9:36AM T41.00007 Exploiting the nonlinear dynamics of a single-electron shuttle for highly regular current transport , MICHAEL MOECKEL, University of Cambridge, F. MARQUARDT, University of Erlangen, Germany, D. SOUTHWORTH, E. WEIG, University of Munich, Germany — A single-electron shuttle consists of a small metallic island (a quantum dot) resting on a nanomechanical resonator which oscillates between two electrodes. This setup has been suggested as a promising way to deliver single electrons one by one and thereby establish a novel current standard. The precision of charge transport will be determined both by the accuracy of charge quantization in the Coulomb blockade regime and the mechanical frequency. The later is generally affected by several not entirely controllable factors. Among those is the nonlinear dynamics which originates from collisions of the shuttle island with the electrodes at higher oscillation amplitudes. Instead of considering this a nuisance, we propose to rather exploit the nonlinearity to fix the oscillation frequency precisely to an external signal via synchronization.

9:48AM T41.00008 Branched comb fingers improve capacitive readout sensitivity to vertical motion in a MEMS sound sensor[1] , RICHARD DOWNEY, GAMANI KARUNASIRI, Naval Postgraduate School — A microelectromechanical (MEMS) device that relies on capacitive readout of vertical, out-of-plane displacements can be made more sensitive by replacing the traditional straight comb fingers with a branched design. A branched structure allows for larger capacitors using shorter fingers. When fabrication design rules limit finger length, a branched design can have greater surface area, greater capacitance, and therefore greater sensitivity to vertical displacements. Applying this concept to a MEMS acoustic direction-finding (DF) sensor, we predict and then demonstrate an approximate doubling of signal output.

[1]NCMR/NSF

10:00AM T41.00009 Optomechanics and integrated photonics and in aluminum nitride[1] , A. VAINSENCHER, J. BOCHMANN, D.D. AWSCHALOM, A.N. CLELAND, Department of Physics and California Nanosystems Institute, University of California, Santa Barbara — Integrated photonic devices based on silicon have proven enormously successful, with low loss and high confinement optical and optomechanical devices. We show that aluminum nitride is also an excellent material for photonic integrated circuits, with an extremely wide bandgap and very significantly strong piezoelectric and electro-optic effects. Optical-grade AlN can be deposited on substrates with a CMOS-compatible process. We demonstrate integrated photonic circuits and optomechanical devices based on this novel material. Operating in the optical telecommunications band, we demonstrate ring resonators with ultrahigh optical Q factors as well as one-dimensional optomechanical crystals operating in the resolved sideband regime with localized 4 GHz mechanical modes. This talk will present recent results with the eventual goal of integrating these devices with superconducting quantum bits.

[1]This work is funded through DARPA/DSO.

10:12AM T41.00010 Control and measurement of an electro-mechanical system with a phase qubit , FLORENT LECOCQ, JOHN TEUFEL, MICHAEL ALLMAN, KATARINA CICAK, FABIO DA SILVA, ADAM SIROIS, JED WHITTAKER, JOE AUMENTADO, RAY SIMMONDS, NIST Boulder — We discuss a hybrid device that merges an electro-mechanical system with a metastable phase qubit. The phase qubit can act as a single photon source and detector, allowing the preparation and readout of a lumped element electrical resonator, whose capacitance is formed by a mechanically compliant vacuum-gap capacitor. Via radiation pressure induced parametric coupling, we can map the quantum state of the 10 GHz electrical resonator on to the long-lived, $\sim$10 MHz fundamental mode of the mechanical oscillator. This work opens the way toward the preparation of complex phonon states of mechanical motion. We will discuss current progress with this device.

10:24AM T41.00011 Design and Construction of Cryogenic Optomechanical System , DONGHUN LEE, MITCHELL UNDERWOOD, DAVID MASON, Department of Physics, Yale University, ANDREW JAYICH, Department of Physics, UCLA, ANYA KASHKANOVA, Department of Physics, Yale University, JACK HARRIS, Department of Physics and Applied Physics, Yale University — One key challenge to observing quantum phenomena in a macroscopic mechanical oscillator is reaching its ground state. To achieve the low temperatures required for this, we utilize resolved sideband laser cooling of a few hundred kHz mechanical oscillator with high mechanical Q (a Si3N4 membrane) inside a high finesse optical cavity, in addition to cryogenically reducing the bath temperature. Realizing high Q and high finesse cavity optomechanical devices in a cryogenic environment requires overcoming a number of challenges. In this talk, we describe the design and construction of such a device working at a bath temperature of 300 mK (in a 3He refrigerator) and suited for operation at lower temperatures (in a dilution refrigerator). The design incorporates in-situ commercial piezo actuators (manufactured by Janssen Precision Engineering) to couple externally prepared laser light into the cold optical cavity. The design also incorporates filtering cavities to suppress classical laser noise, and acoustic and seismic isolation of the experiment.

10:36AM T41.00012 Two-tone experiments and time domain control in circuit nano-electromechanics , F. HOCKE, H. HUEBL, Walther-Meissner-Institut, Bayerische Akademie der Wissenschaften, Garching, Germany, X. ZHOU, A. SCHLIESSER, T. J. KIPPENBERG, École Polytechnique Fédérale de Lausanne (EPFL), Lausanne, Switzerland; Max-Planck-Institut für Quantenoptik, Garching, Germany, R. GROSS, Walther-Meissner-Institut, Bayerische Akademie der Wissenschaften and Physik-Department TU München, Garching, Germany — In the field of optomechanics, a light field trapped in an optical resonator dynamically interacts with a mechanical degree of freedom, enabling cooling and amplification of mechanical motion. This concept of light matter interaction can be transferred to the microwave (MW) regime combining superconducting MW circuits with nanometer-sized mechanical beams, establishing the class of circuit nano-electromechanics. Here, two-tone spectroscopy is a tool to access a wider class of phenomena, employing interference of a pump and a probe tone inside the MW cavity. We discuss electromechanically induced transparency and electromechanically induced absorption employing continuous and pulsed excitation. With the latter technique, we access the dynamics of the hybrid system revealing that the switching dynamics of the transmitted light are not limited by the time constant imposed by the mechanical beam, the slowing of light pulses, and the phonon repopulation of a precooled mechanical mode due to thermal decoherence [1,2]. Our experiments provide a key tool towards full quantum control of electromechanical systems, including squeezing, state transfer and entanglement between mechanical and optical degree of freedom. [1] X. Zhou et al. arXiv:1206.6052 [2] F. Hocke et al. arXiv:1209.4470

10:48AM T41.00013 Reading, writing and squeezing the entangled states of two nanomechanical resonators coupled to a SQUID , GUY COHEN, MASSIMILIANO DI VENTRA, University of California, San Diego — We study a system of two nanomechanical resonators embedded in a dc SQUID. We show that the inductively-coupled resonators can be treated as two entangled qubits with states that can be read from, or written on by employing the SQUID as a displacement detector or switching additional external magnetic fields, respectively. We present a scheme to squeeze the even mode of the state of the resonators and consequently reduce the noise in the measurement of the magnetic flux threading the SQUID. We finally analyze the effect of dissipation on the squeezing using the quantum master equation, and show the qualitatively different behavior for the weak and strong damping regimes. Our predictions can be tested using current experimental capabilities.

Session T42 DCP: Focus Session: Supercooled and Nanoconfined Water II Hilton Baltimore Holiday Ballroom 3 - Anders Nilsson, SLAC

8:00AM T42.00001 Supercooled aqueous solutions: a route to explore water anomalies , PAOLA GALLO, University Roma TRE — In the past years several theoretical and experimental studies have led to a picture according to which the anomalous properties of water might be due to the presence of a liquid-liquid phase transition in the supercooled region possibly terminating in a liquid-liquid critical point, LLCP [1]. I will show molecular dynamics simulations results of ionic aqueous solutions [2,3,4] and of a solution of water and methanol [5] aimed to clarify the effect of these species on water anomalies and the LLCP phenomenon. I will focus on the phase diagram of water in the supercooled region of the solutions in comparison with the bulk to quantify the modifications induced by the presence of the solutes. I will show that the LLCP phenomenon persists for concentrations from low to moderate and that experimental measurements appear easier for solutions. I will also show how indications of the presence of a LLCP nearby can come not only from thermodynamics but also from crossovers in dynamics [6,7] and from the two-body excess entropy behavior [8] as calculated from the structure [9]. I will in particular show that, similar to the bulk, the transition from a fragile behavior to a strong behavior of the liquid is present also in solutions and it is connected to the LLCP phenomenon. These studies point out that experiments in solutions are extremely relevant for the comprehension of low temperature bulk water properties.

8:36AM T42.00002 Probing the Structure of Salt Water Under Confinement with Computation , HEATHER KULIK, Stanford University, ERIC SCHWEGLER, Lawrence Livermore National Laboratory, GIULIA GALLI, University of California, Davis — We have investigated the structure of liquid water around cations (Na^+) and anions (Cl^-) confined inside a (19,0) carbon nanotube with first principles molecular dynamics (FPMD) and theoretical X-ray absorption spectroscopy (XAS). We study the distribution of ions and nature of the ion solvation shells under confinement from molecular dynamics. We also examine the XAS signal of water molecules surrounding Na^+ and Cl^- upon confinement and relate these spectral fingerprints to those of solvated ions in bulk water. We observe unusual trends in the XAS upon confinement of cations and anions that likely stems from variation in the number of acceptor hydrogen bonds in the first solvation shell for the two species. The rigid first solvation shell of Na^+ is rigid whether in bulk or confined solution, disrupting the overall hydrogen bonding network of the rest of the confined water. The solvation shell of Cl^- is considerably more flexible and adapts under confinement to accommodate roughly the same number of acceptor bonds. In our nanotube, we observe an inner bulk-like shell of water and outer shell of interfacial waters, as observed through both FPMD and XAS properties.

8:48AM T42.00003 ABSTRACT WITHDRAWN –

9:00AM T42.00004 Electric Field Fluctuations in Water , DAYTON THORPE, DAVID LIMMER, DAVID CHANDLER, University of California, Berkeley — Charge transfer in solution, such as autoionization and ion pair dissociation in water, is governed by rare electric field fluctuations of the solvent. Knowing the statistics of such fluctuations can help explain the dynamics of these rare events. Trajectories short enough to be tractable by computer simulation are virtually certain not to sample the large fluctuations that promote rare events. Here, we employ importance sampling techniques with classical molecular dynamics simulations of liquid water to study statistics of electric field fluctuations far from their means. We find that the distributions of electric fields located on individual water molecules are not in general gaussian. Near the mean this non-gaussianity is due to the internal charge distribution of the water molecule. Further from the mean, however, there is a previously unreported Bjerrum-like defect that stabilizes certain large fluctuations out of equilibrium. As expected, differences in electric fields acting between molecules are gaussian to a remarkable degree. By studying these differences, though, we are able to determine what configurations result not only in large electric fields, but also in electric fields with long spatial correlations that may be needed to promote charge separation.

9:12AM T42.00005 Solute effects on the thermodynamic and kinetic behavior of water and liquid-liquid transition[1]

, HAJIME TANAKA, Institute of Industrial Science, University of Tokyo — Water is known to be an exceptionally poor glass former, which is one of the characteristic features of water, but its link to the thermodynamic and kinetic anomalies of water remains elusive. Recently we showed that the glass-forming ability and the fragility of a water/salt mixture are closely related to its equilibrium phase diagram.[2] We proposed that frustration between local and global orderings controls both the glass-forming ability and fragility on the basis of experimental evidence. Relying on the same role of salt and pressure, which commonly breaks tetrahedral order, we apply this idea to pure water under pressure. This scenario not only explains unusual behavior of water-type liquids such as water, Si and Ge, but also provides a general explanation on the link between the equilibrium phase diagram, the glass-forming ability, and the fragility of various materials including oxides, chalcogenides, and metallic glasses.[3] We also discuss liquid-liquid transition found in mixtures of water with glycerol[4] and other molecules and its implications.

9:48AM T42.00006 Local Environment Distribution in Ab Initio Liquid Water[1]

, BISWAJIT SANTRA, ROBERT A. DISTASIO, JR., ROBERTO CAR, Department of Chemistry, Princeton University, Princeton, NJ 08544, USA — We have analyzed the distribution of local environments in liquid water at ambient conditions and its inherent potential energy surface (IPES) based on state-of-the-art *ab initio* molecular dynamics simulations performed on 128 molecules implementing hybrid PBE0 exchange [PRB **79**, 085102 (2009)] and van der Waals (vdW) interactions [PRL **102**, 073005 (2009)]. The local environments of molecules are characterized in terms of the local structure index (LSI) [JCP **104**, 7671 (1996)] which is able to distinguish high- and low-density molecular environments. In agreement with simulations based on model potentials, we find that the distribution of LSI is unimodal at ambient conditions and bimodal in the IPES, consistent with the existence of polymorphism in amorphous phases of water. At ambient conditions spatial LSI fluctuations extend up to $\sim$7 Å and their dynamical correlation decays on a time scale of $\sim$3 ps, as found for density fluctuations in a recent study [PRL **106**, 037801 (2011)].

10:00AM T42.00007 Connexions between density and dielectric properties of water[1]

, LUANA PEDROZA, DANIEL ELTON, MARIVI FERNANDEZ-SERRA, Stony Brook University — As it is well known, water has a high dielectric constant, which is connected both to the molecular dipole moment and to the intermolecular bonding through hydrogen bonds. Although some classical force fields can reproduce this dielectric constant, they do not take into account the environment-dependent perturbations of the individual dipoles and their relation to the local structure and network of the liquid. In this work, we investigate in detail the distribution of molecular dipoles for different densities of liquid water, obtained with ab initio molecular dynamics simulations and compare them to those obtained using a classical, polarizable, empirical force field. We calculate the dipole moment for different choices of exchange-correlation functionals, including van der Waals correction. In addition, we analyze the correlation between the dipolar coupling and the vibrational spectrum of water. In this way, we can get a better understanding on how local electronic effects play a role in the determination of global properties of water, such as its dielectric constant and density

10:12AM T42.00008 Quantum Zero Point Effects in Water and Ice[1]

, BETÜL PAMUK, MARIVI FERNÁNDEZ-SERRA, Stony Brook University — Nuclear zero point effects have recently been shown to have an interesting quantum anomaly in ice. In particular, In hexagonal ice Ih, the lattice volume increases when H is replaced by D. This anomalous isotope shift of the lattice parameter increases with temperature, contrary to normal expectations [1]. Free energy calculations within the quasiharmonic approximation, with *ab initio* density functional theory, explain the origin of his anomaly. In this study, we extend our study to show that the anomalous isotope effect persists in amorphous ices, inherent structures of liquid water. This indicates that the anomalous isotope effect on the density of liquid water might be intrinsically related to the one observed in ice, even if their structures are radically different. In addition, we show that clathrate hydrides, also have this anomaly. We make a detailed analysis of the origin of the anomaly and study how the Hbond interaction and the vdW bond in liquid water are modified by these nuclear zero point effects. [1] B. Pamuk *et. al*, Phys. Rev. Lett. **108**, 193003 (2012).

10:24AM T42.00009 First-Principles Investigation of Water Properties at Functionalized Silicon surface[1]

, DONGHWA LEE, ERIC SCHWEGLER, Lawrence Livermore National Laboratory, YOSUKE KANAI, The University of North Carolina, Chapel Hill — Numerous experimental and theoretical investigations have been made to understand the behavior of water molecules under various conditions. Interfacial water behavior at semiconductor interfaces is one of the most important areas of investigation for diverse industrial applications such as crystal growth, lubrication, catalysis, electrochemistry and sensors. Although the terms, hydrophobic and/or hydrophilic, are often used to describe the properties of water in this context at macroscopic level, the effect of hydrophobicity on water behavior at nano-scale interfaces is still not well understood. Computational simulations could offer atomistic basis to build a better foundation for understanding this important dynamics. In this study, first principles molecular dynamics is employed to investigate the water behavior at silicon surfaces that are functionalized with several different molecules. In particular, various analysis methods are used to elucidate the effect of surface polarity on structural and dynamical properties of interfacial water. Our studies show that properties of interfacial water are not always governed by surface polarity alone but also by other atomistic factors.

[1]This work is Prepared by LLNL under Contract DE-AC52-07NA27344.

10:36AM T42.00010 Anatomy of competing quantum effects in liquid water.

, RAFA RAMIREZ, Instituto de Ciencia de Materiales de Madrid (ICMM), SRIRAM GANESHAN, University of Maryland, College Park, M. V. FERNANDEZ-SERRA, Stony Brook University — ct- Molecules like water have vibrational modes with zero point energy well above room temperature. As a consequence, classical molecular dynamics simulations of liquid water largely underestimate the kinetic energy of the ions, which translates into an underestimation of covalent interatomic distances. In this work, we show that it is possible to apply generalized Langevin equation with suppressed noise in combination with Nose-Hoover thermostats to achieve an efficient zero-point temperature of independent modes of liquid water. Using this method we deconstruct the competing quantum effects in liquid water. We demonstrate how the structure and dynamical modes of liquid water respond to non-equilibrium distribution of zero point temperatures on the normal modes.

10:48AM T42.00011 The role of water in surface charge transport on tin dioxide as revealed by the thermal dependence of conductance , ROBERT WEXLER, KARL SOHLBERG, Drexel University — The presence of water on an oxide surface can dramatically alter its electrical properties with important consequences for electrical measurements by scanning probe microscopy, and for the use of semiconducting oxides in sensing applications. Here, the thermal dependence of the surface conductance of tin dioxide is interpreted by combining equilibrium carrier statistics with the Grotthuss mechanism for proton hopping. The functional form of this charge transport model is fit to experimental conductance data for tin dioxide. Next, the important energy parameters in the model are computed with electronic structure methods. Comparing the values of the energy parameters obtained by fitting to those obtained from electronic structure calculations yields new insight into the surface charge transport in tin dioxide. In particular, it is found that mobile protons, freed by the dissociative adsorption of water on the [110] surface, are an essential component of the observed thermal dependence of surface conductance in tin dioxide.

Session T43 DCP: Liquid and Solid Interfaces Hilton Baltimore Holiday Ballroom 2 - Gil Nathanson, University of Wisconsin

8:00AM T43.00001 Characterization of critical micelle concentration of ionic liquid on molecular length scale by X-ray surface scattering and spectroscopy study[1] , WENJIE WANG, Ames Laboratory, Iowa State University, Ames, IA, WOONGMO SUNG, Department of Physics, Sogang University, Seoul 121-742, Korea, WILLIAM LINDEMANN, Ames Laboratory, Iowa State University, Ames, IA,50011, IVAN KUZMENKO, Argonne National Laboratory, Lemont, IL 60439, DOSEOK KIM, Department of Physics, Sogang University, Seoul 121-742, Korea, DAVID VAKNIN, Ames Laboratory, Iowa State University, Ames, IA — Ionic liquids (ILs) with long alkyl chains tend to form micelles in aqueous solutions once the critical micelle concentration (CMC) is reached, a phenomenon commonly described by the Gibbs isotherm for ionic surfactants. We report synchrotron X-ray measurements at far below, near and above the CMC of each IL of 1-dodecyl-3-methyl-imidazolium halides, $[C_{12}mim]X$, (X=Cl,Br,I). Our X-ray reflectivity measurements provide the depth density profiles of the interfacial films formed by the ILs. A liquid state of the alkyl chains can also be identified by grazing incidence X-ray diffraction measurements that reveal the in-plane packing of the IL molecules. The ILs form monolayers on the aqueous surfaces and the cations $[C_{12}mim]^+$ bind with Cl^- and I^- ions with different affinity. We discuss our experimental results of surfactants surface enrichment in the context of Gibbs equations.

8:12AM T43.00002 Predicting In-Situ X-ray Diffraction for the $SrTiO_3$/Liquid Interface from First Principles[1] , KENDRA LETCHWORTH-WEAVER, DENIZ GUNCELER, RAVISHANKAR SUNDARARAMAN, XIN HUANG, JOEL BROCK, T. A. ARIAS, Cornell University — Recent advances in experimental techniques, such as in-situ x-ray diffraction, allow researchers to probe the solid-liquid interface in electrochemical systems under operating conditions. These advances offer an unprecedented opportunity for theory to predict properties of electrode materials in aqueous environments and inform the design of energy conversion and storage devices. To compare with experiment, these theoretical studies require microscopic details of both the liquid and the electrode surface. Joint Density Functional Theory (JDFT), a computationally efficient alternative to molecular dynamics, couples a classical density-functional, which captures molecular structure of the liquid, to a quantum-mechanical functional for the electrode surface. We present a JDFT exploration of $SrTiO_3$, which can catalyze solar-driven water splitting, in an electrochemical environment. We determine the geometry of the polar $SrTiO_3$ surface and the equilibrium structure of the contacting liquid, as well as the influence of the liquid upon the electronic structure of the surface. We then predict the effect of the fluid environment on x-ray diffraction patterns and compare our predictions to in-situ measurements performed at the Cornell High Energy Synchrotron Source (CHESS).

[1]This material is based upon work supported by the Energy Materials Center at Cornell (EMC2), an Energy Frontier Research Center funded by the U.S. Department of Energy.

8:24AM T43.00003 Alumina(0001)/water interface structure and infrared spectra from first-principles molecular dynamics simulations[1] , ERIC SCHWEGLER, Lawrence Livermore National Laboratory, TUAN ANH PHAM, Lawrence Livermore National Laboratory and Department of Chemistry UC Davis, PATRICK HUANG, Lawrence Livermore National Laboratory, GIULIA GALLI, Department of Chemistry and Department of Physics UC Davis — Knowledge of the interaction of water with solid oxide surfaces is of fundamental importance for the stability of solid oxides in aqueous environments. We studied the atomic structure and infrared (IR) spectra of the alumina(0001)/water interface, using molecular dynamics simulations and the Qbox code. We found that the structural properties of the interface, as described within the generalized gradient approximation, are in good agreement with synchrotron X-ray scattering experiments. In addition, a detailed analysis of the computed IR spectra of interfacial water reveals two types of water molecules at the solid-liquid interface: one type participating in strong "ice-like" hydrogen bonding with the oxide surface, and one type of water molecules involved in weak "liquid-like" hydrogen bonding at the interface. Our results provide a molecular interpretation of the "ice-like" and "liquid-like" peaks observed in sum-frequency vibrational spectroscopy experiments.

[1]Work at LLNL was performed under Contract DE-AC52-07NA27344. DOE-CMSN Grant DE- SC0005180 is gratefully acknowledged.

8:36AM T43.00004 Structure, Dynamics, and Viscoelasticity of Nanoparticle Thin Films at the Liquid-Air Interface , LEANDRA BOUCHERON, JACOB STANLEY, YELING DAI, Department of Physics, University of California, San Diego, BINHUA LIN, MATI MERON, Center for Advanced Radiation Sciences, University of Chicago, SURESH NARAYANAN, ALEC SANDY, Advanced Photon Source, Argonne National Lab, OLEG SHPYRKO, Department of Physics, University of California, San Diego — We experimentally probe the structure and inter-particle dynamics of iron oxide nanoparticle thin films self-assembled at the liquid-air interface. We find that upon deposition on a water substrate, iron oxide nanocrystals coated in oleic acid ligands spontaneously arrange themselves into a hexagonally close-packed configuration. At low particle concentrations, this close-packing results in isolated islands of particles distributed across the liquid surface. Compression in a Langmuir-Blodgett trough and the corresponding increase in surface pressure results in the formation of a uniform quasi-2D monolayer. Using X-Ray Reflectivity (XR) measurements, we were able to quantify the overall change in surface-normal film structure due to an increase in surface pressure. Utilizing X-Ray Photon Correlation Spectroscopy (XPCS), we have measured the characteristic timescale of in-plane particle dynamics. I will discuss these results and their relation to viscoelasticity in quasi-2D self-assembled monolayers.

8:48AM T43.00005 Ab initio molecular dynamics study of liquid Li surfaces exposed to deuterium , MOHAN CHEN, JUNCHAO XIA, ILGYOU SHIN, EMILY CARTER, Princeton University — We investigate the structure of liquid Li and its interactions with deuterium atoms using PROFESS (PRinceton Orbital-Free Electronic Structure Software) [1]. This linear-scaling orbital-free density functional theory method is a very fast quantum mechanics technique that allows one to perform ab initio molecular dynamics of metals for a large number of atoms and fairly long times. We adopt the WGC99 kinetic energy density functional that is very accurate for simple metals [2]. We use well validated bulk-derived local pseudopotentials [3] to describe the electron-ion interactions. Key properties of liquid Li will be presented and discussed, such as its bulk and surface structures, etc. Time permitting, we will discuss predictions related to adsorption and absorption of deuterium atoms into Li. This work provides new insights into understanding the surface structure of liquid Li using large-scale ab initio molecular dynamics methods. [1] L. Hung, C. Huang, I.Shin, G. Ho, V. L. Ligneres, and E. A. Carter, Comput. Phys. Comm., 181, 2208 (2010). [2] Y. A. Wang, N. Govind, and E. A. Carter, Phys. Rev. B, 60, 16350 (1999). Erratum: Phys. Rev. B, 64, 089903-1 (2001). [3] C. Huang and E. A. Carter, Phys. Chem. Chem. Phys., 10, 7109 (2008).

9:00AM T43.00006 The effect of support on the characteristics of Pt Nanoparticles[1] , GHAZAL SHAFAI ERFANI, TALAT S. RAHMAN, Department of Physics, University of Central Florida, Orlando, FL 32816 — We have carried out density functional theory calculations within the projector augmented wave scheme (PAW) and the pseudopotential approach to evaluate the effect of the support (γ-alumina and titania) on geometric and electronic structural properties of Pt22, Pt33, Pt44, Pt55 nanoparticles (NPs) with the shape previously characterized by extended X-ray absorption fine structure spectroscopy (EXAFS) [1]. We are in particular interested in the electronic structural changes of the perimeter atoms, as we expect them to play a major role in catalysis. We find stabilization of the NP on the substrate to depend critically on the existence of oxygen vacancies on the surface and the effect to be more prominent for titania than for alumina. On both substrates the average bond-length (first nearest-neighbor distance) expands (1 to 3%) as compared to that of unsupported NPs. We present results for the charge transfer and local density of states of the atoms at the interface and make comparisons with available experimental data on the propensity of these atoms to be chemically active.

9:12AM T43.00007 Optical properties of TiO_2 nanoclusters , MATTI ALATALO, SAMI AUVINEN, MATTI LAHTI, HEIKKI HAARIO, ERIK VARTIAINEN, Lappeenranta University of Technology, JUHO JALAVA, RALF-JOHAN LAMMINMÄKI, Sachtleben Pigments — The structural, electronic and optical properties of TiO_2 nanoclusters have been investigated using first principles calculations. The shape of the clusters is shown to affect the optical properties more than the cluster size in the ultra small particles. We show that the first principles results for the optical properties can be extended towards larger clusters by using the generalized oscillator model, fitted to the first principles data. This allows us to bridge the gap between the atomistic regime, addressable by quantum mechanical calculations up to a few nanometers, and the size region of tens of nanometers, relevant for UV applications. This method provides an extension of the turbidity spectum method, used earlier for determining the size distribution of larger TiO_2 nanoparticles. We also discuss the electronic structure of the clusters. In particular, we provide an explanation for the gap states observed in stoichiometric clusters.

9:24AM T43.00008 Narrowing of band gap in thin films and linear arrays of ordered TiO_2 nanoparticles[1] , YU LIU, Department of Physics and Astronomy, University of California, Irvine, JAMES TAING, Department of Chemistry, University of California, Irvine, CHENG-CHIEN CHEN, Advanced Photon Source, Argonne National Laboratory, ADAM SORINI, Lawrence Livermore National Laboratory, MING H. CHENG, ALEXANDRIA MARGARELLA, Department of Chemistry, University of California, Irvine, HENDRIK BLUHM, ZHI LIU, Lawrence Berkeley National Laboratory, THOMAS DEVEREAUX, Stanford Institute for Materials and Energy Science, SLAC National Accelerator Laboratory, JOHN HEMMINGER, Department of Chemistry, University of California, Irvine — Utilizing ambient pressure synchrotron x-ray spectroscopies, we report the properties of thin films and linear arrays of ordered TiO_2 nanoparticles under in situ water vapor exposure and heating. Our nondestructive depth profiles indicates an enhancement of the density of states (DOS) near the Fermi level due to surface Ti^{3+} states and oxygen vacancies caused by heating isolated TiO_2 nanoparticles. In contrast, introducing water on the TiO_2 interface eliminates oxygen vacancies and increase Ti^{4+} configurations, thereby suppressing the DOS enhancement. Our results suggest that the TiO_2 band gap can be tuned reversibly under water exposure and heating, and isolated TiO_2 nanoparticles can potentially enhance solar absorption efficiency and the life time of electron-hole pairs for photocatalysis.

9:36AM T43.00009 Modification of the wettability of TiO_2 surfaces with ion bombardment. , OSCAR RODRIGUEZ DE LA FUENTE, BEATRIZ MARTINEZ, JUAN ROJO, Departamento de Fisica de Materiales, Universidad Complutense de Madrid — Tailoring the affinity of a surface towards water adsorption is crucial for a number of physicochemical processes. Many applications depend on its proper control, such as those related to cell adhesion, some catalytic phenomena or the development of hydrophobic textiles. TiO_2 is a most interesting material, especially for its enhanced hydrophilicity when illuminated with light. In this work, we have modified rutile TiO_2(110) surfaces with ion bombardment and studied their composition, structure and interaction with water with contact angle measurements (static and dynamic), optical microscopy, AFM, Auger electron spectroscopy, LEED and IRAS. We show how the density of water nucleation centers and the shape of the microdroplets, when the surface is exposed to water vapor, depend on the morphological and chemical state of the surface. In general, we observe that the affinity for water is larger for the flat, non-bombarded surfaces. Indeed, and contrary to most observations reported in the literature, the contact angle of both microscopic and macroscopic droplets is higher for the defective surfaces. We attribute such behavior to the special structure of the first adsorbed molecular water layers, which is strongly influenced by surface defects and the hydrogen bond network.

9:48AM T43.00010 Rotational Tunneling of CH_2D_2 Monolayers on MgO(100) , ANDREW HICKS, JOHN LARESE, University of Tennessee-Knoxville — Understanding the detailed nature of the interactions governing physisorption is a central topic in surface science, with wide ranging energy applications in heterogeneous catalysis, gas separation, and hydrogen storage. For systems with a strong interaction potential relative to the rotational constant of the adsorbate, adsorbed molecules are constrained to minima in the rotational potential. Adsorbed molecules may then tunnel through the rotational barrier between potential minima. Rotational tunneling spectra (RTS) are extremely sensitive to changes in the symmetry and strength of the rotational potential and are unmatched in their ability to probe the electrostatic potentials associated with adsorption sites. Furthermore, RTS can be clearly observed using inelastic neutron scattering. Building upon previous work of CH_4 on MgO (see J.Z. Larese, *Physica B*, 1998), RTS of CH_3D and CH_2D_2 are interpreted using the pocket state (PS) formalism developed by *Hüller et al.* The ground librational state of the adsorbate is split into twelve "pockets", each localized around one of twelve minima in the rotational potential. We report recent RTS of single monolayers of CH_3D and CH_2D_2 adsorbed on the MgO(100) surface using **BASIS** at the SNS at ORNL. These pioneering measurements represent the highest resolution investigation available for this (or any other) RTS. The discussion will include challenges in reconciling the transitions predicted by PS theory and the features observed in the experimental data.

10:00AM T43.00011 Concentration of point defects at metal-oxide surfaces: case study of MgO (100)[1] , NORINA RICHTER, SERGEY LEVCHENKO, MATTHIAS SCHEFFLER, Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin-Dahlem 14195, Germany, SABRINA SICOLO, JOACHIM SAUER, Humboldt-Universitaet zu Berlin, Berlin 10099, Germany — We calculate from first principles the concentration of neutral and charged oxygen vacancies on a doped MgO (100) surface at realistic (T, p_{O_2}) conditions. Vacancy formation energies are computed using hybrid density-functional theory with parameters of the exchange-correlation functional adjusted according to a basic consistency requirement on the Kohn-Sham and G_0W_0 defect transition levels. The parameters are validated by CCSD(T) calculations of formation energies for neutral vacancies using embedded cluster models. Gibbs free energies of formation are obtained using the *ab initio* atomistic thermodynamics approach.[2] We demonstrate that the concentration of surface vacancies is significantly increased due to band bending and Fermi level pinning at the surface, resulting in lower formation energies of charged vacancies.

10:12AM T43.00012 Tuning the Electronic and Chemical Properties of Monolayer MoS_2 Adsorbed on Transition Metal Substrates[1] , WEI CHEN, University of Tennessee, ELTON SANTOS, Harvard University, WENGUANG ZHU, University of Science and Technology of China, EFTHIMIOS KAXIRAS, Harvard University, ZHENYU ZHANG, University of Science and Technology of China — Using first-principles calculations within density functional theory, we investigate the electronic and chemical properties of a single-layer MoS_2 adsorbed on Ir(111), Pd(111), or Ru(0001), three representative transition metal substrates having varying work functions but each with minimal lattice mismatch with the MoS_2 overlayer. We find that for each of the metal substrates, the contact nature is of Schottky type, and the dependence of the barrier height on the work function exhibits a partial Fermi-level pinning picture. Using hydrogen adsorption as a testing example, we further demonstrate that the introduction of a metal substrate can substantially alter the chemical reactivity of the adsorbed MoS_2 layer. The enhanced binding of hydrogen, by as much as about 0.4 eV, is attributed in part to a stronger H-S coupling enabled by the transferred charge from the substrate to the MoS_2 overlayer, and in part to a stronger MoS_2-metal interface by the hydrogen adsorption. These findings may prove to be instrumental in future design of MoS_2-based electronics, as well as in exploring novel catalysts for hydrogen production and related chemical processes.

10:24AM T43.00013 Modifying the Photoluminescence of Monolayer MoS2 by Metal Deposition , DEZHENG SUN, Columbia University and University of California, Riverside, YUMENG YOU, KIN FAI MAK, FAN ZHANG, JAMES HONE, Columbia University, LUDWIG BARTELS, University of California, Riverside, TONY HEINZ, Columbia University — Monolayer MoS2 exhibits strong photoluminescence (PL) due to its direct band gap located at K point. Because of its monolayer thickness, light emission from MoS2 is known to be strongly influenced by interactions with surrounding media [1]. In this study, we have investigated the effect on the photoluminescence of exfoliated monolayers of MoS2 induced by the deposition of gold atoms. The PL from the sample was recorded as a function of amount of gold deposited, up to an effective thickness of about 1 nm. Atomic force microscopy revealed that the gold forms isolated island structures on the surface. A progressive increase in quenching was seen with increasing gold coverage. Deposition of gold on suspended MoS2 samples led to quenching of the PL by more than a factor of 100. Given the low reactivity of gold, we attribute the PL quenching primarily to energy transfer of the photogenerated excitons to the metal clusters. The observed changes in the shape and intensity of emission spectra will be discussed in terms of this mechanism and possible effects of doping induced by the gold deposition.

10:36AM T43.00014 Adsorption and Dynamics behaves of Platinum Atoms on Si(111)-7x7 Surface Studied with Scanning Tunneling Microscopy and First principles Calculation , CHE-FU CHOU, HSUN-TA TU, CHOU-MIN YANG, WAN-SHENG SU, MON-SHU HO, None — In this study, behaves of platinum atoms on Si (111) surface were study in use of ultrahigh vacuum scanning tunneling microscope (STM). The surface morphologies of platinum atoms adsorbed on Si (111) surface were observed. Dynamic study showed how the platinum atoms adsorbing and hopping on Si (111) surface. Activation energy was also calculated by fitting the experimental data. A first principle calculation was then performed to establish the adsorption sites, hopping path and the activation energy in the experiment.

10:48AM T43.00015 An Extremely Simple Route to Large-Area Microchannels and Inorganic Stripes , WEI HAN, BO LI, XUKAI XIN, ZHIQUN LIN, Georgia Institute of Technology — Microchannels were yielded in an extremely simple route by freely evaporating PS latex particle suspension on a rigid substrate, due to the capillary stress generated during the evaporation process that fractured the thin film and the cracks progressed towards the center of the evaporating suspension. The simple tailoring of the upper surface of the imposed confined geometry (i.e., parallel plates or vertical slide) directed the formation of parallel microchannels in a precisely controllable manner over large areas. Quite intriguingly, these prepared microchannel patterns may be served as templates to craft ordered Au stripes with unprecedented regularity. This facile approach opens a new avenue for producing macroscopic patterns and developing microelectronics or microfluidic-based biochips in a simple and controllable manner.

Session T44 DBIO DCP: Focus Session: Intrinsically Disordered Proteins Hilton Baltimore Holiday Ballroom 1 - Daniel Cox, UC Davis

8:00AM T44.00001 Connecting sequence to conformational properties of intrinsically disordered proteins , ROHIT PAPPU, Washington University in St. Louis — Recent work has shown that intrinsically disordered proteins (IDPs) can be classified as coils or globules based on their net charge per residue (NCPR). Naïve annotation of a predictive phase diagram suggests that a majority of IDPs are likely to form disordered globules. Globule formers (as opposed to rigid, folded globules) are likely to have poor solubility profiles and it seems unlikely that the IDP proteome is enriched in globule formers. This raises the possibility that NCPR is an incomplete descriptor of IDP phase behavior. To address this issue, we carried out systematic computational studies on a set of synthetic and naturally occurring IDPs where NCPR is likely to yield questionable designations of IDP phase behavior. Our results show that the polyampholytic nature of IDPs provides a clear descriptor of sequence-ensemble relationships. Our results highlight the connection between linear patterning of oppositely charged residues in polyampholytic sequences and the phase behavior of IDPs / IDRs in sequences where more than 30% of the residues are charged. Analysis of sequence databases shows that ∼70% IDPs/IDRs are sequence-patterned polyampholytes that are likely to form heterogeneous expanded ensembles. This has important implications for the accessibility of short linear interaction motifs that directly influence IDP function.

8:36AM T44.00002 A Binding Model and Similarity for Flexible Modular Proteins[1]

GABRIELL MÁTÉ, CHRISTOPH J. FEINAUER, ANDREAS HOFMANN, Institute for Theoretical Physics, Heidelberg University, Germany, SEBASTIAN GOLDT, Fitzwilliam College, Cambridge University, Cambridge, England, LEI LIU, DIETER W. HEERMANN, Institute for Theoretical Physics, Heidelberg University, Germany — Modular proteins are one of the most commonly found disordered protein motifs. An example is CTCF, a protein that has been named the master waver of the genome i.e., the organizer of the 3D structure of the chromosomes. Using NMR and numerical simulations, much progress has been made in understanding their various functions and ways of binding. Modular proteins are often composed of protein modules interconnected by flexible linkers. They can be imagined as "beads on a string." We argue that when the number of beads is small, these structures behave like a self avoiding random walk. Nevertheless, when binding to a target, linkers can fold in more ordered and stable states. At the same time, folding can influence functional roles. We show that the flexibility of the linkers can boost binding affinity. As a result of flexibility, the conformations of these proteins before and after binding are different. So this implies that generic binding site prediction methods may fail. To deal with this we introduce a new methodology to characterize and compare these flexible structures. Employing topological concepts we propose a method which intrinsically fuses topology and geometry.

8:48AM T44.00003 Spatial clustering of binding motifs and charges reveals conserved functional features in disordered nucleoporin sequences

, DAVID ANDO, MICHAEL COLVIN, University of California, Merced, MICHAEL REXACH, University of California, Santa Cruz, AJAY GOPINATHAN, University of California, Merced — The Nuclear Pore Complex (NPC) gates the only channel through which cells exchange material between the nucleus and cytoplasm. Traffic is regulated by transport receptors bound to cargo which interact with numerous of disordered phenylalanine glycine (FG) repeat containing proteins (FG nups) that line this channel. The precise physical mechanism of transport regulation has remained elusive primarily due to the difficulty in understanding the structure and dynamics of such a large assembly of interacting disordered proteins. Here we have performed a comprehensive bioinformatic analysis, specifically tailored towards disordered proteins, on thousands of nuclear pore proteins from a variety of species revealing a set of highly conserved features in the sequence structure among FG nups. Contrary to the general perception that these proteins are functionally equivalent to homogeneous polymers, we show that biophysically important features within individual nups like the separation, spatial localization and ordering along the chain of FG and charge domains are highly conserved. Our current understanding of NPC structure and function should therefore be revised to account for these common features that are functionally relevant for the underlying physical mechanism of NPC gating.

9:00AM T44.00004 Molecular Dynamics Simulations of the Fluctuating Conformational Dynamics of the Intrinsically Disordered Proteins α-Synuclein and τ

, W. WENDELL SMITH, CARL SCHRECK, Department of Physics, Yale University, ABHINAV NATH, ELIZABETH RHOADES, Department of Molecular Biophysics and Biochemistry, Yale University, COREY O'HERN, Department of of Mechanical Engineering and Materials Science, Yale University — Intrinsically disordered proteins (IDPs) do not possess well-defined three-dimensional structures in solution under physiological conditions. We develop united-atom and coarse-grained Langevin dynamics simulations for the IDPs α-synuclein and τ that include geometric,attractive hydrophobic, and screened electrostatic interactions and are calibrated to the inter-residue separations measured in recent smFRET experiments. We find that these IDPs have conformational statistics that are intermediate between random walk and collapsed globule behavior and demonstrate close resemblance to the known experimental data, with both electrostatics and hydrophobicity strongly influencing the dynamics. We investigate the propensity of α-synuclein to aggregate and form oligomers, and present preliminary results for the aggregation of τ and interactions between these IDPs and small molecules such as heparin and spermine which are known to induce aggregation.

9:12AM T44.00005 Intrinsically disordered segments and the evolution of protein half-life[1]

, M. MADAN BABU, MRC Laboratory of Molecular Biology, University of Cambridge, UK — Precise turnover of proteins is essential for cellular homeostasis and is primarily mediated by the proteasome. Thus, a fundamental question is: What features make a protein an efficient substrate for degradation? Here I will present results that proteins with a long terminal disordered segment or internal disordered segments have a significantly shorter half-life in yeast. This relationship appears to be evolutionarily conserved in mouse and human. Furthermore, upon gene duplication, divergence in the length of terminal disorder or variation in the number of internal disordered segments results in significant alteration of the half-life of yeast paralogs. Many proteins that exhibit such changes participate in signaling, where altered protein half-life will likely influence their activity. We suggest that variation in the length and number of disordered segments could serve as a remarkably simple means to evolve protein half-life and may serve as an underappreciated source of genetic variation with important phenotypic consequences.

9:48AM T44.00006 Structural transitions in the intrinsically disordered Parkinson's protein alpha-synuclein[1]

, DAVID ELIEZER, Weill Cornell Medical College — The protein alpha-synuclein is genetically and histopathologically associated with familial and sporadic Parkinson's disease. Although considered to belong to the category of intrinsically disordered proteins for well over a decade, recent reports have suggested that synuclein may actually exist predominantly in a native, well-structured, tetrameric form. Experiments using in-cell NMR, which bypass potential structural perturbations caused by purification protocols, conclusively demonstrate that recombinant synuclein is in fact highly disordered and monomeric. In the presence of membranes, however, the protein undergoes a coil-to-helix transition to adopt several highly helical conformations, which are proposed to mediate both its normal function and its membrane-induced aggregation into amyloid fibrils.

10:24AM T44.00007 Dimer model for Tau proteins bound in microtubule bundles[1]

, NATALIE HALL, ALEXANDER KLUBER, N. ROBERT HAYRE, RAJIV SINGH, DANIEL COX, University of California, Davis — The microtubule associated protein tau is important in nucleating and maintaining microtubule spacing and structure in neuronal axons. Modification of tau is implicated as a later stage process in Alzheimer's disease, but little is known about the structure of tau in microtubule bundles. We present preliminary work on a proposed model [1] for tau dimers in microtubule bundles (dimers are the minimal units since there is one microtubule binding domain per tau). First, a model of tau monomer was created and its characteristics explored using implicit solvent molecular dynamics simulation. Multiple simulations yield a partially collapsed form with separate positively/negatively charged clumps, but which are a factor of two smaller than required by observed microtubule spacing. We argue that this will elongate in dimer form to lower electrostatic energy at a cost of entropic "spring" energy. We will present preliminary results on steered molecular dynamics runs on tau dimers to estimate the actual force constant.

10:36AM T44.00008 Physical modeling of the conformation of the unfolded proteins of the Nuclear Pore Complex , ANTON ZILMAN, Department of Physics, University of Toronto, MICHAEL OPFERMAN, Department of Physics and Astronomy, Pittsburgh university, ROB COALSON, Department of Chemistry, Pittsburgh University, DAVID JASNOW, Department of Physics and Astronomy, Pittsburgh university — Nuclear Pore Complex (NPC) is a biological "nano-machine" that controls the macromolecular transport between the cell nucleus and the cytoplasm. NPC functions without direct input of metabolic energy and without transitions of the gate from a "closed" to an "open" state during transport. The key and unique aspect of transport is the interaction of the transported molecules with the unfolded, natively unstructured proteins that cover the lumen of the NPC. Recently, the NPC inspired creation of artificial bio-mimetic for nano-technology applications. Although several models have been proposed, it is still not clear how the passage of the transport factors is coupled to the conformational dynamics of the unfolded proteins within the NPC. Morphology changes in assemblies of the unfolded proteins induced by the transport factors have been investigated experimentally in vitro. I will present a coarse-grained theoretical and simulation framework that mimics the interactions of unfolded proteins with nano-sized transport factors. The simple physical model predicts morphology changes that explain the recent puzzling experimental results and suggests possible new modes of transport through the NPC. It also provides insights into the physics of the behavior of unfolded proteins.

Thursday, March 21, 2013 8:00AM - 11:00AM –

Session T45 DBIO: Focus Session: Physics of Cancer I Hilton Baltimore Holiday Ballroom 4 - Kimberly Stroka, Johns Hopkins

8:00AM T45.00001 Unsolved Problems at the Intersection of Physics and Biology , JAN LIPHARDT, UC Berkeley — No abstract available.

8:36AM T45.00002 Does Mammographic Density Distribution Correlate with Location of Breast Cancer Tumors?[1] , CLARE YU, JAMES MITCHELL, University of California, Irvine — The risk of breast cancer is higher in women with denser, stiffer breasts. In mammograms, one measure of breast density is mammographic density. Mammograms involve x-rays, and radiodense material is characterized by white areas on a mammogram. The more white areas there are, the higher the mammographic density and the higher the risk of breast cancer. It is also known that most breast tumors occur in the upper half of the breast. Actually, about half of breast tumors occur in the upper outer quadrant of the breast near the armpit. We have analyzed mammograms and find that the mammographic density (white stuff) is higher in the upper half of the breast where there is more tissue.

[1]This work is supported by the National Cancer Institute through the Princeton Physical Sciences Oncology Center.

8:48AM T45.00003 Metastatic Breast Cancer Cells Collectively Invade Collagen by Following a Glucose Gradient[1] , BO SUN, ROBERT AUSTIN, Princeton University, LIYU LIU, Institute of Physics, Chinese Academy of Sciences, GUILLAUME DUCLOS, Physico-Chimie Curie, JEONGSEOG LEE, AMY WU, Princeton University, YOOSEOK KAM, Moffitt Cancer Center, EDUARDO SONTAG, Rutgers University, HOWARD STONE, JAMES STURM, Princeton University, ROBERT GATENBY, Moffitt Cancer Center — We show that MDA-MB-231 metastatic breast cancer cells collectively invade a three dimensional collagen matrix by following a glucose gradient. We observe that due to the 3D physical deformation of the matrix, as measured by the displacement of reporter beads within the matrix, there exists a long range deformation mechanical field inside the matrix which serves to couple the motions of the invading metastatic cell. The invasion front of the cells is a dynamic one, with different cells assuming the lead on a time scale of 24 hours due to certain cells having higher speeds of penetration, which are not sustained. The front cell leadership is dynamic presumably due to metabolic costs associated with the long range strain field which proceeds the invading cell front, which we have imaged using confocal imaging and marker beads imbedded in the collagen matrix.

9:00AM T45.00004 On physical changes on surface of human cervical epithelial cells during cancer transformations , IGOR SOKOLOV, MAXIM DOKUKIN, Tufts University, NATALIIA GUZ, CRAIG WOODWORTH, Clarkson University — Physical changes of the cell surface of cells during transformation from normal to cancerous state are rather poorly studied. Here we describe our recent studies of such changes done on human cervical epithelial cells during their transformation from normal through infected with human papillomavirus type-16 (HPV-16), immortalized (precancerous), to cancerous cells. The changes were studied with the help of atomic force microscopy (AFM) and through the measurement of physical adhesion of fluorescent silica beads to the cell surface. Based on the adhesion experiments, we clearly see the difference in nonspecific adhesion which occurs at the stage of immortalization of cells, precancerous cells. The analysis done with the help of AFM shows that the difference observed comes presumably from the alteration of the cellular "brush," a layer that surrounds cells and which consists of mostly microvilli, microridges, and glycocalyx. Further AFM analysis reveals the emergence of fractal scaling behavior on the surface of cells when normal cells turn into cancerous. The possible causes and potential significance of these observations will be discussed.

9:12AM T45.00005 Cancer Progression and Tumor Growth Kinetics[1] , KRASTAN BLAGOEV, Physics Division, National Science Foundation, Arlington, VA 22180, USA, JAYASHREE KALPATHY-CRAMER, Department of Radiology, Massachusetts General Hospital, Harvard Medical School and the Martinos Center for Biomedical Imaging, Building 129 13th Stre, JULIA WILKERSON, National Cancer Institute, National Institutes of Health, Building 10, 10 Center Drive, Bethesda, MD 20892, USA, SARA SPRINKHUIZEN, YI-QIAO SONG, SUSAN BATES, BRUCE ROSEN, Department of Radiology, Massachusetts General Hospital, Harvard Medical School and the Martinos Center for Biomedical Imaging, Building 129 13th Stre, TITO FOJO, National Cancer Institute, National Institutes of Health, Building 10, 10 Center Drive, Bethesda, MD 20892, USA — We present and analyze tumor growth data from prostate and brain cancer. Scaling the data from different patients shows that early stage prostate tumors show non-exponential growth while advanced prostate and brain tumors enter a stage of exponential growth. The scaling analysis points to the existence of cancer stem cells and/or massive apoptosis in early stage prostate cancer and that late stage cancer growth is not dominated by cancer stem cells. Statistical models of these two growth modes are discussed.

[1]Work supported by the National Science Foundation and the National Institutes of Health

9:24AM T45.00006 Micropost microenvironments for studying luminal-basal lineage commitment of breast cancer cells , ANAND KESAVARAJU, BO QING, ERIC JABART, Department of Bioengineering, Univeristy of California, Berkeley, MARK LABARGE, Lawrence Berkeley National Laboratory, LYDIA SOHN, Department of Mechanical Engineering, Univeristy of California, Berkeley — MCF-7 breast cancer cells were plated onto polydimethylsiloxane (PDMS) microposts in order to examine the effects of the microenvironment on cell lineage. Different stiffnesses and sizes of the microposts are postulated to impact cell surface marker expression levels. We will provide preliminary results analyzing CD271 and focal adhesion markers such as vinculin. 3D shear flow will also be applied to the microposts to study how external mechanical stimuli affect cancer cells within their microenvironment.

9:36AM T45.00007 Minimizing Platelet Activation-Induced Clogging in Deterministic Lateral Displacement Arrays for High-Throughput Capture of Circulating Tumor Cells , JOSEPH D'SILVA, KEVIN LOUTHERBACK, ROBERT AUSTIN, JAMES STURM, Princeton University — Deterministic lateral displacement arrays have been used to separate circulating tumor cells (CTCs) from diluted whole blood at flow rates up to 10 mL/min (K. Loutherback et al., AIP Advances, 2012). However, the throughput is limited to 2 mL equivalent volume of undiluted whole blood due to clogging of the array. Since the concentration of CTCs can be as low as 1-10 cells/mL in clinical samples, processing larger volumes of blood is necessary for diagnostic and analytical applications. We have identified platelet activation by the micro-post array as the primary cause of this clogging. In this talk, we (i) show that clogging occurs at the beginning of the micro-post array and not in the injector channels because both acceleration and deceleration in fluid velocity are required for clogging to occur, and (ii) demonstrate how reduction in platelet concentration and decrease in platelet contact time within the device can be used in combination to achieve a 10x increase in the equivalent volume of undiluted whole blood processed. Finally, we discuss experimental efforts to separate the relative contributions of contact activated coagulation and shear-induced platelet activation to clogging and approaches to minimize these, such as surface treatment and post geometry design.

9:48AM T45.00008 Mechanical phenotyping of tumor cells using a microfluidic cell squeezer device , ZEINA S. KHAN, NABIOLLAH KAMYABI, SIVA A. VANAPALLI, Texas Tech University, Chemical Engineering Department — Studies have indicated that cancer cells have distinct mechanical properties compared to healthy cells. We are investigating the potential of cell mechanics as a biophysical marker for diagnostics and prognosis of cancer. To establish the significance of mechanical properties for cancer diagnostics, a high throughput method is desired. Although techniques such as atomic force microscopy are very precise, they are limited in throughput for cellular mechanical property measurements. To develop a device for high throughput mechanical characterization of tumor cells, we have fabricated a microfludic cell squeezer device that contains narrow micrometer-scale pores. Fluid flow is used to drive cells into these pores mimicking the flow-induced passage of circulating tumor cells through microvasculature. By integrating high speed imaging, the device allows for the simultaneous characterization of five different parameters including the blockage pressure, cell velocity, cell size, elongation and the entry time into squeezer. We have tested a variety of in vitro cell lines, including brain and prostate cancer cell lines, and have found that the entry time is the most sensitive measurement capable of differentiating between cell lines with differing invasiveness.

10:00AM T45.00009 Quantifying stretching and rearrangement in epithelial sheet migration , RACHEL LEE, University of Maryland, College Park, DOUGLAS KELLEY, Massachusetts Institute of Technology, KERSTIN NORDSTROM, University of Maryland, College Park, NICHOLAS OUELLETTE, Yale University, WOLFGANG LOSERT, University of Maryland, College Park — Although understanding the collective migration of cells, such as that seen in epithelial sheets, is essential for understanding diseases such as metastatic cancer, this motion is not yet as well characterized as individual cell migration. Here we adapt quantitative metrics used to characterize the flow and deformation of soft matter to contrast different types of motion within a migrating sheet of cells. Using a Finite-Time Lyapunov Exponent (FTLE) analysis, we find that - in spite of large fluctuations - the flow field of an epithelial cell sheet is not chaotic. Stretching of a sheet of cells (i.e., positive FTLE) is localized at the leading edge of migration. By decomposing the motion of the cells into affine and non-affine components using the metric D^2_{min}, we quantify local plastic rearrangements and describe the motion of a group of cells in a novel way. We find an increase in plastic rearrangements with increasing cell densities, whereas inanimate systems tend to exhibit less non-affine rearrangements with increasing density.

10:12AM T45.00010 Role of Inflammation and Substrate Stiffness in Cancer Cell Transmigration , SUSAN HAMILLA, KIMBERLY STROKA, HELIM ARANDA-ESPINOZA, University of Maryland — Cancer metastasis, the ability for cancer cells to break away from the primary tumor site and spread to other organs of the body, is one of the main contributing factors to the deadliness of the disease. One of the rate-limiting steps in cancer metastasis that is not well understood is the adhesion of tumor cells to the endothelium followed by transmigration. Other factors include substrate stiffness and inflammation. To test these parameters, we designed an in vitro model of transendothelial migration. Our results suggest that cancer cell transmigration is a two-step process in which they first incorporate into the endothelium before migrating through. It was observed that the cumulative fraction of cancer cells that incorporate into the endothelium increases over time. Unlike leukocytes, which can directly transmigrate through the endothelium, cancer cells appear to have a two-step process of transmigration. Our results indicate that inflammation does not act as a signal for cancer cells to localize at specific sites and transmigrate similarly to leukocytes. Cancer cell transmigration also does not vary with substrate stiffness indicating that tissue stiffness may not play a role in cancer's propensity to metastasize to certain tissues.

10:24AM T45.00011 A contact line pinning based microfluidic device for modeling intramural and interstitial flows[1] , CHIH-KUAN TUNG, Dept of Biological & Environmental Engineering, Cornell University, OLEH KRUPA, Dept of Biomedical Eng., Cornell Univ, ELIF APAYDIN, BEE, Cornell, JR-JIUN LIOU, BME, Cornell, ANTHONY DIAZ-SANTANA, School of Chemical and Biomolecular Eng., Cornell Univ, ABRAHAM D. STROOCK, ChemE, Cornell, MINGMING WU, BEE, Cornell — Fluid flows critically regulate a number of important physiological processes in living systems such as vascular tissue development, immune cell and tumor cell trafficking. However, tools for creating well defined intramural (flow within a vascular tube) and interstitial (flow within a tissue) flows in a physiologically realistic, 3D setting are limited. We will present a contact line pinning based microfluidic platform that is able to create a spatially uniform interstitial flow within a cell embedded biomatrix (type I collagen); and an intramural flow within an engineered vascular tube lined with HUVECs. The created interstitial flow were characterized using a Fluorescence Recovery after Photobleaching (FRAP), to be in the range of 1.2 - 16 μm/s. The intramural flow was measured using a particle tracking method, to be in the range of 6 - 30 μm/s. We further demonstrate that interstitial fluid flows modulate breast tumor cell (MDA-MD-231) morphology heterogeneity and plasticity. We will also discuss the influence of fluid flow on cancer cell migration.

[1]Support for this work is provided by National Health Institute R21CA138366. This work was performed in part at the Cornell NanoScale Facility and Nanobiotechnology Center.

10:36AM T45.00012 The cytotoxic effects of titanium oxide and zinc oxide nanoparticles oh Human Cervical Adenocarcinoma cell membranes , TATSIANA MIRONAVA, Stony Brook University, ARIELLA APPLEBAUM, ELIANA APPLEBAUM, Ma'ayanot Yeshiva High School, SHOSHANA GUTERMAN, Yeshiva University High School for Girls, KAYLA APPLEBAUM, Yeshiva University, NY, DANIEL GROSSMAN, Queens College CUNY, CHRIS GORDON, PETER BRINK, H.Z. WANG, MIRIAM RAFAILOVICH, Stony Brook University — The importance of titanium dioxide (TiO_2) and zinc oxide (ZnO), inorganic metal oxides nanoparticles (NPs) stems from their ubiquitous applications in personal care products, solar cells and food whitening agents. Hence, these NPs come in direct contact with the skin, digestive tracts and are absorbed into human tissues. Currently, TiO_2 and ZnO are considered safe commercial ingredients by the material safety data sheets with no reported evidence of carcinogenicity or ecotoxicity, and do not classify either NP as a toxic substance. This study examined the direct effects of TiO_2 and ZnO on HeLa cells, a human cervical adenocarcinonma cell line, and their membrane mechanics. The whole cell patch-clamp technique was used in addition to immunohistochemistry staining, TEM and atomic force microscopy (AFM). Additionally, we examined the effects of dexamethasone (DXM), a glucocorticoid steroid known to have an effect on cell membrane mechanics. Overall, TiO_2 and ZnO seemed to have an adverse effect on cell membrane mechanics by effecting cell proliferation, altering cellular structure, decreasing cell-cell adhesion, activating existing ion channels, increasing membrane permeability, and possibly disrupting cell signaling.

10:48AM T45.00013 Cell stiffness is a biomarker of the metastatic potential of ovarian cancer cells , WENWEI XU, ROMAN MEZENCEV, BYUNGKYU KIM, LIJUAN WANG, JOHN MCDONALD, TODD SULCHEK, Georgia Institute of Technology, SULCHEK TEAM, MCDONALD TEAM — The metastatic potential of cells is an important parameter in the design of optimal strategies for the personalized treatment of cancer. Using atomic force microscopy (AFM), we show that ovarian cancer cells are generally softer and display lower intrinsic variability in cell stiffness than non-malignant ovarian epithelial cells. A detailed study of highly invasive ovarian cancer cells (HEY A8) and their less invasive parental cells (HEY), demonstrates that deformability can serve as an accurate biomarker of metastatic potential. Comparative gene expression profiling indicate that the reduced stiffness of highly metastatic HEY A8 cells is associated with actin cytoskeleton remodeling, microscopic examination of actin fiber structure in these cell lines is consistent with this prediction. Our results indicate that cell stiffness not only distinguishes ovarian cancer cells from non-malignant cells, but may also be a useful biomarker to evaluate the relative metastatic potential of ovarian and perhaps other types of cancer cells.

Session T46 GIMS: Focus Session: Advances in Scanned Probe Microscopy 1: Scanning Probe Spectroscopy & Novel Applications to C-based Systems

Hilton Baltimore Holiday Ballroom 5 - Alexander Otte, Delft University of Technology

8:00AM T46.00001 A Josephson STM with two niobium tips , ANITA ROYCHOWDHURY, RAMI DANA, MICHAEL DREYER, Laboratory for Physical Sciences, University of Maryland, College Park, JAMES ROBERT ANDERSON, CHRISTOPHER J. LOBB, FREDERICK C. WELLSTOOD, University of Maryland, College Park — We are developing a dual-tipped scanning tunneling microscope (STM) that operates at milliKelvin temperatures. The two tips can be connected and brought into tunneling with a superconducting sample to form a SQUID loop. Our scheme involves holding one of the tips fixed while the other is scanned to image spatial variations in the gauge invariant phase difference on the superconducting surface. We have developed a novel technique to fabricate sharp Niobium tips using a reactive ion etcher. The tips have been tested at 4 K and exhibit both a superconducting gap and atomic resolution on Au(111) and Bi_2Se_3 samples. We will describe the experimental setup, our tip fabrication technique, and present initial results.

8:12AM T46.00002 Electron-Hole Asymmetries in the Locally Inverted $\alpha^2F(\omega)$ Spectrum of a Conventional Superconductor by STM , FRANCIS NIESTEMSKI, Stanford University / SLAC, STEVEN JOHNSTON, UBC, ALEX CONTRYMAN, CHARLIE CAMP, TOM DEVEREAUX, HARI MANOHARAN, Stanford University / SLAC — Utilizing scanning tunneling microscopy to create a superconductor-vacuum-superconductor junction, we invert the measured spectroscopy of the archetypal elemental superconductor Pb utilizing strong-coupling Eliashberg theory to obtain a local $\alpha^2F(\omega)$. This is the STS vacuum analogue of the pioneering McMillan and Rowell sandwich junction [W. L. McMillan and J. M. Rowell Phys. Rev. Lett. 14, 108-112 (1965)]. We find broad underlying agreement with McMillan and Rowell highlighted by previously unobserved electron-hole asymmetries and new fine structure which we discuss in terms of both conventional and unconventional superconducting bosonics.

8:24AM T46.00003 Intermodulation Spectroscopy applied to AFM , DAVID HAVILAND, DANIEL PLATZ, DANIEL FORCHHEIMER, The Royal Institute of Technology (KTH), ERIK THOLÉN, Intermodulation Products AB — Measurement of surface forces at the single atom level is usually achieved by exploiting the enhanced sensitivity of a high quality factor resonator in ultrahigh vacuum, with small measurement bandwidth and therefore slow measurement speed. Frequency modulation AFM allows one to overcome this limitation, at the price of one extra feedback loop and very limited quantitative information about the interaction forces between the tip and the surface while imaging. We have introduced a multi-frequency method called Intermodulation AFM (ImAFM), which can be seen as containing features of both the amplitude modulation and frequency modulation AFM methods. In this talk we describe ImAFM in its most general form, where the nonlinear tip surface interaction is seen as transferring an input drive frequency comb, to an output frequency comb. These frequency combs can represent either amplitude modulated or frequency modulated signals, or both. It is demonstrated how the method optimally exploits the frequency band near resonance to extract as much information as is possible for a given measurement bandwidth. With this frequency-domain information one can reconstruct both conservative and dissipative tip-surface interactions with unprecedented accuracy and speed.

