, ROMAN PUZNIAK, Institute of Physics - Polish Academy of Sciences, ANDREAS ERB, Walther Meissner Institute - Bavarian Academy of Sciences, HUGO KELLER, Physics Institute - University of Zurich — Dimensionality is essential to understand the behavior of vortices in layered cuprate superconductors. A 3D (three-dimensional) to 2D (two-dimensional) crossover takes place when the out-of-plane coherence length becomes smaller than the interplane distance. We directly detected a vortex lock-in transition by torque magnetometry in an overdoped $YBa_2Cu_3O_{7-\delta}$ single crystal of low anisotropy. The locked-in state was observed below the 3D to 2D crossover temperature, independently of extrinsic pinning effects thanks to a high quality clean crystal and the use of a vortex shaking technique. The lock-in is enhanced by decreasing temperature and increasing magnetic field. The shape of the torque signal is in very good agreement with the model developped by Feinberg and Ettouhami [Int. J. Mod. Phys. B **7**, 2085 (1993)] for quasi-2D superconductors, despite the low anisotropy of the material. Additionally, we present a new torque magnetometer design featuring vortex shaking, and compatible with the $Quantum\ Design$ PPMS system.

10:00AM Y36.00011 Investigating the low-field vortex lattice phase diagram in $CeCoIn_5$ with $H \parallel c$[1] , P. DAS, Los Alamos National Laboratory, NM, USA, M. R. ESKILDSEN, University of Notre Dame, IN, USA, E. M. FORGAN, University of Birmingham, UK, H. KAWANO-FURUKAWA, Ochanomizu University, Japan, C. PETROVIC, Brookhaven Natl. Lab., NY, USA — Here we present small angle neutron scattering studies of the vortex lattice (VL) phase diagram in $CeCoIn_5$ in the low-field high-temperature regime with $H \parallel c$ which remained unexplored. While previous studies [A. D. Bianchi $et.al.$ Science **319**, 177 (2008)] reported the phase boundary between the high-field square $\rightarrow$ rhombic $\rightarrow$ hexagonal VLs, the lower boundary between hexagonal $\rightarrow$ rhombic $\rightarrow$ square remained unexplored at higher temperatures where only estimates were provided. We have investigated this regime and mapped out these VL transitions. Interestingly, at the base temperature, no rhombic phase is observed but a direct transition from hexagonal to square phase. A possible explanation for this deviation from earlier reports may be that the current measurements were done following a field-ramp at base temperature rather than field-cool used in previous measurements. This indicates a slight hysteresis associated with this transition. While the measured hexagonal to rhombic phase transition agrees with the earlier estimates, the square VL phase occupies a larger region at higher temperatures than previously estimated.

10:12AM Y36.00012 Vortices in superconducting MoGe pentagon , TAKEKAZU ISHIDA, HO THANH HUY, MASARU KATO, Osaka Prefecture University, MASAHIKO HAYASHHI, Akita University — Vortices in bulk prefer to form a triangular lattice while a mesoscopic superconductor with a size comparable to coherence length ξ or the magnetic penetration depth λ is quite different so as to create particular configuration of vortices. The behavior of such structures in an external magnetic field is strongly influenced by the boundary conditions. Vortex states in superconducting disk, triangle and square pattern have been extensively studied both theoretically and experimentally [B. J. Baelus et al., Phys. Rev. B 69, 064506 (2004)]. We present vortex structures in MoGe pentagon disks imaged by means of a scanning quantum interference device (SQUID) microscopy [Ho Thanh Huy et al., Physica C, in press; DOI 10.1016/j.physc.2012.03.037.] Systematic measurements allow us to reveal how vortex arrangement evolves with the applied magnetic field. Moreover, we found that shell filling rule is subjected to change when a pinning center is introduced. Numerical calculations of vortex structure in pentagon disks on the basis of the nonlinear Ginzburg-Landau theory reveal that there are good agreement between experimental data and theoretical calculations.

10:24AM Y36.00013 Unconventional Vortex States in Nanoscale Superconductors Due to Shape-Induced Resonances in the Inhomogeneous Cooper-pair Condensate , LING-FENG ZHANG, LUCIAN COVACI, MILORAD MILOSEVIC, GOLIBJON BERDIYOROV, FRANCOIS PEETERS, University of Antwerp — Vortex matter in mesoscopic superconductors is known to be strongly affected by the geometry of the sample. Here we show that in nanoscale superconductors with coherence length comparable to the Fermi wavelength the shape resonances of the order parameter results in an additional contribution to the quantum topological confinement leading to unconventional vortex configurations. Our Bogoliubov de Gennes calculations in a square geometry reveal a plethora of asymmetric, giant multivortex, and vortex antivortex structures, stable over a wide range of parameters and which are very different from those predicted by the Ginzburg Landau theory. By modifying the size of the system and the Fermi energy we show that ground states with different symmetries can be obtained. By increasing the temperature we observe first-order transitions from multivortex to giant vortex states. These unconventional states are relevant for high Tc nanograins, confined Bose Einstein condensates, and graphene flakes with proximity induced superconductivity.

10:36AM Y36.00014 Competition between covalent bonding and charge transfer tendencies at complex-oxides interfaces , J. SALAFRANCA, J. TORNOS, J. GARCÍA-BARRIOCANAL, C. LEÓN, J. SANTAMARIA, Universidad Complutense de Madrid, J. RINCÓN, G. ÁLVAREZ, S.J. PENNYCOOK, Oak Ridge National Laboratory, E. DAGOTTO, Oak Ridge National Laboratory and University of Tennessee, M. VARELA, Oak Ridge National Laboratory and U. Complutense de Madrid — Interfaces alter the subtle balance among different degrees of freedom responsible for exotic phenomena in complex oxides, such as cuprate-manganite interfaces. We study these interfaces by means of scanning transmission electron microscopy and theoretical calculations. Microscopy and EEL spectroscopy indicate that the interfaces are sharp, and the chemical profile is symmetric with two equivalent interfaces. Spectroscopy also allows us to establish an oxidation state profile with sub-nanometer resolution. We find an anomalous charge redistribution: a non-monotonic behavior of the occupancy of d orbitals in the manganite layers as a function of distance to the interface. Relying on model calculations, we establish that this profile is a result of the competition between standard charge transfer tendencies involving materials with different chemical potentials and strong bonding effects across the interface. The competition can be tuned by different factors (temperature, doping, magnetic fields...). As examples, we report different charge distributions as a function of doping of the manganite layers. Session Y37 DMP DCOMP: Focus Session: Fe-based Superconductors: Vortices and Critical Fields 345/346 - Morten Eskildsen, University of Notre Dame

8:00AM Y37.00001 Slow Abrikosov- to fast moving Josephson-vortex transition in iron-pnictide superconductors , PHILIP MOLL, Laboratory for Solid State Physics, ETH Zurich, Switzerland — We have observed a novel type of transition of vortex matter from well-pinned Abrikosov to highly mobile Josephson vortices in the iron pnictide high-T_c superconductor SmFeAs(O,F) ($T_c \sim 50K$). This A-to-J transition between the two regimes upon cooling through the temperature T^* is hallmarked by an extraordinary jump of vortex mobility and a pronounced peak in the critical current density. The dissipation below T^* reaches significant fractions of the normal state resistance at all temperatures and fields, far below $H_{c2}\|ab$, estimated well above $100T$ at low temperatures. We show the temperature T^* to coincide with the temperature at which the interlayer coherence length $\xi_c(T)$ equals the SmO layer thickness, hence leading to Josephson-like vortices below and Abrikosov-like vortices above T^*. This transition is surprising, as the material is an only moderately anisotropic superconductor ($\gamma \sim 5-7$), unlike strongly anisotropic, clearly two-dimensional cuprates. The observation of this A-to-J transition highlights the significance of structural layeredness and gives microscopic information about the order parameter in SmFeAs(O,F). This profound change in the nature of the vortex matter in these compounds has eluded discovery until now, as its detection poses two main experimental challenges: The Josephson nature of the vortex matter may only be observed (1) for fields precisely aligned with the FeAs layers(< 0.1deg). Even slightest field misalignments away from the FeAs planes (> 0.1deg) restore dissipation free current transport and very high critical current densities ($\sim 10^6 A/cm^2$) at low temperatures. Secondly (2), currents flowing perpendicular to the layers are essential for the observation, forcing the vortices to slide between the layers. To this end, thin ($< 10\mu m$) high quality single crystals of SmFeAs(O,F) were microstructured and contacted using a Focused Ion Beam.

8:36AM Y37.00002 Superconductivity amid phase inhomogeneity: the case of $K_xFe_{2-y}Se_2$, DESPINA LOUCA, University of Virginia — The recently discovered Fe-based superconductors, $K_xFe_{2-y}Se_2$, is studied using neutron diffraction and the pair density function analysis to investigate the nature of the atomic disorder induced by the K and Fe site vacancies. In this system, both superconductivity and magnetic ordering can coexist, while superconductivity is observed in a narrow range of potassium concentration, between $0.6 < x < 0.8$. While no crystal transition occurs across with x, the Fe site vacancies are ordered in the $\sqrt{5} \times \sqrt{5}$ structure. At high temperatures, the Fe vacancies are not ordered. Why does superconductivity appear in the vicinity of the 0.8 composition? To provide a clue towards the answer, instead of probing the periodic structure, we probed the local atomic structure that provides information regarding the short-range correlations in real space. The results suggest a strong dependence of the Fe-Fe bond lengths to the K concentration. What is unique to this system is that a double-well bond distribution of short and long Fe - Fe bonds exists, originating from the fully occupied Fe site. As the K concentration increases to x=1, the distribution shifts weight from the short to the long while in the superconducting case, it is equal between the two.

8:48AM Y37.00003 Angle and frequency dependent low field microwave absorption in electronically doped Ca 122 pnictides: Comparison of high Tc = 42 K phase in Pr, Nd, Ce and La doping , AUSTIN HOWARD, JONATHAN YUEN, MYRON SALAMON, ANVAR ZAKHIDOV, The University of Texas at Dallas, BING LV, PAUL C. W. CHU, Texas Center for Superconductivity, University of Houston, DANIEL SELLS, National EPR Research Service, University of Manchester — The motivation of this study is to investigate the properties of a unique interfacial superconducting phase in electron-doped Ca 122 pnictides by the Low Field Microwave Absorption (LFMA) technique. Samples are exposed to microwave radiation with frequency ν_{MW} between 1 and 24 GHz, and also to a low strength magnetic field which modulates at $\nu_{mag} = 100$ kHz. Due to their single crystalline nature, the pnictides can be oriented relative to the MW polarization and magnetic field direction. Studying this orientation dependence reveals filament-like micro-interfaces between highly doped regions and poorly doped regions. These interfaces may be responsible for a high $T_c \sim 42$ K superconducting phase. We demonstrate that this higher T_c can be clearly distinguished from the low temperature bulk SC phase by the angle-dependent LFMA method. Additionally, variation of the MW frequency yields changes in the spectra which are in agreement with theoretical predictions.

9:00AM Y37.00004 High, magnetic field independent critical currents in $Ba_{0.6}K_{0.4}Fe_2As_2$ with composite defects , K. KIHLSTROM, MSD, Argonne Nat Lab; Dept of Phys, UIC, L. FANG, Y. JIA, C. CHAPARRO, G. SHEET, H. CLAUS, A. KOSHELEV, U. WELP, MSD, Argonne Nat Lab, G. CRABTREE, MSD, Argonne Nat Lab; Dept of Phys, UIC, W. KWOK, MSD, Argonne Nat Lab, S. ZHU, Phys, Argonne Nat Lab, A. KAYANI, Dept of Phys, WMU, H.F. HU, Dept of Phys, UIUC, J.M. ZUO, Dept of Mat Sci & Eng, UIUC, H.H. WEN, Dept of Phys, Nanjing University, B. SHEN, MSD, Argonne Nat Lab — We investigate the enhancement of vortex pinning by compound defects that are composed of correlated and point defects in $Ba_{0.6}K_{0.4}Fe_2As_2$ crystals with T_c 37.5. Initial irradiation by high-energy heavy ions to a dose matching field of $B = 21$T increases vortex pinning via columnar defects with no degradation of the superconducting transition temperature. Subsequent proton irradiations further enhance the critical current *Jc(H)* by suppressing the motion of vortex kinks between the columnar defects. At a temperature of 5K, we find a critical current density of 5.8 MA/cm^2 that is essentially magnetic field independent in fields up to 7 T. This work supported by the Center for Emergent Superconductivity, an Energy Frontier Research Center funded by the U.S. D.O.E., Office of Science, Office of Basic Energy Sciences and by the D.O.E, Office of Basic Energy Sciences, under Contract No. DE-AC02-06CH11357. 9:12AM Y37.00005 Angle - dependent upper critical field of overdoped $Ba(Fe_{1-x}Ni_x)_2As_2$, JASON MURPHY, M.A. TANATAR, N. NI, S.L. BUD'KO, P.C. CANFIELD, R. PROZOROV, The Ames Laboratory, D. GRAF, National High Magnetic Field Laboratory — In-plane resistivity measurements were used to study the upper critical field, H_{c2}, of single crystals of iron-based superconductor $Ba(Fe_{1-x}Ni_x)_2As_2$ ($x = 0.054$ and $x = 0.072$). An applied magnetic field (up to 35 T) was precisely aligned (with the accuracy better than 0.1^o) parallel to the Fe-As layers and the measurements were taken for $H \parallel ab-$ plane and $H \parallel c-$axis as function of temperature. The determined $H_{c2}(T)$ clearly differs for the two principal directions. The dependence of the upper critical field on the angle Θ between the field direction and the $ab-$plane was measured in isothermal conditions at temperatures close to T_{c0} and at low temperatures $T \ll T_c(H = 0)$. In both temperature regimes $H_{c2}(\Theta)$ clearly deviates from sinusoidal function, expected for orbital H_{c2} [1]. We discuss the origin of this behavior as possible reflection of the angular modulation of the superconducting gap magnitude and the complex warping of the Fermi surface along the c-axis. Work in Ames was supported by the Department of Energy Office of Science, Basic Energy Sciences under Contract No. DE-AC02-O7CH11358.

9:24AM Y37.00006 Multiband, paramagnetic effects and vortices in KFe_2As_2[1] , FREDERIC HARDY, Karlsruher Institut fuer Technologie, IFP, 76021 Karlsruhe, Germany, DAI AOKI, CEA Grenoble, SPSMS-INAC, 38054 Grenoble, France, ROBERT EDER, Karlsruher Institut fuer Technologie, IFP, 76021 Karlsruhe, Germany, ILYA VEKHTER, Department of Physics and Astronomy, Louisiana State University, Baton Rouge, LA 70803, USA, PHILIPP BURGER, ANNA BOEHMER, Karlsruher Institut fuer Technologie, IFP, 76021 Karlsruhe, Germany, ROBERT FISHER, Lawrence Berkeley National Laboratory, University of California, Berkeley, CA 94720, USA, THOMAS WOLF, CHRISTOPH MEINGAST, Karlsruher Institut fuer Technologie, IFP, 76021 Karlsruhe, Germany — We study the normal- and superconducting-state properties of the iron pnictide superconductor KFe_2As_2 using heat-capacity, thermal-expansion and magnetization measurements. In the normal state, our data show strong evidence of the existence of strong local fluctuations and of the coherence-incoherence crossover predicted by theory. In zero field, for $T < T_c$, the temperature dependence of the heat capacity provides evidence for the existence of extremely small energy gaps. The (H,T) phase diagram is also determined down to 80 mK using calorimetric measurements. We reveal the existence of strong paramagnetic effects for field parallel to the Fe_2As_2 planes. We discuss the symmetry of the order parameter and the interplay between multiband, paramagnetic and orbital effects.

[1]Supported by the Deutsche Forschungsgemeinschaft through SPP1458.

9:36AM Y37.00007 Field dependence of the thermal conductivity in the iron-based superconductor KFe_2As_2 , A. JUNEAU-FECTEAU, F.F. TAFTI, S. RENÉ DE COTRET, N. DOIRON-LEYRAUD, L. TAILLEFER, University of Sherbrooke, A.F. WANG, X.G. LUO, X.H. CHEN, University of Science and Technology of China — The behavior of the thermal conductivity in the iron-arsenide KFe_2As_2 at low temperature provides compelling evidence of d-wave superconductivity [1]. Here we report a detailed study of the thermal conductivity in KFe_2As_2 as a function of magnetic field, for two field orientations: perpendicular and parallel to the FeAs planes. The data are in excellent quantitative agreement with theoretical calculations for a d-wave superconductor [2]. Our study also highlights the power of thermal conductivity as a technique to directly measure the upper critical field H_{c2} in a clean type-II superconductor.

9:48AM Y37.00008 Microwave Surface Impedance Measurements on Fe(Se,Te) Single Crystals under Finite Magnetic Fields , HIDEYUKI TAKAHASHI, TATSUNORI OKADA, FUYUKI NABESHIMA, SHINJI KOSHIDA, YOSHINORI IMAI, ATSUTAKA MAEDA, Dept. of Basic Science, the University of Tokyo — We measured the microwave surface impedances of Fe(Se,Te) single crystals under magnetic fields up to 8 Tesla and extracted the flux flow resistivity, ρ_f, to investigate the quasiparticle dynamics inside the vortex core. Previously performed ρ_f measurements on several iron-based superconductors have revealed that the quasiparticle dynamics inside the vortex core can be described as that in the so-called "moderately clean" regime, in which the mean free path is comparable to the coherence length [1,2]. The mean free path in Fe(Se,Te) in the normal state is smaller than those in other superconductors. In addition, London penetration depth shows quadratic temperature dependence because of the strong pair-breaking [3]. Therefore, it is interesting to investigate the ρ_f to clarify whether the strong quasiparticle scattering affects the quasiparticle dynamics inside the vortex core. We also discuss the surface impedances of Fe(Se,Te) thin films which have a higher T_c than the bulk crystals.

10:00AM Y37.00009 ABSTRACT WITHDRAWN –

10:12AM Y37.00010 Flux flow of iron based superconductors[1] , ATSUTAKA MAEDA, Department of Basic Sciences, University of Tokyo — Flux flow measured by the microwave technique is the only one possible technique to pick up the information on the quasiparticles in the vortex core. Theoretically, novel features have been suggested to show up in the flux flow of Fe-based superconductors (SCs) as multiple gapped SCs with possible sign changes. We investigated the flux flow resistivity of various different types of Fe based SCs, such as 111, 122, and 11 systems [1]. It is found that (1) the sign change is not important for the flux flow, (2) we can discuss the gap structure based on the flux flow data, even without performing angle dependent measurement, (3) vortices of Fe-based SC dissipate more energy than expected from the properties in the Meissner state. Together with the flux flow result in many other superconductors such as cuprates, Y_2C_3, and boron carbides, our result suggests the existence of a universal mechanism of dissipation for quasiparticles in the vortex core, probably related with the Andreev reflection at the core boundary. We also discuss the flux flow of cuprate superconductors, in terms of superconductivity fluctuation investigated by ac conductivity and diamagnetisms.

Session Y38 GERA FIAP: Focus Session: Scalable Technologies for Photovoltaics II 347 - Janelle Leger, Western Washington University

8:00AM Y38.00001 High Efficiency Photovoltaics – The Key to Grid Parity , DAVID L. YOUNG, National Renewable Energy Laboratory, Golden CO 80401 — For three decades the photovoltaic (PV) industry has enjoyed roughly a 22% price reduction for each doubling of cumulative production volume. Recently, the PV market has exceeded this trend with module prices dropping to all-time lows. This trend has come mainly from economies-of-scale, incremental efficiency increases, and over supply. However, this PV learning curve is likely to flatten (or even rise) as unsustainable profit margins weed competition and devices near minimal material usage and practical efficiencies. The current market climate, and the strong weighting factor of balance-of-system costs, favor higher efficiency devices. Technologies that cannot reach a minimum module efficiency of about 18% will likely not be competitive. This paper will discuss several evolutionary and revolutionary scalable wafer and thin-film photovoltaic technologies that are likely to remain competitive, and will identify several areas within these technologies in need of scientific breakthroughs.

8:36AM Y38.00002 Local excitation and local collection of photocurrent in thin-film polycrystalline photovoltaic devices , NIKOLAI ZHITENEV, CNST/NIST, HEAYOUNG YOON, MARINA LEITE, YOUNGMIN LEE, SARAH KO, YUE ZHAO, Maryland Nanocenter/UMD and CNST/NIST, ANTHONY GIANFRANCESCO, Worcester Polytechnic Institute and CNST/NIST, PAUL HANEY, ALEC TALIN, CNST/NIST — The power conversion efficiency of commercial solar modules based on thin-film chalcogenide materials is well below the theoretical limits. To understand the underlying physical mechanisms limiting the efficiency, we investigate local photovoltaic properties isolating the difference between the grain bulk (0.5-2 mkm in size) and the grain boundary in CdTe absorber. Local current-voltage measurements are performed using nano-contacts in conjunction with local electron-hole pairs generation comparing multiple injection techniques. First, the carriers are excited using variable energy electron beam enabling measurements with a spatial resolution down to 20 nm. Second, we have developed a novel approach for high-resolution and high-throughput photocurrent imaging downconverting electron beam into a near-field optical source using a thin film (<50 nm) of phosphors. The electron beam is fully absorbed in the phosphors layer, and the cathodoluminescence is used as a local photon source. Third, we generate carriers using a near-filed optical microscope varying the excitation wavelength. The results show that, in a well-optimized material, a large fraction of grain boundaries displays higher photocurrent as compared to grain bulk effectively serving as a three-dimensional distributed photocurrent collector.

8:48AM Y38.00003 Development of InP Based Quantum Well Tunnel Junctions , MICHAEL YAKES, MATTHEW LUMB, MARIA GONZALEZ, CHRISTOPHER BAILEY, IGOR VURGAFTMAN, ROBERT WALTERS, Naval Research Laboratory — In this presentation we demonstrate lattice-matched InAlGaAs quantum well tunnel junctions for an InP-based multi-junction cell. By including two 0.74 eV bandgap InGaAs quantum wells in InP-lattice matched InAlGaAs tunnel junctions with a 1.18eV bandgap, a peak tunnel current density of 113 A/cm^2 was observed, 45 times greater than a baseline bulk InAlGaAs tunnel junction. The differential resistance of the quantum well device is 7.52 x 10^4 Ωcm^2, a 15-fold improvement over the baseline device. The upper bound of the transmission loss to the bottom cell is estimated to be approximately 1.7%. Strain balanced quantum wells will be discussed which have the same benefits of the latticed matched tunnel junctions, but can be made accessible to both InP and GaAs based multi-junction architectures. We will also show the results of a study where a bulk, double heterostructure design is used to mitigate the effects of dopant diffusion and maximize the peak tunnel current, achieving a 15 times improvement in peak tunnel current over the baseline device. We propose that quantum well tunnel junctions with bulk heterostructure diffusion barriers could play a key role in improving performance both at one sun and high sun concentrations.

9:12AM Y38.00005 ABSTRACT WITHDRAWN –

9:24AM Y38.00006 Energy Alignment at Organic/Oxide and Organic/Metal Interfaces: The Effects of Molecular Overlayer Thickness on the HOMO/LUMO Gap and Interfacial Dipole[1] , CHARLES RUGGIERI, SYLVIE RANGAN, SENIA COH, ROBERT BARTYNSKI, Rutgers, The State University of New Jersey — Dye-sensitized solar cells offer the potential for low-cost production with comparable efficiencies to traditional Si-based solar cells. Energy alignment of the dye orbitals with respect to the band edges of the oxide semiconductor substrate is a key parameter in device performance. Using direct and inverse photoemission, XPS, and STM we have investigated the electronic structure and bonding geometry of zinc tetraphenylporphyrin (ZnTPP) molecules adsorbed on a set of four oxide semiconductor and metallic substrates [TiO_2(110), ZnO(11-20), Ag(100) and Au(111)] at monolayer and multilayer coverages. The vacuum levels of the organic/oxide and organic/metal systems were also measured and the interface dipoles determined. The energy level shifts and the width of adsorbate spectral features are qualitatively different for molecules adsorbed on the oxide versus the metal substrates. The HOMO-LUMO energy separation decreases with decreasing molecular overlayer thickness, which is thought to be due to substrate screening properties, but these shifts occur in different ways for the two classes of substrates. Possible origins of this distinct behavior will be discussed.

9:36AM Y38.00007 Simulation and Testing of Type-II Strained-Layer Superlattices for Long Wavelength Thermophotovoltaics , ABIGAIL LICHT, DANTE DEMEO, THOMAS VANDERVELDE, Tufts University — In this presentation we detail our research on long wavelength thermophotovoltaic (TPV) cells, with cutoff wavelength in the 7-9 micron range, which hold the potential for a wide array of applications due to their ability to work with lower temperature sources. We will discuss simulation results on the optimization of structures utilizing type II strained-layer superlattice (SLS) cells and unipolar barriers. The performance of these simulated cells is compared with fabricated cells which were characterizing using calibrated blackbody sources.

9:48AM Y38.00008 Optimization of gain and energy conversion efficiency using front-facing photovoltaic cell luminescent solar concentrator design , MELISSA OSBORN, CARLEY CORRADO, Department of Physics, University of California, Santa Cruz, California 95064, SHIN WOEI LEOW, Jack Baskin School of Engineering, University of California, Santa Cruz, California 95064, EMORY CHAN, The Molecular Foundry, Lawrence Berkeley National Laboratory, Berkeley, CA 94720, BEN BALABAN, SUE CARTER, Department of Physics, University of California, Santa Cruz, California 95064 — Luminescent solar concentrator (LSC) windows with front-facing photovoltaic (PV) cells were built and their gain and power efficiency were investigated. Conventional LSCs employ a photovoltaic (PV) cell that is placed on the edge of the LSC, facing inward. This paper describes a new design with the PV cells on the front-face allowing them to receive both direct solar irradiation and wave-guided photons emitted from a dye embedded in an acrylic sheet, which is optically coupled to the PV cells. Parameters investigated include the thickness of the waveguide, edge treatment of the window, cell width, and cell placement. The data allowed us to make projections that aided in designing windows for maximized overall efficiency. A gain in power of 2.2x over the PV cells alone was obtained with PV cell coverage of 5%, and a power conversion efficiency as high as 6.8% was obtained with a PV cell coverage of 31%. Balancing the trade-offs between gain and efficiency, the design with the lowest cost per watt attained a power efficiency of 3.8% and a gain of 1.6x.

10:00AM Y38.00009 Theoretical and Practical Limits for Transparent Photovoltaics , RICHARD LUNT, Michigan State University — Transparent photovoltaics (TPVs) offer a new paradigm for solar energy harvesting, integration, and deployment. These devices have recently been shown to be enabled by exploiting the excitonic nature of molecular and organic semiconductors.[1] Here, we present the theoretical and practical efficiency limits of these novel electronic architectures as a function of bandgap, transparency and aesthetic quality for both single and multi-junction cells. For example, power-production from ultraviolet and near-infrared photons alone leads to a theoretical single-junction efficiency of 21% in completely transparent structures, compared to 33% for opaque-junctions. This approach for transparent photovoltaics will be contrasted with other semi-transparent approaches, where TPVs with selective absorption offer the highest possible potential for combined transparency and efficiency. The impact of transparent PVs will be discussed for a range of applications from electronic displays to window integration.

10:12AM Y38.00010 Luminescent Solar Concentrators in the Algal Industry , KATIE HELLIER, CARLEY CORRADO, SUE CARTER, University of California Santa Cruz - Carter Lab, ANGELA DETWEILER, LESLIE BEBOUT, NASA Ames Research Center — Today's industry for renewable energy sources and highly efficient energy management systems is rapidly increasing. Development of increased efficiency Luminescent Solar Concentrators (LSCs) has brought about new applications for commercial interests, including greenhouses for agricultural crops. This project is taking first steps to explore the potential of LSCs to enhance production and reduce costs for algae and cyanobacteria used in biofuels and nutraceuticals. This pilot phase uses LSC filtered light for algal growth trials in greenhouses and laboratory experiments, creating specific wavelength combinations to determine effects of discrete solar light regimes on algal growth and the reduction of heating and water loss in the system. Enhancing the optimal spectra for specific algae will not only increase production, but has the potential to lessen contamination of large scale production due to competition from other algae and bacteria. Providing LSC filtered light will reduce evaporation and heating in regions with limited water supply, while the increased energy output from photovoltaic cells will reduce costs of heating and mixing cultures, thus creating a more efficient and cost effective production system.

10:24AM Y38.00011 Monte Carlo Simulations of Luminescent Solar Concentrators with Front-Facing Photovoltaic Cells for Building Integrated Photovoltaics , SHIN WOEI LEOW, Electrical Engineering, University of California Santa Cruz, CARLEY CORRADO, MELISSA OSBORN, SUE CARTER, Physics Department, University of California Santa Cruz — Luminescent solar concentrators (LSCs) have the ability to receive light from a wide range of angles and concentrate the captured light on to small photo active areas. This enables LSCs to be integrated more extensively into buildings as windows and wall claddings on top of roof installations. LSCs with front facing PV cells collect both direct and concentrated light ensuring a gain factor greater than one. It also allows for flexibility in determining the placement and percentage coverage of PV cells when designing panels to balance reabsorption losses, power output and the level of concentration desired. A Monte-Carlo ray tracing program was developed to study the transport of photons and loss mechanisms in LSC panels and aid in design optimization. The program imports measured absorption/emission spectra and transmission coefficients as simulation parameters. Interactions of photons with the LSC panel are determined by comparing calculated probabilities with random number generators. Simulation results reveal optimal panel dimensions and PV cell layouts to achieve maximum power output.

10:36AM Y38.00012 Porous Silicon as Antireflecting Layer[1] , GULSEN KOSOGLU, MEHMET YUMAK, SELIM OKMEN, OZHAN OZATAY, YANI SKARLATOS, CARLOS GARCIA, Bogazici University — The main aim in photovoltaic industry is to produce efficient and energy competitive solar cell modules at low cost. Efficient AntiReflection Coatings (ARC) improve light collection and thereby increase the current output of solar cells. Broadband ARCs are desirable for efficient application over the entire solar spectrum and porous silicon layers as antireflective coating layers provide successful light collection. In the study the most critical physical parameters of porous silicon are examined, homogeneous and uniform porous layers are produced. The photoluminescence spectrum and optical parameters of porous layers have been investigated, and we are now in the process of improving the efficiency of the device by modulating the structure of the porous silicon layers and studying its photovoltaic characteristics.

[1]We would like to thank to Mr. Aziz U. Caliskan and his group for their valuable support from TUBITAK YITAL. This Project is supported by Bogazici University Research Funding: 5782, TUBITAK Grant : 209T099, and Bogazici University Infrared Funding: 6121.

10:48AM Y38.00013 Transparent Luminescent Solar Concentrators for Large-area Solar Windows , YIMU ZHAO, RICHARD LUNT, Michigan State University — Luminescent solar concentrators (LSCs) have recently regained attention as a route for integration into the building envelope. To date, however, these systems have been limited to absorption and emission (glow) in the visible part of spectrum. We have designed and fabricated novel transparent luminescent solar concentrators devices composed of synthesized metal halide nanocrystal phosphorescent luminophores that allow for efficient and selective harvesting of ultraviolet (UV) photons with a near perfect absorption cutoff at the edge of the visible spectrum (430nm) while efficiently down-converting emitted light with a massive stoke shift to the near-infrared (800nm). We have demonstrated transparent LSCs with power efficiency of 0.8% $\pm$ 0.5%, system external quantum efficiency exceeding 35%, and an average transmittance of 82% $\pm$ 1%. We show through experiments and modeling that this architecture has the potential to exhibit up to 1-2% power conversion over module areas > 1 m^2. These concentrators present new opportunities for non-tinted and highly-adoptable solar- windows that can translate into improved building efficiency, enhanced UV-barrier layers, and lower cost solar harvesting systems.

Session Y39 DFD: Swimming, Motility and Locomotion

348 - Alexander Alexeev, Georgia Institute of Technology

8:00AM Y39.00001 ABSTRACT WITHDRAWN –

8:12AM Y39.00002 Navigation and chemotaxis of nematodes in bulk and confined fluids[1] , ALEJANDRO BILBAO, VENKAT PADMANABHAN, Texas Tech University, KENDRA RUMBAUGH, Texas Tech University Health Science Center, SIVA VANAPALLI, JERZY BLAWZDZIEWICZ, Texas Tech University — Small nematodes, such as the model organism *C. elegans*, propel themselves by producing sinuous undulations along the body and perform turns by varying the undulation amplitude. We have recently demonstrated [PLoS ONE 7(7) e40121 (2012)] that such motions can be accurately represented in terms of a piecewise-harmonic body curvature. We combine our harmonic-curvature description with highly accurate hydrodynamic bead-chain models to investigate the swimming efficiency and turning capabilities of the worm in bulk and confined fluids. Our results indicate that for the same change of the curvature-wave amplitude, a swimming nematode turns by a smaller angle compared to a crawling worm. The difference is due to rotational slip with respect to the surrounding medium, but the angles are sufficiently large to allow for efficient turning maneuvers. We use our description of nematode maneuverability to study chemotaxis in both confined and unconfined fluids.

[1]This work was supported by NSF grant No. CBET 1059745.

8:24AM Y39.00003 Nematode Chemotaxis: Gradual Turns, Sharp Turns, and Modulated Turn Angles[1] , AMAR PATEL, Texas Tech University, VENKAT PADMANABHAN, Indian Institutes of Technology Kharagpur, KENDRA RUMBAUGH, Texas Tech University Health Sciences Center, SIVA VANAPALLI, JERZY BLAWZDZIEWICZ, Texas Tech University — We examine strategies used by the soil-dwelling nematode *Caenorhabditis Elegans* for chemotaxis in complex environments. The proposed description is based on our recently developed piecewise-harmonic-curvature model of nematode locomotion [PLoS ONE, 7(7) e40121 (2012)], where random harmonic-curvature modes represent elementary locomotory movements. We show that the previously described gradual-turn and sharp-turn chemotaxis strategies can be unified in our model. The gradual-turn mechanism relies on crawling amplitude changes commensurate with the undulation frequency. The sharp-turn mechanism consists in modulation of the frequency of jumps to large-amplitude modes. We hypothesize that there exists a third strategy, where the nematode adjusts the variance of the amplitude distribution. Such adjustments result in a modulation of the magnitude of random turns, with smaller turns performed when the nematode moves toward the increasing chemoatractant concentration. Experiments are proposed to determine if the third strategy is present in the nematode behavior.

8:36AM Y39.00004 Simulation of model swimmers near ciliated surfaces , HENRY SHUM, ANURAG TRIPATHI, Department of Chemical & Petroleum Engineering, University of Pittsburgh, JULIA YEOMANS, Rudolf Peierls Centre for Theoretical Physics, University of Oxford, ANNA BALAZS, Department of Chemical & Petroleum Engineering, University of Pittsburgh — Biofouling by micro-organisms is problematic on scales from microfluidic devices to the largest ships in the ocean. One solution found in nature for clearing undesired material from surfaces is to employ active cilia, for example, in the respiratory tract. It is feasible to fabricate surfaces covered with artificial cilia actuated by an externally imposed field. Using numerical simulation, we investigate the interactions between these artificial cilia and self-propelled model swimmers. One of the key aims is to explore the possibility of steering swimmers to influence their trajectories through the flow field produced by the cilia. In our simulations, the fluid dynamics is solved using the lattice Boltzmann method while the cilia and model swimmers are governed by elastic internal mechanics. We implement an immersed boundary approach to couple the solid and fluid dynamics.

8:48AM Y39.00005 Underwater propulsion of an internally actuated elastic plate , PETER YEH, LEJUN CEN, ALPER ERTURK, ALEXANDER ALEXEEV, Georgia Institute of Technology — Combining experiments and numerical simulations we examine underwater locomotion of an active (internally powered) flexible bimorph composite. We use Macro-Fiber Composite (MFC) piezoelectric laminates that are actuated by a sinusoidally varying voltage generating thrust similar to that of a flapping fin in carangiform motion. In our fully-coupled three dimensional simulations, we model this MFC bimorph fin as a thin, elastic plate that is actuated by a time-varying internal moment producing periodic fin bending and oscillations. The steady state swim velocity and thrust are experimentally measured and compared to the theoretical predictions. Our simulations provide detailed information about the flow structures around the swimming fin and show how they affect the forward motion. The results are useful for designing self-propelling fish-like robots driven by internally powered fins.

9:00AM Y39.00006 Flow generated by an oscillated elastic filament in viscous fluids , MOUMITA DASGUPTA, ARSHAD KUDROLLI, Clark University — We discuss with experiments the interplay of periodic driving, elasticity, and damping of a cilium in a viscous fluid and the resulting fluid flow. In particular, we oscillate an elastic filament made of PDMS in a viscous Newtonian fluid and observe the generated flow using PIV techniques. The competition between viscous drag and elasticity of the filament is observed to lead to symmetry breaking, resulting in a net flow. The length of the filament is varied to find an optimum length at which maximum net flow is obtained for a given elastic constant of the material and oscillating frequency. We discuss the related coupled oscillator system, and the rich dynamics observed in the context of fluid flow generated by elastic flagella and cilia.

9:12AM Y39.00007 Transmutation of rotational motion into translational diffusion in 3D rotary powered random walkers , AMIR NOURHANI, PAUL LAMMERT, Phys. Dept., Penn State, ALI BORHAN, Chem. Eng. Dept., Penn State, VINCENT CRESPI, Phys. Dept., Penn State — Experimenters have for several years been studying motors with sizes in the 10^{-1}–10^{0} micron range which execute circular motion on scales as small as the motor dimensions in an aqueous environment. Previously, we have studied the normal situation wherein the motor is confined to a plane. Here we consider the case where such confinement is absent. The orbital motion of a particle undergoing regular circular motion in 3D has three rotational degrees of freedom. The introduction of stochasticity into them gives rise to 3D translational motion. A special, and apparently experimentally relevant, case is that of an orbiter in the plane which can flip over, reversing its chirality. We present analytical and simulation results on these transmutations of rotational motion into translational motion

Friday, March 22, 2013 8:00AM - 11:00AM –

Session Y40 DCMP: Surfaces, Interfaces, and Thin Films: Oxides 349 - Michael Pierce, Rochester Institute of Technology

8:00AM Y40.00001 Metal Oxide Growth and Characterization on CVD Graphene , AKITOMO MATSUBAYASHI, JOSEPH ABEL, DHIRAJ PRASAD SINHA, JI UNG LEE, VINCENT LABELLA, College of Nanoscale Science and Engineering, University at Albany, SUNY — Thin metal oxide layers deposited on graphene can be utilized as dielectric barriers between metals and graphene to help isolate a metal contact from the graphene channel. This is important for graphene based spintronic devices as dielectric layers between the ferromagnetic electrode and graphene have been shown to increase the spin relaxation time measured utilizing non-local detection and spin precession measurements. However, simply depositing metal oxide layers such as aluminum oxide on graphene results in non-uniform film lowering the quality of the interface barrier. We will present a systematic study of aluminum oxide layers grown on CVD (chemical vapor deposition) graphene under ultra-high vacuum conditions with and without titanium seed layers. The aluminum oxide layers with the titanium seed layers showed reduced surface roughness. The chemical and structural composition determined by XPS (X-ray photoelectron spectroscopy) will be also presented that shows full oxidation of the aluminum and partial oxidation of the titanium. Our previous work which demonstrated that introducing HfO2 barrier layer in the epitaxial graphene devices on SiC wafer improves the measured lifetime and spin injection efficiency will be briefly presented as well.

8:12AM Y40.00002 Atomically Resolved Surface of Laser-MBE Grown $SrRuO_3$ Thin Films[1] , A. TSELEV, P. GANESH, A.P. BADDORF, S.V. KALININ, Oak Ridge National Laboratory, Oak Ridge, TN — Surface of $SrRuO_3$ (SRO) thin films is of high interest since SRO layers are used as bottom electrodes in oxide heterostructures demanding sharp interfaces. Here we studied SRO films in-situ using STM with atomic resolution. Films were grown on undoped, $SrTiO_3$ substrates by laser-MBE. Depending on preparation conditions, the film surfaces exhibited varying reconstructions. Films deposited at 650°C and annealed at deposition conditions for 15 min. revealed surfaces with double-row 1D-structures along $< 110 >_{pc}$ of SRO. Atoms in the 1D-structures are packed in square or zigzag arrangements. The surface in-between the structures appeared poorly ordered. Similar patterns were observed on surfaces of films deposited at 700°C without anneal. In turn, deposition at 700°C with post-anneal resulted in well-ordered surfaces covered by double-rowed structures with square atomic arrangement. Ab initio DFT calculations show a high local DOS from oxygen adatoms with zigzag and square patterns contributing to STM images. Oxygen atoms have high adsorption energies and will be present at our growth conditions. Surface O-adatoms show AFM coupling to the film, with possible ramifications to understand interfacial bonding/magnetism between SRO and oxide-insulators.

8:24AM Y40.00003 Transport phenomena in $SrVO_3$ thin films , MAN GU, STUART WOLF, JIWEI LU, University of Virginia, UNIVERSITY OF VIRGINIA TEAM — Bulk $SrVO_3$ (SVO) with a $3d^1$ electronic configuration has been found to exhibit metallic and Pauli paramagnetic behavior. We have obtained epitaxial SVO films grown on various substrates (STO, SLAO, LSAT and LAO) using a pulsed electron-beam deposition (PED) technique. The film transport properties were found to be strongly dependent on the substrate. A 40 nm SVO film deposited on an STO substrate exhibited metallic behavior with the electrical resistivity following a T^2 law that corresponds to a Fermi liquid system, the resistance ratio R(300K)/R(2K) was $\sim$ 1.66. Hall measurements showed that the mobility increased slightly as the temperature was decreased. A small positive out-of-plane magnetoresistance was observed, it was only 0.045% at 5 K and 7 Tesla. SVO films with the same thickness grown on SLAO, LSAT and LAO showed semiconducting behavior, the different transport properties in the SVO films could be attributed to the compressive film strain or the different film-substrate interfaces.

8:36AM Y40.00004 High quality, hybrid-MBE growth of $SrVO_3$ thin films[1] , JARRETT MOYER, Department of Physics, Department of Materials Science and Engineering, Pennsylvania State University, CRAIG EATON, Department of Materials Science and Engineering, Pennsylvania State University, ROMAN ENGEL-HERBERT, Department of Materials Science and Engineering, Pennsylvania State University — Vanadium-based transition metal oxides are an intriguing class of materials to study due to the metal-to-insulator (MIT) transitions that arise in many of the binary oxides (i.e. VO_2, V_2O_3, V_2O_5). The perovskite $SrVO_3$ is metallic in bulk; however, it is possible to induce an MIT by modulating the bandwidth through strain or dimensional confinement. A mandatory requirement for controlling the electronic phase transition properties in material systems with strong correlation is the growth of high quality, stoichiometric thin films. This is demonstrated here with the growth of $SrVO_3$ on LSAT (001) substrates using a hybrid-MBE technique, where the Sr is evaporated from an effusion cell and the V is provided through the metal-organic precursor vanadium oxo-tri-isopropoxide (VTIP). The structural properties of films with varying VTIP:Sr ratios are characterized by RHEED, XRD, AFM and TEM. These measurements demonstrate that $SrVO_3$ can be grown with excellent structural quality, atomically flat surfaces and rocking curves of the same width as the substrate, accomplishing a necessary first step in controlling the MIT in $SrVO_3$.

8:48AM Y40.00005 Optimizing Pt/TiO_2 templates for textured PZT growth and MEMS devices , DANIEL POTREPKA, U.S. Army Research Laboratory, Adelplhi, MD 20783, USA, GLENN FOX, Fox Materials Consulting LLC, Colorado Springs, CO 80908, USA, LUZ SANCHEZ[1], Department of Materials Science & Engineering, University of Maryland, College Park, MD 20742, USA, RONALD POLCAWICH, U.S. Army Research Laboratory, Adelplhi, MD 20783, USA — Crystallographic texture of lead zirconate titanate (PZT) thin films strongly influences piezoelectric properties used in MEMS applications. Textured growth can be achieved by relying on crystal growth habit and can also be initiated by the use of a seed-layer heteroepitaxial template. Template choice and the process used to form it determine structural quality, ultimately influencing performance and reliability of MEMS PZT devices such as switches, filters, and actuators. This study focuses on how 111-textured PZT is generated by a combination of crystal habit and templating mechanisms that occur in the PZT/bottom-electrode stack. The sequence begins with 0001-textured Ti deposited on thermally grown SiO_2 on a Si wafer. The Ti is converted to 100-textured TiO_2 (rutile) through thermal oxidation. Then 111-textured Pt can be grown to act as a template for 111-textured PZT. Ti and Pt are deposited by DC magnetron sputtering. TiO_2 and Pt film textures and structure were optimized by variation of sputtering deposition times, temperatures and power levels, and post-deposition anneal conditions. The relationship between Ti, TiO_2, and Pt texture and their impact on PZT growth will be presented.

9:00AM Y40.00006 First-principles calculations of water-based surfactant-assisted growth of polar CaO(111) oxide film , XIN TAN, PETER ZAPOL, Materials Science Division, Argonne National Laboratory, USA — Despite many attempts to grow rocksalt (111) oxide surfaces, the growth of an atomically flat polar oxide film with an arbitrary thickness still remains challenging because of surface roughening during the growth process, such as faceting into neutral {100} surface planes. This seemingly unavoidable behavior leads to a grainy morphology and diminished functionality. Here, we present a first-principles investigation of the surfactant-assisted growth of polar CaO(111) film in the presence of a water-based surfactant, both from thermodynamic and kinetic points of view. We show that water molecules not only supply a surfactant by depositing hydrogen on the surface throughout the growth process, but also supply oxygen atoms as an elemental constituent in the film growth, i.e. water oxygen atoms are easily inserted into the top surface layer of the growing film. We suggest that adding water surfactants to conventional synthesis techniques leads to the continuous presence of hydrogen atoms in the surface region during the growth process, which efficiently quenches polarity and dynamically stabilizes the growth of the polar surface, and thus facilitates the growth of defect-free CaO(111) films with arbitrary thickness.

9:12AM Y40.00007 The Electronic Structure of Nonpolar Surfaces in Insulating Metal Oxides , DANYLO ZHEREBETSKYY, LIN-WANG WANG, Materials Sciences Division, Lawrence Berkeley National Laboratory, Berkeley, CA 94720, USA — Understanding the electronic and geometric structures of metal oxide surfaces has a key interest in many technological areas. A randomly chosen crystal surface has a high probability of being polar, unstable and containing in-gap states due to surface dangling bonds. As a result, the surface should be stabilized by passivation or reconstruction. However, do the nonpolar surfaces of ionic crystals of insulating metal oxides need the passivation or reconstruction similar to covalent crystals? We address this question by analyzing the nonpolar surfaces and their electronic structure for the common crystal structures of metal oxides. The study using periodic DFT calculations is performed for following representatives: Cu2O, ZnO, Al2O3, TiO2, V2O5, WO3, CaTiO3, Mg2SiO4. It has been shown that the nonpolar surface can be constructed out of dipole-free, charge-neutral and stoichiometric unit cells for each crystal. We demonstrate that all constructed and relaxed nonpolar surfaces of the metal oxides show a clear band gap. It should be emphasized that the constructed surfaces are neither reconstructed nor passivated. Additionally, we show a correlation between the electronic structure of the relaxed surfaces and Ewald energies calculated for the surface ions.

9:24AM Y40.00008 In-situ study of Nb oxide and hydride for SRF cavity applications using aberration-corrected STEM and electron energy loss spectroscopy , RUNZHE TAO, ROBERT KLIE, University of Illinois at Chicago, YOONJUN KIM, DAVID SEIDMAN, Northwestern University, LANCE COOLEY, ALEXANDER ROMANENKO, Fermi Lab, UNIVERSITY OF ILLINOIS AT CHICAGO COLLABORATION, NORTHWESTERN UNIVERSITY COLLABORATION, FERMI LAB COLLABORATION — We present an atomic-resolution study of the effects that a 48 hour bake at 120 °C in vacuum has on the high-field properties of Nb-based SRF cavities. This bake results a significant increase in the high-field quality factor Q, reversely, 800 °C bake for 2 hour reduces the H_{c3}/H_{c2}-ratio of cavities. Several mechanisms have been proposed, including an increased NbO_x surface layer thickness and the precipitation of NbH_y. Using a combination of atomic-resolution Z-contrast imaging and electron energy-loss spectroscopy with in-situ heating and cooling experiments, we examine the atomic and electronic structures of Nb and related oxides/hydrides near the cavity surface. We quantify the oxygen diffusion on surface during bake by measuring the local Nb valence using EEL spectra. Also, we demonstrate that hydrogen atoms incorporated into the Nb crystal, forming β-NbH precipitates, can be directly visualized using annular bright field imaging in our aberration-corrected JEOL ARM-200CF. Finally, the effects of the 800 °C baking process on the local hydrogen and other impurity will be examined by in-situ heating and cooling experiments. Our results will be combined with atom-probe tomography to develop a 3-D impurity and phase profile of Nb near the SRF cavity surface.

9:36AM Y40.00009 Incorporation of Non-metal Impurities at the Anatase TiO_2(001)-(1 × 4) Surface

, JUN HEE LEE, Department of Chemistry, Princeton University, Princeton, New Jersey 08544, USA, DANIEL FERNANDEZ HEVIA, Universidad de Las Palmas de Gran Canaria, Campus de Tafira, 35017 Las Palmas de Gran Canaria, Spain, ANNABELLA SELLONI, Department of Chemistry, Princeton University, Princeton, New Jersey 08544, USA — Surface doping of TiO_2 is of special interest because the distribution of impurities at or near the surface can have a significant influence on the photocatalytic properties of TiO_2. We have used first-principles density functional theory (DFT) calculations to determine the incorporation mechanisms of nitrogen (N) and carbon (C), two widely used p-type dopants, at the reconstructed (001) surface of anatase, the TiO_2 polymorph most relevant for photocatalysis. Starting from adsorbed impurities, we identify various incorporation pathways and show that the non-exposed oxygen sites just below the surface play a crucial role in accomodating non-metal impurities at the TiO_2(001) surface. Based on the obtained results, we propose strategies which could help to increase the doping concentration and the photocatalytic activity at the TiO_2 surface by exploiting the morphology of the reconstructed surface [1].

[1] Incorporation of Non-metal Impurities at the Anatase TiO_2(001)-(1 × 4) Surface, arXiv:1209.1602.

9:48AM Y40.00010 TiO_2 Surface Defects with the Tetrahedral Cationic Coordination

, KEN PARK, Department of Physics, Baylor University, VINCENT MEUNIER, Department of Physics, Applied Physics, & Astronomy, Rensselaer Polytechnic Institute, NAN HSIN YU, Department of Physics, Baylor University, WARD PLUMMER, Department of Physics & Astronomy, Louisiana State University — Titanium dioxide is one of the most extensively investigated transition metal oxide. It has well-known applications in catalytically converting toxic organic and inorganic materials to benign products, as well as turning solar energy into a chemical. In these processes, it is believed that surface defects with lower coordination and/or stoichiometry play crucial roles. Our study of a $(2\sqrt{2} \times \sqrt{2})$ R45 reconstructed TiO_2(001) using scanning tunneling microscopy and density functional theory reveals that the basic building blocks of the reconstruction can be modeled as fully stoichiometric nanocluster defects. As in the bulk-terminated (001) surface, the atoms in the nanocluster are under-coordinated, for example, 4-coordinated Ti, 1-coordinated, and 2-coordinated O atoms. However, the absence of neighboring atoms drives the nanocluster to relax into a structure, which possesses tetrahedrally coordinated Ti atoms. This result will be compared and discussed with the reported nanocluster defects on TiO_2(110).

10:00AM Y40.00011 Increase of Structural Phase Transition Temperature with Cr doping in Cr:VO_2 Thin Films

, B.L. BROWN, MARK LEE, University of Texas at Dallas, P. CLEM, C.D. NORDQUIST, T.S. JORDAN, S.L. WOLFLEY, D. LEONHARDT, Sandia, J.A. CUSTER, SSA — Bulk crystal VO_2 has a well-known structural phase transition near $T_c = 68$ °C that separates a low-temperature insulating phase from a high-temperature metallic phase with several orders-of-magnitude resistance contrast between the two phases. We report electrical and optical studies of the effect of Cr doping on the T_c in Cr:VO_2 thin films. Resistivity, Hall effect, and infrared reflectivity all show that Cr doping systematically increases T_c from 50 °C up to ∼ 75 °C at 11% Cr with similar transition width and hysteresis from DC to infrared, but the effect appears to saturate. At the same time, there is a modest decrease in resistance contrast. We will discuss possible effects of both carrier density and scattering changes across T_c on the resistance. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

10:12AM Y40.00012 Non-Destructive Element Specific Density Depth Profiling by Resonant Soft X-ray Reflectometry

, SEBASTIAN MACKE, ADRIANO VERNA, MAURITS HAVERKORT, Max Planck - UBC Centre for Quantum Materials, Canada, ABDULLAH RADI, Department of Chemistry, University of British Columbia, Canada, RONNY SUTARTO, Canadian Light Source, Canada, GEORG CHRISTIANI, GENNADY LOGVENOV, BERNHARD KEIMER, Max-Planck Institute for Solid State Research, Germany, GEORGE SAWATZKY, Quantum Matter Institute, University of British Columbia, Canada, VLADIMIR HINKOV, Max Planck - UBC Centre for Quantum Materials, Canada — X-ray resonant reflectometry (XRR) is the ideal tool to study the depth resolved and element-specific electronic structure of multilayer films. By changing angle, energy and polarization of the incoming beam complete reflectivity maps can be measured leading in principle to an accurate picture of the depth resolved electronic states of thin films. The standard model used in reflectometry is based on compound layers with a defined thickness, roughness and dielectric tensor. But such a simple model is usually not capable to reproduce a full measured reflectivity map. The main reasons are especially contaminations, additional oxide layers and interdiffusion between layers. However, introducing a layer system based on the element specific atomic density and scattering factors instead of dielectrics tensors allows more degrees of freedom for the system and allows to reproduce the reflectivity maps. Thereby the advanced model is capable to retrieve the element specific density profiles of thin films. The method is introduced by analyzing a simple film of PrNiO3 grown on an

10:24AM Y40.00013 Investigation of electronic and magnetic properties of wurtzite NiO thin films[1]

, BRIAN BUSEMEYER, Department of Physics, University of California, Davis, CA 95616-8677 USA, MICHAEL SHAUGHNESSY, Sandia National Laboratories at Livermore, Livermore, CA 94551 USA, LIAM DAMEWOOD, C.Y. FONG, Department of Physics, University of California, Davis, CA 95616-8677 USA — We study the electronic and magnetic properties of wurtzite (B4) NiO thin films grown epitaxially on wide gap semiconductors to understand factors affecting their half-metallic properties, in particular, the effect of film thickness, interface geometry, and dangling bonds. One, two, and four consecutive layers of NiO are considered, both buried within bulk ZnO, and as thin surface films on bulk ZnO. We perform GGA+U calculations, with the U value determined via a self consistent linear response approach. We find that the interface generates small s-p hybridized states at the Fermi energy, which can possibly destroy the half metallicity; these states are likely due to effects from strain at the interface. We also find that the interface can influence the Ni d states in markedly different ways, depending on the geometry and the presence of dangling bonds. These factors can determine whether the interface Ni d states resemble those from Ni in bulk wurtzite NiO, or demonstrate semiconductivity, more akin to d states of Zn atoms within bulk ZnO.

10:36AM Y40.00014 Structure of Oxide Surfaces

, RONG YU, Tsinghua University — Surfaces of metal oxides are of crucial importance for a variety of technological applications such as heterogeneous catalysis, thin film growth, gas sensing, and corrosion prevention. Due to the complexities of oxides in crystal structure and electronic structure, however, the surface science of oxides lags far behind that of metals or semiconductors. Conventional surface-science techniques are usually limited to surfaces of single crystals of conductors. Metal oxides are usually good insulators, making them difficult for conventional surface science techniques. On the other hand, the complex atomic structures of oxides results in too many structural parameters to be determined by spectroscopy or diffraction methods. We will show that the surface structure of oxides can be directly imaged and measured at the sub-angstrom scale using aberration-corrected transmission electron microscopy. The atomic positions of oxide surfaces can be measured to an accuracy of picometers, comparable to that obtained by conventional surface science techniques on single crystals.

10:48AM Y40.00015 UV-induced stable photoconductivity in Indium Oxide films , EHAB ABDELHAMID, RUPAM MUKHERJEE, Wayne State University, DEBABRATA MISHRA, Weizmann Institute of Science, AMBESH DIXIT, Indian Institute of Technology Rajasthan, BORIS NADGORNY, GAVIN LAWES, Wayne State University, GAVIN LAWES GROUP TEAM, BORIS NADGORNY GROUP TEAM — We have investigated the effects of UV radiation on the electrical conductivity of sputter deposited Indium Oxide films for samples annealed under different conditions. The films were annealed in air, hydrogen, argon, nitrogen, and vacuum to modify the microstructure and distribution of point defects. X-ray diffraction shows the formation of polycrystalline single phase films, with the average crystallite size changing under different annealing conditions. We find that the resistance sharply decreases to between 0.1% and 50% of its initial value on exposure to UV irradiation. The magnitude of the decrease depending on the annealing conditions, with the largest relative change occurring in the as-prepared sample (high initial resistance), and the smallest decrease observed in the Hydrogen-annealed film (low initial resistance). This low resistant state is surprisingly stable, having a time constant of several hours or longer to relax to the initial value after the UV illumination is removed.

Session Y42 DBIO: Focus Session: Single Molecule Studies of Nucleotides and Nanomachines

Hilton Baltimore Holiday Ballroom 3 - Keir Neuman, NIH

8:00AM Y42.00001 Length selective accumulation of oligonucleotides in thermal gradients , MORITZ KREYSING, SIMON LANZMICH, DIETER BRAUN, Department of Physics, LMU Munich — Central to most Origin-of-Life scenarios is the possibility for pre-biotic organic molecules to interact in order to form increasingly complex, catalytic molecular machinery ultimately capable of autonomous replication. While strong evidence for the spontaneous synthesis of single nucleotides [1] recently arose, concentrations required to allow these building blocks to polymerize [2] and gain functionality, still seem improbable for early earth conditions. Here, we demonstrate experimentally that temperature gradients across pores, as found in rocks near hydrothermal vents [3], are sufficient to accumulate nucleotides efficiently from dilute solutions. In particular we show that depending on the pores' dimensions, it can act as a length-selective molecular filter. We suggest that equivalent systems could have served as meeting points for long and complex molecules, too rare to find each other in a dilute primordial ocean. Furthermore, we discuss under which conditions this selection could have triggered the evolutionary adaptation of molecular replicators, and how polymerase chain reaction assays could nowadays benefit from the presented concept. References: 1. M. Powner et al., Nature 459 (2009), 2. G. Costanzo et al., ChemBioChem 13 (2012), 3. P. Baaske et al., PNAS (2007)

8:12AM Y42.00002 Reconstructing kinetic pathways from single-molecule FRET experiments using Bayesian inference , JAN-WILLEM VAN DE MEENT, RUBEN L. GONZALEZ, JR., CHRIS H. WIGGINS, Columbia University — Single-molecule FRET studies have enabled observation of conformational transitions in individual molecules, allowing targeted investigations into the mechanistic function of molecular machines. Like in many single-molecule platforms, sm-FRET studies yield observations of hundreds of noisy time series, which report on the same underlying conformational steps, but exhibit significant variations in photophysical properties and kinetic rates. Reconstruction of a consensus kinetic pathway from such noisy measurements is statistically challenging. Hidden Markov Models are widely used to identify states and estimate the associated kinetic rates. Existing techniques perform inference on one time series at a time, yielding variable parameter estimates that must now be 'averaged' using ad-hoc experiment specific post-processing steps. Here, we propose a technique known as Empirical Bayes estimation, which performs simultaneous analysis on a collection of trajectories in an experiment. This results in a single estimate for a consensus kinetic model, as well as a significantly reduced estimation error. By comparing models with different constraints, we show how these methods may be used to test detailed mechanistic hypotheses in a statistically principled, adaptable manner.

8:24AM Y42.00003 Single Molecule Measurements Using Correlation Force Spectroscopy[1] , MILAD RADIOM, Chemical Engineering, Virginia Tech, BRIAN ROBBINS, Mechanical Engineering, Virginia Tech, JOHN WALZ, Chemical Engineering, Virginia Tech, MARK PAUL, Mechanical Engineering, Virginia Tech, WILLIAM DUCKER, Chemical Engineering, Virginia Tech — Thermal noise represents a fundamental limit in force measurements. We describe single molecule measurements using two AFM cantilevers that have lower thermal noise than single-cantilever measurements. We achieve this by measuring the correlated thermal motions of two closely spaced cantilevers. Because only correlated thermal noise is measured, there is lower noise. In addition, the use of two cantilevers produces both decreased hydrodynamic fluid damping and decreased van der Waals forces acting on an AFM probe, both of which are interferences in single molecule measurements. Analysis of the correlated motions reveals molecular damping, a parameter that is not sensed with conventional (pulling) AFM single molecule force spectroscopy. When a molecule is straddled between the two cantilevers, the correlation arises from the solvent coupling as well as stiffness and damping of the molecule. We will describe the technique of correlation force spectroscopy and measurements of the mechanical properties of single polymer chains such as dextran.

8:36AM Y42.00004 A kinetic clutch governs uncoiling by type IB topoisomerases , KEIR NEUMAN, National Institutes of Health — Type IB topoisomerases (Top1B) are essential enzymes that relax excessive DNA supercoiling associated with replication and transcription and are important drug targets for cancer chemotherapy. The natural compound camptothecin (CPT) and the cancer chemotherapeutics derived from it, irinotecan and topotecan, are highly specific inhibitors of human nuclear Type IB topoisomerase (nTop1). We employed a magnetic-tweezers based single-molecule DNA supercoil relaxation assay to measure the torque dependence of human nuclear Top1 relaxation (nTop1) and inhibition by CPT. For comparison, we examined the human mitochondrial (Top1mt) topoisomerase and an N-terminal deletion mutant of nTop1 (Top68). Despite substantial sequence homology in their core domains, nTop1 and Top1mt exhibit dramatic differences in sensitivity to torque and CPT, with Top68 betraying intermediate characteristics. In particular, nTop1 displays nearly torque-independent religation probability, distinguishing it from other Top1B enzymes studied to date. Kinetic modeling reveals a hitherto unobserved torque-independent transition linking the DNA rotation and religation phases of the enzymatic cycle. The parameters of this transition determine the torque sensitivity of religation, and the efficiency of CPT binding. This "kinetic clutch" mechanism explains the molecular basis of CPT sensitivity and more generally provides a framework with which to interpret Top1B activity and inhibition.

9:12AM Y42.00005 Stretch Moduli of Ribonucleotide Embedded Short DNAs , HSIANG-CHIH CHIU, School of Physics, Georgia Institute of Technology, KYUNG DUK KOH, School of Biology, Georgia Institute of Technology, ELISA RIEDO, School of Physics, Georgia Institute of Technology, FRANCESCA STORICI, School of Biology, Georgia Institute of Technology — Understanding the mechanical properties of DNA is essential to comprehending the dynamics of many cellular functions. DNA deformations are involved in many mechanisms when genetic information needs to be stored and used. In addition, recent studies have found that Ribonucleotides (rNMPs) are among the most common non-standard nucleotides present in DNA. The presences of rNMPs in DNA might cause mutation, fragility or genotoxicity of chromosome but how they influence the structure and mechanical properties of DNA remains unclear. By means of Atomic Force Microscopy (AFM) based single molecule spectroscopy, we measure the stretch moduli of double stranded DNAs (dsDNA) with 30 base pairs and 5 equally embedded rNMPs. The dsDNAs are anchored on gold substrate via thiol chemistry, while the AFM tip is used to pick up and stretch the dsDNA from its free end through biotin-streptavidin bonding. Our preliminary results indicate that the inclusion of rNMPs in dsDNA might significantly change its stretch modulus, which might be important in some biological processes.

9:24AM Y42.00006 ABSTRACT WITHDRAWN –

9:36AM Y42.00007 The interplay between single-stranded binding proteins on RNA secondary structure[1]

, YI-HSUAN LIN, RALF BUNDSCHUH, The Ohio State University — RNA-protein interactions are critical for Biology because of their regulatory effects on mRNA and protein levels. There are typically several specific protein binding sites on an RNA molecule. A protein can bind one of these sites only if the RNA folds into a structure that leaves the entire binding site free of base pairs. Therefore, a protein binding to an RNA excludes some of the originally permitted RNA structures, causing a change in the structural ensemble. Thus, the probability of another protein to bind the same RNA at a different site will change upon binding of the first protein. To discover such effects, we combine methods of RNA secondary structure prediction with models of protein-RNA interaction. We focus on an RNA molecule with two protein binding sites. The ensemble of secondary structures of random RNA sequences is considered, and numerical calculations show the existence of a semi-long-range interaction between the protein binding sites mediated by the thermodynamics of the RNA structures. A brief analytic argument for this correlation is given, and a phase transition to a high-temperature phase, possibly related to the molten-glass phase transition of secondary RNA structures, is discussed.

9:48AM Y42.00008 Mechanostability of Proteins and Virus Capsids[1]

, MAREK CIEPLAK, Institute of Physics, Polish Academy of Sciences — Molecular dynamics of proteins within coarse grained models have become a useful tool in studies of large scale systems. The talk will discuss two applications of such modeling. The first is a theoretical survey of proteins' resistance to constant speed stretching as performed for a set of 17134 simple and 318 multidomain proteins. The survey has uncovered new potent force clamps. They involve formation of cysteine slipknots or dragging of a cystine plug through the cystine ring and lead to characteristic forces that are significantly larger than the common shear-based clamp such as observed in titin. The second application involves studies of nanoindentation processes in virus capsids and elucidates their molecular aspects by showing deviations in behavior compared to the continuum shell model. Across the 35 capsids studied, both the collapse force and the elastic stiffness are observed to vary by a factor of 20. The changes in mechanical properties do not correlate simply with virus size or symmetry. There is a strong connection to the mean coordination number $< z >$, defined as the mean number of interactions to neighboring amino acids. The Young's modulus for thin shell capsids rises roughly quadratically with $< z >$ - 6, where 6 is the minimum coordination for elastic stability in three dimensions.

10:24AM Y42.00009 Nanomechanical Response of *Pseudomonas aeruginosa* PAO1 Bacterial Cells to Cationic Antimicrobial Peptides

, SHUN LU, GRANT WALTERS, JOHN DUTCHER, University of Guelph — We have used an atomic force microscopy (AFM)-based creep deformation technique to study changes to the viscoelastic properties of individual Gram-negative *Pseudomonas aeruginosa* PAO1 cells as a function of time of exposure to two cationic peptides: polymyxin B (PMB), a cyclic antimicrobial peptide, and the structurally-related compound, polymyxin B nonapeptide (PMBN). The measurements provide a direct measure of the mechanical integrity of the bacterial cell envelope, and the results can be understood in terms of simple viscoelastic models of arrangements of springs and dashpots, which can be ascribed to different components within the bacterial cell. Time-resolved creep deformation experiments reveal abrupt changes to the viscoelastic properties of *P. aeruginosa* bacterial cells after exposure to both PMB and PMBN, with quantitatively different changes for the two cationic peptides. These measurements provide new insights into the kinetics and mechanism of action of antimicrobial peptides on bacterial cells.

10:36AM Y42.00010 Ion Discrimination by Nanoscale Design[1]

, SUSAN REMPE, DAVID ROGERS, Sandia National Labs — Proteins that form membrane-spanning channels excel at discriminating between molecules on the basis of subtle structural and chemical differences. For example, some channels distinguish between water and ions; others between Na+ (sodium) and K+ (potassium) despite identical charges and only sub-Angstrom differences in size. If we could understand these structure/function relationships, we could potentially harness biological design principles in robust nanoscale devices that mimic biological function for efficient separations. Using ab initio molecular simulations, we have interrogated the link between channel structure and selective transport, both in cellular channels and polymer membranes. Our results emphasize the surprisingly important role of the environment that surrounds ion-binding sites, as well as the coordination chemistry of the binding site for raising or lowering the free energy barrier to transport in both systems.

[1]Support for Sandia Laboratory Research & Development Program is gratefully acknowledged.

10:48AM Y42.00011 Extracting Models in Single Molecule Experiments

, STEVE PRESSE, Indiana University - Purdue University Indianapolis — Single molecule experiments can now monitor the journey of a protein from its assembly near a ribosome to its proteolytic demise. Ideally all single molecule data should be self-explanatory. However data originating from single molecule experiments is particularly challenging to interpret on account of fluctuations and noise at such small scales. Realistically, basic understanding comes from models carefully extracted from the noisy data. Statistical mechanics, and maximum entropy in particular, provide a powerful framework for accomplishing this task in a principled fashion. Here I will discuss our work in extracting conformational memory from single molecule force spectroscopy experiments on large biomolecules. One clear advantage of this method is that we let the data tend towards the correct model, we do not fit the data. I will show that the dynamical model of the single molecule dynamics which emerges from this analysis is often more textured and complex than could otherwise come from fitting the data to a pre-conceived model.

Friday, March 22, 2013 8:00AM - 10:48AM –

Session Y43 DCP: Spectroscopy, Photochemistry, and Electrochemistry Hilton Baltimore Holiday Ballroom 2 - Jeff Owrutsky, Naval Research Laboratory

8:00AM Y43.00001 Quasiparticle Representation of Coherent Nonlinear Optical Signals of Multiexcitons , BENJAMIN FINGERHUT, KOCHISE BENNET, OLEKSIY ROSLYAK, SHAUL MUKAMEL, University of California, Irvine — Elementary excitations of many-Fermion systems can be described within the quasiparticle approach which is widely used in the calculation of transport and optical properties of metals, semiconductors, molecular aggregates and strongly correlated quantum materials. The excitations are then viewed as independent harmonic oscillators where the many-body interactions between the oscillators are mapped into anharmonicities. We present a Green's function approach based on coboson algebra for calculating nonlinear optical signals and apply it onwards the study of two and three exciton states. The method only requires the diagonalization of the single exciton manifold and avoids equations of motion of multi-exciton manifolds. Using coboson algebra many body effects are recast in terms of tetradic exciton-exciton interactions: Coulomb scattering and Pauli exchange. The physical space of Fermions is recovered by singular-value decomposition of the over-complete coboson basis set. The approach is used to calculate third and fifth order quantum coherence optical signals that directly probe correlations in two- and three exciton states and their projections on the two and single exciton manifold.

8:12AM Y43.00002 Surface induced selective deposition of Dysprosium Polyoxometalate on HOPG surface studied by STM and STS , DAVID COSTA MILAN, LT-Nanolab University of Alicante, ELENA PINILLA CIENFUEGOS, SALVADOR CARDONA SERRA, EUGENIO CORONADO MIRALLES, Research Team on Molecular Materials University of Valencia, CARLOS UNTIEDT LECUONA, LT-Nanolab University of Alicante — Scanning Tunneling Microscope (STM) and scanning Tunnelling spectroscopy (STS) techniques have been used to study the Preyssler type Polyoxometalate $K_{12}[DyP_5W_{30}O_{110}]$ molecules deposited on Highly Oriented Pyrolytic Graphite surface (HOPG). Chainlike arrangements of clusters containing two or three molecules, as well as different cluster sizes are observed. As many structural artifacts are present on the graphite surface, like Moiré patterns, that could look like the molecular deposits, we have studied their STS and size to ensure the presence of the POM molecules on the surface. This article shows the possibility of addressing POMs on a flat surface to obtain their electronic properties through STS.

8:24AM Y43.00003 Detecting excited-state vibrational dynamics by broadband infrared or Raman probes; A unified picture based on loop diagrams , KONSTANTIN E. DORFMAN, BENJAMIN FINGERHUT, SHAUL MUKAMEL, University of California, Irvine — Vibrational motions in electronically excited states can be probed either by time and frequency resolved infrared or by off resonant stimulated Raman techniques. Using loop diagrams, which represent forward and backward propagation of the wavefunction we derive similar multipoint correlation function expressions for both signals which are suitable for quantum microscopic simulations. The effective temporal (Δt) and spectral ($\Delta\omega$) resolution of the techniques is not solely controlled by experimental knobs since it also depends on the system dynamics being probed. The Fourier uncertainty $\Delta\omega\Delta t > 1$ is never violated.

8:36AM Y43.00004 Interfacial Matrix Stabilization Spectroscopy (IMSS) studies of CO and O2 interactions with thin films of oxide-supported Au nanoparticles , NINA K. JARRAH, DAVID T. MOORE, Lehigh University — Interfacial Matrix Stabilization Spectroscopy (IMSS) employs energy-dissipating cryogenic matrix isolation techniques combined with FTIR to enable stabilization and detection of pre-reactive complexes of CO and O2 formed on oxide-supported gold nanoparticles (AuNPs). Following deposition of CO and O2 in an argon matrix at 10-20K, annealing to warmer temperatures (28-32K) promotes diffusion of isolated dopant molecules through the matrix to binding sites on a thin film of catalyst. Matrix-solvated pre-reactive complexes form at the surface and are characterized spectroscopically. Comparison of observed complexes in IMSS experiments with results from direct adsorption studies, in absence of a matrix, can provide a measure for the stabilizing effects of matrix solvation. Subsequent surface warming following stabilization of the pre-reactive complexes reveals qualitative information about relative binding energies of formed intermediates of CO, O2, and the supported AuNPs. A series of FTIR spectra mapping the evolution of vibrational bands during the annealing process and tracking the various surface-bound species will be presented and comparisons to direct adsorption experiments will be discussed.

8:48AM Y43.00005 Rotational Spectroscopy at Sub-Angstrom Level: Rotationaland Vibrational Excitations of Molecular Hydrogen measured by the Scanning Tunneling Microscope , SHAOWEI LI, ARTHUR YU, HUI WANG, FREDDY TOLEDO, ZHUMIM HAN, RUQIAN WU, WILSON HO, University of California, Irvine — The power of rotational spectroscopy has long been demonstrated in the frequency domain by microwave spectroscopy, but its application in real space has been limited. Using a scanning tunneling microscope (STM) and inelastic electron tunneling spectroscopy (IETS), we are able to conduct real-space measurements of rotational transitions of gaseous hydrogen molecules physisorbed on Au(110) surface at 10 K. The j=0 to j=2 rotational transition for para-H_2 and HD as well as the v=0 to v=1 vibrational transitions for H_2, D_2 and HD were observed by STM-IETS. By varying the tip-substrate distance, we could precisely investigate how the environmental coupling modifies the structure, including the bond length, of a single molecule with sub-Angstrom resolution. Rotational spectroscopy at the single molecule level provides a powerful tool for chemical identification as well as bond length measurement in both the frequency and space domains.

9:00AM Y43.00006 Two-Photon Ionization of a Low IP Molecule (TDAE) , BYRON SMITH[1], ROBERT COMPTON[2], University of Tennessee, UNIVERSITY OF TENNESSEE CHEMICAL PHYSICS TEAM — Very low ionization potential molecules ($<$ 6 eV) have been studied thoroughly for their use in low temperature plasmas, charge-transfer salts, and as an alternative to liquid scintillation in photomultiplier tubes. One such molecule is tetrakis(dimethylamino)ethylene (TDAE) with a previously measured IP of 5.2 $\pm$ 0.05 eV using electron and photon impact time of flight mass spectrometry.[3] Two-photon ionization photoelectron spectroscopy of TDAE at 441 nm and 355 nm results in an IP of 5.22 $\pm$ 0.14 eV. In addition to the photoelectron peak associated with direct ionization, a peak was observed corresponding to thermal energy electrons ($\sim$ 0 eV). This has been previously assigned to an intense short-lived auto-ionizing state[4] which quickly cools to a zwitterionic intermediate. We assign this state to a collective excitation as an alternative explanation of the source of the slow electrons. The collective state involves electron correlation within the parent molecule as well as the degeneracy of the auto-ionizing state.

9:12AM Y43.00007 Modeling the color of natural dyes , XIAOCHUAN GE, Scuola Internazionale Superiore di Studi Avanzati, Trieste, Italy, ARRIGO CALZOLARI, Centro S3 - CNR-NANO, Modena, Italy, SIMON BINNIE, STEFANO BARONI, Scuola Internazionale Superiore di Studi Avanzati, Trieste, Italy — We report on a theoretical study, based on time-dependent density-functional theory, of various factors affecting the optical properties of a few representative anthocyanins, a class of molecules responsible for the color of many fruits, flowers, and leaves, which have also aroused some interest for photovoltaic applications. We first address the influence of substituting different side groups in the phenyl ring of flavylium dyes. We find that these dyes can be classified into three broad classes, according to the number of peaks (1, 2, or 3) featured in the visible range, and give a rationale to this finding. We then examine the effects of solvent-induced thermal fluctuations and dielectric screening, by calculating the spectrum of a representative molecule in solution, for each one these classes. This is achieved by first running an ab initio molecular dynamics simulation of an explicit model for the water-solvated molecule, and then accumulating time averages of the optical spectra calculated on the fly. The effects of thermal fluctuations are shown to overshadow those of dielectric screening, and more dramatic the larger the number of peaks in the gas phase. The effects of different functionals (GGA vs. hybrids) on the calculated spectra are also addressed.

9:24AM Y43.00008 Terahertz Time-Domain Spectroscopy of Nitrogen Ice[1] , BAGVANTH R. SANGALA, PERRY A. GERAKINES, DAVID J. HILTON, Department of Physics, The University of Alabama at Birmingham, Birmingham, AL 35294-1170, USA — We have used terahertz time-domain spectroscopy from 0.1-1.6 THz to study thin films of solid N_2 from 10-25 K. A temperature dependent absorption line shift was observed near 1.46 THz as the temperature increased from 10 to 25 K, where the center frequency of the absorption line decreased with temperature. We can fit these data to a model assuming a standard Lennard-Jones potential with the addition of a quadrupole-quadrupole interaction. We modeled the shift in the resonant absorption with a lattice expansion that includes previously published thermal expansion coefficients in N_2 ice, the gas-phase Lennard-Jones parameters, and the gas-phase quadrupole moments.

[1]The Authors thank NASA for supporting this research under the grant NSPIRES 07- APRA07-NNX09AI28G

9:36AM Y43.00009 Temperature-dependent and time-resolved emission studies of *cis*-$Ru(bpy)_2(N_3)_2$, HELEN K. GERARDI, NRL, NRC Postdoctoral Research Associate, DOUGLAS J. BROWN, US Naval Academy, RYAN COMPTON, NRL, NRC Postdoctoral Research Associate, WALTER J. DRESSICK, NRL, EDWIN J. HEILWEIL, NIST, JEFFREY C. OWRUTSKY, NRL — The electronic properties of a Ru^{II} cyclometalated dye complex, *cis*-$Ru(bpy)_2(N_3)_2$, were examined with time-resolved and temperature-dependent visible emission measurements. Compared to two related solar cell dye-sensitizer species, *cis*-$Ru(bpy)_2(NCS)_2$ and *cis*-$Ru(bpy)_2(CN)_2$, the azide (N_3) pseudohalide ligand dramatically changes the electronic properties of the dye. The uv-vis absorption spectra of *cis*-$Ru(bpy)_2(N_3)_2$ in various solvents reveal that its metal-to-ligand charge transfer band (MLCT) is located more than 50 nm to the red of the MLCT bands found for the other two complexes. Furthermore, while room temperature emission is readily observed for *cis*-$Ru(bpy)_2(NCS)_2$ and *cis*-$Ru(bpy)_2(CN)_2$, the emission is much weaker for *cis*-$Ru(bpy)_2(N_3)_2$. We report the first observation of luminescence from *cis*-$Ru(bpy)_2(N_3)_2$ by measuring it in 4:1 EtOH:MeOH matrices at temperatures below 140 K. Emission bands are observed at 665 nm and 620 nm (514 nm excitation). The quantum yield of this species was estimated by comparing the integrated emission signal of *cis*-$Ru(bpy)_2(N_3)_2$ to that of *cis*-$Ru(bpy)_2(CN)_2$ at 77 K and was determined to be exceptionally low (6×10^{-4}). The luminescence lifetime of *cis*-$Ru(bpy)_2(N_3)_2$ at 77 K was measured to be approx. 800 ns, implying an extremely slow radiative rate of 780 s^{-1}. The long radiative rate and low quantum yield led us to further investigate the photolability and electrochemical behavior of the azide complex.

9:48AM Y43.00010 How Fissors works: tracking vibrationally adiabatic conformational change with femtosecond stimulated Raman spectroscopy[1] , JEFFREY CINA, PHIL KOVAC, Univ of Oregon, DEPARTMENT OF CHEMISTRY & OREGON CENTER FOR OPTICS TEAM — With the help of a two-dimensional model system comprising a slow conformational degree of freedom and a higher-frequency vibration, we investigate the optical generation and dynamical information content of femtosecond stimulated Raman spectroscopy (FSRS or fissors). Our treatment makes use of an assumption that the motion of a wave packet describing the relatively slow—but still ultrafast—conformational change is vibrationally adiabatic. We present calculated fissors signals for regimes in which the conformational change is or is not sufficiently slow to result in an evolving fissors lineshape whose center frequency tracks the "instantaneous" vibrational frequency.

10:00AM Y43.00011 A photoelectrochemical (PEC) study on graphene oxide based hematite thin films heterojunction (R-GO/Fe_2O_3) , POONAM SHARMA, Dept of Physics & Comp Science, Dayalbagh Educational Institute, Agra, India, MICHAEL ZACHARIAH, Dept of Mechanical Engineering, UMCP, Maryland, SHERYL EHRMAN, Dept of Chemical Engineering, UMCP, Maryland, ROHIT SHRIVASTAVA, SAHAB DASS, Dept of Chem, Dayalbagh Educational Institute, Agra, India, VIBHA R. SATSANGI, Dept of Physics & Comp Science, Dayalbagh Educational Institute, Agra, India, MICHAEL ZACHARIAH, SHERYL EHRMAN COLLABORATION, ROHIT SHRIVASTAVA, SAHAB DASS COLLABORATION, VIBHA R SATSANGI, POONAM SHARMA TEAM — Graphene has an excellent electronic conductivity, a high theoretical surface area of 2630 m^2/g and excellent mechanical properties and, thus, is a promising component for high-performance electrode materials. Following this, GO has been used to modify the PEC response of photoactive material hematite thin films in PEC cell. A reduced graphene oxide/iron oxide (R-GO/Fe_2O_3) thin film structure has been successfully prepared on ITO by directly growing iron oxide particles on the thermally reduced graphene oxide sheets prepared from suspension of exfoliated graphene oxide. R-GO/Fe_2O_3 thin films were tested in PEC cell and offered ten times higher photocurrent density than pristine Fe_2O_3 thin film sample. XRD, SEM, EDS, UV-Vis, Mott-Schottky and Raman studies were carried out to study spectro-electrochemical properties. Enhanced PEC performance of these photoelectrodes was attributed to its porous morphology, improved conductivity upon favorable carrier transfer across the oxides interface.

10:12AM Y43.00012 Site-Specific Photosimulated Reactions of O_2 on $TiO_2(110)$[1] , ZHI-TAO WANG, Pacific Northwest National Laboratory, N. AARON DESKINS, Worcester Polytechnic Institute, IGOR LYUBINETSKY, Pacific Northwest National Laboratory — We report the direct observation at an atomic level with high-resolution scanning tunneling microscopy of photostimulated reactions of single O_2 molecules on reduced $TiO_2(110)$ surfaces at 50 K. Two distinct reactions of O_2 desorption and dissociation occur at different active sites of terminal Ti atoms and bridging O vacancies, respectively demonstrating the critical relation between photoreactivity and adsorption sites on TiO_2. These two reaction channels follow very different kinetics. Hole-mediated O_2 desorption is promptly and fully completed, while electron-mediated O_2 dissociation is much slower and is quenched above some critical O_2 coverage. Density functional theory calculations indicate that both coordination and charge state of an O_2 molecule chemisorbed at specific site largely determine a particular reaction pathway.

[1]This work was supported by the U.S. Department of Energy (DOE) Office of Basic Energy Sciences, Division of Chemical Sciences, and performed at EMSL, a DOE User Facility sponsored by the Office of Biological and Environmental Research and located at PNNL.

10:24AM Y43.00013 Cobalt (hydro)oxide electrodes under electrochemical conditions: a first principle study , JIA CHEN, ANNABELLA SELLONI, Princeton University — There is currently much interest in photoelectrochemical water splitting as a promising pathway towards sustainable energy production. A major issue of such photoelectrochemical devices is the limited efficiency of the anode, where the oxygen evolution reaction (OER) takes place. Cobalt (hydro)oxides, particularly Co3O4 and Co(OH)2, have emerged as promising candidates for use as OER anode materials. Interestingly, recent in-situ Raman spectroscopy studies have shown that Co3O4 electrodes undergo progressive oxidation and transform into oxyhydroxide, CoO(OH), under electrochemical working conditions. (Journal of the American Chemical Society **133**, 5587 (2011))Using first principle electronic structure calculations, we provide insight into these findings by presenting results on the structural, thermodynamic, and electronic properties of cobalt oxide, hydroxide and oxydroxide CoO(OH), and on their relative stabilities when in contact with water under external voltage.

10:36AM Y43.00014 Near-field Nanoscopy and Spectroscopy of Phase Coexistence in $LiFePO_4$ Electrode Microcrystals , IVAN T. LUCAS, University Pierre and Marie Curie, Paris, France, ALEXANDER MCLEOD, University of California, San Diego, JAROSLAW S. SYZDEK, Lawrence Berkeley National Laboratory, DEREK S. MIDDLEMISS, University of Cambridge, ROBERT KOSTECKI, Lawrence Berkeley National Laboratory, D.N. BASOV, University of California, San Diego — Due to instrumental limitations, the microscopic description of lithiation and delithiation processes in low-cost $LiFePO_4$ electrodes has remained uncertain and subject to controversy. Using infrared near-field imaging, we present evidence for a novel coexistence of phases within single $LiFePO_4$ microcrystals. First-principles calculations of the phonon response of lithiated and delithiated end-phases are compared with broadband nano-FTIR (Fourier transform infrared) spectroscopy data to reveal the mid-infrared vibrational signature of lithiation. By resolving this signature at the nano-scale, we observe a propagation of phase boundaries within these crystals over the course of chemical delithiation. In addition, by comparing theoretical modeling with spatially resolved nano-FTIR spectra measured across a single crystal at partial delithiation, we assemble a tomographic view of phases distributed hundreds nanometers beneath the crystal surface. These experiments set the stage for quantitative nano-spectroscopy of new composite electrode materials, assisting in the rational design of next-generation electrical energy storage systems.

Session Y44 DBIO: Focus Session: Novel Experimental Techniques for Probing Cellular Mechanics Hilton Baltimore Holiday Ballroom 1 - Cristian Staii, Tufts

8:00AM Y44.00001 Mechanosensitivity in axon growth and guidance[1] , JEFF URBACH, Department of Physics and Institute for Soft Matter, Georgetown University — In the developing nervous system, axons respond to a diverse array of cues to generate the intricate connection network required for proper function. The growth cone, a highly motile structure at the tip of a growing axon, integrates information about the local environment and modulates outgrowth and guidance, but little is known about effects of external mechanical cues and internal mechanical forces on growth cone behavior. We have investigated axon outgrowth and force generation on soft elastic substrates for dorsal root ganglion (DRG) neurons (from the peripheral nervous system) and hippocampal neurons (from the central) to see how the mechanics of the microenvironment affect different populations. We find that force generation and stiffness-dependent outgrowth are strongly dependent on cell type. We also observe very different internal dynamics and substrate coupling in the two populations, suggesting that the difference in force generation is due to stronger adhesions and therefore stronger substrate engagement in the peripheral nervous system neurons. We will discuss the biological origins of these differences, and recent analyses of the dynamic aspects of growth cone force generation and the implications for the role of mechanosensitivity in axon guidance.

[1]In collaboration with D. Koch, W. Rosoff, and H. M. Geller. Supported by NINDS grant 1R01NS064250-01 (J.S.U.) and the NHLBI Intramural Research Program (H.M.G.).

8:36AM Y44.00002 Electrophysiology of Axonal Constrictions[1] , CHRISTOPHER JOHNSON, PETER JUNG, Ohio University, ANTHONY BROWN, Ohio State University — Axons of myelinated neurons are constricted at the nodes of Ranvier, where they are directly exposed to the extracellular space and where the vast majority of the ion channels are located. These constrictions are generated by local regulation of the kinetics of neurofilaments the most important cytoskeletal elements of the axon. In this paper we discuss how this shape affects the electrophysiological function of the neuron. Specifically, although the nodes are short (about $1\mu m$) in comparison to the distance between nodes (hundreds of μm) they have a substantial influence on the conduction velocity of neurons. We show through computational modeling that nodal constrictions (all other features such as numbers of ion channels left constant) reduce the required fiber diameter for a given target conduction velocity by up to 50% in comparison to an unconstricted axon. We further show that the predicted optimal fiber morphologies closely match reported fiber morphologies.

8:48AM Y44.00003 Role of biomechanical cues on neuronal growth on asymmetric textured surfaces[1] , CRISTIAN STAII, ELISE SPEDDEN, TIMOTHY ATHERTON, Department of Physics and Astronomy and Center for Nanoscopic Physics, Tufts University, KORAY SEKEROGLU, MELIK DEMIREL, Materials Research Institute and Department of Engineering Science, Pennsylvania State University — Axonal growth and the formation of synaptic connections are key steps in the development of the nervous system. Here we present experimental and theoretical results on axonal growth on unidirectional nanotextured surface, and demonstrate that these surface can bias axonal growth. We also perform a systematic investigation of neuronal processes on these surfaces and quantify the role that biomechanical surface cues play in neuronal growth. We show that these surfaces provide a model growth substrates, which allow us to perform systematic studies of the interplay between mechanical, biochemical and topographical cues that contribute to neuronal growth.

9:00AM Y44.00004 The formation of axonal caliber and nodes of Ranvier[1] , YINYUN LI, PETER JUNG, Department of Physics and Astronomy, Ohio University, ANTHONY BROWN, Department of Neuroscience, Ohio State University — A remarkable feature of myelinated neurons is that their axons are constricted at the nodes of Ranvier. These are the locations where axons are directly exposed to the extracellular space and where the vast majority of the ion channels are located. These constrictions emerge during development and have been observed to reduce axonal cross sectional area by factors of more than 10. Combining fluorescent imaging methods with computational modeling, we describe how the nervous system regulates the local caliber of its axons through the regulation of the transport kinetics of its most important cytoskeletal elements, the neurofilaments, matching axon caliber and shape to its physiologic function.

9:12AM Y44.00005 Studying neuronal biomechanics and its role in CNS development , KRISTIAN FRANZE, HANNO SVOBODA, University of Cambridge, UK, LUCIANO DA F. COSTA, University of Sao Paulo, Brazil, JOCHEN GUCK, CHRISTINE HOLT, University of Cambridge, UK — During the development of the nervous system, neurons migrate and grow over great distances. Currently, our understanding of nervous tissue development is, in large part, based on studies of biochemical signaling. Despite the fact that forces are involved in any kind of cell motion, mechanical aspects have so far rarely been considered. Here we used deformable cell culture substrates, traction force microscopy and calcium imaging to investigate how neurons probe and respond to their mechanical environment. While the growth rate of retinal ganglion cell axons was increased on stiffer substrates, their tendency to grow in bundles, which they show *in vivo*, was significantly enhanced on more compliant substrates. Moreover, if grown on substrates incorporating linear stiffness gradients, neuronal axons were repelled by stiff substrates. Mechanosensing involved the application of forces driven by the interaction of actin and myosin II, and the activation of stretch-activated ion channels leading to calcium influxes into the cells. Applying a modified atomic force microscopy technique *in vivo*, we found mechanical gradients in developing brain tissue along which neurons grow. The application of chondroitin sulfate, which is a major extracellular matrix component in the developing brain, changed tissue mechanics and disrupted axonal pathfinding. Hence, our data suggest that neuronal growth is not only guided by chemical signals – as it is currently assumed – but also by the nervous tissue's mechanical properties.

9:24AM Y44.00006 Contact nanomechanical measurements with the AFM , NICHOLAS GEISSE, Asylum Research — The atomic force microscope (AFM) has found broad use in the biological sciences largely due to its ability to make measurements on unfixed and unstained samples under liquid. In addition to imaging at multiple spatial scales ranging from micro- to nanometer, AFMs are commonly used as nanomechanical probes. This is pertinent for cell biology, as it has been demonstrated that the geometrical and mechanical properties of the extracellular microenvironment are important in such processes as cancer, cardiovascular disease, muscular dystrophy, and even the control of cell life and death. Indeed, the ability to control and quantify these external geometrical and mechanical parameters arises as a key issue in the field. Because AFM can quantitatively measure the mechanical properties of various biological samples, novel insights to cell function and to cell-substrate interactions are now possible. As the application of AFM to these types of problems is widened, it is important to understand the performance envelope of the technique and its associated data analyses. This talk will discuss the important issues that must be considered when mechanical models are applied to real-world data. Examples of the effect of different model assumptions on our understanding of the measured material properties will be shown. Furthermore, specific examples of the importance of mechanical stimuli and the micromechanical environment to the structure and function of biological materials will be presented.

9:36AM Y44.00007 Quantitative nano-mechanics of biological cells with AFM , IGOR SOKOLOV[1], Tufts University — The importance of study of living cells is hard to overestimate. Cell mechanics is a relatively young, yet not a well-developed area. Besides just a fundamental interest, large practical need has emerged to measure cell mechanics quantitatively. Recent studies revealed a significant correlation between stiffness of biological cells and various human diseases, such as cancer, malaria, arthritis, and even aging. However, really quantitative studies of mechanics of biological cells are virtually absent. It is not even clear if the cell, being a complex and heterogeneous object, can be described by the elastic modulus at all. Atomic force microscopy (AFM) is a natural instrument to study properties of cells in their native environments. Here we will demonstrate that quantitative measurements of elastic modulus of cells with AFM are possible. Specifically, we will show that the "cell body" (cell without "brush" surface layer, a non-elastic layer surrounding cells) typically demonstrates the response of a homogeneous elastic medium up to the deformation of 10-20%, but if and only if a) the cellular brush layer is taken into account, b) rather dull AFM probes are used. This will be justified with the help of the strong condition of elastic behavior of material: the elastic modulus is shown to be independent on the indentation depth. We will also demonstrate that an attempt either to ignore the brush layer or to use sharp AFM probes will result in the violation of the strong condition, which implies impossibility to use the concept of the elastic modulus to describe cell mechanics in such experiments. Examples of quantitative measurements of the Young's modulus of the cell body and the cell brush parameters will be given for various cells.

10:12AM Y44.00008 Tracking Cytoskeletal Dynamics in Living Neurons via Combined Atomic Force and Fluorescence Microscopy , ELISE SPEDDEN, DAVID KAPLAN, CRISTIAN STAII, Tufts University — Living cells are active mechanical structures which evolve within and in response to their local microenvironments. Various cell types possess different mechanical properties and respond uniquely to growth, environmental changes, and the application of chemical stimuli. Here we present a powerful approach which combines high resolution Atomic Force Microscopy with Fluorescence Microscopy to systematically obtain real-time micrometer and sub-micrometer resolution elasticity maps for live neuronal cells cultured on glass substrates. Through this approach we measure the topography, the elastic properties, and the dynamics of neuronal cells, and identify changes in cytoskeletal components during axonal growth, chemical modification, and changes in ambient temperature. We will also show high resolution elasticity measurements of the cell body and of axons/dendrites during growth, as well as identification of cytoskeletal components during cell growth and environmental changes.

10:24AM Y44.00009 Atomic Force Microscopy Based Cell Shape Index[1] , USIENEMFON ADIA-NIMUWA, VOLKAN MUJDAT TIRYAKI, STEVEN HARTZ, KAN XIE, VIRGINIA AYRES, Michigan State University — Stellation is a measure of cell physiology and pathology for several cell groups including neural, liver and pancreatic cells. In the present work, we compare the results of a conventional two-dimensional shape index study of both atomic force microscopy (AFM) and fluorescent microscopy images with the results obtained using a new three-dimensional AFM-based shape index similar to sphericity index [1]. The stellation of astrocytes is investigated on nanofibrillar scaffolds composed of electrospun polyamide nanofibers that has demonstrated promise for central nervous system (CNS) repair. Recent work by our group has given us the ability to clearly segment the cells from nanofibrillar scaffolds in AFM images [2]. The clear-featured AFM images indicated that the astrocyte processes were longer than previously identified at 24h. It was furthermore shown that cell spreading could vary significantly as a function of environmental parameters, and that AFM images could record these variations [3]. The new three-dimensional AFM-based shape index incorporates the new information: longer stellate processes and cell spreading. [1] AWI. Jay, Biophys. J.:15, 205 (1975) [2] VM Tiryaki, et al, Scanning:34, 316 (2012) [3] VM Tiryaki, et al, Int. J. Nanomed.:07, 3891 (2012)

10:36AM Y44.00010 Response of Quiescent Cerebral Cortical Astrocytes to Nanofibrillar Scaffold Properties[1] , VIRGINIA AYRES, VOLKAN MUJDAT TIRYAKI, KAN XIE, Michigan State University, IJAZ AHMED, DAVID I. SHREIBER, Rutgers, The State University of New Jersey — We present results of an investigation to examine the hypothesis that the extracellular environment can trigger specific signaling cascades with morphological consequences [1]. Differences in the morphological responses of quiescent cerebral cortical astrocytes cultured on the nanofibrillar matrices versus poly-L-lysine functionalized glass and Aclar, and unfunctionalized Aclar surfaces were demonstrated using atomic force microscopy (AFM) and phalloidin staining of F-actin. The differences and similarities of the morphological responses were consistent with differences and similarities of the surface polarity and surface roughness of the four surfaces investigated in this work, characterized using contact angle and AFM measurements. The three-dimensional capability of AFM was also used to identify differences in cell spreading. An initial quantitative immunolabeling study further identified significant differences in the activation of the Rho GTPases: Cdc42, Rac1, and RhoA, which are upstream regulators of the observed morphological responses: filopodia, lamellipodia, and stress fiber formation. The results support the hypothesis that the extracellular environment can trigger preferential activation of members of the Rho GTPase family with demonstrable morphological consequences for cerebral cortical astrocytes. Session Y45 DBIO: Focus Session: Physics of Cancer II Hilton Baltimore Holiday Ballroom 4 - Larry Nagahara, National Institutes of Health

8:00AM Y45.00001 Collective Behavior of Brain Tumor Cells: the Role of Hypoxia , EVGENIY KHAIN, Oakland University, MARK KATAKOWSKI, Henry Ford Hospital, SCOTT HOPKINS, Oakland University, ALEXANDRA SZALAD, XUGUANG ZHENG, FENG JIANG, MICHAEL CHOPP, Henry Ford Hospital — We consider emergent collective behavior of a multicellular biological system. Specifically we investigate the role of hypoxia (lack of oxygen) in migration of brain tumor cells [1]. We performed two series of cell migration experiments. The first set of experiments was performed in a typical wound healing geometry: cells were placed on a substrate, and a scratch was done. In the second set of experiments, cell migration away from a tumor spheroid was investigated. Experiments show a controversy: cells under normal and hypoxic conditions have migrated the same distance in the "spheroid" experiment, while in the "scratch" experiment cells under normal conditions migrated much faster than under hypoxic conditions. To explain this paradox, we formulate a discrete stochastic model for cell dynamics [1,2]. The theoretical model explains our experimental observations and suggests that hypoxia decreases both the motility of cells and the strength of cell-cell adhesion. The theoretical predictions were further verified in independent experiments [1].

8:12AM Y45.00002 Rapid evolution of drug resistance of multiple myeloma in the microenvironment with drug gradients , AMY WU, Princeton University, QIUCEN ZHANG, University of Illinois at Urbana-Champaign, GUILLAUME LAMBERT, University of Chicago, ZAYAR KHIN, ARIOSTO SILVA, ROBERT GATENBY, Moffitt Cancer Center, JOHN KIM, NADER POURMAND, University of California at Santa Cruz, ROBERT AUSTIN, JAMES STURM, Princeton University — Drug resistance in cancer is usually caused by the spatial drug gradients in tumor environment. Here, we culture multiple myeloma in a gradient from 0 to 20 nM of doxorubicin (genotoxic drug) across 2 mm wide region for 12 days. The myeloma cells grew rapidly and formed 3D colonies in the regions with less drug concentration. However, we have seen emergent colonies forming in regions with drug concentration above the minimal inhibitory concentration in less than one week. Once the cells have occupied the regions with less drug concentration, they tend to migrate toward the regions with higher drug concentration in a collective behavior. To characterize their resistance, we collect them from this microfluidic system, for further analysis of the dose response. We find that the IC50 (drug concentration that inhibits 50% of controlled population) of the cells, undergone a drug gradient, increase 16-fold of the wildtype cells. We further discover that these resistant cells express more Multidrug Resistance (mdr) protein, which pumps out the drugs and causes drug resistance, than the wildtype. Our current works on RNA-sequencing analysis may discover other biomolecular mechanisms that may confer the drug resistance.

8:24AM Y45.00003 Hierarchy of Gene Expression as a Biomarker for Breast Cancer Prognosis , MAN CHEN, Rice University — Cancer is a dedifferentiation of healthy cellular and genetic processes. At the same time, specific oncological pathways are activated in the cancer state [1]. Cancer metastasis exposes cancer cells to a variety of microenvironments, in which physics of evolution suggests modularity is a relevant order parameter [2]. We were thus motivated to examine the structure in gene and tissue networks of breast cancer patients. We studied the relation between metastasis and breast cancer network structure. We found that hierarchy of cancer networks distinguishes non-metastatic from metastatic patient populations. We also found that for cancer-associated genes, likelihood of metastasis is correlated with increased network hierarchy. Conversely for tissue networks using all gene data, reduced network structure is correlated with likelihood of metastasis. We suggest hierarchy of gene expression may be useful as a biomarker for breast cancer breast cancer metastasis and recurrence. For those patients with reduced structure, which is at least 5% of the patient population, this biomarker provides a strong signal for likelihood of cancer metastasis.

8:36AM Y45.00004 Ultrasensitive Mirco-Hall Detector for Enumeration and Molecular Profiling of Rare Cells , CHANGWOOK MIN, Massachusetts General Hospital, DAVID ISSADORE, University of Pennsylvenia, JAEHOON CHUNG, HUILIN SHAO, MONTY LIONG, AREZOU A. GHAZANI, CESAR M. CASTRO, RALPH WEISSLEDER, HAKHO LEE, Massachusetts General Hospital — We have recently developed a miniaturized microfluidic chip-based technology, the micro-Hall detector (uHD), that can perform rapid, highly sensitive, and quantitative measurement of individual cells in unprocessed biological samples. The uHD detects the Hall voltage induced by magnetic moments of cells in-flow that have been immunomagnetically tagged with magnetic nanoparticles (MNPs) and bio-orthogonal chemistry. The entire assay is performed on a single microfluidic chip with minimal sample preparation to avoid sample loss and to simplify assay procedure, eliminating the need for any washing and purification steps, and thereby allows cellular diagnostics to be conducted in point-of-care clinical settings. We also demonstrated simultaneous detection of heterogeneous biomarkers on individual cells by targeting different cellular markers with a panel of MNPs. The quantity of each MNP type, and hence the expression level of a target biomarker in a single cell, could be obtained using the particles' distinctive magnetization properties. The clinical use of the uHD was explored by the detection of circulating tumor cells (CTCs) in whole blood of 20 ovarian cancer patients, and drug treatment efficacy was monitored in a mouse tumor model.

8:48AM Y45.00005 Miniaturized holographic imaging system for real-time cellular detection , JUN SONG, Massachusetts General Hospital/Harvard University, HYUNGSOON IM, MONTY LIONG, LIOUBOV FEXON, MISHA PIVOVAROV, Massachusetts General Hospital, RALPH WEISSLEDER, Massachusetts General Hospital/Harvard Medical School, HAKHO LEE, Massachusetts General Hospital — We herein present a miniaturized holographic imaging system for high throughput cellular detection. The system consists of an imager chip with a microfluidic channel built on top. Clinical samples (e.g., blood) are introduced into the fluidic channel, and holographic images of cells are recorded by the imager chip. We then perform computational reconstruction of original cell images, retrieving both the intensity and phase information. For fast image reconstruction, we have implemented parallel computing software and utilized multicore GPU (graphics processing unit) chips. The resulting imaging system enabled high throughput cellular detection; up to 1000 cells/μL could be imaged over a wide detection area (20 mm^2), and cellular images could be reconstructed in real time (20 frames/sec). Furthermore, assays can be performed without extra dilution and washing steps, which significantly simplifies the diagnosis process. This cost-effective, real-time holographic imaging system can be used for target cell detection in point-of-care applications.

9:00AM Y45.00006 Rapid detection and profiling of rare cancer cells with a portable holographic imaging system , HYUNGSOON IM, JUN SONG, MONTY LIONG, LIOUBOV FEXON, MISHA PIVOVAROV, Massachusetts General Hospital, RALPH WEISSLEDER, Massachusetts General Hospital, Harvard Medical School, HAKHO LEE, Massachusetts General Hospital — We herein present the detection and molecular profiling of rare cancer cells, using a chip-based holographic imaging system. In this approach, target cancer cells are labeled with molecular-specific microbeads. Such labeling enables 1) a reliable differentiation between cancer cells and host cells (e.g., leukocytes); and 2) quantitative profiling of target marker expression through bead-counting. A new algorithm for digital image reconstruction and bead counting was developed as well to facilitate the assay. The developed system were able to accurately count more than thousands of beads and cells in a single image. Importantly, the assay could be performed without any dilution or washing steps, minimizing cell loss and simplifying the assay procedure. By counting the number of beads attached on cells, we could also measure the expression levels of different cancer markers, which showed good agreement with profiling results by flow cytometry and fluorescence microscopy. This cost-effective, portable, flow-based holographic imaging system is applicable to detecting rare cancer cells in a large volume of blood samples for point-of-care applications.

9:12AM Y45.00007 A single-molecule view of gene regulation in cancer , DANIEL LARSON, National Cancer Institute / NIH — Single-cell analysis has revealed that transcription is dynamic and stochastic, but tools are lacking that can determine the mechanism operating at a single gene. Here we utilize single-molecule observations of RNA in fixed and living cells to develop a single-cell model of steroid-receptor mediated gene activation. Steroid receptors coordinate a diverse range of responses in higher eukaryotes and are involved in a wide range of human diseases, including cancer. Steroid receptor response elements are present throughout the human genome and modulate chromatin remodeling and transcription in both a local and long-range fashion. As such, steroid receptor-mediated transcription is a paradigm of genetic control in the metazoan nucleus. Moreover, the ligand-dependent nature of these transcription factors makes them appealing targets for therapeutic intervention, necessitating a quantitative understanding of how receptors control output from target genes. We determine that steroids drive mRNA synthesis by frequency modulation of transcription. This digital behavior in single cells gives rise to the well-known analog dose response across the population. To test this model, we developed a light-activation technology to turn on a single gene and follow dynamic synthesis of RNA from the activated locus. The response delay is a measure of time required for chromatin remodeling at a single gene.

9:48AM Y45.00008 Non-covalent interactions of the carcinogen (+)-anti-BPDE with exon 1 of the human K-ras proto-oncogene , JORGE H. RODRIGUEZ, CHRISTOS DELIGKARIS[1], Department of Physics, Purdue University — Investigating the complementary, but different, effects of physical (non-covalent) and chemical (covalent) mutagen-DNA and carcinogen-DNA interactions is important for understanding possible mechanisms of development and prevention of mutagenesis and carcinogenesis. A highly mutagenic and carcinogenic metabolite of the polycyclic aromatic hydrocarbon benzo[α]pyrene, namely (+)-anti-BPDE, is known to undergo both physical and chemical complexation with DNA. The major covalent adduct, a promutagenic, is known to be an external (+)-trans-anti-BPDE-N^2-dGuanosine configuration whose origins are not fully understood. Thus, it is desirable to study the mechanisms of external non-covalent BPDE-DNA binding and their possible relationships to external covalent trans adduct formation. We present a detailed codon-by-codon computational study of the non-covalent interactions of (+)-anti-BPDE with DNA which explains and correctly predicts preferential (+)-anti-BPDE binding at minor groove guanosines. Due to its relevance to carcinogenesis, the interaction of (+)-anti-BPDE with exon 1 of the human K-ras gene has been studied in detail.

[1]Present address: Department of Physics, Drury University

10:00AM Y45.00009 The Causality of Evolution on Different Fitness Landscapes[1] , SAURABH VYAWAHARE, ROBERT AUSTIN, Princeton University, QIUCEN ZHANG, University of Illinois CU, HYUNSUNG KIM, University California Santa Cruz, JOHN BESTOSO, Princeton University — Evolution of antibiotic resistance is a growing problem. One major reason why most antibiotics fail is because of mutations on drug targets (e.g. essential enzymes). Sequencing of clinically resistant isolates have shown that multiple mutational-hotspots exist in coding regions, which could potentially prohibit the binding of drugs. However, it is not clear whether the appearance of each mutation is random or influenced by other factors. In this paper, we compare evolution of resistance to ciprofloxacin from two distinct but well characterized genetic backgrounds. By combining our recently developed evolution reactor and deep whole-genome sequencing, we show different alleles of σ_s factor lead to fixation of different mutations in *gyrA* gene that confer ciprofloxacin resistance to bacteria *Escherichia coli*. Such causality of evolution in different genes provides an opportunity to control the evolution of antibiotic resistance.

10:12AM Y45.00010 Evolution of radiation resistance in a complex microenvironment[1] , SO HYUN KIM, Ehwa Womans University, ROBERT AUSTIN, Princeton University, MONAL MEHTA, ATIF KAHN, Cancer Institute of New Jersey — Radiation treatment responses in brain cancers are typically associated with short progression-free intervals in highly lethal malignancies such as glioblastomas. Even as patients routinely progress through second and third line salvage therapies, which are usually empirically selected, surprisingly little information exists on how cancer cells evolve resistance. We will present experimental results showing how in the presence of complex radiation gradients evolution of resistance to radiation occurs.

10:24AM Y45.00011 Modeling growth and dissemination of lymphoma in a co-evolving lymph node: a diffuse-domain approach[1] , YAO-LI CHUANG, VITTORIO CRISTINI, University of New Mexico, Dept. Pathology, YING CHEN, XIANGRONG LI, University of California, Irvine, Dept. Math, HERMANN FRIEBOES, University of Louisville, Dept. Bioengineering, JOHN LOWENGRUB, University of California, Irvine, Dept. Math — While partial differential equation models of tumor growth have successfully described various spatiotemporal phenomena observed for in-vitro tumor spheroid experiments, one challenge towards taking these models to further study in-vivo tumors is that instead of relatively static tissue culture with regular boundary conditions, in-vivo tumors are often confined in organ tissues that co-evolve with the tumor growth. Here we adopt a recently developed diffuse-domain method to account for the co-evolving domain boundaries, adapting our previous in-vitro tumor model for the development of lymphoma encapsulated in a lymph node, which may swell or shrink due to proliferation and dissemination of lymphoma cells and treatment by chemotherapy. We use the model to study the induced spatial heterogeneity, which may arise as an emerging phenomenon in experimental observations and model analysis. Spatial heterogeneity is believed to lead to tumor infiltration patterns and reduce the efficacy of chemotherapy, leaving residuals that cause cancer relapse after the treatment. Understanding the spatiotemporal evolution of in-vivo tumors can be an essential step towards more effective strategies of curing cancer.

10:36AM Y45.00012 Computational studies on DNA recognition of novel organic and copper anti-tumor compounds , RAFAEL R. NASCIMENTO, MARCOS B. GONÇALVES, HELENA M. PETRILLI, Instituto de Física, Universidade de São Paulo, Brazil, ANA M. D.C. FERREIRA, Instituto de Química, Universidade de São Paulo, Brazil, EMILIANO IPPOLITI, JENS DREYER, PAOLO CARLONI, German Research School for Simulation Sciences, Forschungszentrum Juelich, Germany — The ability of many organic and coordination compounds to bind to DNA and/or damage cellular structures has been largely exploited in anticancer research. Identifying DNA recognition mechanisms have thus important impact on the chemical biology of gene expression and the development of new drugs and therapies. Previous studies on copper(II) complexes with oxindole-Schiff base ligands have shown their potential anti-tumor activity towards different cells, inducing apoptosis through a preferential attack to DNA and/or mitochondria [SIL11]. The binding mechanism of the organic and copper(II) complexes [Cu(isaepy)2]2+ (1) and [Cu(isaenim)]2+ (2) and their modulation at DNA is investigated through theoretical studies. Here we adopted a multi-scale procedure to simulate this large system using molecular docking and classical molecular dynamics. Hybrid Car-Parrinello/Molecular Mechanics calculations were applied to parameterize the copper(II) complexes by using the force matching approach. Free energies of binding are investigated by metadynamics enhanced sampling methods[VAR08]. [SIL11] V. C. da Silveira et. al. JIB 105 (2011) 1692.[VAR08] A. V. Vargiu et. al. Nucl. Acids Res. 36 (2008) 5910.

10:48AM Y45.00013 The positioning logic and copy number control of genes in bacteria under stress[1] , QIUCEN ZHANG, University of Illinois UC, ROBERT AUSTIN, SAURABH VYAWAHARE, Princeton University, ALEXANDRA LAU, Mount Holyoke College — *Escherichia coli* (*E. coli*) cells when challenged with sublethal concentrations of the genotoxic antibiotic ciprofloxacin cease to divide and form long filaments which contain multiple bacterial chromosomes. These filaments are individual mesoscopic environmental niches which provide protection for a community of chromosomes (as opposed to cells) under mutagenic stress and can provide an evolutionary fitness advantage within the niche. We use comparative genomic hybridization to show that the mesoscopic niche evolves within 20 minutes of ciprofloxacin exposure via replication of multiple copies of genes expressing ATP dependent transporters. We show that this rapid genomic amplification is done in a time efficient manner via placement of the genes encoding the pumps near the origin of replication on the bacterial chromosome. The de-amplification of multiple copies back to the wild type number is a function of the duration is a function of the ciprofloxacin exposure duration: the longer the exposure, the slower the removal of the multiple copies.

Session Y46 DBIO DPOLY: Focus Session: Physics of Proteins III Hilton Baltimore Holiday Ballroom 5 - Corey O'Hern, Yale University

8:00AM Y46.00001 Copper Chelation in Alzheimer's Disease Protein , FRISCO ROSE, MIROSLAV HODAK, JERRY BERNHOLC, NCSU - CHiPS — Alzheimer's disease (AD) is a neurodegenerative disorder affecting millions of people in the U.S. AD is primarily characterized at the cellular level by densely tangled fibrils of amyloid-β protein. These protein clusters have been found in association with elevated levels of multiple transition metals, with copper being the most egregious. Interestingly, metal chelation has shown promise in attenuating the symptoms of AD in recent clinical studies. We investigate this process by constructing an atomistic model of the amyloid-β-copper complex and profile the energetic viability in each of its subsequent disassociation stages. Our results indicate that five energetic barriers must be overcome for full metal chelation. The energy barriers are biologically viable in the presence water mediated bond and proton transfer between the metal and the protein. We model the chelation reaction using a consecutive path nudged elastic band method implemented in our *ab initio* real-space multi-grid code to obtain a viable sequence. This reaction model details a physically consistent explanation of the chelation process that could lead to the discovery of more effective chelation agents in the treatment of AD.

8:12AM Y46.00002 Low resolution structures of cold, warm, and chemically denatured cytochrome-c via SAXS , CHRISTOPHER ASTA, ANTHONY BANKS, MARGARET ELMER, TREVOR GRANDPRE, ERIC LANDAHL[1], DePaul University — The results of a small-angle x-ray scattering (SAXS) study of equine cytochrome-c protein under different unfolding conditions are discussed. Although the measured radius of gyration of this protein over a wide range of temperatures and GuHCl concentrations conform to a two-state model, we find different levels of residual structure present depending on whether the protein is cold- or warm- denatured. We present DAMMIF reconstructions of these different unfolded states using 1532 dummy atoms with a 1.5 Angstrom radius, and suggest ways that these different states may be described by the same folding free energy.

8:24AM Y46.00003 Structural dynamics of membrane proteins - time-resolved and surface-enhanced IR spectroscopy , JOACHIM HEBERLE, Freie Universitaet Berlin, Exp. Molecular Biophysics, Arnimallee 14, 14195 Berlin — Membrane proteins are the target of more than 50% of all drugs and are encoded by about 30% of the human genome. Electrophysiological techniques, like patch-clamp, unravelled many functional aspects of membrane proteins but suffer from structural sensitivity. We have developed Surface Enhanced Infrared Difference Absorption Spectroscopy (SEIDAS) to probe potential-induced structural changes of a protein on the level of a monolayer. A novel concept is introduced to incorporate membrane proteins into solid supported lipid bilayers in an orientated manner via the affinity of the His-tag to the Ni-NTA terminated gold surface. General applicability of the methodological approach is shown by tethering photosystem II to the gold surface. In conjunction with hydrogenase, the basis is set towards a biomimetic system for hydrogen production. Recently, we succeeded to record IR difference spectra of a monolayer of sensory rhodopsin II under voltage-clamp conditions. This approach opens an avenue towards mechanistic studies of voltage-gated ion channels with unprecedented structural and temporal sensitivity. Initial vibrational studies on the novel light-gated channelrhodopsin-2 (ChR2) will be presented. ChR2 represents a versatile tool in the new field of optogenetics where physiological reactions are controlled by light.

9:00AM Y46.00004 Multistage Enzymatic Pathways of the Copper-containing Nitrite Reductase (CuNiR) , YAN LI, MIROSLAV HODAK, JERRY BERNHOLC, North Carolina State University, CENTER OF HIGH PERFORMANCE SIMULATION TEAM — Copper-containing nitrite reductase (CuNiR) catalyzes the reduction of NO_2^- to NO in the global nitrogen cycle. Experimental X-ray data have provided good insight into the overall function of CuNiR. However, many important questions, such as the relevance of the conformational change of Asp^{98} as well as the transformation from the O-coordination of the substrate to the N-coordination of the product remain unanswered. We present a computational study of the enzymatic mechanism of CuNiR based on density functional theory. The climbing-image nudged elastic band (CI-NEB) method is used to find the minimum energy pathways and the activation energy barriers of the reaction. Furthermore, the effects of hybrid functionals and solvent on the activation barriers are investigated. A critical residue Asp^{98} is found to control the access to the binding site and to stabilize a previously reported "side-on" coordination of the nitrosyl intermediate, although this geometry does not occur during the reaction. We also find that the transformation of the O- to N-attachment is achieved by an electron transfer from Type I copper.

9:12AM Y46.00005 Single molecule processivity and dynamics of cAMP-dependent protein kinase (PKA) , PATRICK C. SIMS, YONGKI CHOI, CHENGJUN DONG, Department of Physics and Astronomy, University of California, Irvine, ISSA S. MOODY, Department of Molecular Biology and Biochemistry, University of California, Irvine, MARIAM IFTIKHAR, Department of Chemistry, University of California, Irvine, O. TOLGA GUL, Department of Physics and Astronomy, University of California, Irvine, GREGORY A. WEISS, Departments of Molecular Biology and Biochemistry, and Chemistry, University of California, Irvine, PHILIP G. COLLINS, Department of Physics and Astronomy, University of California, Irvine — Using single-walled carbon nanotube (SWNT) transistors, we monitored the processivity and dynamics of single molecules of cAMP-dependent protein kinase (PKA). As PKA enzymatically phosphorylates its peptide substrate, it generates an electronic signal in the transistor that can be monitored continuously and with 20 μs resolution. The electronic recording directly resolves substrate binding, ATP binding, and cooperative formation of PKA's catalytically functional, ternary complex. Statistical analysis of many events determines on- and off-rates for each of these events, as well as the full transistion probability matrix between them. Long duration monitoring further revealed minute-to-minute rate variability for a single molecule, and different mechanistic statistics for ATP binding than for substrate. The results depict a highly dynamic enzyme offering dramatic possibilities for regulated activity, an attribute that is useful for an enzyme that plays crucial roles in cell signaling.

9:24AM Y46.00006 The ribosome as an optimal decoder: a lesson in molecular recognition , TSVI TLUSTY, Institute for Advanced Study, Princeton, YONATAN SAVIR, Harvard Medical School, Systems Biology — The ribosome is a complex molecular machine that, in order to synthesize proteins, has to decode mRNAs by pairing their codons with matching tRNAs. Decoding is a major determinant of fitness and requires accurate and fast selection of correct tRNAs among many similar competitors. However, it is unclear whether the present ribosome, and in particular its large deformations during decoding, are the outcome of adaptation to its task as a decoder or the result of other constraints. Here, we derive the energy landscape that provides optimal discrimination between competing substrates, and thereby optimal tRNA decoding. We show that the measured landscape of the prokaryotic ribosome is indeed sculpted in this way. This suggests that conformational changes of the ribosome and tRNA during decoding are means to obtain an optimal decoder. Our analysis puts forward a generic mechanism that may be utilized by other ribosomes and other molecular recognition systems.

9:36AM Y46.00007 A Bayesian Statistical Approach for Improving Scoring Functions for Protein-Ligand Interactions , SAM Z GRINTER, XIAOQIN ZOU, University of Missouri — Even with large training sets, knowledge-based scoring functions face the inevitable problem of sparse data. In this work, we present a novel approach for handing the sparse data problem, which is based on estimating the inaccuracy caused by sparse count data in a potential of mean force (PMF). Our new scoring function, STScore, uses a consensus approach to combine a PMF with a simple force-field-based potential (FFP), where the relative weight given to the PMF and FFP is a function of their estimated inaccuracies. This weighting scheme implies that less weight will be given to the PMF for any pairs or distances that occur rarely in the training data, thus providing a natural way to deal with the sparse data problem. Simultaneously, by providing the FFP as a substitute, the method provides an improved approximation of the interactions between rare chemical groups, which tend to be excluded or reduced in influence by purely PMF-based approaches. Using several common test sets for protein-ligand interaction studies, we demonstrate that this sparse data method effectively combines the PMF and FFP, exceeding the performance of either potential alone, and is competitive with other commonly-used sparse data methods.

9:48AM Y46.00008 Refinement and Selection of Near-native Protein Structures[1] , JIONG ZHANG, Department of Physics and Astronomy, University of Missouri-Columbia, JINGFEN ZHANG, YI SHANG, DONG XU, Department of Computer Science , University of Missouri-Columbia, IOAN KOSZTIN, Department of Physics and Astronomy, University of Missouri-Columbia — In recent years *in silico* protein structure prediction reached a level where a variety of servers can generate large pools of near-native structures. However, the identification and further refinement of the best structures from the pool of decoys continue to be problematic. To address these issues, we have developed a selective refinement protocol (based on the Rosetta software package), and a molecular dynamics (MD) simulation based ranking method (MDR). The refinement of the selected structures is done by employing Rosetta's relax mode, subject to certain constraints. The selection of the final best models is done with MDR by testing their relative stability against gradual heating during all atom MD simulations. We have implemented the selective refinement protocol and the MDR method in our fully automated server Mufold-MD. Assessments of the performance of the Mufold-MD server in the CASP10 competition and other tests will be presented.

10:00AM Y46.00009 ABSTRACT HAS BEEN MOVED TO H1.00345 –

10:12AM Y46.00010 Diffusion and internal dynamics of proteins in crowded solutions , FELIX ROOSEN-RUNGE, Institute for Applied Physics, University of Tuebingen, Germany, MARCUS HENNIG, Institute for Applied Physics, University of Tuebingen, Germany; Institute Laue-Langevin, Grenoble, France, TILO SEYDEL, Institute Laue-Langevin, Grenoble, France, FAJUN ZHANG, FRANK SCHREIBER, Institute for Applied Physics, University of Tuebingen, Germany — Protein function is determined through the interplay of structure, dynamics and the aqueous, but crowded cellular environment. We present a comprehensive study accessing the full hierarchy of protein dynamics in solutions, e.g. vibrations, interdomain motions and diffusion of the entire protein. Quasi-elastic neutron and dynamic light scattering experiments are performed and compared to theoretical predictions. In crowded solutions, both self diffusion D_s and collective diffusion D_c of protein solutions are well described by colloidal concepts, with D_s reduced to 20% at $\approx 20\%$ volume fraction [1,2]. Separating the motion of the entire protein molecule, the internal motions are accessed under native conditions [3]. We studied the dynamics before, during and after thermal denaturation, supporting the notion of protein unfolding with subsequent chain entanglement. While long-range motions are *reduced* in the denatured state, the local flexibility of side chains is found to be *enhanced*. The frameworks enable further experimental access to the relation of protein function and dynamics at fast time scales. [1] F. Roosen-Runge et al., PNAS 108 (2011) 11815; [2] M. Heinen et al., Soft Matter 8 (2012) 1404; [3] M. Hennig et al., Soft Matter 8 (2012) 1628

10:24AM Y46.00011 Diffusion of molecular oxygen in the red fluorescent protein mCherry[1] , CHOLA REGMI, YUBA BHANDARI, BERNARD GERSTMAN, PREM CHAPAGAIN, Florida International University — The monomeric variants of red fluorescent proteins (RFPs), known as mFruits, have been especially valuable for tagging and tracking cellular processes *in vivo*. Determining the oxygen diffusion pathways in FPs can be important for improving photostability and for understanding maturation of the chromophore. We use molecular dynamics (MD) calculations to investigate the diffusion of molecular oxygen in one of the most useful monomeric RFPs, mCherry. We investigate a pathway that allows oxygen molecules to enter from the solvent and travel through the protein barrel to the chromophore. The pathway contains several oxygen hosting pockets, which are identified by the amino acid residues that form the pocket. The results provide a better understanding of the mechanism of molecular oxygen access into the fully folded mCherry protein barrel and provide insight into the one of the photobleaching processes in this protein.

10:36AM Y46.00012 New insights into the picosecond dynamics solvated proteins , NGUYEN VINH, Department of Physics, Virginia Tech, JIM ALLEN, Institute for Terahertz Science and Technology, Department of Physics, University of California, Santa Barbara, KEVIN PLAXCO, Department of Chemistry and Biochemistry, University of California, Santa Barbara — According to computer simulations, the slowest, largest-scale harmonic motions of solvated biomolecules and the relaxation times of water occur on the picosecond regime. Experimental methods for the characterization of these collective vibrational modes, however, have been severely lacking. In response, we have developed a unique precision and sensitivity dielectric spectrometer. Operating over the frequency range from 0.5 GHz up to 1.1 THz, this spectrometer provides an unparalleled ability to probe the dynamics of water and aqueous proteins over the 100 fs to 100 ps timescale. Using this spectrometer to characterize the collective dynamics of solvated lysozyme we find that the collective vibrational modes of this protein are characterized by a hitherto unrecognized cutoff at 250 GHz (corresponding to 0.6 ps) arising due to the finite size of the molecule. Employing an effective medium approximation to describe the complex dielectric response of the protein in solution we find that each molecule is surrounded by a tightly held layer of 164 ± 5 water molecules that behave as if they are an integral part of the protein. The observation sheds new light on the femtosecond to picosecond collective dynamics of water and solvated biomolecules.

Session Y47 DFD GSNP: Invited Session: Controlling and Exploiting Topological Defects in Liquid Crystals Hilton Baltimore Holiday Ballroom 6 - Kathleen Stebe, University of Pennsylvania

8:00AM Y47.00001 Colloid-in-liquid crystal gels , NICHOLAS ABBOTT, University of Wisconsin-Madison — This presentation will describe investigations of the collective properties of colloidal particles that are dispersed in liquid crystalline solvents. A focus will be directed to recent observations of the gelation of particles dispersed in thermotropic liquid crystals. While a series of studies over the past decade have revealed two distinct mechanisms leading to gelation of particles in liquid crystalline solvents, our recent observations are inconsistent with both and hint at a third mechanism of gelation. These observations will be described along with examples of how the unique mechanical and optical properties of colloid-in-liquid crystal gels enable the design of biotic-abiotic interfaces.

8:36AM Y47.00002 TopologicallyRequired Defects in Nematic Liquid Films over Microposts or in contact with Anisotropic Particles , MOHAMED AMINE GHARBI, Department of Physics and Astronomy. University of Pennsylvania — In this work we present an experimental investigation of topological defects in nematic liquid crystals formed over micropost array with a LC-air interface pinning to the pillar edges or containing washer-shaped microparticles in suspension. For nematic-LC covered microposts with homeotropic anchoring conditions on all boundaries, including the LC-air and LC-substrate interfaces, disclination lines form that bear the signature of the micropost and satisfy global topological constraints of the system. When washer particles with different anchoring conditions are dispersed in homeotropic liquid crystal cells, new topological configurations are observed. In each case, defects are described from both a geometric and topological perspective. Finally, we demonstrate that topological defects created by microposts and washers can generate elastic interactions with dispersed microparticles in nematic liquid crystals. We believe this is a promising route to controlling colloidal self-assembly in complex media.

9:12AM Y47.00003 Control of periodic, quasicrystalline, and arbitrary arrays of liquid crystal defects stabilized by topological colloids and chirality[1] , IVAN SMALYUKH, University of Colorado Boulder — Condensed matter systems with ground-state arrays of defects range from the Abrikosov phases in superconductors, to various blue phases and twist grain boundary phases in liquid crystals, and to skyrmion lattices in chiral ferromagnets. In nematic and chiral nematic liquid crystals, which are true fluids with long-range orientational ordering of constituent anisotropic molecules, point and line defects spontaneously occur as a result of symmetry-breaking phase transitions or due to flow, but they typically annihilate with time and cannot be controlled. This lecture will discuss physical underpinnings of optically patterned and self-assembled two-dimensional arrays of long-term stable point defects and disclination loops bound together by elastic energy-minimizing twisted director structures and/or stabilized by colloids. The topological charge conservation and the interplay of topologies of genus g$>$ 1 particles, fields, and defects provide robust means for controlling three-dimensional textures with arrays of optically- and electrically-reconfigurable defects. In the periodic lattices of defects, we introduce various dislocations (i.e., defects in positional ordering of defects) and use them to generate optical vortices in diffracted laser beams. The lecture will conclude with a discussion of how these findings bridge the studies of defects in condensed matter physics and optics and may enable applications in data storage, singular optics, displays, electro-optic devices, and diffraction gratings.

9:48AM Y47.00004 Nanoparticles at fluid interfaces: how capping ligands control adsorption, stability and dynamics , VALERIA GARBIN, Imperial College London — The spontaneous assembly of nanoparticles at fluid-fluid interfaces is exploited in microfluidic encapsulation, fabrication of nanomaterials, oil recovery, and catalysis. Control over the microstructure formed by interfacial nanoparticles is an important goal in these contexts: the ability to *reversibly* tune the packing fraction enables for nanomaterials with tunable properties, while control over nanoparticle removal and recycling is desirable for green processes. I will discuss how capping ligands can promote interfacial self-assembly by tuning the interfacial energies of the nanoparticles with the fluids. Ligand-mediated particle interactions at the interface then affect the formation of equilibrium and non-equilibrium two-dimensional phases. Important differences with colloidal interactions in a bulk suspension arise due to the discontinuity in solvent properties at the interface, which cause the ligand brushes to rearrange in asymmetric configurations. I will present experimental results for gold nanoparticles capped with short amphiphilic ligands, which spontaneously adsorb at an oil-water interface. Using pendant drop tensiometry, we measured the surface pressure of the nanoparticle monolayer during adsorption and subsequent compression. In contrast to the commonly observed buckling of solid-like films of interfacial particles, upon compression these nanoparticles are mechanically forced out of the interface and into suspension. Area density measurements by a newly developed optical method reveal that ligand-mediated short-range interparticle repulsion enables desorption upon compression. Brownian dynamics simulations corroborate this picture. Therefore, ligand-mediated interactions also determine the fate of nanoparticle monolayers upon out-of-plane deformation.