8:36AM T46.00004 Interaction imaging with amplitude-dependence force spectroscopy , DANIEL PLATZ, DANIEL FORCHHEIMER, Royal Institute of Technology (KTH), Stockholm, Sweden, ERIK THOLÉN, Intermodulation Products AB, Solna, Sweden, DAVID HAVILAND, Royal Institute of Technology (KTH), Stockholm, Sweden — The ultimate goal in atomic force microscopy (AFM) is the combination of imaging with accurate force measurement. Dynamic AFM offers only qualitative information about the tip-surface interaction while imaging, because the sharp cantilever resonance efficiently filters out the high frequency components of the tip-surface. Traditional force measurements are based on slow, point-wise surface approaches and are incompatible with imaging. Here, we present a method called amplitude-dependence force spectroscopy (ADFS) that enables quantitative dynamic force reconstruction at every point of an AFM image, while scanning at normal speeds. ADFS breaks with the paradigm of constant tip oscillation amplitude, as the oscillation amplitude is rapidly modulated at every image point. The measured response gives the amplitude-dependence of the Fourier component of the force at the resonant frequency, which allows for a model-free reconstruction of the tip-surface. We have made rigorous tests of ADS using numerical simulations and have used it for a detailed study of the mechanical properties of polymer surfaces. The amplitude-dependence of the response in dynamic AFM provides a new and coherent framework for the description of conservative and dissipative tip-surface forces.

8:48AM T46.00005 Quantitative Atomic-Resolution Surface Force Field Spectroscopy in Three Dimensions: A *How-To* Guide for Collecting Meaningful Data , MEHMET Z. BAYKARA, Bilkent University, OMUR E. DAGDEVIREN, Yale University, TODD C. SCHWENDEMANN, Southern Connecticut State University, HARRY MÖNIG, Westfaelische Wilhelms-Universitaet Muenster, ERIC I. ALTMAN, UDO D. SCHWARZ, Yale University — Three-dimensional atomic force microscopy (3D-AFM) is being increasingly used to measure the chemical interactions between an atomically sharp probe tip and surfaces of interest in terms of atomic-scale forces and energies in three dimensions. Since the results provided by 3D-AFM may be affected by piezo nonlinearities, thermal and electronic drift, tip asymmetries, and elastic deformation of the tip's apex, these effects need to be considered during data interpretation. In this talk, we analyze the impact of these effects on the data, compare different methods to record atomic-resolution surface force fields, and determine the approaches that suffer the least from associated artifacts. We conclude that efforts to reduce unwanted influence of tip properties on recorded data are indispensable to extract detailed information about atomic-scale properties of the surface.

9:00AM T46.00006 Virtual Scanning Tunneling Microscopy: A local spectroscopic probe of high mobility 2D electron systems , MATTHEW PELLICCIONE, JOHN BARTEL, ADAM SCIAMBI, Stanford University, LOREN PFEIFFER, KEN WEST, Princeton University, DAVID GOLDHABER-GORDON, Stanford University — Many scanning probe techniques have been utilized in recent years to measure local properties of high mobility two-dimensional (2D) electron systems in GaAs. However, most techniques lack the ability to tunnel into the buried 2D system and measure local spectroscopic information. We report scanning gate measurements on a bilayer GaAs/AlGaAs heterostructure that allows for a local modulation of tunneling between two 2D electron layers. We call this technique Virtual Scanning Tunneling Microscopy (VSTM) [1] as the influence of the scanning gate is analogous to an STM tip, except at a GaAs/AlGaAs interface instead of a surface. We present measurements that highlight the spatial resolution and spectroscopic capabilities of the technique.

[1] A. Sciambi, M. Pelliccione *et al.*, Appl. Phys. Lett. **97**, 132103 (2010).

9:12AM T46.00007 Tuning 2D-2D tunneling in high mobility electron systems , JOHN BARTEL, MATTHEW PELLICCIONE, ADAM SCIAMBI, Stanford University, LOREN PFEIFFER, KEN WEST, Princeton University, DAVID GOLDHABER-GORDON, Stanford University — We present measurements on GaAs/AlGaAs bilayer two-dimensional electron systems (2DES) where the tunnel coupling between the 2DES is tunable with a gate. By designing a GaAs/AlGaAs heterostructure with a relatively low energy barrier between the 2DES, reducing the electron density with a gate lowers the effective barrier height between the 2DES and increases the tunnel coupling. We describe the fabrication process developed to realize these samples, along with measurements that take advantage of this tunable tunnel coupling to realize a novel transistor where the gate lies outside the channel region [1]. In addition, the suitability of these devices for scanning gate measurements will be discussed.
[1] A. Sciambi, M. Pelliccione *et al.*, Phys. Rev. B **84**, 085301 (2011).

9:24AM T46.00008 Gate Map Tunneling Spectroscopy of Interactions in Graphene , JUNGSEOK CHAE, Center for Nanoscale Science and Technology, NIST and Maryland NanoCenter, University of Maryland — The local electron density of states (LDOS) in semiconductors and semimetals like graphene can be adjusted with respect to the Fermi energy by using an electric field applied by a nearby gate electrode. In this way interaction physics can be turned on and off as the electron density is modulated at the Fermi level in an applied magnetic field. Interaction physics in graphene has been an interesting subject since the first isolation of single layer graphene, due the singular nature of the Dirac point in the graphene spectrum. The electronic density of states at the Dirac point vanishes and the long-range Coulomb interactions are not effectively screened, which gives rise to a rich spectrum of interaction-driven physics in magnetic fields at low temperatures. In this talk, I will present recent experimental results in graphene on boron nitride substrates using gate mapping tunneling spectroscopy [1]. Gate map tunneling spectroscopy consists of series of single tunneling spectra obtained as a back gate voltage is varied to change the carrier density at the Fermi level. The gate maps show clear variations of the tunneling spectrum as a function of carrier density. The formation of Landau levels (LLs) in magnetic fields up to 8 T is observed to form a staircase pattern in maps of the tunneling conductance in the 2-dimensional tunneling bias voltage-gate voltage plane. LLs modulate the LDOS at the Fermi level as the carrier density is varied with the gate potential. An analysis of the LL peak positions shows that the graphene energy-momentum remains linear at low energies, but that the dispersion velocity is enhanced due to interactions as the density is lowered approaching the Dirac point. Interaction effects are also strongly seen near zero density by the opening of large Coulomb gaps in the tunneling spectra, which will be discussed in terms of the competing effects of residual substrate induced disorder and interactions.

[1] J. Chae *et. al.*, PRL **197**, 116802 (2012)

10:00AM T46.00009 Thermoelectric microscopy for imaging disorder in epitaxial graphene , SANGHEE CHO, STEPHEN KANG, WONDONG KIM, HO-KI LYEO, Korea Research Institute of Standards and Science, EUI-SUP LEE, SUNG-JAE WOO, YONG-HYUN KIM, Korea Advanced Institute of Science and Technology, KI-JEONG KONG, Korea Research Institute of Chemical Technology, ILYOU KIM, HYEONG-DO KIM, Pohang University of Science and Technology, TONG ZHANG, JOSEPH STROSCIO, National Institute of Standards and Technology — Thermopower, an electron transport property, is a measure of thermal energy relative to the Fermi-energy E_F and thus reflects the asymmetry in the density of states (DOS) with respect to E_F. We use thermopower as a microscopic probe of electronic properties of epitaxial graphene grown on SiC(0001), for which a scanning probe microscopy method has been developed by modifying a ultra-high-vacuum atomic force microscope. This method has a particular sensitivity to the electronic states near E_F. We thereby could image structural defects and strain fields that cause distortions in the electronic states near E_F. Such a capability allowed us to explore how the structural disorder is correlated and how the correlation evolves by responding to inherent strain in epitaxial graphene. Furthermore, striking images of atomically varying states and the finding of one-dimensional quantum confinement will be presented, demonstrating the ability to probe local DOS at the extreme scale.

10:12AM T46.00010 Noise Analysis on Graphene Devices via Scanning Noise Microscopy , DUCKHYUNG CHO, Department of Physics, Seoul Nat Univ, MOON GYU SUNG, HYUNGWOO LEE, KWANG HEO, KYUNG-EUN BYUN, TAEKYEONG KIM, DAVID H. SEO, SUNAE SEO, SEUNGHUN HONG, Seoul National University — Until now, the studies about low-frequency noises in electronic devices have mostly relied on the scaling behaviour analysis of current noise measured from multiple devices with different resistance values. However, the fabrication of such multiple devices for noise analysis is a labor-intensive and time-consuming work. Herein, we developed the scanning noise microscopy (SNM) method for nanoscale noise analysis of electronic devices, which allowed us to measure the scaling behaviour of electrical current noises in a graphene-strip-based device. In this method, a conductive atomic force microscopy probe made a direct contact on the graphene strip channel in the device to measure the noise spectra through it. The SNM method enabled the investigation of the noise scaling behaviour using only a single device. In addition, the nanoscale noise map was obtained, which allowed us to study the effect of structural defects on the noise characteristics of the graphene strip channel. Our method should be a powerful strategy for nanoscale noise analysis and play a significant role in basic research on nanoscale devices.

10:24AM T46.00011 Electronic state of carbon material surface by non-contact scanning nonlinear dielectric microscopy , SHIN-ICHIRO KOBAYASHI, YASUO CHO, Research Institute of Electrical Communication, Tohoku University — Non-contact scanning nonlinear dielectric microscopy (NC-SNDM) can detect both topography and microscopic electric dipole moment of semiconducting surfaces. Recently, we clearly observed the atomic surface of graphite and fullerene (C_{60}) molecule on Si(111)-(7×7) surface (7×7 surface) by using second-order amplitude in SNDM signal as a feedback signal. SNDM signal of graphite by NC-SNDM originates from the electrochemical capacitance with tunneling and is related to the density of state (DOS) of an atomic or molecular surface [1,2]. However, a linear DOS was considered to investigate the origin of SNDM signals only when considering the electronic state of graphite surface, interface between C_{60} and 7×7 surface and internal structure of C_{60} on 7×7 surface in NC-SNDM. To resolve this problem, we introduce the general electrochemical capacitance induced by tunneling effect for analysis of NC-SNDM and discuss not only the influence of probe tip on SNDM signal and the origin of current signal but also the characteristics of SNDM signals obtained from graphite and from C_{60} on 7×7 surface

10:36AM T46.00012 Contactless Probing of the Carrier Transport in Carbon Nanotubes Using Dielectric Force Microscopy , YIZE LI, JUN GE, JIA LIU, JIE ZHANG, WEI LU, LIWEI CHEN, Suzhou Institute of Nano-Tech and Nano-Bionics, Chinese Academy of Sciences — We have developed a scanning probe microscopy (SPM) based technique which is named as dielectric force microscopy (DFM) to manipulate and probe the majority carriers in 1-dimentional nanoelectronic materials. We have demonstrated its success in distinguishing semiconducting single-walled carbon nanotubes (SWNTs) from metallic ones, locating semiconducting-metallic junction in SWNTs, determining the majority carrier types in SWNTs and ZnO nanowires, and detecting the electronic doping of SWNTs by gaseous ammonia. To achieve a quantitative measure of the intrinsic carrier transport, we have performed DFM measurement on individual SWNTs, fabricated field effect transistor devices with the individual SWNT serving as the channel, and carried out electrical transport experiment. The results from DFM and transport measurements are quantitatively correlated in an almost perfect fashion allowing the extraction of intrinsic carrier transport properties especially carrier mobility from DFM data without making metal contacts. Furthermore, we have successfully detected the location and behavior of local transport barriers in SWNTs utilizing the nanometer scale resolution feature of DFM.

10:48AM T46.00013 Quantitative Kelvin Probe Force Microscopy of a Single-Walled Carbon Nanotube Transistor

, ELLIOT FULLER, BRAD CORSO, TOLGA GUL, PHILIP COLLINS, University of California at Irvine, UNIVERSITY OF CALIFORNIA AT IRVINE TEAM — Kelvin Probe Force Microscopy (KPFM) is well-suited to measuring the surface potentials of nanoscale devices, including organic thin film, graphene, and silicon nanowire field effect transistors (FETs). However, a primary limitation of KPFM is long-range capacitive coupling of the probe to parts of the sample that are distant from the immediate vicinity of the probe tip. This coupling complicates quantitative measurements and limits most KPFM work to qualitative observations of work function variations. Here, we address these problems to extract potentials along current-carrying, single-walled carbon nanotube (SWNT) FETs. As a low carrier density channel only 1 nm in diameter, SWNTs have extremely weak coupling to a KPFM probe tip, and therefore they provide a unique, limiting geometry that tests the resolving power of KPFM. By directly measuring this SWNT coupling and other, spatially-varying capacitive couplings to the probe tip, we have developed a robust and quantitative method for separating the desired signal, the local surface potential, from other electrostatic effects. The technique can be readily applied to other nanoscale devices to correctly extract work functions, potential gradients, and inhomogeneities in electrochemical potential.

Thursday, March 21, 2013 8:00AM - 11:00AM –

Session T47 GMAG: Invited Session: The Effect of Electric Fields on Magnetism

Hilton Baltimore Holiday Ballroom 6 - Chia-Ling Chien, Johns Hopkins University

8:00AM T47.00001 Voltage controlled magnetic anisotropy in magnetic tunnel junctions

, WEIGANG WANG[1], Department of Physics and Astronomy, Johns Hopkins University Baltimore, MD 21218, and Department of Physics, University of Arizona, Tucson, AZ 85721 — Recently, voltage controlled magnetic anisotropy (VCMA) in 3d transitional ferromagnets (FM) has attracted a great deal of attentions. VCMA has traditionally been explored in multiferroic materials and diluted magnetic semiconductors, but not in metals because of the anticipated negligible effects since the electric field would be screened within 1-2 Å at the metal surface. However, a voltage may exert marked effects if the magnetic properties of ultrathin films are dominated by interfacial magnetic anisotropy. Here we demonstrate a large VCMA effect in perpendicular MgO magnetic tunnel junctions (p-MTJs) with very thin CoFeB layers. The p-MTJs have the key structure of Co40Fe40B20(1.2-1.3nm)/MgO(1.2-2nm)/Co40Fe40B20(1.6nm) exhibiting at room temperature tunneling magnetoresistance in excess of 100%. The perpendicular magnetic anisotropy (PMA) in this system is believed to be stabilized by hybridization between the out-of-plane 3d orbitals of the FM and oxygen 2p orbitals. We show that both the magnitude and the direction of the electric field can systematically alter the PMA of the thin CoFeB layers interfaced with the MgO barrier. Furthermore, under a given electric field, the two CoFeB layers on either side of the MgO barrier respond in the opposite manner as expected. By exploiting the combined effect of spin transfer torque and VCMA in CoFeB/MgO/CoFeB nanopillars, we have accomplished voltage controlled spintronic devices, where the MTJ can be manipulated by a unipolar switching process using consecutive negative voltages less than 1.5 V in magnitude. In this manner, voltage can access the high resistance or the low resistance state of an MTJ with very small current densities. Wang, W.-G., Li, M., Hageman, S. & Chien, C. L. Electric-field-assisted switching in magnetic tunnel junctions. Nature Materials 11, 64 (2012).

8:36AM T47.00002 Voltage-Induced Ferromagnetic Resonance in Magnetic Tunnel Junctions[1]

, ILYA KRIVOROTOV, Department of Physics and Astronomy, University of California, Irvine — Excitation of sub-nanosecond magnetic dynamics by an electric field is a grand challenge in the field of spintronics. The ability to perform high-speed manipulation of magnetization by electric fields rather than by current-induced spin torques or magnetic fields would greatly improve energy efficiency of spintronic devices such as nonvolatile magnetic memory and logic. In this talk, I will discuss our experiments on excitation of ferromagnetic resonance in CoFeB/ MgO/ CoFeB magnetic tunnel junctions by the combined action of voltage-controlled magnetic anisotropy (VCMA) and spin transfer torque [1]. Our measurements reveal that GHz-frequency VCMA torque and spin torque in low resistance (resistance-area product of a few Ohm $\cdot$ μm^2) CoFeB-based magnetic tunnel junctions have similar magnitudes, and thus that both torques are equally important for understanding high-speed voltage-driven magnetization dynamics in CoFeB magnetic tunnel junctions such as magnetization switching and auto-oscillations induced by spin torque. As an example, we show that VCMA can increase the sensitivity of a microwave signal detector based on a magnetic tunnel junction to the sensitivity level of semiconductor Schottky diodes. Our measurements also demonstrate that ferromagnetic resonance in high resistance magnetic tunnel junctions can be excited by VCMA alone without a significant contribution from the spin torque drive. I will conclude this talk with a discussion on how voltage-induced ferromagnetic resonance can be used for quantitative measurements of various voltage-dependent torques in magnetic tunnel junctions: in-plane and perpendicular spin torques as well as VCMA torque.

9:12AM T47.00003 Dynamic magnetization switching and spin wave excitations by voltage-induced torque[1]

, YOICHI SHIOTA, Graduate School of Engineering Science, Osaka University — The effect of electric fields on ultrathin ferromagnetic metal layer is one of the promising approaches for manipulating the spin direction with low-energy consumption, localization, and coherent behavior. Several experimental approaches to realize it have been investigated using ferromagnetic semiconductors [1], magnetostriction together with piezo-electric materials [2], multiferroic materials [3], and ultrathin ferromagnetic layer [4-9]. In this talk, we will present a dynamic control of spins by voltage-induced torque. We used the magnetic tunnel junctions with ultrathin ferromagnetic layer, which shows voltage-induced perpendicular magnetic anisotropy change. By applying the voltage to the junction, the magnetic easy-axis in the ultrathin ferromagnetic layer changes from in-plane to out-of-plane, which causes a precession of the spins. This precession resulted in a two-way toggle switching by determining an appropriate pulse length [8]. On the other hand, an application of rf-voltage causes an excitation of a uniform spin-wave [9]. Since the precession of spin associates with an oscillation in the resistance of the junction, the applied rf-signal is rectified and produces a dc-voltage. From the spectrum of the dc-voltage as a function of frequency, we could estimate the voltage-induced torque.

9:48AM T47.00004 Electric Field as Switching Tool for Magnetic States in Atomic-Scale-Nanostructures , VALERI STEPANYUK, Max-Planck Institute of Microstructure Physics, Halle, Germany — We present the state of the art ab initio studies of the effect of the external electric field on electronic, magnetic and transport properties of atomic-scale nanostructures on metal surfaces. We demonstrate a possibility of a local control and switching of magnetism in such nanostructures [1]. The effect of the electric field on surface-state electrons is discussed [2]. Our results reveal that the local spin-polarization of electrons and the local magnetoresistance on nanoislands can be tuned by the electric field [3,4]. Our studies give a clear evidence that an external surface charging can strongly affect substrate-mediated exchange interactions [5].

10:24AM T47.00005 Electrically-induced ferromagnetism at room temperature in (Ti,Co)O_2: carrier-mediated ferromagnetism[1] , TOMOTERU FUKUMURA, University of Tokyo — Oxide-diluted magnetic semiconductors (DMS) is expected to have high Curie temperature via carrier-mediated ferromagnetism through heavy electron mass and large electron carrier density. We have studied various oxide-DMS such as (Zn,Mn)O [1], and discovered room temperature ferromagnetism in (Ti,Co)O_2 [2]. The origin of ferromagnetism has been discussed for a decade. Previously, the control of ferromagnetism was demonstrated through carrier control by chemical doping [3]. But it was difficult to exclude the defect-mediated ferromagnetism, since the electron donor was the oxygen vacancy [4]. In order to evidence the carrier-mediated ferromagnetism, the electric field control of ferromagnetism is useful [5]. The control of ferromagnetism at room temperature is also important for implementation of spintronic devices. By gating with electric double layer transistor, the ferromagnetism was induced at room temperature, representing electron carrier-mediated ferromagnetism [6]. Chemical doping study in (Ti,Co)O_2 for wider range of carrier density exhibited clearer paramagnetic insulator to ferromagnetic metal transition with increasing carrier density [7]. At a medium carrier density, a ferromagnetic insulator phase appeared possibly related with a phase separation between ferromagnetic and paramagnetic phases. Also, a superparamagnetic phase appeared for excessively reduced sample. Taking all these results into account, previously proposed extrinsic mechanisms such as oxygen vacancy-mediated mechanism [4], metal segregation [8], and superparamagnetism [9] are not correct picture of the ferromagnetism. This study was in collaboration with Y. Yamada, K. Ueno, M. Kawasaki, H. T. Yuan, H. Shimotani, Y. Iwasa, L. Gu, S. Tsukimoto, Y. Ikuhara, A. Fujimori, and T. Mizokawa.

Session U1 DCMP DCP: Invited Session: Hidden Order in URu2Si2 and Possibly Related Compounds Ballroom I - John Mydosh, Kamerlingh Onnes Lab

11:15AM U1.00001 Symmetry Breaking in the Hidden-Order Phase of URu_2Si_2[1] , TAKASADA SHIBAUCHI, Department of Physics, Kyoto University — In the heavy fermion compound URu_2Si_2, the hidden-order transition occurs at 17.5 K, whose nature has posed a long-standing mystery. A second-order phase transition is characterized by spontaneous symmetry breaking, and thus the nature of the hidden order cannot be determined without understanding which symmetry is being broken. Our magnetic torque measurements in small pure crystals reveal the emergence of an in-plane anisotropy of the magnetic susceptibility below the transition temperature [1], indicating the spontaneous breaking of four-fold rotational symmetry of the tetragonal URu_2Si_2. In addition, our recent observation of cyclotron resonance allows the full determination of the electron-mass structure of the main Fermi-surface sheets, which implies an anomalous in-plane mass anisotropy [2] consistent with the rotational symmetry breaking. These results impose strong constraints on the symmetry of the hidden order parameter.

[2] S. Tonegawa *et al.,* Phys. Rev. Lett. **109**, 036401 (2012).

[1]This work has been done in collaboration with R. Okazaki, S. Tonegawa, K. Hashimoto, K. Ikada, Y. H. Lin, H. Shishido, H. J. Shi, Y. Haga, T. D. Matsuda, E. Yamamoto, Y. Onuki, H. Ikeda, and Y. Matsuda.

11:51AM U1.00002 Neutron scattering study of URu_2Si_2 magnetic properties: from hydrostatic pressure to uniaxial stress , FREDERIC BOURDAROT, SPSMS, UMR-E 9001, CEA-INAC/ UJF-Grenoble 1, MDN, 17 rue des Martyrs, F-38054 Grenoble, France — Since the discovery of the unusual magnetic and superconducting properties of URu_2Si_2 in 1985 by Palstra [1], this heavy fermion has been extensively studied. A "Hidden Order" evidences by bulk properties like specific heat, has been found below T_0=17.8K. Neutron scattering in this case is an efficient probe for the study of this compound as large magnetic excitations and an irremovable tiny antiferromagnetic moment are present in this sample. Even though the tiny antiferromagnetic moment aligned along the c-axis at Q_0 is only $\sim 0.01\mu_B$, the magnetic excitations seem to be associated to a large magnetic moment of $\sim 1\ \mu_B$ and show two minimums at Q_0=(1,0,0) but also at Q_1=(0.6,0,0). These magnetic responses have been intensively studied in normal conditions by Broholm [2,3] and our group[4], but also versus magnetic field [5], and more recently under hydrostatic pressure [6]. The result of these experiments seem to indicate that the Hidden Order is linked to the excitation at Q_0 and not to the excitation at Q_1. We will present the revisited magnetic properties of URu_2Si_2 under uniaxial stress along the a-axis [7,8]. Both elastic and inelastic contributions have been measured versus the constraints. In the HO state, as the constraint increases, the AF gap excitation at Q_0 decreases and the tiny moment increases: it seems also that there is a relation between both parameters. On the other hand, the excitation gap at Q_1 is slightly increasing. From our measurement we infer a critical pressure of $\sim$ 0.33 GPa, with a large increase of the antiferromagnetic moment. This behavior is very similar to results under hydrostatic pressure. Combining hydrostatic pressure, uniaxial stress along the a-axis and neutron Larmor diffraction measurements, that gives the lattice distribution of our URu_2Si_2 crystal, we conclude that the magnetic exchange integrals are dominated by the lattice parameter a and not the ratio c/a as usually believed.

12:27PM U1.00003 The hidden order phase in URu_2Si_2: Remarkable nesting and spin-orbital hybridization , PETER OPPENEER, Dept. of Physics and Astronomy, Uppsala University, Uppsala — Aspects of Fermi surface (FS) nesting properties of URu_2Si_2 are analyzed with particular focus on their implication for the mysterious hidden order phase which occurs at 17.5 K. We show that there exist two Fermi surfaces that exhibit unusually strong nesting at the antiferromagnetic wavevector, $\mathbf{Q}_0=(0,0,1)$. The corresponding energy dispersions fulfill the relation $\epsilon_1(\mathbf{k})=-\epsilon_2(\mathbf{k}\pm\mathbf{Q}_0)$ at eight FS hotspot lines on the surfaces. Notably, the spin-orbital characters of the involved $5f$ states are *different*: $j_z=\pm 5/2$ *vs.* $\pm 3/2$, and hence the occurring degenerate Dirac crossings are symmetry protected in the nonmagnetic normal state. Pairing of electrons in these two FSs can commence through interaction with a quasiparticle with wavevector $\mathbf{Q}_0$ and exchange of longitudinal angular momentum Δj_z. Dynamical symmetry breaking through an Ising-like spin-orbital excitation mode at $\mathbf{Q}_0$ with $\Delta j_z=\pm 1$ induces a hybridization of the two states, causing substantial FS gapping. Concomitant spin and orbital currents in the uranium planes can give rise to a rotational symmetry breaking. The existence of such specifically nested FSs in URu_2Si_2 is confirmed in recent experiments.

This work has been performed with S. Elgazzar, J. Rusz, Q. Feng, T. Durakiewicz and J.A. Mydosh.

1:03PM U1.00004 A Hund's rule mechanism for Hidden Spin-Orbital Density Wave in URu_2Si_2[1] , PETER RISEBOROUGH, Temple University — It is proposed that the "Hidden Order" state of URu_2Si_2 corresponds to a combined spin-orbital density wave state, which is stabilized by the inter-orbital Hund's rule coupling. The electronic system is described by the underscreened Anderson Lattice Model, in which there are two-fold degenerate f bands which hybridize with a single conduction band. In the normal state, the bands at the Fermi-energy have almost pure 5f orbital characters in accord with the results of first principles electronic structure calculations. The model Fermi-surface has heavy fermion sheets which exhibit interband nesting and intraband nesting with similar wave vectors. The spin-flip terms of the Hund's rule interaction and the interband nesting produces a second-order phase transition which partially gaps the Fermi-surface, and leads to a state with broken spin-rotational invariance without forming a net ordered magnetic moment. The resulting spin nematic phase is consistent with the magnetic torque experiments of Okazaki *et al.*. The similarity of the interband nesting and the intraband nesting conditions leads to an adiabatic continuity between the "Hidden Order" and Antiferromagnetic phases for small values of the hybridization. The presence of a nearby hybridization gap results in an asymmetric form of the pseudogap caused by the "Hidden Order" transition. Precursor fluctuations of the hidden order parameter, above T_{HO}, lead to the formation of "hot spots" on the Fermi-surface and a depletion of the density of states in the vicinity of the Fermi-energy as is seen by point contact and optical spectroscopies. The amplitude of the precursor fluctuations increase as T_{HO} is driven towards zero, however, the order of the transition switches from second-order to first-order pre-empting the quantum critical point. These results in accord with the change in the order of the transition inferred by Jaime *et al.* from measurements of the specific heat in an applied magnetic field. This model might also be applicable to the enigmatic pseudo-gap phases seen in high-temperature superconductors.

1:39PM U1.00005 Hastatic Order in URu_2Si_2[1] , PREMALA CHANDRA, Rutgers University — The development of collective long-order via phase transitions occurs by the spontaneous breaking of fundamental symmetries. Magnetism is a consequence of broken time-reversal symmetry while superfluidity results from broken gauge invariance. The broken symmetry that develops below 17.5 K in the heavy fermion compound URu_2Si_2 has long eluded such identification. In this talk we show that the recent observation of Ising quasiparticles in URu_2Si_2 results from a spinor order parameter that breaks *double* time-reversal symmetry, mixing states of integer and half-integer spin. Such "hastatic order" hybridizes conduction electrons with Ising $5f^2$ states of the uranium atoms to produce Ising quasiparticles; it accounts for the large entropy of condensation and the magnetic anomaly observed in torque magnetometry. Hastatic order also results in a number of predictions for future experiment: a tiny transverse moment in the conduction sea, a collosal Ising anisotropy in the nonlinear susceptbility and a resonant energy-dependent nematicity in the tunneling density of states.

Session U2 DCMP: Invited Session: Topological Insulators: Surface State Transport Ballroom II

- Joel Moore, University of California, Berkeley

11:15AM U2.00001 Quantum transport in topological insulator nanowires and thin films , JENS H. BARDARSON, University of California, Berkeley — Topological insulators have an insulating bulk but a metallic surface. In the simplest case, the surface electronic structure of a 3D topological insulator is described by a single 2D Dirac cone. The transport properties of such a surface state are of considerable current interest; they have some similarities with graphene, which also realizes Dirac fermions, but have several unique features in their response to magnetic fields. In this talk, I give an overview of some of the main quantum transport properties of topological insulator surfaces. I focus on the efforts to use quantum interference phenomena, such as weak anti-localization and the Aharonov-Bohm effect, to verify in a transport experiment the Dirac nature of the surface state and its defining properties.

11:51AM U2.00002 The strong, weak and anomalous sides of weak topological insulators , ZOHAR RINGEL, Weizmann Institute of Science — Disorder and topology can be thought of as two counter-driving forces. While the former pushes electron wave functions to localize in space, the latter requires them to remain coherent over the entire system. We study the interplay between these two on the surface of a "weakly" topological phase- the Weak Topological Insulator. Using arguments based on flux-insertions and locality, we show that such surfaces cannot undergo a localization transition even when the surface is strongly disordered. We also present a numerical study which further quantifies this result. We then reformulate the same notions, in field theory language, using a novel Z_2-charge-anomaly. This anomaly generalizes the Z-charge-anomaly associated with edges of the Integer Quantum Hall Effect. Besides unifying various aspects of Topological Insulators, the anomaly allows us to calculate new topological properties of TIs in the presence of electric fields.

12:27PM U2.00003 Surface conduction of topological Dirac electrons in bulk insulating Bi_2Se_3 , MICHAEL FUHRER, School of Physics, Monash University — The three dimensional strong topological insulator (STI) is a new phase of electronic matter which is distinct from ordinary insulators in that it supports on its surface a conducting two-dimensional surface state whose existence is guaranteed by topology. I will discuss experiments on the STI material Bi_2Se_3, which has a bulk bandgap of 300 meV, much greater than room temperature, and a single topological surface state with a massless Dirac dispersion. Field effect transistors consisting of thin (3-20 nm) Bi_2Se_3 are fabricated from mechanically exfoliated from single crystals, and electrochemical and/or chemical gating methods are used to move the Fermi energy into the bulk bandgap, revealing the ambipolar gapless nature of transport in the Bi_2Se_3 surface states. The minimum conductivity of the topological surface state is understood within the self-consistent theory of Dirac electrons in the presence of charged impurities. The intrinsic finite-temperature resistivity of the topological surface state due to electron-acoustic phonon scattering is measured to be $\sim$60 times larger than that of graphene largely due to the smaller Fermi and sound velocities in Bi_2Se_3, which will have implications for topological electronic devices operating at room temperature. As samples are made thinner, coherent coupling of the top and bottom topological surfaces is observed through the magnitude of the weak anti-localization correction to the conductivity, and, in the thinnest Bi_2Se_3 samples ($\sim$ 3 nm), in thermally-activated conductivity reflecting the opening of a bandgap.

1:03PM U2.00004 Prediction of weak and strong topological insulators in layered semiconductors.

, CLAUDIA FELSER[1], Max Planck Institute Chemical Physics for Solids — We investigate a new class of ternary materials such as LiAuSe and KHgSb with a honeycomb structure in Au-Se and Hg-Sb layers. We demonstrate the band inversion in these materials similar to HgTe, which is a strong precondition for existence of the topological surface states. In contrast with graphene, these materials exhibit strong spin-orbit coupling and a small direct band gap at the point. Since these materials are centrosymmetric, it is straightforward to determine the parity of their wave functions, and hence their topological character. Surprisingly, the compound with strong spin-orbit coupling (KHgSb) is trivial, whereas LiAuSe is found to be a topological insulator. However KHgSb is a weak topological insulators in case of an odd number of layers in the primitive unit cell. Here, the single-layered KHgSb shows a large bulk energy gap of 0.24 eV. Its side surface hosts metallic surface states, forming two anisotropic Dirac cones. Although the stacking of even-layered structures leads to trivial insulators, the structures can host a quantum spin Hall layer with a large bulk gap, if an additional single layer exists as a stacking fault in the crystal. The reported honeycomb compounds can serve as prototypes to aid in the finding of new weak topological insulators in layered small-gap semiconductors.

1:39PM U2.00005 Manifestation of topological protection in transport properties of epitaxial Bi_2Se_3 thin films[1]

, ALEXEY TASKIN, ISIR, Osaka University — A topological insulator is a new quantum state of matter which can be realized in some materials with a strong spin-orbit coupling. Due to the spin-momentum locking, massless Dirac fermions residing on the surface of a topological insulator are protected from backscattering and cannot be localized by disorder. However, such protection can be lifted in ultrathin films when the three-dimensionality of the sample is lost due to hybridization between top and bottom surfaces. Recently, using Molecular Beam Epitaxy, we succeeded in growing Bi_2Se_3 thin films of sufficiently high quality to present quantum oscillations in magnetotransport [1]. By measuring the Shubnikov-de Haas oscillations in a series of high-quality films, we revealed a systematic evolution of the surface conductance as a function of thickness and found a striking manifestation of the topological protection [2]: The metallic surface transport abruptly diminishes below the critical thickness of $\sim$6 nm, at which an energy gap opens in the surface state and the Dirac fermions become massive. At the same time, the weak antilocalization behavior is found to weaken in the gapped phase due to the loss of π Berry phase. Our results demonstrate the importance of the spin and momentum coupling in maintaining the topological protection of the surface carriers in topological insulators.

Session U3 DCOMP DCMP: Invited Session: Application of the First-Principles and Atomistic Methods to Nuclear Detection Materials

Ballroom III - David Beach, Department of Energy, National Nuclear Security Administration

11:15AM U3.00001 Point Defect Properties of Cd(Zn)Te and TlBr for Room-Temperature Gamma Radiation Detectors[1]

, VINCENZO LORDI, Lawrence Livermore National Laboratory — The effects of various crystal defects in CdTe, $Cd_{1-x}Zn_xTe$ (CZT), and TlBr are critical for their performance as room-temperature gamma radiation detectors. We use predictive first principles theoretical methods to provide fundamental, atomic scale understanding of the defect properties of these materials to enable design of optimal growth and processing conditions, such as doping, annealing, and stoichiometry. Several recent cases will be reviewed, including (i) accurate calculations of the thermodynamic and electronic properties of native point defects and point defect complexes in CdTe and CZT; (ii) the effects of Zn alloying on the native point defect properties of CZT; (iii) point defect diffusion and binding related to Te clustering in Cd(Zn)Te; (iv) the profound effect of native point defects—principally vacancies—on the intrinsic material properties of TlBr, particularly electronic and ionic conductivity; (v) tailored doping of TlBr to independently control the electronic and ionic conductivity; and (vi) the effects of metal impurities on the electronic properties and device performance of TlBr detectors.

11:51AM U3.00002 First-principles calculations of self-trapping of carriers and excitons in NaI and SrI_2

, DANIEL ABERG, Lawrence Livermore National Laboratory — While the general potential of scintillators as radiation detectors has been demonstrated, one of the current goals is to develop materials with improved energy resolution sufficient to detect fissile materials with a low probability of errors at ports, borders, and airports. The poor resolution has been linked to the non-linear response to the gamma ray energy. Fundamental understanding of this requires detailed knowledge of elementary electronic excitation processes. In particular, in most metal halide scintillators charge carriers and excitations localize and create self-trapped species associated with large effective masses and slow diffusivities. First-principles modeling is essential for providing quantitative understanding of the involved microscopic processes. Here, we present comprehensive ab-initio calculations, with techniques ranging from hybrid DFT+exact exchange to self-consistent GW and Bethe-Salpeter approach, for modeling the electronic structure and mobilities of self-trapped carriers and excitons in metal halides with particular attention given to sodium and strontium iodide.

12:27PM U3.00003 Multiscale Modeling of Crystal Growth and Microstructural Evolution of CdZnTe[1]

, CHARLES HENAGER, JR., PNNL, Richland, WA 99352 — Crystal growth models and modeling tools for CdTe and CZT along with experimental melt-growth data will be presented and discussed. The emphasis will be on creating a multiscale-modeling framework that can be applied to solve portions of the crystal quality and reproducibility problem of CZT crystals grown for high-resolution radiation detectors. The growth models and methods include ab initio models of CdTe, ab initio molecular dynamics (MD) models CdTe, MD of solidification of CdTe, equilibrium growth defects in CdTe, and development of coarser-scale microstructural evolution models using phase field methods. These model and theory results will be discussed in terms of designing a multiscale approach to two relevant problems in CZT crystal growth, namely solid-liquid interface (SLI) stability and concurrent defect generation in the hot but cooling CZT solid. This dovetails with recent experimental research focused on the growth of CdTe from Te-rich melts with an emphasis on SLI instability. Experimental data on SLI instabilities will be featured as well as results of transmitted IR data on Te-particle distributions in as-grown CZT. A new mechanism of Te-particle genesis and spatial arrangement in CdTe and CZT is discussed in terms of a Rayleigh instability mechanism coupled with crystallographic SLI instabilities during growth. However, there are gaps in our capabilities at every length and time scale, plus gaps in building coarse-grained models from fine-scale models, in statistical representations of complex equilibria, and in understanding the complexities of solidification in ternary alloy systems where coupled thermal, concentration, stress, liquid flow, and SLI morphological fields exist. The talk concludes with an assessment of methods and approaches to address desired models and simulations of CZT solidification from the melt.

[1]This research was supported by the U.S. Department of Energy under Contract No. DE-AC05-76RL01830.

1:03PM U3.00004 First-principles Electronic Structure Calculations for Scintillation Phosphor Nuclear Detector Materials[1] , ANDREW CANNING, Lawrence Berkeley National Laboratory & UC Davis — Inorganic scintillation phosphors (scintillators) are extensively employed as radiation detector materials in many fields of applied and fundamental research such as medical imaging, high energy physics, astrophysics, oil exploration and nuclear materials detection for homeland security and other applications. The ideal scintillator for gamma ray detection must have exceptional performance in terms of stopping power, luminosity, proportionality, speed, and cost. Recently, trivalent lanthanide dopants such as Ce and Eu have received greater attention for fast and bright scintillators as the optical 5d to 4f transition is relatively fast. However, crystal growth and production costs remain challenging for these new materials so there is still a need for new higher performing scintillators that meet the needs of the different application areas. First principles calculations can provide a useful insight into the chemical and electronic properties of such materials and hence can aid in the search for better new scintillators. In the past there has been little first-principles work done on scintillator materials in part because it means modeling f electrons in lanthanides as well as complex excited state and scattering processes. In this talk I will give an overview of the scintillation process and show how first-principles calculations can be applied to such systems to gain a better understanding of the physics involved. I will also present work on a high-throughput first principles approach to select new scintillator materials for fabrication as well as present more detailed calculations to study trapping process etc. that can limit their brightness. This work in collaboration with experimental groups has lead to the discovery of some new bright scintillators.

[1]Work supported by the U.S. Department of Homeland Security and carried out under U.S. Department of Energy Contract no. DE-AC02-05CH11231 at Lawrence Berkeley National Laboratory.

1:39PM U3.00005 DFT Studies of Semiconductor and Scintillator Detection Materials , KOUSHIK BISWAS, Arkansas State University — Efficient radiation detection technology is dependent upon the development of new semiconductor and scintillator materials with advanced capabilities. First-principles based approaches can provide vital information about the structural, electrical, optical and defect properties that will help develop new materials. In addition to the predictive power of modern density functional methods, these techniques can be used to establish trends in properties that may lead to identifying new materials with optimum properties. We will discuss the properties of materials that are of current interest both in the field of scintillators and room temperature semiconductor detectors. In case of semiconductors, binary compounds such as TlBr, InI, CdTe and recently developed ternary chalcohalide Tl6SeI4 will be discussed. Tl6SeI4 mixes a halide (TlI) with a chalcogenide (Tl2Se), which results in an intermediate band gap (1.86 eV) between that of TlI (2.75 eV) and Tl2Se (0.6 eV). For scintillators, we will discuss the case of the elpasolite compounds whose rich chemical compositions should enable the fine-tuning of the band gap and band edges to achieve high light yield and fast scintillation response.

Thursday, March 21, 2013 11:15AM - 2:15PM –

Session U4 DCMP GQI: Invited Session: Quantum Reservoir Engineering and Feedback Ballroom IV - Steven Girvin, Yale University

11:15AM U4.00001 Cavity-assisted quantum bath engineering[1] , KATER MURCH, QNL, UC Berkeley — In practice, quantum systems are never completely isolated, but instead interact with degrees of freedom in the surrounding environment, eventually leading to decoherence. Precision measurement techniques such as nuclear magnetic resonance and interferometry, as well as envisioned quantum schemes for computation, simulation, and data encryption, rely on the ability to prepare and preserve delicate quantum superpositions and entanglement. The conventional route to long-lived quantum coherence involves minimizing coupling to a dissipative bath. Paradoxically, it is possible to instead engineer specific couplings to a quantum environment that allow dissipation to actually preserve coherence. I will discuss our recent demonstration of quantum bath engineering for a superconducting qubit coupled to a microwave cavity. By tailoring the spectrum of microwave photon shot noise in the cavity, we create a dissipative environment that autonomously relaxes the qubit to an arbitrarily specified coherent superposition of the ground and excited states. In the presence of background thermal excitations, this mechanism increases the state purity and effectively cools the dressed atom state to a low temperature. We envision that future multi-qubit implementations could enable the preparation of entangled many-body states suitable for quantum simulation and computation.

[1]This work was supported by the IARPA CSQ program.

11:51AM U4.00002 Quantum measurement in action[1] , MICHAEL HATRIDGE, Applied Physics, Yale University — A quantum system subject to the infinitely-strong measurement of textbook physics undergoes a discontinuous, random state collapse. However, in practice, measurements often involve a finite-strength, continuous process whose iteration leads to a projective evolution only asymptotically. Moreover, if the observation apparatus is fully efficient informationally, the measured system can remain at all times in a pure state. The stochastic evolution of this pure state is trackable from the measurement record. Thus, an initial superposition of states can be usefully transformed by a partial measurement rather than be entirely destroyed. This striking property has been demonstrated in superconducting qubit experiments in which readout is performed by a microwave signal sent through a cavity dispersively coupled to the qubit, and thereafter processed by an amplifier operating at the quantum limit. Such accurate monitoring of a qubit state is an essential prerequisite for measurement-based feedback control of quantum systems.

[1]Work supported by: IARPA, ARO and NSF.

12:27PM U4.00003 Quantum feedback control in superconducting qubits: Towards creating and stabilizing entanglement in remote qubits , RAJAMANI VIJAYARAGHAVAN, Tata Institute of Fundamental Research, Mumbai, India — Recent advances in superconducting parametric amplifiers have enabled quantum limited measurements of superconducting qubits, ushering in a new era of measurement based control using quantum feedback. Quantum entanglement is a key aspect of the measurement process. Measurement creates a pointer state which is entangled with the system being measured. Typically, one analyzes the pointer state which in turn determines the state of the original system. I will discuss experiments where we entangle the state of a 3D transmon qubit with a coherent microwave field (the pointer) using the circuit QED architecture. The use of parametric amplifiers to analyze the microwave field enables us to actually observe this entanglement and the resulting strong correlations between the states of the pointer and the qubit. We reconstruct quantum trajectories of the qubit state as it evolves during measurement and show that the final state of the qubit is consistent with the trajectories. Further, we use quantum feedback to actively steer the state of the qubit and demonstrate Rabi oscillations which persist indefinitely [1]. Finally, I will discuss how we can use the pointer states to generate entanglement between remote qubits and stabilize them using feedback. Applications to quantum computing and quantum error correction will also be discussed.

1:03PM U4.00004 Quantum Feedback for preparing and stabilizing photon number states of a field stored in a cavity , MICHEL BRUNE, Laboratoire Kastler Brossel, Paris — The stabilization of complex classical systems requires feedback. A sensor performs measurements of the system's state whose result is fed into a controller, which decides on an action bringing the system closer to a target state. Operating feedback for preparing and stabilizing against decoherence a quantum state is a promising tool for quantum control. It is however much more demanding than its classical counterpart, since a quantum measurement by the sensor changes the measured state. We present the first continuous operation of a closed feedback-loop for preparing and stabilizing photon number states of a microwave field stored in a high Q superconducting cavity. The field is probed by non-resonant Rydberg atoms performing a Quantum Non-Demolition photon counting. The feedback action consists either in the injection of a small coherent field pulse with a controlled amplitude and phase or in the emission and absorption of single photons with individual resonant atoms. The atomic measurement results are fed into a real-time controller, which performs an estimation of the field's state before deciding on the actuator action bringing it closer to the target. We stabilize number states up to 7. We discuss perspectives for the stabilization of mesoscopic quantum superpositions.

1:39PM U4.00005 Experimental quantum error correction with trapped ions , PHILIPP SCHINDLER, University of Innsbruck — The computational potential of a quantum information processor can only be utilized if errors occurring during a quantum computation can be controlled and corrected for. Quantum error correction protocols encode the quantum information of a single qubit in a larger register. Errors are then corrected by a quantum-feedback algorithm that is applied repeatedly. We encode a single logical qubit into three physical qubits and perform multiple rounds of error correction with the aid of high-fidelity gate operations and a reset technique for the auxiliary qubits. Furthermore we demonstrate that the same technique can be used to undo a quantum measurement. Full quantum error correction schemes are able to correct for arbitrary errors and enable universal quantum computation, but they require a significant overhead in the number of qubits. This prevents them to be useful for medium-scale systems used for quantum simulation. Therefore, we develop a quantum feedback scheme to reduce the dominant errors in an open-system quantum simulator. Our scheme requires only a single auxiliary qubit regardless of the system size.

Thursday, March 21, 2013 11:15AM - 2:15PM –

Session U5 DCMP: Graphene: Transport and Optical Phenomena: Mesoscopics and Harmonic Generation 301 - Chris Stanton, University of Florida

11:15AM U5.00001 Resonant inelastic transmission through a time-modulated region in graphene , LI CHANG, T. L. LIU, C. S. CHU, Department of Electrophysics, National Chaio Tung University — We investigate a number of resonant transmission processes through a time-modulated-potential region in graphene. Incident energies covering both low and high energy regimes are included, and the time-dependent transmission is treated within a tight-binding model. Three main results are obtained. Dip structures in the transmission are obtained when a band edge is involved. It can occur in the low energy regime, if the graphene is gapped, or in the high energy regime, when a graphene band edge is in the energy neighborhood. These dip structures cause significant deviation from Klein-type perfect transmission. Non-typical Fabry-Pérot interference is observed when, staying upon a dip structure condition, the transmission exhibits an oscillation that has a longer than expected period in L, the width of the time-modulated region. Central band refocusing is found in the low energy regime, where the dominance in the transmission by the central-band will occur periodically with L. In all these results, we have demonstrated and analyzed detail intricate resonant interplays between sideband processes.

11:27AM U5.00002 Charge transport across tunable superlattice barriers in graphene , SUDIPTA DUBEY, AJAY BHAT, VIBHOR SINGH, PRITESH PARIKH, TANUJ PRAKASH, ABHILASH SEBASTIAN, PADMALEKHA K.G., Tata Institute of Fundamental Research, Mumbai, India, KRISHNENDU SENGUPTA, Indian Association for the Cultivation of Sciences, Kolkata, India, VIKRAM TRIPATHI, RAJDEEP SENSARMA, MANDAR DESHMUKH, Tata Institute of Fundamental Research, Mumbai, India — We create an artificial superlattice structure in graphene using an array of top gate and a bottom gate. A superlattice potential modifies the band structure of graphene, so that extra Dirac points appear in the dispersion periodically as a function of the superlattice barrier height. Tuning the amplitude of the barrier thus gives us control over number of Dirac points generated. We have performed measurements on this superlattice structure. Oscillations in resistance are observed when the charge carrier induced by top gate and back gate are of opposite sign. In this region, the number of oscillations increases with increasing gate voltage. Measurements as a function of temperature show that these oscillations persist even at 70 K. The behaviour of these oscillations in presence of magnetic field is also observed. At low magnetic field we see weak localisation behaviour. At high magnetic field, the superlattice is a small perturbation and quantum Hall effect of pristine graphene is restored.

11:39AM U5.00003 Graphene under spatially varying external potentials: Landau levels, magnetotransport, and topological modes , SI WU, MATTHEW KILLI, ARUN PARAMEKANTI, Department of Physics, University of Toronto — Superlattices (SLs) in monolayer and bilayer graphene, formed by spatially periodic potential variations, lead to a modified bandstructure with extra finite-energy and zero-energy Dirac fermions with tunable anisotropic velocities. We theoretically show that transport in a weak perpendicular (orbital) magnetic field allows one to not only probe the number of emergent Dirac points but also yields further information about their dispersion. or monolayer graphene, we find that a moderate magnetic field can lead to a strong reversal of the transport anisotropy imposed by the SL potential, an effect which arises due to the SL induced dispersion of the zero energy Landau levels. This effect may find useful applications in switching or other devices. For bilayer graphene, we discuss the structure of Landau level wave functions and local density of states in the presence of a uniform bias, as well as in the presence of a kink in the bias which leads to topologically bound 'edge states'. We consider implications of these results for scanning tunneling spectroscopy measurements, valley filtering, and impurity induced breakdown of the quantum Hall effect in bilayer graphene.

11:51AM U5.00004 Confinement, transport gap, and valley polarization from a double barrier structure in graphene[1] , DANIEL GUNLYCKE, CARTER WHITE, Naval Research Laboratory — Engineering a gap in graphene without degrading its exceptional transport properties is arguably the main obstacle preventing a breakthrough in graphene-based nanoelectronics. To create such a gap, a lot of effort has been devoted to making graphene nanoribbons. Unlike ordinary nanoribbons, we propose a structure formed between two thin parallel transport barriers that is penetrable by electrons in surrounding graphene states. The transport across this railroad track structure is governed by resonant tunneling through quasi-bound states within the confinement. The transport barriers, modeled by chemically decorated line defects, are highly reflective, causing the resonances to form continuous bands closely matching the band structure of a zigzag ribbon. Because boundary-localized states cannot carry any transport, the resonance bands must terminate at the dimensional crossover between extended and boundary-localized states. As the confined region contains no states near the Fermi level extending across the railroad track structure, electrons approaching it experience a transport gap $E_g = 2\hbar v_F/W$, where W is the separation between the barriers. In addition to offering confinement and a transport gap, the structure allows for nearly perfect valley polarization.

12:03PM U5.00005 ABSTRACT WITHDRAWN –

12:15PM U5.00006 Transport Spectroscopy of gate controlled cavity in CVD bilayer graphene transistor , KYUNGHOON LEE, Department of Electrical Engineering and Computer Science, University of Michigan, YUN SUK EO, CAGLIYAN KURDAK, Randall Laboratory of Physics, University of Michigan, ZHAOHUI ZHONG, Department of Electrical Engineering and Computer Science, University of Michigan — Graphene nanostructure provides an ideal platform for understanding distinctive quantum transport properties such as Klein tunneling and suppression of backscattering due to its chiral nature. Quantum interference of phase coherent electron waves in single-layer graphene has attracted wide attention recently, while few experimental works examine the quantum transport of massive Dirac Fermion in bilayer graphene. To this end, we report the low temperature electrical transport spectroscopy of gate controlled cavity in CVD bilayer graphene transistor. Fabry-Perot like conductance oscillation was observed in both monopolar and bipolar bilayer graphene structures defined by electrostatic gating. Transport comparison between single-layer graphene and bilayer graphene will be also discussed.

12:27PM U5.00007 Tunable superconductivity in decorated graphene[1] , ZHENG HAN, ADRIEN ALLAIN, LAETITIA MARTY, NEDJMA BENDIAB, PIERRE TOULEMONDE, PIERRE STROBEL, JOHANN CORAUX, VINCENT BOUCHIAT, Neel Institute, CNRS-Grenoble, 38042 Grenoble, France — Graphene offers an exposed bidimensional gas of high mobility charge carriers with gate tunable density. Its chemical inertness offers an outstanding platform to explore exotic 2D superconductivity. Superconductivity can be induced in graphene by means of proximity effect (by depositing a set of superconducting metal clusters such as lead [1] or tin nanoparticles). The influence of decoration material, density or particles and disorder of graphene will be discussed. In the case of disordered graphene, Tin decoration leads to a gate-tunable superconducting-to-insulator quantum phase transition [2]. Superconductivity in graphene is also expected to occur under strong charge doping [3] (induced either by gating or under chemical decoration [4], in analogy with graphite intercalated compounds). I will also show preliminary results showing the influence of Calcium intercalation of few layer graphene and progress toward the demonstration of intrinsic superconductivity in such systems. [1] B. 12:39PM U5.00008 Electronic transport experiments on adatom-decorated graphene , E.A. HENRIKSEN, J.P. EISENSTEIN, California Institute of Technology — Single-layer graphene is expected to exhibit a wide range of novel behaviors when decorated with a disperse coating of various adatom species. Toward conducting experiments on these systems, we are developing a cryogenic ultra-high vacuum probe with the capability to explore the electronic transport of graphene and other materials that have been cleaned and annealed *in situ*, followed by coating via the controlled deposition of sub-monolayer coverages of a range of elements. We will report our progress on the fabrication of such thin layers, and on the characterization of surface-modified graphene devices. This work is supported by the DOE under grant No. DE-FG03-99ER45766 and the Gordon and Betty Moore Foundation.

12:51PM U5.00009 Quantum interference noise near the Dirac point in graphene[1] , NINA MARKOVIC, ATIKUR RAHMAN, JANICE WYNN GUIKEMA, Johns Hopkins University — We have studied low-frequency noise characteristics in single layer graphene, focusing specifically on the low-carrier density regime. We show that the 1/f noise at low temperatures is dominated by the time-dependent conductance fluctuations which occur due to quantum interference effects. Close to the Dirac point, the noise is reduced in magnetic field, but the relative noise reduction is larger than what might be expected based on the current theoretical understanding of quantum transport in graphene. The results reflect the inherent symmetry of the system and suggest the importance of additional degrees of freedom.

1:03PM U5.00010 Noise properties of graphene like systems[1] , AVINASH RUSTAGI, C.J. STANTON, University of Florida — The unusual electronic properties of graphene and its potential for applications in nanoscale devices motivated us to study the noise properties of materials that have a graphene-like electronic dispersion. For high values of electric field, we find interesting behavior in the noise properties which appear due to hot electron effects. We study the low-frequency noise based on the Boltzmann-Green function method within the relaxation time approximation considering an inelastic scattering term coming from phonon scattering and an elastic scattering term coming from impurity scattering. The steady-state distribution function is evaluated to calculate the average behavior of physical observables like current and energy. We find that as the field strength is increased, the noise *decreases* from the thermal noise value. We have also studied these properties for electronic dispersion with a gap parameter introduced in the Dirac spectrum. The inclusion of gap in the electronic dispersion causes initial heating of the electrons resulting in an increase in noise for intermediate values of field before it decreases at high fields.

1:15PM U5.00011 Third harmonic generation in graphene , NARDEEP KUMAR, JATINDER KUMAR, CHRIS GERSTENKORN, Department of Physics and Astronomy, The University of Kansas, RUI WANG, Department of Physics and Astronomy, The University of Kansas; Laboratory for Photonics and Quantum Electronics, University of Iowa, HSIN-YING CHIU, Department of Physics and Astronomy, The University of Kansas, ARTHUR SMIRL, Laboratory for Photonics and Quantum Electronics, University of Iowa, HUI ZHAO, Department of Physics and Astronomy, The University of Kansas — We report the measurement of optical third harmonic generation from single-layer graphene and few-layer graphite flakes produced by exfoliation. In the measurements, femtosecond near-infrared laser pulses were used to irradiate the samples. The emission observed scales with the cube of the intensity of the incident near-infrared pulse and with one third of the incident wavelength - both are clear evidences of third harmonic generation. We deduced an effective third-order susceptibility for single layer graphene to be on the order of 10^{-16} m^2/V^2. By measuring a set of flakes with different numbers of atomic layers, we found that for a few layers, the emission scales with the square of the number of atomic layers.

1:27PM U5.00012 Second Harmonic Generation in a Graphe Armchair Nanoribbon , GODFREY GUMBS, YONATAN ABRANYOS, Hunter College of CUNY — The second order nonlinear optical susceptibility $\chi^{(2)}$ for second harmonic generation is calculated for the 11H transition of a graded double quantum well (DQW) structure of undoped-$GaAs/Al_xGa_{1-x}As$. These results are compared with the single quantum well (QW). Our results show that the values of $\chi^{(2)}$ have optimal magnitudes dependent on the width, depth and separation between the QWs in a DQW structure. When the electric field increases, the dipole moment increases due to the increasing separation between the electron and hole wave functions. On the other hand, the oscillator strength of the 11H transition is reduced as a result of the decrease in the overlap of the electron and hole envelope functions. These two competing factors give rise to optimal conditions for the enhancement of the second order nonlinear susceptibility $\chi^{(2)}$. It is demonstrated that $\chi^{(2)}$ for the DQW structure is more enhanced than for the biased single QW.

1:39PM U5.00013 Optical Third-Harmonic Microscopy of Graphene[1] , JERRY I. DADAP, SUNG-YOUNG HONG, NICHOLAS W. PETRONE, PO-CHUN YEH, JAMES C. HONE, RICHARD M. OSGOOD, JR, Columbia University, New York, NY — We report strong third-harmonic (TH) generation in monolayer graphene mounted on an amorphous silica substrate using a photon energy that is three-photon resonant with the exciton-shifted van Hove singularity at the M-point of graphene. Our polarization-dependent and azimuthal rotation measurements confirm the expected isotropic symmetry properties for the TH nonlinear optical process in graphene. Since this monolayer graphene TH signal exceeds that of bulk glass by more than two orders of magnitude, the signal contrast permits background-free scanning of graphene and provides structural information that is difficult to obtain via linear optical microscopy. We also discuss the dependence of TH signals on the number of graphene layers and compare the graphene signal strength with that from crystalline Au(111) sample.

1:51PM U5.00014 Tunable THz Metamaterial Coupled to Graphene , TSUNG-TA TANG, SUFEI SHI, LONG JU, UC Berkeley, FENG WANG, UC Berkeley and Lawrence Berkeley National Laboratory — Metamaterial is a periodic sub-wavelength dielectric structure which can be tailored to have a strong resonance at particular frequencies. However, changing the electromagnetic response of metamaterial often involves changing the design. On the other hand, graphene is an atomic layer of carbon atoms arranged in honeycomb structure and its conductivity in THz regime is highly tunable by changing the Fermi energy of graphene. In our study, we couple graphene to a THz metamaterial device efficiently and demonstrate that the resonance of THz metamaterial can be changed over a wide range by controlling the conductivity of graphene. This graphene-THz metamaterial hybrid device can be used for future THz application such as THz modulator, which can be controlled electrostatically.

2:03PM U5.00015 Tunable plasmonic resonators in Graphene with extreme light confinement[1] , VICTOR BRAR, MIN SEOK JANG, JOSUE LOPEZ, HARRY ATWATER, Caltech, APPLIED PHYSICS -CALTECH TEAM — Graphene plasmons can display a number of interesting properties including small mode volumes, long lifetimes and energies that vary with the sheet charge density. In this work we investigate both experimentally and theoretically the behavior of graphene plasmons in the Mid-IR regime. We find that graphene monolayers that have been patterned with features from 30-100nm can support gate-tunable resonances across the Mid-IR, from 10-5um with charge densities up to 10^{12} e/cm^2. In our extreme limit, we observe that 30nm sized features cut in graphene can support plasmon resonances for light at 6um wavelengths, indicating mode volumes that are $\sim 10^6$ smaller than free space. We further show that these graphene plasmons can couple to phonon polaritons in the supporting dielectric substrate to create multiple new resonances at wavelengths near 10um. These results are analyzed in terms of both analytical calculations and finite element models.

Session U6 DCMP: Focus Session: Graphene - Intercalation, Doping, Characterization 302 - Mark Hybersten, Brookhaven National Laboratory

11:15AM U6.00001 Analysis of the intercalation of oxygen at the Ru(0001)-Graphene interface[1] , DANIEL TORRES, MARK HYBERTSEN, Brookhaven National Laboratory — The process whereby oxygen intercalates at the Ru(0001)-Graphene interface, resulting in systematic electronic decoupling of the graphene layer from the metallic substrate, depends on the interplay between graphene adhesion on the surface and the oxygen adsorption energy. We use density functional theory based calculations, including the effect of van der Waals interaction, to compare the energetics of competing phases in this process. We report three key findings. First, the van der Waals interaction makes a significant contribution to the binding of graphene to Ru(0001). Second, we assess the thermodynamic driving force between uniform oxygen phases on the clean surface and those intercalated at the interface. Third, we consider a series of local 1x1 oxygen patches centered on the raised region of the Ru(0001)-Graphene moiré which illustrate a series of stages in the decoupling of graphene from the Ru(0001) surface.

11:27AM U6.00002 Optical conductivity in bromine-intercalated graphite , ZAHRA NASROLLAHI, SIMA SAEIDI VARNOOSFADERANI, Physics department, University of Florida, Gainesville, Florida, SEFAATTIN TONGAY, Department of Material Science and engineering, University of California, Berkeley, California, ARTHUR F. HEBARD, DAVID B. TANNER, Physics department, University of Florida, Gainesville, Florida — Graphite intercalation compounds have a long and interesting history, with surprising thermal, electrical, and magnetic properties. In this study highly oriented pyrolytic graphite (HOPG) samples were exposed to bromine vapor for times between 20 and 100 minutes. The reflectance was measured using FTIR spectrophotometer, in the far and mid infrared at temperatures between 10 K and 300 K. With increasing the bromination time the reflectance in infrared region increases significantly, that gives rise to the increase of optical conductivity of the material calculated by Kramers-Kronig technique. The variation of scattering rate and charge carrier density in different temperatures for different intercalation times can lead to better understanding of the drastic enhancement of electrical conductivity in the material.

11:39AM U6.00003 Rb-intercalated bilayer graphene studied by high-resolution ARPES , JAMES KLEEMAN, Dept. of Physics, Tohoku University, KATSUAKI SUGAWARA, WPI-AIMR Tohoku University, TAKAFUMI SATO, Dept. of Physics, Tohoku University, TAKASHI TAKAHASHI, Dept. of Physics, Tohoku University; WPI-AIMR Tohoku University — To elucidate the electronic structure at the thinnest limit of the graphite intercalation compound (GIC) C_8Rb, we have performed high-resolution angle-resolved photoemission spectroscopy (ARPES) and low-energy electron diffraction (LEED) on Rb-intercalated bilayer graphene fabricated by in-situ evaporation of Rb atoms onto graphene grown epitaxially on SiC. Using LEED, the creation of an intercalated layer with in-plane geometry identical to bulk GICs was confirmed by the observation of a 2x2 spot pattern consistent with Rb intercalation. From ARPES measurement, we found that the Dirac point is at a binding energy of approximately 1 eV, compared to 0.4 eV in pristine epitaxial graphene on SiC [1]. The Fermi surface of this material was also measured. The critical differences between C_8Rb, its sister compound C_8K, and pristine bilayer graphene will be examined herein.

11:51AM U6.00004 First principles study of Stage-1 graphene intercalates, IBr and ICl[1] , PRIYAMVADA JADAUN, LEONARD F. REGISTER, SANJAY K. BANERJEE, The University of Texas at Austin — In this study we examine, from a first-principles approach, the properties of 2 graphene intercalant systems namely, iodine monochloride (ICl-GIC) and iodine monobromide (IBr-GIC). These materials are being explored as possible interlayer dielectric candidates for 2D-to 2D-tunnel FETs (TFETs) and Bilayer pseudospin FETs (BiSFETs). To do so we employ density functional theory (DFT). Both these intercalants are stage-1 and acceptor type. We first put forth a structural description of these compounds that intercalate 2 successive layers of graphene, stacked AA type as obtained upon relaxation. Subsequently we describe the electronic structure of ICl-GIC and IBr-GIC and use it to predict the device suitability of these intercalants. It is seen that adding a layer of these GIC's to a single layer of graphene does not disturb graphene electronic spectra except for opening a small gap and introducing doping. With the second graphene layer added, coupling between the graphene layers becomes evident through a small amount of band splitting.