10:24AM Y47.00005 Resolving Defect Formation and Dynamics of the Smectic-A Mesophase[1] , NASSER MOHIEDDIN ABUKHDEIR, University of Waterloo — The formation and interaction of defects in liquid crystalline (LC) phases are fascinating both from a fundamental and applied perspective. Smectic LC phases, which have both orientational and translational order, exhibit relatively complex defect structures [1] and dynamics compared to lower order nematics (possessing only orientational order). A simple example of this complexity is that smectic disclination dynamics differ from those of nematics due to additional topological constraints imposed by the presence of translational order. A far less simple example is the presence of focal conic defect domains [1] that arise due to smectic elasticity favouring layer curvature over compression/dilation. Direct experimental observation of defect formation and dynamics of the smectic-A mesophase is challenging due to them occurring on the nano-scale. Theoretical approaches have had substantial success, particularly extensions of the tensorial Landau-de Gennes free energy for nematics [2] to smectic order [3]. Modelling dynamics via the time-dependent Landau-Ginzburg equation [4] has been shown to resolve topologically consistent smectic dynamics which agree with experimentally determined phase transition kinetics [5]. This talk will present an overview of recent research in this area, including the effects of an external field. The results of this research support the use of a relatively complex model of smectic dynamics. Specifically, it is shown that couplings between both short- and long-range orientational/translational order play an important role in smectic defect formation and interaction.

Session Z1 DCMP GIMS: Invited Session: Time- and Angle- Resolved Photoemission Spectroscopy of Complex Materials Ballroom I - Thomas Devereaux, SLAC National Acceleratory Laboratory

11:15AM Z1.00001 Ultrafast Optical Excitation of a Persistent Surface-State Population in the Topological Insulator Bi_2Se_3

, JONATHAN SOBOTA, Stanford University — Bi_2Se_3 is a material which has gained great attention since it was recognized to be a topological insulator. Due to their topologically-protected spin-textured Dirac surface states, topological insulators have been recognized for their potential in device applications, particularly for spintronics. Thus, much of the experimental focus has been on ways to electronically or optically couple to the surface spin-texture. Using time- and angle- resolved photoemission spectroscopy (TR-ARPES), we optically excite p-type Bi_2Se_3 and study the dynamical response of its electronic structure on a femtosecond timescale. The strength of this technique is that its energy- and angle- resolution allows us to study these dynamics directly within the electronic band structure, so that surface and bulk contributions can be separately resolved. We find that optical excitation produces a metastable population of bulk carriers due to the presence of the bandgap. We discuss the coupling of these carriers to the Dirac surface state, which results in a long-lived nonequilibrium surface carrier distribution. This spin-textured population may present a channel in which to drive transient spin-polarized currents.

11:51AM Z1.00002 Ultrafast momentum-dependent quasiparticle dynamics in high-T_c superconductors[1]

, UWE BOVENSIEPEN, University Duisburg-Essen — Femtosecond time- and angle-resolved photoelectron spectroscopy trARPES facilitates insight into electronic relaxation and electronic structure of non-equilibrium states of matter [1]. Hot electrons and holes relax in metals on ultrafast time scales due to the screened Coulomb interaction [2]. In superconductors the relaxation rates of quasiparticles at energies close to the superconducting gap edge are reduced because of the loss of quasiparticle states near E_F. Since in the superconducting state the relaxation of optically excited carriers proceeds partly by Cooper pair reformation, the study of the quasiparticle dynamics bears the potential to analyze the interaction responsible for Cooper pair formation. Results of trARPES will be discussed for optimally doped $Bi_2Sr_2CaCu_2O_{8+\delta}$ in the superconducting state [2] and on $EuFe_2As_2$ in the antiferromagnetic state [3]. In the cuprate system we find a predominant excitation of quasiparticles at momenta near the antinode. We show furthermore, that at excitation densities of several 10 $\mu J/cm^2$ quasiparticle relaxation is dominated by Cooper pair reformation, which again proceeds near the antinode. In the Fe-pnictide material we monitor a difference in the relaxation rate for electrons and holes near the Fermi momentum, which disappears above the Neel temperature. We conclude that this anisotropic relaxation of electrons and holes is a consequence of the optical modification of the antiferromagnetic order. Analysis of energy transfer from electrons to phonons allows to determine the momentum averaged electron-phonon coupling constant λ. We find values below 0.25 for $Bi_2Sr_2CaCu_2O_{8+\delta}$ [5] and below 0.15 for $EuFe_2As_2$ [4].

12:27PM Z1.00003 Measurement of intrinsic Dirac fermion cooling of a topological insulator with time- and angle- resolved photoemission spectroscopy

, YIHUA WANG, MIT — Three-dimensional topological insulator (TI) is a new phase of matter with exotic surface electronic properties. Even though the bulk states have a bandgap, the surface electrons possess a linear energy-momentum dispersion that is protected by the nontrivial topology of TI to cross the Fermi level. These properties provide a promising platform for new physics and applications in future electronics and computers including high-speed quantum information processing, whose performance depends critically on the dynamics of hot carriers. Unlike the case in graphene, helical Dirac fermions in a TI interact not only with phonons but also with an underlying bulk reservoir of electrons. In this talk, we will present our recent results of time- and angle-resolved photoemission spectroscopy (TrARPES) study of a prototypical TI Bi2Se3. We show that TrARPES is a powerful tool to distinguish the coupled dynamics between these different degrees of freedom. With the combined sub-picosecond time resolution and energy-momentum resolution, we have directly visualized the coupling between surface and bulk electrons through phonons. At low temperature, such coupling is suppressed and the unique cooling of surface Dirac fermions by acoustic phonons is revealed through the power law cooling rate dependence on doping level. The effect on the TrARPES spectra from varying excitation photon energy will also be discussed.

1:03PM Z1.00004 Time-resolved ARPES and f-electron coherence[1]

, TOMASZ DURAKIEWICZ, Los Alamos National Laboratory, MPA-CMMS Group, Los Alamos, NM 87544, USA — The coherence temperature, T*, sets an important energy scale in correlated f-electron systems. In this scale the hybridization gap opens at or in the vicinity of the Fermi level and the gap magnitude scales with effective quasiparticle mass. The new quasiparticle bands are heavy, as demonstrated by their small dispersion, and the quasiparticle lifetime is long, as seen by the narrow width of the peaks. Unless magnetic ordering suppresses the gap or mass enhancement is observed due to, e.g., magnetic excitations, the gap scales with effective mass in a universal manner across the heavy fermion systems. Possible deviations from this pattern, e.g. a small finite gap persisting at high temperatures above T* require models beyond a mean-field approach, and may be understood within e.g. the model of periodic array of Anderson impurities with correlations described by coupling to specific boson modes.
Self-energy approach is commonly used in ARPES of correlated systems. The coherent part of the self-energy corresponding to the gap formation is reduced at high temperatures, and the incoherent part corresponds to quasiparticle scattering. The coherent term in the self-energy expresses the mixing of f and d bands and is directly responsible for repulsion, producing the hybridization gap. This theoretical framework provides a direction towards understanding quasiparticle dynamics in correlated electron systems through ultrafast self-energy measurements and modeling. Here we show examples of time-resolved ARPES measurements of f-electron systems, providing valuable information about the evolution of coherence and the dynamics of the related quasiparticle states.

1:39PM Z1.00005 Ultrafast quasiparticle dynamics and pair recombination in cuprate high-temperature superconductors , CHRIS JOZWIAK, Lawrence Berkeley National Lab — Understanding how superconductivity emerges from other competing phases and how this balance evolves through the phase diagram is one of the biggest challenges in the field of high-$T_{\rm C}$ superconductors. By using high resolution time- and angle-resolved photoemission spectroscopy (tr-ARPES) we are able to directly probe the effects of optical excitation on the electronic structure of cuprate superconductors, and study the resulting quasiparticle, superconducting gap, and Cooper pair formation dynamics near their natural time scales. In particular, we observed a pump-induced meltdown of quasiparticles, which occurs only within the energy scale defined by a particular boson mode. This meltdown was observed only below $T_{\rm C}$, suggesting a link between superconductivity and quasiparticles in momentum space where the superconducting gap is zero. We observed that the excited quasiparticle decay dynamics were strongly pump-fluence dependent and consistent with the picture that the observed dynamics reflect actual Cooper pair formation. Further, these quasiparticle recombination dynamics were strongly momentum dependent, increasing away from the superconducting nodes. Direct measurements of momentum dependent superconducting gap dynamics and the evolution of other non-equilibrium spectral phenomena through the phase diagram further illustrate the power of this unique time- and momentum-resolved spectroscopy. These results reveal new windows into the nature of the pairing interaction in high-$T_{\rm C}$ superconductors.

Friday, March 22, 2013 11:15AM - 2:15PM –

Session Z2 DCMP GSNP: Invited Session: Jamming and Rheology of Disordered Systems

Ballroom II - Bulbul Chakraborty, Brandeis University

11:15AM Z2.00001 Impact-activated solidification of dense suspensions , SCOTT WAITUKAITIS, The James Franck Institute at The University of Chicago — Shear-thickening, non-Newtonian fluids have typically been investigated under steady-state conditions. This approach has produced two pictures for suspension response to imposed forcing. In the weak shear-thickening picture, the response is typically attributed to the hydrodynamic interactions giving rise to hydroclusters, small groups of particles interacting through lubrication forces. At the other end of the spectrum, in the discontinuous shear-thickening regime, the response can be seen as a system-wide jamming that is ultimately limited in strength by the system boundaries. While these steady-state pictures have proven extremely useful, some of the most interesting phenomena associated with dense suspensions is transient and local in character. A prototypical example is the extraordinarily large impact resistance of dense suspensions such as cornstarch and water. When poked lightly these materials respond like a fluid, but when punched or kicked they seem to temporarily "solidify" and provide enormous resistance to the motion of the impacting object. Using an array of experimental techniques, including high-speed video, embedded force and acceleration sensing, and x-ray imaging, we are able to investigate the dynamic details this process as it unfolds. We find that an impacting object drives the rapid growth of a jammed, solid-like region directly below the impact site. Being coupled to the surrounding fluid by grain-mediated lubrication forces, this creates substantial peripheral flow and ultimately leads to the sudden extraction of the impactor's momentum. With a simple jamming picture to describe the solidification and an added mass model to explain the force on the rod, we are able to predict the forces on the impactor quantitatively. These findings highlight the importance of the non-equilibrium character of dense suspensions near jamming and might serve as a bridge between the weak and discontinuous shear-thickening pictures.

11:51AM Z2.00002 Dilatancy and shear thickening of particle suspensions , DANIEL BONN, Institute of Physics, University of Amsterdam — Shear thickening is a fascinating subject, as 99.9% of complex fluids are thinning; thickening systems thus are the "exception to the rule" that needs to be understood. Moreover, such tunable systems show very promising applications, e.g. to block large underground pores in oil recovery to maintain a constant oil flow by plugging water filled pores (an approach used in oil recovery by e.g. Shell), or to manufacture bulletproof vests that are comfortable to wear, but stop bullets nonetheless. We study the rheology of non-Brownian particle suspensions (notably, cornstarch) that exhibit shear thickening. Using magnetic resonance imaging (MRI), the local properties of the flow are obtained by the determination of local velocity profiles and concentrations in a Couette cell. We also perform macroscopic rheology experiments in different geometries. The results suggest that the shear thickening is a consequence of dilatancy: the system under flow attempts to dilate but instead undergoes a jamming transition, because it is confined. This proposition is confirmed by an independent measurement of the dilation of the suspension as a function of the shear rate.

12:27PM Z2.00003 Simulations of shear-induced jamming in athermal particulate systems[1] , COREY O'HERN, Yale University — We perform simulations of athermal particulate systems that are prepared in unjammed states with zero static shear modulus and then subjected to successive pure or simple quasistatic shear strains at either fixed packing fraction or fixed pressure. In response to applied shear, these systems jam, forming anisotropic networks of interparticle contacts. We determine the onset of shear-induced jamming as a function of the amplitude of the shear strain, packing fraction, pressure, and system size. We find that the parameter space for shear-induced jamming expands for particles with frictional interactions and nonspherical shapes.

[1]NSF DMR-1006537

1:03PM Z2.00004 Dilatancy and Diffusion in Sheared Granular Materials , JOSHUA DIJKSMAN, Duke University — Disordered materials such as sand, foams and emulsions display a wide variety of different forms of mechanical behavior. Currently the origin of this rich dynamics is the subject of intense study. Experimentally it has proved difficult to probe the microscopic dynamics in these systems. We present an overview of experimental investigations that have been successful in giving more insight into the microstructural dynamics of disordered systems. We focus on shear induced dilatancy and diffusion in quasi statically deformed granular materials and suspensions and contrast the behavior of low and high friction particulate materials. We shall discuss the consequences of our observations in the context of shear banding and jamming phenomena.

1:39PM Z2.00005 Rigidity of Dry Granular Solids , DAPENG BI, Syracuse University — Solids are distinguished from fluids by their ability to resist shear. In traditional solids, the resistance to shear come as an energy cost of straining, which works to distort density modulations that exists in both crystalline or amorphous structures. In our recent work,we focus on the emergence of shear-rigidity in a special class of solids: dry (non-cohesive) granular materials which have no energetically preferred density modulations. In contrast to traditional solids, the emergence of mechanical rigidity in these marginal granular solids is a collective process, which is controlled solely by boundary forces, the constraints of force and torque balance, and the positivity of the contact forces. We develop a theoretical framework based on these constraints, and show that these solids can be characterized by topological invariants and that, in two dimensions, they have internal patterns that are most naturally represented in the space of gauge field of the stress. Broken translational invariance in this gauge space is a necessary condition for rigidity in granular solids. We apply our theory to experimentally shear-jammed states as well as numerically generated jammed force networks to show that the statistics of stress fluctuations, and the ability of jammed configurations to resist deformations can be understood within this theoretical framework.

Session Z3 FEd: Invited Session: Integration of Research and Teaching Excellence: Cottrell Scholars

Ballroom III - Richard Wiener, Research Corporation

11:15AM Z3.00001 Cottrell Scholars Collaborative – Integrating Research and Teaching , JAIRO SINOVA, Texas A&M University — Higher education reform needs to move towards a more interactive and integrated model, in which there is greater curricular emphasis in skill development, multi-discipline integration, and innovative connectivity, rather than traditional content driven curricula. This is even more crucial in STEM education, given our current slow down relative to other countries and the need to remain competitive in a global environment. Successful reforms require a seamless integration of research and teaching where education excellence and research excellence are not viewed by faculty as a zero sum game but as mutually benefitting ingredients of academic success. Cottrell scholars are selected among top ranking young academics with an equal passionate commitment to research excellence and education. Recently, these national group of academics sponsored by the Research Corporation for Science Advancement have created the Cottrell Scholars Collaborative (CSC) which aims at creating a self-supporting group that promotes integration of research and teaching at a national level with different initiatives. I will describe in these talk the aim of this group and the different sponsored projects that CSC is undertaking and the types of collective and individual efforts that are making a difference in sustainable education reform.

11:51AM Z3.00002 Optics for Biophysics: An Interdisciplinary course in Optics for Physicists and Life Science Students , JENNIFER ROSS, University of Massachusetts Amherst — Optics is an applied sub-field of physics that life science researchers utilize daily. Indeed, one cannot open a biological science research journal without seeing five beautiful images of cells. To bridge the gap and educate more life science students in the field of physics, I have developed a new course called "Optics for Biophysics," an interdisciplinary course engaging students from physics, chemistry, life science, and engineering. The course is a team-based learning or studio physics approach combined with a semester-long project. Mini-lectures of 20 minutes are given before students do hands-on group work to understand the concepts. In the project, the students design and build a modern transmitted light microscope. The final aspect of the project is to build a unique module onto the microscope to address a specific biological question.

12:27PM Z3.00003 Stimulating Creativity by Integrating Research and Teaching Across the Academic Disciplines , RICHARD TAYLOR, University of Oregon — Creativity is a human adventure fueled by the process of exploration. But how do we explore our intellectual interests? In this talk, I'll propose that we seek out our creative opportunities using an inherent natural process. This process might, therefore, exploit search strategies found across diverse natural systems – ranging from the way animals forage for food to the way the human eye locates information embedded within complex patterns. The symbolic significance of this hypothesis lies in its call for educational institutes to provide environments that encourage our natural explorations rather those that stamp restrictive, artificial 'order' on the process. To make my case, I'll review some of my own research trajectories followed during my RCSA Cottrell Scholarship at the University of Oregon (UO). My first conclusion will be that it is fundamentally unnatural to declare divides across disciplines. In particular, the infamous 'art-science divide' is not a consequence of our natural creative searches but instead arises from our practical inability to accommodate the rapid drive toward academic specialization. Secondly, divides between research and teaching activities are equally unnatural – both endeavors are driven by the same creative strategy and are intertwined within the same natural process. This applies equally to the experiences of professors and students. I will end with specific success stories at the UO. These include a NSF IGERT project (focused on accelerating students' transitions from classroom to research experiences) and a collaboration between architects and professors to design a building (the recently opened Lewis Integrative Science Building) that encourages daily encounters between students and professors across research disciplines.

1:03PM Z3.00004 Integrated Concentration in Science (iCons): Undergraduate Education Through Interdisciplinary, Team-Based, Real-World Problem Solving[1] , MARK TUOMINEN, University of Massachusetts Amherst — Attitude, Skills, Knowledge (ASK) – In this order, these are fundamental characteristics of scientific innovators. Through first-hand practice in using science to unpack and solve complex real-world problems, students can become self-motivated scientific leaders. This presentation describes the pedagogy of a recently developed interdisciplinary undergraduate science education program at the University of Massachusetts Amherst focused on addressing global challenges with scientific solutions. Integrated Concentration in Science (iCons) is an overarching concentration program that supplements the curricula provided within each student's chosen major. iCons is a platform for students to perform student-led research in interdisciplinary collaborative teams. With a schedule of one course per year over four years, the cohort of students move through case studies, analysis of real-world problems, development of potential solutions, integrative communication, laboratory practice, and capstone research projects. In this presentation, a track emphasizing renewable energy science is used to illustrate the iCons pedagogical methods. This includes discussion of a third-year laboratory course in renewable energy that is educationally scaffolded: beginning with a boot camp in laboratory techniques and culminating with student-designed research projects. Among other objectives, this course emphasizes the practice of using reflection and redesign, as a means of generating better solutions and embedding learning for the long term.

1:39PM Z3.00005 Living the good life: pursuing excellence as a scientist and as a teacher[1] , ERICA CARLSON, Dept. of Physics, Purdue University — Do research and teaching represent competing demands on our time and energy, or have we bought into a false dichotomy? As a scientist, my job is to find truth. As a teacher, my job is to teach the next generation how to find truth. In this talk, I discuss the ways in which research and teaching have been synergistic in my experience, as well as the tension commonly felt among professors (myself included) as to how to "split our time" between the two. I will share a brief synopsis of my teaching philosophy, and I hope to give some insight into what (in my opinion) makes or breaks you as a teacher. I will also share some of my experience in this great adventure we call scientific progress.

[1]Support is gratefully acknowledged from Research Corporation for Science Advancement and NSF DMR DMR 11-06187.

Friday, March 22, 2013 11:15AM - 2:15PM –

Session Z5 DCMP: Focus Session: Graphene: Transport and Optical Phenomena: Hot Electrons and Photocurrents 301 - Alex Holleitner, Technische Universitaet Muenchen

11:15AM Z5.00001 Hot carriers, phonons and electron-phonon decoupling in graphite[1] , TUNG-WU HSIEH, CHIH-WEI LAI, Michigan State University — Visible and near-IR radiation and hot phonons are observed in HOPG graphite following the excitation of picosecond laser pulses at 1.58 eV of fluences exceeding 1000 J/m^2. The optically generated electron-hole carriers lead to non-thermal radiation ranging from 1.2 to 2.8 eV, including black-body-like emissions above the excitation and a broad spectral peak near 1.4 eV. We determine an effective electronic temperature (Te) by fitting the high energy radiation to a Plank spectrum; Tg from G-mode Stokes/anti-Stokes Raman peaks; Tl from spectral line shifts of G-mode. With increasing incident fluence from 10^3 to 10^4 J/m^2, Te, Tg and Tl are decoupled and increase from 1000 to 5000, 1000 to 2500, and 300 to 500K, respectively. At a fluence below 10^3 J/m^2, Te approaches Tg near 2000K, which is $\sim$ 1000K above Tl. This is indicative of quasi-equilibrium, but decoupled, distributions of carriers and phonons. The transient radiation decays within 2ps, limited to instrument response. Similar effects are observed for excitations at 1.53 and 1.49 eV. Experiments are conducted in vacuum at ambient T=300K.

[1]Supported by NSF DMR-0955944.

11:27AM Z5.00002 Doping dependence of the ultrafast relaxation dynamics of hot electrons in graphene

, LIANG ZHAO, JIE SHAN, Case Western Reserve University, KIN FAI MAK, TONY HEINZ, Columbia University — The ultrafast relaxation dynamics of highly excited electrons in graphene has attracted much attention due to both its fundamental interest and its practical importance in relation for optoelectronic devices. Several mechanisms including electron-optical phonon scattering and disorder assisted electron-phonon scattering have been proposed to be responsible for electron cooling on the picosecond time scale. In this work, we apply the technique of two-color femtosecond pump-probe spectroscopy to investigate the electron relaxation dynamics as a function of doping. The photo-induced absorption in graphene is seen to vary rapidly in the first a few 100's fs, followed by a slower decay of $\sim$ ps. The dynamics depend sensitively on the doping level. We will present our analysis of the results in terms of the transient electron chemical potential and temperature and discuss the role of different doping mechanisms, in particular, in the regime where the Fermi energy approaches half of the probe photon energy.

11:39AM Z5.00003 Hot Carrier Transport at the Graphene-Metal Interface Induced by Strong Lateral Photo-Dember Effect[1]

, CHANG-HUA LIU, YOU-CHIA CHANG, NANDITHA DISSANAYAKE, YAOZHONG ZHANG, ZHAOHUI ZHONG, University of Michigan — Ultrafast photo-excitation in a semiconductor can lead to transient spatial charge gradient if electrons and holes have different drift velocities. The charge gradient builds up the transient electric field and causes the subsequent terahertz pulse emission. This phenomenon, known as the photo-Dember effect, was typically considered insignificant in graphene due to its similar electron and hole mobilities. Here, we observe hot carrier transport at the graphene-metal interface driven by the photo-Dember electric field under femtosecond pulse laser excitation. The polarity of hot carrier transport is determined by the asymmetry of electron and hole mobilities of the graphene device and cannot be flipped sign by tuning graphene doping level. This indicates the formation of strong photo-Dember field, dominating over the graphene/metal built-in electric field or thermal electric field. We further analyze the spatial distribution and temporal evolution of the transient electric field near the contact edge by using the drift-diffusion model. The modeling results suggest that strong photo-Dember effect is caused by the low electronic specific heat of graphene and a huge charge gradient near the graphene-metal interface under pulse laser excitation.

11:51AM Z5.00004 Giant Nonlocal Photocurrent at the Charge Neutrality Point in Graphene[1]

, QIONG MA, NATHAN GABOR, NITYAN NAIR, Department of Physics, MIT, WENJING FANG, JING KONG, Department of Electrical Engineering and Computer Science, MIT, PABLO JARILLO-HERRERO, Department of Physics, MIT — Graphene based photosensitive devices have attracted considerable attention due to monolayer graphene's broadband optical absorption and gate tunable capacities. As the quality of graphene increases, emergent phenomena are being observed in both transport and optical measurements. Here we report measurements of giant nonlocal photocurrent that emerges at the charge neutrality point in graphene transistor devices. Scanning photocurrent imaging of uniformly undoped monolayer graphene transistors reveals highly ordered spatial patterns with alternating photocurrent signs as a function of laser position. The charge density dependence of the photoresponse, combined with in-situ improvement of device mobility, reveals a strong correlation between the nonlocal photocurrent and the derivative of the thermopower as a function of charge density. Photocurrent enhancement is pronounced in high-mobility devices and at intermediate temperatures. Such behaviors are suggestive of phonon drag effects that emerge at the charge neutrality point under photoexcitation.

12:03PM Z5.00005 Hot carrier response in gapped bilayer graphene[1]

, GRANT AIVAZIAN, JASON ROSS, Univeristy of Washington, K. WATANABE, T. TANIGUCHI, K. KITAMURA, National Institute for Materials Science, DAVID COBDEN, XIAODONG XU, Univeristy of Washington — Recently bilayer graphene has been shown to develop a bandgap upon breaking of inversion symmetry by a perpendicular electric field that is *in situ* tunable between zero and several hundred meV (corresponding to wavelengths in the mid-IR). Such unique tunability offers bilayer graphene a niche in mid-IR optoelectronic devices where a lack of high performance photodetectors exists. In this work we have performed spatially and temporally resolved photocurrent measurements in a dual-gated bilayer graphene FET under continuous-wave and pulsed laser excitation. We find that photocurrent generation in native bilayer graphene is dominated by hot carriers, as is the case in monolayer graphene, but it behaves very differently from monolayer graphene once a bandgap has been opened.

12:15PM Z5.00006 Supercollision cooling in undoped graphene

, SUNG HO JHANG, ANDREAS BETZ, EMILIANO PALLECCHI, ROBSON FERREIRA, GWENDAL FEVE, JEAN-MARC BERROIR, BERNARD PLAÇAIS, Ecole normale superieure - Paris, ECOLE NORMALE SUPERIEURE - PARIS TEAM, LABORATOIRE DE PHOTONIQUE ET NANOSTRUCTURES COLLABORATION — We have investigated the electron-lattice cooling rate in graphene by means of GHz Johnson noise thermometry. For phonon temperatures (T_{ph}) larger than Bloch-Grüneisen temperature ($T_{\rm BG}$), we find the energy relaxation rate J obeys a cubic law as a function of electron temperature T_e. In this regime, the small Fermi surface of graphene drastically restricts the allowed phonon energy in ordinary electron-phonon scattering, and disorder-assisted supercollisions dominate over the conventional electron-phonon collisions. In the low-temperature regime, for $T_{ph} < T_{\rm BG}$, we regain $J \propto T_e^4$ dependence, which is the signature of standard electron-phonon interaction in the 2D graphene. Beside its implication for electron-phonon physics, our observations are of direct relevance for the performance of graphene bolometers and photo-detectors.

12:27PM Z5.00007 Focused Laser Induced Spatially Controllable p-n junction in Graphene Field-Effect Transistor

, YOUNG DUCK KIM[1], Department of Physics and Astronomy, Seoul National University, MYUNG-HO BAE, Korea Research Institute of Standards and Science, JUNG-TAK SHU, Department of Physics, Sungkyunkwan University, YOUNG SEUNG KIM, Department of Physics, Graphene Research Institute, Sejong University, JOUNG REAL AHN, Department of Physics, Sungkyunkwan University, SEUNG-HYUN CHUN, Department of Physics, Graphene Research Institute, Sejong University, YUN DANIEL PARK, Department of Physics and Astronomy, Seoul National University — Tunable local doping on graphene is an important issue for future graphene-based electronics. Here we investigate a local doping effect by a focused laser irradiation and demonstrate a spatially controllable p-n junction in graphene field-effect transistor. Scanning photocurrent microscopy with varying back-gate voltages reveals the local charge trap in gate oxide near the laser-irradiated region. This is manifested by itself as double peaks in resistance as a function of gate voltage in graphene device, where the region between the double peaks corresponds to the p-n junction. Irradiation of a focused laser on graphene device suggests a new pave to spatially control the doping level, position and size of doped segment on graphene channel in a nondestructive way without high electrical bias, local gate electrode and chemical process.

12:39PM Z5.00008 Multiple regimes of carrier cooling in photoexcited graphene probed by time-resolved terahertz spectroscopy , A.J. FRENZEL, MIT / Harvard University, N.M. GABOR, MIT, P.K. HERRING, MIT / Harvard University, W. FANG, J. KONG, P. JARILLO-HERRERO, N. GEDIK, MIT — Energy relaxation and cooling of photoexcited charge carriers in graphene has recently attracted significant attention due to possible hot carrier effects, large quantum efficiencies, and photovoltaic applications. However, the details of these processes remain poorly understood, with many conflicting interpretations reported. Here we use time-resolved terahertz spectroscopy to explore multiple relaxation and cooling regimes in graphene in order to elucidate the fundamental physical processes which occur upon photoexcitation of charge carriers. We observe a novel negative terahertz photoconductivity that results from the unique linear dispersion and allows us to measure the electron temperature with ultrafast time resolution. Additionally, we present measurements of the relaxation dynamics over a wide range of excitation fluence. By varying the pump photon energy, we demonstrate that cooling dynamics of photoexcited carriers depend on the amount of energy deposited in the graphene system by the pump pulse, not the number of absorbed photons. The data suggest that fundamentally different regimes are encountered for different excitation fluences. These results may provide a unifying framework for reconciling various measurements of energy relaxation and cooling in graphene.

12:51PM Z5.00009 Terahertz generation and picosecond photo-thermoelectric currents in graphene[1] , ALEXANDER HOLLEITNER, Technical University Munich, Walter Schottky Institut and Physics Department — We demonstrate that THz radiation is generated in optically pumped bilayer graphene. The electro-magnetic radiation is detected via a time-domain THz spectroscopy utilizing coplanar metal stripline circuits in combination with an on-chip pump/probe scheme [1]. The striplines act as highly sensitive near-field antennae with a bandwidth of up to 1 THz. Our ultrafast experiments further clarify the optoelectronic mechanisms contributing to the photocurrent generation at graphene-metal interfaces. We verify that both built-in electric fields, similar to those in semiconductor-metal interfaces, and a photo-thermoelectric effect give rise to the photocurrent at graphene-metal interfaces at different time scales. We particularly discuss how the picosecond photocurrents in monolayer graphene depend on the geometry and the thermal coupling of the devices to the environment [2]. We acknowledge the very fruitful cooperation with L. Prechtel, S. Manus, D. Schuh, W. Wegscheider, L. Song, and P. Ajayan.

1:03PM Z5.00010 Optical pure spin current injection in graphene , JULIEN RIOUX, GUIDO BURKARD, Department of Physics, University of Konstanz, D-78457 Konstanz, Germany — Pure spin current injection by optical methods is investigated in single-layer and bilayer graphene within the tight-binding model, including bias and interlayer coupling effects. Interlayer coupling in bilayer graphene has a distinct qualitative effect on the polarization dependence of the spin current injection. In combination with interlayer coupling, which induces trigonal warping of the electronic bands, the bias voltage allows to control the warping at the Fermi surface. The resulting implications for the spin current injection are presented. Unlike the previously presented charge current injection [J. Rioux et al., PRB 83, 195406 (2011)], the effect presented here relies on a single monochromatic beam.

1:15PM Z5.00011 Probing the Optoelectronic Response of a Monolayer MoS_2 Field-Effect Transistor , KATHRYN L. MCGILL, Laboratory of Atomic and Solid State Physics, Cornell University; Kavli Institute at Cornell for Nanoscale Science, KIN FAI MAK, Kavli Institute at Cornell for Nanoscale Science, JOSHUA W. KEVEK, Laboratory of Atomic and Solid State Physics, Cornell University, JIWOONG PARK, Department of Chemistry and Chemical Biology, Cornell University; Kavli Institute at Cornell for Nanoscale Science, PAUL L. MCEUEN, Laboratory of Atomic and Solid State Physics, Cornell University; Kavli Institute at Cornell for Nanoscale Science — Two-dimensional materials contain a wealth of interesting optoelectronic properties. Single-layer molybdenum disulfide (MoS_2), with its broken inversion symmetry, is of particular interest. This broken symmetry results in the formation of direct band gaps at the K and K' valleys in its band structure, allowing long-lived optical excitations. Furthermore, monolayer MoS_2 has valley-dependent electronic properties allowing confinement of charge carriers to a single valley by optical pumping [1]. We have fabricated two- and four-terminal devices based on single layers of MoS_2. We observe an efficient photocurrent response at the two-dimensional semiconductor-metal interface displaying Shottky diode behavior, in which an interfacial field splits excitons at the contacts to produce current. We also find that the photocurrent drastically increases under reverse biasing of the diode. Additionally we are exploring the dependence of this photocurrent response on the polarization state of incident light.

[1] Xiao, D., *et al.*, *Phys. Rev. Lett.* **108**, 196802 (2012).

1:27PM Z5.00012 Photoresponse of Quasi-One Dimensional Graphene Nanostructures , TU HONG, ZEYNAB JARRAHI, YUNHAO CAO, ALEX HUFFSTUTTER, YAQIONG XU, Vanderbilt University — Here, we perform simultaneous photocurrent and photoluminescence measurements of free-standing graphene nanostructures. Their photocurrent intensities show a linear relationship with the incident laser power, whereas their photoluminescence intensities increase non-linearly when the incident power rises. The photoluminescence may result from the thermal radiation generated during hot carrier relaxation. The power dependences of their photoluminescence reveal that these graphene nanostructures are quasi-one dimensional materials.

1:39PM Z5.00013 Hybrid graphene-organic molecule transistors with large photoresponse , SHAO-YU CHEN, Institute of Atomic and Molecular Sciences, Academia Sinica, YI-YING LU, Department of Chemistry, National Taiwan University, FU-YU SHIH, Institute of Atomic and Molecular Sciences, Academia Sinica, PO-HSUN HO, CHUN-WEI CHEN, Department of Materials Science and Engineering, National Taiwan University, YANG-FANG CHEN, Department of Physics, National Taiwan University, YIT-TSONG CHEN, Department of Chemistry, National Taiwan University, WEI-HUA WANG, Institute of Atomic and Molecular Sciences, Academia Sinica, Taiwan — We present large photoresponse in hybrid graphene-organic molecule transistors, which exhibit high gain and large responsitivity. High-quality graphene phototransistors are achieved via resist-free fabrication and noncovalent bonding of the organic molecules. The photocurrent of the devices is tunable with back gate which enables high controllability by electrical means. The strong photoresponse can be attributed to charge transfer and photogating effect in the layer of organic molecules. High photo-sensitivity in the hybrid graphene-organic molecule transistors is promising for the future development of graphene-based optoelectronic applications.

1:51PM Z5.00014 Photocurrent Response of Graphene Heterostructures , JOAQUIN RODRIGUEZ-NIEVA, MILDRED S. DRESSELHAUS, MIT — One of the obstacles to the use of graphene as an alternative to silicon electronics has been the absence of a band gap. One solution to some of the limitations that this obstacle introduces is to integrate graphene into a heterostructure such as a field-effect tunneling transistor that uses an atomically thin dielectric [1]. We explore theoretically some of the interesting properties of optically excited graphene heterostructures, where novel behaviors can appear due to the tunability of the Fermi level and thus, of the charge carrier densities and intrinsic electronic cooling mechanisms. We also discuss possible applications of such types of optically activated heterostructures in different areas of science and engineering. References: [1] L. Britnell, R. V. Gorbachev, R. Jalil, et al., Science, 335, 947-950 (2012)

2:03PM Z5.00015 Near-field spectroscopy of graphene during ultrafast photoexcitation , MARTIN WAGNER, ZHE FEI, ALEXANDER MCLEOD, ALEKSANDR RODIN, University of California San Diego, WENZHONG BAO, University of California Riverside, LINGFENG ZHANG, Boston University, ZENG ZHAO, University of California Riverside, ERIC IWINSKI, MARK THIEMENS, MICHAEL FOGLER, University of California San Diego, ANTONIO CASTRO-NETO, National University of Singapore, CHUNNING LAU, University of California Riverside, FRITZ KEILMANN, Max Planck Institute of Quantum Optics, DIMITRI BASOV, University of California San Diego — Recently, impressive progress in nanoplasmonics of graphene using near-field spectroscopy and imaging has been reported [Z. Fei et al., Nano Lett. 11, 4701 (2011); Z. Fei et al., Nature 487, 82 (2012)]. However, these studies of the interaction of the graphene plasmon with the SiO2 substrate surface phonon were time-independent. Here we combine imaging and material characterization on the nano scale with ultrafast sub-picosecond time resolution and present optical pump broadband mid-infrared probe spectroscopy of graphene. We discuss the optical pump induced changes of the coupled plasmon-phonon modes with respect to carrier density and time-dependence. The difference between ultrafast photoexcitation and conventional electrostatic doping via the field effect is analyzed and compared with modeling.

Friday, March 22, 2013 11:15AM - 2:03PM –

Session Z6 DCMP: Nanotubes and Nanowires (non-carbon): Other Phenomena 302 - Yanjie Zhou, Purdue University

11:15AM Z6.00001 Thin-Film Nanowire Networks for Transparent Conductor Applications: Simulations of Sheet Resistance and Percolation Thresholds , KAREN I. WINEY, ROSE M. MUTISO, MICHELLE C. SHERROTT, Department of Materials Science and Engineering, University of Pennsylvania, AARON R. RATHMELL, BENJAMIN J. WILEY, Department of Chemistry, Duke University — Thin-film metal nanowire networks are being pursued as a viable alternative to the expensive and brittle indium tin oxide (ITO) for transparent conductors. For high performance applications, nanowire networks must exhibit high transmittance at low sheet resistance. Previously, we have used complimentary experimental, simulation and theoretical techniques to explore the effects of filler aspect ratio (L/D), orientation, and size-dispersity on the electrical conductivity of three-dimensional rod-networks in bulk polymer nanocomposites. We adapted our 3D simulation approach and analytical percolation model to study the electrical properties of thin-film rod-networks. By fitting our simulation results to experimental results, we determined the average effective contact resistance between silver nanowires. This contact resistance was then used to quantify how the sheet resistance depends on the aspect ratio of the rods and to show that networks made of nanowires with L/D greater than 100 yield sheet resistances lower than the required 100 Ohm/sq. We also report the critical area fraction of rods required to form a percolated network in thin-film networks and provide an analytical expression for the critical area fraction as a function of L/D.

11:27AM Z6.00002 A simple method to make an electrical connection between ZnO microwire and substrate through nanoscale metal evaporation[1] , HAKSEONG KIM, JINKYUNG LEE, HOYEOL YUN, SANG WOOK LEE, Division of Quantum Phases and Devices, School of Physics, Konkuk University, 143-701, Seoul, Korea, NANO ELECTONICS & NANO MECHANICS TEAM — We developed a simple method to make an electrical connection with nanoscale electrodes on microscale wire using suspended Poly(methyl methacrylate) (PMMA) strings. Less than 90 nm height of Ti/Au made a complete electrical connection on the ZnO microwires of which diameter is around 2 μm. A cross linked PMMA string was bridged between ZnO microwire and substrate for making good electrical connection. The contact resistance of ZnO microwire fabricated by this method was much lower than that of device fabricated by standard E-beam lithography and evaporation. This fabrication method is readily extendible to prepare nano scale electrodes on various micro sized materials and serves as a pathway for studying their mesoscopic transport phenomena.

[1]This work is supported by WCU, BK21 and NRF.

11:39AM Z6.00003 High-performance Flexible Photodetectors based on Aligned Cadmium Sulfide Nanowire Networks , DONG-GUK CHO, Department of Physics and Astronomy, Seoul National University, KWANG HEO, HYUNG-WOO LEE, YONGJU PARK, JINHO PARK, Seoul National University, HYUN-JIN LIM, DUHEE YOON, Sogang University, CHANGHEE LEE, MIYOUNG KIM, Seoul National University, HYEONSIK CHEONG, Sogang University, JONGHYURK PARK, Electronics and Telecommunications Research Institute, JIKANG JIAN, Xinjiang University, SEUNGHUN HONG, Seoul National University — We developed a method to mass-produce aligned cadmium sulfide (CdS) nanowire (NW) network channels for highly flexible and high-performance photodetectors. In this method, CdS NWs were aligned along the molecular patterns on flexible substrates by a directed assembly strategy. The aligned CdS NW patterns were utilized as the channel of flexible photodetectors. The photodetectors based on *aligned* CdS NWs showed $\sim$ 10 times higher photosensitivity and $\sim$ 100 times faster photoresponse than those based on *randomly-oriented* CdS NW networks. Additionally, the stable photoconductive characteristics of our flexible photodetectors were maintained even when the photodetectors were bent down to a 0.2 mm radius of curvature. This simple but efficient strategy should pave the way for the large-scale fabrication of low-cost and high-performance flexible photodetectors based on the aligned CdS NW networks.

11:51AM Z6.00004 Growth of aligned Mo_6S_6 nanowires on a Cu(111)[1] , MARAL AMINPOUR, DUY LE, University of Central Florida, Department of Physics, Orlando FL 32816-2385, USA, DEZHENG SUN, Pierce Hall, University of California, Riverside, CA 92521, USA; Department of Physics, Columbia University, New York, NY 10027, USA, WENHAO LU, CHEN WANG, QUAN MA, LUDWIG BARTELS, Pierce Hall, University of California, Riverside, CA 92521, USA, TALAT S. RAHMAN, University of Central Florida, Department of Physics, Orlando FL 32816-2385, USA — We report the possibility of using the Cu(111) surface for growing molybdenum sulfide nanowire (Mo_6S_6) based on density functional theory and scanning tunneling microscopy investigations [1]. A small lattice mismatch between the nanowires and strong substrate interactions lead to epitaxial growth of the nanowires at alignment with the substrate crystallographic axes and at a preferred inter-wire separation.

12:03PM Z6.00005 Structural Characterization and Transport Properties of GaN nanowires in non-serrated and newly discovered serrated morphologies[1] , ZHENG MA, Department of Physics, Northeastern University, ADAM FRIEDMAN, Materials Science and Technology Division, Code 6361, US Naval Research Laboratory, LATIKA MENON, Department of Physics, Northeastern University — We present results on the synthesis, structural characterization and transport properties of single crystal GaN nanowires in two different morphologies (non-serrated and serrated nanowires). The synthesis of these two types of nanowires is carried out in chemical vapor deposition with Au catalysts. Different from the regularly non-serrated GaN nanowires, the GaN nanowires in "serrated" morphology have been newly discovered by our group. By controlling the growth conditions, it has been demonstrated that GaN nanowires with regular periodic serrations along the surface of the nanowire can be produced under specific conditions as for large-sized Au catalysts and excess concentration of gallium oxide. Detailed structural and morphological characterization studies reveal interesting features for these two growth modes. In an attempt to understand how these structural and morphological variations impact the electrical properties, transport studies on single GaN nanowires (both serrated and non-serrated) are currently underway. The transport properties, namely current versus voltage will be obtained for such nanowires which in turn will reveal important information on the potential applications of such wires in optoelectronic devices.

12:15PM Z6.00006 On/off-current Ratio and Ambipolar Behavior of Narrow Bandgap III-V Nanowire FETs , YANJIE ZHAO, Department of Physics, Purdue University, DREW CANDEBAT, COLLIN DELKER, School of Electrical and Computer Engineering, Purdue University, YUNLONG ZI, Department of Physics, Purdue University, DAVID JANES, JOERG APPENZELLER, School of Electrical and Computer Engineering, Purdue University, CHEN YANG, Department of Physics, Purdue University — III-V nanowires (NW) are promising candidates for future device applications due to the high bulk mobility. Yet the small bandgap may result in undesirable high off-current. Here we establish a simple but reliable model that quantitatively explains how channel bandgap and Schottky barriers at metal contacts affect the ambipolar characteristics and the achievable on/off-current ratios of NW-FETs. Thus one can gain insights of the expected transfer characteristics of a given channel material with certain device structure, and the optimal choice of materials for different device applications in ultimately scaled cases. The physics of electron transport in both ideal case (no Schottky barrier) and practical case (with Schottky barrier) is studied. The impact of Schottky barriers is evaluated by numerical calculation of the tunneling current, and is found to play a critical role for the different characteristics observed. A universal plot of on/off ratio vs. bandgap is presented. The excellent agreement between our simulation predictions and experiment results from InAs, InSb, Ge NWs and CNTs highlights the potential of our approach for understanding narrow bandgap NW-FETs, bridging material development and device applications, and guiding future transistor design.

12:27PM Z6.00007 Resistive Switching in Metal-Nanowire/Polymer Nano-Gap Devices , ROSE M. MUTISO, Department of Materials Science and Engineering, University of Pennsylvania, JAMES K. KIKKAWA, Department of Physics and Astronomy, University of Pennsylvania, KAREN I. WINEY, Department of Materials Science and Engineering, University of Pennsylvania — We recently presented the first examples of reversible resistive switching in bulk, glassy polymer nanocomposites. At compositions near the percolation threshold, Ag nanowire-polystyrene composites exhibit reversible resistive switching upon increase voltage at room temperature. We proposed that switching in these materials is the result of the field-induced formation of Ag filaments that bridge adjacent nanowire clusters, extending the percolation network and decreasing the sample's bulk resistivity. To further understand the switching mechanism and explore possible applications, we have designed and fabricated single-gap nanowire devices comprised of lithographically-defined metal lines separated by polymer-filled nano-gaps. We have successfully demonstrated reversible resistive switching in our nano-gap Ag/PS devices when the gap size is 20 - 100nm, observing highly reversible switching behaviors in some samples with high on/off ratios for over 50 cycles. Preliminary ex-situ high resolution imaging of the devices shows significant gap remodeling after a switching event, implying that the switching mechanism is linked to some form of electromigration of Ag electrodes. Additional ex- and in-situ characterization studies to elucidate observed trends are in progress.

12:39PM Z6.00008 Nonlocal Response of Plasmonic Nanowire Metamaterials in the ENZ Regime , BRIAN WELLS, University of Massachusetts Lowell, ANATOLY ZAYATS, Kings College London, VIKTOR PODOLSKIY, University of Massachusetts Lowell — Nanowire metamaterials are a class of materials formed by an array of aligned plasmonic nanowires embedded in a dielectric host which exhibit strongly anisotropic behavior. For a wide range of excitation frequencies, the optical properties of these systems are dominated by two waves with different polarizations. In contrast to this behavior, in the epsilon-near-zero (ENZ) frequency range, excitation of additional wave mode has been observed. In this frequency range the contribution of spatial dispersion becomes increasingly important and a modified dispersion relationship for the anisotropic metamaterials must be used. The properties of the additional wave need to be taken into consideration during design and analysis of the properties of nanowire-based systems. Here we present analytical and computational studies of the nonlocal optical response of plasmonic nanowire metamaterials. Dispersion of photonic modes of plasmonic metamaterials have been studied as a function of wavelength, geometry, and material parameters. A new analytical description of the optical properties of nonlocal nanowire systems has been developed. It is shown that the optical response of the system results from the coupling of conventional effective-medium-dominated oscillations with plasmon-polariton-type oscillations. The presented model is in agreement with numerical solutions of Maxwell's equations.

12:51PM Z6.00009 ABSTRACT WITHDRAWN –

1:03PM Z6.00010 First-principles study of bio-conjugated ultra-thin silicon nanowires: Interaction with a PNA-RNA double helix , XIAOLIANG ZHONG, WILLIAM SLOUGH, RAVINDRA PANDEY, CRAIG FRIEDRICH, Michigan Technological University — We present the results of a first-principles study based on density functional theory of peptide nucleic acid (PNA) - ribonucleic acid (RNA) double helix conjugated silicon nanowires (SiNWs). The effects of a hexane linker functionalization, probe PNA strand immobilization, and target RNA strand hybridization on the electronic states of the ultra-thin SiNWs in a dry condition are investigated. All of these effects appear to marginally modify the core silicon states of the nanowires, manifested by a low level of p-doping in SiNWs. The intrinsic energy gap of the SiNWs is essentially unchanged, though there exist mid-gap states contributed by the PNA/RNA molecules which tend to localize near the Fermi energy. Overall, the bio-conjugation considered does not appear to significantly affect the intrinsic electronic and transmission states of the ultra-thin SiNWs.

1:15PM Z6.00011 Wide bandwidth nanowire electromechanics on insulating substrates at room temperature , ABHILASH SEBASTIAN, JOHN MATHEW, SHAMASHIS SENGUPTA, MAHESHWAR GOKHALE, ARNAB BHATTACHARYA, MANDAR DESHMUKH, Tata Institute of Fundamental Research, Mumbai, India — We present a simple fabrication scheme for nano-scale devices on insulating substrates. Doubly clamped InAs nanowire resonators with local gate configuration are fabricated on sapphire substrates. Parasitic capacitance is reduced on insulating substrates thus enabling measurements at all temperatures and particularly above room temperature, an essential requirement for NEMS sensors. Mechanical motion of the nanowire is capacitively actuated and detected using a network analyser. This technique provides wide bandwidth radio frequency transduction and allows the nanowire oscillations to be probed at a much faster rate compared to mixing techniques. Both in-plane and out-of-plane vibrational modes of the nanowire are observed and the non-linear response of the resonators is studied. Quality factor of the resonator increases at low temperatures. We also study the relation between mechanical motion and thermal strains in the nanowire. This opens up a new approach in studying thermal properties of nanostructures. Our method of fabrication can be extended to NEMS devices on flexible substrates and other nanostructures.

1:27PM Z6.00012 Enhanced Performance in Flexible Binder-free SWCNT Membrane EDLC[1] , DANHAO MA, PRALAV SHETTY, The Pennsylvania State University, KOFI ADU, The Pennsylvania State University, Altoona College, RAMAKRISHNAN RAJAGOPALAN, The Pennsylvania State University — We present results on an aqueous symmetric double layer electrochemical capacitor (EDLC) constructed with flexible binder-free single wall carbon (SWCNTs) membrane as electrodes. The capacitors were cycled from 0 to 1V @ 10 A/g for 10,000 cycles with 99.9% coulombic efficiency and 94% energy efficiency, and 100% depth of discharge. The power performance of the aqueous symmetric SWCNTs membrane capacitor is almost 100 –1000 times better than commercial non-aqueous EDLC capacitors.

1:39PM Z6.00013 Synthesis and HRTEM Electron Diffraction Characterization of Monocrystalline V_2O_5 , LUISA TAFOYA, LUIS RENDON, PATRICIA SANTIAGO, Instituto de Fisica, Universidad Nacional Autónoma de México, 04510 México D. F., México, ELIZABETH CHAVIRA, Instituto de Investigaciones en Materiales, Universidad Nacional Autónoma de México, 04510 México D. F., México, ERNESTO E. MARINERO, HGST San José Research Center, 3404 Yerba Buena Rd., San Jose, CA 95135, USA, VICENTE GARIBAY, Instituto Mexicano del Petroleo, de Fisica, Eje Lázaro Cárdenas Norte 152. Col. San Bartolo Atepehuacan, 07730; Mexico D.F., México, LEONARDO GONZALEZ, Universidad Autonoma Metropolitana, Azcapotzalco, Av, San Pablo 180, Col. Reynosa , 02200; Mexico D.F., México — We have synthesized V_2O_5 nanorods via solvothermal synthesis. By controlling the synthesis conditions, unidirectional crystalline growth is achieved. HRTEM and XRD studies reveal that the resulting nanorods are monocrystalline and are on average 80 nm in width and readily grow to a few microns in length. Utilizing electron diffraction we investigate the growth of these nanostructures along preferential crystalline planes. XRD confirms also that the crystalline phase of the nanorods is orthorhombic.

1:51PM Z6.00014 Narrow peaks in the current power spectra of nanomechanical resonators. , DONG LIU, Michigan State University, ADRIAN BACHTOLD, JOEL MOSER, Institut Catala de Nanotecnologia, ALEX LEVCHENKO, MARK I. DYKMAN, Michigan State University — We show that the power spectrum of current through a nanomechanical resonator has narrow peaks at the frequencies of mechanical modes. These peaks can be selectively downshifted to low frequencies by applying almost resonant ac source-drain or gate voltage. Our analysis refers to the Coulomb blockade regime, where the current is limited by tunneling through the contacts. Where the tunneling rate largely exceeds the vibration frequency, the analysis can be done in terms of the conductance that adiabatically depends on the displacement of the nanoresonator. In a more general case the current power spectrum near the narrow vibration-induced peaks is related to the vertex correction for the corresponding Green function. The spectral peak at low frequency can result also from the vibration nonlinearity in the absence of inversion symmetry. We note that measuring the power spectra of the current noise provides an alternative to the often complicated direct measurements of the absorption spectrum of coupled electron-vibrational systems.

Session Z7 DMP: Focus Session: Carbon Nanotubes: Synthesis 303 - Eric Stach, Brookhaven National Laboratory

11:15AM Z7.00001 Developing Single-Wall Carbon Nanotubes into an Industrial Material through the Super-Growth CVD Method[1] , DON FUTABA, Nanotube Research Center, AIST — Since the discovery of the carbon nanotube (CNT) 20 years ago, extensive effort has been made to utilize their exceptional intrinsic properties toward industrial applications. However, availability has significantly thwarted these endeavors. In one section of my presentation, I will describe our efforts toward the economical mass-production of single-walled carbon nanotubes (SWCNT) based on the water-assisted chemical vapor deposition technique, from which highly efficient synthesis of vertically aligned SWCNTs grow from substrates (SWCNT forests). Further, I will discuss our work to promote the industrial use of SWCNTs as a member of the Technology Research Association for Single-Walled Carbon Nanotubes (TASC) (A consortium of five companies and AIST founded for the specific purpose of developing SWCNT industrial technology.) Specifically, I will present our progress on developing the technology for the synthetic control of SWCNTs and the development of standardized evaluation techniques for the purpose of understanding the relationship between the SWCNT forest structure, e.g. length, density, crystallinity, etc and the targeted property, e.g. conductivity, mechanical reinforcement, etc. Finally, I will present several examples of applications from composites to CNT-based devices.

[1]Technology Research Association for Single Wall Carbon Nanotubes (TASC), Japan

11:51AM Z7.00002 Oxygen-Assisted Synthesis of Single-Walled Carbon Nanotubes , O. TOLGA GUL, ARITH J. RAJAPAKSE, PHILIP G. COLLINS, University of California, Irvine — Water-assisted chemical vapor deposition (CVD) has become a standard synthesis method for high quality single-walled carbon nanotubes (SWCNTs). Some drawbacks of the water-assisted method, however, include good control of water concentrations in the feedstock and poor control of SWCNT diameters below 2.0 nm. Here, we describe a variation of water-assisted CVD that uses dry feedstocks with a small, controlled quantity of molecular oxygen. Reactions of oxygen with hydrogen in the reaction zone provide all the benefits of water-assisted growth at the substrate while maintaining dry valves and flowmeters. In addition, the oxygen-based technique allows water concentrations in the system to be varied precisely and with short time constants. Perhaps because of the improved control, we find that the SWCNT diameter can be easily tuned by changing the oxygen concentration during the growth phase. Changing the oxygen concentration over the range of 0.5% to 1% varied the resulting SWCNT diameters from 1.5 to 0.5 nm, with typical diameter distributions less than +/- 30%. Control of SWCNT growth within this diameter range is ideal for probing opto-electronic properties of individual SWCNTs and SWCNT devices.

12:03PM Z7.00003 Chirality-controlled synthesis of single-wall carbon nanotubes using vapour phase epitaxy[1] , JIA LIU, Department of Chemistry, University of Southern California, CHUAN WANG, Department of Electrical Engineering, University of Southern California, XIAOMIN TU, NIST, BILU LIU, LIANG CHEN, Department of Electrical Engineering, University of Southern California, MING ZHENG, NIST, CHONGWU ZHOU, Department of Electrical Engineering, University of Southern California, NIST COLLABORATION — Due to the superior electrical properties such as high intrinsic carrier mobility and current-carrying capacity, single wall carbon nanotubes (SWCNT) hold great promise for electronic application. Since the electronic property of a SWCNT strongly depends on its chirality, the lack of synthetic control in chirality has long been recognized as a fundamental impediment in the science and application of SWCNTs Here we demonstrate a general strategy for producing carbon nanotubes with predefined chiralities by using purified single-chirality nanotubes as seeds for subsequent metal-catalyst-free growth, resembling vapour phase epitaxy commonly used for semiconductor films. In particular, we have successfully synthesized (7, 6), (6, 5), and (7, 7) nanotubes, and used Raman spectroscopy to show unambiguously that the original chiralities of the nanotube seeds are preserved. Furthermore, we have performed electrical measurements on synthesized individual (7, 6) and (6, 5) nanotubes, confirming their semiconducting nature. The vapour phase epitaxy approach is found to be highly robust and should enable a wide range of fundamental studies and technological developments.

12:27PM Z7.00005 Towards Single-Chirality Armchair Carbon Nanotube Ensembles using Combined Size Exclusion Chromatography and Density Gradient Ultracentrifugation

, ERIK HAROZ, JUNICHIRO KONO, ROBERT HAUGE, Rice University, STEPHEN DOORN, Los Alamos National Laboratory, CONSTANTINE KHRIPIN, MING ZHENG, National Institute for Standards and Technology — Recently, density gradient ultracentrifugation (DGU) has been shown to produce aqueous ensembles enriched in armchair carbon nanotubes (CNTs), introducing new experimental insight into the photophysics of one-dimensional metals. However, despite these successes, DGU-produced armchair CNT ensembles contain multiple armchair species, which is not ideal for extracting chirality-specific optical quantities. Sample heterogeneity is partly due to tube-to-tube variability in other CNT properties such as end-capping, CNT diameter and length, resulting in differences in the observed CNT mass density. For example, CNT sedimentation velocity increases with decreasing tube length, resulting in a given CNT species appearing in multiple separated fractions after DGU. Here, using surfactant-based, size exclusion chromatography, high-concentration, uniform length CNT fractions were produced. These fractions were subsequently used for armchair enrichment DGU with the expectation that greater uniformity of the starting CNT material will lead to more monodispersed fractions, enhancing separation towards the goal of single-chirality armchair ensembles. The resulting separated fractions were analyzed using optical absorption and resonant Raman spectroscopy to assess improvement in separation.

12:39PM Z7.00006 Removal of surfactants and adducts from solution-processed single-walled carbon nanotubes[1]

, ALEXANDER KANE, Sandia National Laboratories — The use of single-walled carbon nanotubes (SWCNTs) in scalable electronics and optoelectronics requires purification of the material to remove contaminants from the growth, and enrichment of the semiconducting fraction of the material through sorting. Centrifugation of aqueous suspensions of SWCNTs allows for both purification and sorting in successive steps with the aid of surfactants, but the suspension process causes oxidative damage to the SWCNTs and the surfactants are difficult to remove from the SWCNT sidewall after deposition on the substrate. These residual surfactants and adductive defects negatively impact device performance. We present a two-step approach towards reducing this disorder post-deposition using mild oxidation to remove the surfactant followed by vacuum annealing to heal the SWCNT sidewall. Thermal gravimetric analysis and temperature programmed desorption show the optimal conditions and fundamental mechanisms. Characterization of the results using Raman spectroscopy, atomic force microscopy, and electronic transport measurements show that the quality of the material is maintained.

12:51PM Z7.00007 Directed assembly of one-dimensional functional nanostructures

, ERIKA PENZO, MATTEO PALMA, RISHENG WANG, SHALOM J. WIND, Columbia University — One-dimensional (1D) nanostructures have unique electronic, optical and mechanical properties that have attracted intense interest over the past two decades. Single wall carbon nanotubes (SWNTs) and semiconducting nanorods have long been recognized as potential candidates for future nanoelectronic applications. The small size and the fact that these nanostructures are synthesized either at high temperatures or in solution make it difficult to organize them in complex architectures, a key requirement for their exploitation. As a step toward this goal, we are developing approaches leading to the controlled and ordered arrangement of nanoobjects on lithographically patterned, chemically (or biochemically) functionalized surfaces. One approach consists in patterning metallic nanodots that serve as anchors by selective functionalization with single stranded DNA (ssDNA) or with other chemical moieties. End functionalized nanostructures are attached to the dots through DNA hybridization or through a covalent bond. A second approach consists in patterning hydrophilic regions on hydrophobic substrates. Ion-complexed nanostuctures selectively bind to the hydrophilic pattern.

1:03PM Z7.00008 A novel fabrication process of hundreds of field effect transistors around one single carbon nanotube for molecular assembly[1]

, XIAN ZHANG, DANIEL CHENET, BUMJUNG KIM, JAEEUN YU, COLIN NUCKOLLS, JAMES HONE, Columbia University — Carbon nanotube field effect transistors (CNTFETs) can be used both as stand-alone electronic devices and as basis for other devices, but high-throughput fabrication remains an important challenge. In one specifically demanding application, CNTFETs are lithographically 'cut' and rejoined with single molecules in the gap, to yield circuits for studying transport properties of single molecules. Because of the extreme precision required, such devices have a fabrication yield of only a few percent, which severely limits the speed of implementing CNT-molecule devices. In addition, the diversity of CNT structures provides an additional source of heterogeneity that makes collection of meaningful statistics difficult. Here we report a novel fabrication method to produce a chip with over 600 CNTFETs fabricated on one CNT. We use long (1cm) flow-aligned CNTs grown by chemical vapor deposition. Two photolithography steps are then used to pattern contacts and define a mask to burn away extra CNTs by oxygen plasma. We present the statistics of the transport properties of these devices including threshold voltage and on-state resistance. The devices are then lithographically cut and reconnected with DNA to provide consistent measurements of DNA conductance.

[1]I would like to thank the Office of Naval Research (ONR) as well as the program officers who facilitated funding for my scientific work.

1:15PM Z7.00009 Can diamond nanowires grow inside carbon nanotubes?[1]

, ZHEN ZHU, DAVID TOMÁNEK, Michigan State University, YANQUAN FENG, Beijing Institute of Technology — We investigate the possibility of templated growth of diamond nanowires from functionalized diamondoid molecules enclosed in a carbon nanotube (CNT). Our *ab initio* density functional theory studies identify suitable candidate molecules and conditions, under which such molecules may fuse to narrow diamond nanowires with C_8H_8 or C_7H_8 unit cells inside a CNT. We find that the unique environment inside a narrow carbon nanotube, which can be suitably represented by a cylindrical potential, subjects enclosed molecules to a high pressure, caused by "capillary" forces, and orients them in a suitable way favoring fusion and constraining the resulting structure. Based on total energy calculations, we find that fusion of $C_{10}H_{16}$ adamantane molecules requires additional energy, whereas fusion of $C_{14}H_{18}(COOH)_2$ diamantane di-acid molecules in hydrogen atmosphere occurs as an exothermic reaction. Our canonical molecular dynamics calculations at elevated temperatures indicate likely intermediate products occurring during this reaction.

1:27PM Z7.00010 Characteristics of thin graphene sheets prepared by a laser ablation method

, MAKI NAKAMURA, National Institute of Advanced Industrial Science and Technology (AIST), TAKAZUMI KAWAI, NEC Corporation, MICHIKO IRIE, AIST, RYOTA YUGE, NEC Corporation, SUMIO IIJIMA, SHUNJI BANDOW, Meijo University, MASAKO YUDASAKA, AIST — Graphenes are innovative carbon materials having a sheet-like structure; these materials are thought to have many applications in the fields of electrochemistry, biomedicine, and so on. In this study, we showed that thin graphene sheets (TGSs) prepared by a laser ablation method had a distinctive structure: even-number layered graphenes (2-, 4-, 6- and 8-layers) were preferentially grown (ca. 90%), and their population decreased as the layer number increased. These phenomena have not been observed in graphenes prepared with other methods. Our results suggest a new growth mechanism in which single-layer graphene is unstable and bends to form bi-layers, and the bi-layers then go on to stack and form thicker TGSs. The inter-layer distances estimated by transmission electron microscope images were about 15% larger than that of bulk graphite in the bi-layer TGSs, and they approached the bulk value as the layer number increased. Furthermore, we showed surface-selective functionalization of TGSs by mild oxidation with H_2O_2 at room temperature, indicating the possibility of multi-modal functionalization, which will make the graphene more attractive in various applications.

1:39PM Z7.00011 Plasmon Heat Transport Between Vertical Carbon Nanotube Forest and Different Substrates[1] , ANDREI NEMILENTSAU, SLAVA ROTKIN, Department of Physics, Lehigh University — Near-field radiative heat transfer between vertical forest of carbon nanotubes and different metallic and dielectric substrates has been studied using the formalism of the fluctuational electrodynamics. Proper matching between surface plasmons in nanotubes and surface polaritons in the substrate was demonstrated to be crucial for the efficient thermal coupling across the interface. Particularly, thermal Kapitza conductance between nanotubes and such polar dielectrics as quartz, sapphire and GaAs (with surface phonon-polariton energies $\sim$ 30-50 meV) is substantially higher than that between nanotubes and BN and SiC (with polartion energies $>$ 100 meV), or metals (with plasmon-polaritons in the visible range). Further optimization of heat transport can be achieved by tweaking nanotube length.

1:51PM Z7.00012 Unusual thermal conduction characteristics of phase change composites with single-walled carbon nanotube inclusion[1] , SIVASANKARAN HARISH, KEI ISHIKAWA, SHOHEI CHIASHI, JUNICHIRO SHIOMI, SHIGEO MARUYAMA, The University of Tokyo, Japan — Thermal energy storage using phase transition materials is often employed in many engineering applications. However, the low thermal conductivity of such materials inhibits its use for large scale applications. Recently, Zheng et al. [Nature Comm. 2011] demonstrated an efficient technique using graphite suspensions to tune the thermal and electrical conductivity using temperature regulation. In this work, we report large contrasts in thermal conductivity enhancement of nano composites with single walled carbon nanotube (SWCNT) inclusions using first order phase transition process. SWCNTs synthesized by alcohol CVD were dispersed in n-octadecane by tip-sonication with sodium deoxycholate as the surfactant. Thermal conductivity measurements were carried out with transient hot-wire system [Mater. Express 2012]. Thermal conductivity enhancement in the liquid state was found to be nominal and is consistent with the predictions of Maxwell- Garnett type effective medium theory. However, in the frozen state nearly a 2.5 fold increase in thermal conductivity was observed. Similar temperature dependent thermal conductivity contrast was observed when exfoliated graphite nanoplatelets were used as the inclusions.