12:03PM U6.00005 Charge Density Waves on the Graphene Sheets of the Heavily-Doped Superconductor Graphitic Intercalate CaC_6 , C.F. HIRJIBEHEDIN, K.C. RAHNEJAT, London Centre for Nanotechnology (LCN) and U. College London (UCL), UK, C.A. HOWARD, LCN, UCL, and Royal Holloway, U. of London, UK, N.E. SHUTTLEWORTH, S.R. SCHOFIELD, LCN and UCL, UK, K. IWAYA, Tohoku U., Japan, CH. RENNER, U. Geneva, Switzerland, G. AEPPLI, M. ELLERBY, LCN and UCL, UK — The electronic properties of graphitic materials can be readily tuned by adding charge carriers, and high levels of doping can even lead to superconductivity. We used scanning tunnelling microscopy to investigate the graphene-terminated surface of the superconducting graphitic material CaC_6 at temperatures well above T_c=11.5K [1]. We find two distinct surface types that show atomic resolution: one exhibits the expected structure of a graphene lattice superimposed on a hexagonal Ca superlattice while the other has stripes with a period three times that of the underlying Ca superlattice. A periodic distortion was found in the Ca atoms matching the periodicity of the electronic contrast on the graphene sheet, though no displacements of the carbon lattice were detected. Spectroscopic measurements reveal an energy gap in the electronic structure that can be directly associated with the stripe periodicity. This provides strong evidence that the stripes correspond to a charge density wave (CDW) in a graphitic system that also superconducts at lower temperatures, offering an excellent test bed for studying the relationship between these two important phenomena. [1] K.C. Rahnejat et al., Nat. Commun. 2, 558 (2011).

12:15PM U6.00006 Phonon-mediated superconductivity in graphene by lithium deposition , GIANNI PROFETA, Universitá dell'Aquila, MATTEO CALANDRA, FRANCESCO MAURI, CNRS et Université P. et M. Curie — Graphene is the physical realization of many fundamental concepts and phenomena in solid-state physics. However, in the list of graphene's many remarkable properties, superconductivity is notably absent. If it were possible to find a way to induce superconductivity, it could improve the performance and enable more efficient integration of a variety of promising device concepts. To this end, we explore, by first-principles DFT calculations, the possibility of inducing superconductivity in a graphene sheet by doping its surface with alkaline metal adatoms [1], in a manner analogous to which superconductivity is induced in graphite intercalated compounds (GICs). As for GICs, we find that the electrical characteristics of graphene are sensitive to the species of adatom used. However, unlike GICs, we find that lithium atoms should induce superconductivity in graphene at a higher temperature than calcium.

12:27PM U6.00007 Si on epitaxial graphene on SiC: intercalation and graphene-SiC transformation[1] , FENG WANG, KRISTIN SHEPPERD, Georgia Institute of Technology, ALEXEI ZAKHAROV, MAX-lab, EDWARD CONRAD, Georgia Institute of Technology — The interface between epitaxial graphene and bulk SiC plays a dominant role in both the growth and transport properties of graphene on SiC. The differences in diffusion of Si through graphene on the two polar SiC surfaces is related to the different nucleation of Si diffusion channels on the two graphene-SiC interfaces. In this work we use LEEM, XPEEM and XPS to study how the excess Si at the graphene-vacuum interface reorders itself at high temperatures. We show that silicon deposited at room temperature onto multilayer graphene films grown on the SiC($000\bar{1}$) surface rapidly diffuses to the graphene-SiC interface when heated to temperatures above 1020 °C. The Si that does intercalate into the interface can be removed back out to the graphene-vacuum boundary by heating the sample to 1200 °C. Most of the Si evaporates at this temperature, however, a significant amount of Si reacts with the graphene at the vacuum interface and form a relative stable reconstructed (2×2) SiC structure. At significantly higher Si concentrations, graphene at the vacuum interface transforms to SiC.

12:39PM U6.00008 Silicon Layer Intercalation and Interface Properties between Graphene and Metal hosts , YELIANG WANG, JINHAI MAO, LEI MENG, HONGJUN GAO, Institute of Physics, Chinese Academy of Sciences, JUNFENG HE COLLABORATION, SHIXUAN DU COLLABORATION, XINGJIANG ZHOU COLLABORATION, A. H. CASTRO NETO COLLABORATION[1] — Graphene is being considered as a contender as the reference material with extraordinary properties for a post-CMOS technology. The availability of high quality and large scale single crystal graphene is fundamental for it to fulfill its promise in electronic applications. Graphene is usually grown on a metallic substrate from which it has to be transferred before it can be used. However, uncontrolled shear and strain, associated with the transfer and the presence of extended domains, lead to unavoidable tearing, rendering it useless for scalable production. We propose a way to overcome this bottleneck and produce high quality, free standing graphene by intercalating Si in graphene epitaxially grown on metals, like Ru(0001) & Ir(111). This G/Si/metal architecture, produced by the silicon-layer intercalation approach (SIA), was characterized by STM/STS, Raman, and angle resolved electron photoemission spectroscopy (ARPES) and proves the high structural and electronic qualities of the new composite. The SIA eliminates the need for the graphene transfer and also allows for an atomic control of the distance between the graphene and the metal. References: 1. Jinhai Mao, Yeliang Wang, H.-J. Gao, et al., Appl. Phys. Lett. 100, 093101 (2012) (Cover). 2. Lei Meng, Yeliang Wang, H.-J. Gao, et al., Appl. Phys. Lett. 100, 083101 (2012).

12:51PM U6.00009 Na induced changes in the electronic band structure of graphene grown on C-face SiC , CHARIYA VIROJANADARA, CHAO XIA, LEIF JOHANSSON, Department of Physics, Chemistry and Biology, Linkoping University, SE-58183, Linkoping, Sweden — Studies of the effects induced on the electron band structure after Na deposition, and subsequent heating, on a C-face 2 MLs graphene sample will be presented. Na deposition shifts the Dirac point downwards from the Fermi level by about 0.5 eV due to electron doping. After heating at temperatures from around 120 to 300°C, the π-band appears considerably broadened. Collected Si 2p and Na 2p spectra then indicate Na intercalation in between the graphene layers and at the graphene SiC interface. The broadening is therefore interpreted to arise from the presence of two slightly shifted, but not clearly resolved, π-bands. Constant energy photoelectron distribution patterns, E(kx,ky);s , extracted from the clean 2MLs graphene C-face sample look very similar to earlier calculated distribution patterns for monolayer, but not Bernal stacked bi-layer, graphene. After Na deposition the patterns extracted at energies below the Dirac point appear very similar so the doping had no pronounced effect on the shape or intensity distribution. At energies above the Dirac point the extracted angular distribution patterns show the flipped, "mirrored," intensity distribution predicted for monolayer graphene at these energies. An additional weaker outer band is also discernable at energies above the Dirac point, which presumably is induced by the deposited Na.

1:03PM U6.00010 First-Principles Modeling of Low-Energy Electron Diffraction of Few Layer Graphene[1] , JOHN MCCLAIN, University of New Hampshire, JIEBING SUN, Michigan State University, JAMES HANNON, IBM Thomas J Watson Research Center, KARSTEN POHL, JIAN-MING TANG, University of New Hampshire — We present calculations of the low-energy electron microscopy (LEEM) spectra of few layer graphene (FLG) systems using our newly developed theoretical approach based on density-functional theory (DFT). The traditional analysis using multiple scattering off muffin-tin potentials is replaced with a Bloch wave matching approach using self-consistent potentials via DFT to better describe the LEEM spectra, especially in the low energy range. Our calculated results for free-standing FLG exhibit oscillations in reflectivity for energies between 0 and 7 eV, in good agreement with the experimental LEEM spectra of FLG observed on various substrates. The number of oscillations is correlated to the number of graphene layers, a fact often used to determine the number of graphene layers in a sample region. We have calculated FLG on Ni(111)-(1x1) and find that the FLG features dominate those of the bare Ni(111) when two graphene layers are added, as seen in experiments. Our results show that the valleys in the LEEM spectra due to graphene appear only with more than one graphene layer, consistent with our results for free-standing FLG.

[1]We acknowledge funding support from NSF DMR-1006863.

1:15PM U6.00011 Theory of low-energy electron reflectivity from graphene , RANDALL FEENSTRA, NISHTHA SRIVASTAVA, MICHAEL WIDOM, Dept. Physics, Carnegie Mellon University, Pittsburgh, PA, IVAN VLASSIOUK, Oak Ridge National Laboratory, P.O. Box 2008, Oak Ridge, TN — We have developed a self-consistent description of low-energy electron reflectivity spectra, yielding results that compare well with experimental data for graphene on SiC and on Cu substrates (obtained by our group as well as by other groups [1]). Our approach utilizes wavefunctions for a thin multilayer graphene slab, computed with a first-principles method. By combining wavefunctions for positive and negative wavevectors, we forms states with only outgoing character on one side of the slab, and hence deduce the electron reflectivity. For free-standing n-layer graphene, we obtain the reflectivity curves that show n-1 reflectivity minima over the energy range 0 - 10 eV. The minima are shown to arise from states with wavefunctions localized between the graphene layers (not on the layers, as previously suggested [1]). For graphene on a substrate, we match the states on one side of the graphene slab to bulk states of the substrate. For graphene on Cu(111) substrates, we find the same set of reflectivity minima as for free-standing graphene, together with an additional minimum whose location varies with the graphene-Cu separation. Hence, this separation can be deduced by comparing experimental and theoretical spectra. [1] H. Hibino et al., Phys. Rev. B 77, 075413 (2008).

1:27PM U6.00012 Bandgap opening in bilayer graphene via molecular doping[1] , DAVID CAREY, ALEXANDER SAMUELS, University of Surrey — We report the emergence of an electronic bandgap in bilayer graphene through the interaction with physisorbed molecules. The bandgap is found to scale linearly with induced carrier density though a slight asymmetry is found between n-type dopants where the bandgap varies as 47 meV/10^{13} cm^{-2} and p-type dopants where the bandgap varies as 38 meV/10^{13} cm^{-2}. The n-type dopant molecules include tetrathiafulvalene (TTF), cobaltocene and decamethylcobaltocene (DMC) and p-type dopant molecules include NO_2, 2,3-dichloro-5,6-dicyano-1,4-benzoquinone (DDQ) and 3,6-difluoro-2,5,7,7,8,8-hexacyano-quinodimethane (F2-HCNQ). Ammonia is found to be weak amphoteric dopant on bilayer graphene, as it is on single layer graphene, where the charge transfer depends on the orientation of the N atom relative to the upper graphene layer. The bandgap opening is explained in terms of the asymmetric charge distributions on the upper graphene layer which is in contact with the molecules. The high binding energy found upon adsorption of some of these molecules results in an attractive way to a permanent bandgap and when combined with a variable external electric field can either close the gap or widen it still further.

1:39PM U6.00013 Substrate Screening Effects in *ab initio* Many-body Green's Function Calculations of Doped Graphene on SiC[1] , DEREK VIGIL-FOWLER, JOHANNES LISCHNER, STEVEN LOUIE, University of California, Berkeley and Lawrence Berkeley National Lab — Understanding many-electron interaction effects and the influence of the substrate in graphene-on-substrate systems is of great theoretical and practical interest. Thus far, both model Hamiltonian and ab initio GW calculations for the quasiparticle properties of such systems have employed crude models for the effect of the substrate, often approximating the complicated substrate dielectric matrix by a single constant. We develop a method in which the spatially-dependent dielectric matrix of the substrate (e.g., SiC) is incorporated into that of doped graphene to obtain an accurate total dielectric matrix. We present ab initio GW + cumulant expansion calculations, showing that both the cumulant expansion (to include higher-order electron correlations) and a proper account of the substrate screening are needed to achieve agreement with features seen in ARPES. We discuss how this methodology could be used in other systems.

1:51PM U6.00014 Electronic Strengthening of Graphene by Charge Doping[1] , CHEN SI, Tsinghua University, University of Utah, ZHENG LIU, University of Utah, WENHUI DUAN, Tsinghua University, FENG LIU, University of Utah — Graphene is known as the strongest 2D material in nature, yet we show that moderate charge doping of either electrons or holes can further enhance its ideal strength by up to ~17%, based on first principles calculations. This unusual electronic enhancement, versus conventional structural enhancement, of material's strength is achieved by an intriguing physical mechanism of charge doping counteracting on strain induced enhancement of Kohn anomaly, which leads to an overall stiffening of zone boundary K_1 phonon mode whose softening under strain is responsible for graphene failure. Electrons and holes work in the same way due to the high electron-hole symmetry around the Dirac point of graphene, while over doping may weaken the graphene by softening other phonon modes. Our findings uncover another fascinating property of graphene with broad implications in graphene-based electromechanical devices.

[1]The work is support by DOE-BES program. C.S. thanks Tsinghua exchange student fund for supporting her visit at U. of Utah. W. D. thanks support by the Ministry of Science and Technology of China

2:03PM U6.00015 Incremental Tuning of Graphene's Fermi Level by Chemical Doping , KARA BERKE, University of Florida, SEFAATTIN TONGAY, University of California, Berkeley, ARTHUR HEBARD, University of Florida — We report a simple, scalable method for fine tuning the Fermi level of CVD-grown graphene, through controlled chemical doping by the addition of the polymer polyethyleneimine (PEI) to the graphene surface. Graphene samples initially showed p-type behavior before doping. By dropcasting a low concentration solution of PEI in methanol onto graphene, the hole concentration was lowered. Repeated applications to the same sample shift the Fermi level of the graphene through the Dirac point, yielding an increasingly n-type sample. The graphene mobility increases with each application of PEI solution due to charge screening effects. Additionally, the magnetoresistance becomes increasingly linear near the Dirac point, consistent with the existence of charge puddles in neutral graphene.

Thursday, March 21, 2013 11:15AM - 2:15PM –

Session U7 DMP: Focus Session: Carbon Nanotubes: Devices 303 - Junichiro Kono, Rice University

11:15AM U7.00001 Gate Modulation of Contacts in Carbon Nanotube Devices , FRANCOIS LEONARD, Sandia National Laboratories — As the size of electronic devices is reduced, the electrical contacts play an increasingly important role. This is particularly true for contacts to nanomaterials, where new contact phenomena are often observed. In this talk, I will discuss recent numerical simulations to analyze experimental measurements of short-channel carbon nanotube transistors. The results indicate a strong gate modulation of the contact properties, an effect that is distinct from that observed in Schottky barrier nanotube transistors. This modulation of the contacts by the gate allows for the realization of superior subthreshold swings and improved scaling behavior, as observed experimentally. These results further elucidate the behavior of carbon nanotube/metal contacts, and should be useful in the design and optimization of high performance carbon nanotube electronics.

11:51AM U7.00002 Floating Electrode Transistor based on Single-walled Carbon Nanotube Networks for High Source–drain Voltage Operation , JEONGSU KIM, JUHYUNG LEE, HYUNGWOO LEE, TAEKYEONG KIM, HYE JUN JIN, JUYEON SHIN, Department of Physics and Astronomy, Seoul National University, YOUNGKI SHIN, SANGHO PARK, YOONHO KHANG, Process Development Group, Samsung Electronics Co, SEUNGHUN HONG, Department of Physics and Astronomy, Seoul National University — Thin film transistors (TFTs) based on single-walled carbon nanotubes (swCNTs) were reported to exhibit extraordinary characteristics in terms of their conductivity, transparency and flexibility. However, until now, most studies have focused on CNT-TFTs for an operation at a relatively low source–drain voltage below $\sim$ 10 V, while, for some applications such as LCD displays, one needs a rather high source–drain bias voltage. However, such a high voltage bias on source and drain electrodes may reduce the gating effect of conventional CNT-TFT devices by lowering the Schottky barrier and degrade its overall device performance. Herein, we developed floating electrode thin-film transistors (F-TFTs) based on semiconducting swCNT networks for a high source-drain voltage operation. In this device structure, the swCNT network channel was divided into a number of channels connected by floating metallic electrodes. At a high source-drain voltage, the F-TFTs showed a much higher on–off ratio than conventional swCNT-TFTs. This work should provide an important guideline in designing CNT-TFTs for high voltage applications.

12:03PM U7.00003 High Bias Characteristics of Individual, Suspended Carbon Nanotube p-n Junction Photodiodes , SHUN-WEN CHANG, University of Southern California, KEVIN BERGEMANN, University of Michigan, ROHAN DHALL, University of Southern California, JERAMY ZIMMERMAN, STEPHEN FORREST, University of Michigan, STEPHEN CRONIN, University of Southern California — We have recently investigated p-n junction diodes formed by electrostatic doping of individual, suspended, single-walled carbon nanotubes (CNTs) using two gate electrodes positioned beneath a free standing nanotube that bridges source and drain electrodes. The electrostatic field imposed by the two gates polarizes the nanotube along its length, thereby allowing independent control of the "doping" in the nanotube without introducing impurities or defect states. These pn-devices exhibit rectifying diode behavior and finite photoresponse under illumination. Several interesting phenomena are observed at high bias that arise from Schottky contacts formed between the nanotube and its metal contact electrodes and electron tunneling between the n- and p-doped regions. A model is developed explaining this behavior showing evidence for plasmon-induced band gap shrinkage with electrostatic doping.

12:15PM U7.00004 ABSTRACT WITHDRAWN –

12:27PM U7.00005 Transport Study of Carbon Nanotube Networks with Different Ratios of Semiconducting and Metallic Nanotubes , XUAN WANG, ERIK HÁROZ, QI ZHANG, JUNICHIRO KONO, Rice University — An important goal of current nanotechnology research is to obtain a quantitative understanding of how electrons drift and tunnel through junctions of nanostructures and how the overall electrical conductivity of networks of nanostructures is determined. Here, we present a comprehensive study of DC transport properties of macroscopic single-wall carbon nanotube (SWCNT) networks with different ratios of metallic and semiconducting nanotubes. The temperature-dependent resistivity shows that when the length of SWCNT is orders of magnitude smaller than the dimensions of the network, the resistance mainly comes from inter-tube junctions. However, the transport mechanism changes from fluctuation-induced tunneling in metallic-enriched networks to variable range hopping in semiconductor-enriched networks. The magneto resistance (MR) of these two networks also show distinct features. In a metallic enriched network, MR is negative up to 10 Tesla below 70 K which can be explained based on weak localization theory. One the other hand, in a semiconductor-enriched network, MR is mostly positive up to 10 Tesla below 10 K, which can be explained based on the shrinking of electron wave function due to the magnetic field.

12:39PM U7.00006 Electronic durability of flexible transparent coatings from type-specific single-wall carbon nanotubes , JOHN M. HARRIS, MATTHEW R. SEMLER, NDSU, JEFFREY A. FAGAN, NIST, ERIK K. HOBBIE, NDSU — The coupling between mechanical flexibility and electronic performance is evaluated for thin flexible coatings of metallic and semiconducting single-wall carbon nanotubes (SWCNTs) deposited on compliant polymer supports. The microstructure, transparency, and electronic properties of the films are independently characterized using a variety of techniques. Cyclic compression experiments suggest that thin films made from metallic SWCNTs show better durability as flexible transparent conductive coatings, which we attribute to a combination of superior mechanical performance and higher interfacial conductivity. We model the role of van der Waals forces in the strain response of the films.

12:51PM U7.00007 High-frequency performance of scaled carbon nanotube array field-effect transistors , RALPH KRUPKE, Karlsruhe Institute of Technology, MATHIAS STEINER, IBM Thomas J. Watson Research Center, MICHAEL ENGEL, Karlsruhe Institute of Technology, YU-MING LIN, YANGING WU, KEITH JENKINS, DAMON FARMER, IBM Thomas J. Watson Research Center, JEFFORD HUMES, NATHAN YODER, Nanointegris Inc., JUNG-WOO SEO, ALEXANDER GREEN, MARK HERSAM, Northwestern University, PHAEDON AVOURIS, IBM Thomas J. Watson Research Center — We report the radio-frequency performance of carbon nanotube array transistors that have been realized through the aligned assembly of highly separated, semiconducting carbon nanotubes on a fully scalable device platform. At a gate length of 100 nm, we observe output current saturation and obtain as-measured, extrinsic current gain and power gain cut-off frequencies, respectively, of 7 GHz and 15GHz. While the extrinsic current gain is comparable to the state-of-the-art, the extrinsic power gain is improved. The de-embedded, intrinsic current gain and power gain cut-off frequencies of 153 GHz and 30 GHz are the highest values experimentally achieved to date. We analyze the consistency of DC and AC performance parameters and discuss the requirements for future applications of carbon nanotube array transistors in high-frequency electronics.

1:03PM U7.00008 Fabrication and Characterization of Self-Aligned T-gate High-Purity Semiconducting Carbon Nanotube RF Transistors , YUCHI CHE, ALEXANDER BADMAEV, PYOJAE KIM, University of Southern California, ALBORZ JOOYAIE, University of California, Los Angeles, CHONGWU ZHOU, University of Southern California, CHONGWU ZHOU'S NANOLAB TEAM — We applied the scalable self-aligned T-shaped gate design to semiconducting nanotube RF transistors. In this way, the channel length can be scaled down to 140 nm which enables quasi ballistic transport, and the gate dielectric is reduced to 2-3 nm aluminum oxide, leading to quasi quantum capacitance operation. As a result, our nanotube transistors exhibit excellent on-chip device performance and high linearity with channel length scaling down to 140 nm. With T-shaped gate structure, a cut-off frequency up to 22 GHz and power gain frequency of 10 GHz for separated nanotube transistor are achieved. The T-shaped gate design enables high-yield wafer-scale fabrication with controllable gate length scaling. Furthermore, we also characterized the linearity properties of nanotube transistors, with the 1-dB compression point measurement, in source/load pull setup, with positive power gain to our knowledge, for the first time. Above all, our work reveals that the semiconducting nanotube RF transistor is an interesting and promising direction in high frequency device and circuit exploration.

1:15PM U7.00009 Carbon Nanotube Thin Film Transistors Using Carbon Nanotube Electrodes , NARAE KANG, BIDDUT K. SARKER, SAIFUL I. KHONDAKER, Nanoscience Technology Center and Department of Physics, University of Central Florida — Carbon nanotubes (CNTs) have attracted a significant attention in recent years due to their exceptional electronics, optical and mechanical properties. In particular, CNT thin film transistors (TFTs) are considered as promising active components in the next-generation flexible, transparent, and invisible electronics. Due to lack of transparency and flexibility, metal electrodes are not suitable for CNT TFTs in their transparent and flexible electronic applications. In this talk, we will discuss the high-performance CNT TFTs where densely aligned array of metallic single walled carbon nanotubes (SWNTs) were used as source and drain electrodes while semiconducting enriched aligned SWNTs (s-SWNT) were used as a channel material. The both metallic SWNTs in the electrodes and s-SWNTs in the channel are aligned via dielectrophoresis using a high quality surfactant-free solution. We show that the performance of the s-SWNT devices with metallic SWNT electrodes is significantly improved than that of the devices with Pd electrodes. In order to find the information about injection barrier between s-SWNT and metallic SWNT interface, we carry out low temperature electron transport measurement of our devices. We will discuss the detailed analysis of the low temperature data.

1:27PM U7.00010 Dipole induced conductance modulation in chromophore-functionalized single-walled carbon nanotubes , YUANCHUN ZHAO, Department of Physics, University of Wisconsin-Madison, Madison, Wisconsin 53706, CHANGSHUI HUANG, MYUNGWOONG KIM, PADMA GOPALAN, Department of Materials Science and Engineering, University of Wisconsin-Madison, Madison, Wisconsin 53706, MARK ERIKSSON, Department of Physics, University of Wisconsin-Madison, Madison, Wisconsin 53706 — Single-walled carbon nanotubes (SWNTs) are highly sensitive to local electrostatic environments, making SWNT field-effect transistors (FETs) of interest for a number of sensor applications and optoelectronic devices. Here we demonstrate a direct correlation between the conduction of SWNTs and their surrounding dipolar environments. We use azobenzene-based dipolar chromophores, Disperse Red 1 (DR1) and its derivatives to functionalize the sidewalls of SWNTs. The chromophores are coupled with a pyrenebutyric group for realizing noncovalent attachment and to attempt to direct their dipole moments. The functionalizing chromophores produce a dipole field that shifts the threshold voltage (Vth) of the nanotube FET. Under light illumination, these molecules isomerize from the ground trans state to the excited cis state, leading to a decrease of their dipole moments. This dipole moment change acts as an additional gate, causing a shift in Vth. Our results provide a new insight into the photogating mechanisms of the nanotube-chromophore hybrid devices, and they reveal the possibility to modulate optoelectronic properties of nanotube-hybrid devices by designing chromophores with required photosensitive features.

1:39PM U7.00011 Working cycles of devices based on bistable carbon nanotubes , OLEG SHKLYAEV, ERIC MOCKENSTURM, VINCENT CRESPI, Penn State University, CARBON NANOTUBES COLLABORATION — Shape-changing nanotubes are an example of variable-shape sp2 carbon-based systems where the competition between strain and surface energies can be moderated by an externally controllable stimuli such as applied voltage, temperature, or pressure of gas encapsulated inside the tube. Using any of these stimuli one can transition a bistable carbon nanotube between the collapsed and inflated states and thus perform mechanical work. During the working cycle of such a device, energy from an electric or heat source is transferred to mechanical energy. Combinations of these stimuli allow the system to convert energy between different sources using the bistable shape-changing tube as a mediator. For example, coupling a bistable carbon nanotube to the heat and charge reservoirs can enable energy transfer between heat and electric forms. The developed theory can be extended to other nano-systems which change configurations in response to external stimuli.

1:51PM U7.00012 Targeted Placement of Gold Nanoparticles on SWCNT Transistors Using Electrodeposition , YIAN LIU, PAOLA BARBARA, MAKARAND PARANJAPE, Department of Physics, Georgetown University, Washington, D.C. 20057, USA — We present a simple in-situ electrochemical method to target the deposition of gold and other metallic nanoparticles along a single-walled carbon nanotube (SWCNT) field effect transistor (CNTFET). The transistors, fabricated on SiO_2/Si substrates, are passivated by a thin layer of poly(methylmethacrylate), or PMMA. Areas of the PMMA along the carbon nanotube are exposed using electron-beam lithography to target the locations where Au nanoparticles need to be placed. An appropriate potential difference is applied between an in-situ sacrificial gold electrode and the SWCNT, all immersed under a droplet of electrolyte solution. By adjusting the applied voltage and time of deposition, the size of the Au nanoparticle can be controlled from 10 nm to over 100 nm. This method provides better control and is much easier to carry out compared to other site-specific deposition techniques. Such decorated Au nanoparticle/CNTFET heterostructures will allow for a better understanding of single-electron transport behavior, as well as finding application in site-specific biomolecule anchoring for the development of highly sensitive and selective biosensors.

2:03PM U7.00013 Band Gap Modification in Metallic Nanotubes Due to Nanotube-Substrate Interaction , MOH AMER, University of Southern California, ADAM BUSHMAKER, The Aerospace Corporation, STEVE CRONIN, University of Southern California — Previous work shows that a small band gap exists in metallic nanotubes. Here we give a detailed comparison between ultra-clean suspended and on-substrate carbon nanotubes (CNTs) in order to quantify the effect of the substrate on the effective band gap of quasi-metallic nanotubes [1]. Individual CNTs are grown across two sets of electrodes, resulting in one segment of the nanotube that is suspended across a trench and the other segment supported on the substrate. A significant change in the conductance of the suspended segment is observed ($\Delta G/G$ =0.84) with applied gate voltage. This change is attributed to the existence of the small band gap. The on-substrate segment, however, only shows a change in the measured conductance of $\Delta G/G$ =0.11.We used a Landauer model to extract the band gap of these devices. From these fits, the band gaps in the suspended region range from 75 to 100 meV, but are only 5-14.3 meV when the nanotube is in contact with the substrate. The decreased band gap is attributed to localized doping caused by trapped charges in the substrate that result in inhomogeneous broadening of the Fermi energy, which in turn limits our ability to modulate the conductance.

Thursday, March 21, 2013 11:15AM - 2:03PM –

Session U8 DMP: Focus Session: Scanning Tunneling Microscopy of Graphene 307 - Eva Andrei, Rutgers University

11:15AM U8.00001 Defect engineering of graphene , LIN HE, Department of physics, Beijing Normal University — One of the most fascinating aspects of graphene is that its topological features of the electronic states can be fundamentally changed by modifying its local lattice structure. In this talk, I will show how to tune the electronic structures of graphene by defect engineering: (1) we observed superlattice Dirac points and space-dependent Fermi velocity in a corrugated graphene monolayer; (2) we reported angle dependent van Hove singularities (VHSs) of slightly twisted graphene bilayer; (3) we studied the evolution of local electronic properties of twisted graphene bilayer induced by a strain; The strain results in pseudo-Landau levels, which mimic the quantization of massive Dirac fermions in a magnetic field of about 100 T, and valley polarization along a strained graphene wrinkle.

11:51AM U8.00002 Probing Interactions between Graphene and Cu(111) Surface State , LIUYAN ZHAO, Physics Department, Columbia University, SCOTT GONCHER, GEORGE FLYNN, Chemistry Department, Columbia University, ABHAY PASUPATHY, Physics Department, Columbia University, PHYSICS DEPARTMENT COLUMBIA UNIVERSITY COLLABORATION, CHEMISTRY DEPARTMENT COLUMBIA UNIVERSITY COLLABORATION — Monolayer graphene and the surface state of Cu(111) are both examples of two-dimensional electronic states. The quasiparticles in monolayer graphene behave as massless Dirac fermions, whereas the ones in the Cu(111) surface state obey the non-relativistic Schrodinger equation. What is the nature of the interactions when these two states are coupled electronically? We probe these interactions using Scanning Tunneling Microscopy/Spectroscopy (STM/S) to investigate how the Cu(111) surface state has been modified with monolayer graphene overlaid on it. In this presentation, we will show that graphene decreases the band width of the Cu(111) surface state and renormalizes the effective mass of the quasiparticles in the Cu(111) surface state. Further, we will show that the modification of the Cu(111) surface state is independent of the registry between Cu(111) and the graphene crystalline orientations.

12:03PM U8.00003 Visualizing the influence of an isolated Coulomb impurity on the Landau level spectrum in graphene using scanning tunneling microscopy[1] , ADINA LUICAN-MAYER, Argonne National Laboratory, MAXIM KHARITONOV, GUOHONG LI, CHIHPIN LU, IVAN SKACHKO, ALEM-MAR GONCALVES, EVA Y. ANDREI, Department of Physics and Astronomy, Rutgers University — Charged impurities play a crucial role in determining the electronic properties of graphene. We report on experiments that elucidate the effect of an isolated charged impurity on the electronic spectrum of graphene in a magnetic field. Using scanning tunneling microscopy and gated graphene devices, we follow the evolution of quantized Landau levels with carrier density and find that the apparent strength of the impurity is controlled by the partial filling of the Landau levels. At low filling the impurity is cloaked and becomes essentially invisible. The cloaking effect diminishes with filling until, for fully occupied Landau levels, the impurity reaches its maximum strength causing a significant perturbation in the local density of states. In this regime we report the first observation of Landau level splitting due to lifting of the orbital degeneracy.

12:15PM U8.00004 STM/STS study of graphene directly grown on h-BN films on Cu foils , WON-JUN JANG, Department of Physics, Korea University, MIN WANG, SEONG-GYU JANG, MINWOO KIM, SKKU Advanced Institute of Nanotechnology, SEONG-YONG PARK, Graphene Research Center, Samsung Advanced Institute of Technology, SANG-WOO KIM, SKKU Advanced Institute of Nanotechnology, SE-JONG KAHNG, Department of Physics, Korea University, JAE-YOUNG CHOI, Graphene Research Center, Samsung Advanced Institute of Technology, YOUNG JAE SONG[1], SUNGJOO LEE[2], SKKU Advanced Institute of Nanotechnology, SANIT COLLABORATION, DEPARTMENT OF PHYSICS, KOREA UNIVERSITY COLLABORATION, GRAPHENE RESEARCH CENTER, SAMSUNG ADVANCED INSTITUTE OF TECHNOLOGY COLLABORATION — Graphene-based devices on standard SiO2 substrate commonly exhibit inferior characteristics relative to the expected intrinsic properties of graphene, due to the disorder existing at graphene-SiO2 interface. Recently, it has been shown that exfoliated and chemical vapor deposition (CVD) graphene transferred onto hexagonal boron nitride (h-BN) possesses significantly reduced charge inhomogeneity, and yields improved device performance. Here we report the scanning tunneling microscopy (STM) and spectroscopy (STS) results obtained from a graphene layer directly grown on h-BN insulating films on Cu foils. STS measurements illustrate that graphene/h-BN film is charge neutral without electronic perturbation from h-BN/Cu substrate.

12:27PM U8.00005 Kondo quantum criticality in graphene[1] , JINHAI MAO, IVAN SKACHKO, GUOHONG LI, EVA ANDREI, Department of Physics and Astronomy, Rutgers University, Piscataway, New Jersey 08855, USA, DEPARTMENT OF PHYSICS AND ASTRONOMY, RUTGERS UNIVERSITY, PISCATAWAY, NEW JERSEY 08855, USA TEAM — The Kondo effect, observed in the presence of coupling between a local magnetic moment and spin degenerate conduction electrons, is a hallmark of the electronic transport in conventional metallic systems. Screening of the local moment gives rise at low temperatures to characteristic signatures in the density of states and electronic spectral function such as the Kondo resonance. Graphene a strictly two dimensional system with carriers whose electronic properties mimic massless Dirac fermions provides a new paradigm for studying interactions in a system where the density of states is linear and can be made vanishingly small by gating, rather than being constant as is the case in standard metallic systems. We study the effect of interactions between the ultra-relativistic electrons in graphene and local magnetic moments introduced by point vacancies in the honeycomb lattice of graphene. Using scanning tunneling spectroscopy and transport measurements we measure the Kondo quantum critical transition and its dependence on carrier density.

12:39PM U8.00006 Structure and magnetism of cobalt intercalated graphene/Ir(111) via spin-polarized STM , REGIS DECKER, JENS BREDE, Institute of Applied Physics, University of Hamburg, NICOLAE ATODIRESEI, VASILE CACIUC, STEFAN BLUEGEL, Institut für Festkörperforschung, Forschungszentrum Jülich, ROLAND WIESENDANGER, Institute of Applied Physics, University of Hamburg — The presence of intercalation compounds in graphite, i.e. impurities or layer(s) trapped between carbon sheets, can lead to changes in the transport, optical and catalytic properties compared to bulk graphite, or even superconductivity. Here, we present the local structure and magnetic properties of graphene on a magnetic substrate, resolved by spin-polarized STM. The magnetic substrate is obtained by the intercalation of a cobalt layer between graphene and an Ir(111) surface. The atomic structure of the graphene layer is dominated by a highly corrugated Moiré pattern, which arises due to the incommensurability and/or twisting angle of the graphene lattice and the Co/Ir(111) surface. Within the Moiré unit cell three different regions, i.e. top, fcc, and hcp regions are identified. Interestingly, these regions show very different electronic and magnetic signatures in the experiments, defining an atomic-scale magnetic Moiré pattern. The observed spin polarization is compared to density functional theory calculations. The calculations reveal that the bonding between the graphene layer and intercalated Co layer varies from weak to strong within the Moiré unit cell. Moreover, the interaction between the graphene and the intercalated cobalt layer leads to a spin dependent charge rearrangement, which induces magnetism in graphene as observed in experiment.

12:51PM U8.00007 STM/STS studies of Ca-intercalated bilayer graphene , RYOTA SHIMIZU, KATSUAKI SUGAWARA, Advanced Institute for Materials Research (WPI-AIMR), Tohoku University, KOHEI KANETANI, Department of Physics, Tohoku University, KATSUYA IWAYA, Advanced Institute for Materials Research (WPI-AIMR), Tohoku University, TAKAFUMI SATO, Department of Physics, Tohoku University, TAKASHI TAKAHASHI, Advanced Institute for Materials Research (WPI-AIMR), Tohoku University; Department of Physics, Tohoku University, TARO HITOSUGI, Advanced Institute for Materials Research (WPI-AIMR), Tohoku University — We have performed low temperature scanning tunneling microscopy/spectroscopy (STM/STS) measurements on a two-dimensional Ca-intercalated bilayer graphene epitaxially grown on a 6H-SiC(0001) substrate. The STM topographic images clearly resolve each intercalated Ca atom with graphene-based honeycomb lattice. Furthermore, we found a clear $\times 2.5$ modulation in the topography, implying charge density wave or Moiré pattern originated from the interaction with the SiC substrate. Comparison with ARPES measurements provided us of further insight into the Fermi surface deduced from STS.

1:03PM U8.00008 Observing Atomic Collapse in Graphene , YANG WANG, DILLON WONG, Physics Dept. UC Berkeley, LBNL, ANDREY SHYTOV, Shool of Physics, Univ. of Exeter, VICTOR BRAR, Physics Dept. UC Berkeley, LBNL, SANGKOOK CHOI, Physics Dept. UC Berkeley, QIONG WU, Physics Dept. UC Berkeley, LBNL, HSIN-ZON TSAI, Physics Dept. UC Berkeley, WILLIAM REGAN, ALEX ZETTL, Physics Dept. UC Berkeley, LBNL, ROLAND KAWAKAMI, Dept. of physics and astronomy, UC Riverside, STEVEN LOUIE, Physics Dept. UC Berkeley, LBNL, LEONID LEVITOV, Dept. of Physics, MIT, MICHAEL CROMMIE, Physics Dept. UC Berkeley, LBNL — Relativistic quantum mechanics predicts that super-heavy atoms possess unique properties not shared by ordinary atoms. In particular, a very strong electric field around the nucleus should result in "atomic collapse," with an electron component falling onto the nucleus and a positron component escaping to infinity. Predicted by Dirac 80 years ago, atomic collapse has thus far remained experimentally out of reach using accelerator-based techniques. Here we report the observation of atomic collapse on gated graphene devices. The energy and spatial dependence of the atomic collapse state was measured using scanning tunneling microscopy (STM).

1:15PM U8.00009 Molecular adsorbates on HOPG: Toward modulation of graphene density of states[1] , MICHELLE GROCE, THEODORE EINSTEIN, WILLIAM CULLEN, U. of Maryland — Ordered molecular superlattices, particularly those made of planar aromatics with their attendant pi orbitals, have the potential to break the graphene sublattice degeneracy and create a band gap. Trimesic acid (TMA) is a promising candidate due to its self-assembly into symmetry-breaking superlattices nearly commensurate with that of graphene. We have used the graphite (0001) surface as a model system to explore the impact of TMA thin films on band structure. By examining correlations between STM topography and STS maps of corresponding regions, we are able to investigate the effects of TMA on the local density of states.

1:27PM U8.00010 ABSTRACT WITHDRAWN –

1:39PM U8.00011 Current and voltage dependent interactions between a scanning tunneling microscopy tip and a freestanding graphene sample , KEVIN SCHOELZ, PENG XU, STEVEN BARBER, MATT ACKERMAN, PAUL THIBADO, Physics Department, University of Arkanas, Fayetteville AR, 72701 — The two dimensional nature of graphene gives rise to a number of unique properties. Chief among them are the ability to manipulate the electronic properties using mechanical deformations, opening a new field of "straintronics." Previous work from our group demonstrated the ability to manipulate a freestanding graphene sample with atomic precision using electromagnetic manipulation scanning tunneling microscopy (EM-STM). In the EM-STM technique, the tip bias is ramped over a predetermined range while maintaining a constant tunneling current. The resulting change in height of the tip is then recorded. Typical EM-STM measurements show quick movement of the sample between 0.1-1.0 V, and then slower movement after this point. The height of this final plateau is dependent on the tunneling current. To look for the cause of this current dependence $z(I)$ curves taken at a constant tip bias were examined. It was found that at low tip bias (0.1-0.5 V) the sample drops between 10-20 nm, while at high tip bias (1.0-3.0 V) the sample only drops 2-3 nm. This current dependence is attributed to a drop in the electrostatic force as the tip approaches the sample and holes in the benzene rings become more important.

1:51PM U8.00012 Gate-controlled modification of molecular electronic structure at the surface of graphene , ALEXANDER RISS, SEBASTIAN WICKENBURG, HSIN-ZON TSAI, LIANG TAN, MIGUEL MORENO UGEDA, AARON BRADLEY, Department of Physics, UC Berkeley, ALEX ZETTL, STEVEN G. LOUIE, Department of Physics, UC Berkeley; Materials Science Division, Lawrence Berkeley National Laboratory, FELIX R. FISCHER, Department of Chemistry, UC Berkeley, MICHAEL F. CROMMIE, Department of Physics, UC Berkeley; Materials Science Division, Lawrence Berkeley National Laboratory — Understanding the behavior of adsorbed molecules on graphene is important for a variety of reasons, including the fact that they can potentially be used to modify the optical, electronic, catalytic, and magnetic properties of graphene devices. Here we show how gate-induced shifting of the Fermi level of a single graphene layer can be used to induce electronic changes in adsorbed molecules. We have used scanning tunneling microscopy and spectroscopy to characterize the structure and electronic properties of 3,3',3"-(Benzene-1,3,5-triyl)tris(2-cyanoacrylonitrile) (BTC) molecules adsorbed onto the surface of a back-gated graphene device. We observe that the energy (with respect to the Fermi level) of the lowest unoccupied molecular orbital (LUMO) of individual BTC molecules can be tuned by application of a gate voltage. These results show the potential to control the physical and chemical properties of adsorbates via electrostatic gating.

Thursday, March 21, 2013 11:15AM - 2:15PM –

Session U9 DCMP: Three Dimensional Topological Insulators: Chalcogenides and New Materials 308 - Phillip King, Cornell University

11:15AM U9.00001 Spin Control of the topological surface states in 3D topological insulators using polarized light[1] , ANNA GURA, JEFF SECOR, MILAN BEGLIARBEKOV, LUKAS ZHAO, HAIMING DENG, LIA KRUSIN-ELBAUM, Physics Department, City College of New York — The topological surface states of 3D topological insulators (TIs)been shown to interact non trivially with circularly polarized light. Here we report on the study of spin-polarized currents in several 2^{nd} generation TIs, such as Sb_2Te_3, Be_2Te_3, and Bi_2Se_3. In particular, to probe the robustness of the helical current surface states we will contrast the polarization dependence of the photocurrent in as grown crystals and crystals with controlled disorder introduced by magnetic and non-magnetic impurities. These result in the development of a gap in the energy spectrum of surface Dirac fermions (DFs), that is DFs acquire mass. The photo-response contrast between massless and massive Dirac fermions studied under electric field gating conditions will be presented.

[1]Supported in part by NSF-DMR-1122594

11:27AM U9.00002 Highly tunable electron transport in epitaxial topological insulator $(Bi_{1-x}Sb_x)_2Te_3$ thin films , TONG GUAN, Institute of Physics, Chinese Academy of Sciences; Florida State University, XIAOYUE HE, KEHUI WU, YONGQING LI, Institute of Physics, Chinese Academy of Sciences — Three dimensional topological insulators (TI) have potential applications in quantum computation and spintronics. These applications often require an insulating bulk and high tunability in chemical potential. Remarkable progresses have been made in synthesizing new TI material with more insulating bulk by alloying the binary compounds Bi_2Se_3, Sb_2Se_3, Bi_2Te_3 and Sb_2Te_3 in the past couple of years. Here we report the growth of single crystalline $(Bi_{1-x}Sb_x)_2Te_3$ films on $SrTiO_3(111)$ substrates by molecular beam epitaxy. A full range of Sb-Bi compositions have been studied. Optimal Sb composition for minimum bulk conduction was found to be x = 0.5 $\pm$ 0.1. For the samples $(Bi_{0.5}Sb_{0.5})_2Te_3$, the carrier density can be tuned from n-type to p-type with the help of a back-gate. Linear magnetoresistance has been observed at gate voltages close to the maximum in the longitudinal resistance of $(Bi_{0.5}Sb_{0.5})_2Te_3$ sample. These highly tunable $(Bi_{1-x}Sb_x)_2Te_3$ thin films provide an excellent platform to explore the intrinsic transport properties of the three dimensional topological insulators.

11:39AM U9.00003 Iodine doping of p-type topological insulators[1] , INNA KORZHOVSKA, LUKAS ZHAO, HAIMING DENG, CHEN ZHIYI, LIA KRUSIN-ELBAUM, City College of New York-CUNY — We report on the systematic iodine (I) doping of the 'intrinsically' *p*-type 2^{nd} generation topological insulator (TI) Sb_2Te_3. Iodine will introduce additional holes into the system and thus pull the Fermi level E_F 'down' from the Dirac point. Further, at a sufficient hole density, particle correlation effects are also expected to emerge. Iodine was incorporated into Sb_2Te_3 using two methods: (i) post-growth vapor exposure of crystals grown by the Vapor-Liquid-Solid (VLS) technique and (ii) *in-situ* doping of crystals grown in a modified Bridgman setup. The first method is self-limiting and only up to 2 at% iodine is entered, however the *in-situ* doping allowed us to increase iodine content up to 20%. Detailed XRD Rietveld refinement analysis of the doped crystals doping indicates that for the I-content greater than 10% the rhombohedral structure is modified to reflect some extent of the I-Te and I-Sb bonding. We find that iodine doping affects the large diamagnetic susceptibility, particularly at low magnetic fields. Our measurements of Hall resistivity confirm that under doping resistivity remains *p*-type. The contrasting effects of the iodine doping into the intrinsically *n*-type Bi_2Se_3 will be presented.

[1]Supported in part by NSF-DMR-1122594

11:51AM U9.00004 Nuclear Magnetic Resonance Studies of Bulk States of Bi2Se3 , D.M. NISSON, A.P. DIOGUARDI, P. KLAVINS, C.H. LIN, K. SHIRER, A. SHOCKLEY, J. CROCKER, N.J. CURRO, University of California, Davis, Department of Physics, N. J. CURRO NMR GROUP TEAM — We present ^{209}Bi nuclear magnetic resonance (NMR) spectra and relaxation rate data on single crystals of Bi_2Se_3 grown under various conditions, whose carrier concentrations, resistivities, and Shubnikov-de Haas (SdH) frequencies have been measured. Our NMR data reveal properties of the bulk states, which are influenced by the presence of intrinsic carriers. We find that both the Knight shift and the electric field gradient of the Bi is correlated with carrier concentration, and atypical spectral profiles. Surprisingly, spin-lattice relaxation is not strongly temperature dependent.

12:03PM U9.00005 Origin of helical spin texture of topological phase transition family materials $TlBi(Se_{1-x}S_x)_2$, JUSTIN WAUGH, YUE CAO, University of Colorado at Boulder, KOJI MIYAMOTO, TAICHI OKUDA, Hiroshima Synchrotron Radiation Center, CHETAN DHITAL, STEPHEN WILSON, Boston College, DANIEL DESSAU, University of Colorado at Boulder — The unique helically spin-polarized metallic surface states of topological insulators are believed to arise from an odd number of band inversions per unit cell. It is believed that the band inversion in the family of compounds $TlBi(Se_{1-x}S_x)_2$ can be removed by replacing Se by S, removing the spin-polarized surface states. Using spin and angle-resolved photoemission spectroscopy we here show that even on the gapped non-topological "trivial" side of the phase transition (x=0.7), Dirac-like helical spin polarization still exist, as well as small but finite gaps on the topological side of the phase transition (x=0.3). Additional spin helicity inversions are also present in the bulk bands of both samples. We consider various explanations for this effect, including a superposition of domains, massive Dirac states due to thin domains, and Rashba spin orbit splitting at the surfaces.

12:15PM U9.00006 Terahertz Quantum Hall Effect of Dirac Fermions in a Topological Insulator , A. PIMENOV, A. SHUVAEV, TU Vienna, Austria, G. ASTAKHOV, G. TKACHOV, CH. BRUENE, H. BUHMANN, L. W. MOLENKAMP, University of Wuerzburg, Germany — Using THz spectroscopy in external magnetic fields we investigate the low-temperature charge dynamics of strained HgTe, a three dimensional topological insulator. From the Faraday rotation angle and ellipticity a complete characterization of the charge carriers is obtained. In resonator experiments, we observe quantum Hall oscillations at THz frequencies. The 2D density estimated from the period of these oscillations agrees well with direct transport experiments on the topological surface state. The Dirac character of the surface state is proven by the observation of a half-integer plateau in the quantum Hall effect.

12:27PM U9.00007 Various Types of Dirac Cone Materials of Bi_{1-x}Sbx Thin Films , SHUANG TANG, MILDRED DRESSELHAUS, MIT — The band structure of bismuth antimony thin films varies as a function of stoichiometry, film thickness and growth orientation. Different types of Dirac cone materials can be constructed based on the bismuth antimony thin films system, including single-Dirac-cone, bi-Dirac-cone and tri-Dirac cone materials, and also including exact-Dirac-cone, semi-Dirac-cone and quasi-Dirac-cone materials. The degree of anisotropy of a Dirac cone can be controlled, which range from ~ 2 to ~ 14. Interesting transport phenomena are expected in different Dirac cone materials, which may be optimized for different purposes of applications, e.g. thermoelectrics, electronics etc.

12:39PM U9.00008 Dirac fermions, Fermi surface and magnetotransport in bulk crystals of layered SrZnSb2 , KEFENG WANG, LIMIN WANG, Brookhaven National Laboratory, DAVID GRAF, National High Magnetic Field Laboratory, Florida State University, CEDOMIR PETROVIC, Brookhaven National Laboratory — We report evidence for anisotropic Dirac-like pockets and the large magnetoresistance in the quasi-two-dimensional Sb rectangular layers of bulk SrZnSb2 crystals. Due to the two-fold symmetry of the Sb layers, there are three different Dirac-like pockets as revealed by the calculated Fermi surface. Angular dependent in-plane magnetoresistance and oscillation frequencies indicate the quasi-two-dimensional character of the pockets. This is different from the identical Dirac-cone-like points in the Bi square net of SrMnBi2. The large linear magnetoresistance and magnetothermopower were observed in crystals. The magnetoresistance behavior can be described very well by combining the semiclassical cyclotron contribution and the quantum limit magnetoresistance. Magnetic field also enhances the thermopower. Our results can be well understood by the magnetotransport of Dirac states in the bulk band structure. Work at BNL supported by Office of Basic Energy Sciences, US DOE, under contract No. DE-AC02-98C (K. W, L. W and C. P.). Work at the National High Magnetic Field Laboratory is supported by the DOE NNSA DE-FG52-10NA29659, by the NSF Cooperative Agreement No.DMR-0654118, and by the state of Florida (D. G.)

12:51PM U9.00009 $\beta-Ag_2Te$: A topological insulator with strong anisotropy[1] , LAN WANG, AZAT SULAEV, PENG REN, BIN XIA, QINGHUA LIN, TING YU, CAIYU QIU, School of Physical and Mathematical Science, Nanyang Technological University, Singapore, SHUANG-YUAN ZHANG, MING-YONG HAN, Institute of Material Research and Engineering, Singapore, ZHIPENG LI, WEI GUANG ZHU, School of Electrical and Electronic Engineering, Nanyang Technological University, Singapore, QINGYU WU, YUAN PING FENG, LEI SHEN, Department of Physics, National University of Singapore, Singapore, SHUN-QING SHEN, Department of Physics, The University of Hong Kong, Hong Kong, China — We present evidence of topological surface states in β-Ag_2Te through first-principles calculations, periodic quantum interference effect and ambipolar electric field effect in single crystalline nanoribbon. Our first-principles calculations show that β-Ag_2Te is a topological insulator with a gapless Dirac cone with strong anisotropy. To experimentally probe the topological surface state, we synthesized high quality β-Ag_2Te nanoribbons and performed electron transport measurements. The coexistence of pronounced Aharonov-Bohm oscillations and weak Altshuler-Aronov-Spivak oscillations clearly demonstrates coherent electron transport around the perimeter of β-Ag_2Te nanoribbon and therefore the existence of topological surface states, which is further supported by the ambipolar electric field effect for devices fabricated by β-Ag_2Te nanoribbons. The experimentally confirmed topological surface states and the theoretically predicted isotropic Dirac cone of β-Ag_2Te suggest that the material may be a promising material for fundamental study and future spintronic devices.

1:03PM U9.00010 Topological Surface State Observed in Superconducting (Ir1-xPtx)Te2 , TIAN QIAN, HU MIAO, GANG XU, XI DAI, ZHONG FANG, AIFA FANG, NANLIN WANG, HONG DING, Institute of Physics, Chinese Academy of Sciences — Topologically non-trivial surface state is the hallmark of 3D topological insulators and topological superconductors, where spin-orbit coupling (SOC) plays an essential role. By Ir site doping of 5% Pt, the huge SOC material IrTe2 becomes a superconductor with maximal Tc = 3K. Our angle resolve photoemission spectroscopy (ARPES) study combined with LDA analysis demonstrate the surface states of (Ir1-xPtx)Te2 is toplogically non-trivial.

1:15PM U9.00011 Transport properties of crystalline topological insulator $Pb_{1-x}Sn_xSe$[1] , TIAN LIANG, Dept. Phys. Princeton University, New Jersey 08544, QUINN GIBSON, Dept. Chem. Princeton University, New Jersey 08544, JUN XIONG, M.A. HIRSCHBERGER, Dept. Phys. Princeton University, New Jersey 08544, R.J. CAVA, Dept. Chem. Princeton University, New Jersey 08544, N.P. ONG, Dept. Phys. Princeton University, New Jersey 08544 — The narrow-band gap semiconductors $Pb_{1-x}Sn_xSe$ and $Pb_{1-x}Sn_xTe$ have received considerable attention recently following the prediction [1] that they are examples of a topological crystalline insulator with surface states characterized by a mirror Chern number. Several ARPES groups have reported evidence for the topological surface states [2,3]. We have investigated the transport properties of crystals of $Pb_{1-x}Sn_xSe$. For Sn content x bracketing 0.23, we observe strong quantum oscillations from bulk carriers (either n or p type) with concentrations near 2×10^{18} cm^{-3} and mobilities $\sim$ 3,000 cm^2/Vs. The results of experiments to tune the chemical potential into the gap using chemical doping and liquid gating will be reported. References: [1] T. H. Hsieh et al., Nature Commun. **3**, 982 (2012). 1:27PM U9.00012 NMR Studies of the Candidate Topological Superconductor $Sn_{1-x}In_xTe$: Spin-Triplet Superconductivity Robust against Magnetic Impurities , X.R. LU, L. MA, J. DAI, P. WANG, B. NORMAND, W. YU, Department of Physics, Renmin University of China, Beijing, China, R.D. ZHONG, J. SCHNEELOCH, Z.J. XU, G.D. GU, Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory, NY 11973, USA — In-doped SnTe is a low-carrier-density semiconductor with strong spin-orbit coupling, and has been proposed to be a topological superconductor. We report nuclear magnetic resonance (NMR) studies of both ^{119}Sn and ^{125}Te nuclei, performed on single crystals of $Sn_{1-x}In_xTe$, where $T_c = 1.8$ K for $x = 0.1$. Under an applied field of 0.33 T, the spin-lattice relaxation rate $1/^{119}T_1$ drops rapidly below 1.2 K, indicating bulk superconductivity. We observe absolutely no change in the Knight shift with temperature when $T < T_c$, which in NMR is normally an indicator of spin-triplet superconductivity. We find no coherence peak below T_c in $1/^{119}T_1$, suggesting an unconventional order parameter but also the possible role of impurities. In the normal state we find that $1/^{119}T_1$ and $1/^{125}T_1$ have Fermi-liquid behavior at high fields, but at low fields show a large Curie-Weiss-type enhancement indicative of magnetic impurity effects. Thus the fact that T_c in our samples is insensitive to the sample purity suggests that superconductivity in $Sn_{1-x}In_xTe$ is robust against magnetic impurities, in contrast to the situation in conventional superconductors.

1:39PM U9.00013 Electronic Structure Study on a 3D Dirac Semimetal Candidate , Y.L. CHEN, Oxford University, Z.K. LIU, Stanford University, B. ZHOU, S.K. MO, Larence Berkeley National Lab, D. PRABHAKARAN, Oxford University, Z.J. WANG, Z. FANG, X. DAI, Institute of Physics, Chinese Academy of Sciences, Z.X. SHEN, Stanford University, Z. HUSSAIN, Larence Berkeley National Lab — A family of 3D Dirac semimetals candidates (A3Bi, A=alkali metal, B=As, Sb, or Bi) have recently been predicted to exist at the phase transition between a topological and a normal insulator when inversion symmetry is preserved. In such a semimetal, the conduction and valence bands touch only at Dirac points around which the dispersion is linear in all directions, leading to distinct physical properties, such as giant diamagnetism and linear quantum magneto-resistance. We used angle resolved photoemission spectroscopy (ARPES) to study a 3D Dirac semimetal candidate, Na3Bi and revealed interesting electronic structures. We will discuss our observation, its possible topological origin and the connection to recent theory investigation.

1:51PM U9.00014 Competing Orders in the Surface State of Topological Kondo Insulators , JEFFREY BOTIMER, DAE-JEONG KIM, SEAN THOMAS, ZACHARY FISK, JING XIA, University of California, Irvine — The recent discovery of topological (band) insulators (TI) reveals a conceptually new family of quantum materials with novel properties. The bulk energy gap closes at the surface, leading to a gap-less metallic topological surface state. Recently several Kondo insulators have been theoretically proposed in this category, dubbed "Topological Kondo Insulators" (TKI). In a TKI, the topological order arises from strong electron correlation and will display new physics. For example, various broken symmetry orders are expected to compete with the topological order. In this talk we will present electrical transport evidence for a high mobility conducting surface state, as well as magneto-optic evidence for broken time reversal symmetry at the surface of several TKI materials. These results suggest that the surface state of the TKI are not only topological but also magnetic, thus providing a convenient system to study topological magneto-electric effects where magnetization can be induced by pure electric field.

2:03PM U9.00015 Transport Signature of Floquet Majorana Fermions[1] , ARIJIT KUNDU, BABAK SERADJEH, Indiana University, Bloomington — It has been recently predicted that a periodically-driven superconducting quantum wire can support unpaired Floquet Majorana fermions (FMFs), steady-state equal mixtures of electrons and holes bound to the ends of the wire. We further study this proposition and elucidate the range of parameters and drives that give rise to FMFs. We also look for possible transport signatures of FMFs within a non-equilibrium Green's function approach. We analyze the conductance profile for different driving schemes and compare the behavior with that of the static system. We comment on possible experimental setups to observe and exploit FMFs in quantum information processing.

Session U11 DLS: Invited Session: New Laser Techniques for Imaging and Probing at the Nanoscale 310 - Henry Kapteyn, University of Colorado Boulder

11:15AM U11.00001 Optical pump-probe microscopy for biomedicine and art conservation , MARTIN FISCHER, Duke University — Nonlinear optical microscopy can provide contrast in highly heterogeneous media and a wide range of applications has emerged, primarily in biology, medicine, and materials science. Compared to linear microscopy methods, the localized nature of nonlinear interactions leads to high spatial resolution, optical sectioning, and larger possible imaging depth in scattering media. However, nonlinear contrast (other than fluorescence, harmonic generation or CARS) is generally difficult to measure because it is overwhelmed by the large background of detected illumination light. This background can be suppressed by using femtosecond pulse or pulse train shaping to encode nonlinear interactions in background-free regions of the frequency spectrum. We have developed this shaping technology to study novel intrinsic structural and molecular contrast in biological tissue, generally using less power than a laser pointer. For example we have recently been able to sensitively measure detailed transient absorption dynamics of melanin sub-types in a variety of skin lesions, showing clinically relevant differences of melanin type and distribution between cancerous and benign tissue.[1] Recently we have also applied this technology to paint samples and to historic artwork in order to provide detailed, depth-resolved pigment identification. Initial studies in different inorganic and organic pigments have shown a rich and pigment-specific nonlinear absorption signature.[2] Some pigments, for example lapis lazuli (natural ultramarine), even show marked differences in signal depending on its geographic origin and on age, demonstrating the potential of this technique to determine authenticity, provenance, technology of manufacture, or state of preservation of historic works of art.

11:51AM U11.00002 Discovering new physics in magnetic thin films using coherent EUV from high harmonic generation , TOM SILVA, NIST — The understanding of nanoscale magnetism has become much more critical with recent advances in magnetic data storage applications, as bits on a hard disk are already packed at scales of about 20nm. However, a microscopic model of how spins, electrons, photons and phonons interact does not yet exist. This understanding is fundamentally constrained in large part by our limited ability to observe magnetism on all relevant time and length scales. Until recently, measuring magnetization dynamics used either ultrafast visible-wavelength lasers, or X-rays from synchrotrons and free electron lasers. Our recent work has shown that the fastest dynamics in magnetic materials can be captured using extreme ultraviolet (XUV) harmonics – with elemental resolution and at multiple atomic sites simultaneously. We first probed with elemental sensitivity how fast the magnetic state can be destroyed in an Fe-Ni alloy. After exciting an Fe-Ni alloy with a fs laser, the spin sublattices randomize on sub-ps timescales. Surprisingly, even in a strongly coupled ferromagnetic alloy, the demagnetization of Ni lags that of Fe by 10 fs [1]. Moreover, we were able to tune this time lag by diluting the alloy with Cu to further reduce the exchange energy. After a time lag characteristic of the exchange energy, the Ni sublattice demagnetizes at the same rate as Fe. This reveals both how the exchange interaction can mediate ultrafast magnetic dynamics in alloys, and how the intrinsic demagnetization process is site-specific such that spins on one sublattice can interact more strongly with the optical field than spins on the other sublattice. In our latest work, we uncovered evidence of giant spin-currents in magnetic multilayers that are generated in the course of the laser-driven ultrafast demagnetization process [2]. By exciting a magnetic multilayer (Fe/Ru/Ni) with a laser pulse, and separately, yet simultaneously, probing the magnetization response of the Ni and Fe layers when the two layers are aligned with an applied magnetic field, we found that optically induced demagnetization of the top Ni layer causes the buried Fe layer to undergo a transient enhancement of the magnetization, of up to 20 percent. This is due to an intense, majority spin-current that enters the Fe layer.

12:27PM U11.00003 Imaging at the X-ray Frontier: Coherent Diffraction Imaging (CDI) for Nano and Bioscience , JIANWEI (JOHN) MIAO, Department of Physics & Astronomy and California NanoSystems Institute, University of California, Los Angeles — For centuries, lens-based microscopy, such as light, phase-contrast, fluorescence, confocal and electron microscopy, has played an important role in the evolution of modern sciences and technologies. In 1999, a novel form of microscopy, i.e. coherent diffraction imaging (also termed coherent diffraction microscopy or lensless imaging) was developed and transformed our traditional view of microscopy, in which the diffraction pattern of a noncrystalline object or a nanocrystal is first measured and then directly phased to obtain a high resolution image. The well-known phase problem is solved by the oversampling method in combination with iterative algorithms whose principle can be traced back to the Shannon sampling theorem. In this talk, I will briefly discuss the principle of coherent diffraction imaging and illustrate its broad application in nano and bioscience by using synchrotron radiation, high harmonic generation and X-ray free electron lasers.

1:03PM U11.00004 Imaging heterogeneous ultrafast exciton dynamics in organic semiconducting thin films , NAOMI S. GINSBERG, UC Berkeley Departments of Chemistry and Physics — In solid state semiconducting molecular materials used in electro-optical applications, relatively long exciton diffusion lengths hold the promise to boost device performance by relaxing proximity constraints on the locations for light absorption and interfacial charge separation. The architecture of such materials determines their optical and electronic properties as a result of spacing- and orientation-dependent Coulomb couplings between adjacent molecules. Exciton character and dynamics are generally inferred from bulk optical measurements, which can present a severe limitation on our understanding of these films because their constituent molecules are not perfectly ordered. Rather, films of small organic molecules are composed of multiple microcrystalline domains, and this deposition-dependent microstructure can have profound impacts on transport properties. Using ultrafast transient absorption microscopy, we track the time evolution of excitons, domain by domain, in solid state thin films of TIPS-pentacene, a small soluble molecule that has recently been used in organic semiconducting devices because of its high hole mobility. The results from this spatially-resolved nonlinear optical spectroscopy support our hypothesis that bulk optical measurements deleteriously average over heterogeneities in both spatial and electronic structure; we have revealed significant inhomogeneity in exciton dynamics. Domains that appear homogeneous in linear optical microscopy are shown to have spatial variation and defects, and notable differences in exciton character and behavior are observed at domain boundaries. To interpret the contrast we observe with ultrafast dynamics, we correlate our data to local linear absorption, polarization analysis, profilometry, and atomic force microscopy. With this combined approach, we aim to ultimately understand fundamental structure-function relationship in molecular materials to provide predictive power to material development and device efficiency.