2:03PM Z7.00013 Explosive Characteristics of Carbonaceous Nanoparticles[1] , LEONID TURKEVICH, JOSEPH FERNBACK, NIOSH/CDC, ASHOK DASTIDAR, Fauske & Associates, LLC — Explosion testing has been performed on 20 codes of carbonaceous particles. These include SWCNTs (single-walled carbon nanotubes), MWCNTs (multi-walled carbon nanotubes), CNFs (carbon nanofibers), graphene, diamond, fullerene, carbon blacks and graphites. Explosion screening was performed in a 20 L explosion chamber (ASTM E1226-10 protocol), at a (dilute) concentration of 500 g/m^3, using a 5 kJ ignition source. Time traces of overpressure were recorded. Samples exhibited overpressures of 5-7 bar, and deflagration index $K_{St} = V^{1/3}$ $(dp/pt)_{max} \sim$ 10 - 80 bar-m/s, which places these materials in European Dust Explosion Class St-1 (similar to cotton and wood dust). There was minimal variation between these different materials. The explosive characteristics of these carbonaceous powders are uncorrelated with particle size (BET specific surface area). Additional tests were performed on selected materials to identify minimum explosive concentration [MEC]. These materials exhibit MEC $\sim 10^1$ -10^2 g/m^3 (lower than the MEC for coals). The concentration scans confirm that the earlier screening was performed under fuel-rich conditions (i.e. the maximum over-pressure and deflagration index exceed the screening values); e.g. the true fullerene $K_{St} \sim$ 200 bar-m/s, placing it borderline St-1/St-2.

Session Z8 DCMP: Topological Insulators: Transport and interfaces 307 - Rolando Valdes Aguilar, Los Alamos National Laboratory

11:15AM Z8.00001 Time-reversal anomaly and Josephson effect in time-reversal invariant topological superconductors[1] , SUK BUM CHUNG, University of California Los Angeles, JOSHUA HOROWITZ, XIAO-LIANG QI, Stanford University — Topological superconductors are gapped superconductors with protected Majorana surface/edge states on the boundary. In this paper, we study the Josephson coupling between time-reversal invariant topological superconductors and s-wave superconductors. The Majorana edge/surface states of time-reversal invariant topological superconductors in all physical dimensions 1, 2, 3 have a generic topological property which we named as time-reversal anomaly. Due to the time-reversal anomaly, the Josephson coupling prefers a nonzero phase difference between topological and trivial superconductors. The nontrivial Josephson coupling leads to a current-flux relation with a half period in a SQUID geometry, and also a half period Fraunhofer effect in dimension higher than one. We also show that an in-plane magnetic field restores the ordinary Josephson coupling, as a sharp signature that the proposed effect is a consequence of the unique time-reversal property of the topological edge/surface states. Our proposal provides a general approach to experimentally verify whether a superconductor is topological or not.

11:27AM Z8.00002 Symmetry Protected Josephson Supercurrents in Three-Dimensional Topological Insulators , SUNGJAE CHO, BRIAN DELLABETTA, University of Illinois at Urbana-Champaign, ALINA YANG, JOHN SCHNEELOCH, ZHIJUN XU, TONICA VALLA, GENDA GU, Brookhaven National Laboratory, MATTHEW GILBERT, NADYA MASON, University of Illinois at Urbana-Champaign — Coupling the surface state of a topological insulator (TI) to an s-wave superconductor is predicted to produce the long-sought Majorana quasiparticle excitations. However, superconductivity has not been measured in surface states when the bulk charge carriers are fully depleted, i.e., in the true topological regime relevant for investigating Majorana modes. Here, we report measurements of DC Josephson effects in TI-superconductor junctions as the chemical potential is moved through the true topological regime characterized by the presence of only surface currents. We compare our results to 3D quantum transport simulations, and determine the effects of bulk/surface mixing, disorder, and magnetic field; in particular, we show that the supercurrent is largely carried by surface states, due to the inherent topology of the bands, and that it is robust against disorder. Our results thus clarify key open issues regarding the nature of supercurrents in TIs.

11:39AM Z8.00003 Majorana fermions in a superconductor quantum wire connected to normal leads[1] , EDSON VERNEK, Federal University of Uberlândia, ANTÔNIO C.F. SERIDÔNIO, Universidade Estadual Paulista Júlio de Mesquita Filho, JOSÉ C. EGUES, Instituto de Física de São Carlos - USP — We study the appearance of Majorana fermions in a quantum wire connected to a normal lead. We employ a Kitaev model for the wire with induced superconductivity with a full coupling with a normal wire. In comparison with previous study of this problem, our approach has the advantage of allowing us to fine tune the Kitaev Hamiltonian model all the way from its normal to its superconducting topological phase. By developing an exact Green's function calculation scheme, we are to explore the full parameter space of the model via analysis of the electron and the Majorana density of states. Our results show clearly that the main effect of a particle-hole symmetric lead is the broadening of the Majorana density of states at the end of the wire, while particle-hole asymmetric leads are detrimental to the Majorana bound states. We also study the transmission through a quantum dot connected to two normal leads and to a superconducting wire. We show that by driving the wire from its normal to its topological phase, a great change in the transmission function through the dot is observed, clearly indicating the emergence of a Majorana mode in the wire. Although such a signature has already been predicted in recent works, our model leads to substantially different results.

[1]We thank support from FAPESP, FAPEMIG and CNPq.

11:51AM Z8.00004 Majorana Fermions Under Stress , MING GONG, LI MAO, Department of Physics, The University of Texas at Dallas, Richardson, TX, 75080 USA, SUMANTA TEWARI, Department of Physics and Astronomy, Clemson University, Clemson, SC, 29634 USA, CHUANWEI ZHANG, Department of Physics, The University of Texas at Dallas, Richardson, TX, 75080 USA, CHUANWEI ZHANG TEAM, SUMANTA TEWARI TEAM — Spin-orbit coupled semiconductor nanowires with Zeeman splitting in proximity contact with bulk s-wave superconductivity have recently been proposed as a promising platform for realizing Majorana fermions. However, in this setup the chemical potential of the nanowire is generally pinned by the Fermi surface of the superconductor. This makes the tuning of the chemical potential by external electrical gates, a crucial requirement for unambiguous detection of Majorana fermions, very challenging in experiments. Here we show that tunable topological superconducting regime supporting Majorana fermions can be realized in semiconductor nanowires using uniaxial stress. For n-type nanowires the uniaxial stress tunes the effective chemical potential, while for p-type systems the effective pairing may also be modified by stress, thus significantly enhancing the topological minigap. The required stress is within current experimental reach using conventional piezo crystals.

12:03PM Z8.00005 The soft superconducting gap in semiconductor Majorana nanowires[1] , SO TAKEI, BENJAMIN M. FREGOSO, HOI-YIN HUI, ALEJANDRO M. LOBOS, SANKAR DAS SARMA, The University of Maryland College Park, THE CONDENSED MATTER THEORY CENTER AND THE JOINT QUANTUM INSTITUTE TEAM — We theoretically consider the mysterious topic of the soft gap in the tunneling conductance of the proximity-induced superconductivity in a semiconductor-superconductor hybrid structure, where the observation of a zero-bias conductance peak has created considerable excitement because of its possible connection with the elusive zero-energy Majorana mode. The observed experimental superconducting tunneling gap in the semiconductor nanowire looks v-shaped with considerable subgap conductance even at very low temperatures in sharp contrast to the theoretically expected hard BCS gap with exponentially suppressed subgap conductance. We systematically study, by solving the appropriate BdG equations both numerically and analytically, a number of physical mechanisms (e.g. magnetic and non-magnetic disorder, finite temperature, dissipative Cooper pair breaking, interface fluctuations), which could, in principle, lead to a soft gap, finding that only the interface fluctuation effect is a quantitatively and qualitatively viable mechanism that is consistent with the experimental observations. Our work indicates that improving the quality of the superconductor-semiconductor interface would go a long way in enhancing the gap in the hybrid structures being used for studying the Majorana mode.

12:15PM Z8.00006 ABSTRACT WITHDRAWN –

12:27PM Z8.00007 Majorana edge modes of topological exciton condensate with superconductors[1] , BABAK SERADJEH, Indiana University, Bloomington — I study the edge states of the topological exciton condensate formed by a Coulomb interaction between two parallel surfaces of a strong topological insulator. When the condensate is contacted by superconductors with a π phase shift across the two surfaces, a pair of counterpropagating Majorana modes close the gap at the boundary. I propose a nanostructured system of topological insulators and superconductors that hosts unpaired Majorana fermions when and only when the exciton condensate forms. Therefore, measuring the Majorana signal in this structure provides a way of detecting the topological exciton condensate that is uniquely related to its topological nature. The relevant experimental signatures as well as implications for related systems are discussed.

[1]Work published in Physical Review B 86, 121101(R) (2012).

12:39PM Z8.00008 ABSTRACT WITHDRAWN –

12:51PM Z8.00009 Entanglement in a Cooper-pair Splitter based on a Topological Insulator , KOJI SATO, University of California, Los Angeles — We theoretically study a solid state device producing entangled electron pairs that are spatially separated by coupling a superconductor to the helical edge states of a two-dimensional topological insulator. The interacting regions of the edge states are taken to be finite length around the tunneling region to capture the effect of non-interacting leads, and the ends of a given edge are further connected to a beam splitter. By controlling the scattering through such beam splitters, we show that Bell test can be performed via measurement of the current-current correlations.

1:03PM Z8.00010 Current-phase relationship of planar Josephson junctions mediated by the surface states of a topological insulator , C. KURTER, A.D.K. FINCK, C.D. ENGLISH, University of Illinois at Urbana Champaign, Y.S. HOR, Missouri University of Science and Technology, D.J. VAN HARLINGEN, University of Illinois at Urbana Champaign — It is predicted that the presence of Majorana fermions manifests itself with a 4π periodic current-phase relation (CPR) in planar Josephson junctions formed with topological weak links. To test this proposal, we have fabricated planar junctions by depositing Nb leads on exfoliated Bi_2Se_3 single crystals. The temperature and magnetic field dependence of the proximity-induced supercurrent have been examined in various doping regimes accessed via top gating. The critical current modulation with magnetic field deviates from the usual Fraunhofer diffraction pattern, suggesting modifications to a sinusoidal CPR consistent with a $sin(2\phi)$ component. We are corroborating those results with direct measurements of the CPR using a phase-sensitive SQUID interferometry technique.

1:15PM Z8.00011 Signatures of Majorana Fermions in Topological Insulator Josephson Junction Devices , BENJAMIN WIEDER, FAN ZHANG, CHARLES KANE, University of Pennsylvania Department of Physics and Astronomy — We study theoretically the electrical current and low-frequency noise for a linear Josephson junction structure on a topological insulator, in which the superconductor forms a closed ring, and currents are injected from normal regions inside and outside the ring. We find that this geometry offers a unique signature for the presence of gapless 1D Majorana fermion modes that are predicted to exist in the channel when the phase difference ϕ, controlled by the magnetic flux through the ring, is π. We show that for low temperature, the linear conductance jumps by $2e^2/h$ when ϕ passes through π, accompanied by non-local correlations between the currents from the leads inside and outside of the ring. We compute the dependence of these features on temperature, voltage, and linear dimensions, and discuss the implications for experiments.

1:27PM Z8.00012 Spinful Majorana fermions and magnetoelectricity in junctions of semiconductor / superconductor heterostructures[1] , PANAGIOTIS KOTETES, ALEXANDER SHNIRMAN, GERD SCHOEN, Karlsruhe Institute of Technology — Recently, the interest in topological quantum computing has grown due to the appearance of promising platforms for realizing Majorana fermions. The most prominent proposal involves a 1D semiconducting quantum wire in proximity to a bulk s-wave superconductor, where in addition a Zeeman field is applied. Here we investigate the Josephson effect in TNT and NTN junctions, consisting of topological (T) and non-topological (N) phases of semiconductor-superconductor 1D heterostructures in the presence of a Zeeman field [1]. A key feature of our setup is that, in addition to the variation of the phase of the superconducting order parameter, we allow the orientation of the magnetic field to change along the junction. We find a novel magnetic contribution to the Majorana Josephson coupling that permits the Josephson current to be tuned by changing the orientation of the magnetic field along the junction. We also predict that a spin current can be generated and additionally controlled by a finite superconducting phase difference. This new type of coupling not only constitutes a unique fingerprint of Majorana fermions but also provides an alternative pathway for manipulating and braiding topological qubits.

1:39PM Z8.00013 Proximity-effect-induced superconductivity in Bi_2Se_3 and Bi_2Te_3 , LI LU, JIE SHEN, YUE DING, FANMING QU, FAN YANG, JUN CHEN, ZHONGQING JI, GUANGTONG LIU, JIE FAN, XIUNIAN JING, CHANGLI YANG, Daniel Chee Tsui Laboratory, Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China — In this talk I will present our experimental investigations on the proximity effect between conventional superconductors such as Sn, Pb and the strong spin-orbit coupling materials Bi_2Se_3 or Bi_2Te_3 [1-3]. Several types of hybrid devices were fabricated, and their electron transport properties were measured down to ∼10 milli-Kelvin temperatures. The results show that a superconducting phase can be easily induced in Bi_2Se_3 and Bi_2Te_3 single crystals by superconducting Pb electrodes that are deposited on the surface of the former. The induced superconducting phase can be regarded as a true superconducting phase, i.e., it has an energy gap of the order 0.1 meV, and carries a Josephson supercurrent over a distance as far as several microns. The conductance spectrum of the interface between the induced superconducting phase and the normal phase of Bi_2Se_3 or Bi_2Te_3 exhibits a zero-bias peak. Based on the induced superconducting phase, single Josephson junction devices and superconducting quantum interference devices (SQUIDs) were constructied, and their critical supercurrent were investigated as a function of applied magnetic flux. We will discuss the implication of the results in terms of the pairing symmetry of the induced superconducting phase.

1:51PM Z8.00014 Spin-polarized tunneling current through a thin film of a topological insulator in a parallel magnetic field , VICTOR YAKOVENKO, SERGEY PERSHOGUBA, Condensed Matter Theory Center, Department of Physics, University of Maryland, College Park, Maryland 20742-4111, USA — We calculate the tunneling conductance between the surface states on the opposite sides of an ultra-thin film of a topological insulator in a parallel magnetic field B. The parallel magnetic field produces a relative shift of the in-plane momenta of the two surfaces states. An overlap between the shifted Fermi circles and spinor wave functions result in unusual non-monotonic dependence of the tunneling conductance $\sigma(B)$ on the magnetic field B. The conductance $\sigma(B)$ grows with the magnetic field B, which corresponds to a negative magnetoresistance observed in an experiment [2], until it drops down abruptly to zero at the critical magnetic field $B_{\rm cr}$. Because spin orientation of the electronic surface states in topological insulators is locked to momentum, spin polarization of the tunneling current can be controlled by the magnetic field.

2:03PM Z8.00015 Polarization selective micro-Raman spectroscopy of gated 3D topological insulators[1] , JEFF SECOR, MILAN BEGLIARBEKOV, LUKAS ZHAO, HAIMING DENG, LIA KRUSIN-ELBAUM, Physics Department, City College of New York — One of the majors challenges to understanding the behavior of the quantum states in 3D topological insulators (TIs) is a significant carrier conduction in the bulk. Understanding phonons and electron-phonon interactions can shed light on the link between surfaces and the bulk and are critical in potential applications based on TIs. Raman scattering is a fast nondestructive technique used to analyze electron lattice interactions. In this work we study micro-Raman scattering of few quintuple layer thin 2^{nd} generation excellent crystalline quality 3D TIs, such as Sb_2Te_3, Be_2Te_3, and Bi_2Se_3 in the 15-300 K temperature range in order to probe the interaction of circularly polarized light between the lattice phonon modes and helical surface states of TI's. Circularly and linearly polarized light combined with an applied gate bias and the temperature dependence is used to examine the helicity dependence of Raman scatter to analyze the strength of electron-phonon coupling in these systems.

Session Z10 DFD DPOLY GSNP: Invited Session: Elastic Instabilities and Pattern Formation in Structureless Solids 309 - Benny Davidovitch, University of Massachusetts Amherst

11:15AM Z10.00001 Coarsening of patterns from scale free instabilities in soft solids , EVAN HOHLFELD, University of Massachusetts, Amherst — Soft materials such as rubbery solids have hidden, scale-free instabilities that are undetectable by linearized analysis, yet which have no energy barrier for onset. Examples include the nucleation of sharply creased surface folds resembling the sulci on the brain and the nucleation and growth of cavities. These instabilities can be understood as quasi-phase transitions: they have well defined binodal points, form via a nucleation and growth process, and have finite energies of transformation; however, there is no clear phase boundary dividing the "nucleated phase" from the surrounding elastomer. First anticipated by Weierstrass more than 100 years ago, our understanding of these instabilities—so called "Weierstrass needles"—is now rapidly developing as an increasing number of physical examples are being identified. Recent experimental and theoretical work has continued to deepen the analogy between a Weierstrass needle and a more traditional phase transition. Along this line, I will present new results showing how the coarsening of a crease pattern can be understood as a form of Ostwald ripening. I will also discuss classes of systems which might support other examples of Weierstrass needles.

11:51AM Z10.00002 Instabilities in axisymmetrically constrained sheets[1] , JOSÉ BICO, École Supérieure de Physique et de Chimie Indust. de la Ville de Paris — We propose to describe three different situations where a circular sheet is submitted to axisymmetric loads resulting from capillary forces or constrained boundary conditions. In a first case, a thin annulus floating on water is radially compressed by a surface pressure induced by the addition of surfactant molecules outside the annulus. As a consequence the annulus is compressed in the orthoradial direction and wrinkles are observed beyond a critical load. In a second situation, a planar disk is deposited on an adhesive sphere. Can the sheet accommodate the change in gaussian curvature? Wrinkles actually appear at the edge of the disk if the diameter exceeds a critical value. A third experiment finally involves a planar disk squeezed in a spherical mold. While low confinement induces the formation of localized folds, these folds eventually evolve into a cascade of orthoradial wrinkles.

12:27PM Z10.00003 The generation of stress-focusing features in confined elastic sheets , ROBERT SCHROLL, Departamento de Fisica, Universidad de Santiago de Chile — Crumpling is the canonical example of stress focusing in a confined elastic sheet. Subject to a large biaxial confinement, the sheet must bend in multiple directions, which induces Gaussian curvature and therefore strain. This strain is best accommodated by focusing the stress into small regions. In a crumpled sheet, multiple stress-focusing features appear apparently randomly. Here, I present two systems in which stress-focusing features are created in a controlled manner. In the first, a thin sheet is floated on a droplet of water. As the curvature of the droplet is increased, first wrinkles and then a focused features appear on the edge of the sheet. In the second, a focused feature appears at the transition between wrinkle patters of two different wavelengths. The degree of the focusing can be controlled by the confinement, the thickness, and the tension applied transverse to the confinement.

1:03PM Z10.00004 Compression-triggered instabilities of multi-layer systems: From thin elastic membranes to lipid bilayers on flexible substrates , HOWARD A. STONE, Department of Mechanical and Aerospace Engineering, Princeton University — Instabilities are triggered when elastic materials are subjected to compression. We explore new features of two distinct systems of this type. First, we describe a two-layer polymeric system under biaxial compressive stress, which exhibits a repetitive wrinkle-to-fold transition that subsequently generates a hierarchical network of folds during reorganization of the stress field. The folds delineate individual domains, and each domain subdivides into smaller ones over multiple generations. By modifying the boundary conditions and geometry, we demonstrate control over the final network morphology. Some analogies to the venation pattern of leaves are indicated. Second, motivated by the confined configurations common to cells, which are wrapped in lipid bilayer membranes, we study a lipid bilayer, coupled to an elastic sheet, and demonstrate that, upon straining, the confined lipid membrane is able to passively regulate its area. In particular, by stretching the elastic support, the bilayer laterally expands without rupture by fusing adhered lipid vesicles; upon compression, lipid tubes grow out of the membrane plane, thus reducing its area. These transformations are reversible, as we show using cycles of expansion and compression, and closely reproduce membrane processes found in cells during area regulation. The two distinct systems illustrate the influence of the substrate on finite amplitude shape changes, for which we describe the time-dependent shape evolution as the stress relaxes. This talk describes joint research with Manouk Abkarian, Marino Arroyo, Pilnam Kim, Mohammad Rahimi and Margarita Staykova.

1:39PM Z10.00005 Electromechanical instability in soft materials: Theory, experiments and applications , ZHIGANG SUO, School of Engineering and Applied Sciences, Harvard University — Subject to a voltage, a membrane of a dielectric elastomer reduces thickness and expands area, possibly straining over 100%. The phenomenon is being developed as transducers for broad applications, including soft robots, adaptive optics, Braille displays, and electric generators. The behavior of dielectric elastomers is closely tied to electromechanical instability. This instability may limit the performance of devices, and may also be used to achieve giant actuation strains. This talk reviews the theory of dielectric elastomers, coupling large deformation and electric potential. The theory is developed within the framework of continuum mechanics and thermodynamics. The theory attempts to answer commonly asked questions. How do mechanics and electrostatics work together to generate large deformation? How efficiently can a material convert energy from one form to another? How do molecular processes affect macroscopic behavior? The theory is used to describe electromechanical instability, and is related to recent experiments.

Friday, March 22, 2013 11:15AM - 2:15PM –

Session Z11 DPOLY: Invited Session: Nonlinear Mechanics of Glassy Polymers 310 - Robert Hoy, University of South Florida

11:15AM Z11.00001 Rate- and Temperature-Dependent Softening in Polymer Glasses , LEON GOVAERT, Eindhoven University of Technology — It is well established that physical aging in polymer glasses leads to an increase in density, elastic modulus, yield stress and also strain softening. The latter, sometimes referred to as "mechanical rejuvenation," is the phenomenon where the post-yield stress level initially decreases with further deformation until strain hardening sets in. In all constitutive models for glasses proposed until now, the rate and temperature-dependence of the yield stress is regarded to remain unchanged during strain softening. In the present study, it is demonstrated that a large number of polymer glasses (PMMA, PLLA, PS, PVC) display a pronounced change in kinetics (strain-rate dependence) after yield. The phenomenon finds its origin in the fact that, in specific ranges of temperature and strain rate, two different molecular mechanisms may contribute to the yield stress. Due to strain softening the post-yield response is only controlled by one of the two, resulting in a strain-rate and temperature dependence of the yield drop. The universality of the phenomenon is discussed in connection to the alleged influence of secondary transitions on the impact response of polymer glasses. A modification to the traditional models is proposed that enables an accurate description of the mechanical response of solid polymers in the transition range.

11:51AM Z11.00002 How deformation enhances mobility in a polymer glass , DANIEL LACKS, Case Western Reserve University — Recent experiments show that deformation of a polymer glass can lead to orders-of-magnitude enhancement in the atomic level dynamics. To determine why this change in dynamics occurs, we carry out molecular dynamics simulations and energy landscape analyses. The simulations address the coarse-grained polystyrene model of Kremer and co-workers, and the dynamics, as quantified by the van Hove function, are examined as the glass undergoes shear deformation. In agreement with experiment, the simulations find that deformation enhances the atomic mobility. The enhanced mobility is shown to arise from two mechanisms: First, active deformation continually reduces barriers for hopping events, and the importance of this mechanism is modulated by the rate of thermally activated transitions between adjacent energy minima. Second, deformation moves the system to higher-energy regions of the energy landscape, characterized by lower barriers. Both mechanisms enhance the dynamics during deformation, and the second mechanism is also relevant after deformation has ceased.

12:27PM Z11.00003 Can intrachain contributions dominate the stress response of polymer glasses under large deformation? , SHI-QING WANG, University of Akron — Polymer glasses are a structural hybrid in their mechanical responses to large deformation. The primary structure due to the short-range inter-segmental van der Waals bonds yields at small strains. In presence of chain connectivity, brittle failure may be avoided if the chain networking is adequately dense. We show in this presentation how the interplay between the primary structure and chain network dictates deformation, yielding, strain softening, strain localization and "strain hardening" during continuous uniaxial extension at room temperature of a variety of polymer glasses from the brittle (e.g., PS, PMMA) to the ductile (e.g., PC). In particular, our results identify straining of the chain network as the dominant contribution to the mechanical stress in the post-yield regimes.

1:03PM Z11.00004 A Simple Model for Yielding and Strain Hardening in Glassy Polymers , RON LARSON, University of Michigan — Strain hardening has long been an observed feature of polymer glasses in extension; explanations to date have often been phenomenological. Ediger and coworkers (Lee et al. *Science* 323, 231, 2009) have shown in experiments on PMMA glasses that, in addition to strain hardening, polymeric glasses show a remarkable non-monotonicity in the segmental relaxation time both in loading and unloading of stress. Here, we develop a simple constitutive equation that combines recent theories for yielding in simple glasses (Brader et al. PNAS, 106, 15186, 2009) to represent local segmental modes in the polymer, with a dumbbell model for the slow polymer relaxation modes. For a polymer glass under uniaxial loading, the model predicts that the liquefaction of the segmental modes permits strain hardening of the polymer modes to emerge, and once this emerges, it slows the deformation of the material under constant load enough to partially re-vitrify the segmental modes even though the sample remains under stress. In this way, the observed non-monotonicity in the segmental relaxation modes is produced. We show the extension of the work to simple shearing flows, and make (as yet) untested predictions about segmental relaxation rates in shear flows. We also show how to extend the model to include Rouse chain dynamics in place of the over-simplified dumbbell.

1:39PM Z11.00005 Impact-Induced Glass Transition in Elastomeric Coatings[1] , C.M. ROLAND, Naval Research Laboratory — When an elastomer layer is applied to the front surface of steel, the resistance to penetration by hard projectiles increases significantly. It is not obvious why a soft polymer should affect this property of metals, and most rubbers do not. However, we have found that a few are very effective; the requirement is that the polymer undergo a viscoelastic phase transition upon impact. This means that the frequency of its segmental dynamics correspond to the impact frequency. The latter is estimated as the ratio of the projectile velocity to the coating thickness, and is on the order of 10^5 s^{-1} for the experiments herein. Our data and a non-linear dynamics finite-element analysis offer support for this resonance condition as a primary mechanism underlying the penetration-resistance of elastomer-coated metal substrates. The impact-induced phase transition causes large energy absorption, decreasing the kinetic energy of the impacting projectile. However, this energy absorption only accounts for about half the enhanced stopping power of the elastomer/steel bilayer. An additional mechanism is lateral spreading of the impact force, resulting from the transient hardening of the elastomeric during its transition to the glassy state – the modulus of the rubber increases 1000-fold over a time period of microseconds. The penetration-resistance is a very nonlinear function of the coating thickness. Moreover, tests on various metals show that hardness is the principal substrate parameter controlling the contribution of the coating.

Session Z12 DMP GERA FIAP: Focus Session: Thermoelectric Magnetothermoelectric Magnetocaloric 314 - David Singh, Oak Ridge National Laboratory

11:15AM Z12.00001 Enhanced thermoelectric properties via oxygen non-stoichiometry in La_2NiO_4 and $SrTiO_3$, VICTOR PARDO, ANTIA S. BOTANA, Departamento Fisica Aplicada, Universidade Santiago de Compostela, Spain, PAUL M. BACH, VICTOR LEBORAN, FRANCISCO RIVADULLA, CIQUS, Universidade Santiago de Compostela, Spain, DANIEL BALDOMIR, Departamento Fisica Aplicada, Universidade Santiago de Compostela, Spain — We present the results of transport properties calculations and experiments on various oxides. A large enhancement of the thermoelectric properties is predicted[1] via ab initio calculations for $La_2NiO_{4+\delta}$, with electronic-only thermoelectric figure of merit (zT) values exceeding unity for oxygen excess $\delta \leq 0.10$. The effects of lattice strain (caused, e.g. by growth of thin films on different substrates) enhance even further the thermoelectric response. A similar result is obtained at very low electron-doping in bulk $SrTiO_3$ via oxygen removal. This is analyzed experimentally via thermal annealing that depletes oxygen ($\sim$ 1 oxygen vacancy per 10^6 unit cells). In both these systems, the increase in conductivity reached in the metallic limit retains a large thermopower, with the corresponding enhancement of zT. In the case of $SrTiO_3$, experiments indicate[2] that such a small oxygen vacancy level reduces drastically the thermal conductivity by introducing random scattering centers. In the talk, we will discuss the electronic structure origin of the enhancement of the thermoelectric response and how this can be tuned. Results are general and applicable to other non-stoichiometric oxides.

[2]arxiv:1211.1615.

11:27AM Z12.00002 Thermometry and power sensing with SNS proximity structures , RUSSELL LAKE, JOONAS GOVENIUS, VILLE PIETILÄ, KUAN YEN TAN, MIKKO MÖTTÖNEN, COMP Centre of Excellence, Department of Applied Physics, Aalto University, Finland — We present our experimental progress on thermometry employing the superconductor proximity effect in a normal-metal (N) mesoscopic wire between two superconducting (S) electrodes. We have fabricated Al/Au/Al SNS structures with junction lengths in the diffusive transport regime and performed electrical measurements between 300 K and 8 mK. Temperature dependence of the differential resistance shows sensitivity at the millikelvin level at a bath temperature of 8 mK. Specifically, the shape of the proximity effect induced dip in the differential resistance at zero current-bias serves as a direct probe of the N wire temperature. We show that the energy scale of proximity superconductivity in the N wire can be controlled by changing the wire length or by applying a perpendicular magnetic field to tune the temperature detection range. Results are discussed in terms of the temperature and resolving power noise for a thermometer and a power meter, respectively.

11:39AM Z12.00003 Chemical Pressure Effect and Dimer Formation in $(Ba,Sr)Ni_2As_2$ Solid Solutions[1] , TYLER DRYE, SHANTA SAHA, JOHNPIERRE PAGLIONE, Center for Nanophysics and Advanced Materials, Department of Physics, University of Maryland-College Park — Although both $BaNi_2As_2$ and $SrNi_2As_2$ form in $ThCr_2Si_2$ structure, these materials display very different behaviors, owing in part to an important structural difference: while the Sr compound exhibits As-As bonds between layers, the Ba compound lacks these interlayer bonds. Thus, substitution of Sr into $BaNi_2As_2$ produces a positive chemical pressure effect on the system that pulls the NiAs layers closer together and towards As-As dimer formation. We will present the resulting phase diagram as determined by x-ray, chemical composition, electrical resistivity and magnetization measurements.

11:51AM Z12.00004 Quantifying the Local Seebeck Coefficient using Scanning Thermoelectric Microscopy (SThEM)[1] , JENNA WALRATH, YEN-HSIANG LIN, University of Michigan Department of Physics, KEVIN PIPE, University of Michigan Department of Mechanical Engineering, RACHEL GOLDMAN, University of Michigan Department of Materials Science and Engineering — Thermoelectric (TE) devices allow reliable solid-state conversion of heat to electricity. The efficiency of a TE device is determined by the figure of merit, ZT, which is sensitive to the Seebeck coefficient, S. A promising alternative to traditional macroscale measurements of S is scanning thermoelectric microscopy (SThEM), which can profile S with nm resolution [1]. In SThEM, an unheated scanning tunneling microscopy tip acts as a high-resolution voltmeter probe to measure the thermally-induced voltage, V, in a heated sample. However, the temperature (T) gradient is not localized to the sample, and the measured V is a convolution of voltages within the region of non-zero temperature gradient. Therefore we have developed a 1D Fourier heat conduction model to predict the T gradient in the tip and to deconvolute the measured V within the sample. This approach enables direct conversion between the measured V and the local S. [1] H.K. Lyeo et al., Science **303**, 816 (2004).

[1]This material is based upon work supported by the Department of Energy under Award Number DE-PI0000012. Y.H. Lin and R.S. Goldman are supported in part by the DOE under contract No. DE-FG02-06ER46339.

12:03PM Z12.00005 Profiling the Local Seebeck Coefficient with Nanometer Resolution Using Scanning Thermoelectric Microscopy (SThEM)[1] , YEN-HSIANG LIN, JENNA WALRATH, Physics, University of Michigan, RACHEL GOLDMAN, Materials Science & Engineering, University of Michigan — Thermoelectric (TE) devices offer a method of recovering waste heat through solid state conversion of heat to electricity. Nanostructured thermoelectric materials may provide the key to increased efficiencies, which are sensitive to the Seebeck coefficients (S) However, traditional bulk measurement techniques can only provide a spatially averaged measurement of S over the whole sample, which can hardly investigate the effects of nanostructures on S on the nanoscale. A novel technique known as scanning thermoelectric microscopy (SThEM) has recently been developed to measure induced thermal voltages with nanometer resolution In SThEM, an unheated scanning tunneling microscopy tip acts as a high-resolution voltmeter probe to measure the thermally-induced voltage, V, in a heated sample. Here we present a local S measurement using SThEM across an InGaAs P-N junction. The thermovoltage shows an abrupt change of sign within 10 nanometers, which reveals nanometer spatial resolution. We will discuss local S measurements of AlAs/GaAs superlattices (SLs) with various SL periods and compare the local S with scanning tunneling spectroscopy measurements, which will reveal how local electronic states influence thermoelectric properties.

[1]This material is based upon work primarily supported by DOE under grant No. DE-FG02-06 and ER46339 the Department of Energy under Award Number DE-PI0000012.

12:15PM Z12.00006 Scaling of electrical and thermal conductivities in an almost integrable chain , JOEL MOORE, CHRISTOPH KARRASCH, UC Berkeley and Lawrence Berkeley National Laboratory, RONI ILAN, UC Berkeley — Many low-dimensional materials are well described by integrable one-dimensional models such as the Hubbard model of electrons or the Heisenberg model of spins. However, the small perturbations to these models required to describe real materials are expected to have singular effects on transport quantities: integrable models often support dissipationless transport, while weak non-integrable terms lead to finite conductivities. We use translation-invariant matrix-product-state methods to obtain quantitative values of electrical and thermal conductivities in an almost integrable chain (an XXZ spin chain with staggered fields, or equivalently a spinless fermion chain with staggered on-site potentials).

12:27PM Z12.00007 Flexible thermoelectric films using the spin Seebeck effect , AKIHIRO KIRIHARA, MASAHIKO ISHIDA, HIROKO SOMEYA, NEC Corporation, KOICHI KONDO, NAOHARU YAMAMOTO, NEC Tokin Corporation, KEN-ICHI UCHIDA, EIJI SAITOH, Tohoku University, SHIGERU KOHMOTO, TOMOO MURAKAMI, NEC Corporation — Thermoelectric (TE) technologies have been of great interest, since they can directly generate electricity from thermal energy that is available in various places. For making full use of such omnipresent heat, TE devices using the spin Seebeck effect (SSE) potentially open opportunities for large-area TE applications, because of their favorable features such as a simple film structure and convenient scaling capability [1]. In this work, we show a SSE-based flexible TE device, which consists of metallic and magnetic-insulator films on a 25-um-thick polyimide substrate. Novel fabrication processes enabled us to form the magnetic insulator, having a good spin-current-conduction property for the SSE, on the highly flexible organic film. Such flexible TE sheets are readily implementable on various curved or uneven surfaces, leading to versatile energy-harvesting and heat-sensing applications. [1] A. Kirihara, et al., Nature Mat. 11, 686 (2012).

12:39PM Z12.00008 Nonlocal thermoelectric effects and nonlocal Onsager relations in a three-terminal superconducter/ferromagnet proximity system[1] , MATTHIAS ESCHRIG, Royal Holloway, University of London, PETER MACHON, WOLFGANG BELZIG, University of Konstanz, Germany — Heterostructures of ferromagnets and superconductors are presently subject of intense study since they show interesting phenomena based on the singlet-triplet conversion of pairing amplitudes at the interfaces, and the resulting spin-dependent proximity effect. Spectacular examples are long-range triplet Josephson currents due to inhomogeneous magnetic order, or due to the spin-dependence of the interface reflection and transmission amplitudes, which were confirmed in a set of pivotal experiments in 2010. Here, we study thermal and charge transport in a three-terminal setup consisting of a superconducting and two ferromagnetic contacts. We predict that the simultaneous presence of spin-filtering and of spin-dependent scattering phase shifts at each of the two interfaces will lead to giant non-local thermoelectric effects both in clean and in disordered systems. The symmetries of thermal and electric transport coefficients are related to fundamental thermodynamic principles by the Onsager reciprocity. Our results show that a non-local version of the Onsager relations for thermoelectric currents holds in a three terminal quantum coherent ferromagnet-superconductor heterostructure including spin-dependent crossed Andreev reflection and coherent electron transfer processes.

12:51PM Z12.00009 Magneto Themoelectric Generator with Carbon Nanotube Thermal Interfaces , PATRICK T. MCCARTHY, TIMOTHY S. FISHER, School of Mechanical Engineering and Birck Nanotechnology Center, Purdue University, 1205 West State Street, West Lafayette, IN 47907, USA, ERNESTO E. MARINERO, School of Materials Engineering, Purdue University 701 West Stadium Avenue, West Lafayette, IN 47907 and HGST San Jose Research Center, 3404 Yerba Bue — We report the thermal behavior of Gd foils used in a magneto thermoelectric generator cells. The device exploits the ferromagnetic phase transition of gadolinium to drive the movement of a diaphragm "shuttle" whose mechanical energy is converted to electrical form and which enhances heat transfer through both conduction and convection. Efficient heat transfer at mechanical interfaces is critical to increase shuttle speed and the commensurate rate of heat transfer. The synthesis and characterization of carbon nanotube thermal interfaces for the Gd foils are described. The samples generated in this study were consistently measured with total thermal interface resistances in the range of 65–105 mm^2 K/W, a reduction of 55–70% compared to bare Gd ($R_{int} \sim 230$ mm^2 K/W). The addition of carbon nanotube arrays did not alter the magnetic properties of the gadolinium foils and only a slight decrease in the magnetic moment of the gadolinium samples (8–13%) was measured after growth.

1:03PM Z12.00010 Thermomagnetic effects in elemental rare-earth single crystals[1]

, AUDREY M. CHAMOIRE[2], JOSEPH P. HEREMANS[3], The Ohio State University — Thermomagnetic properties and magnetothermal conductivity of elemental rare-earth (R-E) metals are for the first time systematically presented from 80 to 400 K. Measurements are given with heat flux applied along the [100] and the [111] directions since R-E present mainly a hexagonal symmetry at room temperature. This work is motivated by the complex Fermi surfaces of the R-E's and by their magnon contributions to the thermal conductivity. Elemental rare-earths are multicarrier systems involving electron (e) and hole (h) pockets and have a very small thermopowers (S), which can result in large Nernst coefficients. This would be suitable for transverse Nernst cooler since they could be used as a single material with a particular design, then resolving the problems of contact resistances of actual Peltier coolers where materials need to be cascaded. Magnetic field dependent thermal conductivity is used to extract magnon heat conduction. Magnons are bosons, but unlike acoustic phonons they can have energy gaps. Taken together, these two properties should theoretically lead to a non-linear thermal conductivity in the presence of a magnetic field gradient.

1:15PM Z12.00011 Magnetic refrigeration capabilities of magnetocaloric Ni2Mn:75Cu:25Ga[1]

, S.K. MISHRA, C.A. JENKINS, Advanced Light Source, Lawrence Berkeley National Laboratory, Berkeley, CA 94720, I. DUBENKO, T. SAMANTA, N. ALI, Department of Physics, Southern Illinois University, Carbondale, IL 62901, S. ROY, Advanced Light Source, Lawrence Berkeley National Laboratory, Berkeley, CA 94720 — Doping-driven competition between energetically similar ground states leads to many exciting materials phenomena such as the emergence of high-T_c superconductivity, diluted magnetic semiconductors, and colossal magnetoresistance. Doped Ni_2MnGa Heusler alloy, which is a multifunctional ferromagnetic alloy with various exotic physical properties demonstrates this notion of rich phenomenology *via* modified ground spin states. Adopting this generic concept, here we will present a novel doped $Ni_2Mn_{.75}Cu_{.25}Ga$ alloy that offers unprecedented co-existence of the magnetocaloric effect and fully controlled ferromagnetism at room temperature. Application of site engineering enables us to manipulate the ground spin state that leads to the decrease in magnetic transition temperature and also increases the delocalization of the Mn magnetism. SQUID magnetometery suggests that Cu doping enhances the saturation magnetization, coercive field and clarity of magnetic hysteresis loops. By exploiting x-ray absorption techniques and measuring element specific magnetic hysteresis loops, here we will describe the microscopic origin of enhnaced magnetocaloric properties and *d-d* interaction driven charge transfer effects in $Ni_2Mn_{.75}Cu_{.25}Ga$

1:27PM Z12.00012 First successful growth of magnetic thin films of meta-stable monoclinic $Gd_5(Si_xGe_{1-x})_4$

, DAVID C. JILES, RAVI L. HADIMANI, Iowa Sate University, IKENNA C. NLEBEDIM, Iowa State University, Ames Laboratory US DoE, YEVGEN MELIKHOV, Cardiff University, DEPARTMENT OF ELECTRICAL AND COMPUTER ENGINEERING, IOWA STATE UNIVERSITY TEAM, AMES LABORATORY, US DOE. IOWA STATE UNIVERSITY TEAM, WOLFSON CENTRE FOR MAGNETICS, CARDIFF UNIVERSITY TEAM — We report on the first successful growth of magnetic thin films of the giant magnetocaloric material $Gd_5(Si_xGe_{1-x})_4$. This material has been widely studied for its unusual properties including the coupled magnetic-structural phase transition. We report on the successful growth of films of $Gd_5Si_{2.09}Ge_{1.91}$ that can be used in micro-cooling applications. The film was grown by Pulsed Laser Deposition (PLD) on a (001) silicon wafer deposited at 200°C from a polycrystalline target. PLD was achieved using a femtosecond laser with a repetition rate of 1kHz, pulse energy of up to 3.5mJ. The deposited film thickness was $\sim$ 400nm measured using Scanning Electron Microscopy and the composition of the film was analyzed using Energy Dispersive Spectroscopy and found to be close to the target composition. Magnetic measurements were carried out in a SQUID magnetometer. Magnetic moment vs. magnetic field measurement confirmed that the film was ferromagnetic at 200K. The transition temperature of the film was measured from magnetic moment vs. temperature measurements using inflection point. Transition temperature was measured at 280K which was close to the 1^{st} order phase transition temperature of bulk material.

1:39PM Z12.00013 Strain induced ferromagnetism and magnetocaloric effect in LaFe2Si2 thin film

, GUIXIN CAO, GERMAN SAMOLYUK, SIWEI TANG, LIANG QIAO, WENBIN WANG, JIEYU YI, THOMAS ZAC WARD, MICHAEL BIEGALSKI, WOLTER SIEMONS, DAVID MANDRUS, MALCOLM STOCKS, ZHENG GAI, Oak Ridge National Laboratory — Great interest in magnetic refrigeration techniques based on the magnetocaloric effect (MCE) has grown recently due to its high efficiency and environmental friendliness. Although the thin film form of the materials is very important in both application and fundamental research, as the properties of films can be tailored by parameters like epitaxial strain, studies on MCE in single crystal films are limited by the difficulty of the growth. In this work, LaFe2Si2 thin films are successfully tuned from Pauli paramagnetic to ferromagnetic, and MCEs are observed around 50K. The ferromagnetic transition is a first order transition, and the magnetic entropy $\Delta S \approx$-8.5 J/Kg K is obtained under a magnetic field of 7T. The magnetocaloric effect is characterized by a 14 K hysteresis in the field cooling and field warming process. Our temperature dependent X-ray measurements exclude the correlation between the striking MCE of the thin film and structural transition. Density functional theory (DFT) calculations indicate that the strain induced distance variations of Si-Fe bonds control the magnitude of the magnetic moment and MCE.

1:51PM Z12.00014 Entropy changes and the caloric effects in $R_5Si_2Ge_2$ (R=Gd and Tb)[1]

, NILSON DE OLIVEIRA, Universidade do Estado do Rio de Janeiro — It has been experimentally shown that at ambient pressure, the compound $Gd_5Si_2Ge_2$ undergoes a first order transition with giant magnetocaloric effect around this room temperature. Experimental data also show that an applied pressure increases the critical temperature of this compound and keeps the first order phase transition. On the other hand, experimental data show that the compound $Tb_5Si_2Ge_2$ undergoes a second order phase transition with a normal magnetocaloric effect around 100 K. It has also been shown that an applied pressure increases its critical temperature without changing the order of the phase transition. In this work, we calculate the magnetocaloric and barocaloric effects in and $Gd_5Si_2Ge_2$ and $Tb_5Si_2Ge_2$. For this purpose, we use a model of localized magnetic moments including the magnetoelastic interaction. In the model, the order of the phase transition is controlled by the ratio between the exchange interaction and the magnetoelastic coupling parameter. Our calculations show that these compounds exhibit large values of the entropy changes upon pressure variation in good agreement with the available experimental data.

2:03PM Z12.00015 Energy-harvesting at the Nanoscale[1]

, ANDREW JORDAN, University of Rochester, BJÖRN SOTHMANN, University of Geneva, RAFAEL SÁNCHEZ, Instituto de Ciencia de Materiales de Madrid (ICMM-CSIC), MARKUS BÜTTIKER, University of Geneva — Energy harvesting is the process by which energy is taken from the environment and transformed to provide power for electronics. Specifically, the conversion of thermal energy into electrical power, or thermoelectrics, can play a crucial role in future developments of alternative sources of energy. Unfortunately, present thermoelectrics have low efficiency. Therefore, an important task in condensed matter physics is to find new ways to harvest ambient thermal energy, particularly at the smallest length scales where electronics operate. To achieve this goal, there is on one hand the miniaturizing of electrical devices, and on the other, the maximization of either efficiency or power the devices produce. We will present the theory of nano heat engines able to efficiently convert heat into electrical power. We propose a resonant tunneling quantum dot engine that can be operated either in the Carnot efficient mode, or maximal power mode. The ability to scale the power by putting many such engines in a "Swiss cheese sandwich" geometry gives a paradigmatic system for harvesting thermal energy at the nanoscale.

Session Z14 GMAG: Permanent Magnet Materials 316 - George Hadjipanayis, University of Delaware

11:15AM Z14.00001 Magnetic Hardening of $Ce_2Fe_{14-x}Co_xB$, J.F. HERBST, E.J. SKOUG, M.S. MEYER, F.E. PINKERTON, GM R&D Center — Permanent magnets based on $R_2Fe_{14}B$ (R = rare earth element) are essential to a wide variety of applications, among them automotive traction motors. Current state-of-the-art materials rely on R = Nd and Dy, both of which are currently subject to supply and cost instability. A possible alternative is R = Ce, the most abundant rare earth, but $Ce_2Fe_{14}B$ has several disadvantages, including a low Curie temperature (T_c) that restricts the maximum operating point to well below that required for some applications. Given that substitution of Co for Fe is known to enhance T_c significantly in other $R_2Fe_{14}B$ compounds, we systematically investigate magnetic hardening of $Ce_2Fe_{14-x}Co_xB$ by melt spinning alloys having compositions guided by our previous work on the Ce-Fe-B system. We find the range of Co solubility in $Ce_2Fe_{14}B$ to be markedly lower than for other $R_2Fe_{14}B$ materials, a consequence of the fact that $Ce_2Co_{14}B$ apparently does not form.

11:27AM Z14.00002 Mechanochemical synthesis of $(Sm,Pr)_2(Co,Fe)_{17}$ powders for nanocomposite permanent magnets[1] , GEORGE HADJIPANAYIS, ALEXANDER GABAY, WANFENG LI, University of Delaware — Bottom-up fabrication of nanocomposite permanent magnets with enhanced maximum energy product requires large quantities of high-coercivity powder with crystallographically anisotropic particles tens of nanometers in size. In this work, we report a systematic study aimed to employ combination of intensive mechanical milling and calciothermic reduction for preparation of polydispersed $(Sm,Pr)_2(Co,Fe)_{17}$ powders with a predominant-to-significant part of the particles smaller than 100 nm. In addition to the effects of Pr and Fe on the hard magnetic properties of the particles, the study analyzes the influence of excess reducing agent Ca and that of the heat treatment on the particle size distribution, their chemical/structural homogeneity and crystallographic anisotropy. Emphasized is the likely role of the excess Ca facilitating the diffusion-enabled particle growth. Remanent magnetization up to 106 emu/g and intrinsic coercivity up to 14 kOe were obtained.

[1]The work was supported by DOE ARPA-E under grant DE-AR0000046.

11:39AM Z14.00003 High Coercivity Anisotropic Nd2Fe14B Nanoparticles Produced by Planetary Ball Milling[1] , OZLEM KOYLU-ALKAN, GEORGE C. HADJIPANAYIS, Department of Physics and Astronomy, University of Delaware, Neark, DE, USA, DIMITRIS NIARCHOS, IMS, Demokritos, Athens, Greece — The bottom-up fabrication of anisotropic exchange-coupled nanocomposites brings out the necessity of fabrication of magnetically hard nanoparticles with high coercivity. In this study, we have fabricated $Nd_2Fe_{14}B$ nanoparticles from die-upset Nd-Fe-B (MQ3) precursor materials using planetary milling. The MQ3 alloy consists of platelets which are approximately 80 nm in thickness and 500 nm in diameter. Using planetary ball milling we were able to produce $Nd_2Fe_{14}B$ nanoparticles with a size down to 20 nm. However, the size distribution of the milled particles is very broad ranging between 20 nm and 20 μm. A sedimentation experiment was used to separate the different size particles. By allowing bigger particles to sediment in a viscous liquid, we were able to separate different size nanoparticles with a size smaller than 200 nm. The coercivity of particles is found to decrease with particle size. After 60 min sedimentation the collected particles had an average size 100 nm with a coercivity value of 5.4 kOe. The objective of this study is to obtain nanoparticles with a size below 100 nm and a coercivity greater than 10 kOe for the fabrication of anisotropic exchange-coupled nanocomposites.

11:51AM Z14.00004 Synthesis of $CeFe_{10.5}Mo_{1.5}$ with $ThMn_{12}$-Type Structure by Melt Spinning[1] , CHEN ZHOU, MEDA Engineering and Technical Services LLC, MISLE TESSEMA, Optimal CAE Inc., MARTIN MEYER, FREDERICK PINKERTON, GM R and D Center — Rare earth compounds $RFe_{12-x}M_x$ with tetragonal $ThMn_{12}$-type structure are of great interest for potential applications as permanent magnets. These materials serve as precursors for nitriding and hydriding, processes which can dramatically increase the Curie temperature, spontaneous magnetization, and affect the magnetic anisotropy. We report the phase study of $CeFe_{10.5}Mo_{1.5}$ samples melt spun at various surface wheel speeds v_s between 5 and 60 m/s. The results from quantitative Rietveld analysis indicate that the as-spun ribbons are a mixture of primary $CeFe_{10.5}Mo_{1.5}$ phase with impurity phases such as Ce_2Fe_{17}, Fe-Mo compound and $CeFe_2$. At wheel speeds v_s below 25 m/s, $CeFe_{10.5}Mo_{1.5}$ phase accounts for greater than 85 wt%, while the Fe-Mo compound is the only detectable impurity phase. Above v_s = 25 m/s, as the wheel speed increases, $CeFe_{10.5}Mo_{1.5}$ phase decreases monotonically to about 60 wt% at v_s = 60 m/s while the amounts of impurity phases increase. Thermogravimetric measurement indicates that the Curie temperature T_c of the $CeFe_{10.5}Mo_{1.5}$ phase is 340 K. As a result, the best performing sample melt spun at v_s =15m/s only exhibits an energy product BH_{max} =0.121 MGOe at room temperature. Although such a number is modest for a permanent magnet, nitriding is expected to greatly enhance the Curie temperature, and hence the magnetic performance.

12:03PM Z14.00005 Giant magnetic anisotropy in $Li_{3-x}Fe_xN$ permanent magnets[1] , ANTON JESCHE, SRINIVASA THIMMAIAH, SERGEY BUD'KO, PAUL CANFIELD, The Ames Laboratory, Iowa State University, Ames, USA — Single crystals of $Li_2(Li_{1-x}Fe_x)N$ were successfully grown out of Li-flux. Fe-concentrations and lattice parameters were determined by means of single crystal and powder diffraction which also confirmed the substitution of Fe on only one of the Li sites resulting in $Li_{1-x}Fe_x$ layers separated by Li_2N layers. Magnetization measurements revealed a ferromagnetically ordered ground state with Curie temperatures of ~ 60 K for Fe concentrations of $x \approx 20\%$. Large saturation moments of up to $5\,\mu_B$ per Fe atom were found along the hexagonal crystallographic c-axis. These values exceed the spin-only contribution of Fe and are also reflected in correspondingly large effective moments at room temperature. The anisotropy field at $T = 2$ K, defined as intersection of the magnetization for $M \parallel c$ and $M \perp c$, can be estimated to lie well beyond 100 Tesla. Electrical resistivity measurements show insulating behavior and raise questions about the nature of the underlying magnetic exchange mechanism.

[1]This work is supported by the US DOE, Basic Energy Sciences under Contract No. DE-AC02-07CH11358.

12:15PM Z14.00006 Combinatorial search of rare-earth free permanent magnets , TIEREN GAO, ICHIRO TAKEUCHI, SEAN FACKLER, LEI FANG, University of Maryland, YING ZHANG, MATTHEW KRAMMER, IVER ANDERSON, BILL MCCALLUM, Ames Laboratory, UNIVERSITY OF MARYLAND COLLABORATION, AMES LABORATORY COLLABORATION — Permanent magnets play important roles in modern technologies such as in generators, motors, speakers, and relays. Today's high performance permanent magnets contain at least one rare earth element such as Nd, Sm, Pr and Dy. However, rare earth elements are increasingly rare and expensive, and alternative permanent magnet materials which do not contain them are needed by the industry. We are using the thin film composition spread technique to explore novel compositions of permanent magnets without rare-earth. Ternary co-sputtering is used to generate composition spreads. We have thus far looked at Mo doped Fe-Co as one of the initial systems to search for possible compounds with enhanced coercive fields. The films were deposited on Si (100) substrates and annealed at different temperatures. The structural properties of films are mapped by synchrotron diffraction. We find that there is a structural transition from a crystalline to an amorphous state at about 20% atomic Mo. With increasing annealing temperature, the Mo onset concentration of the structural transition increases from 25% for 600°C to 35% for 700°C. We find that some of compounds display enhanced coercive field. With increasing Mo concentration, the magnetization of Fe-Co-Mo begins to switch from in-plane to out-of-plane direction. This work is funded by the BREM (Beyond Rare-earth Magnet) project (DOE EERE).

12:27PM Z14.00007 Electronic structure and equation of state of Sm_2Co_{17} from first-principles DFT+U[1] , PATRICK HUANG, NICHOLAS P. BUTCH, JASON R. JEFFRIES, SCOTT K. MCCALL, Physical and Life Sciences Directorate, Lawrence Livermore National Laboratory — Rare-earth intermetallics have important applications as permanent magnet materials, and the rational optimization of their properties would benefit greatly from guidance from ab initio modeling. However, these systems are particularly challenging for current electronic structure methods. Here, we present an ab initio study of the prototype material Sm_2Co_{17} and related compounds, using density functional theory with a Hubbard correction for the Sm $4f$-electrons (DFT+U method) and ultrasoft pseudopotentials. The Hubbard U parameter is derived from first principles [Cococcioni and de Gironcoli, PRB 71, 035105 (2005)], not fit to experiment. Our calculations are in good agreement with recent photoemission measurements at ambient pressure and the equation of state up to 40 GPa, thus supporting the validity of our DFT+U model.

[1]Prepared by LLNL under Contract DE-AC52-07NA27344.

12:39PM Z14.00008 Effects of pressure on the sturctural and magnetic properties on Sm based permanent magnets[1] , SCOTT MCCALL, NICHOLAS BUTCH, JASON JEFFRIES, PATRICK HUANG, Lawrence Livermore National Laboratory — The magnetic properties of the rare earth-transition metal permanent magnets are sensitive to interatomic spacing and can be tuned by adjusting these parameters. We report the effects of high pressure on the crystal structure and magnetic properties of Sm_2Co_{17} and Sm_2Fe_{17} measured in diamond anvil cells.

[1]This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.

12:51PM Z14.00009 Site-preference and valency for rare-earth sites in (R-Ce)2Fe14B [R=La,Nd] magnets[1] , AFTAB ALAM, Ames Laboratory, Ames Iowa, MAHMUD KHAN, Ames Laboratry, Ames Iowa, R.W. MCCALLUM, D.D. JOHNSON, Ames Laboratory and Iowa State University, Ames Iowa — Rare-earth (R) permanent magnets of R2Fe14B have technological importance due to their high energy products, and they have two symmetry distinct R-sites (Wyckoff 4f and 4g) that affect chemistry and valence. Designing magnetic behavior and stability via alloying is technologically relevant to reduce critical (expensive) R-content while retaining key properties; cerium, an abundant (cheap) R-element, offers this potential. We calculate magnetic properties and Ce site preference in (R1-xCe_x)Fe14B [R=La,Nd] using density functional theory (DFT) methods. The Fe moments compare well with neutron scattering data – remain weakly affected by Hubbard U, but improved with spin-orbit coupling. In (La,Ce)2Fe14B, Ce alloys for $0 < x < 1$ with a preference for smaller R(4f) sites, as observed, a trend we find unaffected by valence. Whereas in (Nd,Ce)2Fe14B, Ce is predicted to have limited alloying ($x < 0.3$) with a preference for larger R(4g) sites, resulting in weak partial ordering and segregation. Curie temperatures versus x were predicted for a typical sample processing and verified experimentally. We shall also present some initial results on the critical mixed valency of Ce in related compounds.

[1]Work at Ames Laboratory was supported by the U.S. Department of Energy, ARPA-E under the REACT program (0472-1526)

1:03PM Z14.00010 Nucleation-Mode Localization in Hard-Soft Nanocomposites[1] , RALPH SKOMSKI, BALAMURUGAN BALASUBRAMANIAN, BHASKAR DAS, D. J. SELLMYER, Department of Physics and Astronomy and NCMN, University of Nebraska — Aligned hard-soft nanocomposites continue to be an active research area in permanent magnetism, challenged by demanding processing requirements but also encouraged by experimental proofs of principle. The approach was initially outlined by Kneller and Hawig (1991), who advocated hard-soft multilayers. Skomski and Coey (1993) considered three-dimensional nanostructures, such as soft spheres in a hard matrix, and predicted an upper energy-product limit of about 1000 kJ/m^3. It is well-established that the dimensions of the soft regions cannot be larger than twice the domain-wall width of the hard phase, but otherwise it was believed that geometry has a rather secondary effect. However, our recent research reveals substantial differences. Soft-in-hard geometries are better than hard-in-soft geometries and embedded soft spheres are better than multilayers. This is in close analogy to the dimensionality-dependent quantum-mechanical delocalization of electrons in an inhomogeneous potential and to the behavior of impurity states in the band gaps of solids. Transparent analytical nucleation-field solutions are found for some geometries and in the limit of very small soft inclusion as a function of the hard-phase coercivity and hysteresis-loop shape.

1:15PM Z14.00011 Frequency dependence of Verdet constant of Bismuth-Doped Rare-Earth Iron Garnets for Magneto-Optic Sensor Applications , MANNIX SHINN, U.S. Naval Research Laboratory, RONGJIA TAO, Temple University, DONG HO WU, ANTHONY GARZARELLA, U.S. Naval Research Laboratory — There is growing interest in applying magneto-optic materials toward sensor applications. One of these applications is to exploit the Faraday Effect to measure magnetic fields. Bismuth-doped rare-earth iron garnets have proven to be highly sensitive Faraday rotators, but their frequency response and dynamic range to magnetic fields require further study. The Faraday Effect was studied in two samples of bismuth-doped rare-earth iron garnets grown in different conditions, and experiments were performed in a static field as well as in a RF field. Static magnetic fields up to 3 kG were used, and we found that the Faraday rotation became saturated at high fields, indicating that the field dependence follows the hyperbolic tangent function. We extracted each sample's Verdet constant from the Faraday rotation at low magnetic fields of < 0.1 kG. These experiments were repeated using different laser probe beam wavelengths, ranging from 405 nm to 2000 nm. We measured the transmission coefficient and the Verdet constant for each sample for different probe beam wavelengths and for an external magnetic field at various frequencies. We will discuss the implication of our experimental results.

1:27PM Z14.00012 Magnetism in Mo-doped Yttrium Iron Garnet , S. KHANRA, Missouri State University, Y. KOLEKAR, University of Pune, M. LANGHOFF, P. KAHOL, K. GHOSH, Missouri State University — Yttrium iron garnet (YIG) is a synthetic garnet and ferrimagnetic, with chemical formula $Y_3Fe_5O_{12}$. In YIG, five iron (III) ions occupy two octahedral and three tetrahedral sites, with the yttrium (III) ions coordinated by eight oxygen ions in an irregular cube. The iron ions in the two coordination sites exhibit different spins, resulting in magnetic behavior. Bulk YIG has been synthesized systematically by solid state reaction method. The formation of pure YIG have been investigated through X-ray diffraction (XRD) beginning from weighing in molar proportions of Y_2O_3 and Fe_2O_3, mixing and grinding, pre-sintering and final sintering at 1300 °C. XRD study shows that YIG exhibits cubic structure with lattice constant of about 12 Å. Magnetization with varying field and temperature has been measured using a SQUID magnetometer. Magnetic measurement of Mo YIG has shown that magnetic moment increase initially and then decreases with Mo doping. Detailed results will be discussed in this presentation. This work is supported by National Science Foundation (Award Number DMR-0907037).

1:39PM Z14.00013 Local imaging of the phase transition in single crystal $Nd_2Fe_{14}B$[1] , MAGDALENA HUEFNER, ADAM PIVONKA, CUN YE, MARTIN BLOOD-FORSYTHE, Harvard University, RUSLAN PROZOROV, PAUL CANFIELD, Ames Laboratory and Iowa State University, JENNIFER HOFFMAN, Harvard University — The magnetic microstructure of hard magnets is of interest for immediate industrial applications and for fundamental understanding of the relationship between microscopic and macroscopic magnetic properties in materials. Of particular interest is $Nd_2Fe_{14}B$, which shows strong anisotropy with an easy axis along the c-axis at room temperature, but undergoes a phase transition around T$\sim$135K to an easy cone magnetization where the magnetic moments are canted away from the c-axis. Here we present magneto-optical Kerr effect (MOKE) and magnetic force microscope (MFM) measurements to investigate the spin-reorientation phase transition in single crystal $Nd_2Fe_{14}B$. The MFM measurements resolve a continuous change in the domain structure from rounded flower-shaped domains of a lateral extent $\sim$200 nm-$\sim$7μm to larger rectangular features of typical width $\sim$1μm and length $\sim$10μm-$\sim$30μm. By imaging the same surface area in small temperature steps across the phase transition we track the evolution of single features.

1:51PM Z14.00014 Magnetization and scanning tunneling spectroscopy studies of $Mn_{1.5}Ga$ films on GaAs(001) , JAESUK KWON, XIN ZHANG, JOHN HATCH, ARCHANA KUMARI, HUI XING, PAYAM TAHERIROSTAMI, HAO ZENG, Physics Department of University at Buffalo, The State University of New York, JEFFREY COGSWELL, JOSEPH A. GARDELLA, Chemistry Department of University at Buffalo, The State University of New York, HONG LUO, Physics Department of University at Buffalo, The State University of New York — Hard magnetic materials have applications in permanent magnets and data storage media. Free of rare earth elements, $L1_0$ structured $Mn_{1.5}Ga$ with high magnetic anisotropy is a potential candidate for such applications. Epitaxial films of $Mn_{1.5}Ga$ with different thicknesses (35 nm – 200 nm) were grown on GaAs(001) by molecular beam epitaxy. Films with thicknesses of 35 nm and 50 nm present uniform surface morphology which consists of overlapping rectangular features with widths and lengths on the order of a few tens to a few hundred nanometers. Measurements of X-ray diffraction reveal the presence of an interfacial layer of Mn_2As between the substrate and $L1_0$ $Mn_{1.5}Ga$. The 200 nm thick film presents a mixture of two different surface structures: domains which consist of faceted tent-like structures and domains with flat terraces (with lateral dimensions of about 500 nm). The magnetic properties of all samples are studied by vibrating sample magnetometer and their correlation with their surface morphology and stoichiometry will be presented. Scanning tunneling spectroscopy measurements of the 200 nm thick $Mn_{1.5}Ga$ film reveal electrical inhomogeneity correlated to the two morphologies. This work was supported by NSF DMR1006286.

2:03PM Z14.00015 Magnetic anisotropy of strained MnGa alloys , RENAT SABIRIANOV, NABIL AL-AQTASH, University of Nebraska at Omaha — MnGa is a promising candidate for Rare Earth free permanent magnet applications because it has a large magnetocrystalline anisotropy. We examine the variation of the magnetocrystalline anisotropy of these alloys as function of bi-axial in-plane strain using ab-initio electronic structure calculations. We employed force theorem to calculate the MAE=E(||)-E($\perp$) as difference of energies of the system with magnetization along and perpendicular to the easy axis. Using projector augmented wave method implemented in VASP we have calculated MAE in MnGa, Mn_3Ga and $Mn_{1+x}Ga_{1-x}$ alloys. We find that the MAE is 2.5MJ/m^3 (0.42meV/u.c.) and 0.12MJ/m^3 (0.07meV/u.c.) in unstrained MnGa and Mn_3Ga, respectively. MAE decreases if bi-axial strain is applied in MnGa. Thus, the anisotropy of this system can be affected by the strain. We also discuss the effect of Mn disorder on MAE in $Mn_{1+x}Ga_{1-x}$ alloys.

Session Z15 GMAG DMP: Focus Session: Frustrated Systems: Artificial and Disordered 317 -

John Cumings, University of Maryland

11:15AM Z15.00001 Two-Dimensional Magnetic Correlations and Partial Long-Range Order in Geometrically Frustrated Sr_2YRuO_6 , EDUARDO GRANADO, UNICAMP - Univ. Estadual de Campinas, JEFFREY W. LYNN, NIST Center for Neutron Research, RENATO F. JARDIM, USP - Univ. de Sao Paulo, MILTON S. TORIKACHVILI, San Diego State University — Geometrically frustrated magnets are fascinating materials displaying a rich variety of physical states. The simplest three-dimensional structure leading to frustrated magnetism and the first one to be investigated is the face-centered cubic (FCC) lattice with antiferromagnetic nearest-neighbor interactions. Sr_2YRuO_6 is a particular example of this, crystallizing in the ordered double perovskite structure with the Ru^{5+} ions defining an FCC magnetic network. Neutron diffraction experiments were performed on this material, revealing planar magnetic correlations that condense into a partial long-range ordered state with coupled alternate antiferromagnetic (AFM) $YRuO_4$ square layers coexisting with the short-range correlations below $T_{N1} = 32$ K. A second transition to a fully ordered AFM state below $T_{N2} = 24$ K is observed. The reduced dimensionality of the spin correlations in an FCC lattice is arguably due to a cancellation of the magnetic coupling between consecutive AFM square layers. The interesting magnetic phenomena observed here in Sr_2YRuO_6 are entirely driven by its lattice geometry, and may also occur in other FCC antiferromagnets.

11:27AM Z15.00002 Neutron Scattering Study of the Double Perovskite FCC Antiferromagnet Ba_2YRuO_6 , J.P. CARLO, Villanova University, J.P. CLANCY, University of Toronto, K. FRITSCH, C.A. MARJERRISON, McMaster University, G.E. GRANROTH, Oak Ridge National Laboratory, H.A. DABKOWSKA, B.D. GAULIN, McMaster University — Magnetic cations in the rock-salt ordered double perovskite structure comprise a geometrically frustrated FCC network of edge-sharing tetrahedra. Previous measurements of the $4d^3$ Ru^{5+} system Ba_2YRuO_6 [1] indicated the existence of long-range commensurate antiferromagnetic order below T_N = 36K, a factor f $\sim$ 15 lower than the Curie-Weiss temperature Θ_W = -522K. We report time-of-flight neutron spectroscopy of Ba_2YRuO_6 confirming the existence of the long-range ordered state below T_N. The magnetic inelastic scattering extends over a bandwidth of $\sim$ 15 meV, and develops a $\sim$ 5 meV gap at the [100] magnetic ordering wavevector at and below T_N. Strong spin-orbit coupling in this $4d^3$ system is expected to result in a j_{eff}=3/2 magnetic moment. This is distinct from the $4d^1$, j_{eff}=3/2 moment which arises in its sister antiferromagnetic FCC compound, Ba_2YMoO_6, which displays an apparent singlet ground state and a $\sim$ 28 meV singlet-tripet gap at low temperatures [2], matching its —Θ_W— $\sim$ 300K. [1] T. Aharen et al. Phys. Rev. B 80, 134423 (2009). [2] J. P. Carlo et al. Phys. Rev. B 84, 100404(R) (2011).

11:39AM Z15.00003 Phase diagram of split 2D dipolar spin ice , TOMMASO ROSCILDE, LOUIS-PAUL HENRY, Ecole Normale Superieure de Lyon — Long-ranged dipolar interactions, which are very natural in artificial square-lattice spin ice, can mask some of the most relevant aspects of spin-ice physics, as they remove the extensive degeneracy of the ground state manifold to give a unique ground state, and they bind monopole pairs into localized spin flips. Following an earlier idea of G. Möller and R. Moessner [Phys. Rev. Lett. 96, 237202 (2006)] we investigate how adding a third direction to square ice allows to recover fundamental traits of spin-ice physics even in the presence of dipolar interactions. Using Monte Carlo simulations based on a generalized loop algorithm, we explore the phase diagram of square dipolar spin ice in which horizontal and vertical dipoles are spatially separated in a third direction (split 2D spin ice). As a function of the splitting we recover a two-fold degenerate staggered state for coplanar dipoles, and a four-fold degenerate "Manhattan" state for strongly split dipoles, separated by a first order transition. The competition between the two states at intermediate splitting leads to a strong suppression of the ordering transition temperatures, and makes space for the observation of a hallmark of spin-ice physics in the paramagnetic phase: pinch points in the static structure factor.

11:51AM Z15.00004 Phase diagram of quantum square ice , LOUIS-PAUL HENRY, PETER HOLDSWORTH, Ecole Normale Supérieure de Lyon, France, FREDERIC MILA, Ecole Polytechnique Fédérale de Lausanne, Switzerland, TOMMASO ROSCILDE, Ecole Normale Supérieure de Lyon, France — We have investigated the ground-state and finite-temperature phase diagram of quantum square ice - realized by the transverse-field Ising model on a checkerboard lattice - using both linear spin-wave (LSW) theory and quantum Monte Carlo (QMC). We generalize the model with different couplings between nearest (J_1) and next-to-nearest (J_2) neighbors on the checkerboard lattice. Our QMC approach generalizes the loop algorithm - very efficient in the study of constrained classical systems - to a "brane algorithm" for quantum systems. At the LSW level the vast degeneracy of the ground-state for $J_1 = J_2$ and $J_2 > J_1$ remains intact; moreover LSW theory breaks down in extended regions of the phase diagram, pointing at non-classical states [1]. Our QMC study goes beyond perturbative schemes and addresses directly the nature of the low-temperature phases. We have critically examined the possibility of a resonating-plaquette state for $J_1 = J_2$, suggested by degenerate perturbation theory on the ice-rule manifold for weak fields. Our QMC results for finite fields confirm the absence of Néel or collinear order, but they do not confirm the presence of resonating-plaquette order, pointing at a possibly more complex non-classical state.

12:03PM Z15.00005 Resonant dynamics of Dirac monopoles and strings in an artificial spin-ice lattice , OLLE HEINONEN, Argonne National Laboratory, SEBASTIAN GLIGA, Max Planck Institute - Halle, ATTILA KAKAY, Peter Gruenberg Institute - Forschungszentrum Juelich, RICCARDO HERTEL, IPCMS, CNRS and UdS, France — Spin ices can occur in atomic structures, in which the magnetic interaction with neighboring vertices cannot be simultaneously minimized at each atomic vertex, leading to frustration. Artificial spin-ice lattices are arrays of patterned elements geometrically arranged to mimic the frustration in such atomic lattices, and have the advantage that their properties are directly observable using microscopy techniques. Artificial spin-ices can support topological defects, such as Dirac monopoles and Dirac strings connecting the monopoles. We present micromagnetic simulations of the resonant dynamics of a square spin-ice lattice. The simulations predict that topological defects give rise to specific signatures in the excitation spectrum of the lattice and that, moreover, the amplitude of a defect-specific resonant peak increases linearly with the number of defects or length of the Dirac line. A measured spectrum therefore allows to both identify the defects in an array as well as to determine their number. In addition, we observe that the main bulk-like FMR spectral peak is split in the presence of defects in the lattice, compared to a defect-free reference state. This splitting is caused by Dirac strings, in which the FMR frequency is increased due to the different magnetostatic coupling of the elements within a string as compared to the rest of the lattice.

12:15PM Z15.00006 Magnon lifetime in the easy-plane antiferromagnets[1] , ALEXANDER CHERNYSHEV, University of California, Irvine, MICHAEL ZHITOMIRSKY, CEA, Grenoble — Considering a prototypical 2D easy-plane antiferromagnet on a square lattice in which gapped excitations coexist with acoustic spin waves, we find that random disorder induces a relaxation of the gapped magnon with the rate that greatly exceed the effect of conventional magnon-magnon scattering. Anomalous disorder-induced T-dependence of the energy gap of the optical magnon and of the scattering rate of the acoustic magnon are also discussed. These can be readily probed by the high-resolution neutron-resonance spin-echo technique. Implications for other systems are discussed and comparison with the available experimental data is presented.

12:27PM Z15.00007 Magnetic enhancement and cluster-glass behavior in $(Sc_{1-x}Er_x)_{3.1}In$[1] , ETERI SVANIDZE, EMILIA MOROSAN, Rice University, MOROSAN QUANTUM MATERIALS LAB TEAM — Sc_3In is a weak itinerant ferromagnet with no magnetic constituents. In this talk, we will present DC and AC magnetization data on $Sc_{3.1}In$ doped with Er^{3+} local moment ions. As x increases in $(Sc_{1-x}Er_x)_{3.1}In$, the Weiss temperature nearly triples up to $x \leq 0.1$. The effective moment per formula unit is larger than the simple sum of the itinerant moment in pure $Sc_{3.1}In$ and the Er^{3+} local moment. Moreover, Er doping of as little as $x = 0.02$ induces a cluster-glass state. The glassy behavior persists up to $x = 0.1$, and a structural transition likely occurs for higher doping levels.

[1]This work is supported by NSF DMR 0847681

12:39PM Z15.00008 Spin Glass Phase in the Disordered Spin Systems , NVSEN MA, DAO-XIN YAO, Sun Yat-Sen University, ANDERS SANDVIK, Boston University — We use quantum Monte Carlo simulations to study a glassy ground state of S = 1/2 quantum spins by using a dimerized J1-J2-J3 Heisenberg model on the square lattice. J1 corresponds to weak bonds, and J2 and J3 are stronger bonds which are randomly distributed on columnar rungs forming coupled 2-leg ladders. By tuning the average value of J2 and J3, the system undergoes Neel glass paramagnetic quantum phase transition. The size of the glass region is affected by the value of the disorder strength. In the glass phase, we find that the uniform susceptibility decreases with T according to $exp(1/T^a)$ with $a < 1$; thus the state is incompressible at $T = 0$ and classified as a Mott glass (MG). At the Neel-MG transition, the susceptibility behaves as $T^{2/z-1}$, where z is the dynamical exponent and it is close to 1.

12:51PM Z15.00009 Microscopic Coexistence of Antiferromagnetic and Spin-Glass States[1] , SHRAVANI CHILLAL, MATTHIAS THEDE, ETH Zuerich, FRED JOCHEN LITTERST, Technische Universitaet Braunschweig, SEVERIAN GVASALIYA, ETH Zuerich, TATIANA SHAPLYGINA, SERGEY LUSHNIKOV, Ioffe Physico-Technical Institute, ANDREY ZHELUDEV, ETH Zuerich — The disordered antiferromagnet PbFe1/2Nb1/2O3 (PFN) is investigated in a wide temperature range by combining Mossbauer spectroscopy and neutron diffraction experiments. It is demonstrated that the magnetic ground state is a microscopic coexistence of antiferromagnetic and spin-glass orders. This speromagnet-like phase features frozen-in short-range fluctuations of the Fe3+ magnetic moments that are transverse to the long-range ordered antiferromagnetic spin component.

[1]This work is partially supported by the Swiss National Fund through MANEP.

1:03PM Z15.00010 Randomness effects on the distorted triangular-lattice antiferromagnets , TORU SAKAI, JAEA, SPring-8, HIROKI NAKANO, Graduate School of Material Science, University of Hyogo — The quantum spin liquid-like behaviors were observed on some distorted tirangular-lattice antiferromagnet organic compounds[1]. If the lattice vibration is much slower than the spin dynamics, the lattice distortion possibly plays a role of the bond randomness in the spin system. Thus inorder to explain the observed spin liquid behavior of the organic compound, we consider the antiferromagnetic Heisenberg model on some distorted triangular lattices with the bond randomness. Using the numerical exact diagonalization we calculated the standard spin glass order parameter, as well as the ordinary Neel order parameter. The present study suggested that the spin glass order can survive in some region where the Neel order vanishes. We will discuss a scenario of the observed spin liquid behavior of the distorted triangular-lattice antiferromagnets, based on the result. [1] Y. Shimizu, K. Miyagawa, K. Kanoda, M. Maesato and G. Saito, Phys. Rev. Lett. 91 (2003) 107001.

1:15PM Z15.00011 Frustrated antiferromagnetism in bulk Ti-doped $BiFeO_3$ ceramics , MIGUEL ANGEL GARCIA, MARA BERNARDO, TERESA JARDIEL, Dpt. Electroceramics, Institute of Ceramic and Glass, CSIC, Madrid, Spain, MARCO PEITEADO, Applied Physics Department, E.T.S.I. Telecomunicación, UPM, Madrid, Spain, FEDERICO MOMPEAN, MAR GARCIA-HERNANDEZ, Institute of Materials Science at Madrid, CSIC, Madrid, Spain, MARINA VILLEGAS, AMADOR CABALLERO, Dpt. Electroceramics, Institute of Ceramic and Glass, CSIC, Madrid, Spain — We present here a magnetic characterization of Ti-doped $BiFeO_3$ prepared by a ceramic route. A detailed analysis of the microstructure revealed that Ti^{+4} is not homogeneously distributed but partially segregated towards Ti enriched grain boundary regions that define Ti-deficient domains with a size distribution of the order of tens of nanometers. Since the size of these domains is smaller than the spin cycloid wavelength (64 nm) they hold a net magnetic moment. Consequently the material exhibits frustrated antiferromagnetism with hysteresis, coercivity and remanance. This ferromagnetic-like behavior vanishes at the Neel temperature of the $BiFeO_3$. The small magnetic moment per domain (M_S ~0.2 emu/g) yields very large coercive fields of 27 KOe at 5 K and 17 KOe at room temperature.

1:27PM Z15.00012 Modeling geometric frustration with magnetic colloids[1] , GABI STEINBACH, SIBYLLE GEMMING, ARTUR ERBE, Helmholtz-Zentrum Dresden-Rossendorf, Institute of Ion Beam Physics and Materials Research, Dresden, Germany, DENNIS NISSEN, MANFRED ALBRECHT, Institute of Physics, Chemnitz University of Technology, Chemnitz, Germany — The implementation of artificial frustrated spin systems can give insight into the mechanisms which lead to the different equilibrium configurations in geometrically frustrated magnetic materials. Prominent artificial systems are the patterns of superconducting rings or nanometer-sized ferromagnetic islands. These are Ising systems allowing two possible in-plane orientations for each macroscopic moment. Here we present an alternative method using magnetically interacting colloids. The spherical shape of the particles allows the modeling of spin systems with continuous symmetry. Micrometer-sized silica particles are half capped with a Co/Pd multilayer thin film. Such thin films on curved surfaces have a predefined net magnetic moment called macrospin. The interaction of such particles in the self-arranged close-packed 2D structure is frustrated. Using video microscopy, the direction of the individual macrospins can be visualized by the spatial orientation of the magnetic caps. This setup allows us to investigate geometric frustration in static systems and in dynamic processes, e.g. during the particle-wise cluster growth. Further, we evaluate the impact of intrinsic defects and control defect formation extrinsically e.g. by varying the growth conditions.

1:39PM Z15.00013 Effect of proton irradiation on the magnetic and magneto-transport properties of TbFeCo metglass , NATTAWUT ANUNIWAT, MANLI DING, JOSEPH POON, JIWEI LU, University of Virginia, BRAD WEAVER, Naval Research Laboratory — The ferrimagnetism in amorphous rare-earth transition metal alloys is well known, and has recently been investigated for applications in perpendicular magnetic random access memory (p-MRAM), which is considered to be a universal memory technology due to the low power dissipation and the non-volatility. The amorphous TbFeCo thin films were deposited by rf magneton sputtering. The as-deposited film exhibited a low saturation magnetization (M_S ~100 emu/cc) and a high perpendicular anisotropy (K_U ~10^6 erg/cc). Hall-bar devices were fabricated for characterizing the magneto-transport behaviors. Both thin film samples and Hall bar devices were exposed to 2 MeV-energy protons with incremental fluences. Magneto-transport and standard magnetic measurements are employed to investigate defects/displacement damages. The magneto-transport suggests that compensation temperature of the film decreases after irradiations. The changes in saturation moments and coercive fields will be discussed as a function of total fluence, which may be related to structural damages.

1:51PM Z15.00014 Heat Capacity and Magnetic Properties of NiMnIn, NiCoMnIn and NiCoMnSn Metamagnetic Materials , JING-HAN CHEN, JOSEPH H. ROSS, JR., Department of Physics and Astronomy and Materials Science and Engineering Program, Texas A&M University, N. BRUNO, J. MONROE, I. KARAMAN, Department of Mechanical Engineering and Materials Science and Engineering Program, Texas A&M University, JIANGUO LI, Department of Materials Science and Engineering, Shanghai Jiaotong University — NiMnIn and NiMnSn Heusler materials feature coupled glassy magnetic and martensitic structural transformations. Co substitution can induce a large magnetocaloric effect near room temperature with little hysteresis, leading to interest for solid-state refrigeration as well as energy recovery. Recent work has also identified NiMnIn compositions with extremely sharp coupled magnetic-structural transformations. We report thermodynamic measurements for a number of these systems. NiMnCoSn melt-spun tapes can be processed to exhibit more well-defined martensitic transformations, however we find the magnetic contributions to the heat capacity to be similar to that of bulk materials. In both cases the magnetic entropy agrees with what is expected for $J = 2$ Mn ions according to the alloy composition. A significant difference in electronic γ points to electronic differences despite the same e/a ratio. NiMnIn alloys include compositions exhibiting sharp λ-like transitions, while in bulk NiCoMnIn compositions the magnetic contribution is increased over the Mn-only value. The kinetic arrest behavior reduces the total magnetic entropy in these materials, and we also examine low-temperature anomalies as further indications of the glassy properties of these materials.

Session Z17 DMP GMAG: Focus Session: Orbital Order 319 - Despina Louca, University of Virginia

11:15AM Z17.00001 Local structure and orbital ordering in $YTiO_3$[1] , BING LI, KEESEONG PARK, SHINICHIRO YANO, DESPINA LOUCA, University of Virginia, BIAO HU, JIANSHI ZHOU, JOHN GOODENOUGH, University of Texas at Austin — $YTiO_3$, with the strongest $GdFeO_3$-typed distortion in $RTiO_3$, is a ferromagnet below T_C of 30 K and many theoretical and experimental studies suggest it is of antiferro-orbital ordering due to magnetic superexchange. Here, the local atomic structure of $YTiO_3$ has been investigated by using elastic (inelastic) neutron scattering and the (dynamic) pair density function analysis from 5 to 350 K. Deviations are observed of the local from the average crystal symmetry and these are attributed to distortions involving the Y and O atoms. In the case of Y, the in-plane $x - y$ displacements result in an antiferrodistortive motion exerting influence on Y-O1 (apical sites of octahedral) bonds seen in the temperature dependence. At the same time, the O ion site in the basal plane of the octahedron is split to two (O2 and O3), giving rise to two unequivalent Ti-O bonds, which results consequently in different tilting of basal plane of octahedra (0.5° larger in O3), A-O covalency and about 2° larger Ti-O-Ti bond angle in O3 sites. These facts may be regarded as the structural evidences on antiferro-orbital ordering in $YTiO_3$ and suggest electron-lattice interaction may play an important role in the orbital ordering, in addition to magnetic superexchange interation.

11:27AM Z17.00002 Quasiparticle mass enhancement and temperature evolution of the electronic structure in ferromagnetic $SrRuO_3$

, DANIEL SHAI, CAROLINA ADAMO, Cornell University, DAWEI SHEN, Shanghai Institute of Microsystem and Information Technology, China, CHARLES BROOKS, JOHN HARTER, ERIC MONKMAN, BULAT BURGANOV, DARRELL SCHLOM, KYLE SHEN, Cornell University — We report high-resolution angle-resolved photoemission spectroscopy (ARPES) studies of epitaxial thin films of the correlated $4d$ transition metal oxide ferromagnet $SrRuO_3$. The Fermi surface in the ferromagnetic state consists of well-defined Landau quasiparticles, exhibiting strong coupling to low-energy bosonic modes which contributes to the large effective masses observed by transport and thermodynamic measurements. Upon warming the material through its Curie temperature, we observe a substantial decrease in quasiparticle coherence, but negligible changes in the ferromagnetic exchange splitting, suggesting that local moments play an important role in the ferromagnetism in $SrRuO_3$.

11:39AM Z17.00003 Temperature-dependent photoluminescence studies of $GdTiO_3$ thin films[1]

, AMIT VERMA, Dept. of Electrical Engineering, Univ. of Notre Dame, SANTOSH RAGHAVAN, Materials Dept., University of California, Santa Barbara, VLADIMIR PROTASENKO, Dept. of Electrical Engineering, Univ. of Notre Dame, SUSANNE STEMMER, Materials Dept., University of California, Santa Barbara, DEBDEEP JENA, Dept. of Electrical Engineering, Univ. of Notre Dame — $GdTiO_3$ (GTO), a Mott-insulator, has acquired increased prominence in last few years since the discovery of a 2-dimensional electron gas (2DEG) at its heterojunction with the band-insulator $SrTiO_3$. These 2DEGs have very large electron densities ($\sim$3x10^{14} cm^{-2}) amounting to half electron per unit cell. To realize many possible applications of this large 2DEG, an understanding of the GTO bandstructure is needed. With this goal in mind, in this work we present photoluminescence (PL) studies of GTO thin films (10nm and 20nm) grown by molecular beam epitaxy (MBE) on (001) LSAT substrates. When pumped with a 325 nm He-Cd laser, we observe a red PL ($\sim$683 nm at 300K) from both GTO thin films at RT. Upon lowering the temperature from 300K to 80K, the PL peak blue shifts by $\sim$0.14eV. Interestingly, the reported activation energy of the resistivity of MBE-grown GTO thin films is also $\sim$0.14eV (Moetakef et al., J. Crystal Growth 355, 166 (2012)). We connect the observed temperature-dependent PL data with the expected electronic bandstructure and electrical resistivity, and explain the sharp transition in the peak that occurs between 120K-200K from $\sim$636nm to $\sim$683nm.

11:51AM Z17.00004 Spin Switching and Magnetization Reversal in Single-Crystal $NdFeO_3$[1]

, SHUJUAN YUAN[2], Shanghai University, China, FANG HONG, University of Wollongong, Australia, LA CHEN, YABIN WANG, WEI REN, JINCANG ZHANG, SHIXUN CAO, Shanghai University, China, GANG CAO, University of Kentucky, USA — We report results of our recent study of single-crystal $NdFeO_3$ that features a strong interaction between 3d and 4f electrons, which generates *two distinct magnetic states* ordered at 17 K and 170 K. This study reveals novel magnetic behavior that is highly sensitive to the orientation and history of magnetic field and is characterized by the following: **(1)** sharply contrasting magnetization, M(T), along the **a** and **c**-axis; **(2)** an abrupt spin-switching along the **a**-axis via a first-order transition below 17 K when the system is *zero-field-cooled*; and **(3)** a progressive magnetization reversal when the system is *field-cooled*. Such behavior suggests an exotic ground state driven by an extraordinary coupling between spin, orbit and lattice degrees of freedom.

12:03PM Z17.00005 Itinerant ferromagnetism in the oxygen-deficient $EuTiO_3$: A first-principles investigation[1]

, HAI-XIA CAO, HAI-SHUANG LU, TIAN-YI CAI, SHENG JU, Department of Physics, Soochow University — Effects of oxygen vacancy on the electronic structure and magnetism in the quantum paraelectric $EuTiO_3$ were investigated from first-principles. In contrast to antiferromagnetism in the pristine $EuTiO_3$, itinerant ferromagnetism was revealed in the oxygen-deficient $EuTiO_3$. The origin lies in the spin-polarized Ti $3d$ states, which mediate a ferromagnetic exchange interaction between almost localized Eu $4f$ spins. In addition, this ferromagnetic exchange coupling was strengthened via the partial occupation of Eu $5d$ states. These findings not only explain the observation of ferromagnetism in the unstrained $EuTiO_3$ thin films, but also demonstrate the potential application of $EuTiO_3$ in magnetoelectronics.

12:15PM Z17.00006 Spin and orbital order separation in colossal magnetoresistive transition

, M.A. HOSSAIN, SLAC National Accelerator Laboratory and Lawrence Berkeley National Laboratory, M.H. BURKHARDT, SLAC National Accelerator Laboratory, E. WESCHKE, Helmholtz-Zentrum Berlin für Materialien und Energie, E. SCHIERLE, Helmholtz-Zentrum Berlin für Materialien und Energie,, M.S. GOLDEN, Van der Waals-Zeeman Institute, University of Amsterdam, Y. TOMIOKA, National Institute of Advanced Industrial Science and Technology (AIST), Japan, Y. TOKURA, University of Tokyo, J. STÖHR, H.A. DÜRR, SLAC National Accelerator Laboratory — Understanding the Colossal magnetoresistive (CMR) process in manganites is one of the grand challenges of modern physics. While the metallic ferromagnetic phase is relatively well understood, the triggering mechanism of the metal-insulator transition is not clear and it is believed that lattice strain in term of polarons play an important role in the mysterious insulating phase. Lattice strain occurs in the charge-orbitally ordered insulating phase via the Jahn-Teller type distortion and therefore, to understand the CMR it is critical to understand the interplay of ferromagnetism and orbital order during the CMR transition itself. In this letter, with high magnetic field dependent Resonant Soft X-ray Scattering measurements, we show that during the CMR process, an insulating antiferromagnetic phase, which is extremely susceptible to magnetic field and temperature, directly competes with metallic ferromagnetism while the robust CE type spin and orbitally ordered regions act as a catalyst to seed these antiferromagnetic regions. This allows us to construct a picture of the competing forces at the heart of CMR.

12:27PM Z17.00007 Charge-ordering transitions without charge differentiation[1]

, YUNDI QUAN, University of California Davis, VICTOR PARDO, Departamento de Fisica Aplicada, Universidade Santiago de Compostela, Spain, WARREN PICKETT, University of California Davis — The distorted perovskite nickelate system $RNiO_3$ (R=rare earth except La) undergoes a metal-insulator transition (MIT) at a temperature that varies smoothly with the R ionic radius. This MIT is accompanied by structural transition which leads to two inequivalent Ni sites in the cell, and has been explained by charge ordering (CO): charge is transferred between the Ni1 and Ni2 sites in a long-range ordered fashion. Experimental data on core binding energies, ionic radii, and Mossbauer shifts are interpreted in terms of Ni cation charges of $3\pm\delta$ with, for example, $\delta \approx 0.3$ for $YNiO_3$. Making use of first principles DFT results and a new approach not invoking integration of the charge density, we find[2] that the Ni $3d$ occupation is identical (to high accuracy) for the two Ni sites. We also present results for other compounds (La_2VCuO_6, $YNiO_3$, $CaFeO_3$, $AgNiO_2$, V_4O_7), all of which have distinct "charge states" that have identical $3d$ occupation. This quantitative procedure will be discussed and some implications will be outlined.

12:39PM Z17.00008 Real Space Imaging of Phase Separation in Mangnites

, KAI DU, LIFENG YIN, JIAN SHEN, State key laboratory of surface physics and Department of Physics, Fudan University, Shanghai 200433, China — Electronic phase separation (EPS) in manganites is generally considered to be responsible for their unusual colossal magneto resistance (CMR) [1-2]. However, the dynamic behavior of EPS and the formation mechanism are still not very clear. Magnetic force microscopy (MFM) is one of the most powerful techniques which enables us to study the magnetic domains and direct image the EPS in real space without damaging the samples. In this work, we use a PPMS (Quantum Design) compatible MFM to study the magnetic domains of La0.7Sr0.3MnO3 (LSMO) thin films on NdGaO3(110) and La0.325Pr0.3Ca0.375MnO3 (LPCMO) thin films on SrTiO3 (100) grown by pulsed laser deposition technique (PLD). The LSMO system shows clear stripe domain pattern [3], while the LPCMO system exhibits large scale domains corresponding to charge-ordered insulating phase and ferromagnetic metallic phase [1]. Their transport properties were studied under a variety of temperatures and magnetic fields. The phase separation in submicron scale and their percolative transport have been confirmed by MFM images and the transport measurement during the imaging.

12:51PM Z17.00009 Effective magnetoelectric tensor of a composite material[1]

, DAVID STROUD, MEHUL DIXIT, Department of Physics, The Ohio State University, Columbus, OH 43210 — We calculate the effective magnetoelectric coefficient tensor of a composite of two single-phase magnetoelectrics in which effect of strain is unimportant. We obtain exact relations for elements of the effective magnetoelectric coefficient tensor entirely in terms of the elements of the individual components, and the composite geometry. The problem is solved by a decoupling transformation that reduces the problem to finding the effective coefficients in a composite of the *same* geometry but with two *in*dependent, curl-free fields. The decoupling transformation is found to be identical to that used in the problem of composite thermoelectrics [2]. Details of the calculation will be presented.

1:03PM Z17.00010 Growth and characterization of high crystalline quality $Co_2FeAl_xSi_{1-x}$ Heusler alloy films on $MgAl_2O_4(001)$ substrates

, BRIAN PETERS, Department of Physics, The Ohio State University, CHRISTIAN BLUM, Leibniz Institute for Solid State and Materials Research (IFW), PATRICK WOODWARD[1], The Ohio State University, SABINE WURMEHL, Leibniz Institute for Solid State and Materials Research (IFW), FENGYUAN YANG, Department of Physics, The Ohio State University — A number of Heusler alloys have been predicted to be half-metallic and are thus ideal candidates for use in spintronics. $Co_2FeAl_xSi_{1-x}$ has been predicted and shown to have some of the highest Tc, saturation magnetization and lowest magnetic damping constant among Heusler half-metals. Here we outline the growth and characterization of the highest crystalline quality epitaxial Heusler films using a novel off-axis UHV sputtering technique. We grow these films onto a closely lattice matched $MgAl_2O_4(001)$ substrate, without the need for a Cr-buffer layer or post annealing, as has been done previously. This eliminates the diffusion of Cr across the interface, thus improving the purity and crystallinity of the films at the interface. X-ray diffraction results demonstrate epitaxial films with distinct Laue oscillations and rocking curves of FWHM as low as 0.0035°, which demonstrates the highest crystalline quality for Heusler films reported to date. Magnetic measurements show highly square hysteresis loops with a remanence of 95-98%, near ideal saturation magnetization, very small coercivities - between 3-8 Oe, pronounced magnetocrystalline anisotropy.

1:15PM Z17.00011 Small bound polarons for ultrafast holography in dielectric $LiNbO_3$[1]

, MIRCO IMLAU, HAUKE BRUENING, HOLGER BADORRECK, ANDREAS BUESCHER, School of Physics, Osnabrueck University, IMLAU RESEARCH GROUP TEAM — Small bound polarons allow for hologram recording with single laser pulses and exceptional photosensitivity in nominally undoped, thermally reduced $LiNbO_3$ [1]. This new type of recording mechanism is of particular interest for the field of nonlinear and ultrafast photonics because of small bound polaron generation on the fs-scale. In this contribution we present our latest results on the emerging field of small bound polarons for fs-holography in the visible spectral range as well as the successful application of the effect for holographic imaging. The impact of two-photon absorption and nonlinear index of refraction is highlighted by studying the temporal dynamics of the diffraction efficiency as a function of time-delay between hologram recording and probing (-6 fs $< \delta t <$ 6 ns). The analysis of the temporal dynamics supports our recent approach (see Ref. [2]) to explain the build-up of the space-charge field on the sub-ps-time scale in the model of optical absorption of small polarons: optically induced polaron hopping to next-neighboring lattice sites is responsible for a fast and efficient charge transport on the nanoscale.

1:27PM Z17.00012 Atomically resolved data for oxide surface analyzed using a local crystallography analysis method

, ZHENG GAI, WENZHI LIN, K. FUCHIGAMI, T. WARD, P. SNIJDERS, J. SHEN, STEPHEN JESSE, SERGEI KALININ, ARTHUR BADDORF, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, Oak Ridge, TN 37831, USA — The emergent physical phenomena of oxides have attracted increasing scientific attention. Here, we report an approach for studying local surface chemistry and order parameter fields based on a local crystallographic analysis of scanning probe microscopy data of oxide surfaces. We obtained initial estimated atom locations by finding the centroid of the remaining isolated regions of pixels, after applying thresholds to the topographic images. Then we determined the refined positions by automatically fitting each atom individually using a shape function. With the refined locations, we can further derive and quantify properties that are not readily clear in the topographic images. This approach was applied to analyze scanning tunneling microscopy data for the surface of La5/8Ca3/8MnO3 (001) and demonstrated distortion domains with different distortion orientations. These studies provide a new pathway to extract and quantify local properties for scanning probe microscopy images. Research was supported (W.L., S.V.K.) by the U.S. Department of Energy, Basic Energy Sciences, Materials Sciences and Engineering Division. This research was conducted at and supported by (Z.G., S.J., A.P.B.) the Center for Nanophase Materials Sciences, which is sponsored at Oak Ridge National Laboratory by the Scientific User Facilities Division, Office of Basic Energy Sciences, U.S. Department of Energy.

1:39PM Z17.00013 Electronic structure and strain-induced Lifshitz transition in epitaxial Ba_2RuO_4 thin films as studied by ARPES , BULAT BURGANOV, CAROLINA ADAMO, DANIEL SHAI, ANDREW MULDER, MASAKI UCHIDA, JOHN HARTER, CRAIG FENNIE, DARRELL SCHLOM, KYLE SHEN, Cornell University — We employ oxide molecular beam epitaxy and *in situ* ARPES to synthesize epitaxial thin films of Ba_2RuO_4, which is isostructural and isoelectronic to the unconventional superconductor Sr_2RuO_4, and characterize its Fermi surface topology and multiorbital quasiparticle dynamics. Although Ba_2RuO_4 cannot be synthesized as bulk single crystals, we epitaxially stabilize thin films on $TbScO_3$ or $SrTiO_3$ substrates. We report a full parametrization of the band structure and compare our results to first-principles calculations as well as our data on Sr_2RuO_4. Unlike in Sr_2RuO_4 we do not observe a surface reconstruction in line with our expectations for the larger Ba cations. We use ARPES to demonstrate that the combination of a larger cation radius, together with epitaxial strain, can be employed to drive a Lifshitz transition in the d_{xy}-like γ band from electron-like in Sr_2RuO_4 to hole-like in Ba_2RuO_4. The ability to control the Fermi surface topology by epitaxial strain is a promising tool for investigating the role of the near-E_F van Hove singularity in superconductivity and magnetism in ruthenates, as well as a general tool for controlling and studying correlated electronic materials.

1:51PM Z17.00014 Conducting states caused by a surface electric dipole in CrN(001) very thin films , ANTIA S. BOTANA, VICTOR PARDO, DANIEL BALDOMIR, Departamento de Física Aplicada, Universidade de Santiago de Compostela, E-15782 Campus Vida s/n, Santiago de Compostela, Spain, PETER BLAHA, Institute of Materials Chemistry, Vienna University of Technology, Getreidemarkt 9/165-TC, A-1060 Vienna, Austria — The changes in the electronic structure of oxides and other correlated compounds caused by electronic reconstructions at their surface and interfaces has attracted much attention recently. CrN shows a magnetostructural phase transition as a function of temperature and controversial electronic properties. It has been argued recently that, with the onset of antiferromagnetic order, CrN as a bulk is always semiconducting, but very close to a metal-insulator transition [1]. In order to check if a small perturbation in the system could drastically change its conduction properties, we have performed electronic structure calculations for CrN in a thin film geometry within the LDA+U method. For thin films with increasing thickness (4-10 layers) starting with a critical thickness of 10 (cubic symmetry) or 6 layers (orthorhombic) the gap closes and conducting states appear. The appearence of metallic states is connected with a structural relaxation at the surface, where Cr (N) atoms buckle inside (outside) forming an effective surface dipole moment. Being CrN a low-gap system, these electric dipoles at the surface are able to shift the bands around the Fermi level significantly enough to drive those thin films metallic.

Session Z18 DMP FIAP GMAG: Focus Session: Spin-torque and Related Magnetic Oscillations

320 - Robert McMichael, National Institute of Standards and Technology

11:15AM Z18.00001 Decoherence and mode-hopping in spin-torque oscillators , PRANABA KISHOR MUDULI[1], Department of Physics, University of Gothenburg, 41296 Gothenburg, Sweden — A Spin Torque Oscillator (STO) is a nano-sized magneto-resistive device that can produce microwave signals in the GHz range as a result of spin transfer torque [1, 2]- a phenomena which is receiving increasing importance in contemporary spintronics research both for fundamental spin physics as well as a number of possible microwave applications e.g., oscillator, detectors and modulators. A very important question, both for fundamental physics as well for applications, is what limits the coherence time of the STO. This is a subject of significant interest recently. Until now theoretical studies have investigated decoherence through thermal noise assuming that only a single mode is excited [3]. On the other hand, experiments clearly show both the existence of multiple modes and persistent mode-hopping between several modes. The impact on coherence time of such mode-hopping has been largely unexplored and a theoretical study of its origin is entirely lacking. In this work, we will present first ever systematic experimental investigations of mode hopping, and its impact on the coherence time in a magnetic tunnel junction based spin torque oscillator [4]. We will discuss micromagnetic simulations and a theoretical treatment to show that the non-conservative fields due to finite damping-either positive or negative (spin torque) -couple individual modes and, in the presence of thermal noise, govern the experimentally observed mode-hopping. Using quantitative analysis of both coherence and dwell times, we will show that mode-hopping could be a limiting factor for STO coherence. Finally we show how our theoretical treatment can be extended to the case of a metallic nanocontact based STO, where anomalous temperature dependence of linewidth is found as result of the mode coupling [5].

11:51AM Z18.00002 Influence of Interlayer Exchange Coupling and Exchange Bias on the Ferromagnetic Resonance Spectra[1] , DIRK BACKES, New York University, BARTEK KARDASZ, Spin Transfer Technologies, JUERGEN LANGER, Singulus Technologies AG, ANDREW D. KENT, New York University — We present a study of the influence of exchange bias and exchange coupling on the shape and width of ferromagnetic resonance (FMR) spectra. Such interactions are employed in pinned synthetic antiferromagnets (SAF), layer stacks in which two ferromagnetic layers are antiferromagnetically coupled due to interlayer exchange coupling (IEC). One of the ferromagnetic layers shares an interface with an antiferromagnet, thus pinning its magnetization due to the exchange bias (EB) effect. It has been shown that quantitative values for the IEC and EB interactions can be determined from FMR dispersion relations [1]. In this work we study how these interactions manifest themselves in the peak intensities and line widths of FMR spectra. For this we adjust the strength of exchange bias and IEC by varying the thickness of PtMn and Ru in PtMn/ 2 CoFe/ Ru/ 2.3 CoFeB layer stacks (thicknesses in nm). We investigate various cases: i) presence or absence of an exchange bias field, combined with different kinds of IEC: ii) strong and weak antiferromagnetic, weak parallel, and no coupling. [1] D. Backes et al., JAP 111, 07C721 (2012).

12:03PM Z18.00003 Spin torque nanooscillators: new applications in information processing[1] , FERRAN MACIA, ANDREW D. KENT, FRANK C. HOPPENSTEADT, New York University — Nanonometer scale electrical contacts to ferromagnetic thin films (STNOs) can provide sufficient current densities to excite magnetic-moment dynamics resulting in emission of short wave-length spin waves. We discuss several applications of spin-wave patterns created from STNOs and their interaction with background oscillations. We review how to encode information in STNOs signals −modulating their amplitude, frequency or phase− and stability against noise. We first model arrays of STNOs in extended ferromagnetic thin films and define conditions to control spin-waves emission directions. We also study arrays of oscillators in patterned ferromagnetic thin films and we put forward a method to build an STNO lookup tables or an STNO based network analyzer. Using spin waves complements digital semiconductor technologies and offers new possibilities for increased memory capacity and computation performance.

12:15PM Z18.00004 Microwave emission by a spin Hall nano-oscillator[1] , RONGHUA LIU, WENG L. LIM, SERGEI URAZHDIN, Department of Physics, Emory University, Atlanta, GA 30322 — In a recently developed class of spintronic devices, the spin Hall effect (SHE) produces a pure spin current controlling the magnetization of ferromagnets. While SHE opens possibilities for new material combinations and device geometries, it also requires innovative approaches to device engineering. We demonstrate coherent microwave generation by a spintronic nanodevice that utilizes local injection of spin current generated by SHE into an extended magnetic film to generate magnetization oscillations, and anisotropic magnetoresistance of the magnetic layer to convert the oscillations into a microwave signal. We will describe our measurements of the dependence of spectral characteristics of the oscillations on current, temperature, and magnetic field. The dependence on current was remarkably similar to the spin-valve nano-oscillators. However, the dependence on temperature was different from the traditional magnetic nano-oscillators, indicating a significant temperature dependence of both the magnetization dynamics and the SHE.

12:27PM Z18.00005 Spintronics r.f. oscillator driven by magnetic field feedback , ASHWIN TULAPURKAR, Department of Electrical Engineering, Indian Institute of Technology-Bombay, Mumbai 400076, India, DINESH DIXIT, Department of Physics, Indian Institute of Technology-Bombay, Mumbai, India, KATSUNORI KONISHI, Graduate School of Engineering Science, Osaka University, Toyonaka, Osaka, Japan, C.V. TOMY, Department of Physics, Indian Institute of Technology-Bombay, Mumbai, India, YOSHISHIGE SUZUKI, Graduate School of Engineering Science, Osaka University, Toyonaka, Osaka, Japan — Magnetic tunnel junctions (MTJ) can be used as nano-scale rf oscillators using spin-transfer torque effect. Here we present an alternative novel mechanism of "magnetic field feedback" for driving MTJs into precessional states. To realize this effect, MTJ needs to be fabricated on top of a co-planar wave-guide. A dc current is passed through MTJ to produce a fluctuating voltage across it as a combination of thermal fluctuations of free layer and magneto-resistance effect. This voltage is applied across co-planar wave-guide to create a fluctuating magnetic field which acts on the free layer to enhance its fluctuations. If the dc current exceeds a critical value, precessional states of free layer are excited. We have derived expression for the critical current using lineralized LLG equation, modified to include the "feedback" magnetic field. We have verified the feedback effect by numerical simulation of stochastic LLG equation including random magnetic field: we find that the damping of the free layer can be increased/decreased by applying –ve/+ve dc current. Simulations show that by applying dc current more than critical current, large amplitude oscillations with high quality factors are possible.

12:39PM Z18.00006 Parallel pumping instabilities of spin wave modes in a nanodisk , ROBERT MCMICHAEL, Center for Nanoscale Science and Technology, NIST, FENG GUO, Center for Nanoscale Science and Technology, NIST and Maryland Nanocenter, University of Maryland, LYUBA BELOVA, Department of Materials Science and Engineering, Royal Institute of Technology, Stockholm — The confined spin wave modes in a magnetic nanostructure are fundamental to the magnetization dynamics, and the majority of studies of these spin waves have used uniform transverse pumping fields to excite the modes. However, our recent ferromagnetic resonance force microscopy measurements have shown that parallel pumping reveals a richer set of resonances than the more conventional transverse pumping. This talk presents measurements and micromagnetic modeling of the parallel pumping process in a 500 nm diameter 25 nm thick Permalloy disk with fields applied in plane. In the experiments, the linear, transversely pumped spectrum at 5.2 GHz is simple, with a main resonance at 38 mT applied field and a weaker mode at 54 mT. At a doubled excitation frequency of 10.4 GHz and high pumping power, five resonances are excited by parallel pumping. Two of these resonances occur at the same fields as the modes observed under transverse pumping, but the most intense mode is one that does not appear in the transverse spectrum. The modeling results show similar behavior, and also provide images of the excited modes. The lowest thresholds for parallel pumping belong not to the nearly uniform "main" precession mode, but to standing waves that propagate along the field direction.

12:51PM Z18.00007 Evidence for non-local damping in individual nano structures with a single magnetic layer , HANS NEMBACH, JUSTIN SHAW, CARL BOONE, TOM SILVA, Electromagnetics Division, National Institute of Standards and Technology, Boulder, CO 80305 — The spin excitation damping α in nanomagnets is a critical parameter for switching in STT-MRAM because the required power depends on α^2. We experimentally demonstrate that intralayer spin-pumping is a significant source of damping. Ferromagnetic resonance spectra were measured by heterodyne magneto-optical microwave microscopy for individual Ni80Fe20 nanomagnets down to 100 nm. Micromagnetic simulations show that one spin-wave mode, i.e. the "center-mode," is distributed throughout the nanomagnet, whereas the two "end-modes" are localized at the ends. α is found to increase for the "center-mode" with decreasing nanomagnet size but shows the opposite trend for the "end-modes." It was proposed that dissipative transverse spin-currents can increase α. Calculations of this additional damping are in agreement with the experimental data. We also used micromagnetics to test the hypothesis that an area of increased damping close to the edges of the nanomagnets forms during patterning. Such simulations predict that α for both spin-wave modes increases with decreasing size of the nanomagnets, contrary to our experimental observations. Thus, we conclude that non-local contributions to α are the dominant mechanism for size-dependence of α.

1:03PM Z18.00008 Ferromagnetic resonance (FMR) spin-pumping in FM/I/NM heterostructures , YONG PU, C. DU, H. WANG, R. ADUR, A. BERGER, J. BEARDSLEY, A. HAUSER, The Ohio State University, P. ODENTHAL, A. SWARTZ, R. KAWAKAMI, University of California-Riverside, J. PELZ, E. JOHNSTON-HALPERIN, F. YANG, P.C. HAMMEL, The Ohio State University — The recent demonstration of the injection of a pure spin current via ferromagnetic resonance (FMR) in the FM electrode, spin-pumping, with no need for an accompanying charge current, promises low-power high-efficiency spin injection in a wide variety of materials. Here we report the demonstration of FMR spin-pumping in Ferromagnet/Insulator/Non-magnetic materials heterostructures via different spin detection techniques, and characterizations of the dynamically injected spin. Our investigation proves the possibility that one can both utilize the advantages of FMR spin-pumping, and simultaneously overcome the well-known resistance mismatch problem, which usually happens for spin injection through a FM/NM direct contact and drastically suppresses the efficiency of spin injection into NM. Furthermore, by individually and systematically varying the magnetic, electrical and mechanical properties of each element of the FM/I/NM heterostructures, we are able to study the fundamental mechanisms for FMR spin-pumping, e.g. coupling range and strength, and role of and interplay between spin, charge, lattice, magnon and phonon degree of freedoms.

1:15PM Z18.00009 Numerical study of spin-dependent transition rates within pairs of dipolar and exchange coupled spins with (s=1/2) during magnetic resonant excitation[1] , MARK LIMES, JINQI WANG, WILLIAM BAKER, SANG-YUN LEE, BRIAN SAAM, CHRISTOPH BOEHME, University of Utah — The effect of dipolar and exchange interactions within pairs of paramagnetic electronic states on Pauli-blockade-controlled spin-dependent transport and recombination rates during magnetic resonant spin excitation is studied numerically using the superoperator Liouville-space formalism. The simulations reveal that spin-Rabi nutation induced by magnetic resonance can control transition rates which can be observed experimentally by pulsed electrically (pEDMR) and pulsed optically (pODMR) detected magnetic resonance spectroscopies. When the dipolar coupling exceeds the difference of the pair partners' Zeeman energies, several nutation frequency components can be observed, the most pronounced at $\sqrt{2}\gamma B_1$ (γ is the gyromagnetic ratio, B_1 is the excitation field). Exchange coupling does not significantly affect this nutation component; however, it does strongly influence a low-frequency component $< \gamma B_1$. Thus, pEDMR/pODMR allow the simultaneous identification of exchange and dipolar interaction strengths.

1:27PM Z18.00010 Configurational Dependence of the Magnetization Dynamics in Spin Valve Systems[1] , RUSLAN SALIKHOV, RADU ABRUDAN, FRANK BRUESSING, KURT WESTERHOLT, HARTMUT ZABEL, Ruhr-Universitaet Bochum, FLORIN RADU, Helmholtz-Zentrum Berlin, ILGIZ A. GARIFULLIN, Zavoisky Physical-Technical Institute Kazan — Spin current related phenomena in F1/N/F2 spin valve heterostructures, where F is a ferromagnetic layer and N is a nonmagnetic metal layer, are important in modern magnetism. Spin valve theory predicts a spin pumping effect with a precessional relaxation rate that depends on the configuration of F1 and F2 [1]. Using time-resolved x-ray resonant magnetic scattering we report on the precessional dynamics of spin valve systems with parallel (P) and antiparallel (AP) orientation. We observe in Co/Cu/Py spin valve systems an increase of the magnetic damping parameter in Py with changing magnetization direction of Py and Co layers from P to AP orientation [2]. Furthermore we studied the temperature dependence of the spin pumping effect and possible other causes for the configurational dependence of the damping parameter, such as domain wall induced coupling or magnetic dipole coupling [3]. The main focus is on Co/Cu/Py and on Co_2MnGe/V/Py trilayers with spin valve properties.

1:39PM Z18.00011 Domain-wall-controlled transverse spin injection , REMBERT DUINE, Utrecht University — We propose an effect whereby a charge current accross a domain wall in a magnetic wire injects a transverse pure spin current in an adjacent normal metal. We compute how this effect may be measured via inverse spin Hall effect detection, and consider its effect on enhancement of spin transfer.

1:51PM Z18.00012 Magnetic Bloch Oscillations in 1D ferromagnets , OLAV SYLJUÅSEN, SERGEY SHINKEVICH, University of Oslo — Domain-walls in certain 1D ferromagnets can oscillate when exposed to a static magnetic field. Such magnetic Bloch oscillations have however not been observed experimentally to date. We have calculated neutron scattering signatures of magnetic Bloch oscillations for the material $CoCl_2 \cdot 2H_2O$, and investigated numerically the possibility of using a laser to generate such oscillations at low temperatures. Our results are positive, and may be used to assist the experimental search for magnetic Bloch oscillations.

2:03PM Z18.00013 Spin-Wave Generation by DW Collision , SEONGHOON WOO, TRISTAN DELANEY, GEOFFREY BEACH, Massachusetts Institute of Technology (MIT) — Spin waves (SWs) in nanoscale metallic ferromagnets have generated much recent interest. Micromagnetic simulations have shown that SWs can couple to and propel DWs by exciting internal resonances, and this effect could be used as a means of low-power DW manipulation. However, generating and detecting large-amplitude exchange-mode SWs is challenging due to their very short wavelengths, which cannot be directly excited by. Here we show, through micromagnetic (OOMMF) simulations, that DWs can be used both to efficiently generate and detect exchange-mode SWs. We first examine SW emission resulting from field-driven DW collisions in Permalloy nanowires. DW annhilation generates intense SW bursts that almost uniformly populate the available SW spectrum across a broad frequency range. The SW power spectrum was characterized as a function of nanowire width, DW topology, and driving field used to induce DW collision. SW bursts were detected through their influence on a third DW pinned at a notch a fixed distance from the DW collision point. SWs induced DW depinning in the presence of background field significantly below the DW depinning field in the absence of SW excitations. The reduction in depinning field dropped with distance between the collision point and the pinned DW, consistent with the decay length due to Gilbert damping. These results show DWs can act as efficient sources of large-amplitude SWs, which can be detected by their influence on a nearby DW. The design of experiments to test these predictions will be discussed.

11:15AM Z19.00001 Tuning thermoelectric power factor by crystal-field and spin-orbit couplings in Kondo lattice materials[1] , SEUNGMIN HONG, POUYAN GHAEMI, University of Illinois at Urbana-Champaign, JOEL MOORE, University of California, Berkeley, and Lawrence Berkeley National Laboratory, PHILIP PHILLIPS, University of Illinois at Urbana-Champaign — We study thermoelectric transport at low temperatures in correlated electron materials, motivated by the recent observation of a high thermoelectric figure of merit(ZT) in $FeSb_2$ at $T \sim 10K$. Even at room temperature, correlations have the potential to lead to high ZT, as in $YbAl_3$, one of the most widely used thermoelectric metals. At low temperature correlation effects are especially worthy of study because fixed band structures are unlikely to give rise to the very small energy gaps $E_g \sim 5K$ necessary for a weakly correlated material to function efficiently at low temperature. We explore the possibility of improving the thermoelectric properties of correlated Kondo insulators through tuning of crystal field and spin-orbit coupling and present a framework to design more efficient low-temperature thermoelectrics based on our results.

11:27AM Z19.00002 Quantum Oscillations of Nitrogen Atoms in Uranium Nitride[1] , S.E. NAGLER, A.A. ACZEL, G.E. GRANROTH, D.L. ABERNATHY, Quantum Condensed Matter Division, Oak Ridge National Laboratory, W.J.L. BUYERS, Canadian Neutron Beam, Center, National Research Council, G.J. MACDOUGALL, Department of Physics, University of Illinois, G.D. SAMOLYUK, G.M. STOCKS, Materials Science and Technology Division, Oak Ridge National Laboratory — The quantum harmonic oscillator is among the very few soluble fundamental models in quantum mechanics and the foundation for understanding phonons in crystalline solids. Inelastic neutron scattering typically reveals acoustic and optic one phonon modes at low energies, and as energy increases a complex continuum of many-phonon excitations. In contrast, measurements using chopper spectrometers at the SNS have shown that for the binary crystal uranium nitride, where the nitrogen atoms are very light compared to the uranium atoms, the response above the optic phonon modes exhibits a remarkable spectrum of well-defined local levels that are equally spaced by 50 meV intervals and that extend to the tenth order 500 meV. The levels are attributed to nearly isotropic, quantum harmonic oscillator behavior of the nitrogen atoms vibrating within a largely static uranium cage. See Nature Communications 3, 1124 (2012).

[1]Work at SNS supported by the US Department of Energy, Office of Basic Energy Sciences, Scientific User Facilities Division and

11:39AM Z19.00003 First-principles study of the Kondo physics of a Pu impurity in a Th host[1] , JIAN-XIN ZHU, Los Alamos National Laboratory, Los Alamos, New Mexico 87545, K. HAULE, Rutgers University, Piscataway, New Jersey 08854, R.C. ALBERS, J.M. WILLS, Los Alamos National Laboratory, Los Alamos, New Mexico 87545 — From the viewpoint of condensed matter physics properties, crystal structure, and metallurgy, plutonium is the most complicated element in the Periodic Table, including a phase diagram with six allotropic phases. Its anomalous properties are related to the special position of Pu in the Periodic Table, which is at the boundary of the light actinides that have itinerant $5f$ electrons and the heavy actinides with localized $5f$ electrons, indicative of a very strongly correlated state. To reveal the role of electronic correlations in Pu, we investigate the electronic structure of a Pu atom embedded in a Th host by combining density functional theory within the local density approximation with the continuous-time quantum Monte Carlo simulation of a Pu impurity. As a hallmark of electronic correlations, the Kondo resonance peak around the Fermi energy is obtained in the local density of states on the Pu impurity. Furthermore, we show that the resonance peak width is narrower for Pu atoms that are at the surface of Th than when compared to those in the bulk, due to a weakened Pu $5f$-ligand hybridization in the former geometry.

11:51AM Z19.00004 Electron Spin Resonance in Antiferro-Quadrupolar Ordered CeB_6[1] , PEDRO SCHLOTTMANN, Florida State University — CeB_6 is a *cubic* heavy fermion compound with a Γ_8 ground-quartet with antiferro-quadrupolar (AFQ) order below 4 K. An ESR signal was observed [1] in the AFQ phase. Single ions with a Γ_8 ground-multiplet should display four transitions, but only one resonance was observed. Several fundamental questions arise: (1) why is only one transition seen, (2) why was this transition observed if the Kondo temperature is larger than the linewidth of the resonance, and (3) can the resonance be explained with localized moments or is an itinerant picture of heavy electron spins necessary? The interplay of AFQ and ferromagnetic correlations on the phase diagram, the magnetization and the ESR linewidth are discussed [2]. In contrast to other Yb and Ce heavy fermion systems displaying an ESR signal, CeB_6 does not have strong magnetic anisotropy with ferromagnetic correlations, rendering an observable narrow resonance [3,4]. The AFQ state is necessary for an ESR signal in the present case [2].

12:03PM Z19.00005 Heavy antiferromagnetic phases in Kondo lattices , ILYA VEKHTER, LEONID ISAEV, Louisiana State University — We propose a microscopic physical mechanism that stabilizes coexistence of the Kondo effect and antiferromagnetism in heavy-fermion systems. We consider a two-dimensional quantum Kondo-Heisenberg lattice model and show that long-range electron hopping leads to a robust antiferromagnetic Kondo state. By using a modified slave-boson mean-field approach we analyze the stability of the heavy antiferromagnetic phase across a range or parameters, and discuss transitions between different phases. We also address connection to experiments on heavy fermion compounds.

12:27PM Z19.00007 Possible Itinerant Moment Contributions to the Magnetic Excitations in Gd, Studied by Neutron Spectroscopy[1] , G.E. GRANROTH, A.A. ACZEL, J.A. FERNANDEZ-BACA, S.E. NAGLER, Oak Ridge National Laboratory — Many experimental features in magnetic superconductors are also present when these complex materials are in the normal state. Therefore studies of simpler itinerant magnets may help provide understanding of these phenomena. We chose to study Gd as it is has an $\sim 0.6\mu_B$ itinerant moment in addition to a $\sim 7.0\mu_B$ localized moment. The SEQUOIA spectrometer, at the Spallation Neutron Source at Oak Ridge National Laboratory, was used in fine resolution mode with E_i=50 meV neutrons, to measure the magnetic excitations in a 12 gm ^{160}Gd single crystal. The crystal was mounted with the $h0l$ plane horizontal and rotated around the vertical axis to map out the excitations. The measured magnetic structure factor for the acoustic modes in the $hh0$ direction has an intensity step at $h \sim 0.3$. Electronic band structure calculations (W. M. Temmerman and P. A. Sterne, J. Phys: Condes. Matter,**2**, 5529 (1990)) show this Q position to be near several band crossings of the Fermi surface. A detailed analysis, including instrumental resolution, is presented to clarify any relationship between the magnetic structure factor and the electronic band structure.

Session Z21 FIAP: Solid State Lighting and Other Semiconductors 323 - Angelo Mascarenhas, National Renewable Energy Laboratory

11:15AM Z21.00001 Interplay of polarization fields and Auger recombination in the efficiency droop of nitride light-emitting diodes[1] , EMMANOUIL KIOUPAKIS, Department of Materials Science and Engineering, University of Michigan, QIMIN YAN, CHRIS G. VAN DE WALLE, Materials Department, University of California, Santa Barbara — The wider adoption of solid-state lighting is hampered by the significant efficiency reduction of nitride light-emitting diodes (LEDs) at high power. Although Auger recombination has been shown to contribute to this efficiency loss, many of the supporting studies focused on bulk materials. In contrast, LEDs consist of quantum wells that exhibit polarization fields, which strongly influence the recombination rates. We use Schrodinger-Poisson calculations in order to investigate the effect of polarization fields in nitride quantum wells on the carrier recombination rates and the efficiency of nitride LEDs. Our results demonstrate that both the efficiency-droop and green-gap problems can be attributed to the combined effect of Auger recombination and the spatial separation of electrons and holes induced by the polarization fields. Our results show that the suppression of polarization fields is a promising solution to improve the high-power efficiency of nitride LEDs.

11:27AM Z21.00002 CuPt atomic ordering and band gap reduction in AlInP for green LED applications , DANIEL BEATON, NREL, KUNAL MUKHERJEE, MIT, KIRSTIN ALBERI, THERESA CHRISTIAN, ANGELO MASCARENHAS, NREL, EUGENE FITZGERALD, MIT — Efficient light emission in the wavelength range of 575-595nm (green/amber) is necessary for high colour rendering index (CRI) colour-mixed white LED light sources. The present lack of efficient light emitters in this range is known as the 'green gap'. However, it is possible to achieve efficient green/amber light emission with III-V semiconductor alloys, specifically by using direct band gap AlInP alloys, where carrier confinement for device application can result from the band off-set between ordered and disordered material of the same composition. The greater size discrepancy between Al and In results in higher degrees of CuPt atomic ordering and larger band gap reductions than typically reported for other order materials, such as GaInP. Samples are grown lattice matched to InGaAs graded buffer layers grown on GaAs substrates and atomic ordering is observed by TEM. Photoluminescence and modulated reflectance characterization are used to quantify the band gap shift as a function of order parameter.

11:39AM Z21.00003 Demonstration of amber-green light emitting diodes with lattice-mismatched AlInP active region , THERESA CHRISTIAN, University of Colorado, Boulder, DANIEL BEATON, National Renewable Energy Laboratory, KUNAL MUKHERJEE, Massachusetts Institute of Technology, KIRSTIN ALBERI, ANGELO MASCARENHAS, National Renewable Energy Laboratory, EUGENE FITZGERALD, Massachusetts Institute of Technology — Future solid-state lamps based on all-LED white light emission will require four emitter colors (red, amber, green, and blue) to achieve good color rendering while maintaining high efficiency. Traditional LED material systems are well-suited to the red and blue ends of the spectrum but there is not yet a clear front-runner material for efficient light emission in the amber-green wavelength range (570 – 595 nm). The compound semiconductor alloy $Al_xIn_{1-x}P$ has the potential to achieve this target due to its high direct bandgap. This talk will present results from our recent fabrication of amber-green LEDs featuring an AlInP double-heterostructure device structure. Cladding layers for carrier confinement are achieved through control of atomic ordering in the AlInP material. To fully exploit the high direct bandgap that occurs at lattice constants below that of GaAs, these devices are grown on InGaAs/GaAs virtual substrates. Devices are characterized in terms of current-voltage behavior, electroluminescence emission spectra and drive current dependence.

11:51AM Z21.00004 Theoretical Analysis of the Band Offsets and Band Bending in (0001) $In_xGa_{1-x}N$/GaN Heterostructures and Quantum Wells , LIANG DONG, Department of Physics, University of Connecticut, S. PAMIR ALPAY, Department of Physics and Institute of Materials Science, University of Connecticut — Valence band offsets (ΔE_V) and built-in electric fields of (0001) $In_xGa_{1-x}N$/GaN heterostructures and quantum wells are studied as a function of In composition x using first principles calculations based on density functional theory (DFT). These properties determine the degree of quantum confinements and wave function overlapping of electrons and holes, and thus the overall efficiencies of electronic/optoelectronic devices based on these structures. We show that with increasing x, ΔE_V of (0001) $In_xGa_{1-x}N$/GaN displays a parabolic bowing in both strain-free (fully relaxed) heterostructures and pseudomorphic quantum wells on c-plane GaN substrates. ΔE_V of (0001) InN/GaN in these two cases (0.98 eV and 0.64 eV, respectively) can be used to explain the deviations in experimental results that vary from 1.1 eV to 0.58 eV. We also show that the DFT calculated built-in electric fields in these constructs agree with continuum-level electrostatic analysis based on Maxwell and Poisson's relations, taking into account the first and second order of piezoelectric couplings.

12:03PM Z21.00005 Effects of quantum-well shape and polarization on simulations of InGaN/GaN multi-quantum-well light-emitting diodes[1] , PATRICK MCBRIDE, QIMIN YAN, CHRIS VAN DE WALLE, University of California at Santa Barbara — We investigate the effects of different InGaN quantum well (QW) profiles in c-plane InGaN/GaN 3-QW blue light-emitting diodes (LEDs) by employing a semi-empirical drift-diffusion model. Our results show that changing the typically assumed square indium profile to one with a smoother interfacial transition leads to a significant modification of the band diagram, carrier overlap, and current-voltage characteristics. In previous works, an *ad hoc* reduction of the polarization field has often been used to generate simulated results that match experiment while the realistic indium profile is not taken into account. However, our results indicate that the indium profile plays an important role in determining the current vs. voltage characteristics of InGaN/GaN heterostructure LEDs.

12:15PM Z21.00006 Plasma assisted molecular beam epitaxy of strain-balanced a-plane InGaN/AlGaN periodic structures , RYAN ENCK, NATHANIEL WOODWARD, C.S. GALLINAT, G.D. METCALFE, HONGEN SHEN, MICHAEL WRABACK, US Army Research Laboratory — A-plane nitride semiconductors have a tunable anisotropic absorption edge that can be exploited to create a compact, broad spectrum THz radiation detector which leverages fiber lasers operating at telecommunication wavelengths. Incident THz radiation is detected by observing the anisotropic change in the anisotropic absorption in the semiconductor of a femtosecond probe pulse by monitoring the polarization rotation of the probe. The sensitivity of this detection method requires a high quality a-plane wurtzite semiconductor with sufficient thickness to provide a large enough polarization rotation as required by the detection scheme. We report on the growth and characterization of strain balanced InGaN/AlGaN periodic structures on various substrates and buffer layers to obtain thick epilayers while maintaining a large absorption anisotropy. We use x-ray diffraction to determine the strain, composition, degree of relaxation, and thickness of our samples and polarization dependent transmission spectroscopy to measure the anisotropic absorption and polarization rotation in these materials

12:27PM Z21.00007 Blue and Green light InGaN/GaN Multiquantum-Well grown by plasma-assisted molecular beam epitaxy[1] , CHIA-HSUAN HU, IKAI LO, CHENG-HUNG SHIH, WEN-YUAN PANG, CHENG-DA TSAI, YU-CHIAO LIN, Department of Physics, Center for Nanoscience and Nanotechnology, National Sun Yat-Sen University, Kaohsiung 80424, Taiwan, R. O. C. — High-efficiency red, green and blue light-emitting diodes (LEDs) can be used in the construction of full color display. We have grown green and blue light InGaN/GaN multiquantum-well (MQW) thin film on sapphire substrate with GaN buffer by using plasma-assisted molecular beam epitaxy. The optical properties of the samples were analyzed by photoluminescence measurement in room temperature. Under constant nitrogen flux condition, we obtained the blue and green emitting bands from different samples by modified the Indium and Gallium flux ratio in MQW. In high nitrogen flux condition, the wavelength shifts to 560nm, which provides an effective way to reach high Indium incorporation LED. In order to improve the quality, we can control the growth temperature and InGaN/GaN thickness. There are more than five order satellite peaks in Double Crystal X-ray Diffraction data. Smooth surface morphology has been verified in our samples by scanning electron microscope.