1:39PM U11.00005 Peering into Cells One Molecule at a Time: Single-molecule and plasmon-enhanced fluorescence super-resolution imaging , JULIE BITEEN, University of Michigan — Single-molecule fluorescence brings the resolution of optical microscopy down to the nanometer scale, allowing us to unlock the mysteries of how biomolecules work together to achieve the complexity that is a cell. This high-resolution, non-destructive method for examining subcellular events has opened up an exciting new frontier: the study of macromolecular localization and dynamics in living cells. We have developed methods for single-molecule investigations of live bacterial cells, and have used these techniques to investigate thee important prokaryotic systems: membrane-bound transcription activation in *Vibrio cholerae*, carbohydrate catabolism in *Bacteroides thetaiotaomicron*, and DNA mismatch repair in *Bacillus subtilis*. Each system presents unique challenges, and we will discuss the important methods developed for each system. Furthermore, we use the plasmon modes of bio-compatible metal nanoparticles to enhance the emissivity of single-molecule fluorophores. The resolution of single-molecule imaging in cells is generally limited to 20-40 nm, far worse than the 1.5-nm localization accuracies which have been attained *in vitro*. We use plasmonics to improve the brightness and stability of single-molecule probes, and in particular fluorescent proteins, which are widely used for bio-imaging. We find that gold-coupled fluorophores demonstrate brighter, longer-lived emission, yielding an overall enhancement in total photons detected. Ultimately, this results in increased localization accuracy for single-molecule imaging. Furthermore, since fluorescence intensity is proportional to local electromagnetic field intensity, these changes in decay intensity and rate serve as a nm-scale read-out of the field intensity. Our work indicates that plasmonic substrates are uniquely advantageous for super-resolution imaging, and that plasmon-enhanced imaging is a promising technique for improving live cell single-molecule microscopy.

Thursday, March 21, 2013 11:15AM - 2:15PM –

Session U12 DMP GERA FIAP: Focus Session: Thermoelectrics Materials II 314 - David Parker, ORNL

11:15AM U12.00001 Anharmonicity and its application in earth abundant thermoelectrics , DONALD MORELLI, Michigan State University — Recently very exciting improvements in the thermoelectric figure of merit have been reported in bulk nanostructured chalcogenides, mostly due to lattice thermal conductivity suppression by nanoscale-level interfaces. A critical issue in these types of structures is maintaining good electrical conductivity while blocking phonon transport. While so-called "endotaxial" nanostructuring, for example, can substantially maintain electron transport across interfaces, generally nanocomposite structures display reduced electrical conductivity which can counteract or in some cases overwhelm the improvements in figure of merit due to thermal conductivity reduction. Additionally, the thermal stability of nanostructured materials at operating temperatures at a significant fraction of the melting point is a concern. Here we describe another approach to reducing lattice thermal conductivity based on designing materials with large lattice anharmonicity. Anharmonic phonon vibrations are the source of intrinsic thermal resistivity in solids and manifest themselves in large Grüneisen parameters. We show that one class of compounds, those containing antimony atoms with a lone pair configuration, exhibits a strongly anharmonic phonon spectrum that leads to intrinsically small lattice thermal conductivity. We have applied this concept to ternary copper-antimony-chalcogenide semiconductors and find that the family of compounds based on the tetrahedrite crystal structure can exhibit thermoelectric figure of merit rivaling that of conventional materials like PbTe. The tetrahedrite family is the most widespread sulfosalt mineral on Earth and we show that the mineral itself can be used directly as a source material for earth abundant thermoelectrics. This may pave the way for many new, low cost applications of thermoelectrics in waste heat recovery and power generation.

11:51AM U12.00002 Phonon lifetime investigation of anharmonicity and thermal conductivity in UO_2[1] , JUDY PANG, Oak Ridge National Laboratory, ALEKSANDR CHERNATYNSKIY, University of Florida, WILLIAM BUYERS, National Research Council, Canada, BENNETT LARSON, Oak Ridge National Laboratory, SIMON PHILLPOT, University of Florida — Understanding low thermal conductivity in UO_2 requires a correct accounting for anharmonic phonon-phonon scattering processes. However, over the last five decades there have been remarkably few high-temperature studies of phonon processes in UO_2 to underpin its widespread use as a reactor fuel. We have used high-resolution inelastic neutron scattering measurements of individual phonon lifetimes (linewidths) and dispersion at 295 and 1200 K to probe anharmonicity and thermal conductivity in UO_2 for individual phonon branches. We found that phonon lifetimes depend strongly on the phonon wave vector and that longitudinal optic phonon modes transport the largest amount of heat, in contrast to recent first principles simulations. The total thermal conductivities calculated using our phonon data demonstrate a quantitative correspondence between microscopic and macroscopic phonon physics. We have also performed density functional theory simulations showing semi-quantitative agreement with phonon lifetimes at 295 K, but larger anharmonicity than measured at 1200 K. These measured phonon dispersion and lifetimes form a benchmark dataset against which numerical simulations including anharmonicity may be assessed.

[1]This research was supported as part of the Center for Materials Science of Nuclear Fuel, an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science.

12:03PM U12.00003 Determination of elastic constants via phonon- imaging for crystals with low symmetry , TIM HEAD, ELIZABETH CARLISLE, Abilene Christian University — We report progress toward using group velocity surface projections, rather than group velocity surfaces directly, to find elastic constants for low symmetry crystals. Direct determination of elastic constants is difficult in general because of the multi-valued nature of the group velocity surface and a lack of experimentally accessible information about phonon polarizations. Projection of group velocity surfaces onto a plane depend strongly on the elastic constants. We use Monte-Carlo simulations of phonon-images based on continuum elasticity theory to move toward a best-fit algorithm to find elastic constant values for crystals of low symmetry given phonon-imaging data.

12:15PM U12.00004 Thermodynamic Effects of Na on the Morphology of PbTe-PbS Nanostructured Thermoelectrics , JEFF DOAK, JIAQING HE, IVAN BLUM, STEVEN GIRARD, LI-DONG ZHAO, DAVID SEIDMAN, MERCOURI KANATZIDIS, VINAYAK DRAVID, CHRIS WOLVERTON, Northwestern University, HUI-QIONG WANG, JIN-CHENG ZHENG, Xiamen University, GILBERTO CASILLAS, MIGUEL JOSE-YACAMAN, University of Texas at San Antonio — The creation of nanostructures via phase separation provides a mechanism for decreasing the lattice thermal conductivity and increasing the figure of merit of bulk thermoelectric materials like PbTe-PbS. The addition of Na to PbTe-PbS drastically alters the morphology of PbS precipitates in the system. To see if this change in morphology can be attributed to equilibrium thermodynamics, we use first-principles density functional theory (DFT) calculations to study the energetics of Na partitioning between PbTe and PbS and Na segregation at PbTe/PbS interfaces. We calculate a variety of Na defects in PbTe and PbS and find that the lowest energy defect in both PbTe and PbS is Na substituted for Pb. From the Na defect formation energies, we find the solubility limit of Na in PbTe and PbS, as well as the partitioning coefficient between PbTe and PbS. We find that Na partitions to PbS over PbTe, in agreement with experiment. We calculate Na segregation energies by substituting Na for Pb at the PbTe/PbS interface and find that Na segregates at the PbTe-side of the interface, in qualitative agreement with atom-probe tomography analysis. Applying the Gibbs adsorption isotherm to Na segregation, we find a corresponding decrease in interfacial energy leading to a change in morphology.

12:27PM U12.00005 Replacement of Ge in GeTe by [Ag+Sb] and rare earths: effect on thermoelectric properties , E.M. LEVIN, M. HANSON, R. HANUS, K. SCHMIDT-ROHR, Ames Laboratory US DOE and Iowa State University — High-efficiency p-type Te-Sb-Ge-Ag (TAGS) thermoelectric materials are based on the GeTe narrow-band self-dopant semiconductor where Ge can be replaced by up to 16 at.% [Ag+Sb]. To understand the effect of Ge replacement by 4 at.% [Ag+Sb] as well as rare earths atoms, we have synthesized and studied XRD, thermopower, electrical resistivity, thermal conductivity, and ^{125}Te NMR of GeTe and $Ag_2Sb_2Ge_{46-x}R_xTe_{50}$ with R=Gd, Dy and x =1, 2. At 700 K, GeTe exhibits a thermopower of +146 μVK^{-1} and a large power factor, 42 $\mu Wcm^{-1}K^{-2}$. Replacement of Ge by [Ag+Sb] and rare earths enhances the thermopower, but slightly reduces the power factor due to an increase in electrical resistivity. The thermal conductivity at 300 K of all alloys studied is reduced by a factor of two compared to GeTe. ^{125}Te NMR spin-lattice relaxation time and resonance frequency reflect changes in carrier concentration. However, decrease of thermal conductivity due to carriers and increase of electrical resistivity are mostly due to a reduction of carrier mobility and indicate strong scattering produced by [Ag+Sb] and rare earth atoms. At 700 K, the thermoelectric figure of merit of GeTe is 0.8, whereas that in $Ag_2Sb_2Ge_{45}Dy_1Te_{50}$ is much larger, 1.2, due to a reduction in thermal conductivity. Enhancement of thermopower is discussed within a model of energy filtering.

12:39PM U12.00006 Primary phase alignment in the Mg-Sb system with a 35T DC magnetic field , SETH IMHOFF, Los Alamos National Laboratory, THOMAS OTT, None, TIM TUCKER, JASON COOLEY, Los Alamos National Laboratory — Primary phase alignment behavior in the Mg-Sb system is explored by solidification of samples in a 35 tesla DC magnetic field. Compositions with multiple solidification reaction pathways are found to have different phase alignment characteristics. In the current study, the orientation of Mg and Sb primary grains do not appear to be strongly influenced, but the α-Mg3Sb2 shows a very strong tendency to align with its long axis perpendicular to the field direction. In comparing two compositions that both first nucleate α-Mg3Sb2 from the melt, it is found that the volume fraction involved in the primary reaction is a controlling factor for the total degree of alignment throughout the structure. This volume fraction dependence is interpreted as hindering free rotation in the liquid.

12:51PM U12.00007 Mapping the Fermi Surface in Nb by Tracking Kohn Anomalies with Neutron Scattering[1] , IYAD AL-QASIR, OLIVIER DELAIRE, VICKIE LYNCH, DOUGLAS ABERNATHY, MATT STONE, Oak Ridge National Laboratory — Electron-phonon interaction in metals is a subject of interest for theoretical and experimental investigations. Phonons in Nb show Kohn anomalies due to the electron-phonon interaction. In this work, we are tracking Kohn anomalies in Nb in the full Brillouin zone experimentally and computationally and relating it to the Fermi surface. We measured the 4-dimensional scattering function, $S(\vec{Q},\omega)$ of Nb as a function of temperature, using time of flight inelastic neutron scattering. The 4D data allow us to map phonon dispersion relations along any direction in the full Brillouin zone. In parallel, density functional theory was used to calculate the electronic band structure and Fermi surface, as well as the phonon dispersion relations and line-widths. We present a quantitative comparison, taking into account experimental resolution. These results point to a new avenue of mapping the Fermi surface and electron-phonon coupling in bulk crystals, complementing existing techniques.

1:03PM U12.00008 Theoretical Study of the Properties of the Type II Clathrates A_xB_{136}(A=alkali atom;B=Si,Ge,Sn0 $\leq$ x $\leq$ 24) , DONG XUE, CRAIG HIGGINS, CHARLEY MYLES[1], Department of Physics, Texas Tech University — Type II clathrate semiconductors have cage-like lattices in which Group IV atoms are tetrahedrally-coordinated and sp^3 covalently bonded. The cages can contain "guest" atoms; usually alkali or alkaline earth atoms. These materials are of interest because of their thermoelectric properties. Motivated by recent experimental and theoretical interest [1,2] in the x dependence of properties of the Si and Ge-based Type II clathrate materials A_xSi_{136} and A_xGe_{136} (A = alkali atom) we are carrying out a systematic theoretical study of the properties of the Type II clathrate systems A_xB_{136}(A = alkali atom; B = Si, Ge, Sn). Recent powder X-ray diffraction experiments have found the very interesting result that in Na_xSi_{136}, for increasing x in the range $0 \leq x \leq 8$ a lattice contraction occurs and that as x is increased further ($8 \leq x \leq 24$), a contrasting lattice expansion results. These observations have motivated us to study the behavior of the lattice constant and other properties as a function of guest concentration in several Type II clathrates. We present results of a density functional based study of the properties of A_xB_{136} as a function of x. Results are discussed for the x dependence of the lattice constant and for other structural and electronic properties of these materials. [1] S. Stefanoski and G. Nolas, Cryst. 1:15PM U12.00009 Light Si Based Clathrates For Thermal Energy Conversion: A First Principles Study[1] , YUPING HE, FAN SUI, SUSAN KAUZLARICH, GIULIA GALLI, UC Davis — Clathrates containing light, earth abundant elements, i.e. Si and Al, are promising materilas for thermoelectric applications, due to their low thermal conductivity, about 2 orders of magnitude smaller than that of bulk Si. However existing Si based clathrates [1] have poor electronic properties for efficient thermal energy conversion. We carried out density functional theory calculations to investigate the electronic and vibrational properties of newly synthesized type I clathrate $K_8Al_8Si_{38}$[2]. We predicted that while Al site occupancy does not substantially affect the structure of these systems, it has a strong influence on their electronic and optical properties. In particular, Al occupancy greatly influences the location of the K atoms, and the magnitude and character of the electronic gap of the clathrate (e.g. Whether direct or indirect). Our findings suggest that $K_8Al_8Si_{38}$ may have much improved electronic properties, compared to several families of clathrates [2] investigated in the recent literature.

1:27PM U12.00010 High pressure effect on structure, electronic structure and thermoelectric properties of MoS_2[1] , HUAIHONG GUO, TENG YANG, ZHIDONG ZHANG, Institute of Metal Research, Chinese academy of Sciences — We systematically study high pressure effect on the shape of the unit cell, electronic structure and transport properties of 2H-MoS_2, based on density functional calculations and the Boltzmann transport theory. Under pressure, the cross-plane lattice size decreases much faster than the in-plane one, due to the van der Waals interaction, and the size reduction becomes more difficult as external pressure exceeds 20 GPa, agreeing with experimental observation. A conversion from van der Waals to covalent bonding is seen in the calculated charge density and obtial projection of the wave functions. Concurrently, the dependence of band structure on pressure shows that a transition from semiconductor to metal occurs at 25 GPa. Band features close to the Fermi level are found to be advantageous for high values of thermopower. Our transport calculations also find pressure-enhanced electrical conductivities, high values of thermopower (up to a few hundred μV/K), and significant values of the thermoelectric figure of merit (above 0.10 for high pressure and even up to 0.65 at 25 GPa) over a wide temperature range. Our study supplies a new route to improve the thermoelectric performance of MoS_2 and of other transition metal dichalcogenides by applying hydrostatic pressure.

1:39PM U12.00011 Dimensional crossover and thermoelectric properties in $CeTe_{2-x}Sb_x$ single crystals , JONG-SOO RHYEE, Kyung Hee University, KYUNG EUN LEE, Samsungtechwin R&D Center, JAE NYEONG KIM, JI HOON SHIM, Pohang University of Science and Technology, BYEONG HUN MIN, YONG SEUNG KWON, Daegu Gyeongbuk Institute of Science and Technology — Several years before, we proposed that the charge density wave is a new pathway for high thermoelectric performance in In_4Se_{3-x} bulk crystalline materials. (Nature v.459, p. 965, 2009) Recently, from the increase of the chemical potential by halogen doped $In_4Se_{3-x}H_{0.03}$ (H=Halogen elements) crystals, we achieved high ZT (maximum ZT 1.53) over a wide temperature range. (Adv. Mater. v.23, p.2191, 2011) Here we demonstrate the low dimensionality increases power factor in $CeTe_{2-x}Sb_x$ single crystals. The band structures of $CeTe_2$ show the 2-dimensional (2D) Fermi surface nesting behavior as well as a 3-dimensional (3D) electron Fermi surface hindering the perfect charge density wave (CDW) gap opening. By hole doping with the substitution of Sb at the Te-site, the 3D-like Fermi surface disappears and the 2D perfect CDW gap opening enhances the power factor up to $x = 0.1$. With further hole doping, the Fermi surfaces become 3-dimensional structure with heavy hole bands. The enhancement of the power factor is observed near the dimensional crossover of CDW, at $x = 0.1$, where the CDW gap is maximized. This research was supported by Basic Science Research Program (2011-0021335), Mid-career Research Program (Strategy) (No. 2012R1A2A1A03005174) through the National Research Foundation of Korea (NRF) funded by the Ministry of Education, Science and Technology, and TJ Park Junior Faculty Fellowship funded by the POSCO TJ Park Foundation.

1:51PM U12.00012 Thickness dependent thermoelectric properties of $SrTiO_3/SrLaTiO_3$ and $SrZrO_3/SrLaTiO_3$ heterostructures , MASATOSHI ISHII, JOHN BANIECKI, Fujitsu Laboratories Ltd., ROBERT SCHAFRANEK, KIAN KERMAN, Harvard University, KAZUAKI KURIHARA, Fujitsu Laboratories Ltd. — Thermoelectric power generators will be required for future sensor network systems. $SrTiO_3$ (STO) [1] is one candidate thermoelectric material due to its non-toxicity and comparable power factor to Bismuth telluride. The energy conversion efficiency of $SrTiO_3$–based thermoelectric energy conversion elements has been reported to be enhanced by quantum size effects, such as the two dimensional (2D) electron gas in $SrTiO_3/SrTi_{0.8}Nb_{0.2}O_3/SrTiO_3$ [2]. Nevertheless, a complete understanding of the mechanisms for the reported increase in efficiency are missing owing to a lack of understanding of the thickness dependence of the transport properties. In the talk, we will present a study of the thickness dependence of the transport properties of $SrTiO_3/SrLaTiO_3$ and $SrZrO_3/SrLaTiO_3$ heterostructures. The $SrZrO_3/SrLaTiO_3$ interface has a large conduction band off-set of 1.9 eV [3] which can be utilized to confine electrons in a 2D quantum well. Characterization of the thermopower, conductivity, and Hall effect will be presented as a function of the $SrLaTiO_3$ thickness down to a few unit cells and the implications of the thickness dependence of the transport properties on carrier confinement and increasing the efficiency STO-based 2DEG quantum well structures will be discussed. Session U13 DCMP: Topological Insulators: Bi2Se3 and Bi2Te2Se 315 - Gregory Jenkins, University of Maryland

11:15AM U13.00001 Topological dangling bonds with large spin splitting and enhanced spin polarization on the surfaces of Bi_2Se_3 , HSIN LIN, Northeastern University, TANMOY DAS, Los Alamos National Laboratory, YOSHINORI OKADA, Boston College, MIKE C. BOYER, W. DOUG WISE, MICHELLE TOMASIK, BO ZHEN, ERIC W. HUDSON, Massachusetts Institute of Technology, WENWEN ZHOU, VIDYA MADHAVAN, Boston College, CHUNG-YUAN REN, National Kaohsiung Normal University, Taiwan, HIROSHI IKUTA, Nagoya University, Japan, ARUN BANSIL, Northeastern University — We investigate the topological surface state properties at various surface cleaves in the topological insulator Bi_2Se_3, via first principles calculations and scanning tunneling microscopy/spectroscopy (STM/STS). While the typical surface termination occurs between two quintuple layers, we report the existence of a surface termination within a single quintuple layer where dangling bonds form with giant spin splitting owing to strong spin-orbit coupling. Unlike Rashba split states in a 2D electron gas, these states are constrained by the band topology of the host insulator with topological properties similar to the typical topological surface state, and thereby offer an alternative candidate for spintronics usage. We name these new states "topological dangling-bond states." The degree of the spin polarization of these states is greatly enhanced. Since dangling bonds are more chemically reactive, the observed topological dangling-bond states provide a new avenue for manipulating band dispersions and spin-textures by adsorbed atoms or molecules. Work supported by DOE.

11:27AM U13.00002 ABSTRACT WITHDRAWN –

11:39AM U13.00003 Transient Surface Photoemission Involving Nonlinear Surface Sheet Polarization Developed on the Doped Bi_2Se_3 Topological Insulator[1] , YUKIAKI ISHIDA, HIROAKI KANTO, WALID MALAEB, SHUNTARO WATANABE, ISSP, Univ. Tokyo, CHUANGTIAN CHEN, TIPC, CAS, AKIKO KIKKAWA, YASUJIRO TAGUCHI[2], YOSHINORI TOKURA[3], CERG, RIKEN ASI, SHIK SHIN[4], ISSP, Univ. Tokyo — Time- and angle-resolved photoemission spectroscopy is performed on the doped Bi_2Se_3topological insulator. We observe unusual variation in the efficiency of photoemission from femto-to-picosecond non-equilibrium particularly when two-dimensional electron gas (2DEG) states are developed on surface, while the surface confinement potential is virtually unchanged. The results indicate that a surface sheet polarization, which is induced nonlinearly by both the photon field and inversion-symmetry-breaking field, grows in magnitude as the 2DEG states become pronounced and opens a so-called surface photoemission channel, $div\mathbf{A}$, that can be varied transiently. Matrix element effects investigated by linearly-polarized angle-resolved photoemission also supports the presence of $div\mathbf{A}$. The asymmetric charge distribution developed around vacuum-surface interface is considered as a key to understand and control Rashba splitting of the 2DEG states.

11:51AM U13.00004 High mobility topological insulator Bi2Se3 exfoliated devices with hexagonal Boron Nitride dielectrics , HADAR STEINBERG, VALLA FATEMI, LUCAS ORONA, JAVIER SANCHEZ-YAMAGISHI, MIT, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, Japan, PABLO JARILLO-HERRERO, MIT — We report electronic transport measurements on double-gated topological insulator Bi2Se3 devices. To obtain both top- and bottom-gating, we exfoliate the Bi2Se3 on standard SiO2-capped Si and coat it with an ultrathin layer of hexagonal Boron Nitride (h-BN), which serves as a dielectric for a top gate. Using both top and bottom gates, we are able to identify the individual contributions of both surfaces and the bulk channel, and show that all three channels have mobilities exceeding 1000 cm2/Vs. Our results suggest that the h-BN transfer technique holds potential for providing a future path for high quality TI density-tunable devices.

12:03PM U13.00005 Magneto-transport study of magnetically-doped Bi2Se3 , JOSEPH HAGMANN, JONATHON LEINER, DAVID HOWE, University of Notre Dame, YONGSEONG CHOI, Argonne National Laboratory, ABDEL AL-ASMADI, The Hashemite University, DAVID KEAVNEY, RICHARD ROSENBERG, Argonne National Laboratory, BRIAN KIRBY, NIST Center for Neutron Research, XINYU LIU, MARGARET DOBROWOLSKA, JACEK FURDYNA, University of Notre Dame — The interesting properties of topological insulators (TIs) arise from the zero energy gap at the Dirac point characterizing their surface states. These gapless chiral modes are attributed to spin-orbit coupling (typically very strong in TIs such as Bi2Se3), together with time reversal invariance (TRI). The introduction of magnetic dopants into a TI lattice can break TRI, providing a powerful tool for opening the gap in the Dirac cone, and for studying its consequences. In this paper we explore this phenomenon by introducing magnetic ions Mn and Fe into Bi sites in the Bi2Se3 lattice. A series of such magnetically-doped Bi2Se3 layers were grown by molecular beam epitaxy on GaAs (001) substrates, with the intention of studying the effects of such doping on the magnetic and electronic properties of this TI alloy. We discuss the results of magnetization, X-ray magnetic circular dichroism (XMCD), and extensive magneto-transport studies carried out to explore how the presence of magnetic ions in the TI lattice affects the magnetic and the electronic properties of these materials.

12:15PM U13.00006 Tuning Quantum Oscillations of Dirac Surface States on the Topological Insulator Bi_2Te_2Se by Ionic Liquid Gating[1] , JUN XIONG, YUEHAW KHOO, SHUANG JIA, ROBERT J. CAVA, NAI PHUAN ONG, Princeton University — An *in-situ* method to tune the chemical potential near the Dirac Point (DP) of a topological insulator (TI) would greatly facilitate several key experiments. However, in as-grown crystals of Bi-based TIs, the chemical potential μ lies high above the DP. Using liquid gating on 50-μm thick crystals of Bi_2Te_2Se, we demonstrate that μ can be tuned by a factor of 6 by observing changes to the Shubnikov-de Haas (SdH) period. A surprise is that the SdH amplitudes increase sharply with gating. Liquid gating allows the n=1 Landau level to be accessed, and the π-Berry phase to be determined with improved accuracy. We will discuss reversibility of liquid gating, and how we may distinguish the purely gating action from chemical reaction.

[1]Supported by NSF-MRSEC (DMR 0819860), Army Research Office (ARO W911NF-11- 1-0379) and DARPA under SPAWAR program (Grant N66001-11-1-4110).

12:27PM U13.00007 Transport studies in topological insulator Bi_2Te_2Se[1] , HELIN CAO, IRENEUSZ MIOTKOWSKI, JIFA TIAN, Department of Physics, Purdue University, YONG CHEN, Department of Physics, School of Electrical and Computer Engineering, Purdue University — Recently, 3D topological insulators, featuring spin helical topological surface states (SS), have attracted strong attention in condensed matter physics. Although the SS have been directly revealed and intensively studied by surface sensitive measurements, such as ARPES and STM, transport measurements remain challenging due to coexistence of the surface and bulk conduction channels and the sensitivity of sample surfaces to ambient exposure. We have grown high quality Bi_2Te_2Se crystals by the Bridgeman method. Resistance showed an insulating behavior followed by saturation at low temperature, indicating surface conduction. Through magnetotransport measurements, we demonstrated high mobility SS on freshly cleaved crystals. The transport signatures of surface Dirac fermions were uncovered from 2D SdH oscillations and non-linear Hall effect. We have also compared transport properties of the samples before and after exposure to air. A giant cusp in magnetoresistance at zero B field was observed after exposure. Our studies may help understand the interplay between the surface and the bulk conduction channels and the degradation of SS due to environmental exposure. We will also present some experimental results of gate tuning and thermoelectric measurements on Bi_2Te_2Se.

[1]We acknowledge support from DARPA MESO program (Grant N66001-11-1-4107).

12:39PM U13.00008 ABSTRACT WITHDRAWN –

12:51PM U13.00009 Promising topological surface states with persistent high spin polarization across Dirac point in Bi_2Te_2Se and Bi_2TeSe_2 , KOJI MIYAMOTO, AKIO KIMURA, TAICHI OKUDA, HIROKAZU MIYAHARA, HIROFUMI NAMATAME, MASAKI TANIGUCHI, Hiroshima University, SERGEY EREMEEV, Tomsk State University, EVGUENI CHULKOV, Donostia International Physics Center, OLEG TERESHCHENKO, Novosibirsk State University — Topological insulators (TIs) have attracted a great deal of atteion as key materials for spintronics technology. Among the established TIs, Bi_2X_3 (X=Se, Te) has been mostly studied because of their relatively large energy gap and the simplest topological surface state (TSS) with helical spin texture. However, an absence of the topological natures of TSS below Dirac point (E_D) has been shown by spin- and angle-resolved photoemission spectroscopy (SARPES) and scanning tunneling spectroscopy under perpendicular magnetic field. It could be a disadvantage for extending its spintronic applications. Recently, one of the ternary tetradymite compounds, Bi_2Te_2Se was shown to be a TI by the ARPES measurement. Importantly, a highly bulk resistive feature in this compound has successfully led to the observation of its surface-derived quantum oscillations in the magnetotransport experiment. We have unambiguously clarified the spin feature of TSS in Bi_2Te_2Se and Bi_2Se_2Te for the first time by our novel SARPES. The markedly high spin polarization of topological surface states has been found to be 77% and is persistent in the wide energy range across E_D in those compounds. The finding promises to extend the variety of spintoronic applications.

1:03PM U13.00010 Low frequency noise in exfoliated $Bi_{1.5}Sb_{0.4}Te_{1.7}Se_{1.3}$ field effect devices , MITALI BANERJEE, SEMONTI BHATTACHARYYA, HARIHARAN N, SUJA ELIZABETH, ARINDAM GHOSH, Department of Physics, Indian Institute of Science, Bangalore 560012, DEPARTMENT OF PHYSICS, INDIAN INSTITUTE OF SCIENCE, BANGALORE 560012 TEAM — Topological insulators are a new class of materials which have emerged as the new paradigm to study the exotic topological phases of matter. Electron transport is studied for field effect devices of $Bi_{1.5}Sb_{0.4}Te_{1.7}Se_{1.3}$ thin films, mechanically exfoliated on Si/SiO_2 substrates. The resistivity initially decreases with decreasing temperature indicating metallic-like behavior. However the resistivity shows an upturn below 13K which can be associated with the weak localization effect. The resistivity as a function of gate voltage shows hysteresis at low carrier densities and is independent of different sweep rates of the gate voltages. In addition to resistivity measurements, we have investigated low frequency noise or "1/f" noise as a function of temperature and gate voltage. The magnitude of 1/f noise increases at lower temperatures and with decreasing carrier densities. At lower carrier densities just like resistivity, noise is also saturated indicating long range disorder in the systems due to selenium vacancies. [1] M. Z. Hasan and C. L. Kane, Rev. Mod. Phys. 82, 3045 (2010) [2] E. Rossi, J. H. Bardarson, M. S. Fuhrer, and S. Das Sarma, Phys. Rev. Lett. 109, 096801 (2012)

1:15PM U13.00011 Scanning tunneling microscopy of topological insulator Bi_2Te_2Se , YINGSHUANG FU, TETSUO HANAGURI, RIKEN Advanced Science Institute, SHUHEI YAMAMOTO, KYUSHIRO IGARASHI, Tokyo Institute of Technology, HIDENORI TAKAGI, RIKEN Advanced Science Institute, University of Tokyo, TAKAO SASAGAWA, Tokyo Institute of Technology — Using scanning tunneling microscopy, we study a prototypical topological insulator Bi_2Te_2Se having suppressed bulk carrier density. Landau level states of its topological surface state remarkably exhibit hysteresis behavior, which shift in energy controllably with the limits of ramping bias, forming hysteresis loops thereafter. The observed hysteresis behavior is attributed to the interplay between a tip-induced gating effect and an impurity-generated random charging effect. This provides a new avenue to controlling the topological surface state.

1:27PM U13.00012 Characterization of surface conducting states in $Bi_{1.5}Sb_{0.5}Te_{1.7}Se_{1.3}$ topological insulator single crystals , JANGHEE LEE, JOONBUM PARK, JAE-HYEONG LEE, JUN SUNG KIM, HU-JONG LEE, Department of Physics, Pohang University of Science and Technology, Pohang 790-784, Republic of Korea — Topologically protected surface state (TSS) of a topological insulator (TI) can be described in terms of a spin-resolved Dirac band with helical-spin texture. In general, however, as-grown TIs are doped so that the surface conduction can be dominated by the bulk conduction. In this study, we minimized the bulk conduction using high-quality $Bi_{1.5}Sb_{0.5}Te_{1.7}Se_{1.3}$ TI thin single crystals, with the Fermi level lying in the bulk gap without gating. We confirmed that the weak anti-localization (WAL) effect and universal conductance fluctuations in our samples arose from the top and bottom surfaces. By back-gate tuning the WAL characteristics, we identified the TSS conducting characteristics and the coupling between the TSS and the topologically trivial two-dimensional electron gas (2DEG) states that emerged due to the band bending near the surface. The ambipolar Hall resistivity of the bottom surface was consistent with the back-gate-voltage dependence of the longitudinal resistance of the TSS. This study provides a highly coherent picture of the surface transport properties of TIs by successfully differentiating the transport of the TSS from those of the bulk conducting state and the topologically trivial 2DEG states.

1:39PM U13.00013 Two Dimensional universal conductance fluctuations in topological insulator Bi2Te2Se microribbons[1] , FENGQI SONG, ZHAOGUO LI, BAIGENG WANG, GUANGHOU WANG, Nanjing University — The universal conductance fluctuations (UCFs), one of the most important manifestations of mesoscopic electronic interference, have not yet been demonstrated for the two-dimensional surface state of topological insulators (TIs) to date. Even if one delicately suppresses the bulk conductance of TI crystals, the fluctuation of the bulk conductance still keeps competitive and difficult to be separated from the desired UCFs of the surface carriers. Here we report on the experimental evidence of the UCFs of the two-dimensional surface state in the bulk insulating Bi2Te2Se nanoribbons. The solely-B$\perp$-dependent UCF is achieved and its temperature dependence is investigated. The surface transport is further revealed by weak antilocalizations. Such quantum interference unexpectedly survives through the limited dephasing length of the bulk carriers in the ternary TI crystals. Based on the temperature-dependent scaling behavior, the electron-phonon interaction is addressed as a secondary source of the surface state dephasing. (Scientific Reports, 2, 595 (2012))

[1]We thank the National Key Projects for Basic Research of China (Grant numbers: 2013CB922103, 2010CB923400, 2011CB922103), the National Natural Science Foundation of China (Grant numbers: 11023002, 11134005, 60825402, 61176088, 11075076),

1:51PM U13.00014 Surface state transport suppression in topological insulators[1] , ANJAN A. REIJNDERS, Y. TIAN, G. POHL, I.D. KIVLICHAN, S.Y. FRANK ZHAO, Y-J. KIM, University of Toronto, S. JIA, R.J. CAVA, Princeton University, D.C. KWOK, N. LEE, S.W. CHEONG, Rutgers University, KENNETH S. BURCH, University of Toronto — An unresolved question in experimental research on topological insulators (TI) is the suppression mechanism of a TI's surface state transport. While room temperature ARPES studies reveal clear evidence of surface states, their observation in transport measurements is limited to low temperatures. A better understanding of this suppression is of fundamental interest, and crucial for pushing the boundary of device applications towards room-temperature operation. In this talk, we report the temperature dependent optical properties of the topological insulator Bi_2Te_2Se (BTS), obtained by infrared spectroscopy and ellipsometry, probing surface and bulk states simultaneously. We see clear evidence of coherent surface state transport at low temperature and find that electron-phonon coupling causes the gradual suppression of surface state transport as temperature rises to 43K. In the bulk, electron-phonon coupling enables the emergence of an indirect band gap transition, which peaks at 43K, and is limited by thermal ionization of the bulk valance band above 43K. For comparison with other resistive TIs, we also discuss the optical properties to $BiSbSe_2Te$.

2:03PM U13.00015 High-Temperature Andreev Tunneling in the Surface States of a Topological Insulator , PARISA ZAREAPOUR, ALEX HAYAT, SHU YANG FRANK ZHAO, MICHAEL KRESHCHUK, ACHINT JAIN, Department of Physics and Institute for Optical Sciences, University of Toronto, ZHIJUN XU, ALINA YANG, G.D. GU, CMP&MS Department, Brookhaven National Laboratory, SHUANG JIA, ROBERT CAVA, Department of Chemistry, Princeton University, KENNETH BURCH, Department of Physics and Institute for Optical Sciences, University of Toronto — Topological insulators (TIs) are materials with high spin-orbit coupling that possess conductive helical surface states. In order to study the exotic properties of the TI surface states, it is favorable to work with TIs that have a low bulk conductivity and exhibit insulating behavior. Bi2Te2Se has been confirmed to have a high bulk resistivity, and it still shows Shubnikov-de Haas oscillations originating from the two-dimensional surface states. We report the observation of coherent Andreev tunneling into the surface states of Bi2Te2Se in high-temperature superconductor $(Bi2Sr2CaCu2O8+\delta)$/Bi2Te2Se junctions fabricated by mechanical bonding method. The differential conductance measurements will be presented in various temperatures and magnetic fields. The characterization of the zero-bias conductance peak observed, suggests that we are tunneling into the surface states of the TI rather than the bulk states.

Session U14 GMAG DMP: Focus Session: Quantum Dynamics in Spin Ice 316 - Satoru Nakatsuji, University of Tokyo

11:15AM U14.00001 Effective S=1/2 Hamiltonians and the Quantum Spin Ice Ground State of $Yb_2Ti_2O_7$, BRUCE D. GAULIN, Department of Physics and Astronomy, McMaster University — New neutron scattering instrumentation offers unprecedented opportunities for mapping out the full dispersion and dynamic susceptibility of magnetic materials. In turn, these measurements can be exploited to determine their microscopic spin Hamiltonians in great detail. We've used these techniques to examine the exotic quantum spin ice ground state of $Yb_2Ti_2O_7$, a pyrochlore magnet, which can be thought of in terms of spins decorating a network of corner-sharing tetrahedra. In this environment, Yb^{3+}displays a ground state crystal field doublet which is very well separated from its excited states, resulting in an effective S=1/2 description for the Yb moments. It's positive Curie-Weiss constant of $\sim$ 0.5 K indicates net ferromagnetic interactions and it displays a g-tensor with XY anisotropy. However strong spin orbit effects give rise to an anisotropic exchange Hamiltonian, which can be understood in quantitative detail by modeling time-of-flight neutron scattering in a high field polarized state with spin wave theory using anisotropic exchange. The resulting Hamiltonian shows strong coupling between local z-components of spin, as in spin ice, but also substantial terms that encourage quantum fluctuations. Armed with the microscopic spin Hamiltonian, the mean field phase diagram and a range of physical properties can be calculated and compared with experiment. We see that any possible ordering is strongly suppressed relative to mean field theory by the presence of geometrical frustration, quantum fluctuations, or both; and the low temperature bulk properties are well accounted for by the effective S=1/2 Hamiltonian we determine.

11:51AM U14.00002 Spin Liquid Regimes at Nonzero Temperature in Quantum Spin Ice: Extension to Finite Temperature of the Phase Diagram of Pyrochlore Magnets , LUCILE SAVARY, University of California, Santa Barbara, LEON BALENTS, Kavli Institute for Theoretical Physics, University of California, Santa Barbara — Many quantum spin liquid theories described so far have not yet benefitted of much attention as regards how they should be interpreted at finite temperature. With growing interest in quantum spin liquid phases and increasingly many material candidates, it is becoming all the more imperative to tackle this matter. Here, we address the finite temperature properties of quantum spin ices, for which quantum spin liquid regimes have been predicted. In particular, we extend to finite temperature the two-dimensional phase diagram found in [PRL 108, 037202 (2012)] using an extension of the gauge mean field theory first introduced in the aforementioned paper. We find that the *quantum* spin liquid features of the $U(1)$ QSL and Coulomb Ferromagnet survive at nonzero temperature and that a first order transition to an entropy-dominated classical spin liquid regime, similar to the classical spin ice liquid, occurs at temperatures lower than a naïve scaling with the strength of the interactions might predict. We discuss our results in light of recent experiments on $Yb_2Ti_2O_7$, where features reminiscent of the well-known classical spin ice phase were reported.

12:03PM U14.00003 Time domain terahertz study of quantum spin ice $Yb_2Ti_2O_7$, LIDONG PAN, YUAN WAN, CHRIS M. MORRIS, Department of Physics and Astronomy, Johns Hopkins University, Baltimore, Maryland 21218, USA, KATE A. ROSS, Department of Physics and Astronomy, McMaster University, Hamilton, Ontario, L8S 4M1, Canada, S.M. KOOHPAYEH, The Institute for Quantum Matter, Department of Physics and Astronomy, Johns Hopkins University, Baltimore, MD 21218 USA, BRUCE D. GAULIN, Department of Physics and Astronomy, McMaster University, Hamilton, Ontario, L8S 4M1, Canada, OLEG TCHERNYSHYOV, N. PETER ARMITAGE, Department of Physics and Astronomy, Johns Hopkins University, Baltimore, Maryland 21218, USA — We report the time domain terahertz spectroscopy study of the quantum spin ice material $Yb_2Ti_2O_7$. Temperature and magnetic field dependence of the transmission spectrum was obtained. Several spin resonance absorption peaks are observed in magnetic field. The results are discussed in comparison with the recently proposed theory of the quantum string excitations in this material.

12:15PM U14.00004 Hidden order in Yb2TI2O7 , ROBERT D'ORTENZIO, Department of Physics and Astronomy, McMaster University, HANNA DABKOWSKA, Brockhouse Institute for Materials Research, SARAH DUNSIGER, Physik-Department E21, Technische Universität München, TATSUO GOKO, Department of Physics, Columbia University, JAN KYCIA, Department of Physics and Astronomy, University of Waterloo, LIAN LIU, Department of Physics, Columbia University, TERESA MEDINA, TIMOTHY MUNSIE, Department of Physics and Astronomy, McMaster University, DAVID POMARANSKI, Department of Physics and Astronomy, University of Waterloo, KATE ROSS, Department of Physics and Astronomy, McMaster University, YASUTOMO UEMURA, Department of Physics, Columbia University, TRAVIS WILLIAMS, Department of Physics and Astronomy, McMaster University, GRAEME LUKE, Canadian Institute for Advanced Research, McMaster University — We report low temperature specific heat and positive muon spin rotation (μ-SR) measurements of both polycrystal and single crystal $Yb_2Ti_2O_7$. Our zero field (ZF) μ-SR shows little spin relaxation temperature dependence in the polycrystal $Yb_2Ti_2O_7$, contrast to previously reported results. We observe no collinear ferromagnetic order, rather a hidden order ground state where spin fluctuations remain dynamic down to 16 mK. Single crystal $Yb_2Ti_2O_7$ zero field μ-SR measurements with the crystallographic <111> direction parallel to the initial muon polarization show small but measurable temperature dependence. In addition, our transverse field (TF) μ-SR measurements show the spin susceptibility undergoes a distinct change at temperatures corresponding to the magnetic transition measured in the specific heat.

12:27PM U14.00005 Single crystals of Yb2Ti2O7 grown by the Optical Floating Zone technique: naturally "stuffed" pyrochlores?[1] , KATE ROSS[2], McMaster University, THOMAS PROFFEN, SNS, Oak Ridge National Laboratory, HANNA DABKOWSKA, McMaster University, JEFFERY QUILLIAM, Universit Paris-Sud, LUKE YARASKAVITCH, JAN KYCIA, University of Waterloo, BRUCE GAULIN, Brockhouse Institute for Materials Research, McMaster University — In the "quantum spin ice" pyrochlore material Yb2Ti2O7, Yb3+ ions are coupled to each other via Ising-like ferromagnetic exchange, creating a situation similar to the highly frustrated classical spin ice compounds, but with significant quantum fluctuations. The ground state of the model resides near two exotic and disordered "quantum spin liquid" phases. The experimentally observed ground state of Yb2Ti2O7 is, however, controversial in the literature. Most samples, except one crystal which orders ferromagnetically, show disordered states with varying properties. The controversy is likely to be related to the presence of structural defects of an unspecified type that are known to cause sample-dependence of the low temperature specific heat, particularly in the single crystal samples. Using neutron powder diffraction, we investigated one pulverized single crystal of Yb2Ti2O7 grown by the standard Optical Floating Zone method, and found evidence that 2.3% excess Yb3+ ions reside on the non-magnetic Ti4+ sites, despite perfect stoichiometry of the starting material. This type of defect lattice is known as a "stuffed" pyrochlore structure. The effect of the stuffed spins is an open question which can now be investigated in detail.

12:39PM U14.00006 $Yb_2Sn_2O_7$: a quantum critical point approaching the ferromagnetic ordering from the quantum spin liquid side[1] , ZHILING DUN, University of Tennessee, HAIDONG ZHOU, University of Tennessee, National High Magnetic Field Laboratory, Florida State University, ALANNAH HALLAS, HARLYN SILVERSTEIN, University of Manitoba, YIMING QIU, NIST Center for Neutron Research, University of Maryland, JOHN COPLEY, NIST Center for Neutron Research, JASON GARDNER, NIST Center for Neutron Research, Indiana University, EUNSANG CHOI, National High Magnetic Field Laboratory, Florida State University, CHRISTOPHER WIEBE, National High Magnetic Field Laboratory, Florida State University, University of Manitoba, University of Winnipeg — The neutron scattering measurements on pyrochlore $Yb_2Sn_2O_7$ show no long range ordering down to 0.05 K but appearance of diffuse scattering, low energy spin wave excitations, and temperature-independent relaxation time below 2 K, which indicate the system enters a quantum dynamics region with ferromagnetic interactions. The AC susceptibility further shows that $Yb_2Sn_2O_7$ enters a "spin freezing" region below 0.14 K. Our results suggest that $Yb_2Sn_2O_7$ sits on a quantum critical point by approaching the ferromagnetic ordering from the spin liquid side.

12:51PM U14.00007 Not so accidental degeneracies: origin of dimensional-reduction in the Quantum Spin Ice $Yb_2Ti_2O_7$, LUDOVIC JAUBERT, Okinawa Institute of Science and Technology, HAN YAN, Northwestern University, OWEN BENTON, NIC SHANNON, Okinawa Institute of Science and Technology — Despite being the best-characterised example of a "quantum spin ice" [1], $Yb_2Ti_2O_7$ remains an enigma. One of its most striking, and puzzling, features are the diffuse, rod-like structures seen in quasi-elastic neutron scattering [2]. These suggest that spin fluctuations in $Yb_2Ti_2O_7$ decouple into independent Kagome planes, even though magnetic ions occupy a fully three-dimensional pyrochlore lattice [3]. Here, we use a combination of lattice gauge theory, spin-wave calculations and Monte Carlo simulation, to show how the dimensional-reduction seen in $Yb_2Ti_2O_7$ follows from a two-dimensional branch of excitations "inherited" from a nearby phase transition. This analysis sheds new light on ground state selection in a wide range of rare-earth pyrochlore oxides, including the model "order-by-disorder" system $Er_2Ti_2O_7$.

1:03PM U14.00008 Thermodynamic properties of 3-dimensional quantum antiferromagnets[1] , RAJIV R.P. SINGH, Physics Department, University of California at Davis, CA 95616, JAAN OITMAA, School of Physics, The University of New South Wales, Sydney 2052, Australia, MICHEL J.P. GINGRAS, Department of Physics and Astronomy, University of Waterloo, Waterloo, Ontario, N2L 3G1, Canada — We present systematic calculations of thermal properties of 3-dimensional quantum antiferromagnets, in the thermodynamic limit, using series expansions. For this purpose, High Temperature Expansions (HTE) are supplemented by Numerical Linked Cluster (NLC) Expansions.[2] These expansions provide essentially exact calculations of thermodynamic properties of the system at (i) all fields at high temperatures and (ii) at all temperatures at high fields. In addition, we show that for classical exchange spin-ice model defined on the pyrochlore lattice, the first order NLC leads to the Pauling approximation, which gives even the zero-field ground state entropy to about one percent accuracy. Thus, these calculations are accurate over a wide parameter range. Results are presented and compared with a variety of experimental systems including pyrochlore materials $Yb_2Ti_2O_7$ and $Er_2Ti_2O_7$ and the Hyper Kagome material $Na_4Ir_3O_8$

1:15PM U14.00009 Seeing the light: Observing photons in quantum spin ice , OWEN BENTON, Okinawa Institute of Science and Technology, OLGA SIKORA, National Taiwan University, NIC SHANNON, Okinawa Institute of Science and Technology — Spin ice, with its magnetic monopole excitations, is perhaps the best studied example of a classical spin liquid. Quantum mechanical tunnelling between the classical ground states of spin ice leads to an exciting new scenario- a quantum spin liquid ground state with emergent photon excitations [1, 2]. Here we explore how this "artificial electromagnetism" would manifest itself in neutron scattering experiments on putative "quantum spin ice" materials. Using lattice gauge theory we make explicit predictions for the ghostly, linearly dispersing magnetic excitations which are the "photons" of this emergent electromagnetism. We find that "pinch points," which are the signal feature of a classical spin ice, fade away as the system approaches its zero-temperature ground state. The predictions of this field theory are shown to be in excellent quantitative agreement with quantum Monte Carlo simulations at zero temperature [3].

1:27PM U14.00010 Dynamical spectra of quantum strings in quantum spin ice , WESLEY FUHRMAN, YUAN WAN, OLEG TCHERNYSHYOV, Johns Hopkins — String-like excitations in quantum spin-ice are a fascinating manifestation of quantum fluctuations and may be observable in materials such as $Yb_2Ti_2O_7$ and $Pr_2Zr_2O_7$. We study quantum spin-ice under external magnetic fields on both the checkerboard and pyrochlore lattice for experimentally relevant conditions. We show that excitations in quantum spin ice may be string-like, and that stronger quantum fluctuations reduce string tension and lead to deconfined monopoles. Additionally, we discuss the crossover from strings to magnons in the high-field regime. We provide predictions for observing strings via inelastic neutron scattering and THz spectroscopy.

1:39PM U14.00011 Quantum Fluctuations in Spin-Ice-Like $Pr_2Zr_2O_7$[1] , JIAJIA WEN, IQM, JHU, KENTA KIMURA, SATORU NAKATSUJI, ISSP, University of Tokyo, COLLIN BROHOLM, IQM, JHU; NCNR, NIST; Neutron Science Directorate, ORNL, MATTHEW STONE, Neutron Science Directorate, ORNL, EIJI NISHIBORI, HIROSHI SAWA, Dept of Applied Physics, Nagoya University — We report the experimental evidence of spin-ice-like correlation and quantum fluctuation in the rare earth pyrochlore $Pr_2Zr_2O_7$. Low temperature magnetization together with high energy inelastic neutron scattering spectrum reveal the single ion crystal field ground state of Pr^{3+} is a non-Krammer's doublet with local <111> anisotropy. Heat capacity and magnetic susceptibility data show no evidence of long range ordering down to 50 mk. The magnetic interaction energy scale is estimated from AC magnetic susceptibility data where an activation energy gap of 1.6 K is extracted from T-dependent relaxation time. The wave vector dependence of quasi-elastic neutron scattering at 0.1 K resembles that of exchange spin ice, including well-defined pinch points. This indicates the 2-in 2-out ice rule is satisfied over the time scale set by the instrumental energy resolution. In contrast, inelastic scattering with energy transfer of 0.25 meV does not show pinch pints, which suggests these fluctuations break the ice rule. The spectral weight of the elastic scattering accounts for less than 10% of the total scattering from the ground state doublet, providing evidence for the strong quantum fluctuation.

1:51PM U14.00012 Universal monopole scaling near transitions from the Coulomb phase , STEPHEN POWELL, Nordita — Certain frustrated systems, such as spin ice and dimer models, exhibit a Coulomb phase at low temperatures, with power-law correlations and fractionalized monopole excitations. Applied perturbations (external field, pressure, etc.) can drive a transition to a phase where the monopoles become confined. I will present a general analysis of behavior in the vicinity of such critical points, incorporating the effects of a nonzero density of thermal monopoles. Scaling theory allows one to arrive at universal results for the crossover phenomena, which can be tested in numerics or experiment. I will also present Monte Carlo results that confirm these predictions for two particular transitions in spin ice.

2:03PM U14.00013 Investigation of the Magnetic Properties in the Pyrochlore $Pr_2Sn_2O_7$[1] , ELIZABETH GREEN, T. HERRMANNSDÖRFER, R. SCHÖNEMANN, Z. WANG, M. UHLARZ, J. WOSNITZA, Hochfeld-Magnetlabor Dresden (HLD), Helmholtz-Zentrum Dresden-Rossendorf, Germany, H.D. ZHOU, Dept. of Physics & Astronomy, University of Tennessee, Knoxville TN, USA — Pyrochloric compounds are best known for their remarkable magnetic properties, particularly the possibility to generate magnetic monopoles excitations at low temperatures. Compared to the A^{3+} ions in the spin ice compounds $A_2Ti_2O_7$ (where A = Ho or Dy), the Pr^{3+} ions in $Pr_2Sn_2O_7$ have a smaller magnetic moment (2.6 μ_B/Pr [1]). This ultimately leads to quantum fluctuations that suppress the spins' ability to freeze [2]. AC susceptibility measurements were performed on a polycrystalline $Pr_2Sn_2O_7$ sample to probe its dynamic ground state for temperatures down to 11 mK. Preliminary results indicate a narrow distribution of relaxation rates which, as evidenced by neutron experiments [3], are governed by quantum tunneling between states. In addition, relaxation times extracted from isothermal frequency sweeps were found, within error, to be temperature independent below 1 K. Future measurements include specific heat from which the field-dependence of the magnetic monopole densities may be extracted.

Session U15 GPC: Focus Session: The Physics of Climate 317 - Robert Behringer, Duke University

11:15AM U15.00001 The New APS Topical Group on the Physics of Climate: History, Objectives and Panel Discussion , JAMES BRASSEUR, Penn State University, ROBERT BEHRINGER, Duke University — The GPC Chair will introduce the new APS Topical Group on the Physics of Climate (GPC), describe its history and objectives, and introduce the current GPC leadership before opening the floor to a panel discussion. The GPC resulted from two petitions that emerged from the controversy that followed the APS Statement on Climate Change (see APS website). The two proposals were merged and an organization committee formed by the APS leadership. After a long organizational period in 2011, the GPC bylaws were finalized with the following key objective: *The objective of the GPC shall be to promote the advancement and diffusion of knowledge concerning the physics, measurement, and modeling of climate processes, within the domain of natural science and outside the domains of societal impact and policy, legislation and broader societal issues. The objective includes the integration of scientific knowledge and analysis methods across disciplines to address the dynamical complexities and uncertainties of climate physics.* The GPC Invited and Focus Sessions at this March meeting are the inaugural GPC events. The Program Committee Chair will moderate a panel between the attending GPC leadership and audience to solicit suggestions for potential future GPC events that advance the GPC objectives.

11:27AM U15.00002 Direct Statistical Simulation of Climate[1] , BRAD MARSTON, Brown University — Non-equilibrium statistical mechanics opens up the possibility of modeling climate directly,[2] bypassing the traditional approach of accumulating statistics from lengthy numerical simulations. One way to implement such Direct Statistical Simulation (DSS) is by systematic expansion in equal-time cumulants.[3] Essential physics of the general circulation can be illustrated with idealized 1- and 2-layer models of the atmosphere.[4] A truncation at second order in the hierarchy of cumulants is equivalent to retaining the interaction between zonal mean flows and eddies. Eddy-eddy interactions appear at higher orders, but care must be taken to keep the higher-order expansions realizable with non-negative probability distribution functions. Live demonstrations of models, and their statistical mechanical solution, will be performed. Possible effects of polar amplification of warming, due to the melting of arctic sea ice, on the mid-latitude jet stream will be illustrated.

11:39AM U15.00003 Atmospheric Lifetimes and Radiative Forcing of CFC-11 and CFC-12 , KENNETH MINSCHWANER, New Mexico Institute of Mining and Technology, LARS HOFFMANN, Forschungszentrum Jülich, ALEX BROWN, University of York, UK, MARTIN RIESE, ROLF MÜLLER, Forschungszentrum Jülich, PETER BERNATH, Old Dominion University — Atmospheric lifetimes for chlorofluorocarbons (CFCs) are important for interpreting their temporal trends and for evaluating their impact on stratospheric chemistry and radiative forcing of climate. The lifetimes of CFC-11 and CFC-12 have been evaluated using global observations of their stratospheric distributions from satellite-based instruments between the period 1992 and 2010. The CFC data sets are from the Cryogen Limb Array Etalon Spectrometer (CLAES), the Cryogenic Infrared Spectrometers and Telescopes for the Atmosphere (CRISTA-1 and CRISTA-2), the Michelson Interferometer for Passive Atmospheric Sounding (MIPAS), and the Atmospheric Chemistry Experiment (ACE). Stratospheric loss rates were calculated using an ultraviolet radiative transfer code with updated molecular cross section and solar irradiance data. Infrared radiative forcings (net flux changes at the tropopause) were determined using CFC distributions from the satellite observations.

11:51AM U15.00004 A cloud microphysical mechanism linking solar activity, atmospheric electricity, and climate[1] , BRIAN TINSLEY, Physics, Space Science, UTDallas — The electrical current density from the ionosphere to the surface changes by tens of percent on the 11-year solar cycle and during transient solar events. This external forcing is accompanied by similar changes due to thunderstorm variability and atmospheric aerosols. The current density deposits space charge in gradients of conductivity associated with stratified clouds and aerosol layers. The space charge, which attaches to droplets and aerosol particles, can be carried deep into clouds by updrafts, and it affects collision rates between droplets and aerosol particles. The most important of these for cloud microphysics are collisions of cloud condensation nuclei (CCN) and ice forming nuclei (IFN) with droplets. These collision rate changes during in-cloud scavenging affect the concentrations of CCN and IFN and the rate of contact ice nucleation. Increases in CCN concentration in deep convective storms have recently been shown to decrease initial precipitation and invigorate the storm with extra release of latent heat of freezing from water not precipitated but carried above the freezing level. The changes in latent heat release account for several sets of correlations of storm vorticity changes with independent inputs that affect the current density. Such dynamical changes can result in regional climate change. A review of models of electrical effects on cloud microphysics, and of observed correlations which support the mechanism, will be presented.

12:03PM U15.00005 Theory of Arctic Sea Ice Loss: Trends, Noise and Bifurcations , JOHN WETTLAUFER, WOOSOK MOON, SAHIL AGARWAL, Yale University — Within the framework of lower order thermodynamic theories for the climatic evolution of Arctic sea ice we isolate the conditions required for the existence of stable seasonally- varying solutions, in which ice forms each winter and melts away each summer. This is done by constructing a two-season model from a continuously evolving theory and showing that seasonally-varying states are unstable under constant annual average short-wave radiative forcing. However, dividing the summer season into two intervals (ice covered and ice free) provides sufficient freedom to stabilize seasonal ice. Perturbation theory shows that the condition for stability is determined by the timing of when the ice vanishes in summer and hence the relative magnitudes of the summer heat flux over the ocean versus over the ice. This scenario is examined within the context of greenhouse gas warming, as a function of which stability conditions are discerned, and interpreted within the framework of a quantification of the noise extracted from satellite data using multifractal detrended fluctuation analysis.

12:15PM U15.00006 Coupling of ocean circulation and sea ice , D.A. KURTZE, Saint Joseph's University, D. S. COMEAU, K. GIMRE, J.M. RESTREPO, University of Arizona — We propose a simple model of the coupling between oceanic circulation and sea ice dynamics on long time scales. The model begins with a one-dimensional Budyko-Sellers energy balance model of ice-albedo feedback, with a linearized temperature dependence of outgoing longwave radiation. This sits atop a box model of ocean circulation, with conventional thermohaline forcing except that surface heat exchange occurs via the Budyko-Sellers model. The ocean and the ice sheet are coupled via advection and plastic flow of ice, and by the thermodynamics of the ice/seawater interface. We use this model to assess how (and by what mechanisms) ocean circulation and ice sheet dynamics affect one another, primarily to investigate the role played by changes in solar input and greenhouse gas forcing, e.g. in the Snowball Earth scenario.

12:27PM U15.00007 Ocean Circulation and its Role in Global Warming , GEOFFREY VALLIS, Princeton University — The surface of the planet is warming because of increased greenhouse gases in the atmosphere. To predict the rate of increase we need to understand how much heat and carbon dioxide are taken up by the ocean. This in turn requires an understanding of both turbulent processes in the upper ocean and the deep, quasi-laminar, overturning circulation. The timescale for the ocean to fully equilibrate to increased greenhouse gases is likely much longer than the timescale on which fossil fuels will still be readily available, and this has important ramifications for what we mean by climate sensitivity. I will discuss these issues with an emphasis on the physical processes of the ocean.

1:03PM U15.00008 Sea surface temperature and short term climate predictability , CONSTANTIN ANDRONACHE, Boston College — Atmospheric processes have a relatively short memory of initial conditions of about two weeks for detailed daily weather prediction. Nevertheless, skilful seasonal forecast is possible in the presence of slow varying boundary conditions (BC) of the atmosphere, such as sea surface temperature anomalies (SSTA) over large oceanic regions. These conditions typically evolve on a much slower time scale than daily weather events and atmospheric predictability can be increased as long as the future evolution of such BC can be predicted. Given the importance of SSTA in the interaction between the ocean and atmosphere, it is of interest to investigate the nature of temporal persistence of large-scale SSTA in the global ocean. We use the global SSTA and investigate possible sources of predictability at seasonal time scale and its impact in various regions of the ocean. Data used are the NOAA Extended Reconstructed Sea Surface Temperature (SST). We show that: 1) SSTA has a persistence that depends largely on regional location in the global ocean; 2) A given SSTA distribution from a particular month, can have corresponding similar configurations in the past, largely due to the recurrence of ENSO events which affect SSTA distribution over vast regions of the global ocean.

1:15PM U15.00009 Comparing the Standard Deviation from the Average Seasonal Surface Temperature Signal for Fourteen Years of Hourly Surface Temperature Data as Recorded at Twenty-Five Stations across the United States of America , JOSEPH TROUT, Richard Stockton College of NJ — In this project, Wavelet analysis was used to analyze and filter fourteen years of hourly temperature data recorded at twenty-five stations across the United States of America. The temperature records where filtered using a fast, discrete wavelet transform, keeping the parts of the signal with periods of approximately twelve months. From these filters signals an average seasonal temperature pattern was produced for each station. The standard deviation for each year at every station was then computed. The trends of the standard deviations were examined for each station for evidence of climate change. Wavelet analysis was used because of the ability of wavelet analysis to analyze both periodic and non-periodic behavior at different time or length scales.

1:27PM U15.00010 Dust shatters like glass: Implications for the climate forcing of mineral dust aerosols , JASPER KOK, Cornell University — Soil-derived mineral dust aerosols impact climate through interactions with clouds, ecosystems, and radiation, which contributes substantially to uncertainties in understanding past and future climate changes. One of the causes of this large uncertainty is that the size distribution of emitted dust aerosols is poorly understood. In fact, a compilation of measurements indicates that regional and global circulation models overestimate the emitted fraction of clay dust aerosols (< 2 μm diameter) by a factor of $\sim 2-8$. I resolve this discrepancy by deriving a simple theoretical expression for the emitted dust size distribution that is in excellent agreement with measurements. This expression is based on the analogy of dust emission with the scale-invariant fragmentation of brittle materials such as glass. Since regional and global circulation models are usually tuned to the shortwave radiative effect of dust, which is dominated by clay aerosols, these findings suggest that models have substantially underestimated the emission of larger silt (> 2 μm diameter) aerosols, which tend to produce a net warming effect. I show that this underestimation of silt aerosol emission has implications for the effect of dust on regional and global climate.

1:39PM U15.00011 Investigation of Solar Cyclic and Climatic Trends in Upper Atmospheric Hydrogen Distributions , SUSAN NOSSAL, EDWIN MIERKIEWICZ, FRED ROESLER, Physics Department, University of Wisconsin-Madison, L. QIAN, S. SOLOMON, ALAN BURNS, High Altitude Observatory, National Center for Atmospheric Research — We will discuss work in progress to better understand solar cyclic and climatic influences on hydrogenous species budgets and distributions from both an observational and modeling perspective. Our Fabry-Perot observations of upper atmospheric hydrogen emissions during solar cycle 23 and during three solar minima (1985, 1997, 2006-2008) establish a reference data set of highly precise, consistently calibrated, thermospheric + exospheric hydrogen column emission observations from Northern mid-latitudes that can be used to compare with future observations and with atmospheric models. We will also discuss use of the National Center for Atmospheric Research's global mean model for sensitivity studies to investigate the response of thermospheric hydrogen to a doubling of carbon dioxide and methane. The results from this study suggest a strong solar cycle dependence and that carbon dioxide cooling may have a greater impact upon the changes in the upper atmospheric hydrogen distribution at solar minimum than do methane increases.