12:39PM Z21.00008 The epitaxial relationship between M-Plane and c-plane GaN grown on gamma-$LiAlO_2$[1] , YING-CHIEH WANG, IKAI LO, CHENG-HONG SHIH, CHIA-HSUENG HU, CHENG-DA TSAI, SHOU-TING YOU, Department of Physics, National Sun Yat-Sen University, Kaohsiung, Taiwan, ROC. — The M-plane and c-plane oriented GaN have been found co-existed in the γ-$LiAlO_2$ substrate grown by molecular beam epitaxy (MBE). Two-step growth with different N/Ga ratios has been used in the experiment at growth temperature 670°C. By the SEM images, the smooth M-plane surface was observed and the c-plane GaN 3-D structures homogenously spread on it. From the scanning of ω-2θ X-ray diffraction pattern, the peaks at 32.295° and 34.505° were attributed to the M-plane and c-plane GaN. The microstructure of the samples was investigated by transmission electron microscopic (TEM) study. It was found that the c-plane and M-plane GaN both were oriented from the substrate with the same growth direction and arranged vertically to the substrate with a periodical pattern. The interfaces between the c-plane and M-plane GaN can be confirmed clearly by one or two monolayer in high resolution TEM images. The stacking faults were found at the edge of c-plane side at the interface that released the dislocation between the M- and c-plane GaN. In summary, we found that the M-plane and c-plane GaN can be assembled on γ-$LiAlO_2$ substrate with a clear phase-transition interface.

12:51PM Z21.00009 Gallium-monochalcogenides mechanically exfoliated at temperatures above room temperature , JOSE FONSECA VEGA, HUI FANG, ALI JAVEY, OSCAR DUBON, University of California - Berkeley — In recent years, there has been an increased interest toward layered 2D materials beyond graphene. Among these III-VI metal-chalcogenide layered semiconductors are interesting materials for 2D applications as the digitally controlled crystal thickness (by the number of layers) opens a new degree of freedom to tailor electronic properties. In this work, thin layers of GaSe and GaTe were obtained via micromechanical exfoliation and transferred onto SiO2/Si substrates at temperatures ranging from room temperature to 75 C. Exfoliation above room temperature showed a dramatic increase in yield and mean surface area for the exfoliated single-crystalline flakes, 75 C and 50 C being the optimum conditions for GaSe and GaTe, respectively. Few-layer flakes were observed through optical microscopy. It was found that GaTe offered an additional challenge for exfoliation; this was attributed to its monoclinic crystal structure, contrasting GaSe's hexagonal structure. Atomic force microscopy thickness measurements determined the amount of layers in the exfoliated flakes. Micro-Raman and photoluminescence spectroscopy reveal an evolution in properties in these materials as a function of thickness. Results from measurements of field-effect transistors will be presented.

1:03PM Z21.00010 Structural and Electronic Properties in multilayer $(BiSe)_n(TiSe_2)_m$ Misfit compounds , BENJAMIN TRUMP, MAXIME SIEGLER, KEN LIVI, TYREL MCQUEEN, Johns Hopkins University — The nature of the charge density wave (CDW) transition in 1T-$TiSe_2$ has been hotly debated, and variously described as a simple CDW to the formation of an excitonic insulator. Here we report the synthesis and basic physical properties of the incommensurate layered chalcogenides $(BiSe)_n(TiSe_2)_m$. Their structure consists of a rock-salt type BiSe layer separated by one or more edge-sharing $TiSe_2$ octahedral layer. These octahedral layers are isomorphic to the layers found in 1T-$TiSe_2$, and thus provide a mechanism to study the electronically driven structural transition in $TiSe_2$ as a function of the number of layers. Structural determinations from electron and x-ray diffraction, using 4/5-D superspace approach, will be presented, and the implications of our results on the understanding of CDW formation in $TiSe_2$ will be discussed. The effects of doping with Cu to observe possible superconducting behavior is also explored.

1:15PM Z21.00011 Optically lossless semiconductors reached by means of bichromatic irradiation , ADIL-GERAI KUSSOW, University of Massachusetts Lowell, Dept. of Physics, US, ALKIM AKYURTLU, University of Massachusetts Lowell, Dept. of Engineering, US — Non-omhic semiconductors are theoretically studied in the fields of two parametrically coupled electromagnetic waves. A second-order non-linearity due to the non-omhicity couples waves and causes exchange energy between the modes. Based on Maxwell's equations and coherence requirements, it is demonstrated that the optical losses in the probe mode are compensated due to the flow of energy from the support mode. Estimates are made to show that the total loss suppression can be realized in semiconductors with low optical dispersion, e.g. zinc telluride (ZnTe), within the mid-IR to Long Wavelength –IR regime, and the appropriate design for the experimental validation is suggested.

1:27PM Z21.00012 Growth morphology of boron doped single crystal diamond , SUNIL KARNA, YOGESH VOHRA, UAB, Birmingham AL — The growing demand of wide band semiconductors entice researcher to investigate electronic properties in diamond. The chemical vapor deposition (CVD) method has shown that various level of doping can be possible in diamond films. The purpose of this study was to investigate the growth morphology and quality of boron doped diamond film with deposition parameters. Various level of boron doped diamond films were synthesized epitaxially on synthetic (100) ib type diamond substrate using microwave plasma assisted CVD. The structural, optical and electrical characterizations were made to study effect of deposition parameters and pretreatment of substrates on surface morphology and growth quality. Raman spectra showed shape modification of the zone center optical phonon line and its downshift with the increasing boron content in the film. Additional bands were also observed in lower wavelength region below optical phonon line. Surface modification of films with increasing boron content has been observed in atomic force microscopy. High growth rate and high quality films were obtained with the addition of a few ppm of nitrogen in feed gas during deposition with little compromise on conductivity. Electrical measurement showed carriers have been transported via two different conduction mechanisms.

1:39PM Z21.00013 Growth and Contrast of Hexagonal Boron Nitride: From Submonolayer Islands to Multilayer Films , JUSTIN KOEPKE, JOSHUA WOOD, ERIC POP, JOSEPH LYDING, University of Illinois at Urbana-Champaign — Strong interest in hexagon boron nitride (h-BN) as a substrate for graphene devices [1] or as a template for growth of other layered compounds [2] has motivated recent attempts to synthesize large scale h-BN by chemical vapor deposition (CVD). We synthesize h-BN by low pressure CVD on polycrystalline Cu foil in a hot wall tube furnace with a heated ammonia borane precursor carried downstream by Ar and H_2 gas. Transmission electron microscopy (TEM) diffraction patterns show that the resulting growths are highly crystalline, with several layers obtained for longer growth times. Short growth times show that the h-BN nucleates in triangular islands at a higher precursor temperature than previously reported in [3] and a lower temperature than reported in [4]. In-air calcination of the Cu foils after partial h-BN growth allows optical contrast of the previously transparent h-BN islands on the Cu foil. This observed resistance to oxidation suggests that grown h-BN films can serve as an insulating anti-corrosion layer.

1:51PM Z21.00014 MOCVD grown hexagonal BN epilayers for DUV photonics , SASHIKANTH MAJETY, JING LI, JINGYU LIN, HONGXING JIANG, Texas Tech University — Hexagonal boron nitride (hBN) has attracted a lot of interest recently owing to its excellent physical properties and its potential use as a template in graphene electronics. We report on the successful growth of hBN epilayers using metal organic chemical vapor deposition (MOCVD) on sapphire and n-AlGaN substrates. P-type conductivity control was also achieved by in-situ Mg doping. This provides us with an opportunity to solve the problem of low quantum efficiency of DUV devices using Al-rich AlGaN alloys due to their extremely low p-type conductivity. Mg doped hBN epilayers grown on insulating templates were p-type with an in-plane resistivity of 2.3 Ω cm. Diode behavior in the p-n structures of p-hBN/n-$Al_{0.62}Ga_{0.38}N$ has been demonstrated. Our results indicate that hBN epilayers have potential for DUV optoelectronic devices and also demonstrate the feasibility of using highly conductive p-type hBN as electron blocking and p-contact layers for AlGaN based deep UV emitters. This work is supported by DOE.

Session Z22 DCMP: He3 - He4 Quantum Fluids 324 - Benjamin Hunt, Massachusetts Institute of Technology

11:15AM Z22.00001 Chiral Phases of Superfluid ^{3}He in an Anisotropic Medium[1] , JAMES SAULS, Northwestern University — I report theoretical results for the phases of superfluid ^{3}He infused into homogeneous uniaxial aerogel. Ginzburg-Landau (GL) theory for a class of equal-spin-pairing (ESP) states in a medium with uniaxial anisotropy is developed and used to analyze recent experiments on uniaxially strained aerogels. For ^{3}He in an axially "stretched" aerogel GL theory predicts a transition from normal liquid into a *chiral* ABM phase in which the chirality axis is aligned along the strain axis. This state is protected from random fluctuations in the anisotropy direction, has a positive NMR shift, a sharp NMR resonance line and is in quantitative agreement with NMR in the high-temperature ESP-1 phase of superfluid ^{3}He in axially stretched aerogel. A second transition into a bi-axial phase is predicted to onset at a slightly lower temperature. This phase is an ESP state, breaks time-reversal symmetry, and is defined by an order parameter that spontaneously breaks axial rotation symmetry. The bi-axial phase has a continuous degeneracy associated with broken axial symmetry. Theoretical predictions for the NMR frequency shifts provide an identification of the ESP-2 phase as the bi-axial state, partially *disordered* by random anisotropy (Larkin-Imry-Ma effect).

[1]Supported by National Science Foundation Grant DMR-1106315.

11:27AM Z22.00002 Topological current at an interface between superfluid ^{3}He A- and B-phases , YASUMASA TSUTSUMI, Condensed Matter Theory Laboratory, RIKEN — At a surface of the superfluid ^{3}He, the surface Andreev bound state accompanied with edge current emerges due to a topological phase transition. The topological phase transition at the surface is occurred because the superfluid gap of the superfluid ^{3}He among topological superfluids is closed at the interface of a topologically trivial vacuum. Since the paring symmetries are different between the superfluid ^{3}He A- and B-phases, topological features are quite different between the A- and B-phases. The A-phase is a chiral superfluid with the spontaneous edge mass current while B-phase is a helical superfluid with the spontaneous edge spin current. At an interface between the A- and B-phase, a topological phase transition is also occurred because they belong in a different topological classification . Then, based on the quasiclassical Eilenberger theory, we discuss topological mass and spin current carried by the bound state at an interface between the A- and B-phases.

11:39AM Z22.00003 Nanofabricated cells for confined ^{3}He , NIKOLAY ZHELEV, ROBERT BENNETT, ROB ILIC, JEEVAK PARPIA, Cornell University, LEV LEVITIN, ANDREW CASEY, JOHN SAUNDERS, Royal Holloway University London — We describe methods for fabrication of Silicon-Glass and all-silicon cells with a height specified to be between 100nm and 1100nm, and with areas on the order of cm x cm. These cells need to meet different requirements, including pressure capability to 30 bar with minimal distortion, and surface roughness which can be characterized and modified as needed to alter the transport characteristics of the confined ^{3}He. The cells are suitable for NMR and Torsion Oscillator measurements on the superfluid phases of ^{3}He.

11:51AM Z22.00004 Study of Liquid ^{3}He Films with MEMS Devices[1] , PAN ZHENG, MIGUEL GONZALEZ, YOONSEOK LEE, Department of Physics, University of Florida, HO BUN CHAN, Department of Physics, The Hong Kong University of Science and Technology — Liquid ^{3}He films with thicknesses of 0.75 and 1.25 μm were established and probed by micro-electro-mechanical (MEMS) resonators each of which consists of a pair of parallel plates with a well defined separation. The mechanical resonances of the devices immersed in liquid ^{3}He were studied in a wide range of temperatures from 10 to 800 mK and at sample pressures of 3, 21, and 29 bar. A crossover from Fermi liquid to classical fluid was observed on warming. In the Fermi liquid regime, the damping coefficient associated with the film exhibits an unexpected temperature dependence below 100 mK. This work demonstrates the capacity of MEMS devices as sensitive probes suitable for the study of quantum fluids in a micrometer scale.

12:03PM Z22.00005 Spin and mass currents on the surface of the topological superfluid, ^{3}He-B[1]

, HAO WU, JAMES SAULS, Northwestern University — The surface excitation spectrum of superfluid ^{3}He-B is discussed for a translationally invariant interface (specular surface). We report calculations of surface spectral spin-current and mass current densities originating from the Andreev bound state and the continuum response. Two branches of gapless Fermions, bound to the surface, disperse linearly with momentum $\vec{p}_\parallel$ along the surface. These states are spin polarized transverse to their direction of propagation, $\vec{p}_\parallel$. The spectral functions reveal the subtle role of the spin-polarized surface states in relation to the ground-state spin current. By contrast, these states do not contribute to the ground-state mass current density. However, the surface states do give rise to a power law suppression of the superfluid mass current for $0 \ll T \ll T_c$, providing a direct signature of the Majorana branches of surface excitations in the fully gapped 3D topological superfluid, ^{3}He-B.

[1]Supported by National Science Foundation Grant DMR-1106315.

12:15PM Z22.00006 Observation of the Larkin-Imry-Ma Effect in Superfluid ^{3}He-A in Aerogel[1]

, J.I.A. LI, Northwestern University, J. POLLANEN, California Institute of Technology, A.M. ZIMMERMAN, C.A. COLLETT, W.J. GANNON, W.P. HALPERIN, Northwestern University — It was proposed by Volovik that ^{3}He-A in aerogel will be a superfluid glass owing to the Larkin-Imry-Ma (LIM) effect where arbitrarily small amounts of disorder can disrupt long range directional coherence of a vector order parameter in a condensed system. Several reports of NMR experiments in ^{3}He-A have been interpreted as evidence for this phenomenon. However it is not trivial to distinguish the LIM effect induced from disorder on a microscopic scale from macroscopic non-uniformity or anisotropy in the aerogel sample. Order parameter disorder from these two possible mechanisms have very different distributions of order parameter orientations directly observable in the width of the NMR spectrum. If a complete LIM effect is operative there should be no contribution to the line width, contrary to previous reports. On warming from the low temperature isotropic state, we find NMR spectrum shifts characteristic of the dipole-locked axial state, i.e. no sign of a LIM superfluid glass. However, on cooling from the normal state this same phase is fully disordered in a LIM state. We will discuss the origin of the different order parameter structures in superfluid ^{3}He-A that result when prepared from the normal state, as compared with warming from the B-phase.

12:27PM Z22.00007 Phase transitions and critical currents in superfluid ^{3}He films[1]

, ANTON VORONTSOV, Montana State University, JAMES SAULS, Northwestern University — Using the quasiclassical theory of superfluidity we investigate thermodynamic and transport properties of superfluid ^{3}He in confined geometries. Classic flow experiments, as well as more recent NMR and flow experiments on superfluidity in slab and film geometries, exhibit inconsistencies between experimental results and existing theoretical models of confinement effects. In order to explain the origin of some of these inconsistencies we describe a theoretical model for confinement effects based on scattering of quasiparticles from rough surfaces that is more general than the 'specular' and 'diffusive' scattering models. Using the this more general boundary scattering model we report theoretical results for (a) the suppression of the superfluid critical temperature T_c^{film}, (b) the confinement-driven transition between A and B phases, T_{AB}, and (c) effects of the surface roughness on the critical current. The new scattering model should provide a more complete framework for analysis of the properties of confined superfluid ^{3}He.

12:39PM Z22.00008 Unusual Behavior of a MEMS Resonator in Superfluid ^{4}He[1]

, MIGUEL GONZALEZ, PAN ZHENG, BYOUNG HEE MOON, ERIK GARCELL, YOONSEOK LEE, Department of Physics, University of Florida, HO BUN CHAN, Department of Physics, The Hong Kong University of Science and Technology — Mechanical resonators based on micro-electro-mechanical systems (MEMS) technology were developed for the study of superfluid ^{4}He [1]. The MEMS device is composed of a movable plate (200 $\times$ 200 μm^2) suspended above the substrate by four serpentine springs. The suspended plate moves parallel to the substrate while maintaining a uniform gap between them. A specific device with a 1.25 μm gap was tested in the superfluid phase of ^{4}He down to 100 mK. The device exhibits an extreme sensitivity to the excitation level below 400 mK, displaying a nonlinear and hysteretic behavior accompanied by switching. This phenomenon might be related to quantum turbulence generated by a rather simple oscillating plate.

12:51PM Z22.00009 Superfluid helium-4 in one dimensional channel[1]

, DUK Y. KIM, SAMHITA BANAVAR, MOSES H. W. CHAN, Department of Physics, Pennsylvania State University, University Park, PA 16802, USA, JOHN HAYES, PIER SAZIO, Optoelectronics Research Centre, University of Southampton, Highfield, Southampton SO17 1BJ, United Kingdom — Superfluidity, as superconductivity, cannot exist in a strict one-dimensional system. However, the experiments employing porous media showed that superfluid helium can flow through the pores of nanometer size. Here we report a study of the flow of liquid helium through a single hollow glass fiber of 4 cm in length with an open id of 150 nm between 1.6 and 2.3 K. We found the superfluid transition temperature was suppressed in the hollow cylinder and that there is no flow above the transition. Critical velocity at temperature below the transition temperature was determined. Our results bear some similarity to that found by Savard *et. al.* [1] studying the flow of helium through a nanohole in a silicon nitrite membrane.

1:03PM Z22.00010 Effect of Helium on Vycor Glass: Anomalous Thermal Conductivity Reduction[1]

, ZHIGANG CHENG, SAMHITA BANAVAR, MOSES H. W. CHAN, The Pennsylvania State University — There is a long history of studying helium adsorbed in Vycor. In this talk we present the results showing that helium can have a profound effect on the thermal conductivity property of Vycor glass. Although the thermal conductivity of liquid ^{4}He is four orders of magnitude higher than that of Vycor, the filling of liquid ^{4}He inside the Vycor pores brings about a three-fold reduction of the thermal conductivity as compared with empty Vycor between 0.06 and 0.5 K. By comparing these results with that of superfluid films, liquid ^{3}He and solid helium in the Vycor pores, we found that heat is conducted primarily through the silica network even when the pores are filled with solid or liquid helium. The dramatic reduction is brought about by the presence of slow sound mode in liquid ^{4}He that greatly facilitates the quantum tunneling of the two level systems (TLS) in the silica which enhances the scattering of the thermal phonons.

[1]This research was supported by NSF Grant No. DMR1103159.

1:15PM Z22.00011 Observation of a New Casimir Effect in Saturated Superfluid ^{4}He Films[1] , JOHN ABRAHAM, GARY WILLIAMS, UCLA, KONSTANTIN PENANEN, Jet Propulsion Lab — We report the results of experiments on saturated superfluid ^{4}He films in the vicinity of the bulk superfluid transition temperature T_λ, measuring the film thickness with a capacitance technique and the superfluid density with third sound. For moderately slow temperature sweep rates (0.5 mK/hr) we measure the critical Casimir film-thinning effect with good resolution, and find that the Kosterlitz-Thouless superfluid onset in the film occurs just at the start of the dip in film thickness. When warming through T_λ at extremely slow rates (a few μK/hr), however, we have observed a sudden large increase in the film thickness (nearly 25 Å in a film initially 480 Å thick) within microkelvins of T_λ. We propose that this is a new type of Casimir effect arising from the viscous suppression of second sound modes in the film, leading to a large free energy difference in the superfluid state that disappears abruptly when second sound ceases to propagate in the bulk helium at T_λ.

1:27PM Z22.00012 Cubic interactions in superfluid ^{4}He , BJORN FÅK, CEA, Grenoble, THOMAS KELLER, MPI, Stuttgart, MICHAEL ZHITOMIRSKY, CEA, Grenoble, ALEXANDER CHERNYSHEV, University of California, Irvine — High-resolution neutron resonance spin-echo measurements of superfluid ^{4}He show that the roton energy does not have the same temperature dependence as the inverse lifetime, in contrast to the Landau-Khalatnikov theory. We present a diagrammatic analysis that attributes this effect to the interaction of rotons with thermally excited phonons via both four- and three-particle processes, the latter being allowed by the broken gauge symmetry of the Bose condensate.

1:39PM Z22.00013 Photon-Roton Modes in Liquid ^{4}He coexist with Bose-Einstein Condensation , HENRY R. GLYDE, Department of Physics and Astronomy, University of Delaware, JACQUES BOSSY, Institut Neel, CNRS-UJF, BP 166, 38042 Grenoble Cedex 9, France, JACQUES OLLIVIER, Institut Laue-Langevin, BP 156, 38042 Grenoble, France, HELMUT SCHOBER, Institut Laue-Langevin, BP 156, 38042 Grenoble, France, Universite Joseph Fourier, UFR de Physique, F38041 Grenoble Cedex 9, France — We present neutron scattering measurements of the phonon-roton (P-R) and layer modes of liquid ^{4}He confined in MCM-41 under pressure up to 38 bar. The data shows unambiguously that the P-R mode exists at low temperature only. As temperature is increased there is a gradual transfer of intensity from the P-R mode to the normal liquid response, which lies at a lower energy at higher pressure. The transfer takes place with no observable mode broadening. The loss of P-R modes is identified with the loss of Bose-Einstein condensation (BEC). The mode giving rise to the specific heat, c_V, of liquid ^{4}He in porous media (e.g. gelsil) at higher temperature is the layer mode since the energy of the mode extracted from c_V and the layer mode energy are the same.

1:51PM Z22.00014 Helium-4 crossover from a 3d superfluid to a 1d Luttinger liquid in a nanopore[1] , BOHDAN KULCHYTSKYY, Mcgill University, ADRIAN DEL MAESTRO, University of Vermont, GUILLAUME GERVAIS, Mcgill University — Quantum Monte Carlo studies of helium-4 below the bulk superfluid transition temperature show that when it is confined to flow in narrow cylindrical pores with nanometer radii, it tends to form concentric shells around a possible inner core. The latter potentially represents an experimental playground for exploring the implications of Luttinger liquid theory for one dimensional quantum fluids. We have performed large scale numerical simulations investigating the crossover from a bulk three dimensional superfluid to a one dimensional Luttinger liquid as the nanopore radius is reduced at low temperature. Measurements of the superfluid density employing both stiffness and angular momentum estimators provide new insights into confinement induced fluctuation effects in strongly interacting quantum fluids.

2:03PM Z22.00015 Metastable pin sites for a superfluid vortex , RENA ZIEVE, INGRID NEUMANN, University of California, Davis — Circulation trapped around a straight, fine wire can be detected through its effect on the wire's vibration. Here we use such a wire in a cylindrical cell to examine pinning of a superfluid helium vortex line at a macroscopic bump. Hydrodynamic considerations imply that, as long as the fluid velocity is fixed and not too large, a vortex can pin at a unique place on the bump. However, for two separate geometries we find that the vortex has metastable locations both at the apex of the bump and near its edge. In one case, the vortex is trapped around the wire, which terminates in the center of a bump on the cylinder endcap. We find that the vortex can follow the entire length of the wire to the bump apex, or it can leave the wire and make its way through the fluid to the edge of the bump. The former situation is more stable, but the latter can also persist for long times. The second geometry involves a free vortex that extends from the wire to a bump on the cylindrical wall of the container. Again our measurements show pinning at multiple sites on the bump. Interaction of the vortex with the surface curvature may produce the unexpected additional pin sites.

2:15PM Z22.00016 Recent Progress in Low-Temperature Research from the Davis Lab at the University of Alberta[1] , JOHN P. DAVIS, XAVIER ROJAS, YIKAI YANG, ANDREJ DUH, GREG POPOWICH, University of Alberta, Department of Physics — In this talk I will briefly describe our recent progress towards new low-temperature experiments at the University of Alberta in the Davis Lab. We are currently setting up two nuclear demagnetization fridges - one new cryostat that has two independent 9 T magnets (the second magnet being useful for a double demag stage or combined high field and low temperature experiments). The other fridge is an older unit that is extensively refurbished, with all new pumping systems. We are planning numerous experiments at the intersection of low-temperature physics and nanoscience, including quantum properties of nanomechancial resonators and quantum fluids in confined geometries. Concerning the latter, we have fabricated high quality microfluidic devices suitable for low-temperature research. We will discuss our progress towards quantum fluids measurements using these devices.

Friday, March 22, 2013 11:15AM - 2:03PM –

Session Z23 FIAP: Semiconductors: Thermodynamic & Optical Properties II 325 -

11:15AM Z23.00001 Excitons in Ultrathin PbI_2 Crystals , ALEXIS TOULOUSE, BENJAMIN ISAACOFF, Physics, University of Michigan, GUANGSHA SHI, EMMANOUIL KIOUPAKIS, Materials Science and Engineering, University of Michigan, MARIE MATUCHOVÁ, Faculty of Nuclear Sciences and Physical Engineering, Czech Technical University in Prague, ROBERTO MERLIN, Physics, University of Michigan — Due to their weak inter-layer van der Waals bonding, layered materials offer the unique possibility to produce natural quantum wells in the form of single and few atomic layer samples. A technique known as micromechanical cleavage, involving repeated cleaving, is used to isolate samples of all thicknesses [1]. Here, we present a combined experimental and theoretical study of band-edge excitons in the layered compound PbI_2 and, in particular, on their behavior as a function of sample thickness. Results of photoluminescence and reflection experiments are reported on samples with thicknesses ranging from a few micrometers down to a few monolayers, as determined by atomic force microscopy measurements. The data display striking and well reproducible changes in the transition from three to two-dimensions, which will be compared with results of first-principles calculations of the electronic band structure based on density functional and many-body perturbation theory. Computational resources were provided by the DOE NERSC facility. [1] A. K. Geim et. al. Nature Materials 6, 183 (2007)

11:27AM Z23.00002 Second harmonic generation from few-layer MoS2 and BN , YILEI LI, YI RAO, KIN FAI MAK, YUMENG YOU, SHUYUAN WANG, TONY HEINZ, Columbia University — We have measured optical second harmonic generation (SHG) from few-layer MoS2 and hexagon BN samples. In both materials, we observe SHG for odd numbers of layers. However, no appreciable SHG signal is observed for samples with even numbers of layers. This general behavior is compatible with the fact that individual layers of each material are non-centrosymmetric, thus allow SHG in the dipole approximation. For even layer thickness, on the other hand, the overall structures become centrosymmetric, with adjacent layers producing canceling contributions. In the case of odd layer thickness, we observe strong in-plane variation of the SHG signal with polarization. From this dependence, we can determine crystallographic axes in the material by a purely optical measurement. We also discuss the evolution of the signal strength in the two material systems with thickness (for odd layer numbers), considering both propagation effects and the evolution of the electronic structure of the material with thickness [1].

11:39AM Z23.00003 Low Temperature Optical Spectroscopy of Excitons and Trions in Monolayer MoS2 , CHANGJIAN ZHANG, Cornell.University, HAINING WANG, FARHAN RANA, Cornell University — Monolayer MoS2 is a two-dimensional (2D) semiconductor with optical properties different from conventional inorganic semiconductors. We will present our results on low temperature absorption and photoluminescence (PL) spectroscopy of monolayer MoS2 crystals. As a result of the large carrier effective masses and low dielectric screening in the 2D geometry, the excitons in MoS2 are tightly bound with large binding energies. We find that the prominent peak at $\sim$1.9 eV in both PL and absorption spectra at low temperatures is split in two: an exciton peak and a trion peak. The binding energies of trions, measured relative to the excitons, are extremely large and in the 30-35 meV range. We find that the trion peak acquires more spectral weight than the exciton peak as the electron density increases, and also broadens due to increased scattering with electrons. The temperature dependence of the exciton and trion PL intensities enables us to determine the radiative recombination efficiencies as a function of the temperature. We also observe Stokes shifts of $\sim$5 meV of both exciton and trion peaks, indicative of lattice distortions accompanying the quasiparticles (i.e. polarons) in this highly polar crystal.

11:51AM Z23.00004 Ultrafast Optical Pump-Probe Studies of Photoexcited Carrier Dynamics in Mono-Layer MoS2 , HAINING WANG, CHANGJIAN ZHANG, FARHAN RANA, Cornell University — Mono-layer MoS2 is a 2D semiconductor with a direct bandgap. We present, for the first time, ultrafast optical pump-probe measurements results on the relaxation dynamics of photoexcited carriers in monolayer MoS2. Pulses at energies 2.74 eV and 1.37 eV with width 100 fs are used in our experiments. The pump photon energy is larger than the bandgap, and the probe is below the optical absorption edge. Our results show that the differential transmission of the probe is negative with three distinct features: i) an initial probe absorption due to two-photon absorption involving also the pump pulse ii) a fast relaxation transient lasting to about 1ps in which the differential transmission recovers by almost 90%. iii) a very slow recovery of the transient that lasts about 200ps. We explain the observed transients in terms of the relaxation of the carriers to the conduction band bottom, followed by the formation of excitons and trions, and the response of the excitons and trions. The extremely large exciton and trion binding energies make these states much more preferable than the free carrier states in the bands. The contributions of interband and intraband processes to the observed transients will be explained and the extracted relaxation and recombination rates will be discussed.

12:03PM Z23.00005 Optical behavior of native defects in ZnO[1] , JOHN L. LYONS, DANIEL STEIAUF, AUDRIUS ALKAUSKAS, ANDERSON JANOTTI, CHRIS G. VAN DE WALLE, Materials Department, University of California, Santa Barbara — The behavior of native defects in ZnO has been fiercely debated for years, yet questions still remain regarding their fundamental properties. Once blamed for causing unintentional n-type conductivity, it is now well-established that native donors are highly unlikely to act as shallow donors in as-grown material. Still, both native donors and acceptors may be present in some samples, acting as either compensating acceptors or deep donors that may inhibit attempts to obtain high-conductivity n-type ZnO. In this work, we re-examine the properties of native donors and acceptors in ZnO using hybrid density functional calculations, which allow for the quantitative prediction of defect transition levels and formation energies. We focus on the optical and electrical properties of these defects, and calculate both their optical and thermodynamic transition levels. Most of the defects give rise to deep, broad luminescence signals that can serve as a means of experimentally verifying the nature of the center. We also examine how interactions with hydrogen interstitials affect the properties of these defects.

12:15PM Z23.00006 Strain-gradient dominated emission energy shift of pure-bending ZnO wire , DAPENG YU, XUEWEN FU, XIAOBING HAN, QIANG FU, Peking University, WANLIN GUO, ZHUHUA ZHANG, Nanjing University of Aeronautics and Astronautics, PEKING UNIVERSITY COLLABORATION, NANJING UNIVERSITY OF AERONAUTICS AND ASTRONAUTICS COLLABORATION — High special/energy resolution cathodoluminescence (CL) spectroscopy enables us to make precise investigation on the optical/electronic fine structures in nanostructures. The linear distribution of strain gradient from tensile to compression in bent ZnO nano/microwires provides ideal conditions to address the modification of the electronic structures by strain in semiconductor materials. Radial line scan of the CL spectroscopy along bent ZnO wires at liquid helium temperature shows very fine excitonic emission structures, which demonstrates systematic red shift towards the increase of tensile strain, and blue shift as well as excitonic peak splitting towards the increase of compressive strain. Strain-gradient is found to dominate the overall red-shift of the emission energy at a pure bending configuration.

12:27PM Z23.00007 Electronic structure and optical properties of $CuYO_2$ nanocrystals[1] , MUHAMMAD HUDA, Department of Physics, University of Texas at Arlington, YANFA YAN, Department of Physics, University of Toledo, JOHN A. TURNER, MOWAFAK M. AL-JASSIM, National Renewable Energy Laboratory, Golden, CO — A unique class of highly stabile, self-saturated and self-charge-compensated delafossite nanocrystals has been identified. The density functional theory (DFT) study of structural and electronic properties of these nano-crystalline $CuYO_2$ will be presented. To have a better estimate of the electronic excitation energies, and consequently the optical gap, time dependent DFT has been employed as well. The goal is to show, first of all, that these unique set of nanocrystals exists, and to study whether the nano-phase can modify the electronic properties for enhanced optical absorption. It has potential application as photocatalysts for H_2 production by water splitting.

12:39PM Z23.00008 Contactless Electroreflectance Characterization of a Triple Asymmetric Coupled Quantum Well Active Region of a ZnCdMgSe-Based Quantum Cascade Laser , JOEL DE JESUS, THOR GARCIA, The Graduate Center, CUNY, NY 10016, SIDDHARTH DHOMKAR, Queens College - CUNY, NY 11367, ARVIND RAVIKUMAR, CLAIRE GMACHL, Princeton University, Princeton, NJ 08544, AIDONG CHEN, The City College of New York - CUNY, NY 10031, MARIA TAMARGO, The Graduate Center, CUNY, NY 10016 — Quantum cascade lasers (QCL) with emission at wavelengths below 4μm are difficult to achieve from conventional GaAs and InP based systems due to the small conduction band offset (CBO) of those materials. The II-VI materials ZnCdSe/ZnCdMgSe, with as much as 1.1 eV CBO and no inter-valley scattering, are excellent candidates to achieve this goal. We grew by MBE a QCL structure made of ZnCdSe and ZnCdMgSe lattice matched to InP. Triple asymmetric coupled quantum well (3ACQW) structures were also grown which contain only the active region of the QCL separated by quaternary barrier layers. The 3ACQW structure was characterized by contactless electroreflectance (CER). A model based on the transfer matrix method (TMM) was used to identify the CER transitions and to predict the Fourier transform infra-red (FT-IR) absorption spectrum of the full QCL structure. Excellent agreement between the predicted and the experimental FT-IR absorption peaks was observed.

12:51PM Z23.00009 Design of N-doped anatase TiO_2 photocatalyst with visible-light-response based on Ti-O bond weakening[1] , L.-C. YIN, G. LIU, H.-M. CHENG, None, ADVANCED CARBON DIVISION TEAM — Nitrogen bulk doping is an effective strategy to change the electronic structures of anatase TiO_2 photocatalyst for visible light response improvement. Unfortunately, it is hard to achieve nitrogen bulk doping in practice, due to both limited thermodynamic solubility of substitutional nitrogen and N-induced recombination centers. It remains challenging yet highly desirable to develop new doping approach to increase nitrogen solubility in bulk. This challenge is originally stemmed from both strong Ti-O bond and charge difference (O^{2-} versus N^{3-}) between lattice oxygen and nitrogen dopant. In this work, we propose a new doping approach to promote the bulk substitution of lattice oxygen with nitrogen in bulk anatase TiO_2, based on the Ti-O bond weakening by pre-implanted interstitial boron.[1] By using the first-principles calculations, we study the interstitial boron induced Ti-O bonding weakening and the thermodynamics/kinetics changes for nitrogen bulk doping.[2] In experiment, we realize to synthesize a bulk gradient B-N co-doping red anatase TiO_2 microsphere which has an extended absorption edge up to ca. 700 nm covering the full visible light spectrum and has a bandgap varying from 1.94 eV on its surface to 3.22 eV in its core by gradually elevating VBM. This approach could be extended to modify other electronic materials that demand bulk substitutional doping. 1. G. Liu, J. Pan, L. C. Yin et al., Adv. Funct. Mater., 2012, 22, 3233. 2. G. Liu, L. C. Yin, J. Q. Wang et al., Energy Environ. Sci. 2012, 5, 9603.

1:03PM Z23.00010 Ultrafast Time- and Phase-Resolved Second Harmonic Generation , JAMES MCIVER, CHANGMIN LEE, DARIUS TORCHINSKY, NUH GEDIK, MIT, GEDIK GROUP TEAM — Ultrafast pump-probe experiments typically measure the changes in the amplitude of the probe light after it interacts with a sample as a function of pump time delay. However, measured amplitude change is typically a result of multiple processes happening in the sample. It is usually not possible to isolate these different processes from the measured amplitude response. Here we show using GaAs and Bi2Se3 as test samples that by probing interferometrically, phase information about the pump-probe signal can also be acquired. We find that different components of the signal in general have different optical phases associated with them, which can be isolated by changing the path length difference within the interferometer. We show that phase information about second harmonic light generated by the sample can also be obtained and we report progress toward realizing simultaneous phase- and time-resolved second harmonic pump-probe measurements.

1:15PM Z23.00011 First-principles study of γ-ray detector materials in perovskite halides[1] , JINO IM, HOSUB JIN, Northwestern University, CONSTANTINOS C. STOUMPOS, DUCK YOUNG CHUNG, Argonne National Laboratory, ZHIFU LIU, JOHN A. PETERS, BRUCE W. WESSELS, Northwestern University, MERCOURI G. KANATZIDIS, Northwestern University; Argonne National Laboratory, ARTHUR J. FREEMAN, Northwestern University — In an effort to search for good γ-ray detector materials, perovskite halide compounds containing heavy elements were investigated. Despite the three-dimensional network of the corner shared octahedra and the extended nature of the outermost shell, its strong ionic character leads to a large band gap, which is one of the essential criteria for γ-ray detector materials. Thus, considering high density and high atomic number, these pervoskite halides are possible candidate for γ-ray detector materials. We performed first-principles calculations to investigate electronic structures and thermodynamic properties of intrinsic defects in the selected perovskite halide, $CsPbBr_3$. The screened-exchange local density approximation scheme was employed to correct the underestimation of the band gap in the LDA method. As a result, the calculated band gap of $CsPbBr_3$ is found to be suitable for γ-ray detection. Furthermore, defect formation energy calculations allow us to predict thermodynamic and electronic properties of possible intrinsic defects, which affect detector efficiency and energy resolution.

1:27PM Z23.00012 Temporal long-range order in exciton-polariton condensates , ALEX HAYAT, CHRISTOPH LANGE, LEE ROZEMA, ROCKSON CHANG, SHREYAS POTNIS, HENRY VAN DRIEL, AEPHRAIM STEINBERG, University of Toronto, MARK STEGER, DAVID SNOKE, University of Pittsburgh, LOREN PFEIFFER, KENNETH WEST, Princeton University — We demonstrate temporal long-range off-diagonal order in microcavity exciton-polariton dynamic condensation, by interference between two separate condensates, generated at different times and with different momenta. In our pulsed resonantly-injected condensates, stimulated polariton-polariton scattering results in spectral narrowing of the dynamic condensates and thus in longer coherence times. We study the temporal decay of the long-range order by monitoring the interference visibility between the condensates. We show that it strongly depends on the excitonic fraction of the polaritons and the corresponding polariton-polariton interaction strength, as well as on the temperature and pump intensity. Moreover, polariton interaction yields a blue shift of the condensate energy, which appears as a time-dependent shift in the interference pattern. These results show a direct evidence of temporal long-range order in dynamic condensates as well as demonstrate a new method for probing their ultrafast dynamics, opening new directions in the fundamental study of coherence in matter.

1:39PM Z23.00013 Statistics of Data Fitting: Flaws and Fixes of Polynomial Analysis of Channeled Spectra[1] , WILLIAM KARSTENS, Saint Michael's College, DAVID Y. SMITH, University of Vermont and Argonne National Laboratory — Starting from general statistical principles, we have critically examined Baumeister's procedure* for determining the refractive index of thin films from channeled spectra. Briefly, the method assumes that the index and interference fringe order may be approximated by polynomials quadratic and cubic in photon energy, respectively. The coefficients of the polynomials are related by differentiation, which is equivalent to comparing energy differences between fringes. However, we find that when the fringe order is calculated from the published IR index for silicon* and then analyzed with Baumeister's procedure, the results do not reproduce the original index. This problem has been traced to 1. Use of unphysical powers in the polynomials (e.g., time-reversal invariance requires that the index is an even function of photon energy), and 2. Use of insufficient terms of the correct parity. Exclusion of unphysical terms and addition of quartic and quintic terms to the index and order polynomials yields significantly better fits with fewer parameters. This represents a specific example of using statistics to determine if the assumed fitting model adequately captures the physics contained in experimental data. The use of analysis of variance (ANOVA) and the Durbin-Watson statistic to test criteria for the validity of least-squares fitting will be discussed. *D.F. Edwards and E. Ochoa, Appl. Opt. 19, 4130 (1980).

1:51PM Z23.00014 Resolving sub-phonon wavelength superlattices using photoacoustic spectroscopy[1] , JEREMY CURTIS, University of Alabama at Birmingham, ANDREW STEIGERWALD, Vanderbilt University, JOHN RENO, CINT, Sandia National Laboratory, DAVID HILTON, University of Alabama at Birmingham, NORMAN TOLK, Vanderbilt University — We have investigated the coherent acoustic phonon spectroscopic response of a mutilayer GaAs/$Al_xGa_{1-x}As$/AlAs heterostructure with varying layer thickness and Al concentration. The optical response shows a low frequency effective Brillouin oscillatory response and an additional time-dependent change in reflectivity arising from the multilayer features. We can also resolve structural features less than the spatial width of the acoustic strain pulse. We model the optical response from each feature and develop general criteria of the layer thickness and the acoustic strain width that determine the total response. This allows us to determine whether the optical response of a given layer will be superimposed on the overall Brillouin response or will provide an individual Brillouin response from within the layer. Our results help provide a basis for a nondestructive method of determining material properties in stratified media.

11:15AM Z24.00001 Universal properties of the Higgs mode near quantum critical points , SNIR GAZIT, DANIEL PODOLSKY, ASSA AUERBACH, Physics Department, Technion, IL-32000 Haifa, Israel — Spontaneous symmetry breaking of relativistic models with $O(N)$ symmetry results in the emergence of two elementary excitations: the Goldstone modes and the Higgs mode. The massive Higss mode can decay into pairs of Goldstone modes, broadening the spectral line and hence questioning its visibility. Recently a set of *scalar* response functions was introduced, in which the Higgs mode appears as a well defined peak [1]. We investigate the universal properties of the scalar susceptibility near the quantum critical point in 2+1 dimensions for $N = 2$ and $N = 3$ using Monte Carlo simulation. We demonstrate that the scalar spectral function contains a peak associated with the Higgs mode, which remains well-defined even upon approach to the critical point. We extract properties that characterize the Higgs peak, including the fidelity of the peak and the ratio ω_H/Δ between the Higgs energy on the ordered side and the single particle gap on the disordered side. The universal nature of these results make them relevant to a broad range of experiments in condensed matter and atomic systems.

11:27AM Z24.00002 Deconfined quantum criticality in bipartite SU(N) antiferromagnets in two dimensions[1] , MATTHEW S. BLOCK, RIBHU K. KAUL, Department of Physics & Astronomy, University of Kentucky — The theory of deconfined quantum criticality shatters the celebrated paradigm of the Landau-Ginzburg-Wilson description of phase transitions by allowing for direct, continuous, quantum phase transitions between conventional, ordered phases that spontaneously break fundamentally different symmetries of the system. In this talk, I will present new results of a quantum Monte Carlo study of a local, SU(N) symmetric, antiferromagnetic spin model on the honeycomb and anisotropic rectangular lattices. In particular, I will show evidence for the existence of a continuous phase transition separating conventional Néel and valence bond solid ordered phases, as well as comparisons of the extracted critical exponents for sufficiently large values of N to those calculated analytically via a $1/N$ expansion solution of the CP^{N-1} gauge field theory that is believed to accurately describe the behavior at the critical point. In combination with previous results of a similar study on the square lattice, this allows for a robust understanding of how the existence of deconfined quantum criticality depends on the lattice symmetries as a function of N, and therefore gives a complete picture of the phenomenon in bipartite SU(N) systems in two dimensions.

[1]Partial financial support was received from NSF DMR-1056536.

11:39AM Z24.00003 Valence bond solid order and phase transitions of honeycomb lattice models , KENJI HARADA, Graduate school of informatics, Kyoto university, Japan, HARUHIKO MATSUO, Research Organization for Information Science and Technology, Japan, TAKAFUMI SUZUKI, Graduate school for engineering, University of Hyogo, Japan, SYNGE TODO, NAOKI KAWASHIMA, Institute for Solid State Physics, University of Tokyo, Japan — We investigate the ground states of generalized SU(N) Heisenberg models on honeycomb lattices. From large-scale quantum Monte Carlo simulations, we confirm the columnar valence bond solid (c-VBS) orders for $N \geq 5$ at low temperatures, which corresponds to Kekulé distortion. It is consistent with Read and Sachdev's prediction[N. Read and S. Sachdev, Phys Rev B **42**, 4568 (1990)]. If we introduce the designed six-body interactions on hexagonal plaquettes, the c-VBS order occurs even in the SU(2) case. While the c-VBS state on a square lattice breaks Z_4 rotational symmetry, Z_3 rotational symmetry breaks on a honeycomb lattice. The difference may changes the nature of c-VBS phase. In particular, we will report phase transitions from a c-VBS phase to a paramagnetic or Néel phase in details. These results give us insight for deconfinement critical phenomena.

11:51AM Z24.00004 Exotic quantum criticality in triangular lattice anti-ferromagnets[1] , RIBHU KAUL, University of Kentucky — We introduce and study a generalized sign-problem free quantum anti-ferromagnet on the triangular lattice. Our Hamiltonian is shown to be a natural generalization of the popular bipartite SU(N) anti-ferromagnet to non-bipartite lattices. At $N = 2$ our model is unitarily equivalent to a model of an XY superfluid (SF). Consistent with a large-N mapping to a certain quantum dimer model, we find evidence for valence bond solid (VBS) order with a large $\sqrt{12} \times \sqrt{12}$ unit cell. We show that there is a direct transition between these two phases that takes place between $N = 11$ and $N = 12$. For $N = 10, 11$ we use a four spin coupling parameter to tune through a new exotic "deconfined" continuous transition between SF and VBS.

12:03PM Z24.00005 Efficient computation of GW energy level corrections for molecules described in a plane wave basis , BRUNO ROUSSEAU, JONATHAN LAFLAMME JANSSEN, MICHEL CÔTÉ, University of Montreal — An efficient computational approach is presented to compute the ionisation energy and quasiparticle band gap at the level of the GW approximation when the Hilbert space is described in terms of plane waves. The method relies on ab initio calculations as a starting point. Then, the use of the Sternheimer equation eliminates slowly convergent sums on conduction states. Further, the Lanczos method is used to efficiently extract the most important eigenstates of the dielectric operator. This approach avoids the explicit computation of matrix elements of the dielectric operator in the plane wave basis, a crippling bottleneck of the brute force approach. The method is initially applied to organic molecules of current interest in the field of organic photovoltaics. Given the completeness of the plane wave basis, systematic convergence studies can be conducted. Furthermore, the method can readily be extended to describe polymers, which are also of interest for photovoltaic applications, but remain a significant computational challenge for methods based on localized basis sets.

12:15PM Z24.00006 Thermodynamics of the 2D t-J Model , WILLIAM PUTIKKA, Physics Department, The Ohio State University — Very accurate calculations for the temperature dependence of the energy of the 2D Heisenberg AF on a square lattice have been done recently. By combining the results of these calculations with the known low temperature behavior of the Heisenberg entropy and results from high temperature series expansions at higher temperatures the Heisenberg entropy can be accurately calculated for all temperatures. This allows the Heisenberg entropy to be used as a known quantity in the calculation of the doped t-J model entropy. The high temperature series for the entropies of the t-J, Heisenberg and spinless fermion models can be combined as $S_{tJ} - S_{AF}(J^*) - S_{SF}(n^*)$ to produce a small difference which can then be extrapolated to low temperatures. Here $S_{AF}(J^*)$ is the Heisenberg entropy evaluated at a shifted value of J and $S_{SF}(n^*)$ is the spinless fermion entropy evaluated at a modified density. By choosing J^* and n^* appropriately very good convergence for the series of the entropy differences can be obtained. The final t-J entropy is then found by readding the known functions $S_{AF}(J^*)$ and $S_{SF}(n^*)$. The integrated entropy is then fit to the high temperature free energy to find the ground state energy and the full temperature dependent free energy.

12:27PM Z24.00007 ABSTRACT WITHDRAWN –

12:39PM Z24.00008 Description of renormalization effect of multiband systems and its application within CMRA theory , JUN LIU, YONGXIN YAO, CHEN LIU, WENCAI LU[1], CAI-ZHUANG WANG, KAI-MING HO, Iowa State University — Many interesting physical phenomena, especially those observed in strongly correlated systems, incur a multiband description. A relatively accurate description of these systems is very important to clarify the origin of the observed physics. The recently proposed correlated matrix renormalization approximation (CMRA) introduces a new route to address this problem. As a variational approach, it makes use of possible renormalizations on the density matrix to correctly absorb effects resulting from strong electron-electron interactions. It performs quite well on different H systems. However, the generalization to multiband cases can be nontrivial. In this talk, I will discuss about how renormalization effects can be incorporated into the density matrix in the multiband case, and show the performance of the resulting CMRA on different dimer systems.

12:51PM Z24.00009 Continuum limits of 12 flavor QCD , YANNICK MEURICE, University of Iowa — QCD with 12 flavors of quarks is one of the most popular model for lattice strong dynamics. We present recent results concerning the mass and volume dependence of the discontinuities observed in the average plaquette, chiral condensate and Polyakov loop. We compare the hypothesis of bulk and finite temperature phase transitions for the scaling of the Fisher's zeros. We discuss various types of continuum limits that can be defined for these lattice models.

1:03PM Z24.00010 Condensation of Anyons in Frustrated Quantum Magnets[1] , ROLANDO SOMMA, CRISTIAN BATISTA, Los Alamos National Laboratory — One dimensional quantum magnets can realize exotic states of matter such as Luttinger liquids, valence bond solids, and spin supersolids. A unique feature of 1D systems is that transmutations of particle statistics preserve the range and local nature of interactions. This is the main reason behind the success of spin-fermion transformations, such as the Jordan-Wigner mapping, for solving 1D quantum magnets. A simple generalization of such transformations allows for a mapping between spins and anyons, unusual particles that generalize the concepts of bosons and fermions. By exploiting this generalization, in this talk we will present the exact ground states of S=1/2 frustrated XXZ ladders, and introduce an efficient method for computing the relevant correlation functions. The novel states we find are *anyon condensates* that spontaneously break the Hamiltonian symmetry associated with the particle-number conservation. In contrast to the familiar Bose-Einstein condensates, the condensed particles satisfy anyonic statistics.

1:15PM Z24.00011 Fulde-Ferrell-Larkin-Ovchinnikov and topological superconducting phase in one dimensional optical lattice , RUILIN CHU, The University of Texas at Dallas, AN ZHAO, University of Hong Kong, MING GONG, The University of Texas at Dallas, SHUNQING SHEN, University of Hong Kong, CHUANWEI ZHANG, The University of Texas at Dallas — The recent experimental realization of spin-orbit coupling in ultracold atom systems provides new arena for us to explore new quantum states. In this work, we explore the Fulde-Ferrell-Larkin-Ovchinnikov (FFLO) phase and topological superconducting phase of spin-orbital coupled Fermions in one dimensional optical lattice using the Density matrix renormalization group (DMRG) method. We demonstrate that the FFLO phase is energetically favored for in-plane Zeeman field while the topological superconducting phase is favored for out-of-plane Zeeman field. The entanglement entropy for these two phases are also examined.

1:27PM Z24.00012 Probing Lee-Yang Zeros and Time-domain Phase Transitions , BO-BO WEI, REN-BAO LIU, Department of Physics and Center for Quantum Coherence, The Chinese University of Hong Kong, Hong Kong, China — As a foundation of statistical physics, Lee and Yang in 1952 proved that the partition functions of thermal systems can be zero at certain points (called Lee-Yang zeros) on the complex plane of magnetic field. In the thermodynamic limit, the Lee-Yang zeros approach to real numbers at the critical temperature. However, the imaginary Lee-Yang zeros have not been regarded as experimentally observable since they occur at imaginary field or temperature, which are unphysical. Here we show that the coherence of a probe spin coupled to a many-body system presents zeros as a function of time that are one-to-one mapped to the Lee-Yang zeros of the many-body system. In the thermodynamic limit, of which the Lee-Yang zeros form a continuum, the probe spin coherence presents a sudden death and a sudden birth at critical times corresponding to the edge singularities of the Lee-Yang zeros. By measuring the probe spin coherence, one can directly reconstruct the partition function of a many-body system. These discoveries establish the concept of critical times for phase transition in analogue to critical temperature, and also provide a universal approach to studying interacting many-body systems through measuring coherence of only one probe spin (or one qubit in quantum computing).

1:39PM Z24.00013 Strength of the effective Coulomb interaction at metal and insulator surfaces , ERSOY SASIOGLU, CHRISTOPH FRIEDRICH, STEFAN BLÜGEL, Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich and JARA, 52425 Jülich, Germany — The effective on-site Coulomb interaction (Hubbard U) between localized electrons at surfaces of solids is expected to be enhanced due to the reduced coordination number and the subsequent reduced screening. By means of first-principles calculations in conjunction with the constrained random-phase approximation [1] within the FLAPW method, we show that this is indeed the case for simple metals and insulators but not necessarily for transition metals and insulators that exhibit pronounced surface states [2]. In the latter case, the screening contribution from surface states as well as the influence of the band narrowing can increase the electron polarization to such an extent that the expected decrease is overcompensated. In some cases the U parameter is substantially reduced, e.g. by around 30% for the Cr(100) surface, contrary to conventional wisdom. It also depends on the properties of the surface states for different surface orientations, e.g. 10% [2%] reduction [enhancement] of U for MgO (110) [MgO (100)]. We show a systematic study for prototype materials including transition-metal surfaces.

1:51PM Z24.00014 A Symmetrized Basis for Transitions in the Heisenberg Model[1] , ROGER HAYDOCK, Department of Physics, University of Oregon, C.M.M. NEX, Materials Science Institute, University of Oregon — The spin-S Heisenberg model has 2S+1 states on each site, for which there are $(2S+1)^2$ possible transitions between these states. For N sites there are $(2S+1)^N$ states and $(2S+1)^{2N}$ transitions between states. This rapid increase in the number of transitions with sites appears to limit calculations to just a few sites. However for transitions induced by spin-spin interactions, we construct a symmetrized basis which only grows as 2^{N-3}, making possible computations for much larger systems.

2:03PM Z24.00015 Failure of the Holstein model to describe strong electron-phonon coupling[1] , CLEMENS P.J. ADOLPHS, MONA BERCIU, Department of Physics and Astronomy, University of British Columbia — We point out an inconsistency in the most widely used theoretical models that describe systems with strong electron-phonon coupling. Both the Holstein and the Fröhlich models assume that lattice distortions are sufficiently small to justify treating them to linear order. At strong coupling, however, it is well established that these models predict the formation of a small polaron, with potentially considerable local lattice distortions, invalidating the original assumption. Here we use the momentum average approximation to study the effect of higher-order coupling terms in the Holstein model. We show that they have drastic consequences on the properties of the polaron when compared to the linear model, and that these effects cannot be captured by a linear model with renormalized parameters.

Session Z28 GSNP: Focus Session: Wrinkling 336 - Douglas Holmes, Virginia Polytechnic Institute and State University

11:15AM Z28.00001 Wrinkling patterns of thin sheets glued to a negative curvature surface , RASTKO SKNEPNEK, MARK BOWICK, XU MA, Syracuse University, ZHENWEI YAO, Northwestern University — Gauss's Theorema Egregium provides an intimate connection between the metric and the Gaussian curvature of a surface. If a thin sheet is adhered to a substrate with a negative Gaussian curvature it will experience stress due to the curvature-driven change of its metric. In the inextensible limit any changes of metric are not possible and the sheet will relieve the stress by locally deforming via wrinkles or folds. Using geometric arguments and numerical simulations of a non-linear elastic model we analyse the wrinkling pattern as a function of the shape of the adhering substrate.

11:27AM Z28.00002 Drag Control through Wrinkling on Curved Surfaces[1] , DENIS TERWAGNE, Department of Civil and Environmental Engineering, Massachusetts Institute of Technology, Cambridge, MA USA, PEDRO REIS, Department of Civil and Environmental Engineering and Department of Mechanical Engineering, Massachusetts Institute of Technology, Cambridge, MA USA — We present the results of an experimental investigation on the wrinkling of positively curved surfaces and explore their use towards drag reduction applications. In our precision model experiments we make use of rapid prototyping techniques to cast samples with custom geometry and material properties out of silicone-based rubbers. Our structures consist of a thin stiff shell that is chemically bonded to a thicker soft substrate. The substrate contains a spherical cavity that can be depressurized, under controlled volume conditions, to compress the ensemble structure. Under this compressive loading, the initially smooth outer-shell develops complex wrinkling patterns. We systematically characterize and quantify the morphology of the various patterns and study the phase diagram of the system. We consider both geometric and material quantities in the parameter space. Moreover, since the wrinkling patterns can be actuated dynamically using a pressure signal, we systematically characterize the aerodynamic behavior of our structures in the context of fluid drag reduction. An added advantage of our novel mechanism is that it allows for both dynamic switching and tuning of the surface morphology, thereby opening paths for drag control.

11:39AM Z28.00003 Folds and crease from wrinkles , MAZEN DIAB, TENG ZHANG, RUIKE ZHAO, HUAJIAN GAO, KYUNG-SUK KIM, Brown University — We present stability and post bifurcation analyses of free-surface deformation from wrinkles to folds and creases, caused by lateral compression of a neo-Hookean material with varying elastic modulus with depth from the free surface. The post-bifurcation behavior of the wrinkle mode is investigated by high order perturbation as well as finite element analyses. We show that there is a critical strain beyond which the initial wrinkle mode is unstable. Using the finite element software ABAQUS, we reveal other deformation mode that may emerge due to the nonlinear bifurcation of the material surface. Bifurcation chart is constructed and shows that localized modes such as crease and fold may emerge depending on the geometric and material properties.

11:51AM Z28.00004 Mechanics of Graded Wrinkles , SHABNAM RAAYAI-ARDAKANI, MARY BOYCE, Massachusetts Institute of Technology — Shark skin is known for its anti-fouling and self-cleaning properties. In attempts to mimic this pattern for getting similar properties, different surface patterns such as Sharklet and wrinkles have been previously introduced. Wrinkled patterns have gained importance in applications such as microfluidics, wetting and adhesion. Through buckling of a thin film of stiff material on a substrate of softer material, and maintaining symmetric geometries, ordered wrinkled patterns can be created. However, it can be shown that using the same principle, by changing the geometry of the surface, the dimensions of the wrinkles can be altered. This alteration turns ordered wrinkles into graded wrinkles which have more resemblance to shark skin than the ordered wrinkles, maintaining the same wave length while each wave having different amplitude. Here using finite element models, experiments and analytical solutions, the relations between different geometries and the resulting patterns were investigated.

12:03PM Z28.00005 Wrinkling in Cellular Structured Composites , NARGES KAYNIA, Massachusetts Institute of Technology, YANING LI, University of New Hampshire, MARY C. BOYCE, Massachusetts Institute of Technology — Many structured composites found in nature possess undulating and wrinkled interfacial layers that regulate mechanical, chemical, acoustic, adhesive, thermal, electrical and optical functions of the material. This research focused on the formation of wrinkling patterns in cellular structured composites and the effect of the wrinkling pattern on the overall structural response. The cellular composites consisted of stiffer interfacial layers constructing a network submerged in a soft matrix. Analytical and finite element models were developed to capture various aspects of the wrinkling mechanism. The characteristics of the undulation patterns and the instability modes were investigated as functions of model geometry and material composition. Mechanical experiments were designed to further explore the modeling results. The cellular composite samples were fabricated by using different types of elastomers and by varying the geometry and the material properties. The experimental and numerical results were consistent with the analytical predictions. The results in this research improve understanding of the mechanisms governing the undulation pattern formation in cellular composites and can be used to enable on-demand tunability of different functions to provide, among others, active control of wave propagation, mechanical stiffness and deformation, and material swelling and growth.

12:15PM Z28.00006 Numerical Simulation of the Combined Bending, Stretching, and Wrinkling of Thin Sheets , MICHAEL TAYLOR, Harvard University, DAVID STEIGMANN, University of California, Berkeley, KATIA BERTOLDI, Harvard University — A two-dimensional theory of plates and shells derived from three-dimensional finite elasticity is presented. The approach is based on a systematic small thickness expansion of the exact three-dimensional strain energy density of the plate or shell. The theory involves the small thickness explicitly and accounts for both bending and stretching in a unified framework. Thus, wrinkling instabilities in thin sheets are accommodated as a natural outgrowth of the model. The plate model is demonstrated numerically via a specially designed finite difference code utilizing the method of dynamic relaxation. The code is used to simulate several equilibrium deformations of thin sheets and plates undergoing finite deformation with wrinkling.

12:27PM Z28.00007 Understanding and Controlling Morphological Transitions of Wrinkles , ALFRED CROSBY, University of Massachusetts Amherst — The ability to generate micron and sub-micron structures across extensive lengths on soft materials surfaces is critical for numerous technologies, yet current fabrication methods do not provide cost-effective solutions for these diverging demands. In Nature, elastic instabilities often are used to produce materials structures on small scales from simple building blocks to achieve necessary performance on larger, macroscopic size scales. We present an overview of our efforts to understand and use elastic instabilities, such as wrinkling and folding, to define surface structures with advantageous properties. In particular, we address two questions related to morphological transitions: the roles of overstress and curvature on selecting the specific wrinkle morphology created under equibiaxial stress conditions; and non-linear transitions, including wrinkle-to-fold, and the suppression of such transitions to achieve high-aspect ratio wrinkle structures. The lessons described provide new insight into the physics of these complex material deformations while also introducing scalable methods that are expected to help transfer elastic instabilities into current technologies.

1:03PM Z28.00008 Transition from wrinkles to crumples in an elastic sheet[1] , HUNTER KING, NARAYANAN MENON, University of Massachusetts, Amherst — A circular sheet confined to a surface of increasing curvature initially breaks azimuthal symmetry creating a finite pattern of radial wrinkles along its perimeter. At larger curvature, sharp crumpled features emerge and dominate the shape. Using optical profilometry, we study the transition from wrinkling to crumpling of a polystyrene sheet floating on a drop of glycerol by measuring the spatial distribution of curvatures of the sheet as a function of drop curvature. We observe that collisions of neighboring wrinkles at their tips generate cusps. These cusps subsequently sharpen and merge to produce large crumpled features, around which gaussian curvature focuses. Surprisingly, the stress field in the central, unwrinkled portion is not sensitive to the appearance of crumpled features. The transition shows little hysteresis and is smooth with respect to measured quantities.

1:15PM Z28.00009 Wrapping a sphere: stress relaxation by wrinkling , EVAN HOHLFELD, BENNY DAVIDOVITCH, University of Massachusetts Amherst — The low energy deformations of thin elastic sheets are isometries because these incur no stretching energy while the cost of bending is small. Since there is no isometric map of a flat sheet, i.e. a developable surface, onto the surface of a sphere, it is natural to suspect that any such map must cost finite stretching energy. However, I will show that there are an enormous number of almost isometric mappings which approximate a sphere with arbitrary accuracy and with arbitrarily small stretching energy. I will construct an example using multiscale analysis of a radial wrinkle pattern in a thin elastic sheet bent over a sphere. These techniques could be applied to other wrinkling problems and to problems connected to developable surfaces, e.g. textures in smectic liquid crystals.

1:27PM Z28.00010 Wrinkling of Inhomogeneously Strained Thin Polymer Films , YU-CHENG CHEN, ALFRED J. CROSBY, University of Massachusetts Amherst — Wrinkles occur due to a mechanical instability when sufficient strain is applied to an incompressible thin film attached to a deformable substrate. For wrinkles made with a polymer film supported on a soft elastomer, the amplitude is directly proportional to the wavelength and the square root of the applied strain. This dependence has been confirmed with ideal substrates where the global strain is homogeneously distributed, but the influence of strain inhomogeneity has not been considered previously. We use the contact line wrinkling technique to prepare polystyrene thin films with periodic regions of different wrinkle amplitudes, hence strains, on soft substrates. The surfaces with inhomogeneous wrinkle amplitudes and directions approach a homogeneous structure upon the application of sufficiently large strains. The surface becomes homogeneous at a relatively small strain due to the growth rate difference between pre-wrinkles and new wrinkles. Moreover, we find the pre-wrinkled region starts strain localizing prior to the initially flat region. We derive relationships to describe these processes, providing fundamental knowledge of the wrinkling mechanism.

1:39PM Z28.00011 Hydrostatic and Flow Measurements on Wrinkled Membrane Walls , OZGUR OZSUN, KAMIL L. EKINCI, Boston University — In this study, we investigate structural properties of wrinkled silicon nitride (SiN) membranes, under both hydrostatic perturbations and flow conditions, through surface profile measurements. Rectangular SiN membranes with linear dimensions of 15 mm $\times$ 1.5 mm $\times$ 1 μm are fabricated on a $500-\mu$m-thick silicon substrate using standard lithography techniques. These thin, initially flat, tension-dominated membranes are wrinkled by bending the silicon substrate. The wrinkled membranes are subsequently incorporated as walls into rectangular micro-channels, which allow both hydrostatic and flow measurements. The structural response of the wrinkles to hydrostatic pressure provides a measure of the various energy scales in the problem. Flow experiments show that the elastic properties and the structural undulations on a compliant membrane completely dominate the flow, possibly providing drag reduction. These measurements pave the way for building and using compliant walls for drag reduction in micro-channels.

Session Z29 GSNP: Complex Networks and Their Applications II 337 - Erin Rericha, Vanderbilt University

11:15AM Z29.00001 Consensus and transitions in coupled Sznajd networks , MATTHEW LUDDEN[1], University of Maine — In this work we investigate two coupled square lattice networks undergoing Sznajd model dynamics. The coupling between the networks is quantified by a coupling strength p. Monte Carlo simulations indicate that the exit probability of each network (to reach either all spins up or all down) depends on p and the initial density of up spins d in the other network. For fixed initial densities, we find a critical coupling p_c, above which no further changes in the exit probability are observed. We also find p_c to decrease linearly with increasing d. The consensus time scales with system size as L^{α}, where $\alpha = \alpha(p,d)$. The conditions that must be met for the two networks to reach consensus are also considered.

11:27AM Z29.00002 Topological Influence On Network Of Coupled Chemical Oscillators , JIE ZHAO, ERIN RERICHA, Vanderbilt University, VANDERBILT BIOPHYSICS COLLABORATION — Networks of interacting nodes are ubiquitous in biological and communication systems. Recently the manner of the network connections, be it through of activator or inhibitor signals, and the topology of the network has received theoretical attention with the goal of finding networks with optimal synchronization and information transmission properties. In preparation for building an experimental system to examine these predictions, we numerically explore networks of Belousov-Zhabotinsky oscillatory nodes connected through unidirectional links of activator species. We measure the time required for the nodes to synchronize as a function of the network topology. While we observe a trend of smaller synchronization times with increasing first non-zero eigen values, we find that the most important factor in determining synchronization time is the initial phase difference between the oscillators. We find that the synchronization times for a given network topology, as determined from a uniform distribution of initial phase differences, is best described with a skewed Gaussian. To better understand the factors underlying this distribution, we look at the synchronization times in a three-node network as a function of both initial conditions and model parameters.

11:39AM Z29.00003 Extreme Fluctuations in Stochastic Network Synchronization with Time Delays[1] , D. HUNT, B.K. SZYMANSKI, G. KORNISS, Rensselaer Polytechnic Institute — We study the effects of nonzero time delay on the extreme fluctuations about the mean in complex networks with local relaxation dynamics in the presence of noise. This extends our previous results for average fluctuations [2,3] by considering the typical behavior of the worst-case node as the system evolves in the steady state. Within our previously established framework of the synchronizability of such systems, we consider the changes in the distribution of extremes for various delays in particular networks and the scaling behavior of the average extremal values vs. system size across ensembles of similar networks. For networks with sufficient randomness in their structure, the distribution of the global extreme is in the same universality class as that of an ensemble of independent variables, similarly to the case of zero time delay. Specifically, it asymptotically approaches the Fisher-Tippet-Gumbel extreme-value limit distribution. The local trends for individual nodes (esp. those of high degree) within the network, as well as the scaling behavior of the global extreme, however, can be adversely affected by large time delays.

11:51AM Z29.00004 The Joint Effect of Network Topology and Update Functions on the Stability of Boolean Networks , SHANE SQUIRES, ANDREW POMERANCE, EDWARD OTT, MICHELLE GIRVAN, University of Maryland–College Park — Boolean networks are dynamical systems commonly used to model biological systems such as gene regulatory networks and neural networks. In a Boolean network, the state of each node can take one of two values, which is updated at discrete time steps using an update function that depends only on the states of its inputs on the previous time step. We study the stability of attractors in a Boolean network with respect to small perturbations. While recent past work has addressed the separate effects on stability of nontrivial network topology and update functions, only very crude information exists on how these effects interact. We present a general solution for finding the stability of Boolean networks, considering the joint effects of network topology and update functions. In particular, we show that the predictions of our approach agree with simulations of Boolean networks with threshold update functions.

12:03PM Z29.00005 Asymptotically inspired moment-closure approximation for adaptive networks , MAXIM SHKARAYEV, Iowa State University — Dynamics of adaptive social networks, in which nodes and network structure co-evolve, are often described using a mean-field system of equations for the density of node and link types. These equations constitute an open system due to dependence on higher order topological structures. We propose a systematic approach to moment closure approximation based on the analytical description of the system in an asymptotic regime. We apply the proposed approach to two examples of adaptive networks: recruitment to a cause model and adaptive epidemic model. We show a good agreement between the mean-field prediction and simulations of the full network system.

12:15PM Z29.00006 Optimizing Nutrient Uptake in Biological Transport Networks , HENRIK RONELLENFITSCH, ELENI KATIFORI, Max Planck Institute for Dynamics and Self-Organisation (MPIDS), 37077 Goettingen, Germany — Many biological systems employ complex networks of vascular tubes to facilitate transport of solute nutrients, examples include the vascular system of plants (phloem), some fungi, and the slime-mold *Physarum*. It is believed that such networks are optimized through evolution for carrying out their designated task. We propose a set of hydrodynamic governing equations for solute transport in a complex network, and obtain the optimal network architecture for various classes of optimizing functionals. We finally discuss the topological properties and statistical mechanics of the resulting complex networks, and examine correspondence of the obtained networks to those found in actual biological systems.

12:27PM Z29.00007 Paradoxical Behavior of Granger Causality , ANNETTE WITT[1], DEMIAN BATTAGLIA[2], Max-Planck Institute for Dynamics and Self-Organization, ALEXANDER GAIL[3], German Primate Center — Granger causality is a standard tool for the description of directed interaction of network components and is popular in many scientific fields including econometrics, neuroscience and climate science. For time series that can be modeled as bivariate auto-regressive processes we analytically derive an expression for spectrally decomposed Granger Causality (SDGC) and show that this quantity depends only on two out of four groups of model parameters. Then we present examples of such processes whose SDGC expose paradoxical behavior in the sense that causality is high for frequency ranges with low spectral power. For avoiding misinterpretations of Granger causality analysis we propose to complement it by partial spectral analysis. Our findings are illustrated by an example from brain electrophysiology. Finally, we draw implications for the conventional definition of Granger causality.

12:39PM Z29.00008 Direct and indirect effects in causal networks , ANDREAS KRÄMER, Ingenuity Systems, Inc. — Literature-derived networks of biomolecular interactions representing cause-effect relationships generally contain many indirect relationships where the actually observed causal effect results from a sequence of events represented in the same network. A statistical method is developed, based on an Ising-like spin model operating on the edges of the network, to distinguish between direct and indirect effects using only the network structure itself. This allows to identify paths representing likely causation mechanisms.

12:51PM Z29.00009 Extraction of hidden information by efficient community detection in networks[1] , JOOYOUNG LEE, JUYONG LEE, Korea Institute for Advanced Study, STEVEN GROSS, University of California, Irvine — Currently, we are overwhelmed by a deluge of experimental data, and network physics has the potential to become an invaluable method to increase our understanding of large interacting datasets. However, this potential is often unrealized for two reasons: uncovering the hidden community structure of a network, known as community detection, is difficult, and further, even if one has an idea of this community structure, it is not a priori obvious how to efficiently use this information. Here, to address both of these issues, we, first, identify optimal community structure of given networks in terms of modularity by utilizing a recently introduced community detection method. Second, we develop an approach to use this community information to extract hidden information from a network. When applied to a protein-protein interaction network, the proposed method outperforms current state-of-the-art methods that use only the local information of a network. The method is generally applicable to networks from many areas.

1:03PM Z29.00010 Scaling of Minimum Dominating Sets in Various Scale-Free Network Ensembles[1] , F. MOLNAR, S. SREENIVASAN, B.K. SZYMANSKI, G. KORNISS, Rensselaer Polytechnic Institute — We study the scaling behavior of the size of minimum dominating sets (MDS) in scale-free networks, with respect to network size N and power-law exponent γ [Nacher et al., NJP 073005 (2012)]. Network samples are constructed by either the configuration model (CM) via multigraphs, or exact degree sequence sampling methods. The MDS is found by a sequential greedy algorithm. We control the average degree by setting an appropriate lower degree cutoff $k_{\min}$. Two subtypes of networks are studied according to the maximum degree cutoff $k_{\max}$. Our results show that when $k_{\max} = \sqrt{N}$ all networks have similar scaling. The size of MDS is linear with respect to N, and for a given N, it increases for low γ values. When $k_{\max} = N - 1$, we find a structural difference between CM networks, and networks constructed by exact sampling methods. For the latter, we find a scaling transition of the MDS size from O(N) to O(1) at approximately $\gamma \approx 1.9$, due to the appearance of star subgraphs with O(N) central degree. For a given N, the size of MDS increases for higher γ values. However, in CM networks the MDS scales linearly with N, and for a given N, it is non-monotonic with respect to γ. Finally, we find that a partial MDS, which dominates only a certain fraction of the network, has the same scaling as full domination, even for as low as 30% dominated fraction.

1:15PM Z29.00011 ABSTRACT WITHDRAWN –

1:27PM Z29.00012 Graphicality of random scale-free networks with general degree cutoffs , YONGJOO BAEK, DANIEL KIM, Department of Physics, KAIST, MEESOON HA, Department of Physics Education, Chosun University, HAWOONG JEONG, Department of Physics, KAIST — We study graphicality of random scale-free networks with arbitrary degree cutoffs in the thermodynamic limit, which refers to realizability of degree sequences randomly generated with the degree exponent γ and the upper degree cutoff k_c as the number of nodes N goes to infinity. While a recent study[1] found that only degree sequences with $\gamma > 2$ or $\gamma < 0$ are graphical if $k_c = N - 1$ using the graphicality criterion proved by Erdős and Gallai,[2] we generalize the study to different upper cutoffs. To ensure graphicality of degree sequences, it is found that the upper cutoff must be lower than $k_c \sim N^{1/\gamma}$ for $\gamma < 2$, whereas any upper cutoff is allowed for $\gamma > 2$. This is also numerically verified, using both random and deterministic sampling of degree sequences. Our result can be interpreted as giving a fundamental constraint on the structure of random scale-free networks.

1:39PM Z29.00013 Phase transition of biconnected components in scale-free networks , PURIN KIM, Department of Physics and Astronomy, Seoul National University, DEOK-SUN LEE, Department of Natural Medical Sciences and Department of Physics, Inha University, BYUNGNAM KAHNG, Department of Physics and Astronomy, Seoul National University — In information-transport and biological systems, there can be more than one pathway between two nodes, so that there is a backup in case one pathway is inactive. The size of such biconnected nodes can be an important measure of the robustness of a system. The giant biconnected components of diverse real-world networks suggest the importance of scale-free topology in the biconnectivity. Thus, here, we consider a critical behavior of the largest biconnected component as links are added and form a random scale-free network. The critical exponents $\beta_{(\mathrm{BC})}$ and $\beta_{(\mathrm{SC})}$ associated with the order parameter of the percolation transition of biconnected and single-connected components, respectively, are compared. We obtain that $\beta_{(\mathrm{BC})}/\beta_{(\mathrm{SC})} = \lambda - 1$ for $2 < \lambda < 3$ and 2 for $\lambda > 3$, where λ is the exponent of the degree distribution in scale-free networks. We also obtain the finite-size scaling behavior of the order parameter analytically and numerically.

Session Z31 DPOLY: New Computational Methods in Polymer & Soft Matter Physics 339 - Gary Leuty, The University of Akron

11:15AM Z31.00001 Simulations of Coarse Grain Entangled Polymeric Systems: From Thermodynamics to Rheology , ABELARDO RAMIREZ-HERNANDEZ, JUAN DE PABLO, Institute for Molecular Engineering, The University of Chicago — Coarse-grained models have been proposed for description of soft materials over length and time scales unattainable by using atomistic models. Polymeric materials present particular challenges, because characteristic length and time scales generally span several orders of magnitude. Most coarse-grained models resort to soft effective interaction potentials, with the result that important effects are lost, including those created by the non-crossability of long polymer chains. In this work we generalize a particle-based coarse-grained approach, which has been successfully used in the past to describe the structure and thermodynamics of homopolymers and block polymers, to the study of linear and non-linear rheology in polymer melts well above the entanglement molecular weight. Entanglements are represented by slip-springs introduced at the two-chain level, as fluctuating interactions between neighboring pairs of polymeric molecules. The model is shown to exhibit scaling laws for the mean square displacement and shear viscosity that are consistent with those observed in tube theories and in experiments. Comparison between simulation and experimental results shows that the model is capable of describing quantitatively the linear and non-linear rheology of homopolymer melts and blends

11:27AM Z31.00002 Model for the shear viscosity of suspensions of star polymers and other soft particles , CARLOS MENDOZA, Materials Research Institute, UNAM — We propose a model to describe the concentration dependence of the viscosity of soft particles. We incorporate in a very simple way the softness of the particles into expressions originally developed for rigid spheres. This is done by introducing a concentration-dependent critical packing, which is the packing at which the suspension looses fluidity. The resultant expression reproduces with high accuracy the experimental results for suspensions of star polymers in good solvents. The model allows to explain a weak increase of the viscosity observed in the case of diblock copolymer stars suggesting that the reason for this peculiar behavior is mainly a consequence of the softness of the particles. In the semi-dilute regime, suspensions of star polymers are modeled using the Daoud-Cotton picture to complete the description in the whole concentration regime.

11:39AM Z31.00003 Systematic and Simulation-Free Coarse-Graining of Polymer Melts using Soft Potentials , DELIAN YANG, QIANG WANG, Colorado State University — Full atomistic simulations of many-chain systems such as polymer melts are not feasible at present due to their formidable computational requirements. Coarse-grained models have to be used instead, where the segments interact with soft potentials that allow complete overlapping. This enables systematic coarse-graining with different N (number of segments on each chain) at constant invariant degree of polymerization controlling the system fluctuations. In this work we use integral-equation theories and a relative entropy framework for coarse-graining to investigate how the soft potential varies with N and how well the coarse-grained models can reproduce both structural and thermodynamic properties of the original system. This will provide us with a quantitative basis for choosing small N-values that can still capture the chain conformational entropy, a characteristics of polymers.

11:51AM Z31.00004 Solvent Entropy in and Coarse-Graining of Polymer Lattice Models , QIANG WANG, PENGFEI ZHANG, Department of Chemical and Biological Engineering, Colorado State University — In conventional lattice models for polymeric systems, each lattice site is occupied by at most one polymer segment, and an unoccupied lattice site is often treated as a solvent molecule. This self- and mutual-avoiding walk requires that all lattice sites, polymer segments, and solvent molecules have the same volume. Since a polymer segment here is the coarse-grained representation of a group of real monomers, this incorrectly accounts for the solvent entropy (i.e., size ratio between polymer segments and solvent molecules). It also limits the coarse-graining capability of such models, where the invariant degree of polymerization controlling the system fluctuations is too small (thus exaggerating the fluctuations) compared to that in most experiments. Here we show how to properly account for the solvent entropy in new lattice models with multiple occupancy of lattice sites [Q. Wang, **Soft Matter 5**, 4564 (2009); **6**, 6206 (2010)], and present a quantitative coarse-graining strategy that ensures both the solvent entropy and fluctuations in experimental systems are properly accounted for using the new lattice models.

12:03PM Z31.00005 Recent developments in the VOTCA package for coarse-graining , CHRISTOPH JUNGHANS, Los Alamos National Lab — Coarse-graining is a systematic way of reducing the number of degrees of freedom used to represent a system of interest. The Versatile Object-oriented Toolkit for Coarse-graining Applications (VOTCA) provides a uniform interface to commonly used coarse-graining techniques such as iterative Boltzmann inversion, force-matching, and inverse Monte Carlo. Further, it provides a flexible modular platform for the further development of new coarse-graining techniques. Recently two new methods for coarse-graining have been added to the package and got tested on SPC/E water and methanol-water mixtures. We will discuss these results in comparison to earlier structure-based studies, but also talk about the development of non-structure-based model.

12:15PM Z31.00006 Coarse-graining of Polystyrene in Various Environments by Iterative Boltzmann Inversion[1] , ROLAND FALLER, BESTE BAYRAMOGLU, UC Davis, Chemical Engineering & Materials Science — We have developed mesoscale models for polystyrene (PS) oligomers in various environments following the Iterative Boltzmann Inversion Technique for polymer coarse–graining with and without confinement. Bond, bending angle, torsion angle distributions and radial distribution functions between PS monomers show that local structures were reproduced very well, while a small discrepancy remained in the reproduction of global structures (radii of gyration and end–to–end distances), which is probably due to end effects. Speed–up in polymer dynamics with each model was monitored by scaling factors calculated based on characteristic relaxation times of the end monomers as well as diffusivities of the chains. Results show that coarse–graining is most successful for the highest concentration system (melt) and least for the lowest concentration (dilute solution) due to the stronger slowdown of diffusive and rotational dynamics in atomistic simulations with concentration. The speed–up in the confined solution system was found to be greater than in the unconfined solution system due to the same reason except that confinement slows down the dynamics in that situation. We also characterize the limits to which extent the same models can be used for different degrees of confinement.

12:27PM Z31.00007 Complex Langevin Simulation of the Coherent States Formulation of Polymer Field Theory[1] , XINGKUN MAN, Chemical Engineering, University of California, Sant Barbara, KRIS DELANEY, Mateirals Research Laboratory, University of Clifornia, Santa Barbara, HENRI ORLAND, Institut de Physique Theorique, CE-Saclay, CEA, GLENN FREDRICKSON, Chemical Engineering, University of California, Sant Barbara — In 1969, Edwards and Freed adapted the "coherent state" methods employed in the second quantization formalism of quantum many-body theory to study polymer networks. Since its introduction into polymer science, this formalism has been largely neglected and to our knowledge, has never been applied as a basis for numerical simulations, even for linear polymers. However, in contrast to the Edwards auxiliary-field framework, this alternative polymer field theory has several attractive features, including an action or effective Hamiltonian with an explicit, finite-order, and semi-local polynomial character. We thus revisited the CS formalism and show that these characteristics have advantages both for analytical and numerical studies of linear polymers at equilibrium. For this purpose, we developed a new Complex Langevin sampling scheme that allows for simulations within the CS formalism with stable and efficient numerical characteristics. We anticipate that this methodology will facilitate efficient simulations of a wide range of systems, including complicated branched and networked polymers and liquid crystalline polymers.

12:39PM Z31.00008 Using adaptive-mesh refinement in SCFT simulations of surfactant adsorption , SCOTT SIDES, Tech-X Research, RAJEEV KUMAR, Oak Ridge National Lab, BEN JAMROZ, ROBERT CROCKETT, ALEX PLETZER, Tech-X Research — Adsorption of surfactants at interfaces is relevant to many applications such as detergents, adhesives, emulsions and ferrofluids. Atomistic simulations of interface adsorption are challenging due to the difficulty of modeling the wide range of length scales in these problems: the thin interface region in equilibrium with a large bulk region that serves as a reservoir for the adsorbed species. Self-consistent field theory (SCFT) has been extremely useful for studying the morphologies of dense block copolymer melts. Field-theoretic simulations such as these are able to access large length and time scales that are difficult or impossible for particle-based simulations such as molecular dynamics. However, even SCFT methods can be difficult to apply to systems in which small spatial regions might require finer resolution than most of the simulation grid (eg. interface adsorption and confinement). We will present results on interface adsorption simulations using PolySwift++, an object-oriented, polymer SCFT simulation code aided by the Tech-X Chompst library that enables via block-structured AMR calculations with PETSc.

12:51PM Z31.00009 ABSTRACT WITHDRAWN –

1:03PM Z31.00010 Embedding methods: application and development , JIN CHENG, Chemistry Department, Princeton University, FLORIAN LIBISCH, EMILY CARTER, Department of Mechanical and Aerospace Engineering, Princeton University — Correlated-wavefunction/density functional theory (CW/DFT) embedding methods aim to combine the formally exact correlation treatment in CW methods with the high efficiency of DFT. By partitioning a system into a cluster and its environment, each part can be treated independently. Different embedding schemes have been proposed. The density-based scheme searches for a global embedding potential mediating the interaction on the DFT level. The potential can then be used in CW calculations, e.g., to investigate hot-electron assisted H_2 dissociation on Al and Au surfaces. Experimentally, optical excitations of plasmons efficiently create the required hot electrons. The embedded CW calculations validates that the hot electrons play a key role. However, this method neglects the back-action of the cluster on the environment. To solve this problem, a potential-based scheme has been proposed [*J. Chem. Phys.*, 135, 194104 (2011)] that allows for a self-consistent combination of different ab-initio methods. Such an embedding potential thus goes beyond the DFT level. The heterogeneity involved poses various numerical challenges. We report on efforts to construct appropriate basis sets and pseudopotentials as well as to optimize the numerical procedure.

1:15PM Z31.00011 Ion distributions near dielectric interfaces from Car-Parrinello molecular dynamics[1] , VIKRAM JADHAO, Northwestern University, FRANCISCO SOLIS, Arizona State University, MONICA OLVERA DE LA CRUZ, Northwestern University — Free charges in media characterized by different dielectric constants and separated by thin boundaries are basic models for studying phenomena in both biological and synthetic materials. Knowing the distributions of ions near the dielectric interfaces between these media is crucial towards understanding the structural and physical properties of these systems. We present a new Car-Parrinello molecular dynamics method for simulating charges in heterogeneous media and computing such distributions. This method is founded on a true energy functional of induced charge density which enables the replacement of the expensive solution of the Poisson equation at each simulation step with an on-the-fly computation of polarization effects. Our simulations track the exact induced density at all times and demonstrate excellent energy conservation. The method is applied to study models of a charged colloid in polar solvent, ions near a liquid-liquid emulsion droplet, and charged biological macromolecule in aqueous solution. Results for ionic density profiles for different dielectric contrasts, ion concentrations, ion valencies, and different interfacial shapes are presented.

1:27PM Z31.00012 Monte Carlo approaches for a particle at a diffusivity interface and the "Ito-Stratonovich dilemma" , MYKYTA V. CHUBYNSKY, HENDRICK W. DE HAAN, GARY W. SLATER, Department of Physics, University of Ottawa, Canada — Diffusion of a particle in a fluid is often described by the overdamped Langevin equation (OLE). However, when the fluid is inhomogeneous, the stochastic term in the OLE is ambiguous (the "Ito-Stratonovich dilemma"). Different interpretations of this term correspond to different stochastic calculi that may be appropriate in different physical situations. Concentrating on the case when two fluids with different viscosities are separated by a sharp interface, we develop two lattice Monte Carlo algorithms, both giving the choice between calculi (including Ito, Stratonovich, and "isothermal"). We validate the algorithms considering a 1D system with the interface in the middle between two walls and particles starting at the interface and comparing the simulation results to both theory and molecular dynamics simulations, with Langevin Dynamics corresponding to isothermal and Brownian Dynamics to Ito calculi. This simple system turns out to have surprisingly rich behavior. The algorithms have also been applied to a model of polymer translocation.

1:39PM Z31.00013 Application of atomic-orbital projections to the study of the electronic properties of metal-organic frameworks , LUIS AGAPITO, Department of Physics, University of North Texas, ARRIGO CALZOLARI, ANDREA FERRETTI, Istituto Nanoscienze CNR-NANO-S3, Modena, Italy, MARCO NARDELLI, Department of Physics, University of North Texas — Metal-organic frameworks (MOF) are a new class of artificial crystalline materials. Because of their flexibility for synthesis and instrinsic ultrahigh surface area and porosity, MOFs show superior performance in gas storage, catalysis, and sensing applications. We use an efficient projection of plane-wave wavefunctions onto atomic orbitals for studying the electronic properties of these intriguing materials. The present scheme harnesses the robust periodic algorithms and systematic convergence of the plane-wave method for an atomistic electronic (Landauer conductance) and chemical (charge transfer, bond and atomic charge) analysis that provides guidelines for the design of MOF electronic materials.

11:15AM Z32.00001 Electro-coflow as a means to study whipping instabilities in electrified liquid jets , JOSEFA GUERRERO MILLAN, Georgia Institute of Technology, VENKAT GUNDABALA, Indian Institute of Technology (IIT) Bombay, ALBERTO FERNANDEZ-NIEVES, Georgia Institute of Technology — Whipping is a non-axisymmetric instability that appears in electrified jets. In air, it usually manifests in a chaotic fashion preventing its detailed experimental characterization. We use electro-coflow to generate a steady-state whipping structure and quantify its wave-like properties, which we understand from simple force balances.

11:27AM Z32.00002 Do electroviscous effects impact the hydraulic conductance of xylem? A theoretical inquiry[1] , MICHAEL SANTIAGO, VINAY PAGAY, ABRAHAM STROOCK, Cornell University — Experiments show that the hydraulic conductance of plant xylem (K) varies with the ionic-strength (I) and pH of the sap, a behavior usually attributed to the swelling of hydrogels that cover bordered pits—conduits that interconnect individual xylem vessels. These gels are believed to swell at low I or large pH, and thus decrease the flow cross-section and K. But experiments have shown behaviors that contradict this hypothesis, where a decrease in I serves to increase K. Here, we investigate whether these observations could be explained by electroviscous effects in the pores of bordered pits, since the literature suggests that pits are covered by materials that develop electric charge in aqueous solution, e.g. lignin and pectin. We use experimental measurements from the literature, combined with standard electrokinetic theory, to estimate the electroviscous effect of I and pH on K. We find that K varies non-monotonically with I and can drop to a minimum of 0.8 of its maximum value, and that our predictions fit the available experimental data for physiologically relevant conditions in I and pH. We conclude that electrokinetics could explain, at least partially, the observed changes in K, and propose experiments to test this hypothesis.

[1]This material is based upon work supported by the National Science Foundation Graduate Research Fellowship under Grant No. DGE 1144153.

11:39AM Z32.00003 Microfluidic route to generation of celloidosomes , VENKATA GUNDABALA, SERGIO MARTINEZ-ESCOBAR, School of Physics, Georgia Institute of Technology, Atlanta, USA, SAMANTHA MARQUEZ, Maggie L. Walker Governor's School for Government and Internation al Studies, Richmond, VA, USA, MANUEL MARQUEZ, YNano LLC, 14148 Riverdowns South Dr., Midlothian, Virginia 23113-3796, USA, ALBERTO FERNANDEZ-NIEVES, School of Physics, Georgia Institute of Technology, Atlanta, USA, MICROFLUIDICS TEAM — Here we present a microfluidic method to generate alginate particles with a liquid core and a shell with yeast cells encapsulated in it. This particular class of celloidosomes with cells embedded into the thin shell region at the surface, allows for easy access of oxygen to the cells improving their viability. The liquid core opens the possibility of encapsulating multiple types of cells into the core and the shell. The microfluidic method involving double emulsion technology employed here ensures robust control over the size of the particles and density of the encapsulated cells. The study has shown that the stability of the inner core is very much dependent on the viscosity of the oil used for collecting the emulsion.

11:51AM Z32.00004 Dynamics assembly of magnetic microparticles suspended in moving droplets under the influence of magnetic fields[1] , HELMUT STREY, ERIC BROUZES, TRAVIS KRUSE, Stony Brook University — Droplet microfluidics has experienced tremendous growth, particularly since it is well suited for single-cell manipulation and analysis. As mature methods for high throughput droplet manipulation have been developed a technological bottleneck of current droplet microfluidics is that because droplets are separated, sequential chemical reactions are more difficult to achieve. For example, it is very difficult to concentrate target molecules, especially since every reaction step adds volume to the droplets. Our solution to this problem is to employ functionalized magnetic beads inside droplets. The basic idea is that an external magnetic field could be used to concentrate the magnetic beads in one part of the droplet and those could then be extracted by splitting the droplet. Here we present an experimental study of the self-assembly of superparamagnetic microparticles that are suspended in moving droplets and experience a combination of forces due to the internal fluid flow fields and external magnetic fields. We observed that this interplay of flow fields coupled to the formation of particle assemblies leads to the formations of stable patterns depending on the flow speed and magnetic field strength. An understanding of this dynamic assembly is critical in employing external forces for applications in separation and sorting.

12:03PM Z32.00005 Droplet pairing and coalescence control for generation of combinatorial signals , EUJIN UM, Princeton University, MATTHEW ROGERS, Firmenich Inc., HOWARD STONE, Princeton University — A co-flowing aqueous phase with an immiscible oil phase in a microchannel generates uniformly spaced, monodisperse droplets, which retain their shape by not touching each other or by being stabilized with surfactants at the oil-water interface. However, droplet coalescence is required in many advanced applications, which can be achieved by a complex channel geometry or size differences in the droplets, and as well as by procedures to reduce the effect of a surfactant. These approaches, again, hinder the stability of droplets further downstream. We designed a microchannel which consistently inserts gas-bubble between droplets so that pairing and coalescence of droplets occurs even in the presence of surfactant, and yet prevents unwanted merging with other droplets. Aqueous droplets placed between the bubbles alter their relative speeds and spacing, and consequently we study the change in the number of droplet pairings in relation to the characteristics of the bubbles and the volume of aqueous droplets. By integrating this approach with droplets of different materials, we can program the output sequence of droplet compositions, and such complex combinatorial signals generated are aimed for concentration gradient generation and dynamic stimulation of biological cells with chemicals.

12:15PM Z32.00006 Microfluidic Printing and Ablation of Metallic Films by Modulated Capillary and Maxwell Stresses , GERRY DELLA ROCCA, SANDRA TROIAN, California Institute of Technology, MC 128-95, Pasadena, CA 91125 — Liquid dosing strategies for micro/nanofluidic applications normally rely on interior flow driven by external pressure gradients. To maintain a constant flow rate, the effective pressure drop over a given length conduit must scale inversely as the fourth power in the conduit radius, as prescribed by the Hagen-Poiseuille relation. For micron or nanoscale capillaries, this constraint requires enormous pressure gradients and external control mechanisms. This burden, coupled with the likelihood of occlusions due to gas bubbles, contaminants or carrier particles, limits the usefulness of internal flow strategies for applications involving emission of charged droplets or ions. In this talk, we focus on capillary flow in slender V grooves as a more robust and self-regulating fluidic delivery system. When coupled with spatiotemporal modulation of Maxwell stresses induced by an external electric field, beams of droplets or ions can be metered reliably and effectively. Here we explore the steady state, transient and oscillatory flow characteristics of microscale metallic films in V-grooves subject to capillary and Maxwell stresses. The geometry investigated will focus on printing and ion ablation of thin films for electronic circuits and photovoltaic displays.

Friday, March 22, 2013 11:15AM - 2:03PM –

Session Z33 DPOLY: Focus Session: Organic Electronics and Photonics - Morphology and Structure II

11:15AM Z33.00001 Correlating polymer solution conformation and thin film nanostructure: Implications for BHJ processing[1] , RAJEEV DATTANI, ALISYN NEDOMA, NATALIE STINGELIN, JENNY NELSON, JOAO CABRAL, Imperial College London — We study the solution properties of polymer-fullerene mixtures by a combination of dynamic light scattering, viscometry, small angle neutron scattering and microscopy. Specifically, the kinetics of polymer conformation (Rg and Rh) and interaction changes are mapped as function of polymer-particle concentration, overall concentration in solution and age. A model system of polystyrene and C60 fullerene was selected for this study, in addition to the P3HT/PCBM pair, which is currently explored in photovoltaic applications. The solution properties show a clear correlation to the resulting thin film nanostructured composite morphology. Our future work will further link it to bulk heterojunction solar cell performance.

11:27AM Z33.00002 Chemical Effects in Solution on the Formation of Film Morphology in Bulk Heterojunction Organic Solar Cells , JONG KUK KOH, WON TAE CHOI, KOOKHEON CHAR, Seoul National University — A novel method to control the active layer morphology of bulk heterojunction(BHJ) organic solar cells will be presented in this study. The effect of solvent quality, chemical effect in solution, on the morphology of poly(3-hexylthiophene) (P3HT):phenyl-C61-butyric acid methyl ester (PCBM) active layer has been investigated. The solubility of solvent can be controlled by mixing other types of additional solvents (additives) to the P3HT:PCBM blend solution, which could adjust the association and/or solvation characteristics for both P3HT and PCBM solutes in mixed solvents. As a result, the control over the solubility has a definitive effect on the film morphology. We report a new additive, 2-chlorophenol, which could drive P3HT to have more association character and, PCBM to have more solvation character in the mixed solvent. Higher P3HT crystallinity was achieved due to more association character in the presence of 2-chlorophenol. Also, the higher solvation character of PCBM leads to the reduced size of PCBM agglomerates, as confirmed by SANS measurements. Based on these results, P3HT:PCBM BHJ solar cell devices were fabricated, with maximum power conversion efficiency of 3.24%, which is 43% enhancement when compared with the reference.

11:39AM Z33.00003 Effect of solvent annealing on phase separation of donor/acceptor species in organic mixtures[1] , MIRIAM CEZZA, Department of Materials Science and Engineering, University of Maryland, College Park, MD, QIAN SHAO, Department of Chemistry and Biochemistry, University of Maryland, College Park, MD, SHY-HAUH GUO[2], RAYMOND J. PHANEUF[3], Department of Materials Science and Engineering, University of Maryland, College Park, MD — Studies on phase separation of mixtures of tetranitro zinc- phthalocyanine (tn-ZnPc) and [6,6]-phenyl-C_{61}-butyric acid methyl ester (PCBM) were performed in which we controlled the evaporation rate of the solvent (chloroform). Phase-contrast AFM analysis reveals that slowing down the evaporation rate of the solvent facilitates the nucleation of the donor component, and the two components phase-separate. The size of the molecular agglomerates and single small particles decreases for slow solvent evaporation and the density of small particles per unit area increases by an order of magnitude over the range studied.

11:51AM Z33.00004 Precise Structural Development and its Correlation to Function in Conjugated Polymer: Fullerene Thin Films by Controlled Solvent Annealing , HUIPENG CHEN, Department of Chemistry, University of Tennessee, SHENG HU, Department of Chemical and Biomolecular Engineering, University of Tennessee, HUIDONG ZANG, BIN HU, Department of Material Science and Engineering, University of Tennessee, MARK DADMUN, Department of Chemistry, University of Tennessee — The structural evolution and function of solvent processed poly(3-hexylthiophene):[6,6]-phenyl-C_{61}-butyric acid methyl ester (P3HT:PCBM) bilayers with controlled exposure to ortho-dichlorobenzene solvent vapor is examined. Different from thermal annealing, where the structure develops (P3HT crystallization and PCBM phase separation) in seconds, solvent vapor annealing provides more precise morphological control and a more detailed picture of the competing processes that drive the structural development. This work shows that P3HT crystallization and PCBM phase separation occur in different stages with solvent annealing. The interdiffusion of PCBM and P3HT and crystallization of P3HT occurs in the first stage, while in the second stage, the phase separation of PCBM from P3HT and agglomeration of PCBM occurs. Therefore, the sequential nature of these processes clearly documents that the phase separation of PCBM from P3HT *is not* driven by P3HT crystallinity, but by the thermodynamic driving force of mixing (the miscibility limit of PCBM in P3HT) Correlation of the morphology to device performance indicates that both sufficient P3HT crystallization and PCBM phase separation are crucial in the optimization of the morphology of the active layer.

12:03PM Z33.00005 Controlling donor/acceptor interface structure by processing solvents in organic solar cells , WEI MA, NC State University, LONG YE, Institute of Chemistry, Chinese Academy of Sciences (ICCAS), GANN ELIOT, NC State University, JIANHUI HOU, Institute of Chemistry, Chinese Academy of Sciences (ICCAS), HARALD ADE, NC State University — The nature of the interface structure between donor and acceptor are known to be critical for fullerene-based solar cells, yet have not been widely studied due to limitations of common characterization techniques. We show that processing solvents are an effective way to control the interface structure (sharp, fractal, or diffuse) of the active layer and thus impact device performance. Six different solvents or solvent mixtures are used as processing solvents in PDPP3T with $PC_{71}BM$ blends to investigate the impact of solvents on interface properties. Interface roughness is revealed by analysing the scaling of high-q data of resonant soft x-ray scattering profiles. We find that with the presence of DIO, rough interfaces are always observed. While rough interfaces provide shorter average distances for excitons to reach donor/acceptor interfaces, they also enhance recombination and are thus not ideal. When CF is used as one component, a sharp or slightly diffuse interface is induced. However, over-pure domains (especially mixed CF with DIO) are also created that seem to negatively impact performance. Overall, the mixture of ternary yields the highest PCE of 6.7%.

12:15PM Z33.00006 A comparative study of the morphology of flow and spin coated P3HT:PCBM films[1] , JOSE CHAPA, ALAMGIR KARIM, The University of Akron — Polymer solar cells are attractive due to the possibility of using cheaper materials and processing techniques for mass production of solar panels. Previous methods of fabricating polymer solar cells are suitable in laboratory conditions but are not scalable for industrial production. In this study, thin films of the photoactive blend of poly(3-hexylthiophene) (P3HT) and fullerene derivative [6,6]-phenyl-C61-butyric acid methyl ester (PCBM) were prepared by flow coating, which is suitable for industrial manufacturing of solar cells. P3HT:PCBM blends were cast from different solvents, and the morphology of flow coated and spin coated films was compared. The surface morphology and optical properties of P3HT:PCBM films were characterized with optical microscopy, AFM, and UV-vis absorption spectroscopy. The degree of P3HT order was higher in flow coated films, as compared to spin coated films. Films flow coated using chloroform solutions had a higher thermal stability and an enhanced degree of phase separation as compared to spin coated films. Flow coated films from chlorobenzene solutions had a lower thermal stability and a smaller length scale of phase separation. This study demonstrates that flow coating is a suitable alternative technique for fabricating polymer solar cells.

12:27PM Z33.00007 Microstructure of self-assembled all-conjugated donor-acceptor block copolymers for organic solar cells , MICHAEL BRADY, Materials Department, UC Santa Barbara, SUNG-YU KU, Materials Research Laboratory, UC Santa Barbara, JUSTIN COCHRAN, Department of Chemistry, UC Santa Barbara, CRAIG HAWKER, EDWARD KRAMER, MICHAEL CHABINYC, Materials Department, UC Santa Barbara — All-conjugated diblock copolymers (CBCPs), with donor and acceptor blocks, form intriguing alternatives to polymer/fullerene bulk heterojunction (BHJ) blends as low-cost photovoltaics. BHJs comprise a phase-separated thin film microstructure, in which chemically distinct domains of donor and acceptor enable exciton dissociation at their interface and transport of free charges through continuous n- and p-type paths to the electrodes. GIWAXS, AFM, soft X-ray spectroscopy (NEXAFS), and resonant scattering (RSoXS) are used to probe the structure of films of CBCPs that have an electron-donating P3HT block and an electron-accepting poly-(diketopyrrolopyrrole-terthiophene) (DPP) block. Thermal annealing after casting causes these CBCP films to form ordered domains on the scale of the exciton diffusion length, with ca. 50 nm in-plane lamellar spacings, with crystallites of each block present. GIWAXS diffraction peaks from the (100), (200), and (300) alkyl chain stacking planes for crystals of each block show (h00) orientation toward the out-of-plane direction, with the (010) pi-stacking vectors in the film plane. CBCP processing-structure studies have enabled the control of chain ordering and orientation at both length scales, and thus the formation of optimal BHJ morphologies.

12:39PM Z33.00008 Controlled Domain Swelling for Block Copolymer-Based Solar Cells , ALISYN NEDOMA, RAJEEV DATTANI, JAMES BANNOCK, PAUL WESTACOTT, JOAO CABRAL, Imperial College London, CENTRE FOR PLASTIC ELECTRONICS COLLABORATION — Block copolymers seem ideally suited materials for solar cells because they self-assemble to form highly-ordered domains on the same length scale as the diffusion length of an exciton. Success has thus far been limited by the tendency of block copolymers to disorder at low loadings of fullerene; a consequence of Timmerman's Rule whereby preferential interactions between the fullerene and one block of the copolymer tend to destabilize the microstructure. We present a method for balancing the volumetric swelling of one block by swelling the other block with a commensurate amount of the homopolymer. This technique is demonstrated for a model polymer system and extended to a conjugated rod-coil block copolymer.

12:51PM Z33.00009 Observation the Nanoscale Blending Morphology of P3HT:PCBM Bulk-Heterojunction by Energy-Filtered TEM and Contrast Transfer Function. , NOPPORN RUJISAMPHAN, ISMAT SHAH, University of Delaware — The efficiency of bulk-heterojucntion organic solar cells is strongly related to the blending morphology of donor and acceptor materials. By understanding the intermixed morphology would improve device performance. Herein, we present the ways to improve contrast images in the transmission electron microscopy of P3HT:PCBM. In general, TEM images took at the focus point gives one low contrast. We take advantage of the contrast transfer function (CTF) to improve contrast images in bright field TEM. By changing the defocus values, the fibril structure of the P3HT is obviously observed and distinguished. In order to observe the nanoscopic blending morphology, fibril size, and distribution of those fibrils, we carry out the energy filtered TEM (EFTEM). The energy window centered at 19 eV with the slit width energy of 7 ev is selected for looking only P3HT domain. In contrast, the energy window is centered at 25, and 30 eV for observing PCBM domains with the same slit width energy for a comparison. When used the window at 19 ev, we are able to clearly observe the P3HT fibril structure with the diameter and the length of 15 ± 1 nm and 51 ± 20nm, respectively. The diameter size of those fibrils did not change even in the annealed samples implying that the PCBM diffused only into an amorphous region of P3HT. The distribution of those fibrils seemed to be homogeneous without any preferred direction. Together with XRD results, we found that in only one P3HT fibrils, there are 40 pi-pi stacking layers with 9 layers parallel to the fibril length.

1:03PM Z33.00010 Cross-sectional nanoscale morphology and interfacial band alignment of phase-separated polymer/fullerene by scanning tunneling microscopy and spectroscopy , M.C. SHIH[1], Y.P. CHIU, B.C. HUANG, Department of Physics, National Sun Yat-sen University, Kaohsiung, 80424, Taiwan, C.C. LIN, S.S. LI, Department of Materials Science and Engineering, National Taiwan University, Taipei, 10617 Taiwan, C.S. CHANG, Institute of Physics, Academia Sinica, Taipei 11529, Taiwan, C.W. CHEN, Department of Materials Science and Engineering, National Taiwan University, Taipei, 10617 Taiwan — The efficiency of organic films based on poly(3-hexylthiophene) (P3HT) and methanofullerene derivative (PCBM) was shown to be strongly dependent on the crystalline order inside. Through the suitable annealing process, the well-crystallized organic P3HT:PCBM films can be fabricated to enhance their charge transport. To further improve the efficiency of photo-induced charge separation and transport as well as the corresponding photocurrent, more detailed electronic information at both interfaces of the donors/accepters and photoactive-layer/electrode will be essential. In this work, cross-sectional scanning tunneling microscopy and spectroscopy were employed to investigate the interfacial properties of P3HT:PCBM films. The vertical phase distribution and local electronic structures across the interfaces of substrate/organic film and P3HT/PCBM are obtained at the atomic resolution. These electronic structures also provide direct observations of the interfacial band alignments, suggesting the possible carrier transport mechanism of P3HT:PCBM organic films.

1:15PM Z33.00011 Enhanced Photocurrent in a Photovoltaic Cell involving a Nonconjugated Conductive Polymer, Poly(β-pinene) , M. SANGAL, G. TELANG, M. THAKUR, Photonic Materials Research Laboratory, Auburn University, AL — Photovoltaic cells have been fabricated using titanium dioxide/doped poly(β-pinene)/carbon on ITO glass-substrates. Photocurrents and photo-voltages for different intensities of light (from a white illuminant light bulb, emission at 300-700 nm) have been measured. Use of iodine-doped nonconjugated conductive polymer film has led to significant enhancement of photocurrent compared to previous reports which included a different cell structure with undoped polymer-C_{60} composites. A maximum photocurrent of about 0.3 mA was observed for a light intensity of about 5mW/cm^2. The maximum photo-voltage as observed was about 0.6 V for the same light intensity.

1:27PM Z33.00012 Molecular Imaging of Ultrathin Pentacene Films: Evidence for Homoepitaxy , YANFEI WU, GREG HAUGSTAD, C. DANIEL FRISBIE, University of Minnesota — Ultrathin polycrystalline films of organic semiconductors have received intensive investigations due to the critical role they play in governing the performance of organic thin film transistors. In this work, a variety of scanning probe microscopy (SPM) techniques have been employed to investigate ultrathin polycrystalline films (1-3 nm) of the benchmark organic semiconductor pentacene. By using spatially resolved Friction Force Microscopy (FFM), Kelvin Probe Force Microscopy (KFM) and Electrostatic Force Microscopy (EFM), an interesting multi-domain structure is revealed within the second layer of the films, characterized as two distinct friction and surface potential domains correlating with each other. The existence of multiple homoepitaxial modes within the films is thus proposed and examined. By employing lattice-revolved imaging using contact mode SPM, direct molecular evidence for the unusual homoepitaxy is obtained.

1:39PM Z33.00013 Understanding the growth of nanoscale organic semiconductors: the role of substrates[1] , MINA YOON, KAI XIAO, KENDAL W. CLARK, AN-PING LI, DAVID GEOHEGAN, BOBBY SUMPTER, SEAN SMITH, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, CENTER FOR NANOPHASE MATERIALS SCIENCES, OAK RIDGE NATIONAL LABORATORY TEAM — Our recent studies have demonstrated how substrates can be used to control the synthesis of nanoscale organic semicorductors. In particular, we study the growth mechanism of oriented crystalline organic nanowires consisting of M-TCNQF4 (M=Cu or Ag) from vapor-solid chemical reaction (VSCR). Our experimental and theoretical study combining time-resolved in situ X-ray diffraction and first-principles atomistic calculations indicate that the selectivity of different metals to induce nanowire growth depends strongly upon effective charge transfer between the organic molecules and the metal substrates. Understanding how to control the VSCR growth process may enable the synthesis of novel organic nanowires with axial or coaxial p/n junctions for organic nanoelectronics and solar energy harvesting. Another example is the growth of another promising organic semiconductor, CuPc assemblies on graphene(s) and Si substrates, where we investigate the role of the substrates in controlling the orientational arrangement of the molecules and their growth modes. Our theoretical study supports the various experimental observations from STM, TEM, and GIXS.

1:51PM Z33.00014 Temperature Dependent Anisotropic Step-Flow Growth of Metal Phthalocyanine on Silicon Studied by Scanning Probe Microscopy[1] , SEAN WAGNER, Department of Physics and Astronomy, Michigan State University, RICHARD LUNT, Department of Chemical Engineering and Materials Science, Michigan State University, PENGPENG ZHANG, Department of Physics and Astronomy, Michigan State University — Control of highly ordered organic molecular thin films is currently of intense interest for integration into modern electronics due to the tunable nature of organic molecules. Here, we study the initial growth of archetypal zinc phthalocyanine (ZnPc) and copper phthalocyanine (CuPc) on the deactivated Si(111) surface. Using scanning probe microscopy (SPM), we demonstrate access to a new quasi-epitaxial anisotropic step-flow growth for both ZnPc and CuPc with a *single* dominant long-range ordered relationship between the organic crystalline film and the substrate, uniquely distinct from inorganic epitaxial step-flow growth. This growth mode is largely attributed to the molecular diffusion and preferential nucleation at step edges enabled by the deactivated Si surface. We demonstrate the transition of growth modes by varying substrate temperature during deposition, altering the balance between diffusion and step- and island- nucleation rates. Access to the anisotropic step-flow growth offers new potential for the integration of highly-ordered organic thin films in silicon-based electronics.

Session Z34 DPOLY: Polymeric Glasses 342 - Yunlong Guo, Princeton University

11:15AM Z34.00001 Nanostructured glassy polymer films deposited via matrix assisted pulsed laser evaporation , KIMBERLY SHEPARD, RODNEY PRIESTLEY, Princeton University — It has recently been illustrated that nanostructured glassy polymer films can be formed via Matrix Assisted Pulsed Laser Evaporation (MAPLE). During the MAPLE process, a pulsed laser beam strikes a target, which is made of a frozen dilute polymer solution held under high vacuum. The interaction between laser light and target causes phase explosion and subsequent formation of a plume, containing clusters of polymer and solvent. The solvent is pumped off as the plume travels away from the target. The plume is collected on a temperature-controlled substrate, where a polymer film forms at a controlled, slow growth rate. The glassy films formed by MAPLE can exhibit an unusual combination of material properties. For instance, a significant reduction in density may be accompanied with a simultaneous increase in thermal/kinetic stability. These interesting material properties are a result of the films' nanostructured morphology, i.e., they exhibit a nanoglobular morphology. Here, we present further evidence connecting the global film properties to those of the nanoscale building blocks, i.e., the nanoglobules. In addition, we explore the impact of concentration (a key processing parameter) on the morphology of the films. Finally, we demonstrate the generality of nanostructured film formation via MAPLE for a series of poly(n-methacrylate)s.

11:27AM Z34.00002 Acid Diffusion in a Reacting Polymer Glass , ABHIJIT PATIL, GINUSHA PERERA, YOGENDRA PANDEY, MANOLIS DOXASTAKIS, GILA STEIN, Dept of Chemical Engg, University of Houston — The acid-catalyzed deprotection of glassy polymer films is an important process in photolithography. It is well-established that acid diffusion controls the deprotection kinetics, but simple Fickian transport models cannot capture experimental data. We examined the acid-catalyzed deprotection of a glassy poly(4-hydroxystyrene-co-tertbutylacrylate) resin using infrared absorbance spectroscopy and stochastic simulations. Experimental data were interpreted with a model that explicitly accounts for acid transport, where heterogeneities at local length scales are introduced through a non-exponential distribution of waiting times between successive hopping events. Subdiffusive behavior predicts key attributes of the observed deprotection rates, such as fast reaction at short times, slow reaction at long times, and a non-linear dependence on acid loading. These studies suggest that macroscopic deprotection rates are controlled by a strongly non-Fickian acid transport in the glassy polymer resin.

11:39AM Z34.00003 Effect of Hydrogenation on the Glass Transition Temperatures of Novel Ring-Opened Polynorbornenes , ADAM BURNS, SHENG LI, RICHARD REGISTER, Princeton University — Ring-opening metathesis polymerization (ROMP) of norbornene-type monomers has been demonstrated as a facile way to produce block copolymers incorporating semicrystalline, glassy, and rubbery blocks. Of particular interest are block copolymers, made by ROMP, with thermoplastic elastomeric properties. For this application we seek blocks with glass transition temperatures (T_g) in excess of 100 ^{o}C. To this end, novel substituted norbornene-type monomers with large, rigid substituents have been investigated. A key consequence of the ROMP mechanism is that unsaturation in the monomer is preserved in the polymer. Unsaturation in the polymer backbone is susceptible to degradation; therefore, hydrogenation is required to enhance the long-term stability of these polymers. Hydrogenation can also have a significant impact on the thermal behavior. To investigate this, we have synthesized ROMP polymers of 5-phenyl-2-norbornene and 5-cyclohexyl-2-norbornene. Hydrogenation yielded derivatives with saturated backbones. This series of polymers provides a systematic study on the influence of hydrogenation on the T_g of glassy ROMP polymers. We find that saturation of the side group increases the T_g by 14 ^{o}C, irrespective of backbone saturation. Conversely, saturation of the backbone reduces T_g by 17 ^{o}C for both aromatic and cycloaliphatic side groups. When compared to analogous studies on other ROMP polymers, it becomes clear that these trends are difficult to predict, highlighting the importance of experimental measurements.

11:51AM Z34.00004 Observing density-dependent formation of a fragile glass in surface-bound molecular chains , L.I. CLARKE, M.P. ROMAN, D.R. STEVENS, M.C. SCOTT, J.R. BOCHINSKI, Dept. of Physics, NC State University, Raleigh, NC 27695 — Dynamics within a monolayer collection of surface-bound substituted-alkyl chains are studied with narrow-band dielectric spectroscopy. A transition from independent (intra-molecular) motion to complex, glassy (inter-molecular) motion is observed as the surface density increases. At high density, both the glassy mode [1,2] and the sub-T_g relaxation [3] have a direct analogy to the equivalent relaxations in polyethylene. Thus, this experimental approach enables observation of the formation of a fragile glass as an explicit function of density. Addition of a strong terminal dipole shows the transition occurring at lower density, dipole-mediated interacting dynamics in the low density regime, and increased dominance of the sub-T_g local mode. We will discuss results from monolayers and an analogous siloxane-based substrate where alkyl chain-chain distance can be similarly controlled. [1] M. C. Scott et al. *ACS Nano* **2**, 2392 (2008). 12:03PM Z34.00005 States of Water in Non-Equilibrium Glassy Polymers , ERIC DAVIS, YOSSEF ELABD, Chemical and Biological Engineering Department, Drexel University — For many applications (e.g., packaging, medical devices) a deeper fundamental understanding of the molecular nature of water in glassy polymer coatings is of significant interest. In this study, the sorption and diffusion of water in two glassy polymers, poly(methyl methacrylate) (PMMA) and poly(styrene) (PS), were measured with both quartz crystal microbalance (QSM) and time-resolved Fourier transform infrared-attenuated total reflectance (FTIR-ATR) spectroscopy. Non-Fickian diffusion was observed in both PMMA and PS using both experimental techniques due to the non-equilibrium state of the polymers. The specific states of water were observed with FTIR-ATR spectroscopy, where dimers exist in PMMA below a critical concentration and larger clusters were observed above this concentration. Contrastingly, water only exists in PS as larger clusters over the entire sorption isotherm. A correlation between the states of water and the diffusive activation energy of water was observed. Additionally, the pseudo-equilibrium water sorption isotherms in PMMA and PS were accurately predicted with the non-equilibrium statistical associating fluid theory (NE-SAFT). We predict that the combination of time-resolved FTIR-ATR spectroscopy and NE-SAFT can be used on other water-glassy polymer systems to provide a molecular understanding of non-equilibrium sorption and diffusion.

12:15PM Z34.00006 Role of quantum effects in the glass transition[1] , VLADIMIR NOVIKOV, ALEXEI SOKOLOV, Department of Chemistry, University of Tennessee, Knoxville, TN 37996 and Chemical Sciences Division, ORNL, Oak Ridge, TN 37831 — It is shown that quantum effects lead to a significant decrease of the glass transition temperature T_g with respect to the melting temperature T_m, so that the ratio T_g/T_m can be much smaller than the typical value of 2/3 in materials where T_g is near or below $\sim$ 60 K. Furthermore, it is demonstrated that the viscosity or structural relaxation time in such low temperature glass-formers should exhibit highly unusual temperature dependence, namely a decrease of the apparent activation energy upon approaching T_g (instead of traditional increase).

12:27PM Z34.00007 Potential energy landscape contribution to the dynamic heat capacity , JOHN MCCOY, New Mexico Tech, JONATHAN BROWN, Ohio State University — The dynamic heat capacity of a simple polymeric, model glass former was computed using molecular dynamics simulations by sinusoidally driving the temperature and recording the resultant energy. The underlying potential energy landscape of the system was probed by taking a time series of particle positions and quenching them. The resulting dynamic heat capacity demonstrates that the long time relaxation is the direct result of dynamics resulting from the potential energy landscape.

12:39PM Z34.00008 Coarse grained dynamics in the glass phase , ANTON SMESSAERT, JÖRG ROTTLER, University of British Columbia — Atomic scale dynamics in glasses is dominated by extended periods of localized vibration, where the crowded surroundings of a particle act as a cage. Collective motion is necessary to escape the cage, and the succession of particle jumps or hops leads to diffusion. Each jump is an elementary relaxation event since the local structure is stable until a jump occurs. The link between local dynamics and structural properties has become of increasing interest in recent years. Aging of the mechanical response has been tied to a power-law distribution of persistence times in the cages, and concentration of hops into dynamical heterogeneities (DH) was observed in granular media and simulations of supercooled liquids in 2D. These studies were limited to small systems or hop detection in subsets, because of the post processing requirements. We present results based on a new algorithm that allows us to detect the hops of all particles during a molecular dynamics simulation. This complete coarse-grained "map" of the dynamics allows us to directly investigate temporal and spatial correlations between relaxation events. Furthermore, we can readily identify DH using a cluster algorithm and we explore the impact of aging and deformation on the size and shape of DH.

12:51PM Z34.00009 Dynamic Deformation of Thermosetting Polymers—All Atomistic Simulations , MESFIN TSIGE, Department of Polymer Science, The University of Akron, Akron, OH, NATALIA SHENOGINA, SHARMILA MUKHOPADHYAY, Department of Mechanical and Materials Engineering, Wright State University, Dayton, OH, SOUMYA PATNAIK, Propulsion Directorate, Air Force Research Laboratory, Dayton, OH — We are using all-atom molecular dynamics simulations to investigate the interconnection between structural and mechanical properties of highly cross-linked polymer networks. In this study we focused on the widely used resin-hardener system composed of DGEBA epoxy oligomers and aromatic amine hardener DETDA. Accurate cross-linked models were developed using the effective cross-linking procedure that enables to generate thermoset structures with realistic structural characteristics. These models were used to examine the elastic properties of thermosetting networks with various degrees of curing and length of resin strands both in glassy and rubbery states. In our recent study we employed static deformation approach to estimate potential energy contribution to the mechanical response. In the present work we are using dynamic deformation approach which takes into account both potential energy and thermal motions in the structure. Uniaxial, volumetric and shear dynamic deformation modes were used to obtain Young's, bulk, shear moduli and Poisson's ratio directly. We also calculated elastic constants using formulae of linear elasticity and analyzed the results obtained by direct deformation and interconversion methods. The elastic properties determined from these two approaches are in good agreement with each other and also with experimental data.

1:03PM Z34.00010 How melt stretching affect the brittle-ductile transition temperature of polymer glasses , SHIWANG CHENG, SHI-QING WANG, University of Akron — Upon increasing temperature a brittle polymer glass can turn ductile. PMMA is a good example. For a while this brittle-ductile transition (BDT) was thought to be determined by the emergence of a secondary relaxation....[1−3] On the other hand, it has been known for a long time...[4−6] that predeformation in the melt state (e.g., melt stretching) can also make brittle glasses behave in a ductile manner. This transformation has recently received a satisfactory explanation based on a picture of structural hybrid for polymer glasses....[7] It appears that BDT is dictated by the relative mechanical characteristics of the primary structure (due to the van der Waals bonds) and the chain network. The present work, based on conventional Instron tensile extension tests and DMA tests, shows that melt stretching does not alter the secondary relaxation behavior of PMMA and PC yet can turn them the brittle PMMA ductile and the ductile PC brittle. Moreover, sufficient melt stretching makes the brittle PS ductile although it does not produce any secondary relaxation process. .1. Monnerie, L.; Laupretre, F.; Halary, J. L. *Adv. Polym. 1:15PM Z34.00011 Influence of entanglements on glass transition temperature of polystyrene , TOSHIAKI OUGIZAWA, YOSHINORI KINUGASA, Tokyo Institute of Technology — Chain entanglement is essential behavior of polymeric molecules and it seems to affect many physical properties such as not only viscosity of melt state but also glass transition temperature (Tg). But we have not attained the quantitative estimation because the entanglement density is considered as an intrinsic value of the polymer at melt state depending on the chemical structure. Freeze-drying method is known as one of the few ways to make different entanglement density sample from dilute solution. In this study, the influence of entanglements on Tg of polystyrene obtained by the freeze-dried method was estimated quantitatively. The freeze-dried samples showed Tg depression with decreasing the concentration of precursor solution due to the lower entanglement density and their depressed Tg would be saturated when the almost no intermolecular entanglement was formed. The molecular weight dependence of the maximum value of Tg depression was discussed.

1:27PM Z34.00012 Translation-rotation decoupling and nonexponentiality in room temperature ionic liquids , PHILIP GRIFFIN, Dept. of Physics, University of Tennessee, ALEXANDER AGAPOV, Dept. of Chemistry, University of Tennessee, ALEXEI SOKOLOV, Dept. of Chemistry, University of Tennessee, and ORNL — It is generally accepted that room temperature ionic liquids (RTILs) have many characteristics in common with prototypical molecular glass formers. In order to understand the glassy dynamics of RTILs, we have measured the temperature dependence of structural relaxation time and self diffusion in three imidazolium based RTILs. We demonstrate that self diffusion decouples from structural relaxation in these systems as the temperature is decreased toward Tg, but the degree of decoupling is shown to be exceptionally small. In addition to the weak decoupling, we demonstrate that the temperature dependence of structural relaxation time in all three liquids can be well described by a single Vogel-Fulcher-Tammann (VFT) function over 13 decades in time. Furthermore, the stretching of the structural relaxation is shown to be temperature independent over the same range of timescales, i.e. time-temperature superposition is valid for these ionic liquids in the entire temperature range. These properties are at odds with the usual behavior of most "fragile" glass forming liquids. We suggest that these differences may result from strong and directional intermolecular interactions characteristic to RTILs.

1:39PM Z34.00013 Statistical Properties of Fluctuating Local Phases and Fluctuating Local Relaxation Rates in Glass-forming Liquids , GCINA MAVIMBELA, HORACIO E. CASTILLO, Department of Physics and Astronomy, Ohio University, AZITA PARSAEIAN, Materials Research Center, Northwestern University — Using our recently developed method [1], we determine fluctuating local phases, and their time derivatives, the "local relaxation rates", in simulation data of glass forming systems. We determine probability distribution functions (PDFs)and power spectra of the time derivatives at different temperatures. Some of the temperatures are such that the systems are aging for the duration of the simulations and for some of the temperatures, the systems reach equilibrium during the duration of the simulations. We study how the power spectra change with temperature. For the aging systems, we study how the PDFs vary with time.

1:51PM Z34.00014 The Defect Diffusion Model of Glass-Forming Liquids[1]

, JOHN FONTANELLA, Physics Department, U.S. Naval Academy, JOHN BENDLER, BSC, Inc., MARY WINTERSGILL, Physics Department, U.S. Naval Academy, MICHAEL SHLESINGER, Office of Naval Research — The defect diffusion model (DDM) provides an explanation of many properties of glass-forming liquids. For example, it has been used to interpret dielectric relaxation (alpha and beta relaxations and the boson peak), viscosity, ionic conductivity, (including the effects of temperature and pressure) positron annihilation lifetime spectroscopy data, the physical basis of fragility, scaling, the ratio of the apparent isochoric activation energy to the isobaric activation enthalpy and its relationship to monomer volume, and correlation lengths. In the model, the glass transition, Tg, occurs because of rigidity percolation. In addition the transition at T_B (or T_{LL}) is associated with mobility percolation. In the simplest form of the DDM, a supercooled liquid contains mobile single defects (MSDs) and immobile, clustered single defects (ICSDs). Consequently, dynamic heterogeneity is a natural feature of the model. If the glass transition did not intervene, all MSDs would disappear at a critical temperature Tc. In the present talk, the model will be used to comment on the change of heat capacity, thermal expansion coefficient and compressibility at Tg.

2:03PM Z34.00015 Phase behaviour of a 2D system exhibiting inverse melting[1]

, AHMAD ALMUDALLAL, Memorial University of Newfoundland, SERGEY BULDYREV, Yeshiva University, IVAN SAIKA-VOIVOD, Memorial University of Newfoundland — We calculate the phase diagram for a square-shoulder square-well potential in two dimensions using Monte Carlo simulation techniques. This potential has been previously used as a model for understanding the connection between the anomalous properties of liquid water and a hypothesized metastable liquid-liquid critical point. In our phase diagram, we find that melting lines appear to be first order, and that one of them exhibits a maximum temperature as well as a maximum pressure, indicating inverse melting (crystallization upon heating) over a small range in pressure. We apply Hamiltonian Gibbs-Duhem integration to find potential parameters that maximize the pressure range over which inverse melting occurs.

11:15AM Z42.00001 Casein Kinase 2 Reverses Tail-Independent Inactivation of Kinesin-1[1]

, JING XU, University of California, Merced — Kinesin-1 is a plus-end microtubule-based motor, and defects in kinesin-based transport are linked to diseases including neurodegeneration. Kinesin can auto-inhibit via a head-tail interaction, but is believed to be active otherwise. Here we report a tail-independent inactivation of kinesin, reversible by the disease-relevant signalling protein, casein kinase 2 (CK2). The majority of initially active kinesin (native or tail-less) loses its ability to interact with microtubules in vitro, and CK2 reverses this inactivation (approximately fourfold) without altering kinesin's single motor properties. This activation pathway does not require motor phosphorylation, and is independent of head–tail auto-inhibition. In cultured mammalian cells, reducing CK2 expression, but not its kinase activity, decreases the force required to stall lipid droplet transport, consistent with a decreased number of active kinesin motors. Our results (Nat. Commun., 3:754, 2012) provide the first direct evidence of a protein kinase upregulating kinesin-based transport, and suggest a novel pathway for regulating the activity of cargo-bound kinesin.

11:51AM Z42.00002 Investigation of the kinesin stepping mechanism via simulated annealing[1]

, B.D. JACOBSON, S.J. KOCH, S.R. ATLAS, Department of Physics and Astronomy, University of New Mexico — As kinesin processes along the microtubule, the cycle of different chemical states and physical conformations that the protein assumes can be represented by a kinetic model. Such models are preferred for numerical calculations since information about the kinesin stepping mechanism at all levels, from the atomic to the microscopic scale, is fully contained in the particular states of the cycle, in how states transition, and in the rate constants associated to each transition. This greatly simplifies the model of the mechanism while providing a reliable physical picture. We have developed a methodology that optimizes a kinetic model for kinesin built with a minimum of a priori assumptions about the mechanism. We combine Markov chain calculations and simulated annealing optimization to find the rate constants that effectively fit experimental data on kinesin speed and processivity. This optimization scheme leads us to choose the cycle that is most likely to realize the kinesin step. We report details of our kinetic model simulations which best fit experimental data for both single-molecule and gliding motility assays at varying ATP concentrations.

12:03PM Z42.00003 The Role of Secondary Structure on the Mechanical Properties of Titin

, RAVI KAPPIYOOR, DANIEL DUDEK, ISHWAR PURI, Virginia Tech — Elastomeric proteins are characterized by high resilience and low stiffness. Recent work suggests that charge interactions between the proteins and water have a large role in these mechanical properties. However, some elastomeric proteins are nonpolar, and, as such, do not have high charge interactions with the surrounding water. This indicates that there are also other factors at work. We consider the role of secondary structure (i.e. alpha helices and beta sheets) on the mechanical properties of one such elastomeric protein, titin. Molecular dynamics simulations are performed on four different configurations: (i) the PEVK domain of titin (little secondary structure in its natural state), (ii) an immunoglobulin-like domain of titin (high secondary structure in its natural state), (iii) the same immunoglobulin-like domain with all of its secondary structure artificially removed, and finally (iv) the PEVK domain linked to the immunoglobulin-like domain in its natural state. These simulations will provide key insight on the role of secondary structure on mechanical properties, which can be used to more efficiently design smart materials.