1:51PM U15.00012 Using multiple equilibria in precipitation to understand self-aggregation of deep tropical convection in a warming climate[1] , SHARON SESSIONS, STIPO SENTIC, DAVID RAYMOND, New Mexico Institute of Mining and Technology — Understanding mechanisms of convective organization is currently an important problem in tropical meteorology. Recent numerical simulations show that the tendency for deep tropical convection to self-aggregate increases as sea surface temperatures (SSTs) increase. This has significant implications for hurricane genesis in a warming climate. Investigating the conditions over which convection self-aggregates requires large domains and is therefore computationally expensive. An alternative approach utilizes the analogy between multiple equilibria in limited domain simulations, and the dry and precipitating regions in a large domain with self-aggregated convection. Multiple equilibria refers to a steady state which either exhibits a completely dry troposphere or persistent precipitating deep convection under identical forcing conditions. The large scale circulation is parameterized based on the assumption that horizontal gradients in temperature are small in the tropics. Understanding the mechanisms which permit multiple equilibria on small domains is a computationally economic approach to understanding self-aggregation. We show how multiple equilibria depend on SSTs, and thus provide insight to self-aggregation in a warming climate.

Session U16 GMAG DMP: Focus Session: Magnetic Molecules and Antiferromagnetic Chains

318 - Andrew Kent, New York University

11:15AM U16.00001 Transverse Field and Random-Field Ising Ferromagnetism in Mn_{12}-acetates[1] , PRADEEP SUBEDI, New York University — Single molecule magnets (SMMs) single crystals can exhibit long range ferromagnetic order associated with intermolecular interactions, principally magnetic dipole interactions. With their high spin ($S \sim 10$) and strong Ising-like magnetic anisotropy, they are model materials to the study of physics associated with Transverse-Field Ising Ferromagnet Model (TFIFM). We have measured magnetic susceptibility of single crystals of the prototype SMM, Mn_{12}-acetate, and of a new high-symmetry variant, Mn_{12}-ac-MeOH. At zero transverse field the inverse susceptibility of both SMMs is found to accurately follow a Curie-Weiss law with an intercept at a non-zero temperature $T_{cw} \sim 0.9$ K, indicating a transition to a ferromagnetic phase due to dipolar interactions. With increasing transverse field, the susceptibility and the Curie-Weiss temperature decreases due to increase in spin fluctuations but the nature of the decrease is very different in the two materials. We find that in Mn_{12}-ac-MeOH, the suppression of ferromagnetism by the transverse field is consistent with TFIFM, while the suppression of ferromagnetism by the transverse field is considerably more rapid in Mn_{12}-acetate. Previous studies show that due to solvent disorder Mn_{12}-acetate has an intrinsic distribution of discrete tilts of the molecular magnetic easy axis from the global easy axis of the crystal. Thus with the application of transverse field, the molecules with tilted easy axis experience an additional field along their easy axis and give rise to a distribution of random-fields that further destroys the long-range order, suggesting that this prototypical molecular magnet is a realization of Random-Field Ising Ferromagnet (RFIFM).

[1]Work performed in collaboration with: A. D. Kent, Physics Dept., NYU, Bo Wen, M. P. Sarachik, Physics Dept., CCNY, CUNY, Y. Yeshurun, Physics Dept., Bar Ilan U, A. J. Millis, Physics Dept., Columbia U, and G. Christou, Chemistry Dept., U of Florida.

11:51AM U16.00002 Geometric-phase interference in a Mn_{12} single-molecule magnet with four-fold rotational symmetry[1] , SPENCER ADAMS, EDUARDO H. DA SILVA NETO, SAITI DATTA, JOHN WARE, Department of Physics, Amherst College, Amherst, MA 01002, CHRISTOS LAMPROPOULOS, GEORGE CHRISTOU, Department of Chemistry, University of Florida, Gainesville, FL, YURI MYAESOEDOV, ELI ZELDOV, Department of Condensed Matter Physics, The Weizmann Institute of Science, Rehovot, Israel — We study the magnetic relaxation rate Γ of the single-molecule magnet Mn_{12}-tBuAc as a function of magnetic field component H_T transverse to the molecule's easy axis. When the spin is near a magnetic quantum tunneling resonance, we find that Γ increases abruptly at certain values of H_T. These increases are observed just beyond values of H_T at which a geometric-phase interference effect suppresses tunneling between two excited energy levels. The effect is washed out by rotating H_T away from the spin's hard axis, thereby suppressing the interference effect. Detailed numerical calculations of Γ using the known spin Hamiltonian accurately reproduce the observed behavior. These results are the first experimental evidence for geometric-phase interference in a single-molecule magnet with true four-fold symmetry. Furthermore, the results demonstrate that geometric-phase-interference effects can play a role in the thermally assisted tunneling regime.

12:03PM U16.00003 Synthesis and spectroscopic characterization of the single molecule magnet Mn_{12}-acetate[1] , SHI YUAN, YEWON GIM, S.L. COOPER, Department of Physics and Frederick Seitz Materials Research Laboratory, University of Illinois at Urbana-Champaign — The single molecule magnet $[Mn_{12}O_{12}(CH_3COO)_{16}(H_2O)_4]\cdot 2CH_3COOH\cdot 4H_2O$ (abbreviated as Mn_{12}-acetate) system is currently of great interest because it exhibits a number of fascinating properties, such as quantum tunneling of magnetization and unusual relaxation behavior. High-quality single crystals of Mn_{12}-acetate were grown and characterized by X-ray diffraction and magnetization measurements. Room temperature micro-Raman (inelastic light) scattering results on these crystals show phonon spectra consistent with earlier measurements. The frequencies of several Mn-O phonon modes exhibit anomalous behavior as a function of temperature. Studies of the Raman active phonons as functions of magnetic field and pressure are being conducted to better understand the role of different phonons in magnetic quantum tunneling in this system.

12:15PM U16.00004 B and C doped Cuboctohedral Mn_{13} Clusters with Giant Magnetic Moments , PURU JENA, MENGHAO WU, Physics Department, Virginia Commonwealth University, Richmond, VA 23284, PROF.JENA TEAM — Using first-principles calculations based on gradient corrected density functional theory we show that an otherwise distorted icosahedric Mn_{13} ferrimagnetic cluster, when doped with six B or C atoms, transforms into a ferromagnetic cuboctahedral cluster with a magnetic moment that is an order of magnitude larger than that of the pure Mn_{13} cluster. The origin of this magnetic transition is attributed to the change in the Mn-Mn interatomic distance resulting from the structural transformation. These doped clusters remain ferromagnetic with giant moments even after removing a B or C atom. However, similar doping with N atom does not lead to ferromagnetic ordering and $Mn_{13}N_6$ remains ferrimagnetic with a magnetic moment of only 3 μ_B, just as in its parent Mn_{13} cluster.

12:27PM U16.00005 Geometry and magnetic structure variation in manganese-oxide clusters determined by a self-consistent, LCAO method[1]

, KRISTEN WILLIAMS, US Army Research Lab, Aberdeen Proving Ground, MD 21005, JOSEPH HOOPER, Dept. of Physics, Naval Postgraduate School, Monterey, CA 93943 — *Ab initio* simulations are used to study the variation in geometry and magnetic structure in Mn_xO_y (x =3,4; y =1,2) clusters. The groundstate wavefunctions for clusters with different magnetic coupling (ferromagnetic, ferrimagnetic and antiferromagnetic) are modeled with linear combinations of atomic orbitals (LCAOs). Self-consistent energies for different spin isomers are calculated by constraining the magnetic moments of Mn atoms constituting each basis AO. The ferrimagnetic and antiferromagnetic ground-state structures of Mn_xO_y are 0.16–1.20 eV lower in energy than their ferromagnetic isomers. The presence of oxygen thus stabilizes low-spin isomers relative to the preferred high-spin ordering of bare Mn_3 and Mn_4. Each cluster has a preferred overall magnetic moment, and no evidence is seen of competing states with different spin multiplicities. However, non-degenerate isomags (clusters that possess the same spin multiplicity but different arrangements of local moments) do contribute to peak broadening observed in negative-ion photoelectron spectra. Proper accounting for all possible isomags is shown to be critical for accurate comparison with experimental spectra.

12:39PM U16.00006 Exploring Magnetic Interactions of an Mo_3O_{13} Trimer Containing Compound: $La_5Mo_6O_{21}$

, WILLIAM PHELAN, The Johns Hopkins University, RACHEL BEAL, Northwestern University, JAMES NEILSON, JOHN SHECKELTON, PATRICK COTTINGHAM, The Johns Hopkins University, ANNA LLOBET, Los Alamos National Laboratory, TYREL MCQUEEN, The Johns Hopkins University — When searching for exotic magnetic ground states, it is often useful to seek out materials with certain geometric networks such as: triangular, kagome, and even square lattices with uniform magnetic exchange. Recently, the formation of a condensed valence bond state was proposed to explain the physical properties of $LiZn_2Mo_3O_8$. This low-temperature ground state emanates from the interactions of one unpaired electron residing on the Mo_3O_{13} magnetic subunits. Thus, compounds containing related Mo_3O_{13} subunits may prove to be a fertile playground for the study of magnetic interactions between these molecule-like clusters. Earlier structural reports of $La_5Mo_6O_{21}$ showed that this compound was built from these subunits, as well as, 1-D "double lambda" perovskite-like MoO_6 octahedra. The Mo atoms residing on the Mo_3O_{13} trimers and the double lambda units have oxidation states of 4+ and 5+, respectively. Consequently, the magnetic response and entropy loss ca. 10 K are likely due to the magnetic interactions between the double lambda units and not the Mo_3O_{13} trimers. In this presentation, the analysis of the total neutron scattering of $La_5Mo_6O_{21}$ will be used to draw correlations between the structure and the properties.

12:51PM U16.00007 Magnetic Response of Mn(III)F(salen) at Low Temperatures[1]

, J.-H. PARK, C.C. BEEDLE, NHMFL, O.N. RISSET, M.J. ANDRUS, D.R. TALHAM, Dept. Chem., Univ. Florida, M.K. PEPRAH, E.S. KNOWLES, M.W. MEISEL, Dept. Phys. and NHMFL, Univ. Florida, M. SHIDDIQ, S. HILL, Dept. Phys. and NHMFL, Florida State Univ., A. PODLESNYAK, G. EHLERS, S.E. NAGLER, Quantum Condensed Matter Division, ORNL — Due to a report suggesting Mn(III)F(salen), salen = $H_{14}C_{16}N_2O_2$, is a $S = 2$ Haldane system with $J/k_B = 50$ K and no long-range order down to 2 K,[2] we have studied its magnetic response. Torque magnetometry, down to 20 mK and up to 18 T, revealed a feature at 3.8 T when $T < 400$ mK. ESR ($\sim$ 200 GHz) studies, using single crystals at 4 K and in 5 T, have not detected any signal. The low-field, high-T susceptibility is unchanged for $P < 1.0$ GPa. Using a randomly-oriented, powder-like, deuterated (12 of 14 H replaced by D) sample, neutron scattering data, acquired with the CNCS at SNS, are not consistent with a uniform system consisting of $S = 2$ Heisenberg antiferromagnetic chains. The INS data show strong, dispersionless excitations, suggesting the possibility of isolated magnetic clusters.

[1]Supported by NSF via DMR-1005581 (DRT), DMR-0804408 (SH), DMR-1202033 (MWM), and DMR-0654118 (NHMFL) and by the DOE BES Scientific User Facilities Division for work at ORNL.

1:03PM U16.00008 Anisotropic thermal expansion and magnetostructural coupling in $CuSb_2O_6$[1]

, ALWYN REBELLO, MICHAEL G. SMITH, JOHN J. NEUMEIER, Montana State University — Low-dimensional (Quasi-1D or 2D) spin $S = \frac{1}{2}$ solid-state systems exhibit intriguing electronic and magnetic properties that deserve fundamental attention.[2] Besides, they have long been the subject of intense investigation since the discovery of high-T_c superconductivity in cuprates. Here we present results on anisotropic thermal expansion (TE) and magnetic properties in single crystalline $CuSb_2O_6$ in the temperature range $5 < T < 350$ K. We observe spin-flop transitions for magnetic field applied in $a(b)$ axis, but not in c. Our TE data reveals a magnetoelastic coupling in the vicinity of paramagnetic to antiferromagnetic phase transition around T_N. Also, the temperature dependence of 1D short range magnetic correlations in $CuSb_2O_6$ above T_N is reflected in the changes in sample length measured using high resolution dilatometer. Using the scaling of thermal expansion data with the heat capacity data around T_N,the pressure derivative of T_N is obtained as dT_N/dP= -0.11(1) K/GPa.

1:15PM U16.00009 Heat conduction in the one-dimensional AF spin chain compound $CuSb_2O_6$[1]

, NARAYAN PRASAI, JOSHUA L. COHN, University of Miami, MICHAEL G. SMITH, ALWYN REBELLO, JOHN J. NEUMEIER, Montana State University — We report thermal conductivity (κ) measurements on single crystals of the $S = 1/2$ antiferromagnetic spin-chain compound $CuSb_2O_6$ over the temperature range $5K \leq T \leq 300K$. A much larger spin contribution to κ is evident along the spin chains ([110] direction) than along [100] and [010]. The possible roles of spin-phonon scattering and twinning will be discussed along with κ measurements in applied magnetic field.

[1]This material is based upon work supported by the U.S. Department of Energy Office of Basic Energy Sciences grant DE-FG02-12ER46888 (Univ. Miami) and the National Science Foundation under grant DMR-0907036 (Mont. St. Univ.).

1:27PM U16.00010 Multiple magnetic transitions of the pseudo-1D antiferromagnet CoNiTAC

, DANIEL TESKE, Oklahoma Panhandle State University, JOHN E. DRUMHELLER, Montana State University — Magnetic susceptibility and crystal growing methods are reported for the pseudo-one-dimensional antiferromagnet $\left[(CH_3)_3\,NH\right]\,Co_{1-x}Ni_xCl_3 \cdot 2H_2O$ (abbreviated CoNiTAC). For high quality single crystals in the Ni mole fraction range $0.1 < x < 0.6$, two magnetic transitions with transition temperatures separated on the order of 0.1 K were observed. This indicates the possibility of a transition due to a change in the canting angle.

1:39PM U16.00011 Anomalous transport and thermalization in Heisenberg spin chains , PETER PRELOVSEK, JACEK HERBRYCH, Jozef Stefan Institute, SI-1000, Ljubljana, Slovenia, ROBIN STEINIGEWEG, Institute for Theoretical Physics, Technical University of Braunschweig, D-38106 Braunschweig, Germany — In spite of long history 1D spin systems still offer challenging open questions, mostly regarding finite-temperature spin and heat transport as well as the relevance for recent experiments on spin-chain materials. In the talk some recent findings regarding properties of anisotropic spin-1/2 Heisenberg chains, both integrable and nonintegrable, will be presented. Within the Ising-type regime we show that the integrable XXZ model unveils the coexistence of anomalous and normal diffusion resolving in this way conflicting conclusions on Mott insulators. In the gapless regime numerical results in the hydrodynamic regime, consistent with the normal spin diffusion for a nonintegrable model, reveal vanishing current decay rate in the integrable case. The behavior is closely related to the thermalization phenomena in spin-chain systems so that diagonal matrix elements for integrable models show evident deviations from the eigenstate thermal hypothesis. In a weakly perturbed integrable system the finite-size scaling reveals that the crossover between anomalous and normal regime is given by a scale related to the scattering length. The theory of thermal conductivity in spin chains and the relation to recent experiments will be also discussed.

1:51PM U16.00012 Quench dynamics of the Heisenberg chain[1] , DEEPAK IYER, NATAN ANDREI, Department of Physics & Astronomy, Rutgers University — We study the time evolution of the one dimensional Heisenberg chain after a quench from strongly (anti-)ferromagnetic coupling to the isotropic point ($\Delta = 1$). We generalize the Yudson integral representation for arbitrary states to the Heisenberg model and use it to study time-evolution of observables and correlation functions.

[1]This work is supported by NSF grant no. DMR1006684.

2:03PM U16.00013 Quenching Dynamics of Anisotropic Heisenberg Model through a Critical Point[1] , WENSHUO LIU, DEEPAK IYER, NATAN ANDREI, Rutgers University — We study the quenching dynamics of the anisotropic Heisenberg model (XXZ model) with the Yudson contour representation, which is a general method of obtaining the dynamics of integrable models. It replaces the summation over all Bethe eigenstates by integrals over continuous momentum on carefully chosen contours. We begin by applying it to the few-particle case of XXZ model, and then focus on a quenching through the critical point: how a antiferromagnetic phase evolve with time into a spin fluid phase.

Thursday, March 21, 2013 11:15AM - 2:15PM –

Session U17 DMP GMAG: Focus Session: Femtoscale Multiferroics 319 - Sang-Wook Cheong, Rutgers University

11:15AM U17.00001 Ultrafast Imaging of Real Space Response Functions , YAO WANG, CHUNJING JIA, Department of Applied Physics, Stanford, CA 94305, BRIAN MORITZ, THOMAS DEVEREAUX, Stanford Institute of Materials and Energy Sciences, SLAC NATIONAL ACCELERATOR LABORATORY 2575 Sand Hill Road, Menlo Park, CA 94025 — Understanding the dynamics of spin and charge excitations are critical for the study of correlated materials, such as cuprates. Inelastic X-ray scattering can reveal extensive information related to ultrafast dynamical details about the spin and charge structure factors. To obtain a theoretical understanding, we performed small-cluster exact diagonalization calculations utilizing single-band and three-band Hubbard models with both periodic and open boundary conditions. We demonstrate the ability to track long time behavior; and show that this method can be utilized to study the response dynamics of various materials, such as correlated and chemical systems as well as biological molecules.

11:27AM U17.00002 Time resolved terahertz and second harmonic investigations in multiferroic $R\mathrm{MnO_3}$ and $R\mathrm{Mn_2O_5}$, ROLANDO VALDES AGUILAR, Y-M. SHEU, A. TAYLOR, R.P. PRASANKUMAR, D. YAROTSKI, Center for Integrated Nanotechnologies, Los Alamos National Laboratory, NM 87545, E. ABREU, J. ZHANG, R. AVERITT, Physics Department, Boston University, Boston, MA 02215, S-W. CHEONG, Department of Physics & Astronomy, Rutgers University, Piscataway NJ 08854 — The dynamical aspects of magneto-electric interactions has been a very active area of research in multiferroic materials. Through linear far infrared and terahertz spectroscopies it has been shown that electric dipolo active excitations, called electromagnons, exist in some multiferroic materials and complex magnets. An unexplored area of investigation has been the non-linear response of these excitations to strong electromagnetic fields. We investigate the time resolved response of electromagnons in multiferroic materials using high-electric-field terahertz spectroscopy and second harmonic generation at infrared frequencies. We will report results on the well characterized multiferroics $TbMnO_3$, $TbMn_2O_5$ and YMn_2O_5.

11:39AM U17.00003 Transient magnetic states in the multiferroic frustrated spin chain compound $\mathrm{Ca_3CoMnO_6}$, JAE WOOK KIM, E.D. MUN, M. JAIME, N. HARRISON, D. RICKEL, V. ZAPF, NHMFL/MPA-CMMS, LANL, J.D. THOMPSON, MPA-CMMS, LANL, Y. KAMIYA, C. BATISTA, T4/CNLS, LANL, H. YI, Y. OH, S.-W. CHEONG, RCEM/Dept. of Physics and Astronomy, Rutgers Univ. — We report the discovery of transient magnetic states in a frustrated Ising spin chain system Ca_3CoMnO_6 that are observed only within a certain range of magnetic field (B) sweep rates. Spin chains are composed of alternating Co^{2+} and Mn^{4+} spins along the c-axis and arranged in a triangular lattice in the *ab*-plane. At zero field, the spins order in a $\uparrow\uparrow\downarrow\downarrow$ configuration that allows for ferroelectric polarization (P). Previous work shows that when DC field is applied along the c-axis, a $\uparrow\uparrow\uparrow\downarrow$ spin structure with a 1/2 magnetization (M) plateau is stabilized around $B \sim 15$ T and P disappears. However, when applying B with various sweep rates using a 60 T shaped-pulse magnet we find transient features in the M, P, and magnetostriction ($\Delta L/L$). We found one step at 4 T with sweep rate of 75 T/s and another step at 6 T when further increasing the rate to 960 T/s, both below the M =1/2 plateau. We attribute this time dependence to the magnetic frustration from both interchain and intrachain exchange interactions between Ising-like Co^{2+} spins which can leads to the creation of magnetic microphases. Thus the evolution of M with external parameters is not a straightforward canting or rotation of spins, but could be a progression through many different ordered microphases that are close in energy. This strongly suggests that an ANNNI-like model is appropriate to describe this system.

11:51AM U17.00004 Femtoscale magnetically induced lattice distortions in multiferroic $TbMnO_3$, HELEN WALKER, DESY, Hamburg, Germany — Magnetoelectric multiferroics, as exemplified by $TbMnO_3$, exhibit both magnetic and ferroelectric long range order. Whilst the magnetic order is mostly understood, the origin of the ferroelectricity has proved more elusive. Competing models ascribe the ferroelectricity to either charge transfer[1] or ionic displacements.[2] I will review how a new experimental technique, exploiting the interference between charge and magnetic X-ray scattering, enabled our resolution of femtometric ionic displacements[3] in $TbMnO_3$. In so doing, I will demonstrate not only that our data provide decisive support for microscopic models attributing P to ionic displacements, but also the importance of including both symmetric and antisymmetric magnetic interactions in any such models.

12:27PM U17.00005 Coherent magnon and acoustic phonon dynamics in rare earth doped BiFeO3 multiferroic thin films , KATHLEEN DOIG, University of Oxofrd, FREDERIC AGUESSE, ANNA-KARIN AXELSSON, Imperial College London, SAM JONES, University of Oxofrd, RON SYNOWICKI, J. A. Woollam , NEIL ALFORD, Imperial College London, JAMES LLOYD-HUGHES, University of Oxofrd — Magnetoelectric (ME) multiferroics, with coupled electric and magnetic order parameters, exhibit novel physics and have applications in information storage, spintronics and photovoltaics. BiFeO3 is one of the few room temperature multiferroics, but suffers from weak ME coupling. Lanthanide substitution on the Bi site enhances the remnant polarization, saturation magnetization and ME coupling. We investigated the dynamics of ME coupling in the time domain via ultrafast spectroscopy. Coherent magnons and acoustic phonons are impulsively excited and probed in BiLaDyFeO3 thin films using femtosecond laser pulses. Coupling to distinguishable acoustic phonon modes in the film and substrate yields the elastic constants in conjunction with spectroscopic ellipsometry. After substitution of Bi with Dy a rapid magnetoelectric coupling to weak ferromagnetic order creates a magnon oscillation at 75GHz, indicative of a Dzyaloshinskii-Moriya interaction energy of 0.31meV. Additional substitution with non-magnetic La suppresses this mode. The behaviour under a magnetic field and correlation with magnetisation studies confirms the assignment of the magnon mode. Our optical approach allows the extraction of parameters otherwise difficult to recover experimentally.

12:39PM U17.00006 Effect of Ultrafast Thermal Quenching on $Nd_{0.67}Sr_{0.33}MnO_3$[1] , A. MANSOUR, KH ZIQ, A. SALEM, King Fahd University of Petroleum and Minerals, R. MANSOUR, University of Dammam — We have successfully performed an ultrafast thermal quenching of $Nd_{1-x}Sr_xMnO_3$ (x=0.33) from 1200°C down to -196°C in a fraction of a second, at ambient pressure. This allowed us to freeze and investigate the physical properties of the material that have been formed at high temperatures. Resistivity measurements showed a 27 K reduction in the metal-insulator transition (MIT) temperature of the quenched sample compared to the as-grown sample. Whereas magnetic measurements revealed $<$2 K shift in the antiferromagnet-ferromagnet (AFM-FM) transition temperature with a significant broadening in the AFM-FM transition accompanied with a decrease in the low temperature magnetization. Moreover, ultrafast quenching significantly widens the temperature range of the magnetoresistance(MR) from few degrees to over 200 K. Here we present physical interpretations of the results in accordance with X-ray and structural analysis.

[1]This work was supported by the Deanship of Scientific Research at KFUPM under grant number JF101014.

12:51PM U17.00007 Verwey Transition in Magnetite: How fast does an insulator become a metal? , ROOPALI KUKREJA, S. DE JONG, W.F. SCHLOTTER, J. TURNER, W.S. LEE, Y.D. CHUANG, H.A. DURR, SLAC National Accelerator Laboratory, CA, USA, N. PONTIUS, T. KACHEL, A. FOHLISCH, Helmholtz-Zentrum Berlin for Materialien und Energie, Berlin, Germany, F. SORGENFREI, M. BEYE, W. WURTH, DESY, Hamburg, Germany, C. TRABANT, C.F. CHANG, C. SCHUSSLER-LANGAHEINE, Universatit zu Koln, Institute of Physics, Koln, Germany — Magnetite (Fe3O4), is the first oxide where a relationship between electrical conductivity and fluctuating/localized charges was observed, with a drop in conductivity by two orders of magnitude at TV=123K. The Verwey transition is accompanied by a structural change from monoclinic to cubic symmetry. Despite decades of research and indications that charge and orbital ordering play an important role, the mechanism behind the Verwey transition is yet unclear. Recently, three-Fe-site lattice distortions called trimerons have been identified as the true microscopic face of electronic order in low temperature insulating phase. We studied the real time response of insulating magnetite to optical excitation with ultrafast soft X-ray scattering. We discover this to be a two-step process. After an initial femtosecond destruction of individual trimerons in the corresponding lattice, we observe a phase separation into residual insulating trimeron and cubic metallic phases on a 1.0 $\pm$ 0.2 picosecond timescale.

1:03PM U17.00008 Complex Magnetic Interactions in A-site and B-site Doped Multiferroic $TbMnO_3$, MARGO STARUCH, Department of Physics, University of Connecticut, MENKA JAIN, Department of Physics and Institute of Materials Science, University of Connecticut — Multiferroic materials have been of great interest in recent years due to a number of potential applications in random access memory or spintronics devices. $TbMnO_3$ in particular has attracted attention since the discovery of significant magnetoelectric coupling. The possibility of ferroelectricity in rare-earth chromites has also been examined recently through x-ray diffraction and dielectric measurements. Although several studies have looked at Cr-doped $LaMnO_3$, the nature of the Mn–Cr interactions is still controversial and no studies have been performed where the parent compound is multiferroic. In the present work, bulk $Tb_{1-x}A_xMnO_3$ (A = Ca^{2+} or Sr^{2+}) and $TbMn_{1-y}Cr_yO_3$ have been synthesized via solution route. The structural evolution as determined through x-ray diffraction and Raman spectroscopy is consistent with a reduction in the orthorhombic distortion. Magnetic properties distinct from the parent compound, including ferrimagnetism and ferromagnetism, have been observed due to the Mn^{3+}–Mn^{4+} or Mn^{3+}–Cr^{3+} interactions. These complex interactions between the Mn^{3+}/Mn^{4+}, Cr^{3+}, and Tb^{3+} moments will be discussed in detail.

1:15PM U17.00009 The domain walls of antiferromagnetic $TbMnO_3$ thin films , C. DAUMONT, S. FAROKHIPOOR, Solid state for electronic materials, University of Groningen, C. MAGEN, EMES-CNRS, Toulouse and Instituto de Nanociencia de Aragón, Universidad de Zaragoza, D. RUBI, Solid state for electronic materials, University of Groningen and GIA and INN, CAC-CNEA, San Martin, S. VENKATESAN, Department of Chemistry and Center for NanoScience, Ludwig-Maximilians University Muenchen, E. SNOEK, EMES-CNRS, Toulouse and Instituto de Nanociencia de Aragón, Universidad de Zaragoza, M. DOEBLINGER, A. MUELLER, C. SCHEU, Department of Chemistry and Center for NanoScience, Ludwig-Maximilians University Muenchen, B. NOHEDA, Solid state for electronic materials, University of Groningen — In bulk $TbMnO_3$ below 28K, the Mn sublattice orders as an antiferromagnetic cycloidal spin structure. This breaks inversion symmetry and induces a macroscopic electrical polarization: $TbMnO_3$ is a multiferroic material with a strong magnetoelectric coupling. Contrary to the bulk, $TbMnO_3$ thin films grown on (001)-$SrTiO_3$ substrates show ferromagnetic-like behavior with a magnetic moment of 1.5μ_B/f.u. at 15K. However, the thickness dependence of the magnetic moments is not consistent with magnetism homogeneously distributed through the film. Additionally, epitaxial strain enables the stabilization of different symmetries and particular domain configurations at nanometric scales. Large strain gradients and/or lowering of symmetry at the boundaries of these domains allow the appearance of physical responses distinct from those of the domains. In this work we investigate the contribution of the domain walls to the magnetic moment.

1:27PM U17.00010 Giant magnetoresistance spin valves exchange-biased by ferroelectric $BiFeO_3$ thin films , X. ZHANG, National Institute of Standards and Technology, S. MARUYAMA, University of Maryland, College Park, P.J. CHEN, G. FENG, National Institute of Standards and Technology, T.R. GAO, University of Maryland, College Park, R.D. SHULL, National Institute of Standards and Technology, I. TAKEUCHI, University of Maryland, College Park — The recent demonstrations of electric-field-driven magnetization control in ferromagnet(FM)/$BiFeO_3$ bilayer systems [1,2] have attracted considerable interest because of the potential applications in spintronics. In this study, giant magnetoresistance (GMR) spin valves (Co/Cu/Py/Ta) were fabricated on $SrRuO_3$/$BiFeO_3$ films by magnetron sputtering at a base pressure of 2×10^{-8} Torr and with an external field of 300 Oe. The presence of exchange bias between the $BiFeO_3$ layer and the ferromagnetic Co layer is established by magnetization and electronic transport data. The heterostructure was patterned in a rectangular shape with a width of about 20 μm and a length up to 100 μm. The GMR characteristics of the patterned devices were systematically studied and directly compared to that obtained from identically fabricated structures on NiO and SiO_2, respectively. How these results relate to the realization of reversible control of the GMR spin valve effect by an electric field will be discussed.

1:39PM U17.00011 Magnetic and magnetoelectric excitations of BiFeO3 , NOBUO FURUKAWA, Dept Physics, Aoyama Gakuin University , MASAAKI MATSUDA, Quantum Condensed Matter Division, Oak Ridge National Laboratory, JASON T. HARALDSEN, Theoretical Division and Center for Integrated Nanotechnologies, Los Alamos National Laboratory, SHIN MIYAHARA, Asia Pacific Center for Theoretical Physics, Pohang University of Science and Technology, RANDY S. FISHMAN, Materials Science and Technology Division, Oak Ridge National Laboratory — We have determined a model which describes the magnetic and magnetoelectric excitations of multiferroic $BiFeO_3$. Using the full magnetic dispersion relations which are obtained by neutron inelastic scattering measurements [1], parameters for the Heisenberg model with 1st and 2nd neighbor exchange couplings as well as Dzyaloshinskii-Moriya interaction and the single ion anisotropy are estimated. The model also shows excellent agreements with the observed peaks in THz [2] and Raman [3] spectroscopies, which leads to successful assignments of the excitation modes to these peaks. We also discuss that the mode observed at 21.5 cm^{-1} is an electromagnon excitation which should be both magnetic and electric active. This can be verified by the non-reciprocal directional dichroism measurements. *REFERENCES:* [1] Matsuda et al., PRL **109**, 067205 (2012). [2] Talbayev et al., PRB 83, 094403 (2011). 1:51PM U17.00012 Theory of spin-orbit enhanced electric-field control of magnetism in multiferroic $BiFeO_3$[1] , ROGERIO DE SOUSA, MARC ALLEN, Department of Physics and Astronomy, University of Victoria, BC, Canada, MAXIMILIEN CAZAYOUS, Laboratoire Materiaux et Phenomenes Quantiques, Universite Paris Diderot-Paris 7, France — We present a microscopic theory that shows the importance of spin-orbit coupling in multiferroic compounds with heavy ions. In $BiFeO_3$ (BFO) the spin-orbit coupling at the bismuth ion sites results in a special kind of magnetic anisotropy that is linear in the applied E-field. We show how this interaction is capable of disrupting the magnetic cycloid state of bulk BFO, leading to a remarkable level of E-field control of magnetism. R. de Sousa, M. Allen, and M. Cazayous, arXiv:1209.6612.

2:03PM U17.00013 Evolution of the magnetic structure in (Sm,Bi)FeO3 Thin Films , WILLIAM RATCLIFF, NIST Center for Neutron Research, National Institute of Standards and Technology, Gaithersburg, Maryland 20899, USA, AMY POOLE, Paul Scherrer Institut, CH-5232 Villigen, Switzerland, MECHTHILD ENDERLE, Institut Laue-Langevin, BP 156, 38042 Grenoble Cedex 9, France, SHINGO MARUYAMA, V. ANBUSATHAIAH, ICHIRO TAKEUCHI, Department of Materials Science and Engineering, University of Maryland, College Park, MD 20424 — BiFeO3 is a multiferroic, which is ordered at room temperature. In this compound, the magnetic and ferroelectric domains are coupled and magnetic domains can be switched with an electric field [1]. It has recently been found that doping Sm onto the Bi site drives the system from rhombohedral to orthorhombic ordering [2]. Furthermore, near the phase boundary, application of an electric field can drive the material between the two structures. It is an open question as to whether the magnetic structure follows. In this talk, I share our recent neutron diffraction results on the magnetic structure of Sm doped BiFeO3 thin films. [1] T. Zhao, A. Scholl, F. Zavaliche, K. Lee, M. Barry, A. Doran, M. P. Cruz, Y. Session U18 GMAG DMP FIAP: Focus Session: Spin-Dependent Phenomena in Semiconductors - Spin Seebeck and Magneto-optics 320 - Berry Jonker, Naval Research Laboratory

11:15AM U18.00001 Electric Field-Driven Coherent Spin Reorientation of Optically Generated Electron Spin Packets in InGaAs[1] , BERND BESCHOTEN, II. Physikalisches Institut, RWTH Aachen University — Full electric-field control of spin orientations is one of the key tasks in semiconductor spintronics. We demonstrate that electric field pulses can be utilized for phase-coherent 2-pi spin rotation of optically generated electron spin packets in InGaAs epilayers using time-resolved Faraday rotation. Through spin-orbit interaction, the electric-field pulses act as local magnetic field pulses. By the temporal control of these pulses, we can turn on and off electron spin precession and thereby rotate the spin direction into arbitrary orientations in a 2-dimensional plane [1]. Moreover, we apply two subsequent electric field pulses of opposite field polarity to perform spin echo studies of the diffusing spin packet by reversing both the spin precession and the drift direction. In this spin-echo type spin drift experiment we find an unexpected spin rephasing, which is evident by a doubling of the spin dephasing time.

11:51AM U18.00002 Interacting drift-diffusion theory for photoexcited electron-hole gratings in semiconductor quantum wells[1] , KA SHEN, GIOVANNI VIGNALE, University of Missouri-Columbia — Phase-resolved transient grating spectroscopy in semiconductor quantum wells has been shown to be a powerful technique for measuring such an elusive quantity as the electron-hole drag resistivity ρ_{eh}, which depends on the Coulomb interaction between the carriers. In this paper we develop the interacting drift-diffusion theory, from which ρ_{eh} can be determined, given the measured mobility of an electron-hole grating. From this theory we predict a cross-over from a high-excitation-density regime, in which the mobility has the "normal" positive value, to a low-density regime, in which Coulomb-drag dominates and the mobility becomes negative. At the crossover point, the mobility of the grating vanishes.

12:03PM U18.00003 Carrier and Spin Dynamics in InAsP Ternary Alloys[1] , MICHAEL MEEKER, KELLY MCCUTCHEON, MITHUN BHOWMICK, BRENDEN MAGILL, GITI A. KHODAPARAST, Virginia Tech, JOE G. TISCHLER, Naval Research Labs, SUKGEUN G. CHOI, NREL, CHRIS J. PALMSTRØM, Univ. of California Santa Barbara — The recent rapid progress in the field of spintronics involves extensive measurements of carrier and spin relaxation dynamics in III-V semiconductors. In addition, as the switching rates in electronic and optoelectronic devices are pushed to higher frequencies, it is important to understand carrier dynamic phenomena in semiconductors on femtosecond time-scales. In this work, we employed time and polarization-resolved differential transmission measurements in near and mid-infrared, to probe carrier and spin relaxation times in several InAsP ternary alloys. Our results demonstrate the unique and complex dynamics in this material system that can be important for electronic and optoelectronic devices. We present our experimental observations and compare them with the observations in InAs and InP.

12:15PM U18.00004 Time resolved Magneto-Photoluminescence in $InAs_xP_{1-x}$ alloys[1] , TRAVIS MERRITT, MICHAEL MEEKER, GITI A. KHODAPARAST, Virginia Tech, STEPHEN MCGILL, NHMFL, Florida, JOE G. TISCHLER, Naval Research Labs, SUKGEUN G. CHOI, NREL, CHRIS J. PALMSTRØM, Univ. of California Santa Barbara — Recently, g-factor engineering has attracted much attention for potential applications in spintronics. In the case of $InAs_xP_{1-x}$ alloys, a wide range of g-factors, including g=0, can be achieved. In order to probe the band-structure and the dynamics of photo-excited carriers in $InAs_xP_{1-x}$ epitaxial films with x=0.13, 0.4, we measured NIR absorption spectra at 4K and 300K, as well as magneto- photoluminescence spectra in both the time and frequency domain for magnetic fields in the range of 0-15T and temperatures in the range of 4-90K. From the temporal measurements, we observed strong tunability in the relaxation dynamics as a function of excitation wavelength. We present these experimental observations and compare them with theoretical calculations.

12:27PM U18.00005 Probing of the Nature of Carrier Recombination in GaInNAs epilayers using Optical Spin Injection[1] , YUTSUNG TSAI, BIPLOB BARMAN, THOMAS SCRACE, ATHOS PETROU, SUNY Buffalo, M. FUKUDA, I.R. SELLERS, University of Oklahoma, M.A. KHALFIOUI, CRHEA-CNRS,France — Optical pumping experiments have been performed on as-grown and p-type MBE grown GaInNAs epilayers. The PL peak of the nominally undoped as-grown sample exhibits the characteristic S-shaped dependence of dilute nitride material for T $<$ 60 K [1]. This is associated with carrier recombination via localized states at low temperatures. The reflectance spectra on the other hand map the band-to-band free carrier transition, displaying a Varshni-type behavior. In the p-type material the S-dependence of the PL disappears, and the PL peak coincides with the reflectance spectrum at all temperatures. This indicates band-to-band, rather than localized exciton recombination, in the p-type GaInNAs at all temperatures. This picture was verified by optical pumping experiments. In the undoped sample a large degree of circular polarization was evident only at T $>$ 60 K: below 60 K the polarization is small, and coincident with the reflectance peak. In the p-type samples, on the other hand, non-zero circular polarization, whose maximum matches the peak PL energy, was evident at all temperatures.

12:39PM U18.00006 Dynamic spin Seebeck coefficient and thermo-spin Hall conductivity in systems with Rashba and Dresselhaus spin-orbit coupling[1] , JESUS MAYTORENA, PRISCILLA IGLESIAS, Centro de Nanociencias y Nanotecnologia, Universidad Nacional Autonoma de Mexico — The generation of spin currents by thermal gradients is a central issue of spin caloritronics. In addition to the recently observed spin Seebeck effect, a transverse thermoelectric effect has been proposed. This is the generation of a spin Hall current by a temperature gradient in a two-dimensional electron gas (2DEG) with Rashba spin-orbit interaction (SOI). We calculate the spin Seebeck coefficient and the thermo-spin Hall conductivity tensor of the spin current response induced by a frequency dependent temperature gradient in a 2DEG with Rashba and Dresselhaus SOI. We consider quantum wells grown in the main crystallographic directions. The spin splitting caused by SOI opens the possibility of resonant effects due to transitions between the spin-split subbands in response to alternating thermoelectric fields and temperature gradients in the THz regime. The spin current response shows characteristic spectral features in notable contrast to the pure Rashba coupling case. Such behavior is caused by the reduced symmetry of the momentum space available for transitions and the presence of critical points. This anisotropic dynamic response could be useful for spin manipulation via thermal means.

12:51PM U18.00007 Phonon Drag in InSb: Experiment[1] , JOSEPH P. HEREMANS, Dept. of Mechanical Engineering and Dept. of Physics, Ohio State University, Columbus, OH 43210, HYUNGYU JIN, CHRISTOPHER M. JAWORSKI, Department of Mechanical Engineering, Ohio State University, Columbus OH 43210, STEWART BARNES, Department of Physics, University of Miami, Coral Gables, FL 33124 — A thermoelectric power is reported in a thermocouple in which both arms are made of the same material (n-type InSb) with the same electron concentration, but the phonons have different mean free paths at cryogenic temperatures. This experiment, inspired by [1], isolates the phonon-drag contribution to the thermopower from the diffusion thermopower. The experiment decouples the behavior of the subthermal phonons that drag the electrons, and the thermal phonons that carry most heat. We add data on the contributions of both to the thermal conductivity. This sheds new light on the details of the physical mechanism behind the giant spin-Seebeck effect (GSSE) recently observed [2] on the same material. The GSSE signal was attributed to a combination of electron-phonon drag that pushes the electrons, which are spin-polarized by Zeeman splitting, far from thermal equilibrium, and strong spin-orbit interactions that make the Zeeman splitting sensitive to the electron momentum. Furthermore, we may have found experimental clues about the nature of the phonon force [3]. 1. T. H. Geballe and G. W. Hull, Conference de physique des basses temperatures, p 460, Paris, 1955 2. C.M. 1:03PM U18.00008 Phonon Drag in InSb: Theory and "spin"-motive force , STEWART BARNES, Department of Physics, University of Miami, Coral Gables, FL 33124 , JOSEPH HEREMANS, Department of Mechanical and Aerospace Engineering, and Department of Physics, The Ohio State University, Columbus, OH 43210, — The phonon number operator $\hat{n} \rightarrow \sin^2 \frac{\theta}{2}$ defines the Euler angle θ and with the phase ϕ this maps to a precessing spin. Defined are a "spin" Berry phase and a "spin"-motive force (smf)[1]. Unlike an emf, an smf can act upon neutral phonons. Tradition[2] has sub-thermal phonons as central to the thermopower of semi-conductors. The momentum given to these phonons, by the temperature gradient, is transferred to the electrons by "drag" where it cancels a Seebeck effect electric field $\vec{E}$. Here, for InSb at low temperatures, thermal phonons actually relax momentum via boundary and umklapp scattering and energy conservation involves sub-thermal phonons, created by anharmonic effects, with a frequency $\hbar\omega_{\vec{q}} \sim k_B(dT/dx)\ell$ where ℓ is the phonon mean-free-path (mfp). The resulting smf acting upon the thermal phonons produces a "spin" voltage $\sim (k_B/e)\Delta T \sim 100\mu$V/K. Via the electron-phonon interaction, the smf, multiplied by the ratio ℓ_{ep}/ℓ, where ℓ_{ep} is the electron-phonon mfp, are detected, but not created by the few electrons in our InSb samples. [1] S. E. Barnes and S. Maekawa, Phys. Rev. Lett. **98**, 246601 (2007) [2] C. Herring, Phys. Rev. **95**, 954 (1954).

1:15PM U18.00009 Planar Nernst effect and Spin dependent Seebeck effect on Py/Ag thin films[1]

PRIYANGA JAYATHILAKA, DUSTIN BELYEA, TATIANA EGGERS, HILLARY KIRBY, CASEY W. MILLER, Department of Physics, University of South Florida — We are reporting a systematic study of planar Nernst effect (PNE) and Spin dependent Seebeck effect (SDSE) measurements and their relation to the Anisotropic Magneto Resistance (AMR) on Py thin films grown on SiOx substrates by magnetron sputtering. A 30nm thick Py film was followed by a 15nm of Ag cross electrodes. An in-situ mask exchanging system was allowed the Py and Ag to grow without breaking the vacuum. The sample was placed on top of two thermal baths which were independently controlled by a PID controller. A constant temperature gradient of 15K/cm was applied along the sample and the resultant voltages across the Ag electrodes were measured by nanovoltmeters as the field was swept. In measuring AMR no thermal gradient was applied, and a constant current was applied using a function generator. Both PNE and SDSE showed an AMR like field dependence and angular dependence. SDSE showed a Cos^2 (θ) angular dependence and PNE showed a Sin (2θ) angular dependence. AMR showed the same angular dependence along the Py film and across the Py film respectively. This suggests both PNE and SDSE behave similar to the AMR in thin films.

1:27PM U18.00010 Theory of thermal spin-charge coupling in electronic systems[1]

BENEDIKT SCHARF, Department of Physics, University at Buffalo SUNY, Buffalo, New York 14260, USA, ALEX MATOS-ABIAGUE, Institute for Theoretical Physics, University of Regensburg, 93040 Regensburg, Germany, IGOR ŽUTIĆ, Department of Physics, University at Buffalo SUNY, Buffalo, New York 14260, USA, JAROSLAV FABIAN, Institute for Theoretical Physics, University of Regensburg, 93040 Regensburg, Germany — The interplay between spin transport and thermoelectricity offers several novel ways of generating, manipulating, and detecting nonequilibrium spin in a wide range of materials. Here, we formulate a phenomenological model in the spirit of the standard model of electrical spin injection to describe the electronic mechanism coupling charge, spin, and heat transport and employ the model to analyze several different geometries containing ferromagnetic (F) and nonmagnetic (N) regions: F, F/N, and F/N/F junctions which are subject to thermal gradients (i.e., the spin-dependent Seebeck effect). Furthermore, we study the Peltier and spin-dependent Peltier effects in F/N and F/N/F junctions.

Session U19 DCMP: Metal-Insulator Transitions II 321 - Rongwei Hu, University of Maryland

11:15AM U19.00001 MBE synthesis and characterization of charge ordered $La_{1/3}Sr_{2/3}FeO_3$ thin films

REBECCA SICHEL-TISSOT, ROBERT DEVLIN, Drexel University, PHILIP RYAN, JONG-WOO KIM, Argonne National Laboratory, ALEX DAGG, University of California, Riverside, STEVEN MAY, Drexel University — $La_{1/3}Sr_{2/3}FeO_3$ (LSFO) is a transition metal oxide which exhibits strongly correlated electronic behavior. When cooled below 180-190K, an electronic phase transition occurs during which the resistivity abruptly increases. LSFO was deposited on (001) $SrTiO_3$ substrates using molecular beam epitaxy (MBE). The transition temperature T* = 183 K was measured from a sharp increase in the resistivity and confirmed by the appearance of x-ray reflections with wavevectors of q = n/3[111]. Oxygen loss from the film over a period of 8 months was observed to have significant effects on the structural and electronic properties, but was shown to be reversible by annealing in oxygen. This work is supported by the Office of Naval Research under grant number N00014-11-1-0664. Work at the Advanced Photon Source is supported by the U.S. Department of Energy (DOE), Office of Basic Energy Sciences under contract DE-AC02-06CH11357.

11:27AM U19.00002 Strain dependence of the electronic phase transition in epitaxial $La_{1/3}Sr_{2/3}FeO_3$ films[1]

ROBERT DEVLIN, REBECCA SICHEL-TISSOT, Department of Materials Science and Engineering, Drexel University, PHILLIP RYAN, JONG-WOO KIM, Advanced Photon Source, Argonne National Laboratory, STEVE MAY, Department of Materials Science and Engineering, Drexel University — The electronic transport properties of $La_{1/3}Sr_{2/3}FeO_3$ thin films were experimentally investigated as a function of epitaxial strain. In bulk, this compound exhibits a first-order electronic phase transition at 198 K accompanied by an abrupt change in resistivity. In order to investigate how different epitaxial strain states affect the abruptness and temperature of the transition, thin $La_{1/3}Sr_{2/3}FeO_3$ films were grown using molecular beam epitaxy on $SrTiO_3$ $DyScO_3$ and (La,Sr)(Al,Ta)O_3 imparting +0.9% +1.8% and -0.05% strain, respectively. The transition temperatures were determined through resistivity measurements as well as synchrotron x-ray diffraction of (4/3 4/3 4/3) peaks, which are a direct signature of an additional ordering below the transition temperature. We find that the transition temperature measured through resistivity and the integrated intensity of the (4/3 4/3 4/3) peaks are in excellent agreement. The variation in transition temperature and the abruptness of the transition will be presented for the films grown on the various substrates.

11:39AM U19.00003 Electrical Transport in Iron Cobalt Silicide Nanowires

DREW REBAR, Louisiana State University-Baton Rouge, JOHN DEGRAVE, SONG JIN, University of Wisconsin-Madison, JOHN DITUSA, Louisiana State University-Baton Rouge — Iron silicide is a small gap insulator with fascinating physical properties that can be made metallic and magnetic when doped with cobalt. With the substitution of cobalt for iron, Fe1-xCoxSi, the material undergoes an insulator-to-metal transition becoming a half metal for a wide range of x. The ground state is helimagnetic with distinct itinerant character. It has been demonstrated by others that an exotic intermediate magnetic vortex or skyrmion state exists between the helimagnetic and ferromagnetic phases in small applied fields. Electron transport in bulk Fe1-xCoxSi has been found to be dominated by electron-electron interaction effects similar to what has been found in prototypical semiconductors such as Si:P. Here we probe low temperature electron transport in CVD-grown Fe1-xCoxSi nanowires with x=0.05. The reduced dimensionality presents the opportunity to characterize the conductivity where only the phase-coherent contribution may be constrained to one dimension. Results of low temperature transport measurements of these wires will be presented.

11:51AM U19.00004 Exploring $Fe_{1-y}Co_xSi$ near the insulator-to-metal transition , YAN WU, Department of Physics and Astronomy, Louisiana State University, BRAD FULFER, JULIA CHAN, Department of Chemistry, Louisiana State University, DAVID YOUNG, JOHN DITUSA, Department of Physics and Astronomy, Louisiana State University — FeSi is a nonmagnetic narrow gap insulator with interesting temperature-dependent magnetic and optical properties. Doping FeSi with Mn or Co introduces hole or electron a charge carriers as well as additional magnetic moments. Our previous investigations show that for Mn doping near the insulator-metal-transition(IMT) an intriguing field sensitive non-Fermi-Liquid behavior results from the underscreening of the $S = 1$ impurity moments. Here we explore the case of electron doping via Co substitution for concentrations very near the IMT. Our magnetic susceptibility measurements indicate an underlying competition between screening of the magnetic moments at low y and ferromagnetic ordering at higher Co-concentrations. Our carrier transport measurements indicate that the IMT occurs near $y = 0.01$ and that above 2 K electron-electron interaction effects dominate the magnetoresistance. However, for $T < 1$ K, high magnetic fields induce an enhance charge carrier mobility for samples with $y \sim 0.01$. We will present data comparing the magnetotransport of the Co and Mn doped samples in order to compare electron and hole doping in proximity to the IMT.

12:03PM U19.00005 Doping induced metallization of a narrow gap insulator $FeGa_3$, MONIKA GAMZA, Brookhaven National Laboratory, AKSHAT PURI, Stony Brook University, JAN TOMCZAK, Rutgers University, JIM QUINN, Stony Brook University, MEIGAN ARONSON, Stony Brook University and Brookhaven National Laboratory — Narrow gap semiconductors attract great interest owing to an unusual metallization process which remains poorly understood despite decades of extensive research [1]. Here, we report on the effects of hole doping on properties of a nonmagnetic semiconductor $FeGa_3$ with a band gap of 0.4 eV [2]. By means of electrical resistivity, magnetization and specific heat measurements performed on single crystals grown from gallium flux we have found that a substitution of Mn for Fe in $Fe_{1-x}Mn_xGa3$ ($0.005 < x < 0.03$) yields an insulating state at high temperatures with residual magnetic moments. With lowering temperature, resistivity deviates from an activation-type behavior and nearly saturates at T<100 K. Finally, it drops by as much as two orders of magnitude at temperature of 6 K, indicating a metal-insulator transition. Magnetization measurements did not show magnetic order associated with the transition. When an external magnetic field is applied, the metal-insulator transition moves to lower temperatures and eventually the resistivity returns to the insulating-type behavior in fields higher then of 5 Tesla.

12:15PM U19.00006 Role of long range Coulomb interaction near the disorder driven metal-insulator transition in $Ga_{1-x}Mn_xAs$, S. MAHMOUDIAN, Florida State University, E. MIRANDA, Univ. of Campinas, V. DOBROSAVLJEVIC, Florida State University — Surprising signatures of interaction effects on disorder-driven localization have recently been observed by scanning tunneling microscopy of $Ga_{1-x}Mn_xAs$, where visualizing the electronic wave function near the metal-insulator transition revealed[1] a pronounced suppression of the local tunneling density of states (LDOS) and enhanced localization only near the Fermi energy. These features highlight the limitation of the non-interacting picture, and point to the crucial importance of the long-range Coulomb interaction. Here, we implement a theoretical approach based on the recently developed Typical-Medium Theory,[2] the conceptually simplest approach to interaction-localization. We show that the presence of long-range Coulomb interaction leads to the simultaneous opening of a soft pseudogap in both the typical (geometrically averaged) and the average (algebraically averaged) LDOS, as the transition is approached. This result is consistent with the experimentally observed features of the STM spectra, suggesting new experiments that should be performed to fully characterize the quantum critical behavior at the metal-insulator transition

12:27PM U19.00007 Fitting of Diverging Thermoelectric Power in a Strongly Interacting 2D Electron System of Si-MOSFETs , HYUN-TAK KIM, ETRI in Korea — The diverging-effective mass (DEM) in a metallic system is evidence of strong correlation between fermions in strongly correlated systems. The identification of the DEM still remains to be revealed The effective mass, $m^*=m_o/(1-\rho^4)$ [1] where ρ is band filling helps clarify the diverging thermoelectric power, S, measured in inhomogeneous Si-MOSFET systems [2]. As a carrier density n_s decreases, S increases rapidly This is regarded as the metal-insulator transition (MIT) near $n_c \approx 79\times10^{-1}cm^{-2}$, where n_c is about 0.02% to $n_{Si} \approx 3.4\times10^{-14}cm^{-2}$ in Si. This can be solved in assuming that $\rho = n_c/n_s$ increases as n_s decreases. n_c is an excited(doped) carrier density in the semiconductor induced by gate and can be also regarded as a metallic carrier density, that is, $n_c \equiv n_{seminon} = n_{metal}$. n_s is given as $n_{tot} \equiv n_s = n_c + n_{seminon}$ where $n_{seminon}$ is a carrier density in a nonmetallic phase. The carrier density measured by Hall effect is the sum of carriers both induced by gate field and generated by MIT. Moreover, a larger metallic phase is not made due to a conducting path in the field-effect structure after a metallic phase is formed. Thus, increasing n_s indicates increasing n_{non}; this corresponds to an over-doping to increase inhomogeneity. It's fitting is given from $S = (\alpha\pi^3 k_B^2 T/3e)(1/E_F) = (\alpha 8\pi^3 k_B^2 T/3h^2)(m^*/e^* n_c) = S_o(1/\rho)(1/(1-\rho^4))$, where $e^* = \rho e$ [1], $\rho = n_c/n_s$, T=0.8K, $m^* = m_o/(1-\rho^4)$ [1], α =0.6, and $S_o = (\alpha 8\pi^3 k_B^2 T/3h^2)(m_o/en_c) \approx 12.36$ are used. The data S [2] are closely fitted by m* [1] Physica C 341-348(2000)259. [2] Phys. Rev. Lett. 109 (2012) 096405.

12:39PM U19.00008 Metal-insulator and glass transitions in a 2D electron system in Si MOSFETs with a screened Coulomb interaction[1] , PING V. LIN, DRAGANA POPOVIĆ, Natl. High Magnetic Field Lab., Florida State Univ. — We present a study of conductivity σ of a 2D electron system (2DES) in Si MOSFETs with the oxide thickness $d_{ox} = 7$ nm. In the low density regime of interest, the average electron-electron (e-e) separation is larger than d_{ox}, so that the e-e interaction is screened by the metallic gate. The carrier density n_s was changed at a high temperature $T \approx 20$ K, the 2DES was then cooled to a desired T with a fixed n_s, and σ was measured as a function of time t. At the lowest n_s, in the insulating regime, transport occurs via variable-range hopping. Near the critical density n_c on the metallic side of the metal-insulator transition (MIT), the time-averaged $\langle\sigma(T)\rangle$ follows a power-law behavior, giving a reliable extrapolation of $\langle\sigma(n_s, T = 0)\rangle$. The critical exponents are discussed and compared to the case of the MIT with long-range Coulomb interactions. The statistical analysis of the fluctuations in $\sigma(t)$ provides evidence for the glassy freezing of electrons for $n_s < n_g$ ($n_c < n_g$) as $T \to 0$, similar to the results on samples with long-range interactions. The data suggest that interacting droplet models, rather than hierarchical pictures of glassy dynamics, might be more appropriate.

12:51PM U19.00009 Valence Band Character of $NiS_{2-x}Se_x$ using 3p-3d Resonant ARPES , GARAM HAN, YEONGKWAN KIM, YOONYOUNG KOH, BEOMYOUNG KIM, DONGJOON SONG, JUNGJIN SEO, WONSHIK KYUNG, Institute of Physics and Applied physics, Yonsei university, Korea, KYUNGDONG LEE, Department of Physics, Inha university, Korea, CHANGYOUNG KIM, Institute of Physics and Applied physics, Yonsei university, Korea — Understanding the strong correlated system is one of the most challenging tasks in condensed matter physics. Especially, the metal insulator transition (MIT) has been one of the major topics recent few decades. $NiS_{2-x}Se_x$ is known as one of famous material which has MIT. The cubic pyrite NiS_2 is a charge-transfer (CT) insulator. NiS_2 attracts particular interest as it easily forms a solid solution with $NiSe_2$ ($NiS_{2-x}Se_x$) which, while being isoelectronic and isostructural to NiS_2, is nevertheless a good metal. MIT, induced by Se alloying, is observed at low temperature (T) for x=0.45. Perucchi and his collaborators revealed closed relation between MIT and band width through comparison of infrared spectroscopy result and LDA calculation. However, it was only an indirect observation, and is inconsistent with recent proposal that NiS_2 is not a CT insulator but an insulator due to the bonding-antibonding splitting in the S – S (Se – Se) dimers. To reveal the true mechanism in the MIT in $NiS_{2-x}Se_x$, resonant photoemission experiment is essential. According to competing theories (CT insulator and insulator due to bonding-antibonding splitting), it is expected that the character of the main band that is responsible for the MIT should be different. Therefore, we performed 3p->3d resonant ARPES for various Se dopings (x=0.43; insulator, x=0.5, 0.7, 2.0; metal) and observed a significant change between on- and off-resonances near the MIT. Our experimental result supports that the origin of MIT in $NiS_{2-x}Se_x$ is the CT theory rather than the dimer theory.

1:03PM U19.00010 Low temperature conductance spectra of STO at the nanoscale , ALIREZA MOTTAGHIZADEH, QIAN YU, ALEXANDRE ZIMMERS, HERVE AUBIN, Laboratoire de Physique et d'Etudes des Materiaux (LPEM), UMR 8213, ESPCI ParisTech-CNRS- UPMC, 10 Rue Vauquelin, 75005 Paris, France — The electronic properties of transition metal oxide materials depend on the electronic carrier density, which can be tuned with the oxygen stoichiometry. In binary MOx or ternary perovskite ABOx, it has been shown that upon applying a strong electric field, oxygen vacancies can be created or displaced in the material. This effect is responsible for the memristive behavior recently discovered in TiO2 materials by HP laboratory and launched a worldwide renew interest into ionics. We present a study of oxygen ions vacancies displacement in SrTiO3, the archetype perovskite oxide. For this work, metallic electrodes, separated by distances about 100 – 300 nm, are deposited on the surface of a STO crystal and ions migration procedures and current-voltage characteristics measurements are done at low temperature, T $\sim$ 260 mK. Upon applying large voltage up to 30 V, oxygen vacancies migration is identified as the apparition of resistance switching events in current-voltage characteristics. Detailed measurements of the junction show that the switching event led to the formation of a nanosized region of highly doped STO, located within the electrodes where the current-voltage characteristics show the presence of the doped in-gap states. This work was supported by the French ANR grants 10-BLAN-0409-01 and 09-BLAN-0388-01.

1:15PM U19.00011 Crystalline and Magnetic Anisotropy of the $3d$ Transistion-Metal Oxides , ANDREAS SCHRÖN, Institut für Festkörpertheorie und -optik, Friedrich-Schiller-Universität Jena, Max-Wien-Platz 1, 07743 Jena, Germany, CLAUDIA RÖDL, Laboratoire des Solides Irradiés, École Polytechnique, CNRS, CEA-DSM, 91128 Palaiseau, France, FRIEDHELM BECHSTEDT, Institut für Festkörpertheorie und -optik, Friedrich-Schiller-Universität Jena, Max-Wien-Platz 1, 07743 Jena, Germany — The $3d$ transition-metal oxides (TMOs) are subject of debate since many decades due to their extraordinary properties, such as the formation of an antiferromagnetic ordering AFM2 below their Néel temperature. Many studies, both experimental and theoretical, focus only on MnO and NiO, where the crystalline anisotropy is solely driven by exchange striction along the unique symmetry axis in the [111] direction and where the magnetic anisotropy is explained in terms of magnetic dipole interactions. In the other TMOs, FeO and CoO, however, orbital magnetization and spin-orbit interaction play an additional, yet crucial role for both crystalline and magnetic anisotropy. We present density-functional theory (DFT) studies including an on-site interaction U of the crystalline and magnetic anisotropy of the electronic systems with non-collinear spins. The influence of the (semi-)local description of exchange and correlation (XC) by means of the local density approximation (LDA) and generalized gradient approximation (GGA) on the orbital moments in FeO and CoO and the implications on the aforementioned properties is investigated. We discuss the quenching of the orbital magnetization due to the gradient corrections.

1:27PM U19.00012 Spatially resolved dynamic susceptibilities of disordered two dimensional Hubbard model[1] , NANDINI TRIVEDI, OINAM NGANBA MEETEI, The Ohio State University — We predict the existence of an emergent metallic phase in the disordered two dimensional Hubbard model [1] that has recently been confirmed by experiments on 1T-TaS_2 intercalated with Cu. The metallic state has a finite dc conductivity but unusual dynamical properties. We present here a comprehensive analysis of the spatially resolved spin susceptibility, screened charge density, and optical conductivity of the disordered Hubbard model. We develop a new method in which the exact eigenstates from inhomogeneous mean-field theory are used to calculate dynamical susceptibilities within the random phase approximation. By combining the non-perturbative effects of self-consistent mean-field theory with analytical perturbative methods, this approach gives insights about fluctuations near the quantum phase transitions. We make several predictions which can be directly tested in spatially resolved experiments.

1:39PM U19.00013 Dual fermion approach for disordered interacting fermion systems , SHUXIANG YANG, Louisiana State University, PATRICK HAASE, University of Goettingen, HANNA TERLETSKA, Louisiana State University, Brookhaven National Laboratory, ZIYANG MENG, JUANA MORENO, MARK JARRELL, Louisiana State University, THOMAS PRUSCHKE, University of Goettingen — Understanding the combined effect of electron-electron interaction and disorder is one of the crucial questions in condensed matter physics. There is an obvious need of theoretical tools which allow to treat both these effects on equal footing. To study the intricate interplay of these effects, we generalize our recently proposed dual fermion approach to include both electron-electron interaction and disorder. Since the constraint imposed on the dual-space Feynman diagrams in the disordered case does not apply to those generated due to interactions, it is essential to treat elastic scattering processes due to the disorder separately from the inelastic scattering processes due to the pure interaction and mixed contributions. I will discuss the resulting diagrammatic formalism and an algorithm for its implementation. The possible applications for the Anderson Falicov-Kimball and the Anderson-Hubbard models are also discussed.

1:51PM U19.00014 Dual fermion method for disordered electronic systems , HANNA TERLETSKA, Brookhaven National Laboratory, SHUXIANG YANG, ZI YANG MENG, JUANA MORENO, MARK JARRELL, Louisiana State University — While the coherent potential approximation (CPA) is the most commonly used theoretical method to study disordered systems, it by construction misses non-local correlations and Anderson localization. We have recently extended the dual fermion approach [1] to disordered non-interacting systems using the replica method, which allows one to included such non-local physics. Our method utilizes an exact transform to the dual variables, and includes inter-site scattering via diagrammatic perturbation theory in dual fermion space, with the CPA being a zeroth-order approximation. Analyzing one-particle quantities we demonstrate good agreement between our results and those from the dynamical cluster extension of the CPA. Moreover, by calculating the dc conductivity we show that our approach successfully captures weak localization missing in the CPA. This method as a natural extension of CPA, and presents a powerful alternative to existing cluster extensions of CPA. It can be used in various applications, including systems with disorder and interactions.