12:15PM Z42.00004 Revealing Transient Interactions between Phosphatidylinositol-specific Phospholipase C and Phosphatidylcholine–Rich Lipid Vesicles[1] , BOQIAN YANG, UMass-Amherst, TAO HE, Boston College, CÉDRIC GRAUFFEL, NATHALIE REUTER, Univ. of Bergen, MARY ROBERTS, Boston College, ANNE GERSHENSON, UMass-Amherst — Phosphatidylinositol-specific phospholipase C (PI-PLC) enzymes transiently interact with target membranes. Previous fluorescence correlation spectroscopy (FCS) experiments showed that *Bacillus thuringiensis* PI-PLC specifically binds to phosphatidylcholine (PC)–rich membranes and preferentially interacts with unilamellar vesicles that show larger curvature. Mutagenesis studies combined with FCS measurements of binding affinity highlighted the importance of interfacial PI-PLC tyrosines in the PC specificity. All-atom molecular dynamics simulations of PI-PLC performed in the presence of a PC membrane indicate these tyrosines are involved in specific cation-pi interactions with choline headgroups. To further understand those transient interactions between PI-PLC and PC-rich vesicles, we monitor single fluorescently labeled PI-PLC proteins as they cycle on and off surface-tethered small unilamellar vesicles using total internal reflection fluorescent microscopy. The residence times on vesicles along with vesicle size information, based on vesicle fluorescence intensity, reveal the time scales of PI-PLC membrane interactions as well as the curvature dependence. The PC specificity and the vesicle curvature dependence of this PI-PLC/membrane interaction provide insight into how the interface modulates protein-membrane interactions.

12:27PM Z42.00005 Single-Molecule Discrimination within Dendritic Spines of Discrete Perisynaptic Sites of Actin Filament Assembly Driving Postsynaptic Reorganization , THOMAS A. BLANPIED, Department of Physiology, University of Maryland School of Medicine — In the brain, the strength of synaptic transmission between neurons is principally set by the organization of proteins within the receptive, postsynaptic cell. Synaptic strength at an individual site of contact can remain remarkably stable for months or years. However, it also can undergo diverse forms of plasticity which change the strength at that contact independent of changes to neighboring synapses. Such activity-triggered neural plasticity underlies memory storage and cognitive development, and is disrupted in pathological physiology such as addiction and schizophrenia. Much of the short-term regulation of synaptic plasticity occurs within the postsynaptic cell, in small subcompartments surrounding the synaptic contact. Biochemical subcompartmentalization necessary for synapse-specific plasticity is achieved in part by segregation of synapses to micron-sized protrusions from the cell called dendritic spines. Dendritic spines are heavily enriched in the actin cytoskeleton, and regulation of actin polymerization within dendritic spines controls both basal synaptic strength and many forms of synaptic plasticity. However, understanding the mechanism of this control has been difficult because the submicron dimensions of spines limit examination of actin dynamics in the spine interior by conventional confocal microscopy. To overcome this, we developed single-molecule tracking photoactivated localization microscopy (smtPALM) to measure the movement of individual actin molecules within living spines. This revealed inward actin flow from broad areas of the spine plasma membrane, as well as a dense central core of heterogeneous filament orientation. The velocity of single actin molecules along filaments was elevated in discrete regions within the spine, notably near the postsynaptic density but surprisingly not at the endocytic zone which is involved in some forms of plasticity. We conclude that actin polymerization is initiated at many well-separated foci within spines, an organization that may be necessary for the finely tuned adjustment of synaptic molecular content that underlies functional plasticity. Indeed, further single-molecule mapping studies confirm that actin polymerization drives reorganization of molecular organization at the synapse itself.

1:03PM Z42.00006 Solvated dissipative electro-elastic network model of hydrated proteins , DANIEL MARTIN, Arizona State University — Elastic network models coarse grain proteins into a network of residue beads connected by springs. We add dissipative dynamics to this mechanical system by applying overdamped Langevin equations of motion to normal-mode vibrations of the network. In addition, the network is made heterogeneous and softened at the protein surface by accounting for hydration of the ionized residues. Solvation changes the network Hessian in two ways. Diagonal solvation terms soften the spring constants and off-diagonal dipole-dipole terms correlate displacements of the ionized residues. The model is used to formulate the response functions of the electrostatic potential and electric field appearing in theories of redox reactions and spectroscopy. We also formulate the dielectric response of the protein and find that solvation of the surface ionized residues leads to a slow relaxation peak in the dielectric loss spectrum, about two orders of magnitude slower than the main peak of protein relaxation. Finally, the solvated network is used to formulate the allosteric response of the protein to ion binding. The global thermodynamics of ion binding is not strongly affected by the network solvation, but it dramatically enhances conformational changes in response to placing a charge at the a the active site.

1:15PM Z42.00007 Single Molecule Electron Paramagnetic Resonance , RICHELLE M. TEELING-SMITH, EZEKIEL JOHNSTON-HALPERIN, MICHAEL G. POIRIER, P. CHRIS HAMMEL, The Ohio State University — Electron paramagnetic resonance (EPR) is a powerful spectroscopic tool for studying the dynamics of biomolecular systems. EPR measurements on bulk samples using a commercial X-band spectrometer provide insight into atomic-scale structure and dynamics of ensembles of biomolecules. Separately, single molecule measurements of biomolecular systems allow researchers to capture heterogeneous behaviors that have revealed the molecular mechanisms behind many biological processes. We are merging these two powerful techniques to perform single molecule EPR. In this experiment, we selectively label double-stranded DNA molecules with nitrogen-vacancy (NV) center nanodiamonds and optically detect the magnetic resonance of the NV probe. Shifts and broadening of our EPR peaks indicate the changing position of the attached DNA relative to the applied magnetic field. Using this new technique, we have successfully measured the first EPR spectrum of a single biomolecule. By controlling the geometry of the diamond and the applied magnetic field, we will quantitatively determine the rotational and translational dynamics of single biomolecules. This research provides the foundation for an advanced single molecule magnetic resonance approach to studies of complex biomolecular systems.

1:27PM Z42.00008 Turning a Single Molecule into an Electric Motor , CHARLES SYKES, Tufts University — Significant progress has been made in the construction of molecular motors powered by light and by chemical reactions, but electrically-driven motors have only just been demonstrated [1,2] after many theoretical proposals. Studying the rotation of molecules bound to surfaces offers the advantage that a single layer can be assembled, monitored and manipulated using the tools of surface science. Thioether molecules constitute a simple, robust system with which to study molecular rotation as a function of temperature, electron energy, applied fields, and proximity of neighboring molecules. A butyl methyl sulphide (BuSMe) molecule adsorbed on a copper surface can be operated as a single-molecule electric motor. Electrons from a scanning tunneling microscope are used to drive directional motion of the BuSMe molecule in a two terminal setup. Moreover, the temperature and electron flux can be adjusted to allow each rotational event to be monitored at the molecular-scale in real time. The direction and rate of the rotation are related to the chiralities of the molecule and the tip of the microscope (which serves as the electrode), which illustrates the importance of the symmetry of the metal contacts in atomic-scale electrical devices. [1] Experimental Demonstration of a Single-Molecule Electric Motor H. L. Tierney, C. J. Murphy, A. D. Jewell, A. E. Baber, E. V. Iski, H. Y. Khodaverdian, A. F. McGuire, Nikolai Klebanov and E. C. H. 1:39PM Z42.00009 Characterization of cellular traction forces at the single-molecule level , ALEXANDER DUNN, Department of Chemical Engineering, Stanford University — The ability of cells to generate and respond to mechanical cues is an essential aspect of stem cell differentiation, embryonic development, and our senses of touch and hearing. However, our understanding of the roles of mechanical force in cell biology remains in its infancy, due largely to a lack of tools that measure the forces generated by living cells at the molecular scale. Here we describe a new technique termed Molecular Force Microscopy (MFM) that visualizes the forces exerted by single cellular adhesion molecules with nm, pN, and sub-second resolutions. MFM uses novel FRET-based molecular tension sensors that bind to a glass coverslip and present a binding site for integrins, a ubiquitous class of cell adhesion proteins. Cell-generated forces stretch the MFM sensor molecules, resulting in decreased FRET with increasing load that can be imaged at the single-molecule level. Human foreskin fibroblasts adhere to surfaces functionalized with the MFM probes and develop robust focal adhesions. FRET values measured using MFM indicate forces of between 1 and 4 pN per integrin, thus providing the first direct measurement of the tension per integrin molecule necessary to form stable adhesions. The relatively narrow force distribution suggests that mechanical tension is subject to exquisite feedback and control at the molecular level.

Session Z43 DCP: Catalysis and Chemical Reaction Dynamics Hilton Baltimore Holiday Ballroom 2 - James Skinner, University of Wisconsin

11:15AM Z43.00001 Room-temperature self-cleaning molecular sensing by catalytic reactions[1] , KEITH H. WARNICK, BIN WANG, Dept. of Phys. and Astr., Vanderbilt University, DAVID E. CLIFFEL, DAVID W. WRIGHT, Dept. of Chem., Vanderbilt University, RICHARD F. HAGLUND, SOKRATES T. PANTELIDES, Dept. of Phys. and Astr., Vanderbilt University — New sensing techniques using self-cleaning nanosensors for molecular detection are in demand. Here we describe a room-temperature process in which a nanostructured substrate catalyzes the reaction of a target molecule with atmospheric oxygen and the reaction energy is absorbed by the substrate, where it can in principle be detected. Specifically, we report first-principles calculations describing a reaction catalyzed by Fe-porphyrin at room temperature that breaks O_2, incorporates an oxygen into the methyl group of 2,4-dinitrotoluene (DNT) and releases 1.9 eV per reaction. The atomic oxygen left on the Fe site can be removed by reacting with another DNT molecule, making the whole process self-cleaning. The reaction energy absorbed by the substrate can in principle be detected optically, as for example, by detecting the metal-insulator phase transition in VO_2. We further explore issues of sensitivity and selectivity in exploiting this reaction for solid-state molecular sensing.

11:27AM Z43.00002 A density functional theory study of structure-property relationships for Pt-Ni alloy catalysts , LIANG CAO, Department of Physics and Astronomy, Johns Hopkins Univesity, TIM MUELLER, Department of Materials Science and Engineering, Johns Hopkins University — The ORR (Oxygen Reduction Reaction) is an important reaction in devices such as metal-air batteries and PEMFCs (Polymer Electrolyte Membrane fuel cells). Pure Pt is one of the most successful electrode catalysts for this key reaction. However, due to its expense, numerous efforts have been made to find a new catalysis system based on Pt bimetallic alloys, in which Pt is partially replaced by less expensive metals, such as Ni, Co and Fe. Experimental and theoretical works have shown that Pt3Ni alloys have a higher ORR activity than pure Pt. In order to investigate the enhanced catalytic activity, cluster expansions corresponding to a simplified 9-layer Pt-Ni slab model are built to accurately and quickly predict the energies of surfaces as a function of atomic order. With the help of this model, we can study systematically the atomic structure and the surface geometry of Pt3Ni surface system at a variety of temperature and chemical environments, and we can calculate the adsorption binding energies of O, OH and H on both equilibrium and non-equilibrium Pt-Ni(111) surfaces. Also, we can investigate the effects of off-stoichiometry on surface by searching for stable ground states under different concentrations.

11:39AM Z43.00003 First-principles design of a dynamically tunable catalyst for CO_2 capture and conversion , BABATUNDE ALAWODE, ALEXIE KOLPAK, Massachusetts Institute of Technology — Due to its role in climate change, there is great interest in finding ways to take advantage of the vast amount of waste CO_2 we produce by its conversion to useful substances. This approach is currently impractical due to the high temperatures and pressures generally required for the synthesis of compounds using CO_2 as a precursor. To make direct CO_2 capture and conversion economically viable, new materials able to catalyze the conversion reactions at significantly milder conditions will be essential. In this work, we use DFT computations to design a dynamically tunable ferroelectric oxide-supported thin film catalyst that can capture CO_2 directly from the emission stream and convert it into methanol. One promising candidate for a dynamically tunable catalyst of this type is $Zn_xO_y/PbTiO_3$. We demonstrate that switching the polarization of the ferroelectric substrate substantially changes the surface atomic and electronic properties of the heterostructure, thereby alternately encouraging strong CO_2 adsorption and desorbing the products. Our approach may lead not only to new technologies for reducing emissions, but also to novel catalysts that could decrease energy consumption for industrial-scale synthetic processes.

11:51AM Z43.00004 Preferential condensation of β RDX on In metal surfaces , TERRENCE JACH, NIST, Gaithersburg, MD, ILANA G. GOLDBERG, Transportation Security Laboratory, Atlantic City, NJ, FERNANDO D. VILA, Dept. of Physics, U. of Washington, Seattle, WA — The energetic compound cyclotrimethylene-trinitramine (RDX) normally crystallizes out of solution at standard temperature and pressure in the α form. This consists of two nitro groups in pseudoaxial positions in relation to the C-N ring, and one nitro group in a pseudoequatorial position in an orthorhombic lattice. A metastable phase, labeled the β phase, is difficult to create and rarely observed. It consists of all three nitro groups in pseudoaxial positions, occupying a trigonal lattice. We have observed by means of Raman spectroscopy that RDX crystallized from solution on In metal foil preferentially adopts the β phase. We discuss a possible mechanism for this behavior in the context of recently published DFT calculations for RDX on a metal cluster.

12:03PM Z43.00005 Catalytic properties of Pt nanoclusters on defective graphene , IOANNA FAMPIOU, ASHWIN RAMASUBRAMANIAM, University of Massachusetts Amherst — Metal nanoparticles on carbon supports hold promise as electrocatalysts in direct methanol fuel cells, proton-exchange membrane fuel cells, and hydrogen fuel cells. Pt nanoclusters on carbon supports have been shown to possess superior catalytic activity and increased selectivity in a variety of electrochemical reactions as compared to bulk Pt electrodes; however, the underlying mechanisms remain poorly understood. We examine the interaction of Pt nanoclusters with point defects in graphene using first-principles density functional theory. The presence of defects in graphene supports enhances the Pt-carbon bonding, which suppresses cluster sintering thus allowing for sustained catalytic performance. Furthermore, stronger binding of clusters at defects is found to increase the tolerance of bound Pt nanoparticles towards CO poisoning. Finally, we examine the role of defective graphene supports on the activity of the cluster for the CO oxidation reaction and obtain estimates for CO-oxidation kinetics. Our results suggest possible avenues for controlling the dispersion and catalytic activity of Pt nanoclusters on carbon supports via defect engineering.

12:15PM Z43.00006 Catalytic Role of Au Nanowires[1] , EDISON DA SILVA, ANA PAULA F. NASCIMENTO, Institute of Physics "Gleb Wataghin", UNICAMP, 13083-970, Campinas - SP, Brazil, MIGUEL A. SAN-MIGUEL, Physical Chemistry Department, University of Seville, E41012, Seville, Spain — The oxidation of CO in linear atomic chains (LACs) of Au nanowires (NW) is studied by means of density functional theory calculations using quasi-static (T=0) and finite temperature *ab initio* molecular dynamics simulations. The adsorption of O_2 and CO molecules on the LAC lead to the formation of an intermediate O_2CO complex. Upon thermal activation at room temperature, the complex is able to proceed to oxidation forming a CO_2 molecule and leaving an atomic O impurity into the Au LAC. We report the conditions under which this oxidation pathway takes place. This process also explains the appearance of unusual large Au-Au bond distances in the LAC and attributed to the presence of atomic impurities.

12:27PM Z43.00007 Rationale for the high reactivity of the interfacial sites in methanol reaction on Au/TiO2(110) , SAMPYO HONG, TALAT RAHMAN, University of Central Florida — We have performed density functional theory calculations of methanol decomposition on gold nanoparticle supported on a partially reduced TiO2(110) surface. Our calculations show that the adsorption geometry of 13 atom gold nanoparticle strongly depends on the reduction level of the TiO2(110) surface such that a 30% reduced TiO2(110) surface prefers a hemispherical shape while a 10% reduced TiO2(110) surface prefers a flat shape. This hemispherical geometry of gold nanoparticle has a highest density of interfacial sites among the investigated geometries (flat, spherical, hemispherical ones), which may be a reason for the known high reactivity of interfacial sites towards various reactions on supported gold nanoparticles. We have found that methanol decomposition reaction occurring in the interfacial sites is much facile than that occurring in the non-interfacial sites of TiO2(110) surface in agreement with experiment [1]. We have found that the high activity of the interfacial sites is in fact, a result of charge transfer induced Coulomb interaction among the gold, reactant, and reducible TiO_2 atoms through the formation of ionic O-Au bond between gold and methoxy in the active sites, which turns the participating perimeter gold atom cationic. A direct result of such charge transfer induced repulsion is tilting of the methoxy axis, which leads to facile reaction of methoxy through C-H scission with the bridge oxygen atoms that are readily available from the reducible support. Work supported by DOE Grant No. DE-FG02-07ER15842. [1] S. A. Tenney, B. Cagg, M. Levine, W. He, K. Manandhar, and D. A. Chen, *Surf. Sci.* 606, 1233 (2012).

12:39PM Z43.00008 Dispersion-corrected first-principles calculation of terahertz vibration, and evidence for weak hydrogen bond formation[1] , MASAE TAKAHASHI, YOICHI ISHIKAWA, Tohoku University, HIROMASA ITO, RIKEN — A weak hydrogen bond (WHB) such as CH–O is very important for the structure, function, and dynamics in a chemical and biological system WHB stretching vibration is in a terahertz (THz) frequency region Very recently, the reasonable performance of dispersion-corrected first-principles to WHB has been proven. In this lecture, we report dispersion-corrected first-principles calculation of the vibrational absorption of some organic crystals, and low-temperature THz spectral measurement, in order to clarify WHB stretching vibration. The THz frequency calculation of a WHB crystal has extremely improved by dispersion correction. Moreover, the discrepancy in frequency between an experiment and calculation and is 10 1/cm or less. Dispersion correction is especially effective for intermolecular mode. The very sharp peak appearing at 4 K is assigned to the intermolecular translational mode that corresponds to WHB stretching vibration. It is difficult to detect and control the WHB formation in a crystal because the binding energy is very small. With the help of the latest intense development of experimental and theoretical technique and its careful use, we reveal solid-state WHB stretching vibration as evidence for the WHB formation that differs in respective WHB networks

[1]The research was supported by the Ministry of Education, Culture, Sports, Science and Technology of Japan (Grant No. 22550003).

12:51PM Z43.00009 Superior Long range Electric Transport of Organometallic Wire via Stepping Stone mechanism and First Principles Study of Length dependence of Thermoelectric Effects , HISAO NAKAMURA, TAKAO ISHIDA, YOSHIHIRO ASAI, The National Institute of Advanced Industrial Science and Technology (AIST) — We revealed the role of metal centers for superior long-range electric transport in organometallic-complex wires via stepping stone mechanism, which is recently proposed in Ref. 1]. We also found that the transport properties of organometallic molecular wire have some advantages to create thermoelectric devices, such as phonon mismatching effect, superior long range transport, and quantum interferences of conducting orbitals. We analyzed the length dependence and metal species dependence of the figure of merit (ZT) with including phonon thermal conductivity based on the first principles calculations. [1] K. Terada, H. Nakamura, K. Kanaizuka, M. Haga, Y. Asai, and T. Ishida, ACS Nano, 6, 1988-1999 (2011).

1:03PM Z43.00010 Oxygen Molecule Adsorption and Dissociation on Boron-doped Fullerene BC_{59} , SHIZHONG YANG, LEI ZHAO, FENG GAO, GUANG-LIN ZHAO, EBRAHIM KHOSRAVI, DIOLA BAGAYOKO, Southern University and A&M College — We studied the oxygen molecule adsorption and dissociation on boron-doped fullerene (B-C_{59}) from first principles spin polarized density functional theory method simulation. The results show that O_2 molecule can be adsorbed and partially reduced on the Pauling sites of B-C_{59}. The results are compared with those of nitrogen-doped fullerene (N-C_{59}). From the comprehensive simulation results, some implications in catalyst application are given.

1:15PM Z43.00011 Reaction Energies of Oxides using Random Phase Approximation , JUN YAN, JENS HUMMELSHOEJ, JENS NØRSKOV, Stanford University — Oxides are widely used in industrial heterogeneous catalysis, photo catalysis, electrochemistry and in making batteries and fuel cells. To facilitate the computational engineer and design of novel materials in these fields, it is vital important to quantitatively predict the formation and reactions energies of the oxides. LDA/GGA, the success of which has largely relied on the mysterious error cancellation in the exchange-correlation term, generally failed for these oxides, showing systematic and non-canceling errors. Recently, the use of exact exchange (EXX), plus correlation energy from Random Phase Approximation (RPA) emerges as a promising approach to obtain non-empirical exchange-correlation terms. Exact exchange energy is free of self-interaction error, while RPA correlation energy takes into account dynamic electronic screening and is fully non-local. EXX+RPA has shown to systematically improve lattice constants, atomization energies, adsorption energies, reaction barriers for a wide range of systems that have ironic, covalent and van der Waals interactions. In this talk I will present our results comparing RPA and GGA functional for the formation and reaction energies of oxides.

1:27PM Z43.00012 Oxygen vacancy formation in doped ceria: Effects of electron localization and ion local distortion[1] , ZHENPENG HU, Nankai University — Density functional theory with plus U approximation has been used to study property of doped ceria, especially oxygen vacancy formation energy on doped CeO_2 surface. Surfaces with substitutional dopants having lower valence than Ce(IV) have been studied in detail. Based on our results, there are two factors affecting the formation energy of oxygen vacancy: electron localization to form polaron, and local distortion around dopant while vacancy generating. We discuss related application for these rules in catalysis process.

1:39PM Z43.00013 Two-State Reactivity in Hydrocarbon Oxidation by FeO+: New Insight through Temperature Dependent Kinetics , SHAUN ARD, JOSH MELKO, NICK SHUMAN, ALBERT VIGGIANO, AFRL — Oxidative activation of C-H and C-C bonds is the rate limiting step in many catalytic applications. Transition metals and their oxides are the active component in numerous catalysts as they have proven to be efficient in the activation of these bonds. We report the temperature dependence of reaction kinetics from 120-700K for reactions of FeO^+ with CH_4, C_2H_2, C_2H_4, and C_2H_6 for the first time, in an effort to improve the mechanistic understanding, and from that the efficiency of these important reactions. The rate constants were found to decrease smoothly with temperature for each hydrocarbon, except for that with methane which displayed an abrupt change in temperature dependence. The branching fractions for the alcohol producing channels were also found to decrease with temperature for each hydrocarbon, with the exception of ethane where it remained constant. Implications of these results towards catalytic applications and theoretical modeling of these systems will be discussed. Specifically, the role of spin orbit coupling in determining the probability of spin inversion, and thus the importance of the "two-state reactivity" model applied to many transition metal oxide and hydrocarbon reactions will be addressed.

1:51PM Z43.00014 Charge relaxation dynamics of an electrolytic nanocapacitor[1] , VAIBHAV THAKORE, JAMES HICKMAN, Department of Physics and NanoScience Technology Center, University of Central Florida, Orlando FL — Understanding charge relaxation dynamics in confined nanospaces with overlapping electric double layers (EDLs) is critical for the development of efficient electrochemical energy storage, energy conversion and bioelectrochemical sensing devices. Using Lattice Boltzmann (LB) method, results from simulations of an electrolytic nanocapacitor subjected to a step potential at t = 0 are presented here for various degrees of EDL overlap, solvent viscosities, ratios of cation to anion diffusivity and electrode separations. A continuously varying molecular speed dependent relaxation time is proposed for use with the LB equation that, unlike the single relaxation time Bhatnagar-Gross-Krook approximation, recovers the correct microscopic description of molecular collision phenomena and holds promise for enhancing the stability of the LB algorithm. Simulations for large EDL overlap showed oscillatory behavior for ionic current densities as opposed to monotonic relaxation to equilibrium for low EDL overlap. Further, at low solvent viscosities and large EDL overlap, an anomalous plasma-like collective behavior of oscillating ions at a frequency much lower than the plasma frequency of the electrolyte was observed and as such it appeared to be purely an effect of nanoscale confinement.

Session Z44 DBIO: Focus Session: Cell Mechanics III Hilton Baltimore Holiday Ballroom 1 - Eric Dufresne, Yale University

11:15AM Z44.00001 Energy barriers for cellular rearrangements in tissues[1] , DAPENG BI, J.H. LOPEZ, J.M. SCHWARZ, M. LISA MANNING, Syracuse University — The behavior of cellular aggregates strongly influences morphogenesis, cancer growth and wound healing. While single cell mechanics has been extensively studied, the collective dynamics of cells inside a tissue is not well understood. Recent experiments have shown cells in tissues behave like fluids on long timescales and solids on shorter timescales, and exhibit caging behavior at intermediate timescales as they are more tightly packed. These observations are reminiscent of dynamic slowing down and dynamical heterogeneities due to mutual confinement and crowding of particles glassy systems. A common and crucial feature of glassy systems is the existence of a Potential Energy Landscape (PEL) for local rearrangements. For thermal glassy materials, when these barriers are large compared to thermal fluctuations, its rheology is dependent on the PEL and external mechanical driving. In contrast, cells in a tissue are non-thermal and overcome energy barriers in the PEL mainly through local active processes, i.e. making new adhesions and cell shape changes. We numerically map the PEL of a confluent tissue as functions of different transition pathways and single cell properties. Analytical calculations are also performed to find the minimal energy shapes for 2-D confluent cell packings.

11:27AM Z44.00002 Motion of individual and coupled amoebae during collective migration , CHENLU WANG, MEGHAN DRISCOLL, SAGAR CHOWDHURY, SATYANDRA K. GUPTA, University of Maryland-College Park, CAROLE PARENT, National Cancer Institute, National Institutes of Health, WOLFGANG LOSERT, University of Maryland-College Park — Collective migration is a ubiquitous natural phenomenon. We analyzed the migration of Dictyostelium Discoideum amoebae, which migrate both individually and collectively. We previously found that individually and collectively migrating cells have similar speed and straightness. We analyzed the effects of cell-cell contact and cell-surface contact on cell characteristics, such as adhesion, speed, and shape. We found that in the absence of cell-surface contact, cells form irregular clumps, yet are still able to migrate collectively in response to an external signal. Individually migrating cells exhibit waves of high boundary curvature that travel from the fronts to the backs of cells. By comparing the shape dynamics of individual cells and groups of cells, we found that these boundary curvature waves can be transmitted from one cell to another.

11:39AM Z44.00003 Cellular Particle Dynamics simulation of biomechanical relaxation processes of multi-cellular systems[1] , MATTHEW MCCUNE, IOAN KOSZTIN, Department of Physics and Astronomy, University of Missouri, Columbia, Missouri 65211, USA — Cellular Particle Dynamics (CPD) is a theoretical-computational-experimental framework for describing and predicting the time evolution of biomechanical relaxation processes of multi-cellular systems, such as fusion, sorting and compression. In CPD, cells are modeled as an ensemble of cellular particles (CPs) that interact via short range contact interactions, characterized by an attractive (adhesive interaction) and a repulsive (excluded volume interaction) component. The time evolution of the spatial conformation of the multicellular system is determined by following the trajectories of all CPs through numerical integration of their equations of motion. Here we present CPD simulation results for the fusion of both spherical and cylindrical multi-cellular aggregates. First, we calibrate the relevant CPD model parameters for a given cell type by comparing the CPD simulation results for the fusion of two spherical aggregates to the corresponding experimental results. Next, CPD simulations are used to predict the time evolution of the fusion of cylindrical aggregates. The latter is relevant for the formation of tubular multi-cellular structures (i.e., primitive blood vessels) created by the novel bioprinting technology.

11:51AM Z44.00004 Effects of TNF-alpha on Endothelial Cell Collective Migration , DESU CHEN, Biophysics Program, University of Maryland, College Park, DI WU, JOSE HELIM ARANDA-ESPINOZA, Bioengineering Department, University of Maryland, College Park, WOLFGANG LOSERT, Department of Physics, University of Maryland, College Park — Tumor necrosis factor (TNF-alpha) is a small cell-signaling protein usually released by monocytes and macrophages during an inflammatory response. Previous work had shown the effects of TNF-alpha on single cell morphology, migration, and biomechanical properties. However, the effect on collective migrations remains unexplored. In this work, we have created scratches on monolayers of human umbilical endothelial cells (HUVECs) treated with 25ng/mL TNF-alpha on glass substrates. The wound healing like processes were imaged with phase contrast microscopy. Quantitative analysis of the collective migration of cells treated with TNF-alpha indicates that these cells maintain their persistent motion and alignment better than untreated cells. In addition, the collective migration was characterized by measuring the amount of non-affine deformations of the wound healing monolayer. We found a lower mean non-affinity and narrower distribution of non-affinities upon TNF-alpha stimulation. These results suggest that TNF-alpha introduces a higher degree of organized cell collective migration.

12:03PM Z44.00005 ABSTRACT WITHDRAWN –

12:15PM Z44.00006 Mitotic wavefronts mediated by mechanical signaling in early Drosophila embryos , LOUIS KANG, University of Pennsylvania, TIMON IDEMA, Delft University of Technology, ANDREA LIU, TOM LUBENSKY, University of Pennsylvania — Mitosis in the early Drosophila embryo demonstrates spatial and temporal correlations in the form of wavefronts that travel across the embryo in each cell cycle. This coordinated phenomenon requires a signaling mechanism, which we suggest is mechanical in origin. We have constructed a theoretical model that supports nonlinear wavefront propagation in a mechanically-excitable medium. Previously, we have shown that this model captures quantitatively the wavefront speed as it varies with cell cycle number, for reasonable values of the elastic moduli and damping coefficient of the medium. Now we show that our model also captures the displacements of cell nuclei in the embryo in response to the traveling wavefront. This new result further supports that mechanical signaling may play an important role in mediating mitotic wavefronts.

12:27PM Z44.00007 Cells as Drops and Drops as Cells , ERIC R. DUFRESNE, Yale University — How do the mechanical properties of tissues emerge from the interactions of individual cells? To shed some light on this fundamental biological question, we consider a model system of clusters of cohesive cells adherent to soft substrates. We quantify traction forces over a wide range of cluster sizes. The scaling of traction stresses with cluster size suggests the emergence of an apparent surface tension for large colonies. To explore the possible impact of cellular surface tension on physiology, we consider the behavior of liquid droplets on soft substrates. In this case, we find that the competition of surface tension and substrate elasticity can lead to rich phenomenology, mimicking certain aspects of the physiology of cells and tissues.

1:03PM Z44.00008 Control Parameter Description of Eukaryotic Chemotaxis[1] , EBERHARD BODENSCHATZ, GABRIEL AMSELEM, ALBERT BAE, MATHIAS THEVES, CARSTEN BETA, MPI Dynamics and Self-Organization — The chemotaxis of eukaryotic cells depends both on the average concentration of the chemoattractant and on the steepness of its gradient. For the social amoeba Dictyostelium discoideum, we test quantitatively the prediction by Ueda and Shibata [Biophys. J. 93 11 (2007)] that the efficacy of chemotaxis depends on a single control parameter only, namely, the signal-to-noise ratio (SNR), determined by the stochastic fluctuations of (i) the binding of the chemoattractant molecule to the transmembrane receptor and (ii) the intracellular activation of the effector of the signaling cascade. For SNR 1, the theory captures the experimental findings well, while for larger SNR noise sources further downstream in the signaling pathway need to be taken into account.

1:15PM Z44.00009 Mathematical Modeling of Bacterial Growth[1] , SAMINA MASOOD, University of Houston Clear Lake — We develop a mathematical model for the study of bacterial growth. This model reproduces the growth curve from one equation as well as we can fit it to the experimental data. All the parameters of the model are discussed and compared with the already existing models. Experimental data for the bacterial growth is shown to fit this model.

1:27PM Z44.00010 Measuring the correlation between cell mechanics and myofibroblastic differentiation during maturation of 3D microtissues[1] , RUOGANG ZHAO, WEIGANG WANG, Johns Hopkins University, THOMAS BOUDOU, CHRISTOPHER CHEN, University of Pennsylvania, DANIEL REICH, Johns Hopkins University — Tissue stiffness and cellular contractility are two of the most important biomechanical factors regulating pathological transitions of encapsulated cells, such as the differentiation of fibroblasts into myofibroblasts - a key event contributing to tissue fibrosis. However, a quantitative correlation between tissue stiffness and cellular contraction and myofibroblast differentiation has not yet been established in 3D environments, mainly due to the lack of suitable 3D tissue culture models that allow both tissue remodeling and simultaneous measurement of the cell/tissue mechanics. To address this, we have developed a magnetic microtissue tester system that allows the remodeling of arrays of cell-laden 3D collagen microtissues and the measurement of cell and tissue mechanics using magnetically actuated elastomeric microcantilevers. By measuring the development of cell/tissue mechanical properties and the expression level of α-smooth muscle actin (α-SMA, a marker for myofibroblast differentiation) during a 6 day culture period, we found microtissue stiffness increased by 45% and α-SMA expression increased by 38%, but tissue contraction forces only increased by 10%, indicating that tissue stiffness may be the predominant mechanical factor for regulation of myofibroblast differentiation. This study provides new quantitative insight into the regulatory effect of cell and tissue mechanics on cellular function.

1:39PM Z44.00011 Effects of Polymer Surfaces on Proliferation and Differentiation of Embryonic Stem Cells and Bone Marrow Stem Cells , SISI QIN, Materials Sciences and Engineering at Stony Brook University, WENBIN LIAO, YUPO MA, Stony Brook Medical Center, MARCIA SIMON, Stony Brook Dental School, MIRIAM RAFAILOVICH, Materials Sciences and Engineering at Stony Brook University, STONY BROOK MEDICAL CENTER COLLABORATION, STONY BROOK DENTAL SCHOO COLLABORATION — Currently, proliferation and differentiation of stem cell is usually accomplished either *in vivo*, or on chemical coated tissue culture petri dish with the presence of feeder cells. Here we investigated whether they can be directly cultured on polymeric substrates, in the absence of additional factors. We found that mouse embryonic stem cells did not require gelatin and could remain in the undifferentiated state without feeder cells at least for four passages on partially sulfonated polystyrene. The modulii of cells was measured and found to be higher for cells plated directly on the polymer surface than for those on the same surface covered with gelatin and feeder cells. When plated with feeder cells, the modulii was not sensitive to gelatin. Whereas the differentiation properties of human bone marrow stem cells, which are not adherent, are less dependent on either chemical or mechanical properties of the substrate. However, they behave differently on different toughness hydrogels as oppose to on polymer coated thin films.

1:51PM Z44.00012 An Elastic Model of Blebbing in Nuclear Lamin Meshworks[1] , CHLOE FUNKHOUSER, Northwestern University, RASTKO SKNEPNEK, Syracuse University, Northwestern University, TAKESHI SHIMI, ANNE GOLDMAN, ROBERT GOLDMAN, MONICA OLVERA DE LA CRUZ, Northwestern University — A two-component continuum elastic model is introduced to analyze a nuclear lamin meshwork, a structural element of the lamina of the nuclear envelope. The main component of the lamina is a meshwork of lamin protein filaments providing mechanical support to the nucleus and also playing a role in gene expression. Abnormalities in nuclear shape are associated with a variety of pathologies, including some forms of cancer and Hutchinson-Gilford progeria syndrome, and are often characterized by protruding structures termed nuclear blebs. Nuclear blebs are rich in A-type lamins and may be related to pathological gene expression. We apply the two-dimensional elastic shell model to determine which characteristics of the meshwork could be responsible for blebbing, including heterogeneities in the meshwork thickness and mesh size. We find that if one component of the lamin meshwork, rich in A-type lamins, has a tendency to form a larger mesh size than that rich in B-type lamins, this is sufficient to cause segregation of the lamin components and also to form blebs rich in A-type lamins. The model produces structures with comparable morphologies and mesh size distributions as the lamin meshworks of real, pathological nuclei.

2:03PM Z44.00013 The actin cytoskeleton of chemotactic amoebae operates close to the onset of oscillations[1] , CHRISTIAN WESTENDORF, JOSE NEGRETE JR., MPI Dynamics and Self-Organization, Goettingen, Germany., ALBERT BAE, Department of physics, University of California, San Diego, CA, USA., RABEA SANDMANN, EBERHARD BODENSCHATZ, MPI Dynamics and Self-Organization, Goettingen, Germany., CARSTEN BETA, Institute of Physics and Astronomy, University of Potsdam, Germany. — We report evidence that the actin machinery of chemotactic Dictyostelium cells operates close to an oscillatory instability. The averaged F-actin response of many cells to a short-time pulse of cAMP is reminiscent of a damped oscillation. At the single-cell level, however, the response dynamics ranged from short, strongly damped responses to slowly decaying, weakly damped oscillations. Furthermore, in a small subpopulation, we observed self-sustained oscillations in the cortical F-actin concentration. We systematically exposed a large number of cells to periodic pulse trains. The results indicate a resonance peak at periodic inputs of around 20 s. We propose a delayed feedback model that explains our experimental findings based on a time-delay in the actin regulatory network. To quantitatively test the model, we performed stimulation experiments with cells that express GFP-tagged fusion proteins of Coronin and Aip1. These served as markers of the F-actin disassembly process and thus allow us to estimate the delay time. Based on this independent estimate, our model predicts an intrinsic period of 20 s, which agrees with the resonance observed experimentally.

Session Z45 DBIO: Focus Session: From Molecules to Cells Hilton Baltimore Holiday Ballroom 4 - Herbert Levine, Rice University

11:15AM Z45.00001 Molecular Circuits that control Bacillus sporulation , GUROL SUEL, UT Southwestern — No abstract available.

11:51AM Z45.00002 Signal processing in eukaryotic chemotaxis , IGOR SEGOTA, ARCHANA RACHAKONDA, CARL FRANCK, Cornell University — Unlike inanimate condensed matter, living cells depend upon the detection of chemical signals for their existence. First, we experimentally determined the chemotaxis response of eukaryotic *Dictyostelium* cells to static folic acid gradients and show that they can respond to gradients as shallow as 0.2% across the cell body. Second, using Shannon's information theory, we showed that the information cells receive about the gradient exceeds the theoretically predicted information at the receptor-ligand binding step, resulting in the violation of the data processing inequality. Finally, we analyzed how eukaryotic cells can affect the gradient signals by secreting enzymes that degrade the signal. We analyzed this effect with a focus on a well described *Dictyostelium* cAMP chemotaxis system where cAMP signals are affected by an extracellular cAMP phosphodiesterase (PDE) and its inhibitor (PDI). Using a reaction-diffusion model of this set of interactions in the extracellular space, we show that cells can effectively sense much steeper chemical gradients than naively expected (up to a factor of 12). We also found that the rough estimates of experimental PDE and PDI secretion rates are close to the optimal values for gradient sensing as predicted by our model.

12:03PM Z45.00003 Bridging from Replication to Translation with a Thermal, Autonomous Replicator Made from Transfer RNA[1] , DIETER BRAUN, FRIEDERIKE M. MÖLLER, Systems Biophysics, Center for Nanoscience, LMU Munich, HUBERT KRAMMER, Systems Biophysics, Physics Department, Center for Nanoscience, Ludwig Maximilians Universität München — Central to the understanding of living systems is the interplay between DNA/RNA and proteins. Known as Eigen paradox, proteins require genetic information while proteins are needed for the replication of genes. RNA world scenarios focus on a base by base replication disconnected from translation. Here we used strategies from DNA machines to demonstrate a tight connection between a basic replication mechanism and translation [1]. A pool of hairpin molecules replicate a two-letter code. The replication is thermally driven: the energy and negative entropy to drive replication is initially stored in metastable hairpins by kinetic cooling. Both are released by a highly specific and exponential replication reaction that is solely implemented by base hybridization. The duplication time is 30s. The reaction is monitored by fluorescence and described by a detailed kinetic model. The RNA hairpins usetransfer RNA sequences and the replication is driven by the simple disequilibrium setting of a thermal gradient [2] The experiments propose a physical rather than a chemical scenario for the autonomous replication of protein encoding information.

12:15PM Z45.00004 Symmetrical charge-charge interactions in ionic solutions and implications for cell division[1] , ESHEL FARAGGI, Research and Information Systems, LLC — As is well known in electrolyte theory, electrostatic fields are attenuated by the presence of mobile charges in the solution. This seems to limit the possibility of an electrostatic repulsion model of biological interactions such as cell division. However, for a system of two charges in an ionic solution it is found that in the context of the symmetries of the system, the electrostatic repulsion between the two parts of a dividing cell are considerably increased as compared to the electrostatic repulsion between two bare charges in a dielectric. This increase in repulsion, directly resulting from interactions between the symmetrical parts of the solute system, was found to be dependent on the magnitude of the charges and the separation between them. It was also found that this increases reaches a steady state for separation greater than a solvent determined length scale related to the Debye length. These findings strongly suggest that electrostatic interactions can play a crucial part in the physical forces that are involved in biological interactions. Most fundamentally this work presents a general physical force by which one can mechanically understand cell division. Such understanding will lead to unforetold new ways in medicine, biology, chemistry, and physics.

12:27PM Z45.00005 Motorized Glasses and Crystals: Microscopic Models of Active Matter and the Cytoskeleton , PETER WOLYNES, Rice University — The interior of cells is constantly forming and reconfiguring via molecular processes that dissipate chemical energy. I will discuss simulations and analytical theories of the quasi-equilibrium phase diagram of simple models of motorized crystals and motorized network glasses. The nonequilibrium nature of molecular motors leads also to dynamical transitions to states with collective sustained flows. Analogies of these dynamical transitions seem to occur in natural and artificially reconstituted cytoskeletons.

1:03PM Z45.00006 Tension-dependent dynamic microtubule model for metaphase and anaphase phenomena , EDWARD BANIGAN, University of Pennsylvania, Dept. Physics and Astronomy, MICHAEL LAMPSON, University of Pennsylvania, Dept. Biology, ANDREA LIU, University of Pennsylvania, Dept. Physics and Astronomy — During cell division, chromosome pairs align at the center of a bipolar microtubule (MT) spindle and oscillate as MTs attaching them to the cell poles polymerize and depolymerize. Pairs later separate as shrinking MTs pull each chromosome toward its respective cell pole. We present a minimal model for these processes. We use the measured tension-dependence of single MT kinetics [1] and extrapolate for compressed MTs. We apply these to a stochastic many MT model, which we solve numerically and with master equations. We find that tension dependence enhances the speed of chromosome pulling by retracting MTs. The force-velocity curve for the single chromosome system is bistable and hysteretic. Above some threshold load, tension fluctuations induce MTs to spontaneously switch from a pulling state into a growing, pushing state. To recover pulling from the pushing state, the load must be reduced far below the threshold. This leads to oscillations in the two-chromosome system. Unlike other models, our model also captures breathing oscillations. We also explore how various components control chromosome dynamics through MT rate constants alone. [1] Akiyoshi et al. (2010) Nature 468, 576.

1:15PM Z45.00007 Cytoskeleton dynamics studied by dispersion-relation fluorescence spectroscopy , RU WANG, LEI LEI, YINGXIAO WANG, Beckman Institute for Advanced Science and Technology, University of Illinois at Urbana-Champaign, ALEX LEVINE, Department of Chemistry & Biochemistry and Department of Physics & Astronomy, University of California at Los Angeles, GABRIEL POPESCU, Beckman Institute for Advanced Science and Technology, University of Illinois at Urbana-Champaign — Fluorescence is the most widely used microscopy technique for studying the dynamics and function in both medical and biological sciences due to its sensitivity and specificity. Inspired by the spirit of spatial fluorescence correlation spectroscopy, we propose a new method to study the transport dynamics over a broad range of spatial and temporal scales. The molecules of interest are labeled with a fluorophore whose motion gives rise to spontaneous fluorescence intensity fluctuations that can be further analyzed to quantify the governing molecular mass transport dynamics. We analyze these data by the dispersion relation in the form of a power law,$\Gamma(q) \sim q^{\alpha}$, which describe the relaxation rate of fluorescence intensity fluctuations, Γ, vs. the wavenumber, q. We used this approach to study the interplay of various cytoskeletal components in intracellular transport under the influence of protein-motor inhibitors. We found that after actin is depolymerized, the transport becomes completely random for a few minutes and then it starts to organize deterministically again. We conclude that the disrupted cytoskeletal components first diffuse in the cytoplasm, but then become attached to microtubules and get transported deterministically.

1:27PM Z45.00008 Stress Generation by Actin-Myosin Networks and Bundles[1] , ANDERS CARLSSON, NILUSHI DASANAYAKE, Washington University, Department of Physics — Forces and stresses generated by the action of myosin minifilaments are calculated in idealized computer-generated actin networks and bundles. The networks are generated as random collections of actin filaments in two dimensions, and bundles are obtained by constraining the filament orientations. The actin filaments are crosslinked and attached to two fixed walls. Myosin minifilaments are placed on actin filament pairs and allowed to move and deform the network so that it exerts forces on the walls. The vast majority of simulation runs end with contractile minifilament stress, because minifilaments rotate into energetically stable contractile configurations. This process is aided by the bending of actin filaments, which accomodates minifilament rotation. Stresses for bundles are greater than those for isotropic networks, and antiparallel filaments generate more tension than parallel filaments. The forces transmitted by the actin network to the walls of the simulation cell often exceed the tension in the minifilament itself.

1:39PM Z45.00009 Cytoplasmic streaming emerges naturally from hydrodynamic self-organisation of a microfilament suspension , FRANCIS WOODHOUSE, RAYMOND GOLDSTEIN, DAMTP, University of Cambridge — Cytoplasmic streaming is the ubiquitous phenomenon of deliberate, active circulation of the entire liquid contents of a plant or animal cell by the walking of motor proteins on polymer filament tracks. Its manifestation in the plant kingdom is particularly striking, where many cells exhibit highly organised patterns of flow. How these regimented flow templates develop is biologically unclear, but there is growing experimental evidence to support hydrodynamically-mediated self-organisation of the underlying microfilament tracks. Using the spirally-streaming giant internodal cells of the characean algae Chara and Nitella as our prototype, we model the developing sub-cortical streaming cytoplasm as a continuum microfilament suspension subject to hydrodynamic and geometric forcing. We show that our model successfully reproduces emergent streaming behaviour by evolving from a totally disordered initial state into a steady characean "conveyor belt" configuration as a consequence of the cell geometry, and discuss applicability to other classes of steadily streaming plant cells.

1:51PM Z45.00010 Coordinated Switching of Bacterial Flagellar Motors in a Single E. Coli[1] , BO HU, YUHAI TU, IBM Thomas J. Watson Research Center — The swimming of Escherichia coli is propelled by its multiple flagellar motors. Each motor spins either clockwise or counterclockwise, under the control of an intracellular regulator, CheY-P. A long standing question is whether these motors work independently or not. There can be two mechanisms (extrinsic and intrinsic) to coordinate the switching of bacterial motors. The extrinsic one arises from the fact that different motors in the same cell sense a common biochemical signal (CheY-P) which fluctuates near the motors' response threshold. An alternative, intrinsic mechanism is direct motor-motor coupling which makes synchronized switching energetically favorable. Here, we develop simple models for both mechanisms and uncover their different hallmarks. A quantitative comparison to the recent experiments suggest that the direct coupling mechanism may be accountable for the observed sharp correlation between motors in a single E. coli. Possible origins of this coupling are discussed.

2:03PM Z45.00011 High-Content Movement Analysis as a Diagnostic Tool in *C. elegans* , PETER WINTER, ANDREA LANCICHINETTI, Department of Chemical and Biological Engineering, Northwestern University, LEAH KREVITT, Department of Biological Sciences, Northwestern University, LUIS AMARAL, Department of Chemical and Biological Engineering, Northwestern University, RICK MORIMOTO, Department of Molecular Biosciences, Rice Institute for Biomedical Sciences, Northwestern University — Many neurodegenerative diseases manifest themselves through a loss of motor control and give us information about the underlying disease. This loss of coordination is observed in humans and in the model organisms used to study neurodegeneration. In *Caenorhabditis elegans*, there is an extensive genetic library of strains that lack functional neuronal signaling pathways and expressing proteins associated with neurodegenerative diseases. While most of these strains have decrease motility or cause paralysis, relatively few have been screened to look for more subtle changes in motor control such as stiffness, twitching, or other changes in behavior. we use high-resolution position and posture data to automatically analyze the movement of worms from different genetic backgrounds and characterize 14 movement characteristics. By creating a quantitative mapping between the movement characterization and an online database of gene annotation, gene expression, and anatomy, we aim to predict a likely set of cellular and molecular disruptions. This work provides a proof of concept for the use of detailed movement analysis to uncover novel disruptions in certain motor control processes. Knowledge of the molecular origin of these disruptions provided by our understanding of *C. elegans* genetics and physiology could lead to new diagnostic and therapeutic targets for neurodegenerative disease.

Session Z46 DBIO: Focus Session: Physics of Proteins IV Hilton Baltimore Holiday Ballroom 5 - Andrea Markelz, State University of New York at Buffalo

11:15AM Z46.00001 Is tertiary structure really required for specific function of a protein?[1] , MIKIO KATAOKA, Graduate School of Materials Science, Nara Institute of Science and Technology — A protein is folded into the unique tertiary structure spontaneously based on the information encoded in the amino acid sequence. It has been believed that the unique tertiary structure is required for the expression of its specific function. However, the discovery of intrinsically disordered proteins (IDP) raised a question whether the structure is really required to function. Some IDP's are folded by the recognition and binding of their targets called coupled folding and binding. We have created many mutants of staphylococcal nuclease (SNase) which have interesting properties. One category of mutants cannot take native structures but show enzymatic activity. Another type of mutants takes stable native structures without activity, despite that the active site residues are completely conserved. The former can be regarded as a model system of IDP. They show ligand-induced folding which is similar to the coupled folding and binding. The mechanism of induced folding has been studied intensively by stopped-flow CD. The reason why activity is lost in the latter mutants will be discussed based on the crystal structure. Consequently, I would like to discuss about the relationship among structure, function and dynamics.

11:51AM Z46.00002 Structure–Function Studies on Receptor Activation of Photoactive Yellow Protein , SANDIP KALEDHONKAR, SHUO DAI, Department of Physics, Oklahoma State University, Stillwater, OK, 74078, RACHANA RATHOD, WOUTER HOFF, Department of Microbiology and Molecular Genetics, Oklahoma State University, Stillwater, OK, 74078, AIHUA XIE, Department of Physics, Oklahoma State University, Stillwater, OK, 74078, XIE COLLABORATION, HOFF COLLABORATION — Biological signaling in cells starts with detection of stimuli from ever changing environment, results in relay of signal, and finishes with particular cellular response. Photoactive yellow protein (PYP) from a salt loving *Halorhodospira halophila* bacterium is a blue light photoreceptor protein for negative phototaxis and a structural prototype of PAS domain superfamily of signaling and regulatory proteins. Upon absorption of a blue photon by its negatively charged p-coumaric acid (pCA) chromophore, the receptor state (off-state) undergoes photocyclic process, leading to large amplitude protein quake that results in PYP receptor activation. To understand the structural basis of receptor activation we employ time-resolved FTIR spectroscopic techniques combined with site-specific mutation to search for a key residue involved in protein quake. We will discuss the strategies and experimental results in light of hydrogen bonding network, active site structure and protein quake in PYP. The signaling mechanism leaned from PYP may have implication to understand signal transduction in other proteins.

12:03PM Z46.00003 Reconciling the concurrent fast and slow cycling of proteins on gene promoter[1] , WEI WANG, YAOLAI WANG, FENG LIU, Department of Physics, Nanjing University, China — Proteins appeared to cycle on and off the gene promoters with both long and short periods. We proposed a model to explore the dynamics of promoter-protein interactions, which enable gene transcription to proceed orderly and cyclically. We analytically proved that the intervals between two successive productive interactions are less than tens of seconds. Fitting of the model to the experimental data suggests that proteins rapidly cycle on and off the promoter, with the binding time less than several minutes. Different proteins kick in at different phases of the transcriptional cycle, and the percentage of promoters bound by specific proteins in a cell population oscillates with a period of 40min. We thus reconcile the fast and slow cycling of proteins and reveal the essential mechanism of transcription dynamics.

12:15PM Z46.00004 Dynamics and pathway of electron tunneling in repair of damaged DNA by photolyase[1] , ZHEYUN LIU, XUNMIN GUO, CHUANG TAN, JIANG LI, YA-TING KAO, LIJUAN WANG, The Ohio State University, AZIZ SANCAR, University of North Carolina School of Medicine, DONGPING ZHONG, The Ohio State University — Through electron tunneling, photolyase, a photoenzyme, restores damaged DNA into normal bases. Here, we report our systematic characterization and analyses of three electron transfer processes in thymine dimer restoration by following the entire dynamical evolution during enzymatic repair with femtosecond resolution. Using (deoxy)uracil and thymine as dimer substrates, we unambiguously determined the electron tunneling pathways for the forward electron transfer to initiate repairing and for the final electron return to restore the active cofactor and complete the repair photocycle. Significantly, we found that the adenine moiety of the unusual bent cofactor is essential to mediating all electron-transfer dynamics through a super-exchange mechanism, leading to a delicate balance of time scales. The active-site structural integrity, unique electron tunneling pathways and the critical role of adenine assure these elementary dynamics in synergy in this complex photorepair machinery to achieve the maximum repair efficiency close to unity.

[1]The authors thank Drs. Chaitanya Sexana, Yi Yang, and Chen Zang for the initial help with experiment, and Prof. Sherwin Singer and Dr. Ali Hassanali for discussion.

12:27PM Z46.00005 Electronic measurements of single-molecule processing by DNA polymerase I , YONGKI CHOI, Department of Physics and Astronomy, University of California, Irvine, TIVOLI OLSEN, Department of Chemistry, University of California, Irvine, TOLGA GUL, BRAD CORSO, CHENGJUN DONG, Department of Physics and Astronomy, University of California, Irvine, WILLIAM BROWN, Department of Chemistry, University of California, Irvine, GREGORY WEISS, Department of Molecular Biology, University of California, Irvine, PHILIP COLLINS, Department of Physics and Astronomy, University of California, Irvine — A single-molecule nanocircuit technique is applied to continuously monitor DNA replication activity by the enzyme DNA polymerase I (Pol I). Using single copies of Pol I bound to a single-walled carbon nanotube device, an electrical signal was generated to reveal enzymatic function and dynamic variability. Continuous, single-molecule-resolution recordings were obtained for Pol I processing homopolymeric DNA templates over 10 minutes and through >10,000 DNA replication events. Processivity of up to 40 nucleotide bases was directly observed, and statistical analysis of the recordings determined key kinetic parameters for the enzyme's open and closed conformations. We observe that the closed complex forms a phosphodiester bond in a highly efficient process >99.8% of the time, with a mean duration of only 0.3 ms for all four dNTPs. The rate-limiting step for replication occurs during the enzyme's open state, but with a duration that is nearly twice as long for dATP or dTTP incorporation than for dCTP or dGTP. Taken together, the results provide a wealth of new information complementing prior work on the mechanism and dynamics of DNA polymerase.

12:39PM Z46.00006 Coupling between Switching Regulation and Torque Generation in Bacterial Flagellar Motor , JIANHUA XING, Virginia Tech, FAN BAI, Peking University, TOHRU MINAMINO, Osaka University, ZHANGHAN WU, Virginia Tech, KEIICHI NAMBA, Osaka University — The bacterial flagellar motor plays a crucial role in both bacterial locomotion and chemotaxis. Recent experiments reveal that the switching dynamics of the motor depend on the rotation speed of the motor, and thus the motor torque, nonmonotonically. Here we present a unified mathematical model that treats motor torque generation based on experimental torque-speed curves and the torque-dependent switching based on the Ising type conformational spread model. The model successfully reproduces the observed switching rate as a function of the rotation speed, and provides a generic physical explanation independent of most details. A stator affects the switching dynamics through two mechanisms: accelerating the conformational flipping rate of individual rotor-switching units, which contributes most when the stator works at a high torque and thus a low speed; and influencing a larger number of rotor-switching units within unit time, whose contribution is the greatest when the motor rotates at a high speed. Consequently, the switching rate shows a maximum at intermediate speed, where the above two mechanisms find an optimal output. The load-switching relation may serve as a mechanism for sensing the physical environment, similar to the chemotaxis mechanism for sensing the chemical environment.

12:51PM Z46.00007 ABSTRACT WITHDRAWN –

1:03PM Z46.00008 Investigating a simple model of protein folding for evidence of self-organized criticality , JOELLE MURRAY, ANDREW CLELAND[1], ADDISON WISTHOFF[2], Linfield College — Protein folding is a complex, multi-faceted process with many drivers. Systems of this type are ubiquitous in nature and many behave as self-organizing critical (SOC) systems. Does protein folding exhibit self-organizing critical behavior? To answer this question, we developed a simple model of the folding process and searched for evidence of self-organized critical behavior. Furthermore, we investigated whether or not the parameters defining self-organization can shed light on the protein folding process.

1:15PM Z46.00009 Investigating the nature of folded protein structure with the aid of crystalline and amorphous models[1] , DENIZ TURGUT, OSMAN OKAN, ANGEL GARCIA, RAHMI OZISIK, Rensselaer Polytechnic Institute — Three-dimensional structure of a protein is closely tied with its function. Understanding the folded shape of a protein provides crucial information both in identifying the function and engineering custom proteins that will perform desired functions. In the current work, based on the symmetries present in the local neighborhood of residues in the folded protein structure, we investigated the possibility of creating protein-like structures from crystalline and amorphous models. Parameters like Radial Distribution Function and Bond Orientational Order Parameter [Steinhardt PJ, Nelson DR, Ronchetti M, Phys Rev B 1983, 28, 784] were used to identify the similarities between the created model structures and over 400 folded protein structures. The results show both similarities and differences between folded protein structures and those obtained from crystalline or amorphous models.

1:27PM Z46.00010 The Dynamical Transition and DNA hybridization , DEEPU GEORGE, KATHERINE NIESSEN, ANDREA MARKELZ, Physics, University at Buffalo, SUNY, Buffalo, NY 14260 — Terahertz spectroscopy has contributed to the understanding of the so-called biomolecular dynamical transition [1,2], which has been related to the anharmonic motions necessary to biomolecular function. It has been established that the 220 K transition is associated with solvent dynamics. Recently there has been some evidence that correlated motions of proteins also contribute to the THz response, and possibly a lower temperature dynamical transition arises from internal molecular motions. Here we examine how the temperature dependent THz response changes upon binding of single stranded DNA polynucleotide chains. THz time-domain spectroscopy (THz TDS) transmission measurements are performed on solution phase single stranded DNA (5 bases in length) for a specific sequence GCGCG, its complement CGCGC, and the hybridized pair. Our preliminary results show that while we have consistent decrease in the net dielectric response with binding, the dynamical transition does not change.

1:39PM Z46.00011 The power of hard-sphere models for proteins: Understanding side-chain conformations and predicting thermodynamic stability[1] , ALICE QINHUA ZHOU, COREY O'HERN, LYNNE REGAN, Yale University — We seek to dramatically improve computational protein design using minimal models that include only the dominant physical interactions. By modeling proteins with hard-sphere interactions and stereochemical constraints, we are able to explain the side-chain dihedral angle distributions for Leu, Ile, and other hydrophobic residues that are observed in protein crystal structures. We also consider inter-residue interactions on the distribution of side-chain dihedral angles for residues in the hydrophobic core of T4 lysozyme. We calculate the energetic and entropic contributions to the free energy differences between wildtype T4 lysozyme and several mutants involving Leu to Ala substitutions. We find a strong correlation between the entropy difference and the decrease in the melting temperature of the mutatants. These results emphasize that considering both entropy and enthalpy is crucial for obtaining a quantitative understanding of protein stability.

1:51PM Z46.00012 Role of the different factors contributing to long lived quantum coherence in the FMO complex , NAYELI ZUNIGA-HANSEN, RUSSELL CEBALLOS, MARK S. BYRD, None — The Fenna-Matthews-Olson (FMO) complex is one of the most widely studied photosynthetic complexes. It occurs as a trimer with three identical subunits that contain eight bacteriochlorphylls embedded in a protein environment. The observation of long lived quantum coherence and the remarkably high efficiency with which energy transfer takes place in the FMO complex has brought much attention to try to understand the mechanism behind it. We study the different factors that contribute to the long lived coherence in this complex by looking at the interplay of different parameters within the intermediate regime, where the strength of the coupling to the environment is comparable to the strength of the coupling between the sites of the system. We attempt to verify if the environmental modes due to the protein backbone have an effect on the energy transfer or if it is inherently robust due to its structure.

2:03PM Z46.00013 Dielectric response of hydrated proteins[1] , DMITRY MATYUSHOV, Arizona State University — We study dipolar susceptibility of hydrated proteins, representing the average dipole moment induced at the hydrated protein by a uniform external field. This parameter shows remarkable variation among proteins. We find a negative value of the dipolar susceptibility for some proteins, which implies a dia-electric dipolar response and negative dielectrophoresis. Such proteins, even though carrying significant permanent dipole moments, repel from the electric field. This outcome is the result of a negative cross-correlation between the protein and water dipoles, compensating for the positive variance of the intrinsic protein dipole in the overall dipolar susceptibility. We therefore suggest that the dipolar response of proteins in solution is strongly affected by the coupling of the protein surface charge to the hydration water. The protein-water dipolar cross-correlations are long-ranged, extending approximately 2 nm from the protein surface into the bulk. A similar correlation length of about 1 nm is found for the electrostatic potential. The model is applied to the analysis of light absorption by protein solutions in the THz window of radiation. Here we also find significant deviations of the absorption coefficient from the predictions of traditional theories.

Session Z47 DBIO GSNP: Invited Session: Active, Non-Equilibrium Dynamics in Complex Cellular Networks Hilton Baltimore Holiday Ballroom 6 - Margaret Gardel, University of Chicago

11:15AM Z47.00001 Probing mechanics and activity of cytoskeletal networks using carbon nanotubes[1] , NIKTA FAKHRI, Georg-August-Universitaet Goettingen — We use single-walled carbon nanotubes (SWNTs) as multi-scale micro-probes to monitor transport and fluctuations in cytoskeletal networks. SWNTs are nanometer-diameter hollow carbon filaments with micrometer lengths and a tunable bending stiffness. Their persistence length varies between 20-100 microns. We study the motion of individual SWNTs in reconstituted actin networks by near-infrared fluorescence microscopy. At long times, SWNTs reptate through the networks. At short times, SWNTs sample the spectrum of thermal fluctuations in the networks. We can calculate complex shear moduli from recorded fluctuations and observe power-law scaling in equilibrium actin networks. In the non-equilibrium cytoskeleton of cells we have targeted SWNTs to kinesin motors and thereby to their microtubule tracks. We observe both transport along the tracks as well as active fluctuations of the tracks themselves.

11:51AM Z47.00002 F-actin Buckling Coordinates Contractility and Severing in a Biomimetic Actomyosin Cortex , MICHAEL MURRELL, University of Chicago — No abstract available.

12:27PM Z47.00003 Criticalities in crosslinked actin networks due to myosin activity , MICHAEL SHEINMAN, VU University — Many essential processes in cells and tissues, like motility and morphogenesis, are orchestrated by molecular motors applying internal, active stresses on crosslinked networks of actin filaments. Using scaling analysis, mean-field calculation, numerical modelling and *in vitro* experiments of such active networks we predict and observe different mechanical regimes exhibiting interesting critical behaviours with non-trivial power-law dependencies. Firstly, we find that the presence of active stresses can dramatically increase the stiffness of a floppy network, as was observed in reconstituted intracellular F-actin networks with myosin motors and extracellular gels with contractile cells. Uniform internal stress results in an anomalous, critical mechanical regime only in the vicinity of the rigidity percolation points of the network. However, taking into account heterogeneity of motors, we demonstrate that the motors, stiffening any floppy network, induce large non-affine fluctuations, giving rise to a critical mechanical regime. Secondly, upon increasing motor concentration, the resulting large internal stress is able to significantly enhance unbinding of the network's crosslinks and, therefore, disconnect the initially well-connected network to isolated clusters. However, during this process, when the network approaches marginal connectivity the internal stresses are expected to drop drastically such that the connectivity stabilizes. This general argument and detailed numerical simulations show that motors should drive a well connected network to a close vicinity of a critical point of marginal connectivity. Experiments clearly confirm this conclusion and demonstrate robust critical connectivity of initially well-connected networks, ruptured by the motor activity for a wide range of parameters. M. 1:03PM Z47.00004 Nonequilibrium stabilization of an RNA/protein droplet emulsion by nuclear actin , CLIFFORD BRANGWYNNE, Princeton University — Actin plays a structural role in the cytoplasm. However, actin takes on new functions and structures in the nucleus that are poorly understood. The nuclei of the large oocytes of the frog *X. laevis* specifically accumulate actin to reach high concentrations; however, it remains unclear if this actin polymerizes into a network, and what, if any, structural role such an actin network might play. Here, we use microrheological and confocal imaging techniques to probe the local architecture and mechanics of the nucleus. Our data show that actin forms a weak network that spatially organizes the nucleus by kinetically stabilizing embedded liquid-like RNA/protein bodies which are important for cell growth. In actin-disrupted nuclei this RNA/protein droplet emulsion is destabilized leading to homotypic coalescence into single large droplets. Our data provide intriguing new insights into why large cell nuclei require an actin-based structural scaffold.

1:39PM Z47.00005 Nonequilibrium motion of chromosomal loci in living cells , JULIE THERIOT, Stanford University — No abstract available.