2:03PM U19.00015 Metal-Insulator Transitions in Crystalline Phase Change Materials , WEI ZHANG, RWTH Aachen , Germany, ALEXANDER THIESS, Forschungszentrum Jülich, Germany, PETER ZALDEN, RWTH Aachen University, Germany, RUDOLF ZELLER, PETER DEDERICHS, Forschungszentrum Jülich, Germany, JEAN-YVES RATY, University of Liege, Belgium, MATTHIAS WUTTIG, RWTH Aachen University and JARA, Germany, STEFAN BLÜGEL, Forschungszentrum Jülich and JARA, Germany, RICCARDO MAZZARELLO, RWTH Aachen University and JARA, Germany — Phase-change materials are capable of undergoing fast and reversible transitions between amorphous and crystalline phase upon heating and have been exploited in data storage applications based on the strong optical/electrical contrast between the two phases. Recently, compelling evidence for a metal-insulator transition (MIT) solely due to disorder has been observed in the crystalline PCM $Ge_1Sb_2Te_4$ (GST) and similar compounds: upon annealing at temperatures T below 548K, the system exhibits insulating behavior due to Anderson localization; at higher T, it shows metallic behavior. In contrast to the MITs observed in other systems such as P-doped Si, in GST correlation effects do not play a role and the MIT occurs at fixed stoichiometry. In this work, we present a Density Functional Theory study of this effect. We consider a set of very large models of GST containing one to several thousand atoms and different degree of disorder. We identify the microscopic mechanism that localizes the electron wavefunctions near the Fermi energy in the insulating phase: these states are localized inside regions having large vacancy consequent dissolution of these vacancy clusters. These results could help to develop new device based on multiple resistance states.

Session U20 DMP: Focus Session: Mesoscopics - Preparation, Superconductivity and Magnetism 322 - Jacobo Santamaria, Universidad Complutense

11:15AM U20.00001 A Novel Nano-Assembly Technique for the Creation of Ultra-Low Disorder, Locally-Tunable One-Dimensional Systems with Carbon Nanotubes , JONAH WAISSMAN, MAAYAN HONIG, SHARON PECKER, AVISHAI BENYAMINI, ASSAF HAMO, SHAHAL ILANI, Weizmann Institute of Science — Carbon nanotubes offer exciting prospects for studies of fundamental physics in one dimension due to their propensity for clean, defect-free growth, and long lengths. Recent technological advances have allowed for the creation of zero-dimensional ultra-clean nanotube devices, leading to new physics. But to date, the full potential of these molecules for full-fledged experiments in extended one-dimensional geometries is still unrealized, owing to fundamental limitations in making complex and clean devices. In this talk, we will describe a new nano-assembly technique to create suspended carbon nanotube devices of large complexity and with extremely low levels of electronic disorder. We demonstrate the creation of devices with multiple electrostatic gates and devices that combine several nanotubes positioned at chosen distances from each other. These capabilities open the door to a wide array of new experiments on the physics of electrons, spins and mechanics in one dimension.

11:27AM U20.00002 Towards FIB patterning of commercial SiN membranes for sensitive magneto-calorimetry , KURTIS WICKEY, Department of Physics, The Ohio State University, THOMAS KENT, ROBERTO MYERS, Department of Material Science and Engineering, The Ohio State University, JOSEPH HEREMANS, Department of Mechanical Engineering, The Ohio State University, EZEKIEL JOHNSTON-HALPERIN, Department of Physics, The Ohio State University — Investigating magnetocaloric effects in thin films, spin-thermal coupling, and the heat capacity of 2D materials such as graphene, germanene, and MoS_2 requires small (hundreds of microns and less) thermally isolated platforms with sensitivity to comparably small heat capacities. Previously, calorimeters fabricated on amorphous SiNx membranes have been used due to their low thermal conductivity and compatibility with standard fabrication techniques. Here, we use a focused ion beam (FIB) to remove large portions of commercial SiNx membranes, leaving a platform that is thermally isolated from the Si frame by narrow supporting legs. This approach allows the fabrication of the calorimeter around existing samples such as flakes of MoS_2, pre-patterned mesas of magnetic thin films, etc. The thermal isolation of the platform ensures uniform temperature without the use of the thermally conducting layer present in unpatterned membrane calorimeters, further improving the sensitivity of our calorimeters. We will discuss our progress towards realizing these calorimeters.

11:39AM U20.00003 Atomic Calligraphy , MATTHIAS IMBODEN, Boston University, FLAVIO PARDO, CRISTIAN BOLLE, Bell Labs / Alcatel-Lucent, HAN HAN, AMMAR TAREEN, JACKSON CHANG, JASON CHRISTOPHER, BENJAMIN CORMAN, DAVID BISHOP, Boston University — Here we present a MEMS based method to fabricate devices with a small number of atoms. In standard semiconductor fabrication, a large amount of material is deposited, after which etching removes what is not wanted. This technique breaks down for structures that approach the single atom limit, as it is inconceivable to etch away all but one atom. What is needed is a bottom up method with single or near single atom precision. We demonstrate a MEMS device that enables nanometer position controlled deposition of gold atoms. A digitally driven plate is swept as a flux of gold atoms passes through an aperture. Appling voltages on four comb capacitors connected to the central plate by tethers enable nanometer lateral precision in the xy plane over 15x15 sq. microns. Typical MEMS structures have manufacturing resolutions on the order of a micron. Using a FIB it is possible to mill apertures as small as 10 nm in diameter. Assuming a low incident atomic flux, as well as an integrated MEMS based shutter with microsecond response time, it becomes possible to deposit single atoms. Due to their small size and low power consumption, such nano-printers can be mounted directly in a cryogenic system at ultrahigh vacuum to deposit clean quench condensed metallic structures.

11:51AM U20.00004 Oxidation of atomic scale patterns prepared by scanning probe techniques[1] , KAI LI, NAMBOODIRI PRADEEP, JOSEPH FU, LEI CHEN, RICHARD SILVER, National Institute of Standards and Technology, NATIONAL INSTITUTE OF STANDARDS AND TECHNOLOGY TEAM — Scanning probes offer a potential alternative technology pathway in practical atomic scale devices and developing atom-based dimensional standards. However, the process steps, such as atomic scale lithography and subsequent pattern transfer need considerable optimization before the technology can be utilized for manufacturing applications. Nanoscale patterns are prepared in UHV on a hydrogen passivated silicon surface using STM by selectively removing H atoms. These patterns can then be used for further chemical processing such as oxidation and RIE. Conventional Si oxidation processes that require a high temperature and moisture-rich environment are known to damage the hydrogen-protected area. The challenge is to produce a strong SiO_2 hard etch mask on the patterned area without affecting the hydrogen passivation layer. Currently we are developing a new low temperature oxidation process that starts with exposing the patterned areas to oxide/moisture at temperatures below H desorption. The presentation will focus on the details of near atomic scale oxide chemistry relevant to processing nanoscale patterns. We will also present our approach to fabricating stable, atomically defined calibration standards based on the crystal lattice.

12:03PM U20.00005 Fabrication of Flat Freestanding Silicon Nanomembranes , KYLE MCELHINNY, Materials Science and Engineering and Materials Science Program, DAVID CZAPLEWSKI, Center for Nanoscale Materials, Argonne National Laboratory, GOKUL GOPALAKRISHNAN, Materials Science and Engineering and Materials Science Program, MARTIN HOLT, Center for Nanoscale Materials, Argonne National Laboratory, PAUL EVANS, Materials Science and Engineering and Materials Science Program — Silicon nanomembranes are suspended single crystal sheets of silicon, tens of nanometers thick, with areas in the thousands of square micrometers. Freestanding nanomembranes provide an ideal system for studying the physics of nanoscale crystalline materials and find application in novel electronic and photonic materials and devices. Challenges in fabrication arise due to buckling in response to stresses in the silicon-on-insulator starting material. In equilibrium, the elastic energy of the membrane is minimized by distributing the buckling distortion across the entire membrane. We demonstrate that flat nanomembranes can be created by utilizing a modification of traditional membrane fabrication procedures. This new scheme produces an elastically metastable structure, in which the buckling is redistributed to a small area near the edges of the membrane. An energetically favorable mechanism for this redistribution will be discussed. Membranes with thicknesses from 315 nm down to 6 nm have been fabricated, showing vertical deviations of less than 10 nm across an area covering 100 μm $\times$ 100 μm. X-ray scattering experiments performed on these structures demonstrate the importance of the ability to fabricate crystallographically uniform and flat nanomembranes.

12:15PM U20.00006 Mesoscopic relaxations in homoepitaxial systems and their effect on oxygen adsorption , OLEG O. BROVKO, WUWEI FENG, HOLGER L. MEYERHEIM, VALERI S. STEPANYUK, JÜRGEN KIRSCHNER, Max Planck Institute of Microstructure Physics, Halle, Germany — The importance of mesoscopic relaxations in heteroepitaxial systems has been recognized quite a while ago. Both theoretical predictions and subsequent experimental observations have clearly shown the importance of mesoscopic relaxations for electronic, magnetic and geometric properties of heteroepitaxial nanostructures. The implications of mesoscopic relaxations in *homoepitaxial* systems, however, despite theoretical predictions of their importance, are still not fully understood. In the present joint experimental and theoretical paper, by the example of Fe nanoislands grown homoepitaxially on a p(1x1)O/Fe(001) surface we demonstrate that relaxations at the edges of nanoislands do not only determine the electronic and geometric structures of nanoislands' rims but also govern the oxygen adsorption thereon. Contraction of metallic bonds at the edge of Fe nanoislands leads to a corrugation of the edges and the substrate around, which inevitably leads to a change in adsorption height and electronic structure of oxygen atoms residing on the island. Our results outline the importance of mesoscopic relaxations in homoepitaxial nanostructures for the system's electronic and structural properties and the adsorption of light elements and molecules thereon.

12:27PM U20.00007 Synthesis of Low Density Metallic Nanowire Network[1] , EDWARD BURKS, CHAD FLORES, DUSTIN GILBERT, KAI LIU, University of California, Davis CA 95618, THOMAS FELTER, Sandia National Laboratory, Livermore CA 94551, SUPAKIT CHARNVANICHBORIKARN, SERGEI KUCHEYEV, JEFFERY COLVIN, Lawrence Livermore National Laboratory, Livermore CA 94551 — Highly porous metallic nanostructures have been shown to possess interesting thermal, electrical and mechanical properties due in part to their high surface areas and low densities. In this work, ion track-etched membranes were used as a template for electrodeposition to realize a low density interconnected copper nanowire network. Polycarbonate membranes (3-6 microns thick) were first irradiated with energetic Xe^{6+} ions at normal incidence and multiple 45 degree azimuthal angles. The total irradiation density was $2x10^9$ tracks/cm^2. Following a UV/ozone treatment, NaOH was used to preferentially etch the latent tracks of ion damage, creating intersecting nanopores in the polycarbonate matrix. A thin metal layer was then sputtered onto one side of the now-porous membrane to be used as a working electrode. Selected metals such as Cu and Co were then electrodeposited from a sulfate electrolyte into the pores, filling the membrane with an interconnected wire network. The polycarbonate membrane was then folded onto itself several times, and dichloromethane was used to dissolve away the polycarbonate. So far densities as low as 40mg/cm^3 have been achieved. Structural and magnetic properties of such networks have been investigated.

12:39PM U20.00008 Superconducting vortex dynamics in nanostructured hybrids based on Fe single-crystal nanotriangles , JOSE VICENT, ALICIA GOMEZ, ELVIRA GONZALEZ, Universidad Complutense, 28040 Madrid (Spain), MIGUEL IGLESIAS, JAVIER PALOMARES, Instituto Ciencia Materiales, CSIS, 28049 Madrid (Spain), NADIA SANCHEZ, Instituto de Magnetismo Aplicado,28230 Madrid, (Spain), FEDERICO CEBOLLADA, Escuela Superior Telecomunicacion, Universidad Politecnica, 28040 Madrid (Spain), JESUS GONZALEZ, Instituto Ciencia Materiales, CSIS, 28049 Madrid (Spain) — Arrays of Fe single-crystal nanotriangles have been fabricated by Electron Beam Lithography. These arrays are embedded in superconducting Nb thin films. We have studied the superconducting vortex lattice motion on the periodic pinning potentials induced by the magnetic arrays. The vortex dynamics can be controlled through tailoring the magnetic stray field configurations. Which are due to different magnetic remanent states of the Fe single-crystal nanostructures. These configurations have been modified by changing the direction of the saturating applied field and also by using different orientations of the Fe magneto-crystalline easy axes within the triangles.

12:51PM U20.00009 Suppression of Superconductivity in Small Clusters of Proximity-Coupled Superconducting Islands[1] , MALCOLM DURKIN, University of Illinois Urbana-Champaign, SERENA ELEY, Sandia National Laboratories, SARANG GOPALAKRISHNAN, Harvard University, NADYA MASON, University of Illinois Urbana-Champaign — We report transport measurements of proximity-coupled arrays of mesoscopic niobium islands patterned on gold films. We show that superconductivity in the individual islands depends on the number of nearest neighbors, even for island diameters much larger than the superconducting coherence length. We also investigate the length scale where superconductivity in single islands approaches the bilayer approximation. This work is relevant to the understanding of metallic states and quasi-superconductivity in 2D systems [1]. [1] S. Eley, S. Gopalakrishnan, P. Goldbart, and N. Mason, Nature Phys. 8, 59-62 (2012)

1:03PM U20.00010 Electric-field induced superconducting ball formation: new physics of superconductors or a flawed experiment? , R.S.B. GHOSH, J.E. HIRSCH, University of California San Diego — In 1999, Rongjia Tao, P.W. Anderson and coworkers reported the discovery of a surprising new effect in high temperature superconductors (Phys. Rev. Lett. 83, 5575 (1999)): in the presence of a large electric field, millions of superconducting microparticles spontaneously aggregated into balls of macroscopic dimensions. Subsequently, Tao and coworkers reported that the same effect takes place in low temperature conventional superconductors (Physica C 377, 357 (2002)). If true, this effect would be evidence for novel physics of superconductors, not described by BCS theory. However our experimental studies with high temperature superconductors show that (i) ball formation also occurs in the absence of an applied electric field, and (ii) the phenomenon also occurs at temperatures above the superconducting transition temperature. Possible origins of the phenomenon and implications for theories of superconductivity are discussed.

1:15PM U20.00011 Electric-Field Induced Formation of Superconducting Balls , R. TAO, X. XU, E. AMR, H. TANG, Dept. of Physics, Temple University, Philadelphia, PA — Ghosh and Hirsch recently claimed that many micrometer-size particles in liquid nitrogen, as large as between 25 μm and 32 μm, can be aggregated into balls by shaking. It turns out that they performed their experiments with liquid nitrogen in open air, the moisture condensed on their particle surface leading to ball aggregation by shaking. We repeated their shaking experiment and found that dry BSCCO, YBCO and Pb powders in liquid nitrogen do not form any balls by shaking in a glove bag filled with dry nitrogen gas. No matter how we shake the samples, these powders do not aggregate together. However, when we open the glove bag and let the air come to the samples, BSCCO, YBCO and Pb all form some balls quickly by shaking. Also inside the dry glove bag, when we apply an electric field and slowly increase it, superconducting particles form balls within two critical electric fields, E_{c1} and E_{c2} ($E_{c1} < E_{c2}$), while non-superconducting particles do not form balls at all. The electric field induced superconducting ball formation reveals that the area of interaction between electric field and superconductors requires more investigation. However, the phenomenon can be explained within the BCS theory.

1:27PM U20.00012 Characterization of spin induced subgap states in superconductor/quantum dot/superconductor junctions , GEDIMINAS KIRSANSKAS, BRIAN ANDERSEN, KARSTEN FLENSBERG, JENS PAASKE, Center for Quantum Devices, Niels Bohr Institute, University of Copenhagen, DK-2100 Copenhagen Ø, Denmark — We examine the emergence of subgap states in a junction consisting of two superconducting leads coupled to spinful Colomb blockaded quantum dot. The system is modeled by an effective Kondo model, which gives rise to so-called Yu-Shiba-Rusinov states inside the gap. We determine the dispersion of these states with an applied phase difference across the junction and study their dependence on an applied magnetic field. Also the effects of coupling asymmetry to the leads and deviation from the particle-hole symmetric point are addressed.

1:39PM U20.00013 High critical-current superconductor-InAs nanowire-superconductor junctions , SIMON ABAY, Department of Microtechnology and Nanoscience (MC2), Chalmers University of Technology, 412 96 Göteborg, Sweden, HENRIK NILSSON, Division of Solid State Physics, Lund University, 221 00 Lund, Sweden, FAN WU, C.M. WILSON, Department of Microtechnology and Nanoscience (MC2), Chalmers University of Technology, 412 96 Göteborg, Sweden, H.Q. XU, Division of Solid State Physics, Lund University, 221 00 Lund, Sweden, PER DELSING, Department of Microtechnology and Nanoscience (MC2), Chalmers University of Technology, 412 96 Göteborg, Sweden — We report on InAs nanowires coupled to superconducting leads with high critical current and widely tunable conductance. We implemented a double lift-off nanofabrication method to get very short nanowire devices with Ohmic contacts. We observe very high critical currents of up to 800 nA in a wire with a diameter of 80 nm. The current-voltage characteristics of longer and suspended nanowires display either Coulomb blockade or supercurrent depending on a local gate voltage, combining different regimes of transport in a single device. In addition, both the conductance and the critical current of the suspended devices increased step-wise as a function of the local gate voltage.

1:51PM U20.00014 In-Plane Magnetic Field Tolerance of a Nanobridge SQUID Magnetometer[1] , NATANIA ANTLER, ELI M. LEVENSON-FALK, RAVI NAIK[2], SHAY HACOHEN-GOURGY, R. VIJAY, I. SIDDIQI, QNL, UC Berkeley — We describe the operation of a nanobridge SQUID magnetometer subject to an in-plane magnetic field of up to 60 mT. The magnetometer is comprised of a nanobridge SQUID with two aluminum weak links embedded in a 4-8 GHz microwave tank circuit for dispersive readout. We obtain a flux sensitivity of 17 $n\Phi_0/Hz^{1/2}$ with 50 MHz of instantaneous bandwidth in zero magnetic field. This effectively corresponds to single spin resolution, within a 1 Hz bandwidth, for nanomagnets placed within 100-200 nm from the nanobridge edge. We find that the effective flux sensitivity only degrades by a factor of $\sim$3 up to 60 mT of applied field. Finally, we describe progress towards magnetization dynamics measurements in different spin species such as Cobalt nanoclusters and Bismuth implanted in Silicon-28.

Session U21 FIAP: Nanotechnology Applications: Advances in Sensors and Therapies 323 - Michael Naughton, Boston College

11:15AM U21.00001 Protein typing of circulating microvesicles allows real-time monitoring of glioblastoma therapy , HUILIN SHAO, JAEHOON CHUNG, Harvard University, Center for Systems Biology, LEONORA BALAJ, Harvard Medical School, RALPH WEISSLEDER, HAKHO LEE, Harvard University, Center for Systems Biology — Glioblastomas shed large quantities of small, membrane-bound microvesicles (MVs) into the circulation. While these hold promise as potential biomarkers of therapeutic response, there remain hurdles to their identification and quantitation. Here, we describe a highly sensitive and rapid analytical technique for profiling circulating MVs directly from blood samples of glioblastoma patients. MVs, introduced onto a dedicated microfluidic chip, are labeled with target-specific magnetic nanoparticles and detected by a miniaturized nuclear magnetic resonance system. Compared with current standard assays (e.g., Western blotting, ELISA and flow cytometry), this integrated system has a much higher detection sensitivity, and can differentiate glioblastoma multiforme (GBM) MVs from non-tumor host cell-derived MVs. The system further showed that circulating GBM MVs could serve as a surrogate for primary tumor by reflecting its molecular signature and a predictor of treatment-induced changes. We expect that this converging nanotechnology platform would have a wide range of applications, providing both an earlier indicator of drug efficacy and a potential molecular stratifier for human clinical trials.

11:27AM U21.00002 Bioelectronic Device Mimicking Human Sensory System based on Nanovesicle-Carbon Nanotube Hybrid Structure , DAESAN KIM, HYE JUN JIN, SAN HUN LEE, Seoul National University, TAE HYUN KIM, Soonchunhyang University, JUHUN PARK, HYUN SEOK SONG, TAI HYUN PARK, SEUNGHUN HONG, Seoul National University — We have developed a nanovesicle-based bioelectronic nose (NBN) that could mimic the receptor-mediated signal transmission of human olfactory systems and recognize a specific odorant. The NBN was comprised of a single-walled carbon nanotube (CNT)-based field effect transistor and cell-derived nanovesicles containing human olfactory receptors and calcium ion signal pathways. Importantly, the NBN took advantages of cell signal pathways for sensing signal amplification. It enabled $\sim$100 times higher sensitivity than that of previous bioelectronic noses based on only olfactory receptor protein and CNT transistors. The NBN sensors exhibited a high sensitivity of 1 fM detection limit and a human-like selectivity with single-carbon-atomic resolution. Furthermore, these sensors could mimic a receptor-mediated cellular signal transmission in live cells. This versatile sensor platform should be useful for the study of molecular recognition and biological processes on cell membranes and also for various practical applications such as food conditioning and medical diagnostics.

11:39AM U21.00003 Fabrication of Wearable Sensors for Human Health Monitoring through Magnetically Directed Assembly Techniques[1] , AZAR ALIZADEH, JEFFREY ASHE, MATTHEW MISNER, YANZHE YANG, SHENG ZHONG, MING YIN, JOLEYN BREWER, JASON KARP, GE Global Research — Many previous efforts to modify patient monitors for remote or wearable use have suffered from high cost, poor performance, and low medical acceptance. A new technology approach is needed to enable these clinical benefits and to satisfy challenging economic, clinical, and user-acceptance criteria. Here, we present results on our initial efforts aimed at designing and building a prototype multi-wavelength arrayed photoplethysmograph (PPG) by using magnetically directed self-assembly (MDSA). We will discuss novel approaches in magnetic nanomaterial design, synthesis and deposition to enable MDSA based manufacturing. We will also demonstrate that multiple devices can be deposited through heterogeneous MDSA. The novel MDSA technology could make such PPG sensors a reality.

[1]This effort is sponsored by the Department of the Army under award W81XWH1110833

11:51AM U21.00004 Low-power, fast, selective nanoparticle-based hydrogen sulfide gas sensor[1] , ALLEN SUSSMAN, Department of Physics, University of California at Berkeley, Berkeley, California 94720, USA, WILLIAM MICKELSON, Center of Integrated Nanomechanical Systems, University of California at Berkeley, Berkeley, California 94720, USA, A. ZETTL, Department of Physics, University of California at Berkeley, Berkeley, California 94720, USA — We demonstrate a small, low-cost, low-power, highly sensitive, and selective nanomaterials-based gas sensor. A network of tungsten oxide nanoparticles is heated by an on-chip microhotplate while the conductance of the network is monitored. The device can be heated with short pulses, thereby drastically lowering the power consumption, without diminishing the sensor response. The sensor shows high sensitivity to hydrogen sulfide and does not have significant cross sensitivities to hydrogen, water, or methane, gases likely to be present in operation. A sensing mechanism is proposed, and its effect on electronic properties is discussed.

[1]The authors thank Eni S.p.A, the National Science Foundation-supported Center of Integrated Nanomechanical Systems under Grant No. EEC-083819 and U.S. Department of Energy Contract No. DE-AC02-05CH11231

12:03PM U21.00005 Nanocoax-based molecular imprint polymer for electrochemical biosensor[1] , BINOD RIZAL, MICHELLE ARCHIBALD, LAURA SIMKO, TIMOTHY CONNOLLY, STEPHEN SHEPARD, MICHAEL J. BURNS, THOMAS C. CHILES, MICHAEL J. NAUGHTON, Boston College — We have used molecular imprint polymerization (MIP) on planar, nanopillar, and nanocoax structures to fabricate label-free, all-electronic electrochemical biosensors with high selectivity and sensitivity. MIP-based films of $\sim$ 7 nm thickness are formed on gold-coated surfaces by electropolymerization of a solution containing phenol and a target protein (streptavidin, at 100 μg/ml, or 1 nanomole concentration) and subsequent removal of exposed target protein, leaving behind its molecular imprint. With its molecular memory, MIP subsequently specifically recognizes and binds target protein with attomolar sensitivity, detected via differential pulse voltammetry. We will discuss and compare the results of MIP for different proteins on planar, nanopillar, and nanocoax structures, along with their respective ultimate sensitivities.

12:15PM U21.00006 High-Q Gold and Silicon Nitride Bilayer Nanostrings[1] , TUSHAR S. BISWAS, ABDUL SUHEL, BRADLEY D. HAUER, ALBERTO PALOMINO, KEVIN S.D. BEACH, JOHN P. DAVIS, University of Alberta — Nanostrings are attractive for sensing applications due to their small mass and ease of fabrication, yet very high quality factors (Q). We have fabricated and measured nanostrings from high stress silicon nitride resulting in high Q, and have discerned the dominant dissipation mechanism in our devices. This will provide a method to further improve our devices. In addition, to render our strings chemically sensitive, we decided to deposit a chemically functionalizable layer on the top of our strings. We have shown that the addition of a gold layer for this purpose does not adversely affect the Q of the fundamental mode. As an added bonus, the differences in thermal expansion between different layers make the strings sensitive to temperature changes. This enables actuation of the strings' motion using an alternating current though the gold layer, via a thermoelastic mechanism, and provides integrated actuation that averts any external actuation scheme.

12:27PM U21.00007 Real-Time Control of Biological Motor Activity using Graphene-polymer Hybrid Bioenergy Storage Device , DONG JUN LEE, KYUNG-EUN BYUN, DONG SHIN CHOI, EUNJI KIM, DAESAN KIM, Seoul National University, DAVID SEO, HEEJUN YANG, Samsung Research Park, SUNAE SEO, Sejong University, SEUNGHUN HONG, Seoul National University, HYBRID NANODEVICE LAB TEAM, SAMSUNG RESEARCH PARK TEAM — Biological motors have been drawing an attention as a key component for highly efficient nanomechanical systems. For such applications, many researchers have tried to control the activity of motor proteins through various methods such as microfluidics or UV-active compounds. However, these methods have some limitations such as the incapability of controlling local biomotor activity and a slow response rate. Herein, we developed a graphene-polymer hybrid nanostructure-based bioenergy storage device which enables the real-time control of biomotor activity. In this strategy, graphene layers functionalized with amine groups were utilized as a transparent electrode supporting the motility of biomotors. And conducting polymer patterns doped with adenosine triphosphate (ATP) were electrically deposited on the graphene and utilized for the fast release of ATP by electrical stimuli through the graphene. Such controlled release of ATP allowed us to control the motility of actin filaments propelled by myosin biomotors in real time. This strategy should enable integrated nanodevices for the real-time control of biological motors to the nanodevices, which can be a significant stepping stone toward hybrid nanomechanical systems based on motor proteins.

12:39PM U21.00008 Graphene for Biomedical Implants , THOMAS MOORE, Department of Bioengineering, Clemson University, Clemson, SC 29634, RAMAKRISHNA PODILA, Department of Physics, Clemson University, Clemson, SC 29634, FRANK ALEXIS, Department of Bioengineering, Clemson University, Clemson, SC 29634, APPARAO RAO, Department of Physics, Clemson University, Clemson, SC 29634, CLEMSON BIOENGINEERING TEAM, CLEMSON PHYSICS TEAM — In this study, we used graphene, a one-atom thick sheet of carbon atoms, to modify the surfaces of existing implant materials to enhance both bio- and hemo-compatibility. This novel effort meets all functional criteria for a biomedical implant coating as it is chemically inert, atomically smooth and highly durable, with the potential for greatly enhancing the effectiveness of such implants. Specifically, graphene coatings on nitinol, a widely used implant and stent material, showed that graphene coated nitinol (Gr-NiTi) supports excellent smooth muscle and endothelial cell growth leading to better cell proliferation. We further determined that the serum albumin adsorption on Gr-NiTi is greater than that of fibrinogen, an important and well understood criterion for promoting a lower thrombosis rate. These hemo-and biocompatible properties and associated charge transfer mechanisms, along with high strength, chemical inertness and durability give graphene an edge over most antithrombogenic coatings for biomedical implants and devices.

12:51PM U21.00009 Controlling the drug release rate from electrospun phospholipid polymer nanofibers with micro-patterned diamond-like carbon (DLC) coating , SOKI YOSHIDA, Department of Mechanical Engineering, Keio University, TERUMITSU HASEBE, Department of Radiology, Tokai University Hachioji Hospital, TETSUYA SUZUKI, ATSUSHI HOTTA, Department of Mechanical Engineering, Keio University — An effective way of controlling drug release from polymer fibers coated with thin diamond-like carbon (DLC) film was introduced. It is highly expected that electrospinning will produce polymer fiber and useful for drug delivery systems. The drug release rate should be rather precisely controlled in order to prevent side effects due to the burst drug-release from polymers. Our previous research has already revealed that the micro-patterned DLC could control the drug release rate from biocompatible polymer films. In this study, the drug release profile of the polymer fibers with DLC was investigated. Hydrophilic 2-methacryloyloxyethyl phosphorylcholine (MPC) was selected as a typical biocompatible polymer. It is well known that the MPC polymers show good hemocompatibility and that both MPC and DLC are excellent biocompatible materials with antithrombogenicity. The DLC/MPC composites could therefore be extensively utilized for blood-contacting medical devices. The percentile covered area with patterned DLC on MPC fibers containing drug was varied from 0% (without DLC) to 100% (fully covered). It was found that the drug eluting profiles could be effectively controlled by changing the covered area of micro-patterned DLC coatings on MPC.

1:03PM U21.00010 New Approaches to Targeted Drug Delivery , JAMES COOPER, WILLIAM OLIVER, University of Arkansas, DANIEL FOLOGEA, Boise State University — For targeted drug delivery, one of the primary drawbacks lies with the inability to design a delivery system that can be loaded with a variety of drugs and biomolecules. Motivated by this challenge, we will present data showing 400 nm liposomes loaded via the novel method of lysenin pores. These pores are approximately 3 nm in diameter and can be closed with divalent and trivalent ions in addition to charged polymers. This new method allows for the controllable passage of large biomolecules such as DNA and protein without the inherent problems common to active and passive loading methods. We will show proof-of-concept results of this method using fluorescent calcein as a drug simulator. Furthermore, data demonstrating current attempts at loading DNA will also be presented.

1:15PM U21.00011 Nonspecific targeting of iron oxide nanoparticles to the liver, kidney and spleen: A novel approach to achieving specificity , MAHESHIKA PALIHAWADANA ARACHCHIGE, AMANDA FLACK, XUEQUN CHEN, JING LI, DAVID OUPICKY, Y.-C. NORMAN CHENG, YIMIN SHEN, BHANU JENA, GAVIN LAWES, Wayne State University — Recently, there has been significant interest in developing Fe_3O_4 nanoparticles for biomedical applications including targeted drug delivery and magnetic resonance imaging. One of the major problems in these applications is the undesirable filtration of these materials by the mononuclear phagocyte system. Preliminary magnetic resonance imaging and magnetization studies on hyaluronic acid coated nanoparticles injected intravenously into mice confirm that the nanoparticles accumulate in the liver, spleen, and kidneys. To identify whether certain specific proteins are responsible for nanoparticle accumulation in these organs, we exposed hyaluronic acid coated nanoparticles to proteins extracted from the liver, spleen, and kidneys, together with blood plasma proteins, then subsequently used gel electrophoresis and mass spectroscopy to identify the proteins binding to the nanoparticles. We find that the unwanted accumulation of nanoparticles in these organs can potentially be attributed to specific binding by a small number of proteins. By appropriately functionalizing the iron oxide nanoparticles, we expect that the nanoparticles uptake in the liver, spleen, and kidneys will be reduced.

1:27PM U21.00012 ABSTRACT WITHDRAWN –

1:39PM U21.00013 Interaction of Nucleobases with Semiconducting Nanotubes and Nanocages: Does the Solvent Matter? , ZHOUFEI WANG, Department of Physics, South China Agricultural University, Guangzhou, China, WILLIAM SLOUGH, HAIYING HE, RAVINDRA PANDEY, Department of Physics, Michigan Technological University, Houghton, MI 49931, SHASHI KARNA, US Army Research Laboratory, Weapons and Materials Research Directorate, ATTN: RDRL-WM, Aberdeen Proving Ground, MD 21005-5069 — The tremendous advancement in nanotechnology has brought great promise in the area of bio-applications. Nanoscale materials and structures have attracted a lot of interest for their potential applications in biosensing, biorecognition, luminescent probes for DNA, biomedical labeling, drug delivery etc. Gaining fundamental understanding of the interaction of bio-systems with nanomaterials is critical in putting all these applications into full play. Despite the fact that most of these interactions appear in aqueous environment, the solvent effect has often been neglected in previous computational studies. In this talk, we will report our comparison study of nucleobases interacting with BN nanotubes and chalcogenide nanocages with/without considering the aqueous solution, based on first-principles calculations. The results reveal a significant effect from the water solution, which may largely reduce the interaction energy due to the polarization of the dielectric solvent medium.

Thursday, March 21, 2013 11:15AM - 2:15PM –

Session U22 DCMP: Optical Properties of Nanowires 324 - Joe Tischler, Naval Research Laboratory

11:15AM U22.00001 Exciton Dynamics in Hexagonal InP Nanowires[1] , MASOUD KAVEH-BAGHBADORANI, Department of Physics, University of Cincinnati, Cincinnati, OH 45221, U.S.A, WOLFGANG LANGBEIN, School of Physics and Astronomy, Cardiff University, Cardiff CF24 3AA, U.K, QIANG GAO, CHENNUPATI JAGADISH, Department of Electronic Materials Engineering, Australian National University, Canberra, ACT 0200, Australia, HANS-PETER WAGNER, Department of Physics, University of Cincinnati, Cincinnati, OH 45221, U.S.A — We study the exciton dynamics in InP nanowire ensembles by intensity- and temperature-dependent photoluminescence (PL) measurements, time-correlated-single-photon-counting (TCSPC) and heterodyne detected four-wave-mixing experiments (HFWM). The InP nanowires were grown on fused silica substrate by 50 nm gold catalyst metal-organic-vapor-phase-epitaxy at a temperature of 450 $^{\circ}$C resulting in nearly wurtzite type nanowires. The PL measurements at 15 K show a strong emission band at 837 nm and two weak side bands at nearly 820 and 860 nm. The bands are tentatively attributed to trapped, free and zinc-blende related exciton transitions, respectively. With increasing temperature the free-exciton band gains importance relative to the dominating trapped exciton band while the low energy band vanishes. TCSPC measurements show an increasing PL decay rate of all emission bands with increasing temperature most pronounced for the low energy band. The result agrees with the exciton population dynamics obtained from three-beam HFWM measurements. Photon echo experiments at 80 K reveal an ultrafast exciton dephasing time of less than 100 fs which is attributed to scattering with a high carrier background in these nanowires.

[1]The support of the Australian Research Council is kindly acknowledged.

11:27AM U22.00002 Time Resolved Photoluminescence Studies of ZnO and Zn_2SnO_4 Nanowires for Solar Cells Applications[1] , BAICHHABI RAJ YAKAMI, MEG MAHAT, Department of Electrical Engineering, University of Wyoming, JIAJUN CHEN, LIYOU LU, WENYONG WANG, Department of Physics and Astronomy, University of Wyoming, JON M. PIKAL, Department of Electrical Engineering, University of Wyoming — Sensitized nanowires (NWs) are a promising option for solar cells. They serve as the support structure for the absorbing centers, provide interfacial charge separation, and transport to the anode. Most work has focused on binary oxides, but ternary oxides have advantages due to flexibility in the properties of the oxide. Here we report on the photoluminescence (PL) and Time Resolved PL (TRPL) of Zinc oxide (ZnO) and Zinc Tin Oxide (ZTO) NWs grown by Chemical Vapor Deposition. The ZnO NWs show strong band gap emission and weak but resolvable defect emission peaks. The PL from the ZTO NWs does not show any band gap emission and absorption measurements confirm that these NWs have a direct forbidden transition. The ZTO NWs do have a board visible emission peak, which is usually attributed defects and oxygen vacancies. TRPL of the band gap emission in ZnO NWs yield a carrier lifetime of 1.4ns. The TRPL of the defect peaks in ZTO NWs are more complicated, showing a multi-exponential decay but with an overall decay rate similar to the ZnO NWs. This indicates that the expected increase in carrier lifetime in the ZTO NWs is not currently realized likely due to defect recombination, and additional optimization of the NW growth process may yield improved performance.

[1]DOE

11:39AM U22.00003 Picosecond carrier dynamics within the band structure of single InP nanowires with zincblende and wurtzite symmetries , M. MONTAZERI, Y. WANG, H.E. JACKSON, L.M. SMITH, Dep. of Physics, University of Cincinnati, Cincinnati, OH, J.M. YARRISON-RICE, Dep. of Physics, Miami University, Oxford, OH, T. BURGESS, H.H. TAN, Q. GAO, C. JAGADISH, Dep. of Electronic Materials Engineering, Australian National University, Australia, Canberra, ACT, Australia — Low temperature transient Rayleigh scattering spectroscopy (TRS) is used to probe the carrier dynamics of single zincblende (ZB) and wurtzite (WZ) InP nanowires (NW). The NWs were MOCVD grown using 50 nm Au-nanoparticles. For ZB NWs, the TRS signal reveals various dynamical processes of the electrons within the conduction band as well as the holes in the degenerate heavy/light bands and the split-off band. The fundamental and the split-off band gaps are measured at 1.423eV and 1.529eV. For WZ NWs, we observe three excitonic resonances associated with the hole bands A at 1.501eV, B at 1.534eV and C at 1.66eV. We also observe clear transitions between the same A and B bands and the second conduction band, resulted from zone folding of the L-valley, which is measured at $\sim$ 230meV higher than the first. The lifetimes of the A, B and C excitons at $\sim$ 800ps, $\sim$ 400ps and $\sim$ 50ps respectively. In addition, a type II transition between electrons confined to small zincblende inclusions and holes confined to the wurtzite is identified which marks the ZB-WZ band-offset. We acknowledge the NSF (DMR-1105362, 1105121), ECCS-1100489 and the ARC.

11:51AM U22.00004 Electronic and optical properties of InN nanowires from first principles[1] , DYLAN BAYERL, EMMANOUIL KIOUPAKIS, University of Michigan Department of Materials Science and Engineering — Group-III-nitride nanowires are promising materials for photovoltaic and solid-state-lighting applications. We use first-principles calculations to investigate the electronic and optical properties of InN nanowires. Density functional theory provides the ground-state properties to which we subsequently apply quasiparticle corrections with the GW method. We thereby accurately predict the electronic band gaps, effective masses, and band dispersions of these nanostructured materials. We further solve the Bethe-Salpeter equation to predict the optical absorption spectra of InN nanowires as a function of cross-sectional dimension and geometry. We demonstrate that quantum confinement can increase the fundamental gap in InN nanowires as high as near-ultraviolet energies.

[1]This research was supported as part of CSTEC, an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science. Computational resources were provided by the DOE NERSC facility.

12:03PM U22.00005 Stark Effect of Excitons in a Quantum Nano-rod with Parabolic Confinement[1] , S.K. LYO, U. California, Irvine, CA — We study the exciton binding energy and the oscillator strength as a function of a DC electric field in a quasi-one-dimensional quantum dot (*i.e.*, nano rod) with parabolic confinements in the conduction and valence bands. The relative importance of the quantum confinement and electron-hole interaction is examined by varying the the linear confinement length (*i.e.*, rod length). We find an abrupt decrease of the oscillator strength, loss of exciton binding energy, and a sudden increase of the root-mean-square average of electron-hole separation as the excitons are dissociated at the threshold field. The field dependence of the effects are also investigated as a function of the rod length and the radius of the nano rod. The numerical results are applied to GaAs and CdSe rods.

[1]This work was supported by DOE/BES under Contract No.DE-AC04-94AL85000.

12:15PM U22.00006 Observation of quantum dots in GaAs/AlGaAs core-multishell nanowire quantum well tubes[1] , TENG SHI, HOWARD JACKSON, LEIGH SMITH, University of Cincinnati, JAN YARRISON-RICE, Miami University, CHANGLIN ZHENG, PETER MILLER, JOANNE ETHERIDGE, Monash University, BRYAN WONG, Sandia National Laboratories, QIANG GAO, HARK TAN, CHENNUPATI JAGADISH, Australian National University — We use photoluminescence excitation (PLE) spectroscopy to study the electronic structure of GaAs/$Al_xGa_{1-x}As$ core-multishell nanowires (NW) which define 4 nm GaAs quantum well tubes (QWTs) embedded inside AlGaAs barriers wrapped around a central 50 nm GaAs core. HAADF-STEM images of NW cross-sections show a GaAs layer wrapped around the hexagonal facets with some tapering. Numerical calculations of this structure show the ground states are localized along the corners of the hexagonal QWT. Because of the strong quantum confinement, localized states can easily be formed through width or alloy concentration fluctuations. By using a hemispherical solid immersion lens, we are able directly observe such localized quantum dots (QDs) and map the emission of QDs with a spatial resolution of 600 nm in a single NW. Excitation and emission light polarized parallel and perpendicular to the NW long axis show multiple QDs along the NW long axis with $\sim$100 micro-eV emission lines. PLE measurements on single dots reveal excited state transitions between confined light or heavy holes to electrons at or above the AlGaAs conduction band barrier.

[1]We acknowledge the NSF through DMR-1105362, 1105121 and ECCS-1100489, DOE and the ARC.

12:27PM U22.00007 Photocurrent Spectroscopy of ZB and WZ InP Nanowire Ohmic devices , K. PEMASIRI, S. PERERA, H.E. JACKSON, L.M. SMITH, University of Cincinnati, OH, J.M. YARRISON-RISE, Miami University, Oxford, OH, S. PAIMAN, Q. GAO, H.H. TAN, C. JAGADISH, Australian National University, Canberra, Australia — We use photocurrent spectroscopy to study InP nanowire Ohmic devices having either Zincblende (ZB) or wurtzite (WZ) crystal structures at 10K. Photolithography is used to fabricate Ohmic Ti/Al contact pads separated by 5 μm. Using a tunable Ti-Sapphire laser, photocurrent is measured as a function of bias voltage and excitation energy. At low temperatures (10 K), the ZB device shows strong evidence for excitonic resonance peaks at 1.425eV and 1.539eV relevant to the degenerate heavy and light holes band and the split-off band. The WZ device shows three excitonic peaks at 1.504eV, 1.530eV, and 1.655eV corresponding to the A, B and C valence band energies, respectively. These energies coincide with recent photoluminescence excitation measurements. In some WZ InP nanowire devices, the A, B and C peaks have been observed at 20-30meV higher energies compared to above, suggesting a possible quantum confinement in the nanowires. The polarization dependence of photocurrent spectra measured from 275nm ZB nanowire and 20nm WZ nanowire shows very good agreement with theoretical absorption of light by nanowires as a function of diameter and photon energy. We acknowledge the NSF through DMR-1105362, 1105121 and ECCS-1100489, and the ARC.

12:39PM U22.00008 Photocurrent spectroscopy of GaAs/GaP hetero-structured nanowires[1] , P. KUMAR, H.E. JACKSON, L.M. SMITH, University of Cincinnati, OH, USA, J. YARRISON RICE, Miami University, Oxford, OH, USA, J.H. KANG, Q. GAO, H.H. TAN, C. JAGADISH, The Australian National University, Canberra, ACT 0200, Australia — We study the photocurrent from photoexcited charge carriers in GaAs/GaP axial and radial hetero-structured nanowires (NWs). These NWs are grown using Metal-Organic Chemical Vapor Deposition (MOCVD) in [111]B direction with Au nano-particles as catalysts. As grown axial GaAs/GaP NWs are sonicated in methanol and dispersed on Si-SiO insulated substrate. Photolithography followed by Ti/Al (20nm/300nm) metal evaporation and lift-off is used to fabricate contacts in Metal-semiconductor-metal across single NW. Spatial imaging of photocurrent at different wavelengths distinguishes the GaP and GaAs regions in these NWs. Peak photocurrent is observed around GaP region for light wavelengths $\sim$ 458nm whereas peak photocurrent is shift towards GaAs region for light wavelength $\sim$ 800nm. Photocurrent measurements in GaAs/GaP strained core-shell NWs are in progress.

[1]We acknowledge the NSF through DMR-1105362, 1105121 and ECCS-1100489, and the ARC.

12:51PM U22.00009 Photocurrent spectroscopy of single ZB GaAs and GaAs/AlGaAs core-shell nanowires[1] , BEKELE BADADA, LEIGH SMITH, HOWARD JACKSON, Department of Physics, University of Cincinnati, Ohio 452210-0011, USA, JAN YARRISON-RICE, Department of Physics, Miami University, Oxford, Ohio 45056, USA, TIM BURGESS, CHENNUPATI JAGADISH, Department of Electronic and Materials Engineering, Australian National University, Canberra, ACT, 0200, Australia — We investigate the band structure of single ZB GaAs nanowires and GaAs/$Al_{0.5}Ga_{0.5}$As core shell nanowires using photocurrent spectroscopy at room and low temperatures. The single nanowire devices were fabricated photolithographically to define Ti (20nm)/Al (300nm) metal contacts on either end the nanowire. Photocurrent measurements were performed using CW excitation from a tunable CW Ti-Sapphire laser (775nm-890nm) and a broadly tunable (550-960 nm) pulsed excitation from a coherent super continuum photonic crystal fiber. At room temperature we observe an Urbach tail near the absorption edge at 1.42 eV for both GaAs and GaAs/ $Al_{0.5}Ga_{0.5}$As core-shell nanowires. In the core shell structure, we also observe the exponential tail from the $Al_{0.5}Ga_{0.5}$As superimposed on the GaAs absorption in the core. The 2eV onset is consisant with 50%. At low temperature, 10K, similar measurements were performed and a peak is observed near the band edge $\sim$ 1.50-1.51 eV for both bare and core-shell structure for GaAs reflecting the contribution of excitons to the photocurrent.

[1]We acknowledge the NSF through DMR-1105362, 1105121 and ECCS-1100489, and the ARC.

1:03PM U22.00010 Strain-induced piezoelectric field effects on the optical properties of ZnO nanowires[1] , WENHAO GUO, SHUIGANG XU, NING WANG, M.M.T. LOY, SHENGWANG DU, Hong Kong University of Science and Technology — In our work, we report the evidence of piezoelectric effects which modifies the spatial distribution of the photo-generated carriers in bent ZnO nanowires. This piezoelectric effect, together with strain-induced changes of the energy band structure, results in redshift of free exction photo-luminescence emission in strained ZnO nanowires. The net redshift is only dependent on the strain, independent on the diameter of the nanowire unless the depth of depletion layer is comparable to the size of nanowire. The experimental results obtained by the near-field scanning microscopy agree well with our numerical simulation.

[1]The work was supported by the Hong Kong Research Grants Council under Project Nos. CityU5/CRF/08, 604009, 603408, and HKUST11/CRF/11G (or HKU8/CRF/11G).

1:15PM U22.00011 Tip-enhanced Raman scattering of an InGaN/GaN quantum well on a single GaN nanorod , EMANUELE POLIANI, MARKUS WAGNER, AXEL HOFFMANN, JANINA MAULTZSCH, Technische Universität Berlin, 10623 Berlin, Germany, JUAN SEBASTIAN REPARAZ, Catalan Institute of Nanotechnology, 08193 Bellaterra, Spain, MARTIN MANDL, WERNER BERGBAUER, MARTIN STRASSBURG, Osram Opto Semiconductors GmbH, 93055 Regensburg, Germany — Vertical GaN nanorods with double In0.2Ga0.8N/GaN quantum well were studied by tip-enhanced Raman spectroscopy (TERS). Exploiting the spatial resolution below the diffraction limit, we were able to perform a Raman map of the nanorod top part with 35 nm spatial resolution. Undetectable in the far field, enhanced phonons belonging to InGaN, InN rich regions and GaN were detected and analyzed as Raman shift map. These enhanced spatially resolved phonons revealed an Indium cluster region nucleated at the end of a planar dislocation in the GaN core. The dislocation continues inside the cluster area as an interface between zinclende and wurtzite modification. A narrow localized strain zone was found close to the interface on the zinc blende side surrounding material. On the wurtzite side instead, the Raman map of the GaN surface optical phonon revealed a more extended charge depletion region.

1:27PM U22.00012 Raman Spectroscopy on GaAs/GaP Nanowire Axial Heterostructures[1] , YUDA WANG, MOHAMMAD MONTAZARI, LEIGH SMITH, HOWARD JACKSON, University of Cincinnati, JAN YARRISON-RICE, Miami University, QIANG GAO, JUNG-HYUN KANG, CHENNUPATI JAGADISH, Australian National University — We use Raman scattering to study the spatially-resolved strain and stress in Zinc Blende GaAs/GaP axial heterostructure nanowires at room temperature. The nanowires are grown by Metal-Organic Chemical Vapor Deposition in the [111] direction with Au nano particles as catalysts. After initial growth of a 6 μm-long GaP wire, a short GaAs segment is grown. Since Raman scattering reflects the phonon energies that are in turn related to the stress, we control the polarization of the incident and scattered light to acquire and resolve the TO1 (Transverse Optical) and TO2 phonon modes of both GaAs and GaP. High spatial resolution Raman scans along the nanowires show that the GaAs/GaP interface is clearly identifiable. Within the GaP section of the wire, GaP TO modes are observed at lower energies compared to bulk GaP since it is under tension, while GaAs shell TO modes are at higher energies than bulk GaAs since it is under compression. A strain gradient exists across the interface so the GaP phonon energies shift to lower and GaAs phonon shift to higher energies as one approaches the interface.

[1]We acknowledge the NSF through DMR-1105362, 1105121 and ECCS-1100489, and the ARC.

1:39PM U22.00013 Anisotropic surface plasma resonance in self-assembled ErSb quantum nanostructures of tunable shape and orientation , DANIEL OUELLETTE, Physics Department, University of California, Santa Barbara, HONG LU, Materials Department, University of California, Santa Barbara, SASCHA PREU, Chair of Applied Physics, Univ. of Erlangen-Nuremberg, Germany, JUSTIN WATTS, BEN ZAKS, MARK SHERWIN, Physics Department and Institute for Terahertz Science and Technology, University of California, Santa Barbara, ARTHUR GOSSARD, Materials Department, University of California, Santa Barbara — Incorporation of erbium during MBE growth of GaSb leads to various self-assembled, semi-metallic ErSb nanostructures. At the lowest concentration, spheres of diameter 4-5 nm are observed. By contrast, at 7-10% Er, $\sim$5 nm diameter nanowires self-align along the $< 001 >$ growth direction, and at 15-20%, the nanowires align in the growth plane along the $< \bar{1}10 >$ direction. Light polarized along the wires is strongly attenuated over a broad range from THz to near-IR. By contrast, light polarized perpendicular to the wires experiences minimal attenuation apart from a very strong surface plasma resonance at 0.46 eV. Surprisingly, the resonant frequency of the nanospheres is slightly higher than that of the wires, despite the smaller depolarization factor. Motivated by this observation and estimates of the confinement energy, we construct an effective medium theory for the nanostructures which includes a single characteristic intersubband transition. This model provides an excellent description of the IR reflectance and transmittance over the whole range of Er concentration, in contrast to a model which excludes the effect of quantum confinement.

1:51PM U22.00014 Continuous frequency multiplication in a strongly driven modulated nanowire[1] , KATHLEEN HAMILTON, ALEXEY KOVALEV, AMRIT DE, LEONID PRYADKO, University of California, Riverside — High-order harmonic generation in a bulk solid strongly driven by a few-cycle pulsed infrared laser has recently been observed [1]. We consider the possibility of observing an analogous effect using a continuously driven, single-band one-dimensional metal. In the absence of phonon scattering, the quantum efficiency of frequency tripling for such a system can be as high as 93%. Combining the Floquet quasi-energy spectrum with the Keldysh Green's function technique, we derive the quantum transport equation for strongly and rapidly driven electrons in the presence of weak scattering by phonons. The power absorbed from the driving field is continuously dissipated by phonon modes, leading to a quasi-equilibrium in the electron distribution. We assume terahertz frequency range, and use the Kronig-Penny model with varying effective mass to establish dimensions and modulation periodicity of an InAs/InP nanowhisker. Driving such nanowhiskers could lead to efficient third and higher-harmonic generation. [1] S. Ghimire et al., Nature Physics 7, 138-141 (2011).

[1]This research was supported in part by the U.S. Army Research Office under Grant No. W911NF-11-1-0027, and by the NSF under Grant No. 1018935.

2:03PM U22.00015 Generation of core-shell structures and segregation of dopants in Si/SiO_2 nanowires , SUNGHYUN KIM, JI-SANG PARK, K.J. CHANG, Department of Physics, Korea Advanced Institute of Science and Technology, Daejeon 305-701, Republic of Korea — Oxidized Si nanowires (SiNWs) are usually synthesized by subsequent thermal annealing of as-grown SiNWs. It has been observed that B diffusivity is enhanced during thermal annealing in SiNWs, similar to the phenomena called transient enhanced diffusion or oxidation enhanced diffusion in planar Si/SiO_2 interfaces. However, previous theoretical studies have been focused on hydrogen or hydroxyl terminated SiNWs. In this work, we generate realistic atomic models for oxidized SiNWs in which crystalline Si core is sheathed by amorphous SiO_2 by using a combined approach of classical molecular dynamics simulations with first-principles density functional calculations. For realistic core-shell structures, we investigate the stability and segregation behavior of B and P dopants. A single substitutional B is more stable in the Si core, with a very small energy variation with the radial position of B. On the other hand, B dopants easily segregate to the oxide shell with the aid of Si self-interstitials generated during thermal oxidation. In contrast to B dopants, P dopants prefer to reside in the Si core even in the presence of Si self-interstitials but tend to aggregate in the Si region near the interface, forming nearest-neighbor donor pairs which are electrically inactive.

Session U23 FIAP: Semiconductors: Theory and Spectra I 325 -

11:15AM U23.00001 Atomic Multiplets in X-ray Spectroscopies of Solids[1] , BERNARD DELLEY, ANNE-CHRISTINE ULDRY, Paul Scherrer Institut, Villigen, Switzerland — The electronic structures of compounds involving open d- and f- shell are studied frequently by X-ray and electron spectroscopies. For a better understanding of the multiplets arising in spectra involving one or more open shells, we have developed recently an easy to use program multiX,[2] which is available to download.[3] This first step allows the inclusion of the crystal environment as a crystal field entered simply as positions and charges of a cluster of atoms around the core hole site. This often gives valuable insights in the case of x-ray absorption spectroscopy (XAS) and resonant inelastic x-ray spectroscopy (RIXS) measurements. However, in many cases it is desirable to allow for hybridization of the open shell electrons with the orbitals of neighbor atoms. This requires dealing with a significantly larger active Hilbert space. This is addressed with our recent Lanczos-based procedure to calculate spectra. First results will be discussed.

[1]Swiss SNF grant 200021-129970 is gratefully acknowledged.

11:27AM U23.00002 The Physical Content of Eigenvalues from Density Functional Theory (DFT) , D. BAGAYOKO, L. FRANKLIN, Department of Physics, Southern University and A&M College, C. EKUMA, Department of Physics and Astronomy, Louisiana State University, Y. MALOZOVSKY, Department of Physics, Southern University and A&M College — The density functional theory (DFT) of Hohenberg and Kohn rests on the energy functional $E_v[n]$ assuming its minimum for the *correct density* n(**r**), with the admissible functions restricted by the condition$N[n] = \int n(r)dr = N$, where N is the number of particles in the system under study. We show that, for such a system, there is an infinite number of basis sets (of localized orbitals) for which N is fixed while the density is not necessarily the correct one. Consequently, the eigenvalues obtained with self consistent DFT calculations using a single basis set do not necessarily have any particular physical content. The physical content is ensured only by the search and utilization of *the optimal basis set* that yields *the minima of the occupied energies* and physically meaningful values of low laying unoccupied energies. Further, by virtue of the Rayleigh theorem, there exist many basis sets larger than the optimal one [and that contain it] for which some unoccupied energies are lowered on account of a mathematical artifact. We illustrate these points in the cases of ZnO, TiO_2, and $SrTiO_3$. The calculated band gaps and other properties of these materials are in excellent agreement with experiment. Work funded by in part by the National Science Foundation, through LASiGMA [NSF AwardEPS-1003897, No. NSF (2010-15)-RII-SUBR, and No. HRD-1002541], LONI [Award No. 2-10915], and the Louisiana Space Consortium (LaSPACE).

11:39AM U23.00003 Beyond the GW approximation: a second-order screened exchange correction , PATRICK RINKE, FABIO CARUSO, XINGUO REN, MATTHIAS SCHEFFLER, Fritz-Haber-Institut, Berlin, Germany, NOA MAROM, University of Texas, Austin, USA — Despite the success of the GW method in describing the photoemission spectra of solids, molecules and clusters, challenges remain. For aromatic molecules for example absolute as well as relative positions of ionisation energies and affinities are not well reproduced in perturbative G_0W_0 schemes with different starting points as well as in self-consistent GW [1], sometimes even giving the wrong orbital order. Motivated by renormalized second-order perturbation theory [2] for the ground-state energy, we propose a second-order screened exchange correction (SOSEX) to the GW self-energy. This correction follows the spirit of the SOSEX correction to the random-phase approximation for the electron correlation energy and reduces the self-correlation error. The performance of the GW+SOSEX scheme has been benchmarked for a set of molecular systems, including the G2 set, commonly used acceptor molecules, benzene and the azabenzene molecules. We find that the SOSEX correction improves the description of the spectral properties including the orbital order with respect to the different GW schemes, highlighting the importance of reducing the self-correlation error.

11:51AM U23.00004 GW calculations of the bandgap of pyrite under various conditions , BRIAN KOLB, ALEXIE KOLPAK, Massachusetts Institute of Technology — Iron pyrite holds great promise as a solar cell material because of it's near optimal bandgap (0.95 eV) and its high optical absorbance. Nevertheless, real solar cells made from this material suffer from poor performance. In particular, the low open circuit voltage of around 200 meV precludes pyrite's use in effective solar cell devices. Several theories have been proposed to explain this low open-circuit voltage including bulk defects, intrinsic surface states within the gap, and surface defects. Careful DFT calculations have shown that bulk defects are exceedingly rare. Further, the calculations do not exhibit intrinsic surface states within the gap. Researchers disagree about the effect of surface defects, particularly sulfur deficiencies, on the bandgap. This work combines DFT with GW calculations of the bandgap to address some of the most fundamental and important questions about the cause of the low open-circuit voltage of pyrite solar cells including the true role of surface defects, the nature of the interface with metal electrodes, and the effect of phonons on the bandgap. This investigation is undertaken with an eye toward engineering a pyrite-based material that can perform well in real solar cell applications.

12:03PM U23.00005 GW at the interface: CH_3OH and H_2O on TiO_2(110) , DUNCAN MOWBRAY, ANNAPAOLA MIGANI, AMILCARE IACOMINO, Universidad del Pais Vasco UPV/EHU, E-20018 San Sebastian, Spain, JIN ZHAO, University of Science and Technology of China, Hefei, Anhui 230026, China, HRVOJE PETEK, University of Pittsburgh, Pittsburgh, Pennsylvania 15260, USA, ANGEL RUBIO, Universidad del Pais Vasco UPV/EHU, E-20018 San Sebastian, Spain — Electronic level alignment at the interface between an adsorbed molecular layer and a semiconducting substrate determines the activity and efficiency of many photocatalytic and photovoltaic materials. However, a quantitative description of the states at the interface remains elusive, due to the computational complexity of quasiparticle GW based algorithms. We compare density functional theory (DFT) calculations and quasiparticle techniques with ultraviolet photoelectron spectra and two photon photoemission spectra to determine the level of theory required to obtain an accurate description of occupied and unoccupied states at the interface. Specifically, we consider GGA DFT, hybrid DFT and G_0W_0, $scGW1$, $scGW_0$, and $scGW$ quasiparticle calculations for the interface between rutile TiO_2(110) and methanol or water. We find the quasiparticle energy shifts Δ are linearly dependent on the fraction of the wave function density within the molecular layer f_{mol} and the bulk substrate f_{bulk}. For the unoccupied states, the same correlation holds for all the molecular layers studied. This allows one to describe the quasiparticle energy shifts semi-quantitatively for larger molecular layers on TiO_2(110) based on more tractable DFT calculations.

12:15PM U23.00006 *Ab-initio* Calculations of Electronic Properties of InP and GaP[1] , YURIY MALOZOVSKY, LASHOUNDA FRANKLIN, Department of Physics Southern University and A&M College, CHINEDU EKUMA, Department of Physics and Astronomy, Louisiana State University, GUANG-LIN ZHAO, DIOLA BAGAYOKO, Department of Physics Southern University and A&M College — We present results from *ab-initio*, self consistent local density approximation (LDA) calculations of electronic and related properties of zinc blende indium and gallium phosphides (InP & GaP) We employed a local density approximation (LDA) potential and implemented the linear combination of atomic orbitals (LCAO) formalism. This implementation followed the Bagayoko, Zhao, and Williams (BZW) method, as enhanced by Ekuma and Franklin (BZW-EF). This method searches for the optimal basis set that yields the minima of the occupied energies. This search entails methodically increasing the size of the basis set, up to the optimal one, and the accompanying enrichment of angular symmetry and of radial orbitals. Our calculated, direct band gap of 1.398 eV (1.40 eV) for InP, at the Γ point, is in excellent agreement with experimental values. We discuss our preliminary results for the indirect band gap, from Γ to X, of GaP. We also report calculated electron and hole effective masses for both InP and GaP and the total (DOS) and partial (pDOS) densities of states.

[1]This work was funded in part by the National Science Foundation and the Louisiana Board of Regents, through LASiGMA and LS-LAMP, [EPS-1003897, No. NSF (2010-15)-RII-SUBR, and HRD-1002541] and by the Louisiana Optical Network Initiative (LONI) at SUBR.

12:27PM U23.00007 Computational study of the Effect of Sulfur Passivation on GaAs Heterojunction Solar Cells[1] , TED YU, UCLA, Department of Mathematics, RAMESH LAGHUVAMARAPU, UCLA, Department of Electrical Engineering, LIANG YAN, WEI YOU, UNC, Chapel Hill, Department of Chemistry, DIANA HUFFAKER, UCLA, Department of Electrical Engineering, CHRISTIAN RATSCH, UCLA, Department of Mathematics — We report DFT calculations that study the effect of sulfur passivation ($(NH_4)_2S$ and octanethiol) on GaAs surfaces. Sulfur passivation of GaAs solar cells is an area of interest, as it improves the I-V characteristics of heterojunctions by decreasing the density of surface states. We elucidate the fundamental mechanism of sulfur passivation on GaAs by showing how the sulfur species react with different reconstructed GaAs (100) and (111B) surfaces. Using state of the art hybrid functionals to calculate band structures and density of states, we find that a reconstructed GaAs surface does not have mid-gap surface states. Therefore, we show that sulfur passivation does not reduce surface states on reconstructed surfaces. We also study arsenic vacancies and adatoms on these surfaces to determine the energies of creating these imperfections. They lead to mid-gap surface states that are shown to be energetically plausible in certain GaAs surface reconstruction. We study the most energetically favorable surface reconstructions with As vacancies and show how sulfur passivation plays a role in removing surface states. These results will guide in the selection of passivating agents for GaAs solar cells and lead to a better understanding of such systems.

[1]We appreciate the support of the NSF, Grant Number: DMR-1125931

12:39PM U23.00008 CsSnX3 (X= Cl, Br, I) band structure calculations by the QSGW method[1] , LING-YI HUANG, WALTER R.L. LAMBRECHT, CWRU — $CsSnX_3$ (X=Cl,Br,I) perovskite compounds are of interest because of their strong photoluminescence and their potential application to solar cells. We present quasiparticle self-consistent GW (QSGW) calculations for the cubic (α-phase) including spin-orbit coupling and study the changes in band structures from the α-phase to the β- and γ-phases in LDA. The QSGW gaps are in good agreement with experiment. An analysis of the orbital character of the bands shows that they have an "inverted" band structure: the VBM has a non-degenerate s-like character (Sn-s and X-p antibonding), while the (CBM) has Sn-p character. The strongly intra-atomic dipole allowed nature of the direct gap explains the high photoluminescent intensity. The low hole mass indicates high hole mobility in agreement with experiment. The pressure dependence of the gap is found to be anomalous: the band gap decreases when the lattice constant is decreased. Effective masses and the Kohn-Luttinger type Hamiltonian of the CBM are extracted from the band structures and subsequently used to estimate exciton binding energies using our calculated dielectric constants. These indicate a much lower exciton binding energy for CsSnI3 than recently proposed.

12:51PM U23.00009 Quasiparticle band structures and interface physics of SnS and GeS , BRAD MALONE, School of Engineering and Applied Sciences, Harvard University, EFTHIMIOS KAXIRAS, School of Engineering and Applied Sciences, Harvard University and Department of Physics, Harvard University — Orthorhombic SnS and GeS are layered materials made of earth-abundant elements which have the potential to play a useful role in the massive scale up of renewable power necessary by 2050 to avoid unmanageable levels of climate change. We report on first principles calculations of the quasiparticle spectra of these two materials, predicting the type and magnitude of the fundamental band gap, a quantity which shows a strong degree of scatter in the experimental literature. Additionally, in order to evaluate the possible role of GeS as an electron-blocking layer in a SnS-based photovoltaic device, we investigate the band offsets of the interfaces between these materials along the three principle crystallographic directions. We find that while the valence-band offsets are similar along the three principle directions, the conduction-band offsets display a substantial amount of anisotropy.

1:03PM U23.00010 Ab Initio Study of Quasiparticle and Excitonic Properties of MoS2 , DIANA QIU, FELIPE JORNADA, STEVEN LOUIE, UC Berkeley and Lawrence Berkeley National Lab — MoS2 is a layered, transition-metal dichalcogenide that can be cleaved into single-layer sheets, in a manner similar to graphene. Monolayer MoS2 has a direct band gap, strong spin-orbit coupling and strongly enhanced photoluminescence, compared with the bulk. MoS2's interesting electronic and optical properties mean that it could have many applications in single-layer electronic devices, but on the theoretical level, when many-electron interaction effects are included, there is still some uncertainty about the quasiparticle and excitonic properties of MoS2. We use first-principles calculations to study the quasiparticle band structure and optical absorption spectrum of MoS2 at the GW+BSE level. We include spin-orbit coupling as a perturbation either before or after the GW calculation of the band structure, and we demonstrate that our calculations are fully converged with respect to the dielectric cutoff and summation over empty bands. This work was supported by NSF grant No. DMR10-1006184 and U.S. DOE under Contract No. DE-AC02-05CH11231. Computational resources have been provided by NERSC.

1:15PM U23.00011 Strain Modulation on electric-optical properties of Graphene and ZnO micro/nanowires , XUEWEN FU, ZHIMIN LIAO, HANCHUN WU, YANG-BO ZHOU, JUN XU, School of physics, Peking University, Beijing, China, WANLIN GUO, Institute of Nano Science, Nanjing University of Aeronautics and Astronautics, Nanjing 210016, P. R. China, Nanjing, China, DAPENG YU, School of physics, Peking University, Beijing, China — Strain increasingly prevails in micro- and nano-structures, and has important influence on the crystal and electronic structures. But its role in these structures remains unclear. The strain dependence of conductance of monolayer graphene has been studied here. The results illustrate the notable transitions: the slight increase, the dramatic decrease, and the sudden dropping of the conductance by gradually increasing the uniaxial strain. The graphene conductance behaves reversibly by tuning of the elastic tensile strain up to 4.5%, while it fails to recover after the plastic deformation at 5%. We also investigated the bending strain effect on the photoresponse of ZnO micro/nanowires and found larger photoconductivity and faster rising speed when photo-excitation is localized at the bending region in atmospheric environment, while the rising speeds are almost the same when photo-excitations are localized at the bending and straight regions under vacuum. The bending strain induced improvement of the UV photoresponse in air was well explained by the coupling of piezoelectric effect and surface oxygen adsorption/desorption procedure on the bent ZnO microwire.

1:27PM U23.00012 Electronic Structure of N-doped TiO , JAMES LEWIS, BARRY HAYCOCK, GARY LANDER, West Virginia University, Morgantown, WV 26501, United States, BINAY PRASAI, DAVID DRABOLD, Ohio University, Athens, OH 45701, United States — Via *ab-initio*density functional theory calculations, we present evidence of the most energetically stable atomic configuration for nitrogen-doped amorphous TiOand analysis of the electronic structure. This material receives much attention in the literature due to it's proposed photocatalytic applications, however synthesis of the crystalline form is an unfavorable process. Nitrogen doping has previously been shown to enable absorption in the visible in crystalline TiO2. As compared to crystalline TiO2, thin films of a- TiOdo not need thermal treatment and have other production advantages such as less dependence on substrate materials. With control of the electronic structure of the amorphous phase via doping the electronic characteristics can be taken advantage of without the costly production of crystalline TiO. N-doping of the amorphous phase introduces tail states to the valance band.

1:39PM U23.00013 Majorana fermions in vortex lattices , RUDRO BISWAS, University of Illinois at Urbana-Champaign — We consider Majorana fermions tunneling between vortices, within an array of such vortices in a 2D chiral p-wave superconductor. We calculate that the tunneling amplitude for Majorana fermions in a pair of vortices is proportional to the sine of half the difference between the global order parameter phases at the two vortices. Using this result we study tight-binding models of Majorana fermions in vortices arranged in a triangular or square lattice. In both cases we find that this phase-tunneling relationship leads to the creation of superlattices where the Majorana fermions form macroscopically degenerate 'flat' bands at zero energy, in addition to other dispersive bands. This finding suggests that in vortex arrays tunneling processes do not change the energies of a finite fraction of Majorana fermions and hence brighten the prospects of topological quantum computing with a large number of Majorana states.

1:51PM U23.00014 Ultrafast intersystem crossing in nickel porphyrins , JAVIER FERNANDEZ-RODRIGUEZ, JUN CHANG, A.J. FEDRO, MICHEL VAN VEENENDAAL, Department of Physics, Northern Illinois University, DeKalb, IL 60115 — We study the relaxation dynamics to the metastable state in laser-pumped nickel porphyrins. We use a ligand-field model which takes into account the crystal field created by the porphyrin ring and axial ligands. We propose different decay pathways in terms of charge-transfer and metal-center intermediate states By accounting for the energy redistribution of the lattice vibrations we get an irreversible decay to the metastable state within the order of a few hundred femtoseconds. We show how non-equilibrium time-dependent x-ray absorption at the Ni K-edge measurements can elucidate the nature of the intermediate states involved in the decay. Understanding radiationless transitions in transition-metal complexes is of interest for their relevance for the design of photocatalytic systems and photothermal sensitizers for cancer treatment.

Thursday, March 21, 2013 11:15AM - 2:15PM –

Session U24 DCOMP: Focus Session: Recent Developments in Density Functional Theory III

326 - Pieremanuele Canepa, Wake Forest University

11:15AM U24.00001 Recovering hidden Bloch character: Unfolding Electrons, Phonons, and Slabs[1] , PHILIP B. ALLEN, Stony Brook University, TOM BERLIJN, University of Florida, DAVID CASAVANT, University of Maryland, JOSE SOLER, Universidad Autonoma de Madrid — One of the main problems of first principles supercell calculations is the band folding problem. As the supercell gets larger, the bands get folded into a smaller Brillouin zone and cease to give information about the Bloch character of the underlying normal cell. To tackle this problem an unfolding formalism has been implemented in first principles calculations via several techniques [1-5]. Here we will present an extended unfolding formalism for finite systems and exemplify it with first principles calculations of a Si (111) slab.

11:27AM U24.00002 Exponential supercell convergence of the exact exchange energy via truncated coulomb potentials[1]

RAVISHANKAR SUNDARARAMAN, T. A. ARIAS, Department of Physics, Cornell University, Ithaca, NY — Hybrid density functionals have become increasingly popular as a solution to mitigate the self-interaction error in semi-local density functionals, but widespread application to periodic systems has been limited by computational cost. This cost is exacerbated by poor k-point convergence due to the $G \to 0$ singularity in the exact exchange energy, in spite of several singularity correction methods such as auxilliary function integration,[2,3] image subtraction,[4] and spherical truncation of the coulomb potential.[5] We analyze these rather disparate methods in an intuitive formalism based on Wannier function localization, which naturally suggests the truncation of the Coulomb potential on the superlattice Wigner-Seitz cell. We demonstrate that this scheme systematically exhibits the best k-point convergence, comparable to that of semi-local functionals, even for low-symmetry and reduced-periodicity systems where previous methods fail.

11:39AM U24.00003 Large-scale DFT calculations with the ONETEP program on metallic systems

ALVARO RUIZ-SERRANO, CHRIS-KRITON SKYLARIS, University of Southampton — We present a direct energy minimization method based on the Kohn-Sham formulation of Mermin's extension of density functional theory (DFT) to finite electronic temperature for large-scale calculations on metallic systems. Our approach employs norm-conserving pseudopotentials for the core electrons, whereas the valence electrons are accurately described using a set of localized orbitals, optimized in-situ in terms of a high-resolution periodic-sinc (psinc) basis set equivalent to plane-waves. The localization constraint results in predictable sparsity patterns that simplify the algebraic operations with matrices, while the description in terms of psinc functions allows near-minimal matrix sizes. As a consequence, the traditional computational bottleneck due to diagonalization of the Hamiltonian matrix is greatly reduced, allowing calculations on larger systems. Additionally, we take advantage of available parallel eigensolvers to enhance the efficiency of the method. We present a number of validation results on metallic systems of increasing complexity and size, including calculations on nanoparticles of more than a thousand atoms.

11:51AM U24.00004 On the Generalization of Homogeneous Coordinate Scaling in Density Functional Theory[1]

LAZARO CALDERIN, The Pennsylvania State University — The scaling properties of functionals find direct applications in the design, testing and use of approximated kinetic-energy and exchange-correlation functionals. Methods, such as the so called orbital-free, benefit from approximations to both functionals, while Kohn-Sham Density Functional Theory approximates only the exchange-correlation functional. In this talk we will introduce a generalization of the uniform scaling of coordinates, that not only embodies all previously known scaling and related results, but also leads to new and important properties of functionals.

[1]Support from the Materials Research Institute and Research Computing and Cyberinfrastructure at Penn State University is greatfuly acknowledged.

12:03PM U24.00005 Non-linear eigensolver-based alternative to traditional SCF methods[1]

BRENDAN GAVIN, ERIC POLIZZI, Univeristy of Massachusetts, Amherst — The self-consistent iterative procedure in Density Functional Theory calculations is revisited using a new, highly efficient and robust algorithm for solving the non-linear eigenvector problem (i.e. H(X)X = EX;) of the Kohn-Sham equations. This new scheme is derived from a generalization of the FEAST eigenvalue algorithm, and provides a fundamental and practical numerical solution for addressing the non-linearity of the Hamiltonian with the occupied eigenvectors. In contrast to SCF techniques, the traditional outer iterations are replaced by subspace iterations that are intrinsic to the FEAST algorithm, while the non-linearity is handled at the level of a projected reduced system which is orders of magnitude smaller than the original one. Using a series of numerical examples, it will be shown that our approach can outperform the traditional SCF mixing techniques such as Pulay-DIIS by providing a high converge rate and by converging to the correct solution regardless of the choice of the initial guess. We also discuss a practical implementation of the technique that can be achieved effectively using the FEAST solver package.

[1]This research is supported by NSF under Grant #ECCS-0846457 and Intel Corporation.

12:15PM U24.00006 The pole expansion and selected inversion technique for solving Kohn-Sham density functional theory at large scale[1]

LIN LIN, Lawrence Berkeley National Laboratory, MOHAN CHEN, WEINAN E, Princeton University, LIXIN HE, University of Science and Technology of China, JIANFENG LU, Duke University, CHAO YANG, Lawrence Berkeley National Laboratory, LEXING YING, University of Texas at Austin — The standard diagonalization based method for solving Kohn-Sham density functional theory (KSDFT) requires N eigenvectors for an O(N) * O(N) Kohn-Sham Hamiltonian matrix, with N being the number of electrons in the system. The computational cost for such procedure is expensive and scales as O(N^3). We have developed a novel pole expansion plus selected inversion (PEXSI) method, in which KSDFT is solved by evaluating the selected elements of the inverse of a series of sparse symmetric matrices, and the overall algorithm scales at most O(N^2) for all materials including metallic and insulating systems without any truncation. The PEXSI method can be used with orthogonal or nonorthogonal basis set, and the electron density, total energy, Helmholtz free energy and atomic force are calculated simultaneously and accurately without using the eigenvalues and eigenvectors. Combined with atomic orbital basis functions, the PEXSI method can be applied to study the electronic structure of boron nitride nanotube and carbon nanotube with more than 10,000 atoms on a single processor.

12:27PM U24.00007 Density Functional Theory of Thermoelectric Phenomena[1]

GIOVANNI VIGNALE, FLORIAN EICH, University of Missouri-Columbia, MASSIMILIANO DI VENTRA, University of California - San Diego — We introduce a non-equilibrium density functional theory of local temperatures and associated heat currents that is particularly suited for the study of thermoelectric phenomena. This theory rests on a local temperature field coupled to the energy density operator. We prove the basic theorems of the theory and discuss the construction of approximate functionals.

[1]Work supported by DOE grants No. DE-FG02-05ER46203 and DE-FG02-05ER46204.

12:39PM U24.00008 Simulated non-contact atomic force microscopy based on real space pseudopotentials and density functional theory , MINJUNG KIM, JAMES CHELIKOWSKY, The University of Texas at Austin — Non-contact atomic force microscopy (nc-AFM) is a commonly used technique in surface and nano science owing to its high-resolution and ease of implementation. Theoretical simulations of nc-AFM have been able to facilitate the interpretation of experimental images. However, first-principles AFM simulations can be computationally intensive and problematic if the morphology of the AFM tip is unknown. We introduce an efficient simulation method that does not include an explicit morphology for the tip as suggested by Chan and coworkers.[1] Our method is based on a real space implementation of pseudopotentials constructed using density functional theory. We illustrate the method by simulating nc-AFM images for binary semiconducting materials, *e.g.*, the GaAs(110) surface, and compare our results to previously performed first principles simulations as well as experimental data.

12:51PM U24.00009 Dynamical Steps in the Time-Dependent Exchange-Correlation Potential[1] , KAI LUO, NEEPA MAITRA, Hunter College and CUNY Graduate Center, PETER ELLIOTT, Max-Planck Institute for Microstructure Physics, JOHANNA FUKS, ANGEL RUBIO, Dpto. Fisica de Materiales, Universidad del Pais Vasco — It was recently demonstrated that the exact correlation potential of time-dependent density functional theory (TDDFT) generically develops step and peak features that have a density-dependence that is non-local in space and time [arXiv:589981]. Usual adiabatic functional approximations fail to capture these steps, yet these same functionals work quite well for excitation spectra. We investigate the role of the steps in the linear response regime.

[1]NSF CHE-1152784 & DOE DE-SC0008623.

1:03PM U24.00010 Time-Dependent Spin-Density Functional Theory for strongly correlated systems[1] , VOLODYMYR TURKOWSKI, TALAT S. RAHMAN, Department of Physics and NanoScience Technology Center, University of Central Florida, Orlando, FL — We present a formulation of the basic principles for a time-dependent spin-density functional theory (TDSDFT) capable of describing the main properties of strongly correlated systems. Electron-electron correlations are contained in the correlation part of the exchange-correlation (XC) kernel, which we construct using some exact results for the Hubbard model of strongly correlated electrons. The principal feature of the theory is nonadiabaticity of the XC kernel, which corresponds to a local time-resolved (oscillating in time) electron-electron interaction. As in dynamical mean-field theory, in TDSDFT such interaction defines the main properties of correlated systems, including satellite Hubbard peaks in the electronic spectrum. We demonstrate that the corresponding nonadiabatic XC kernel reproduces main features of the spectrum of the Hubbard dimer and infinite-dimensional Hubbard model, some of which are impossible to obtain within the adiabatic approach. We test the theory by applying it to several strongly correlated materials, including calculation of nonequilibrium response of these systems.

[1]Work supported in part by DOE Grant DE-FG02-07ER46354.

1:15PM U24.00011 Time-dependent density functional theory of extreme environments , RUDOLPH MAGYAR, LUKE SHULENBURGER, MICHAEL DESJARLAIS, Sandia National Laboratories — We describe the challenges involved when using time-dependent density functional theory (TDDFT) to describe warm dense matter (WDM) within a plane-wave, real-time formulation. WDM occurs under conditions of temperature and pressure (over 1000 K and 1 Mbar) where plasma physics meets condensed matter physics. TDDFT is especially important in this regime as it can describe ions and electrons strongly out of equilibrium. Several theoretical challenges must be overcome including assignment of initial state orbitals, choice of time-propogation scheme, treatment of PAW potentials, and inclusion of non-adiabatic effects in the potential energy surfaces. The results of these simulations are critical in several applications. For example, we will explain how the TDDFT calculation can resolve modeling inconsistencies in X-ray Thompson cross-sections, thereby improving an important temperature diagnostic in experiments. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

1:27PM U24.00012 Direct calculation of exciton binding energies with time-dependent density-functional theory[1] , ZENGHUI YANG, CARSTEN ULLRICH, University of Missouri - Columbia — Excitons are coupled electron-hole pairs below the band gap in bulk semiconductors. They are vital to photovoltaics, but they are hard to obtain in a TDDFT calculation, due to usually employed exchange-correlation kernels lacking the long-range part. Another difficulty comes from the usual method of applying TDDFT on bulk materials which calculate the spectrum - though suitable for continuum excitations, this approach does not upfront yield the binding energy of the discrete excitonic excitations. We develop a method in analog with the Casida equation formalism, in which exciton binding energies are obtained directly. We calculate exciton binding energies for both small- and large-gap semiconductors with this method. We study the recently published 'bootstrap' exchange-kernel within our method, and we extend the formalism to treat triplet excitons.

1:39PM U24.00013 Nonlocal formulation of spin Coulomb drag in nanostructures: implications for time-dependent current-density-functional theory[1] , CARSTEN A. ULLRICH, University of Missouri-Columbia, IRENE D'AMICO, University of York — The spin Coulomb drag (SCD) effect occurs in materials and devices where charged carriers with different spins exchange momentum via Coulomb scattering. This causes frictional forces between spin-dependent currents that lead to dissipation and limit spin mobilities. We consider the role of the SCD in the damping of intersubband spin plasmons in semiconductor quantum wells, and show that a local density approximation leads to overdamping. A nonlocal formulation of the SCD is developed which agrees with experimental observations of spin plasmon linewidths. General consequences for using density-functional approaches to describe electronic many-body effects in nanostructures are discussed.

[1]This work was supported by DOE grant DE-FG02-05ER46213 (C.A.U.), EPSRC Grant No. EP/F016719/1, and Royal Society Grant No. IJP 2008/R1 JP0870232 (I.D'A.).

1:51PM U24.00014 Alternative time-dependent optimized effective potential[1] , VLADIMIR NAZAROV, Research Center for Applied Sciences, Academia Sinica, Taipei 11529, Taiwan — The OEP is known as a single-particle potential minimizing the expectation value of a many-body Hamiltonian on the set of eigen-functions of a single-particle Hamiltonian [1]. The time-dependent (TD) OEP can be constructed with the TD quantum stationary-action principle [2]. Very useful conceptually in DFT and TDDFT, both OEPs are not practicable due to the complexity of their implementations. Here we report a TDOEP by minimizing the difference of LHS and RHS of the TD Schrödinger equation [3]. If the orbitals are varied, then the TD Hartree-Fock equations are reproduced. Similarly, we now find the OEP. New OMP does not involve the inversion of the density-response function χ_s, which greatly facilitates implementations. Accordingly, the exchange-correlation kernel f_{xc} involves of χ_s^{-1} only, not its quadratic counterpart. To show the power of this method, we work out the $f_{xc}^h(q,\omega)$ of the homogeneous electron gas to be used with the nearly-free electrons theory, where f_{xc}^h is the main input [4].

2:03PM U24.00015 Dynamical Hyperpolarizabilities from Real-Time Density Functional Theory , VLADIMIR GONCHAROV, KALMAN VARGA, Vanderbilt University — The explicitly time dependent wave function obtained in the framework of Real-Space, Time-Dependent Density Functional Theory captures the essential physics and allows a non-perturbative calculations of important observables. We generalize finite-difference method typically used to calculate static hyperpolarizabilities to the dynamical case [1] and compute nonlinear optical response functions to the third order inclusively. The method is simple and free of errors associated with basis function based methods. Comparison with experimental results for a range of molecules including C_{60} is presented.

Session U25 GQI: Superconducting Qubits: Qubit-Field Interactions and Qubit Theory 327 - Jay Gambetta, IBM

11:15AM U25.00001 Cavity-Mediated Landau-Zener Interferometry Between Two Superconducting Qubits[1] , C.M. QUINTANA, K.D. PETERSSON, L.W. MCFAUL, S.J. SRINIVASAN, A.A. HOUCK, J.R. PETTA, Princeton University — Avoided crossings between two energy levels as a function of some external parameter are common to many quantum mechanical systems. In the field of circuit quantum electrodynamics (cQED), the energies of superconducting qubits can be tuned via applied magnetic flux, and a microwave cavity-mediated coupling between two qubits placed in the same resonator leads to an avoided crossing in the system's energy spectrum when the two singly-excited qubit states become degenerate. We utilize such an avoided crossing between two transmon qubits to explore Landau-Zener transition physics, using nanosecond timescale flux bias pulses to non-adiabatically traverse the avoided crossing. We explore the dynamics of single- and double-passage through the resulting "beam splitter" of two-qubit states. In particular, we test the general asymptotic Landau-Zener formula for non-adiabatic transition probabilities and demonstrate the creation of two-transmon entanglement via a single passage through the beam splitter. We also study interference phenomena associated with double passage through the avoided crossing (analogous to an optical interferometer), and explore the dependence of the interference fringes on the level velocity with which the passages are made.

11:27AM U25.00002 First-order sideband transitions with flux-driven asymmetric transmons , J.D. STRAND, M.E. WARE, Syracuse University, FELIX BEAUDOIN, McGill University, ALEXANDRE BLAIS, Sherbrooke, T. OHKI, B. JOHNSON, BBN Technologies, B.L.T. PLOURDE, Syracuse University — We present data demonstrating first-order sideband transitions between a qubit and a resonator performed with a digitally synthesized waveform coupled to the qubit loop as a magnetic flux. The resulting first-order sideband transitions are much faster (up to 85 MHz in our measurements) than second-order processes and have the potential to create fast quantum gates. The frequency of the red sideband can also be made quite low, typically a few hundred MHz in our experiment, and at these low frequencies expensive microwave generators are not required, simplifying the control electronics and making the process more scalable. We chose to test this process with asymmetric transmons in which one junction is several times larger than the other. This asymmetry creates a shallow flux modulation curve that is optimum for this flux-driven sideband process.

11:39AM U25.00003 Manipulating Kerr effects in a superconducting cavity via a superconducting qubit , VICTOR V. ALBERT, GERHARD KIRCHMAIR, BRIAN VLASTAKIS, ZAKI LEGHTAS, MAZYAR MIRRAHIMI, S.M. GIRVIN, R.J. SCHOELKOPF, LIANG JIANG, Yale University — Typically, models of qubit-cavity interactions in superconducting circuits have included terms strictly linear in amplitude of the cavity modes. Due to ever-increasing experimental ability to realize larger coupling strengths, induced nonlinearities in the cavity contribute significantly to the dynamics and thus need to be accounted for. Such nonlinearities include interactions between the photon numbers of two cavity modes (cross-Kerr) and between a mode and itself (self-Kerr). Motivated by the recent experimental demonstration of self-Kerr in superconducting cavities, we investigate quantum control of Kerr effects via a dispersively coupled superconducting qubit, which not only enables us to enhance or suppress the Kerr coupling, but also opens the possibility to investigate higher order Kerr effects.

11:51AM U25.00004 Giant Cross Kerr Effect via a Superconducting Artificial Atom , I.-C. HOI, C.M. WILSON, G. JOHANSSON, T. PALOMAKI, Department of Microtechnology and Nanoscience (MC2), Chalmers University of Technology, Sweden, T.M. STACE, B. FAN, Centre for Engineered Quantum Systems, School of Physical Sciences, University of Queensland, Australia, A. FRISK KOCKUM, L. TORNBERG, P. DELSING, Department of Microtechnology and Nanoscience (MC2), Chalmers University of Technology, Sweden — We investigate the effective interaction between two microwave fields, mediated by a superconducting artificial atom (transmon qubit) which is strongly coupled to a coplanar transmission line. The interaction between the fields and atom realizes an effective cross Kerr coupling. Using this, we demonstrate average Kerr phase shifts of up to 25 degrees per photon with both coherent microwave fields at the single-photon level. Our results provide an important step towards quantum gates with propagating photons in the microwave regime.

12:03PM U25.00005 Requirements for Electromagnetically Induced Transparency in a Transmon , J.E. ROBINSON, Laboratory for Physical Sciences, College Park, MD, S. NOVIKOV, Z.K. KEANE, B. SURI, Department of Physics, University of Maryland and Laboratory for Physical Sciences, College Park, MD, F.C. WELLSTOOD, Department of Physics, University of Maryland, College Park, MD, B.S. PALMER, Laboratory for Physical Sciences, College Park, MD — In the dressed atom picture, a three-level system can interact with two photons via the Autler-Townes (AT) effect, where the system exhibits two peaks separated by the generalized Rabi frequency of the coupling photon. The system can also exhibit electromagnetically induced transparency (EIT), where the first excited state is made transparent to the probe photon by a strong coupling drive. We examine the results from a multi-tone measurement in a transmon qubit coupled to a 3D cavity, which exhibits an AT splitting, as expected from the dressed atom picture, similar to previous results.[1,2] We will discuss the requirements for a crossover from an AT doublet to an EIT signal, as they relate to the limitations of our device. We will also examine the quantum information implications of realizing EIT in superconducting system.

12:15PM U25.00006 Probing Electromagnetically Induced Transparency in a Transmon , SERGEY NOVIKOV, Dept. of Physics, University of Maryland, J.E. ROBINSON, Laboratory for Physical Sciences, Z.K. KEANE, Dept. of Physics, University of Maryland, Laboratory for Physical Sciences, B. SURI, Dept. of Physics, University of Maryland, F.C. WELLSTOOD, JQI, CNAM, Dept. of Physics, University of Maryland, B.S. PALMER, Laboratory for Physical Sciences — We have designed, fabricated, and measured a transmon made from a single Al/AlOx/Al Josephson-Junction on a sapphire substrate with $f_{01} \sim 5$ GHz. The transmon was mounted in a 3D microwave cavity (OFHC copper, $f_c \sim 7.5$GHz), similar to other recent experiments[1,2]. The observed coherence times were $T_1, T_2^* \sim 10\mu$s allowing us to investigate the possibility of electromagnetically induced transparency (EIT) and other population trapping effects, such as the Autler-Townes (AT) splitting. We will discuss the experiments to look for and distinguish between AT and EIT given the constraints placed by the transmon and the readout limitations imposed by the cavity.

12:27PM U25.00007 cQED Susceptibility of Superconducting Transmons coupled to a Microstrip Resonator Cavity , DAVID PAPPAS, MARTIN SANDBERG, JIANSONG GAO, MICHAEL VISSERS, NIST, ANTON KOCKUM, GORAN JOHANSSON, Chalmers University, NIST COLLABORATION — The light-matter interaction of multi-level transmons strongly coupled to a cavity and the external drive field are measured over a wide frequency and power range. The transmons are fabricated from TiN capacitor plates with small Al/AlOx/Al shadow evaporated junctions. The long T1's of these devices, approximately 10 us, allow for a rich spectrum of doubly dressed states to be observed and modeled. Both single- and two-photon absorption features are identified as the drive power is increased. Quantitative agreement of the absorption spectra in both the weak and strong drive limits is obtained using the measured junction properties and the temperature.

12:39PM U25.00008 Tunable Coupling between Two Resonators Controlled by a Flux Qubit: the Quantum Switch , E. HOFFMANN, M. HAEBERLEIN, A. BAUST, M.J. SCHWARZ, E.P. MENZEL, H. HUEBL, F. DEPPE, A. MARX, R. GROSS, TU Muenchen and Walther-Meissner-Institut, Germany, D. ZUECO, CSIC-Universidad de Zaragoza, Spain, J.-J. GARCIA RIPOLL, IFF-CSIC, Madrid, Spain, E. SOLANO, Universidad del Pais Vasco UPV/EHU and Ikerbasque, Spain — In the field of quantum information processing, superconducting circuits have become a well-established platform. In particular, systems consisting of a few qubits and/or harmonic oscillator circuits have been investigated. When scaling up these systems, it seems practical to aim for active guidance elements allowing for a directed transmission of quantum signals. One way to achieve this is by implementing switchable coupling between two microwave resonators. We show experimental progress on two superconducting transmission line resonators, where a superconducting flux qubit mediates a controllable coupling - the Quantum Switch. We show an experimental characterization of such a device and discuss spectroscopic evidence for the switching behavior.

We acknowledge support from the DFG via SFB 631, the German excellence initiative via NIM, and EU projects CCQED, SOLID and PROMISCE, the Basque Foundation for Science, Basque Government IT472-10, and Spanish MICINN FIS2009-12773-C02-01, DZ granted by ARAID

12:51PM U25.00009 Catch-Disperse-Release Readout for Superconducting Qubits[1] , EYOB A. SETE, ERIC MLINAR, ALEXANDER N. KOROTKOV, University of California, Riverside, ANDREI GALIAUTDINOV, University of Georgia, Athens, JOHN M. MARTINIS, University of California, Santa Barbara — We analyze a qubit readout scheme for superconducting qubits via controlled capture, dispersion, and release of a microwave field. A tunable coupler is used to decouple the microwave resonator from a transmission line during dispersive interaction with the qubit, thus circumventing the Purcell effect. We show that fast and high-fidelity qubit readout can be achieved for nonlinear dispersive qubit-resonator interaction and for sufficiently adiabatic tuning of the qubit frequency. Interestingly, the Jaynes-Cummings nonlinearity results in quadrature squeezing of the microwave field which leads to a significant decrease in measurement error. The effects of qubit anharmonicity and imperfect quantum efficiency of the microwave amplification on the measurement error are also discussed.

1:03PM U25.00010 Realizing a Deterministic Teleportation Protocol in Superconducting Circuits , LARS STEFFEN, MARKUS OPPLIGER, MATTHIAS BAUR, ARKADY FEDOROV, ANDREAS WALLRAFF, ETH Zurich — Teleportation of a quantum state may be used for distributing entanglement between distant qubits in quantum communication and for realizing universal and fault-tolerant quantum computation. Previously, we have demonstrated the implementation of a teleportation protocol, up to the single-shot measurement step, with superconducting qubits coupled to a microwave resonator [1]. Using full quantum state tomography and calculating the projection of the measured density matrix onto the basis states of two qubits has allowed us to reconstruct the teleported state with an average output state fidelity of 86%. In ongoing experiments we attempt to implement single shot read-out and feed-back to perform full deterministic quantum teleportation.

1:15PM U25.00011 Methods for entanglement in circuit QED , FELIX MOTZOI, MOHAN SAROVAR, UC Berkeley, MICHAEL GOERZ, CHRISTIANE KOCH, U. Kassel, BIRGITTA WHALEY, UC Berkeley — We discuss some progress in methods of generating entanglement in superconducting qubit architectures. We focus on the minimal time required to generate a perfect entangler in a given system, specifically by combining simultaneously multiple given forms of coupling. Typically the different terms will generate different dynamics and when multiple coupling terms exist one will have a choice about which local equivalence class to use to generate entanglement. Here, we consider the case where we want to simultaneously include the different forms of coupling that will be present in the circuit QED system, such as direct coupling, cavity mediated coupling, or virtual transitions in the multi-qubit space, with similar interaction strengths. No specific gate is targeted, but rather entanglement generation is optimized. Incoherent effects such as measurement/feedback based control can also be included to generate entanglement, even when the qubits are spatially separated (i.e. in different cavities) and no interaction exists.

1:27PM U25.00012 Tuning from coherent interaction to super- and subradiance with artificial atoms in a 1D waveguide , KEVIN LALUMIÈRE, ALEXANDRE BLAIS, Université de Sherbrooke, BARRY C. SANDERS, University of Calgary, ARJAN F. VAN LOO, ARKADY FEDOROV, ANDREAS WALLRAFF, ETH Zurich — Taking advantage of the near ideal spatial mode-matching, strong interaction between light and artificial atoms fabricated in a 1D waveguide has been demonstrated experimentally [1]. Here, we study the situation where multiple and possibly un-identical atoms are fabricated in the same waveguide. We find that atom relaxation and Lamb-shift are modified, leading to collective effects. Depending on the distance between the artificial atoms, or equivalently the phase shift accumulated by light traveling from one atom to another, we find that it is possible to tune between a strong modification of individual atomic relaxation with the formation of sub- and superradiant states, and a strong modification of the Lamb-shift leading to a coherent exchange-type interaction between the atoms. These predictions are based on a master equation derived for an inhomogeneous set of atoms coupled to a transmission line. Comparison with experimental results will be discussed.

1:39PM U25.00013 Quantum dynamics of triplet superconducting circuits[1] , DAVID G. FERGUSON, JENS KOCH, JAMES SAULS, Northwestern University — We generalize the formalism of "circuit quantization" [1] to circuits comprised of spin-triplet superconducting elements. This introduces the dynamics associated with the spin of the Cooper pairs in addition to the phase and charge dynamics. The dynamics of the order parameter for spin-triplet superconductors is encoded in the vector $\vec{d}$ for the spin-projections of the Cooper pairs, which is coupled to the dynamics of the electronic spin polarization, $\vec{S}$. At frequencies below the superconducting gap, $\hbar\omega \ll \Delta$, the classical spin dynamics is described by Leggett's equations for $\vec{d}$ and $\vec{S}$ [2]. Weak spin-orbit coupling ($E_{\text{s-o}} \ll \Delta$) leads to frequency shifts of the normal-state spin resonance. Quantization of a spin-triplet superconducting circuit is achieved by including the Hamiltonian that generates Leggett's equations. Analytical and numerical results for the spectra of the quantized Hamiltonians of varrious circuits are reported. As a case study, we highlight the low energy excitation frequencies of two triplet superconductor islands coupled by a Josephson junction.

1:51PM U25.00014 A Vector Potential for Flux Qbits , ELIOT KAPIT, Oxford University, ERICH MUELLER, Cornell University — We design a superconducting circuit, based on three junction flux qbits, in which the motion of magnetic flux mimics the behavior of charged lattice bosons hopping in a magnetic field. For realistic device parameters one can reach the strongly interacting bosonic quantum Hall limit where one will find anyonic excitations. We explore the design principles for using these circuits to study many-body physics, for example explaining how the magnitude and phase of the effective hopping matrix elements can be controlled by tuning offset voltages. The circuits could be used for topological quantum computation.

2:03PM U25.00015 ABSTRACT WITHDRAWN –

Thursday, March 21, 2013 11:15AM - 2:15PM –

Session U26 GQI: Focus Session: Semiconductor Qubits - Impurity Complexes

328 - Kai-Mei Fu, University of Washington

11:15AM U26.00001 Single-atom spin qubits in silicon[1] , ANDREW DZURAK, University of New South Wales — Spin qubits in silicon are excellent candidates for scalable quantum information processing (QIP) due to their long coherence times and the enormous investment in silicon MOS technology. Here I discuss qubits based upon single phosphorus (P) dopant atoms in Si [1]. Projective readout of such qubits had proved challenging until single-shot measurement of a single donor electron spin was demonstrated [2] using a silicon single electron transistor (Si-SET) and the process of spin-to-charge conversion. The measurement gave readout fidelities $> 90\%$ and spin lifetimes $T_{1e} > 6$ s [2], opening the path to demonstration of electron and nuclear spin qubits in silicon. Integrating an on-chip microwave transmission line enabled single-electron spin resonance (ESR) of the P donor electron. We used this to demonstrate Rabi oscillations of the electron spin qubit, while a Hahn echo sequence revealed electron spin coherence times $T_{2e} > 0.2$ ms [3]. This time is expected to become much longer in isotopically enriched ^{28}Si devices. We also achieved single-shot readout of the ^{31}P nuclear spin (with fidelity $> 99.6\%$) by monitoring the two hyperfine-split ESR lines of the P donor system. By applying (local) NMR pulses we demonstrated coherent control of the nuclear spin qubit, giving a coherence time $T_{2n} > 60$ ms.

11:51AM U26.00002 Measurements of spin life time of an antimony-bound electron in silicon , T.M. LU, Sandia National Laboratories, N.C. BISHOP, Retired, L.A. TRACY, R. BLUME-KOHOUT, T. PLUYM, J.R. WENDT, J. DOMINGUEZ, M.P. LILLY, M.S. CARROLL, Sandia National Laboratories — We report our measurements of spin life time of an antimony-bound electron in silicon. The device is a double-top-gated silicon quantum dot with antimony atoms implanted near the quantum dot region. A donor charge transition is identified by observing a charge offset in the transport characteristics of the quantum dot. The tunnel rates on/off the donor are first characterized and a three-level pulse sequence is then used to measure the spin populations at different load-and-wait times in the presence of a fixed magnetic field. The spin life time is extracted from the exponential time dependence of the spin populations. A spin life time of 1.27 seconds is observed at B = 3.25 T. This work was performed, in part, at the Center for Integrated Nanotechnologies, a U.S. DOE, Office of Basic Energy Sciences user facility. The work was supported by the Sandia National Laboratories Directed Research and Development Program. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

12:03PM U26.00003 Shuttling electrons on and off As donor atoms in silicon , A.M. TYRYSHKIN, S.A. LYON, Princeton University, C.C. LO, R. LO NARDO, J.J.L. MORTON, University College London, S. SIMMONS, University of Oxford, C.D. WEIS, T. SCHENKEL, Lawrence Berkeley National Laboratory, J. BOKOR, University of California Berkeley, J. MEIJER, D. ROGALLA, Ruhr-Universitat Bochum — Hybrid quantum devices where electron spins are used for state initialization, fast manipulation, long range entanglement and detection, while nuclear spins are used for long term storage promise revolutionary advantages. Here we report our first experiments using a silicon-based device that utilizes electron and nuclear spins of arsenic donors. The device is a large-area, parallel-plate capacitor fabricated on a silicon-on-insulator (SOI) wafer where the SOI layer is implanted with arsenic donors, and a back gate is formed in the silicon below the buried oxide by a high-energy boron implantation. The electrons can be controllably stripped from the donors and then reintroduced to the ionized donors by applying appropriate gate voltages. We use ensemble ESR experiments (X-band, magnetic field of 0.35 T) to track the occupancy of the donors during these operations. Pulsed ESR is used to characterize the spin state of the donor electrons and the effect of applied electric fields below the ionization threshold. The spin state of the arsenic nuclei, and the effect of electron removal and reintroduction on the nuclear state is expected to be observable in pulsed ENDOR experiments. The work is funded by LPS and NSF-MWN.

12:15PM U26.00004 Electronic structure of sub-surface Boron acceptors in silicon for potential qubits , RAJIB RAHMAN, Purdue University, West Lafayette, IN 47906, USA, JAN MOL, University of New South Wales, Sydney 2052, Australia, GERHARD KLIMECK, Purdue University, West Lafayette, IN 47906, USA, SVEN ROGGE, University of New South Wales, Sydney 2052, Australia — Single acceptors in silicon are investigated as potential qubits. Due to the p-type nature of the valence band (VB), the acceptor states are less susceptible to the hyperfine interaction of the neighboring nuclear spins. The presence of a stronger spin-orbit coupling in the VB also enables the possibility of an all-electric qubit control. Whereas donor qubits exhibit exchange oscillation with separation distance due to conduction band valleys, Boron acceptors are expected to have smoother exchange curves. We investigate the electronic structure of single Boron acceptors in silicon in the presence of electric field, strain, magnetic field, and interfaces. Bulk Boron acceptors have a four-fold degenerate ground state 45 meV above the VB with angular momentum states of 3/2 and 1/2. An interface splits this manifold into Kramer's doublets. Application of E and B fields allow several possibilities for forming a two-level qubit driven by an ac electric field. We compare calculations from atomistic tight-binding theory to scanning tunneling microscope (STM) measurements and k.p calculations. The tight-binding method captures additional wavefunction symmetries due to the crystal that help to explain the STM measurements.

12:27PM U26.00005 Interface-split Kramers doublets for acceptor-based qubits in silicon , JAN MOL, JOSEPH SALFI, University of New South Wales, RAJIB RAHMAN, Purdue University, SVEN ROGGE, University of New South Wales — Single dopants in silicon form a particular attractive platform for hosting spin quantum bits (qubits). The effective spin-3/2 states of acceptor-bound holes in silicon can be used to store bits of quantum information for several μs. Strong coupling of spin and momentum in the silicon valence band allows for rapid electrical manipulation of the hole spin. Acceptors in silicon have a four-fold degenerate ground-state, reflecting character of the top of the valence band. Symmetry breaking, by an electric field, strain or confinement, lifts this degeneracy, resulting in two Kramers doublets. The states within these isolated Kramers doublets are protected against decoherence by time reversal symmetry and form the working levels of a hole spin qubit. Here we investigate the effect of the presence of an interface on the ground-state energy splitting of individual sub-surface acceptors, as a function of dopant depth, by means of low temperature scanning tunneling spectroscopy. The depth of individual acceptors is determined by probing the Coulomb potential of the ionized acceptor nuclei. Resonant tunneling through the localized acceptor states provides a direct measure of the excited state spectrum of single dopants.

12:39PM U26.00006 Towards isolating a single impurity-bound hole , RUSSELL BARBOUR, TODD KARIN, KAI-MEI FU, University of Washington, YOSHIRO HIRAYAMA, Tohoku University, ARNE LUDWIG, ANDREAS WIECK, Ruhr-Universität Bochum — Single acceptor-bound holes embedded in III-V semiconductor quantum wells could provide an ideal qubit system for scalable quantum information processing and quantum computation. This system combines strong homogenous optical transitions and millisecond long spin coherence times in a fabrication ready material (GaAs). However, single acceptor-bound excitons (A^0X) have yet to be optically isolated even in the purest bulk GaAs samples. This is primarily due to the high acceptor density (10^{14} cm^{-3}) and exceptional optical homogeneity. We propose using stimulated emission depletion microscopy (STED) to increase our optical resolution far beyond the diffraction limit in order to spatially isolate a single acceptor-bound exciton. We report the first demonstration of stimulated emission of acceptor-bound excitons at 4.2K. We resonantly excite the $A^0$1s-A^0X transition and apply a second laser with high power (P=10mW) resonant with the 2s two-hole transition (THT). We observe a 30 percent reduction in the 1s PL intensity when the STED laser is resonant with the THT's. We will present our two-laser spectroscopy work that explores this coherent system and discuss our progress towards isolating a single acceptor-bound exciton using STED microscopy.

12:51PM U26.00007 Ultrafast coherent optical control of a single diamond spin[1] , L.C. BASSETT, F.J. HEREMANS, D.D. AWSCHALOM, Center for Spintronics and Quantum Computation, University of California, Santa Barbara, California 93106, G. BURKARD, Department of Physics, University of Konstanz, D-78457 Konstanz, Germany — As an optically addressable solid-state electronic spin, the nitrogen-vacancy (NV) center in diamond has great promise for applications in quantum information science and metrology. At temperatures below ≈ 10 K, the NV center's optical fine structure facilitates coherent coupling between the electronic spin and light, providing the means for all-optical spin control and other applications in quantum optics. Here, using ultrafast optical pump-probe techniques, we investigate the interplay of orbital, vibrational, and spin dynamics on timescales ranging from femtoseconds to nanoseconds. These techniques provide a flexible and powerful probe of orbital dynamics in the NV center's optically excited state, and enable optical spin control with sub-picosecond resolution.

[1]Work supported by AFOSR, ARO, and DARPA.

1:03PM U26.00008 All-optical quantum dynamical control of an NV center spin in diamond[1] , B.B. BUCKLEY, C.G. YALE, D.J. CHRISTLE, F.J. HEREMANS, L.C. BASSETT, D.D. AWSCHALOM, Center for Spintronics and Quantum Computation, University of California, Santa Barbara, California 93106, G. BURKARD, Department of Physics, University of Konstanz, D-78457 Konstanz, Germany — The nitrogen-vacancy (NV) center in diamond has emerged as a promising optically addressable qubit candidate, but optical methods are usually used only for spin initialization and readout through the defect's spin-dependent intersystem crossing (ISC) transition. Quantum dynamical control typically requires the application of microwave magnetic fields, limiting possible applications. Here, we demonstrate an all-optical method for unitary, arbitrary-axis spin control of single NV spins below 10 K based on stimulated Raman transitions[2]. Using our recently-demonstrated arbitrary-basis spin initialization and readout, we perform time-domain spin coherence measurements on single NV center spins solely with optical pulses. These techniques enable individual addressing of proximal NV center spins and could be used to probe other previously-inaccessible defect spin systems without ISC spin addressability.

1:15PM U26.00009 Experimental control of a nuclear spin quantum register in diamond with decoherence-protected gates , TIM HUGO TAMINIAU, TOENO VAN DER SAR, Kavli Institute of Nanoscience, Delft, V. V. DOBROVITSKI, Ames Laboratory and Iowa State University, RONALD HANSON, Kavli Institute of Nanoscience, Delft — Nuclear spins are one of the most promising candidates for long-lived quantum bits that store and process quantum information. Individual nuclear spins in diamond have been addressed using the nearby electron spin of a nitrogen vacancy center. However, the relatively fast decoherence of the electron spin limits coherent control to the nearest, strongly coupled, nuclear spins. Here, we employ decoherence-protected gates [1] to access individual spins embedded in a bath of nuclear spins that are weakly coupled to an electron spin [2]. We demonstrate the initialization, control and readout of the nuclear spins and discuss our recent progress in implementing two-qubit entangling operations between nuclear spins. These results greatly extend the number of available quantum bits in diamond and provide a way towards tomography with single nuclear spin sensitivity even in decohering environments. 1:27PM U26.00010 Entanglement by measurement and Bell inequality violation with spins in diamond , WOLFGANG PFAFF, TIM TAMINIAU, LUCIO ROBLEDO, HANNES BERNIEN, Kavli Institute of Nanoscience Delft, Delft University of Technology, The Netherlands, MATTHEW MARKHAM, DANIEL TWITCHEN, Element Six, Ltd., Ascot, United Kingdom, RONALD HANSON, Kavli Institute of Nanoscience Delft, Delft University of Technology, The Netherlands — Single spins in diamond have emerged as a promising platform for quantum information processing in the solid state. In particular, individual nuclear spins coupled to nitrogen-vacancy (NV) centers have been recognized as excellent candidates for solid state qubits, because they combine outstanding stability, excellent control by spin resonance techniques, and high-fidelity optical initialization and readout provided by the NV center. Here we report the achievement of a milestone towards quantum computation with spins: The creation of high quality quantum entanglement between two nuclear spins in diamond. Such entanglement is an important resource for quantum computation and lies at the heart of many key quantum protocols, such as teleportation and error correction. We show that we can produce entangled states of high fidelity using a projective quantum measurement. Our technique is non-destructive, and thus leaves the quantum information that is required for further computation unharmed. This enables us to demonstrate the violation of Bell's inequality for the first time with spins in the solid state. Reference: Pfaff et al., Nature Physics, doi:10.1038/nphys2444 (2012).

1:39PM U26.00011 Pulsed ESR of photo-polarized NV centers in diamond at X-band magnetic fields , BRENDON ROSE, ALEXEI TYRYSHKIN, STEPHEN LYON, Princeton U., CHRISTOPH WEIS, THOMAS SCHENKEL, LBNL — Recently nitrogen-vacancy (NV) color centers in diamond have become the focus of many studies aimed towards their use as quantum bits (qubits) in quantum computing applications and as precision magnetic field sensors in scanned imaging applications. The NVs have a ground triplet state (S=1) with ZFS of 2.88 GHz. It has been previously shown that optical excitation, when shining green light at low magnetic fields (below 100 G), polarizes spins preferentially into the T_0 state. Here we will report an X-band pulsed ESR measurement and demonstrate that the optical spin polarization is more complex at higher magnetic fields (3400 G) and can lead to preferential spin polarization into T_+ and T_- states, instead of T_0. This effect can be understood from a simple one electron spin Hamiltonian and depends mainly on the relative orientation of the ZFS and external magnetic field. In addition, we observe strong ESEEM effects originating from the central nitrogen nucleus which are most prominent when measuring the T_0 to T_- transition and when the field is along the ZFS. From the orientation dependence of ESEEM we are able to accurately determine the nitrogen hyperfine and nuclear quadrupole tensors. Spin coherence of 0.8 ms is seen at 10 K, limited by 1 percent of magnetic ^{13}C nuclei in our natural diamond sample.

1:51PM U26.00012 Polytype control of spin qubits in silicon carbide[1] , A.L. FALK, B.B. BUCKLEY, G. CALUSINE, W.F. KOEHL, A. POLITI, D.D. AWSCHALOM, Center for Spintronics and Quantum Computation, University of California, Santa Barbara, California 93106, USA, V.V. DOBROVITSKI, Ames Laboratory and Iowa State University, Ames, Iowa 50011, USA, C.A. ZORMAN, P. X.-L. FENG, Case School of Engineering, Case Western Reserve University, Cleveland, OH 44016, USA — The search for coherently addressable spin states in technologically important materials is a promising direction for solid-state quantum information science. Silicon carbide, a particularly suitable target, is not a single material but a collection of about 250 known polytypes, each with its own set of physical properties and technological applications. We show that in spite of these differences, the 4H-, 6H-, and 3C-SiC polytypes all exhibit optically addressable spins with long coherence times [1]. These results include room temperature spins in all three polytypes and suggest a new method for tuning quantum states using crystal polymorphism. Long spin coherence times allow us to use double electron-electron resonance to measure magnetic dipole interactions between spin ensembles in inequivalent lattice sites of the same crystal. Since such inequivalent spin have distinct optical and spin transition energies, these interactions could lead to dipole-coupled networks of separately addressable spins.

2:03PM U26.00013 Defects as qubits in 3C and 4H polymorphs of SiC[1] , LUKE GORDON, AUDRIUS ALKAUSKAS, WILLIAM F. KOEHL, ANDERSON JANOTTI, DAVID D. AWSCHALOM, CHRIS G. VAN DE WALLE, University of California, Santa Barbara — Using hybrid functional calculations we study defects in SiC that can serve as qubits for quantum computing. We investigate the divacancy in 4H- and 3C-SiC and the N-V center in 3C-SiC, in which the N impurity replacing a C atom is sitting next to a Si vacancy. The calculated excitation and emission energies of the divacancy in 4H-SiC are in excellent agreement with the available experimental data. Most importantly, we predict that the neutral divacancy and the negatively charged NV center in 3C-SiC have all the required characteristics to serve as qubits; in addition, both defects are stable in n-type 3C-SiC, which is in principle easy to fabricate. We calculate luminescence lineshapes and Huang-Rhys factors for these defects in 4H and 3C-SiC, and compare with experimental photoluminescence spectra.

Session U27 GQI: Quantum Entanglement: Theory and Experiment 329 - Andrews Doherty, University of Sydney

11:15AM U27.00001 Positivity of Partial Transpose and Separability of Dicke state mixtures , ELIE WOLFE, SUSANNE YELIN, University of Connecticut — We study mixtures of permutation symmetric (Dicke) states, with a special focus on superradiance time evolution. For such systems we develop necessary separability criteria for general N-qubit systems based on the condition of Positive Partial Transpose. We also compose sufficient separability criteria for the specific cases of two and three qubits. Comparing the criteria we prove that, for Dicke state mixtures, the PPT test is always sufficient to imply full separability.

11:27AM U27.00002 Polynomial invariants to quantify Four-body Correlations[1] , SANTOSH SHELLY SHARMA[2], Depto. de fisica, Universidade Estadual de Londrina, Londrina Pr, Brazil, NARESH KUMAR SHARMA, Depto. de Matematica, Universidade Estadual de Londrina, Londrina Pr, Brazil — Local unitary invariance and notion of negativity fonts are used as the principle tools to construct four qubit polynomial invariants of degree 8, 12, and 24. Determinants of negativity fonts are linked to matrices obtained from state operator through selective partial transposition. Our general aim is to construct the polynomial invariants that quantify entanglement due to $K-$body correlations in an N-qubit ($N?K$) pure state. This is done by constructing N-qubit invariants from multivariate forms with $(K-1)$-qubit invariants as coefficients. In particular, the invariant that quantifies entanglement due to N-body correlations is obtained from a biform having as coefficients the $N-1$ qubit invariants. A polynomial invariant that is non-zero on four qubit pure states with four-body correlations and zero on all other states, is identified. Classification of four qubit states into seven major classes, using criterion based on the nature of correlations, is discussed.

11:39AM U27.00003 Numerical Calculations of the Three Tangle for Mixed States , SAMUEL RODRIQUES, PETER LOVE, Haverford College — We present a steepest descent convex roof optimization algorithm, using the Cayley parametrization of the unitary group, which can be used to calculate the convex roof of any entanglement monotone on mixed states. We use the algorithm to calculate the three tangle on a set of states for which the tangle is known analytically, and show that our results are in good agreement with the analytical calculations. We then randomly generate a set of full-rank three qubit states, of varied mixedness and tangle, calculate the tangle on these states using our convex roof algorithm, and also calculate the lower bound on the three-tangle which has been provided by Eltschka and Siewert[1]. We thus provide a profile of the strength of the Eltschka-Siewert bound, as a function of mixedness and tangle. [1] "Optimal Witnesses for Three Qubit Entanglement from Greenberger-Horne-Zeilinger Symmetry," Eltschka, C. and Siewert, J., forthcoming. arXiv: 1204.5451

11:51AM U27.00004 Quantum steering ellipsoids: The way to represent two qubits[1] , SANIA JEVTIC, MATTHEW PUSEY, DAVID JENNINGS, TERRY RUDOLPH, Imperial College London — A single qubit state is faithfully represented as a vector in the Bloch sphere. A two qubit state may be faithfully represented as two vectors and a quantum steering ellipsoid (QSE) in the Bloch sphere. When Alice and Bob share a pair of qubits, the QSE is the geometric set of states that Bob can steer Alice's qubit to when he implements all possible measurements on his qubit. We argue that the QSE is the way one should visualise a two qubit state and show how the correlative properties of the state manifest themselves in this paradigm, in particular we give simple conditions for when the state is entangled, or has discord. We will also present novel features of the two qubit state that are revealed by the QSE formalism, and show that a state corresponding to an ellipsoid with non-zero volume contains a new type of correlation. Such a state is a useful resource in a game where Bob succeeds if he can steer Alice's qubit to three states with linearly independent Bloch vectors.

12:03PM U27.00005 Quantum Discord Bounds the Amount of Distributed Entanglement[1] , MARCO PIANI, Institute for Quantum Computing, University of Waterloo, TAN KOK CHUAN, Centre for Quantum Technologies, National University of Singapore, JEAN MAILLARD, Blackett Laboratory, Imperial College London, KAVAN MODI, Department of Physics, University of Oxford, TOMASZ PATEREK, Nanyang Technological University, Singapore, MAURO PATERNOSTRO, Queen's University, Belfast — The ability to distribute quantum entanglement is a prerequisite for many fundamental tests of quantum theory and numerous quantum information protocols. Two distant parties can increase the amount of entanglement between them by means of quantum communication encoded in a carrier that is sent from one party to the other. Intriguingly, entanglement can be increased even when the exchanged carrier is not entangled with the parties. However, in light of the defining property of entanglement stating that it cannot increase under classical communication, the carrier must be quantum. Here we show that, in general, the increase of relative entropy of entanglement between two remote parties is bounded by the amount of nonclassical correlations of the carrier with the parties as quantified by the relative entropy of discord. We study implications of this bound, provide new examples of entanglement distribution via unentangled states, and put further limits on this phenomenon.

12:15PM U27.00006 Topological Classification of Types of Quantum Discord Evolutions[1] , NGA NGUYEN, ROBERT JOYNT, Physics Department, University of Wisconsin-Madison, Madison, WI 53706 — Quantum discord is a type of quantum correlation that has recently attracted extensive attention. One question that is of experimental importance is how quantum correlations such as entanglement and discord are erased by external noise. A general classification of time evolution is seen to depend essentially on the understanding of the topology of the set C of concordant (zero-discord) states. In the 2-qubit case, we show that C is a 9-dimensional simply-connected manifold with boundary that can be embedded in the 15-dimensional space of 2-qubit density matrices. This yields 6 topologically distinct categories for the joint time evolution of entanglement and discord that exhaust all possibilities. We show that these 6 categories can be obtained in one physical model using independent or correlated random telegraph noise sources in the Markovian regime. Transition between these categories is of topological nature and is governed by changing physical parameters or initial conditions.

12:27PM U27.00007 Mutual Preservation of Entanglement , ANDRZEJ VEITIA, University of Columbia — We study a generalized double Jaynes-Cummings (JC) model where two entangled pairs of two-level atoms interact indirectly. We focus on the case where the cavities and the entangled pairs are uncorrelated. We show that there exist initial states of the qubit system so that two entangled pairs are available at all times. In particular, the minimum entanglement in the pairs as a function of the initial state is studied. Finally, we extend our findings to a model consisting of multi-mode atom-cavity interactions. We use a non-Markovian quantum state diffusion (QSD) equation to obtain the steady-state density matrix for the qubits. We show that the multi-mode model also displays dynamical preservation of entanglement.

12:39PM U27.00008 Quantum geometry and entanglement in the Rabi model , JUSTIN WILSON, VICTOR GALITSKI, University of Maryland at College Park — In composite systems, entanglement can be useful for control since one system's properties become fundamentally linked with another system's properties. One way of measuring entanglement is with a quantity called I-concurrence, a generalization of concurrence to systems that have more states than a qubit. We show that I-concurrence can be rewritten in terms of quantum geometric quantities. In particular, we show a dependence on the Hilbert-Schmidt distance measure on the Hilbert space of one of the subsystems. Using this quantity and the recently exactly solved Rabi model, we calculate the entanglement between eigenstates in the Rabi model.

12:51PM U27.00009 Classical Analogs of Quantum Entanglement[1] , BRIAN LA COUR, The University of Texas at Austin — Quantum computing algorithms rely upon entanglement and context-based measurements, properties that are well exhibited by atomic or photonic systems. In some cases, these properties can be mimicked by cleverly contrived classical systems. We present a notional scheme for such classical analogs and compare their predictions to those of an associated quantum system. Entanglement is verified operationally using quantum tomography, wherein the quantum mixed state is inferred from measurements on a complete orthonormal set of Hermitian observables. Using the Peres-Horodecki criterion for separability, we examine the partial transpose of the estimated density matrix to establish a necessary, and in some cases sufficient, condition for entanglement. Through the use of Monte Carlo simulations, we find that certain classical systems do indeed exhibit a measurably significant level of entanglement.

1:03PM U27.00010 Robust distant-entanglement generation using coherent multiphoton scattering[1] , CHING-KIT CHAN, ITAMP, Harvard University, L. J. SHAM, University of California San Diego — The generation and controllability of entanglement between distant quantum states have been the heart of quantum computation and quantum information processing. Existing schemes for solid state qubit entanglement are based on the single-photon spectroscopy that has the merit of a high fidelity entanglement creation, but with a very limited efficiency. This severely restricts the scalability for a qubit network system. Here, we describe a new distant entanglement protocol using coherent multiphoton scattering. The scheme makes use of the postselection of large and distinguishable photon signals, and has both a high success probability and a high entanglement fidelity. Our result shows that the entanglement generation is robust against photon fluctuations, and has an average entanglement duration within the decoherence time in various qubit systems, based on existing experimental parameters.

1:15PM U27.00011 Optical control of entangled states in semiconductor quantum wells , MARIO BORUNDA, Oklahoma State University and Harvard University, ESA RASANEN, Tampere University of Technology, University of Jyvaskyla, and Haravrd University, THOMAS BLASI, Harvard University and Technisch Universitat Munchen, ERIC HELLER, Harvard University — The ability to coherently control arbitrary two-electron states, and to maximize the entanglement, opens up further perspectives in solid-state quantum information. In this talk, we present theory and calculations for coherent high-fidelity quantum control of many-particle states in semiconductor quantum wells. We have shown that coupling a two-electron double quantum dot to a terahertz optical source enables targeted excitations that are one to two orders of magnitude faster and significantly more accurate than those obtained with electric gates. The optical fields subject to realistic physical constraints are obtained through quantum optimal control theory that is applied in conjunction with the numerically exact solution of the time-dependent Schrodinger equation.

1:27PM U27.00012 Persistent Quantum Beats and Long-Distance Entanglement from Waveguide-Mediated Interactions[1] , HUAIXIU ZHENG, HAROLD U. BARANGER, Duke University — We study photon-photon correlations and entanglement generation in a one-dimensional waveguide coupled to two qubits with an arbitrary spatial separation [1]. Such a system can be realized by coupling a 1D open transmission line to superconducting qubits. To treat the combination of nonlinear elements and 1D continuum, we develop a novel Green function method. The vacuum-mediated qubit-qubit interactions cause quantum beats to appear in the second-order correlation function. We go beyond the Markovian regime and observe that such quantum beats persist much longer than the qubit lifetime. A high degree of long-distance entanglement can be generated, increasing the potential of waveguide-QED systems for scalable quantum networking. [1] H. Zheng, and H. U. Baranger, arXiv:1206.4442 (2012).

1:39PM U27.00013 PPLN Device Characterization and Novel Entanglement Schemes , SEAN KRUPA, ERIC STINAFF, Department of Physics & Astronomy, Ohio University, Athens, OH, DAVID NIPPA, LEE OESTERLING, Battelle Memorial Insitute, Columbus, OH — Bright sources of entangled photons are of great interest in the quantum information community, and the non-linear optical process of Spontaneous Parametric Downconversion (SPDC) is a well-known means to create entangled photons. Additionally, periodic polling has emerged as a viable choice for quasi-phase matching the downconverted photons rendering them useful for experimentation. Periodically Poled Lithium Niobate (PPLN) is among the best choices for these materials as it optically robust, temperature tunable, and commercially available. The addition of waveguide structures in PPLN devices not only increase its viability as a source of entangled photons but can also become an integral part of the entanglement schemes as well. Thorough characterization of PPLN devices is essential for the optimization of SPDC and their use to create entangled states. We will report characterization results for wave-guided PPLN devices including: waveguide geometry, fiber coupling efficiency, polling period details, and downconversion efficiency. Of particular interest is our device's ability to be used for novel entanglement states involving one or more waveguides.

1:51PM U27.00014 Measurement of the joint spectrum of entangled photons using rotary dispersion , DANIEL JONES, TODD PITTMAN, University of Maryland, Baltimore County — We report a new method of observing the spectral entanglement of photons generated in spontaneous parametric down-conversion (PDC). In contrast to previous methods based on spatial or temporal dispersion, our method is based on rotary dispersion and polarization measurements. Our experiment utilizes a variation of the Sénarmont compensator in order to rotate the polarization state of the entangled signal and idler photons. By passing the photons through several stages of these "rotators," we essentially create a Lyot filter in which we can directly correlate an analyzer measurement after the rotators with a specific wavelength, within a resolution defined by the theory. This method is fundamentally different than previous experiments to measure the joint spectrum of PDC photons because of the periodicity of using analyzers as the measurement devices. The periodicity of the analyzers causes a trade-off between the resolution of the device and the maximum bandwidth of the entangled photons that can be measured.

2:03PM U27.00015 Realistic loophole-free Bell test with atom-photon entanglement , COLIN TEO, Centre for Quantum Technologies, MATEUS ARAÚJO, MARCO QUINTINO, Departamento de Fisica, Universidade Federal de Minas Gerais, JIŘÍ MINÁŘ, DANIEL CAVALCANTI, Centre for Quantum Technologies, VALERIO SCARANI, Centre for Quantum Technologies; Department of Physics, National University of Singapore, MARCELO TERRA CUNHA, Departamento de Matematica, Universidade Federal de Minas Gerais, MARCELO SANTOS, Departamento de Fisica, Universidade Federal de Minas Gerais — The establishment of nonlocal correlations, guaranteed through the violation of a Bell inequality, is not only important from a fundamental point of view, but constitutes the basis for device-independent quantum information technologies. Although several nonlocality tests have been performed so far, all of them suffered from either the locality or the detection loopholes. Recent studies have suggested that the use of atom-photon entanglement can lead to Bell inequality violations with moderate transmission and detection efficiencies. In this paper we propose an experimental setup realizing a simple atom-photon entangled state that, under realistic experimental parameters available to date, achieves a significant violation of the Clauser-Horn-Shimony-Holt Bell inequality. Most importantly, the violation remains when considering typical detection efficiencies and losses due to required propagation distances.

Session U28 GSNP: Focus Session: Tunable Materials 336 - Jongmin Shim, University at Buffalo, The State University of New York

11:15AM U28.00001 Bukliball and Beyond: 3-D Soft Auxetic Metamaterials , JONGMIN SHIM, Harvard University / University at Buffalo, SAHAB BABAEE, JAMES C. WEAVER, NIKITA PATEL, ELIZABETH R. CHEN, KATIA BERTOLDI, Harvard University — We present a new class of 3-D soft metamaterials whose microstructure can be dramatically changed in response to mechanical loading. Patterned spherical shells, the Buckliballs (PNAS 109(16):5978) which undergo undergoing a buckling-induced structural transformation under pressure, are employed as building blocks, and are assembled to construct 3-D super-structures. We present procedures to guide the selection of both the building blocks and their arrangement, and design materials with tunable 3-D auxetic behavior that exploit buckling as the actuation mechanism. The validity of the proposed material design is demonstrated through both experiments and finite element simulations. This pattern transformation induced by a mechanical instability opens the possibility for fabrication of 3-D auxetic materials/structures over a wide range of length scales.

11:27AM U28.00002 Grayscale gel lithography: From umlti-strips to responsive origami , MYUNGHWAN BYUN, RYAN HAYWARD, Department of Polymer Science and Engineering, University of Massachusetts Amherst, CHRISTIAN SANTANGELO, Department of Physics, University of Massachusetts Amherst — Non-uniform swelling of hydrogel sheets with two-dimensional (2D) patterns of crosslink density has the potential to yield a rich array of three-dimensional (3D) structures, yet many of the design rules remain poorly understood. Here, we study the geometrically simple case of "multi-strips", consisting of alternating parallel strips of high and low crosslink density. These materials are patterned using sequential UV exposure of a photo-crosslinkable polymer film through two photomasks. We show that these materials deform by rolling around the axis perpendicular to the interface between the regions, with a characteristic dimension that depends on the strip width and sheet thickness. However, beyond a critical minimum strip width, the material remains flat, instead forming an anisotropically swelled state that provides fruitful information on the contrast in modulus between the two regions. We also consider the deformation of sheets patterned with multiple regions that define geometrically incompatible rolling axis. Finally, we discuss the formation of hinges based on symmetric tri-strips that can be used to defined fold patterns, yielding responsive gel origami structures.

11:39AM U28.00003 Materials with Tailored Thermal Expansion Coefficient , KATIA BERTOLDI, JIA LIU, SICONG SHAN, SUNG HOON KANG, Harvard University — Designing materials with tailored coefficient of thermal expansion (CTE) has applications in a number of fields, including biomedical and mechanical engineering and solar energy. It is particularly important to combine a desired (usually low) CTE with mechanical robustness. Most of previous work has been focused on designing low-CTE materials by modifying compounds at the chemical level. It is also possible to design materials with tailored CTE by using specific topologies of different materials to achieve overall properties outside the range of the constituent materials. Here, we exploit buckling in laminated periodic structures to design materials whose coefficient of thermal expansion can be tuned (from positive to negative) by varying the unit cell geometry.

11:51AM U28.00004 Buckligami: Actuation of soft structures through mechanical instabilities , ARNAUD LAZARUS, PEDRO REIS, Massachusetts Institute of Technology — We present a novel mechanism for actuating soft structures, that is triggered through buckling. Our elastomeric samples are rapid-prototyped using digital fabrication and comprise of a cylindrical shell patterned with an array of voids, each of which is covered by a thin membrane. Decreasing the internal pressure of the structure induces local buckling of the ligaments of the pattern, resulting in controllable folding of the global structure. Using rigid inclusions to plug the voids in specific geometric arrangements allows us to excite a variety of different fundamental motions of the cylindrical shell, including flexure and twist. We refer to this new mechanism of buckling-induced folding as "buckligami." Given that geometry, elasticity and buckling are the underlying ingredients of this local folding mechanism, the global actuation is scalable, reversible and repeatable. Characterization and rationalization of our experiments provide crucial fundamental understanding to aid the design of new scale-independent actuators, with potential implications in the field of soft robotics.

12:03PM U28.00005 Shaping and morphing three dimensional structures using thin film stress , DAVID GRACIAS, Johns Hopkins University — The spatial patterning and stimuli-responsive manipulation of mechanical stresses within thin films can be used to self-assemble static and reconfigurable materials and devices. I will discuss the utilization of stresses associated with the minimization of surface tension, the relaxation of polycrystalline films, and the differential cross-linking of polymers and hydrogels to realize assembly and reversible actuation of functional structures of importance in electronics, optics and medicine.

12:39PM U28.00006 Tunable phononic crystals through dielectric elastomers , DAVID HENANN, KATIA BERTOLDI, Harvard University — Phononic crystals are periodic materials that display phononic band gaps – frequency ranges in which elastic waves are prohibited. Through deformation of the periodic structure the frequency ranges of band gaps may be adjusted or new band gaps may be created. Phononic materials made from elastomers enable large reversible deformation and, as a result, significant tunability of the phononic properties. Dielectric elastomers may be used in phononic crystals, in which deformation is actuated through the application of an electrical voltage, opening the door for easily tunable phononic crystals. In order to realize these exciting capabilities, robust simulation and design tools are needed. We have developed finite-element technology to address this problem and have applied these tools to designing phononic crystals with band gaps tuned through the application of voltage. The key ingredients of our finite-element tools are (i) the incorporation of electro-mechanical coupling, (ii) large-deformation capability, and (iii) an accounting for inertial effects. We present an application of our simulation capability to the design of a phononic crystal consisting of a square array of circular-cross-section threads embedded in a dielectric elastomeric matrix.

12:51PM U28.00007 Tunable Mechanical Response in Biholar Elastic Media , BASTIAAN FLORIJN, HENK IMTHORN, MARTIN VAN HECKE, Leiden University — We probe the mechanics of 2D and 3D elastic media that are structured with arrays of holes of two different sizes. Hole size ratio plays a crucial role for the mechanical response - allowing to tune the Poisson ratio and qualitative response of the material under uniaxial loading. Biaxial and triaxial loading of these biholar structures leads to a wealth of new phenomena, including mechanically switchable hysteresis and memory effects.

1:03PM U28.00008 Coupling geometrical frustration with mechanical instabilities to design surfaces with three dynamically changing states , SUNG KANG, SICONG SHAN, KATIA BERTOLDI, Harvard University — The interplay between mechanical instabilities and non-linear deformation in soft, porous structures give us the exciting opportunities to design materials that can suddenly change from one shape to another in response to an external stimulus. Based on this approach, there have been an increasing number of studies demonstrating reversible pattern formation between two states. Inspired by triple-shape-memory polymers [1], here we show a new mechanism to generate three-state ordered pattern formation using athermal process by exploiting buckling and geometrical frustration of cellular structures. Our new approach allows dynamical switching among three successive states simply by varying the external stimuli. Moreover, our scale-independent mechanism based on geometry and mechanical instability can provide a unique opportunity for studying dynamics of complex pattern formation with tunable surface properties. Reference: [1] I. Belin, S. Kelch, R. Langer, and A. Lendlein, Proc. Natl. Acad. Sci. USA, 103, 18043-18047 (2006).

1:15PM U28.00009 Shape transformations in liquid crystal elastomers with complex microstructure[1] , VIANNEY GIMENEZ-PINTO, JONATHAN SELINGER, ROBIN SELINGER, Kent State University — Recent experimental and theoretical studies have reported thermal-induced shape transformations in nematic liquid crystal elastomer (LCE) sheets with a complex director field. Director twist across the film thickness induces formation of twisted or curled structures whose chiral sense switches with temperature [1]. Using finite element simulations, we explore more complex director geometries that produce a variety of different actuation behaviors. We explore films containing a $+1$ topological defect with radial or azimuthal director alignment; and stripes and checkerboard patterns of twisted domains. We compare our results with recent experimental studies by D. Broer and coworkers and theoretical work by Modes and Warner. These results demonstrate the potential for application of LCE materials as mechanical actuators. [1] Y. Sawa, F. Ye, K. Urayama, T. Takigawa, V. Gimenez-Pinto, R. L. B. Selinger, and J. V. Selinger, PNAS 108, 6364 (2011).

1:27PM U28.00010 Soft 3-D Phononic Crystals: Design and engineering of the band-gap and propagation directionality , PAI WANG, SAHAB BABAEE, JONGMIN SHIM, KATIA BERTOLDI, Harvard University, BERTOLDI'S GROUP TEAM — We present a new class of 3-D bi-continuous soft phononic crystals. Different solid-fluid inter-penetrating periodic micro-structures are proposed for the geometric configurations. Buckling and large deformation of the meta-material is intentionally exploited as a novel and very simple approach to tune and transform the phononic band gaps as well as the preferential propagation directions of acoustic and elastic waves. The nonlinear effects of both geometry and material behavior during the deformation are investigated. The dispersion relations of deformed phononic crystals are calculated by using frequency domain numerical simulations on the unit cell of spatial periodicity. The characteristics of soft phononic crystals are demonstrated with tunable band-gaps, adjustable directionality and adaptive refractive index. This study provides us with a deeper understanding of the design parameters and engineering guidelines for various potential applications, including sound filters in noise-cancelling devices, wave guides, acoustic imaging equipment and vibration isolators.

1:39PM U28.00011 Multifunctional Applications of Nanostructured Mechanical Metamaterials[1] , LIFENG WANG, Department of Civil & Environmental Engineering, Clarkson Univeristy — Mechanical metamaterials have been shown to possess extraordinary properties, and thus have been of great interest to mathematicians, physical scientists, material scientists, and biologists. A large part of the study of materials science is to obtain new structure-property-function relationships needed for achieving optimized mechanical properties. Here, we demonstrate the potential to design and fabricate periodically ordered structures. These structures are shown to have a unique combination of stiffness, strength, and energy absorption, as well as damage tolerance. The results provide guidelines to advance the digital design (materials by design) and manufacturing concepts (advanced manufacturing) into the realm of engineered materials with desired properties and further to create multifunctional materials. For example, the periodic nature of the structures enables mechanically tunable band gap (phononic or photonic) materials, and tunable sensors in tissue engineering.

1:51PM U28.00012 Fluid-structure Interactions for the Design of Adaptive Acoustic Metamaterials , FILIPPO CASADEI, KATIA BERTOLDI, Harvard University, . TEAM — The present research focuses on the analysis of fluid-structure interactions as a new paradigm for the design of adaptive phononic crystals and acoustic metamaterials. Whereas in conventional design procedures couplings between structures and fluids represent a source of concern due to the possible onset of catastrophic instabilities, in this research such interactions are exploited as the enabling mechanism for mechanical adaptation. Analytical and numerical models illustrate how such interactions can be exploited for the design of periodic structures with wave propagation properties that can be controlled by the surrounding fluid environment. Analysis of the dispersion relations computed for one-dimensional phononic crystals and acoustic metamaterials show that the location of frequency bandgaps is directly correlated to the conditions of the external fluid flow. Direct simulations of assemblies of finite size and preliminary experimental results are presented to further illustrate the concept.

Session U29 GSNP: Focus Session: Jamming: Marginal Solids II 337 - Joshua Dijksman, Duke University

11:15AM U29.00001 Shear jamming in granular materials[1] , JIE ZHANG, Institute of Natural Sciences and Department of Physics, Shanghai Jiao Tong University, Shanghai 200240, China — For frictionless particles with purely repulsive interactions, there is a critical packing fraction ϕ_J below which no jammed states exist. Frictional granular particles in the regime of $\phi < \phi_J$ act differently under shear: early experiments by Zhang & Behringer at Duke University show jammed states can be created by the application of shear stress. Compared to the states above ϕ_J, the shear-jammed states (SJS) are mechanically more fragile, but they can resist shear. Formation of these states requires the anisotropic contact network as a backbone and these new states must be incorporated into a more general jamming picture (Bi et al Nature 2011). If time permits, I will present some new results from recent experiments at SJTU aimed towards understanding the more detailed nature of SJS and the transition from unjammed states to SJS.

[1]This work is in collaboration with Bob Behringer at Duke University, Dapeng Bi (now at Syracuse) and Bulbul Chakraborty at Brandeis University. The work at SJTU is in collaboration with Ling Zhang and several undergrads in the physics department.

11:51AM U29.00002 Compression and Shear Driven Jamming of Frictionless U-Shaped Particles in Two Dimensions[1] , THEODORE MARSCHALL, University of Rochester, ANDREW LOHEAC, SCOTT FRANKLIN, Rochester Institute of Technology, STEPHEN TEITEL, University of Rochester — We simulate a system of soft, frictionless, U-shaped particles (staples), under both isotropic compression and uniform shear flow in two dimensions. The shape of the particles allows them to interlock, causing a geometry induced particle cohesion. We investigate the jamming transition of this system as the packing fraction is increased, in an effort to learn whether such geometric cohesion in novel shaped frictionless particles can produce effects similar to what is found for frictional smooth disks.

[1]This work has been supported by NSF grants CBET-1133722 and CBET-1133126, as well as by the resources of the Center for Integrated Research Computing at the University of Rochester.

12:03PM U29.00003 Shear Reversibility in Model Granular Systems , CARL SCHRECK, Yale University, ROB HOY, University of Southern Florida, MARK SHATTUCK, City College of New York, COREY O'HERN, Yale University — Athermal particulate systems such as foams and granular media are out-of-thermal equilibrium and therefore must be externally driven using shear or vibration to explore different configurations. Of particular interest is being able to predict and control the structural and mechanical properties of athermal systems as a function of the driving mechanism. In this work, we show numerically how particle collisions in cyclically sheared hard sphere systems can lead to microreversibility. We map out the steady-state "phase diagram" as a function of packing fraction (ϕ) and strain amplitude (γ_{max}), and identify "point-reversible" states at low ϕ and γ_{max} in which particles do not collide over the course of a shear cycle, and "loop-reversible" states at intermediate ϕ and γ_{max} in which particles undergo numerous collisions but return to their initial positions at the end of each shear cycle. Loop-reversiblity is a novel form of self organization that gives rise to non-fluctuating dynamical states over a broad range of packing fractions from contact percolation to jamming, i.e. $\phi_P = 0.55$ to $\phi_J = 0.84$ in two dimensions.

12:15PM U29.00004 Stress dynamics of a 2D dense granular system near shear jamming[1] , JIE REN, JOSHUA DIJKSMAN, ROBERT BEHRINGER, Duke University — We study the dynamics of pressure and shear stress in a frictional 2D dense granular system using a novel apparatus that can provide fixed-volume shear without generating inhomogeneities. Under increasing shear strain, the system's pressure shows a strong increase with strain, characterized by a "Reynolds coefficient," $R = d^2P/d\gamma^2$. R depends only on packing fraction ϕ, and shows a strong increase as ϕ approaches ϕ_J from below. In the meantime, the system's shear stress shows a non-monotonic behavior with increasing strain. It first increases with strain as the system is in "fragile" states and builds up long force chains along the compression direction. After a certain amount of strain, force chains along the dilation direction starts to build up, and the system transfers into a "shear-jammed" state and the shear stress starts to decrease with strain. Under oscillatory shear, both pressure and shear stress show limit-cycle behavior and reach steady states after many cycles. However, the limit cycles of pressure and shear stress are very different: the pressure exhibits a hysteresis-free parabolic curve, while the shear stress exhibits a strongly hysteretic loop.

12:27PM U29.00005 Shear jamming in a two dimensional granular system without basal friction , HU ZHENG, Tongji University, JOSHUA DIJKSMAN, ROBERT BEHRINGER, Duke University — Two dimensional granular systems are an important tool to explore the dynamics of granular materials. However, traditional experimental methods could not avoid the effects of friction between particles and the base on which they rest. Here, we develop a novel apparatus which allows us to tune the basal friction of the particles. We do so by submersing the particles in a density matched liquid, thus removing the normal force, hence the friction, between the particles and base. We use this technique to investigate the effect of shear jamming found by Bi et. al. (2011) by probing the overall shear stress, particle motion and the photoelastic response of the particles under simple shear.

12:39PM U29.00006 Bagnold and linear scalings in shearing simulations of massive particles[1] , DANIEL VÅGBERG, PETER OLSSON, Umeå University, Sweden, S. TEITEL, Dept. of Physics and Astronomy, University of Rochester, NY — We consider the rheology of massive bidisperse soft-core discs in two dimensions driven by a constant shear rate $\dot{\gamma}$ at zero temperature. We study how the behavior depends on the details of the dynamics, by investigating three different models for the energy dissipation. In these models the dissipation from two colliding particles are proportional to (1) the total velocity difference, (2) the normal component of the velocity difference, (3) the tangential component of the velocity difference, respectively. It turns out that these seemingly minor differences have major implications for the scaling of the pressure p with respect to $\dot{\gamma}$. The system can exhibit linear scaling, $p \sim \dot{\gamma}$, or Bagnold scaling, $p \sim \dot{\gamma}^2$, depending on the details of the dissipation used. It is found that the onset of linear scaling is related to the appearance of force chains spanning the system.

12:51PM U29.00007 Relaxation time, viscosity and scaling at densities below jamming[1] , PETER OLSSON, Umeå University, Sweden — We simulate soft-core bidisperse frictionless disks in two dimensions with overdamped dynamics at zero temperature and densities below jamming. We first prepare configurations by shearing at several constant shear rates $\dot{\gamma}$. These configurations are then used as starting points for simulations *without* shearing that relax the system to zero energy. From these simulations we determine both the relaxation time, τ, and the average path length traversed by the particles to reach the zero energy state. We find that τ diverges algebraically as a function of density, $\tau \sim (\phi_J - \phi)^{-\beta}$, if $\dot{\gamma}$ in the preparatory simulations is sufficiently small. We further find that the shear viscosity η can be formally related to τ, and that this gives a way to understand the origin of corrections to scaling in the scaling analysis of η[1]. The presence of the exponent $\beta + y$, where $y \approx 1.1$, in the scaling of the deviations from the $\dot{\gamma} \to 0$ limit, $\eta(\phi, \dot{\gamma})/\eta(\phi, \dot{\gamma} \to 0) = f((\phi_J - \phi)^{-(\beta+y)}\dot{\gamma})$ [1], is also given an intuitive interpretation.

1:03PM U29.00008 Shear shocks in fragile matter , VINCENZO VITELLI, STEPHAN ULRICH, NITIN UPADHYAYA, Leiden University — Random media, like polymer networks, covalent network glasses, or grains under pressure can be viewed as elastic networks composed of springs and balls. The shear moduli of these types of materials typically vanish as the network connectivity z approaches a critical value. In this talk, I show that shear strains propagate as diffusive fronts, whose **width diverges** and whose **transverse speed of sound vanishes**, as the transition is approached. Consequently, in this regime, linear theory breaks down, giving rise to **nonlinear transverse waves**. Comparison of the analytical front profile to molecular dynamics simulations allows the extraction of the material constants of the network. Interestingly, even an **undamped network** yields a **diverging effective viscosity** caused by leaking of energy into non-affine degrees of freedom.

1:15PM U29.00009 Soft particle packings near jamming: correlations in static structure , KAMRAN KARIMI, CRAIG MALONEY, Carnegie Mellon University — We extend our previous results report on 2D simulations of soft harmonic packings at various area fractions φ above the jamming point φ_c. We employ several statistical analyses to determine whether one or more characteristic lengths can be associated with either the quenched stress field in the packing or the structure of local elastic moduli. First, we define a locally anisotropic variant of the standard two-point correlation function. This anisotropic correlation function follows a power law even in globally isotropic stress states with a φ independent exponent and no discernible cutoff within the statistically accessible regime. Secondly, we define a coarse-grained stress field on a scale R. The average anisotropic component and the fluctuations in the trace can both be collapsed onto similar master curves after rescaling R by a characteristic length scale ξ. ξ accelerates as φ approaches φ_c, consistent with a divergence at φ_c. Surprisingly, a similar analysis on the local coarse-grained elastic modulus tensor shows a non-trivial power-law scaling behavior as a function of the coarse-graining size yet no characteristic ξ as exhibited by the stress.

1:27PM U29.00010 Elastic modulus of solid-like microsphere heaps , CARLOS ORTIZ, KAREN DANIELS, ROBERT RIEHN, North Carolina State University — We study the elastic modulus of heaps of repulsive microspheres to gain insight into the nature of the rigidity of the material. The heaps are initially created by flowing a colloidal microsphere suspension towards a flat-topped ridge placed within a quasi two-dimensional microfluidic channel. The suspension flow-rate determines the heap size via the angle of repose. Using fluorescence video microscopy, we measure the fluorescent heap size until it reaches steady state. We directly visualize the elastic recoil of these steady state heaps in response to controlled changes in the fluid flow rate. We change the flow rate by an amount Δv in a step-like fashion, and measure the amplitude of the bulk heap deformation ΔA. We investigate both compressions and decompressions of varying amplitudes with respect to the steady state. Three deformation regimes are observed. No deformations are observed below a critical perturbation magnitude Δv_c. Above Δv_c, deformation amplitudes are linear with Δv. However, for large perturbations, nonlinear deformation amplitudes are observed, and their relationship is asymmetric with respect to compression and decompression.

1:39PM U29.00011 Investigating the stability of jammed systems with respect to generalized boundary deformations , SAMUEL SCHOENHOLZ, CARL GOODRICH, OLEG KOGAN, ANDREA LIU, University of Pennsylvania, SIDNEY NAGEL, University of Chicago — At zero temperature and applied stress, amorphous packings of spheres exhibit a jamming transition as a function of packing fraction. Above the jamming transition, systems of repulsive spheres have a nonzero bulk moduli. However, some jammed states prepared with periodic boundary conditions are unstable to shear. These instabilities motivate several questions: How does the fraction of systems that exhibit instabilities scale with packing fraction and system size? Are there other classes of boundary deformations with respect to which jammed packings could be unstable, and if so, how can they be explored? We answer these questions by considering each finite packing with periodic boundary conditions in d dimensions as the basis of an infinite hypercubic lattice. We study the properties of modes that do not respect the periodicity of the initial system and thereby characterize the linear response to a large class of boundary deformations. In this way we systematically explore the effects of system size and packing fraction on stability with respect to these boundary deformations, and show that our results can be understood in terms of competition between plane waves and anomalous vibrational modes associated with the jamming transition.

1:51PM U29.00012 Strong reduction of the rigidity of repulsive contact systems at vanishingly low temperatures[1] , HAJIME YOSHINO, SATOSHI OKAMURA, Department of Earth and Space Science, School of Science, Osaka University — Contrarily to ordinary solids, the amorphous solid states of repulsive contact systems such as colloids and emulsions may not be regarded simply as harmonic states [2]. We studied the rigidity, i. e. the shear-modulus of such a class of systems at vanishingly low but finite temperatures using the cloned liquid approach [3] and molecular dynamic simulations. Our result implies breakdown of the commutation of the thermodynamic limit $N \to \infty$ and zero temperature limit $T \to 0$ for the response to shear: we found the rigidity in the limit $T \to 0$ is significantly smaller and exhibit a different scaling compared with that at $T = 0$. Interestingly the rigidity in the limit $T \to 0$ exhibits the same scaling as the pressure, as observed experimentally in emulsions[4]. Detailed numerical examination suggests that the strong stress relaxation is due to contact opening events activated at vanishingly small temperatures.

2:03PM U29.00013 Mechanical instability at finite temperature[1] , XIAOMING MAO, University of Michigan, CARLOS I. MENDOZA, Universidad Nacional, Mexico, ANTON SOUSLOV, Georgia Institute of Technology, TOM C. LUBENSKY, University of Pennsylvania — Rigidity transitions have been well studied in a wide range of athermal systems such as jammed packings and diluted lattices, in which the balance between the number of degrees of freedom and constraints generally determines the onset of mechanical instability, as predicted by Maxwell. The effects of thermal fluctuations on these transitions, however, have not yet been systematically studied. Characterizing rigidity transitions at finite temperature is very important to the understanding of fundamental problems such as the relation between the glass transition and jamming. We report an analytic study of a finite-temperature rigidity transition in the square lattice. At zero temperature, this lattice exhibits a continuous transition between the square phase and a phase composed of rhombic cells as the nonlinear potential connecting next-nearest-neighbors vary. At nonzero-temperature, diverging vibrational entropy associated with the floppy modes play a very important role in selecting the phase and determining the order of the transition. We calculate the phase diagram of this system and identify interesting behaviors such as negative thermal expansion.

Session U30 DCMP: Glassy Materials: Colloids, Traffic, Disordered Crystals, Etc. 338 - Peter Schall, University of Amsterdam

11:15AM U30.00001 Criticality in dynamic arrest: Correspondence between glasses and traffic , DANIEL MIEDEMA, ASTRID DE WIJN, BERNARD NIENHUIS, PETER SCHALL, University of Amsterdam — Dynamic arrest is a general phenomenon across a wide range of dynamic systems including glasses, traffic flow, and dynamics in cells, but the universality of dynamic arrest phenomena remains unclear. We connect the emergence of traffic jams in traffic flow to the dynamic slow down in glasses. A direct correspondence is established by identifying a simple traffic model as a kinetically constrained model. In kinetically constrained models, the formation of glass becomes a (singular) phase transition in the zero temperature limit. Similarly, using the Nagel-Schreckenberg model to simulate traffic flow, we show that the emergence of jammed traffic acquires the signature of a sharp transition in the deterministic limit, corresponding to overcautious driving. We identify a true dynamical critical point marking the onset of coexistence between free flowing and jammed traffic, and demonstrate its analogy to the kinetically constrained glass models.

11:27AM U30.00002 Glass-like dynamics of a structural colloidal crystal in a disordered potential landscape[1] , KEVIN APTOWICZ, West Chester University of Pennsylvania, TIM STILL, MATTHEW GRATALE, YE XU, ARJUN YODH, University of Pennsylvania — Disordered solids exhibit a boson peak at low frequencies, where many more modes appear than is expected for sound modes behavior. The origin of the boson peak remains unclear, although two explanations have risen to the forefront: (i) the boson peak is composed of quasi-localized modes arising from peculiarities of the interatomic forces in amorphous materials and (ii) the boson peak is the amorphous equivalent of the Van Hove singularity in crystalline systems. We experimentally explore these two possible explanations by studying a quasi-two-dimensional colloidal structural crystal residing in a disordered potential landscape. The potential landscape is generated by non-uniform heating of the sample. Thermophoretic effects lead to a heterogeneous force distribution that is tunable with temperature. With this experimental geometry, we explore the evolution of the density of vibrational states as a function of the strength of the disorder potential landscape.

[1]This work is funded by DMR-1206231 (K.B.A.), PENN-MRSEC DMR11-20901 (A.G.Y.), NASA NNX08AO0G (A.G.Y.), and DMR12-05463 (A.G.Y.).

11:39AM U30.00003 Correlations Between Structure, Vibrational Modes and Collective Motion in Dense Attractive 2D Colloidal Packings[1]

, MATTHEW LOHR, TIM STILL, University of Pennsylvania, Department of Physics and Astronomy, KEVIN APTOWICZ, West Chester University, Department of Physics, YE XU, MATTHEW GRATALE, ARJUN YODH, University of Pennsylvania, Department of Physics and Astronomy — In this work, we investigate the microscopic dynamics of quasi-2D dense attractive colloidal systems. We confine bidisperse polystyrene spheres between glass coverslips in a suspension of water and 2,6-lutidine; as we increase the temperature of the sample into a critical regime, lutidine wets the colloids, creating a strong attractive interaction (>4kT). We specifically study suspensions in the "dense gel" regime, i.e., at a volume fraction high enough that the attractive particles form a spanning cluster, yet just low enough that there exists some structural heterogeneity larger than the individual particle size. We track the particle locations via bright-field video microscopy and analyze the dynamics of both lower-volume-fraction gel states and higher-volume-fraction glassy states. Despite similarities in local structure, we find several consistent differences in the dynamic and vibrational properties of these two extreme systems. Specifically, we observe a drastic change of the presence of low-frequency modes between the two states. These modes appear to be coupled to collective motion of large groups of particles. By investigating the correlation between these collective motions and local packing structures, we gain further insight into the origins of dynamic heterogeneity in disordered systems.

[1]This work is supported by funding from NSF grant DMR12-05463 and PENN MRSEC grant DMR11-20901.

11:51AM U30.00004 Resolving structural modifications of colloidal glasses by combining x-ray scattering and rheology

, DMITRY DENISOV, TRIET DANG, University of Amsterdam, The Netherlands, BERND STRUTH, Deutsches Elektronen-Synchrotron, Hamburg, Germany, GERARD WEGDAM, PETER SCHALL, University of Amsterdam, The Netherlands — Glasses have liquid-like structure, but exhibit solid-like properties. A central question concerns the relation between the structure and mechanical properties of glasses, but structural changes remain difficult to resolve. We use a novel combination of rheology and x-ray scattering to resolve structural changes in colloidal glasses and link them directly to their mechanical behavior. By combining stress and structure factor measurements, we resolve shear induced changes in the nearest neighbor configuration as a function of applied stress, allowing us to elucidate the structural origin of the genuine shear banding transition of glasses. Our results reveal a coupling between structural parameters and the applied shear that underlies this instability: the non-monotonic behavior of the flow curve is directly mirrored in simple structural measures such as the position, the width, and the height of the nearest neighbor peak of the structure factor. Besides small changes in the nearest neighbor distances, our results underscore the importance of anisotropy in the structure of out of-equilibrium systems, in agreement with structure analysis of jammed and unjammed granular packings.

12:03PM U30.00005 Free energy transition of sheared colloidal glasses

, MINH TRIET DANG, ROJMAN ZARGAR, DANIEL BONN, PETER SCHALL, University of Amsterdam — Glasses have liquid-like structure, but solid-like properties. An important question concerns the relation between the macroscopic flow behavior and the microscopic structure. However, for atomic glasses, microscopic configurations are prohibitively difficult to visualize due to the small molecular length scales. Here, we use a colloidal glass to directly visualize and analyze particle configurations of quiescent and sheared colloidal glasses. We determine the free volumes of the particles, and relate this free volume distribution directly to the free energy of the glass. This allows us to obtain novel insight into the relation between rigidity/flow and changes in the amorphous structure. We identify a clear change in the free energy at the transition from homogenous to inhomogenous flow.

12:15PM U30.00006 Phonon Dispersion and Elastic Properties of Two-Dimensional Soft Particle Colloidal Crystals and Glasses[1]

, TIM STILL, Department of Physics and Astronomy, University of Pennsylvania, Philadelphia PA 19104, USA, KE CHEN, Beijing National Laboratory for Condensed Matter Physics, Chinese Academy of Sciences, China, PETER J. YUNKER, CARL P. GOODRICH, SAMUEL SCHOENHOLZ, ANDREA J. LIU, A.G. YODH, Department of Physics and Astronomy, University of Pennsylvania, Philadelphia PA 19104, USA — We investigate phonon dispersion relations and associated mechanical properties of two-dimensional colloidal glasses and crystals composed of soft, thermoresponsive microgel particles whose temperature-sensitive size facilitates in-situ variation of particle packing fraction. The phonon modes were measured using particle tracking and displacement covariance matrix techniques. Measurements of the hexagonal crystal served to check our methodology and, as expected, the observed phonon dispersion was largely in agreement with theoretical expectations. Measurements of phonon dispersion in the glassy colloids, as a function of packing fraction above the jamming transition, permitted study of the scaling of bulk and shear moduli as a function of packing fraction. We performed numerical simulations and were able to recover the experimental findings. Moreover, the obtained shear moduli are in good agreement with rheological measurements.

[1]We gratefully acknowledge financial support from the NSF through DMR12-05463, the PENN MRSEC DMR11-20901, and NASA NNX08AO0G. T. S. acknowledges financial support from DAAD.

12:27PM U30.00007 Aggregation, Gelation and Glass Transition in Mixed Suspension of Polystyrene Microsphere and Poly(N-isopropyl-acrylamide) Microgel[1]

, GUANGCUI YUAN, CHUANZHUANG ZHAO, CHARLES C. HAN, Institute of Chemistry, Chinese Academy of Science, JOINT LABORATORY OF POLYMER SCIENCE & MATERIALS, ICCAS TEAM — Poly(N-isopropylacrylamide) microgel is adsorbable to the polystyrene microsphere surface. The saturated adsorption concentration of microgel (Φ_{*MG}) is in a linear relationship with the given concentration of microsphere (Φ_{MS}). Depending on the concentration of microgel (Φ_{MG}) added into the suspension microspheres, the microgel can induce bridging ($\Phi_{MG} < \Phi_{*MG}$), stabilizing ($\Phi_{MG} = \Phi_{*MG}$) and depletion ($\Phi_{MG} > \Phi_{*MG}$) effect. With combination of various Φ_{MS} and Φ_{MG}/Φ_{*MG}, different structures including stable solution, bridging and depletion cluster, bridging and depletion gel, attractive glass and repulsive glass, were obtained. The transitions between these states were investigated by rheology and microscopy. Two-step yielding behavior was observed in attractive glass, which was contributed from bridging bonds of microgels and caging effect of dense microspheres.

12:39PM U30.00008 Dynamics of concentrated dicolloid particles[1]

, MARK M. PANCZYK, NORMAN J. WAGNER, ERIC M. FURST, University of Delaware — Nonspherical colloidal particles exhibit a variety of equilibrium structures, including colloidal crystals. However, with increasing concentration, particle dynamics in these suspensions slow, and the creation of equilibrium close-packed structures may be ultimately inhibited by the presence of a glass transition. For dicolloid particles, dimer particles with asymmetric or symmetric lobes, suspension dynamics have been studied using Stokesian dynamics simulations [1] and mode-coupling theory [2], and the glass transitions have been determined using rheology [3]. In this study, the dynamics of polystyrene dicolloids in water are measured by diffusing wave spectroscopy (DWS) at particle concentrations between 1 and 60 volume percent. Relaxation times of the dicolloid particle suspensions are determined as a function of particle concentration and shape. Strong particle localization occurs at the highest concentrations. The localization lengths measured by DWS are compared to their mode coupling theory predictions.

12:51PM U30.00009 On the Absence of Red Structural Color in Colloidal Glasses , SOFIA MAGKIRIADOU, Department of Physics, Harvard University, Cambridge, MA, USA, JIN-GYU PARK, School of Engineering and Applied Sciences, Harvard University, Cambridge, MA, USA, YOUNG-SEOK KIM, Korea Electronics Technology Institute, S.Korea, GI-RA YI, Department of Polymer Science and Engineering, Sungkyunkwan University, Suwon, Gyunggi 440-746, S.Korea, VINOTHAN N. MANOHARAN, School of Engineering and Applied Sciences, Harvard University, Cambridge, MA, USA — When a colloidal glass is illuminated, the short-ranged spatial correlations between neighboring particles can give rise to constructive interference for a particular wavelength. Unlike the structural colors arising from Bragg diffraction in colloidal crystals, the colors of these colloidal glasses are independent of angle due to the disordered, isotropic microstructure. We therefore call them "photonic glasses." A similar coloration mechanism is found in the feathers of certain birds. However, there are few examples of red photonic glasses either in nature or in colloidal systems. Using scattering theory, we show that the absence of red photonic glasses can be explained by the wavelength-dependence of the single-particle scattering cross-section, which can override the interference condition set by the structure. We propose ways to overcome this obstacle, and we report on experimental methods to make non-iridescent, structural red color.

1:03PM U30.00010 Structure/dynamics coupling in suspensions of microgel particles on their approach to the glass , A. FERNANDEZ-NIEVES, J. CLARA-RAHOLA, Georgia Tech, P.N. SEGRE, Oxford College, A.B. SOUTH, L.A. LYON, Georgia Tech — We measure the structure factor, S(q), and the q-dependent diffusion coefficient, D(q), of dense suspensions of pNIPAm microgel particles. We do this at different temperatures, and hence different swelling degrees, at constant generalized volume fraction, and find dramatic changes in behavior. While for certain temperatures, 1/D(q) follows the behavior of S(q), at other temperatures the behavior of these two quantities completely decouples. Interestingly, this behavior correlates with fragility: Structure/dynamics decoupling is observed for suspensions resembling strong glass formation.

1:15PM U30.00011 Evolution of dynamical facilitation approaching the glass transition , RAPHAEL CANDELIER, LJP - UPMC, ASAPH WIDMER-COOPER, School of Chemistry, University of Sydney, DAVID REICHMAN, Columbia University, GIULIO BIROLI, IPhT - CEA, OLIVIER DAUCHOT, EC2M - ESPCI — We investigate the relaxation dynamics of simulated dense bidimensional supercooled liquids composed of softly interacting particles. We show that the long time scale dynamical heterogeneities result from the aggregation of several elementary relaxation events, themselves formed by collective leaps. By varying the temperature, we show that for low temperatures there is a growing excess of probability to find cage jumps that are close both in space and time, and that the network of spatio-temporal facilitation evolves towards a collection of clearly defined large events. We discuss these observations and specifically the relative importance of facilitation when approaching the glass transition.

1:27PM U30.00012 Aging in dense colloids through the growth and breakup of strongly correlated clusters[1] , SKANDA VIVEK, STEFAN BOETTCHER, Physics Dept., Emory University, PAOLO SIBANI, University of Southern Denmark — Colloidal systems exhibit glassy behaviour under the right physical conditions that can be observed through mean square displacements in experiments. Our phenomenological model of aging in colloids is based on the growth and breakup of strongly correlated clusters, which introduces dynamical heterogeneity in the system.[2] Particles move and associate into clusters that can break up with a probability that decreases with cluster size. Different colloidal density regimes correspond to different probabilities. The mean square displacements measured in this system for a low density colloid shows a linear increase in time and shows a linear increase in log-time for high densities, which matches experimental data. The cluster breakup rate was measured to be uniform in time for low densities and $\propto 1/t$ in the aging regime, which provides a clock for the slowing down of the dynamics. Measurements of the four-point susceptibility χ_4 show a peak indicating the response to a growing lengthscale that satisfies a scaling relation with sample age, t_w. For larger t_w, χ_4 peaks higher, and decays more slowly with time, which we hypothesize is due to the dominance of relatively stable large clusters.

1:39PM U30.00013 Pinning Susceptibility at the Jamming Transition[1] , AMY GRAVES, ELLIOT PADGETT, Swarthmore College, CARL GOODRICH, ANDREA LIU, University of Pennsylvania — Jamming in the presence of fixed or pinned obstacles, representing quenched disorder, is a situation of both practical and theoretical interest. We study the jamming of soft, bidisperse discs in which a subset of discs are pinned while the remaining particles equilibrate around them at a given volume fraction. The obstacles provide a supporting structure for the jammed configuration which not only lowers the jamming threshold, ϕ_J, but affects the coordination number and other parameters of interest as the critical point is approached. In the limit of low obstacle density, one can calculate a pinning susceptibility χ_P, analogous to the magnetic susceptibility, with obstacle density playing the role of the magnetic field. The pinning susceptibility is thus expected to diverge in the thermodynamic limit as $\chi_P \propto |\phi - \phi_J|^{-\gamma_P}$. Finite-size scaling calculations allow us to confirm this and calculate the critical exponent, γ_P.

[1]Acknowledgement is made to the Donors of the Petrolium Research Fund administered by the American Chemical Society, Swarthmore College's Eugene M. Lang Faculty Fellowship, NSF grant DMR-1062638 and DOE grant DE-FG02-05ER46199.

1:51PM U30.00014 Probing the depinning transition: contrasting lattice and continuum models , YAN-JIUN CHEN, LASSP, Cornell University, STEFANO ZAPPERI, IENI-CNR, Milano,Italy, and ISI in Torino, Italy, JAMES P. SETHNA, LASSP, Cornell University — Models of depinning are used to study a wide variety of disordered systems where there are interfaces with jerky motion, including magnetic domain wall motion, fluid imbibition, and superconductor vortex lines. Analytic results from field theories are written in continuous time and space coordinates; but efficient algorithms are often done with cellular automata (CA). The equivalence of CA rules with the continuum models were justified by the appearance of a cusp in the disorder correlator after a finite-number of RG steps, especially for avalanche behavior that involve many degrees of freedom. However, in between this abrupt behavior, there exist slower dynamics where the avalanche almost stops, involving fewer degrees of freedom, and these regions may alter the scaling, as seen in recent studies of plastic deformation in crystals and crackling noise in glasses. Also, in our simulations, we find that discretization may introduce unwanted effects or relevant perturbations, such as a broken rotational symmetry. We compare and contrast results of the spatial and temporal structure of depinning from lattice and continuum simulations, and also provide complete functional forms to describe crossovers between different model classes.

2:03PM U30.00015 Dynamical Instabilities of a Brownian Particle in Weak Adhesion. , DEEPAK KUMAR, SHANKAR GHOSH, SHOBO BHATTACHARYA, Tata Institute of Fundamental Research, DEPARTMENT OF CONDENSED MATTER PHYSICS AND MATERIALS SCIENCE TEAM — Dynamical processes involved in weak adhesion are explored through a single cycle of an optically trapped Brownian colloidal silica particle detaching from, and reattaching to, a glass substrate immersed in a fluid in the presence of an externally applied force. Micro-rheology, video-microscopy and Nyquist noise measurements reveal both stochastic and deterministic dynamics of the process. When analyzed in terms of the viscoelastic response of the stress coupling medium between the objects, the unsticking instability shows remarkable similarities with yielding and fracture-mechanics of macro-scale solids. The resticking dynamics demonstrates stochastic instabilities through a spatio-temporally punctuated descent of the particle down an energy landscape with a hierarchy of metastable minima.

Session U31 DMP DPOLY DBIO: Focus Session: Assembly & Function of Biomimetic & Bioinspired Materials III 339 - Shengfeng Cheng, Sandia National Laboratories

11:15AM U31.00001 Multiscale self-assembly of DNA-functionalized nanoparticles and cationic phospholipids[1]

, SUNITA SRIVASTAVA, DMYTRO NYKYPANCHUK, OLEG GANG, Brookhaven National Laboratory — Cationic phospholipids (CLs) when mixed with oppositely charged biomolecules exhibit rich structural diversity including lamellar, inverted hexagonal, honeycomb and rectangular columnar phases. Our study explores how CLs can be used to control the organization of nanoparticles (NP) and their ligands on molecular and nano scales by tuning lipid composition. We utilized a synchrotron-based x-ray scattering to probe in-situ electrostatic assembly of double stranded (ds) DNA-functionalized nanoparticles with cationic phospholipids. The assembly of the DNA-NP and CLs is driven by attraction between negatively charged ds-DNA and positively charged CLs. We investigated the role of DNA length, lipid charge density and charge ratio on structural behavior of the assembly. Interplay of electrostatic interaction and curvature effects results in hierarchical organizations in which DNA-NP and CLs exhibit lamellar and hexagonal phases at different length scales.

11:27AM U31.00002 Revealing Structural Transformations during Crystallization of DNA-Nanoparticle Assemblies

, YUGANG ZHANG, FANG LU, Center for Functional Nanomaterials, Brookhaven National Laboratory, DANIEL VAN DER LELIE, Research Triangle Institute International, Research Triangle Park, NC, OLEG GANG, Center for Functional Nanomaterials, Brookhaven National Laboratory — Nanoparticle assembly via sequence-specific DNA recognition emerges as a powerful strategy for the fabrication of nanoparticle (NP)-based crystalline materials. Generally, a delicate thermal annealing is essential for the crystallization of NPs from kinetically trapped disordered states. Due to the complex coupling between interactions, entropic and chain effects in these systems, the crystallization pathway remains an intricate and open question. Herein, we present an experimental study of the crystallization process for DNA-directed nanoparticle assembly systems using synchrotron-based small angle x-ray scattering (SAXS). We demonstrated the effects of two crystallization-dominant factors, namely, temperature and volume fraction, on the structural transformation and order development. By combining a single component and binary systems we uncovered the evolution of global and local particle arrangements, such as correlation length, compositional disorder and coordination number, during the phase transformation. Research was supported by the U.S. Department of Energy, Office of Basic Energy Sciences, under Contract No. DE-AC02-98CH10886.

11:39AM U31.00003 Modeling Lattice Structures of DNA-Coated Nanoparticles with Tetrahedral Linkers

, JOSHUA NEITZEL, Wesleyan University, Middletown, CT, OLEG GANG, Brookhaven National Laboratory, FRANCIS STARR, Wesleyan University — Much attention has recently focused on using DNA as a linking agent to engineer nanoparticle (NP) lattices with specific geometries. There has been success generating a broad range of crystal symmetries, but the formation of a tetrahedral or diamond lattice has been particularly challenging. We use molecular simulations to examine a combination of NP uniformly coated with DNA that connect via linking units that incorporate tetrahedral structure. We test the stability of spherical NP-DNA complexes with tetrahedral linkers in a 1:1 ratio, which allow for a variety of lattices, including a diamond structure. Previously postulated interpenetrating diamond lattices are also possible.

11:51AM U31.00004 Directed assembly of hierarchical light-harvesting complexes using virus capsid scaffolds and DNA origami tiles

, DEBIN WANG, Lawrence Berkeley National Laboratory, STACY CAPEHART, University of California, Berkeley, SUCHETAN PAL, MINGHUI LIU, Arizona State University, JOLENE LAU, Lawrence Berkeley National Laboratory, HAO YAN, Arizona State University, MATTHEW FRANCIS, University of California, Berkeley, JIM DEYOREO, Lawrence Berkeley National Laboratory, LBNL TEAM, UCB TEAM, ASU TEAM — Directed assembly of nanostructures with molecular precision is of great importance to develop an insightful understanding of assembly pathways and dynamics as well as to derive new functionalities. In this work, we explore the use of virus capsids and DNA origami tiles as 3D scaffolds and 2D templates for directed assembly of light-harvesting molecules and plasmonic gold nanoparticles to achieve tunable photoemission. Bacteriophage MS2 virus capsids with well-defined spherical macromolecular structures are genetically modified to provide predictable steric arrangements of light-harvesting molecules. DNA origami tiles act as programmable planar templates to provide higher-order organization of oligonucleotide-functionalized light-harvesting capsids and plasmonic gold nanoparticles. The direct observation of distance dependent photoluminescence emission is carried out by our correlative approach combining atomic force microscopy and confocal fluorescence microscopy, which is in good agreement with our numerical simulation and theoretical calculation. This work will facilitate the construction of multicomponent biological-metal hybrid plasmonic nanostructures for nanophotonics and biosensing applications.

12:03PM U31.00005 Shape Remodeling Assemblies in Biologically Inspired Materials[1]

, CYRUS SAFINYA, Materials, Physics, and Molecular, Cellular, and Developmental Biology Departments, University of California at Santa Barbara — Much of our research is inspired by, and directed at, understanding the formation of novel structures (both relatively static and highly dynamic) with distinct shapes and morphologies observed in charged biological systems. The structures, in turn, often correlate to specific functions. For example, charged nanoscale tubules and rods and their assemblies are of interest in a range of applications, including as templates for hierarchical nanostructures, encapsulation systems, and biosensors. A series of studies will be described on charged biological assemblies exhibiting "molecularly-triggered" dynamical shape changes. In particular, we will focus on protein and lipid based nanotubule formation through small molecule stimuli-induced shape remodeling events. The systems include invertible protein nanotubes from two-state tubulin-protein building blocks and lipid nanotubes and nanorods from curvature stabilizing lipids (mimicking membrane curvature generating proteins).

[1]Funded by DOE-BES grant number DOE-DE-FG02-06ER46314 (protein and lipid assembly, lipid synthesis, structure-function) and NSF-DMR-1101900 (phase behavior).

12:39PM U31.00006 Visualizing DNA Nanoparticle Motion under Graphene Liquid Cell TEM

, QIAN CHEN, Department of Chemistry and Miller Institute for Basic Research in Science, University of California, Berkeley, JESSICA SMITH, JUNGWON PARK, SOMIN LEE, Department of Chemistry, University of California, Berkeley, ALEX ZETTL, Department of Physics, University of California, Berkeley, PAUL ALIVISATOS, Department of Chemistry, University of California, Berkeley; Materials Sciences Division, Lawrence Berkeley National Laboratory — We think of a simple colloidal nanocrystal as one type of artificial atoms. They mutually interact, cluster into artificial molecules, and further arrange into macroscopically functional artificial solids. The "atomic" resolution dynamics of this bottom-up strategy in materials design is studied here in a system of artificial molecules composed of DNA and nanoparticle. The observation of dynamics in their liquid environment is recently enabled by graphene liquid cell transmission electron microscopy (TEM). In comparison to conventional TEM, wherein the assembled 3D artificial structures are dried out during sample preparation and thus are collapsed, this graphene liquid cell introduces a special local liquid structure that retains the conformations as well as the dynamics of the assemblies. In situ imaging of correlated motions of DNA and nanoparticle provides insights into the design principles of artificial nanocrystal molecules and solids linked by DNA.

12:51PM U31.00007 Controlling Assembly and Crystallization of S-layers on Diblock Copolymer Patterns , ILJA GUNKEL, Lawrence Berkeley National Laboratory, MAGALÍ LINGENFELDER, BART STEL, École polytechnique fédérale de Lausanne (EPFL), Lausanne, Switzerland, XIAODAN GU, THOMAS RUSSELL, University of Massachusetts at Amherst, JAMES DEYOREO, Lawrence Berkeley National Laboratory — Block copolymers (BCPs) self-assemble into arrays of nanoscopic morphologies, including lamellar, cylindrical, and spherical microdomains, that serve as ideal templates for the fabrication of nanostructured materials. The size of the microdomains is a function of the polymer size so tuning the copolymer's molecular weight allows for a precise control over the dimension of the BCP morphologies. Moreover, the heterogeneous chemical nature of BCPs allows them to be used as templates for well-defined protein adsorption. Here, we used nanoscopic BCP patterns as templates to study the assembly of S-layer proteins SbpA from Lysinibacillus sphaericus (ATCC 4525) by in-situ Atomic Force Microscopy (AFM). The templates were formed by polystyrene-b-poly(ethylene oxide) BCPs of various molecular weights after spin coating on solid surfaces and subsequent controlled solvent-vapor annealing. Our results show that by controlling the chemical contrast in templates of different geometry and periodicity, protein assemblies could be directed exclusively to the hydrophobic domains of the template. More importantly, our high-resolution AFM measurements indicate that the proteins crystallized in their native lattice while following the structure of the underlying template by preferential adsorption.

1:03PM U31.00008 Structural control in model microtubule self-assembly[1] , SHENGFENG CHENG, MARK STEVENS, Sandia National Laboratories — Being able to control the structure formed in self-assembly is the goal of many nanoscience studies. Here we explore various ways to control the structure of self-assembled tubules. We have previously developed a model wedge-shaped monomer that can self-assemble into tubule structures. We now add chirality and a lock-and-key mechanism to the model to enhance structural control of the self-assembly. Previously, we found that helical tubes are frequently formed despite the fact that chiral symmetry is not present in the monomer. We now identify the physical origin of helicity as the large overlap in the energy distributions between nonhelical and helical tubes. The helical tubes typically undergo a twist deformation that lowers the energy substantially. We find that a modification of the location of binding sites on the bottom and top surfaces of the wedge into a lock-and-key configuration leads to a better control of the helicity and twist deformation of the assembled tubes. Better control occurs when the interaction strength between the vertical binding sites is stronger than that between the lateral ones. We can also control the pitch of the helicity by adjusting the location of binding sites on the lateral surfaces of the monomer. Our results shed new light on the structure of in vitro microtubules formed with various numbers of protofilaments of tubulins, which also exhibit twisted structures when the number is different from 13.

[1]Supported by DOE BES Award KC0203010

1:15PM U31.00009 Self-folding polyhedra and analogies to biomolecular assembly , SHIVENDRA PANDEY, Department of Chemical and Biomolecular Engineering, Johns Hopkins University, Baltimore, MD 21218, GOVIND MENON, Division of Applied Mathematics, Brown University, Providence, RI 02906, DAVID GRACIAS, Department of Chemical and Biomolecular Engineering, Johns Hopkins University, Baltimore, MD 21218 — We detail model studies aimed at uncovering design principles that govern the self-assembly of polyhedral structures from two-dimensional precursors using surface tension forces. For a given polyhedron, there are a very large number of two-dimensional precursor nets that can be utilized, and remarkably many of these will self-assemble but with varying yields. We uncovered design rules that suggest striking analogies to biomolecular assembly such as observed in proteins and viruses. For example our studies revealed that the compactness of two-dimensional nets determines the yield of self-folding polyhedra and that certain intermediates and pathways were preferred. Consequently, a search algorithm was implemented to screen the large numbers of nets (e.g. 2.3 million for the truncated octahedron) and find high-yielding precursors. This assembly process represents a model system that can be utilized to design and then visualize self-assembly processes. The model system, design rules and findings will be discussed. References: S. Pandey, M. Ewing, A. Kunas, N. Nguyen, D. H. Gracias and G. Menon, Algorithmic design of self-folding polyhedra, *PNAS* 108, 50, 19885-19890 (2011).

1:27PM U31.00010 Functional quantum dot-protein nano bio-assembly for superior light harvesting applications , EVREN MUTLUGUN, URARTU OZGUR SAFAK SEKER[1], PEDRO LUDWIG HERNANDEZ- MARTINEZ, Nanyang Technological University and Bilkent University, VIJAY KUMAR SHARMA, Bilkent University, VLADIMIR LESNYAK, NIKOLAI GAPONIK, ALEXANDER EYCHMÜLLER, Technical University of Dresden, HILMI VOLKAN DEMIR, Nanyang Technological University and Bilkent University — The formation of functional bio-assemblies is crucial for the advanced biophotonic applications. In this work, we formed a nano bio-assembly, consisting of green fluorescent protein (GFP) and inorganic quantum dots (QDs), to employ as an excitonic biofunctional composite to use for light harvesting and biosensing applications. Using QDs as donor molecules with the acceptor GFP in the formed bio-assembly, we observed up-to 15-fold enhancement on the GFP emission, mediated by the strong nonradiative energy transfer. The lifetime modifications of the donor-acceptor pair were studied as a function of the number of proteins per quantum dot, and in good agreement with the proposed theoretical model based on the excitonic interaction among the species. Apart from the light harvesting system, a biosensing medium was also established, facilitated by the enzymatic activity destructing the light harvesting complex. The energy transferring QD-GFP complex was controllably modified by the addition of trypsin, by destroying the bond in between the QD-GFP complex, as verified by the observation of lifetime modifications. In summary, we developed functional excitonic nano-bio-assemblies, which we believe will open up new possibilities for advanced biophotonic applications.

1:39PM U31.00011 Controlling size and patchiness of soft nanoparticles via kinetically arrested co-assembly of block copolymers , JOSE SANTOS, MARGARITA HERRERA-ALONSO, Department of Materials Science and Engineering, Johns Hopkins University — Engineering patchy particles from block copolymers provides an effective route for the preparation of nanoparticles with surface heterogeneity and unique properties. In the current work, co-assembly of block copolymers amphiphiles with distinct macromolecular architectures under kinetically arrested conditions was used to control the size and patchiness of polymeric nanoparticles. The block copolymer mixture is composed of linear and linear-dendritic polymeric amphiphiles, the later of which provides pre-assembled "patches" with well-controlled dimensions and chemical functionality. Parameters including but not limited to the molecular diffusity of the amphiphiles and the kinetics of self-assembly were found to play an important role on the control of the particle size and formation of the patches. The patchy particles are stable for several months and its stability against protein/blood plasma solutions can be tuned. We will also discuss the use of these constructs to probe nanoparticle-cell interactions.

1:51PM U31.00012 Structural color of butterflies: The case of Papilio butterflies[1] , BEOM-JIN YOON, JUNG OK PARK, MOHAN SRINIVASARAO, School of Materials Science and Engineering, Georgia Institute of Technology, Atlanta, GA — The term "structural color" is often used to describe color produced by a material possessing periodic variations in refractive index, which is commonly observed in many species of butterflies. Papilio butterflies commonly have multilayered bowl structures on their wing scales but the resulting colorations are different each other. Papilio ulysses has blue colored wing and Papilio palinurus shows green coloration on its wing, while Papilio blumei has green coloration on the wing scales but display a blue colored tail. We investigated the structures of the scale on the wings of Papilio butterflies using focused ion beam milling and analyzed the structural origin of the structural color from each Papilio butterfly. The coloration mechanism was attributed to the combination of the multilayer reflection from different feature size coupled with additive color mixing.

Session U32 DPOLY: Charged Polymers and Ionic Liquids 340 - Mu Ping Nieh, University of Connecticut

11:15AM U32.00001 An Optimized Solvation Theory for Charged Macromolecules Immersed in Aqueous Electrolyte Solutions , ZAVEN OVANESYAN, BHARAT MEDASANI, MARCELO MARUCHO, University of Texas at San Antonio, MONICA OLVERA DE LA CRUZ GROUP AT NORTHWESTERN UNIVERSITY COLLABORATION — In this talk, we introduce an accurate solvation model based on integral equation theory to study highly interacting charged systems. This approach is able to account for strong ion screening effects on charged macromolecules where conventional approaches may be inappropriate. A detailed knowledge of the structural arrangement of ions and solvent molecules in the vicinity of macromolecules is of crucial importance to get a microscopic understanding of these polyelectrolyte systems. We present the results obtained for ion-sphere density profiles, integrated charge and mean-electrostatic potential. These calculations are generated at low computational cost without losing important structural features of these strongly interacting charged systems. The results predict charge inversion and are in good agreement with Monte Carlo simulations.

11:27AM U32.00002 Effect of Ion Content on Conductivity and Morphology of Single-Ion Conducting Ionomers , JING-HAN HELEN WANG, Department of Chemical Engineering, The Pennsylvania State University, RALPH H. COLBY, Department of Materials Science and Engineering, The Pennsylvania State University — Ionomers based on short poly(ethylene oxide) side chains and sodium sulfonated styrene are synthesized by reversible addition fragmentation chain transfer (RAFT) polymerization, to systematically study the effect of ion content and counterion species on ionic conductivity. Glass transition temperature increases gradually as ions are incorporated at low ion content then sharply as the ion content reaches 1:4 ions to ether oxygen (EO) ratio. Dielectric relaxation spectroscopy is used to measure the conductivity, dielectric constant and segmental relaxations in these ionomers. The ionomer with 1:80 ions to EO ratio shows highest room temperature conductivity that results from the best combination of number density of simultaneously conducting ions and their mobility, assessed by an electrode polarization model. The micro-phase separation that is anticipated in the ionomers with higher ion contents is probed by x-ray scattering. Sodium counterions are mostly trapped in ionic aggregates while larger counterions, such as tetramethylammonium, exhibit higher conductivity and conducting ion concentration.

11:39AM U32.00003 Charge regulation and local dielectric function in planar polyelectrolyte brushes , RAJEEV KUMAR, National Center for Computational Sciences, Oak Ridge National Laboratory, Oak Ridge, TN-37831, BOBBY SUMPTER, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, Oak Ridge, TN-37831, S. MICHAEL KILBEY II, Department of Chemistry, University of Tennessee, Knoxville, TN-37996 & Center for Nanophase Materials Sciences, Oak Ridge National Laboratory — Understanding the effect of inhomogeneity on the charge regulation and dielectric properties, and how it depends on the conformational characteristics of the macromolecules is a long-standing problem. In order to address this problem, we have developed a field-theory (J. Chem. Phys. 136, 234901 (2012)) to study charge regulation and local dielectric function in planar polyelectrolyte brushes. The theory is used to study a polyacid brush in equilibrium with a bulk solution containing monovalent salt ions, solvent molecules, and pH controlling acid. In particular, we focus on the effects of the concentration of added salt and pH of the bulk in determining the local charge and dielectric function. Our theoretical investigations reveal that the dipole moment of the ion-pairs formed as a result of counterion adsorption on the chain backbones play a key role in affecting the local dielectric function. Furthermore, an increase in the bulk salt concentration is shown to increase the local charge inside the brush region.

11:51AM U32.00004 Resolving the Difference in Electric Potential within a Charged Macromolecule[1] , SHUANGJIANG LUO, JINGFA YANG, JIANG ZHAO, Institute of Chemistry, Chinese Academy of Sciences — The difference of the electric potential between the middle and end of polystyrene sulfonate (PSS-) chain is discovered experimentally. Using a pH-responsive fluorophore attached to these two locations on the PSS- chain, the local pH value was determined by single molecule fluorescence technique: photon counting histogram (PCH). By the observation of a very high accumulation of proton (2-3 orders of magnitude in concentration) at the vicinity of the PSS- as the result of the electrostatic attraction between the charged chain and protons, the electric potential of the PSS- chain is determined. A higher extent of counterion adsorption is discovered at the middle of the PSS- chain than the chain end. The entropy effect of the counterion adsorption is also discovered - upon the dilution of protons, previously adsorbed counterions are detached from the chain.

[1]Project supported by National Natural Science Foundation of China (NSFC)

12:03PM U32.00005 Effects of the dielectric inhomogeneity in polyelectrolyte solution , ISSEI NAKAMURA, ZHEN-GANG WANG, Division of Chemistry and Chemical Engineering, California Institute of Technology — We study the effects of dielectric inhomogeneity on the statistical properties of polyelectrolyte in solution, developing a new lattice Monte Carlo method based on the bond fluctuation model with a local algorithm for computing the electrostatic interactions. Our theory accounts for the difference in the dielectric properties between the polymer backbone and the solvent. Taking the coil-globule transition of a single polyelectrolyte in solvent as an example, we show that the chain conformation and the degree of counterion condensation are substantially affected by the electrostatic response of the polymer backbone.

12:15PM U32.00006 Polyelectrolyte solutions in solvents of extremely high dielectric constant , THOMAS SEERY, University of Connecticut, SERGEY FILLIPOV, JIRI PANEK, PETER CERNOCH, PETR STEPANEK, Institute of Macromolecular Chemistry, Academy of Sciences of the Czech Republic — The physics of polyelectrolyte solutions are of great importance in understanding various processes in nature but they pose a challenge due to their complex behavior. For strong electrolytes discussed here the fraction of the condensed counterions depends on the charge density of polyion, i.e., 1-1/zλ where z is the valence of the counterions, and λ is the reduced coupling constant defined by .$\lambda = l_B/a$Here a is the distance between ions on the polyion and l_B is the Bjerrum length $l_B = \frac{e^2}{4\pi\varepsilon_0\varepsilon kT}$ where e is the elementary charge, ε the dielectric constant of the solvent, k the Boltzmann constant and T absolute temperature. The Bjerrum length is the distance between charged species (counterions, co-ions or charged monomers) when the electrostatic energy between them is equal to the thermal energy kT. We exploit the strong temperature dependence of dielectric constant of N-methylformamide to vary the Bjerrum length in a solution of polyelectrolytes (sodium polystyrene sulfonate) and to thus investigate the dynamic properties of salt-free solutions over a broad temperature range, from +54 to –58^{o}C. Fast and slow diffusion processes are observed. The ratio of diffusion coefficients, D_s/D_f , increases and the ratio of amplitudes A_s/A_f decreases, both by a factor of about two in this temperature range corresponding to the expected temperature variation of the Bjerrum length.

12:27PM U32.00007 Highly-correlated charges in polyelectrolyte gels , CHARLES SING, JOHANNES ZWANIKKEN, MONICA OLVERA DE LA CRUZ, Northwestern University — Polyelectrolyte gels are ubiquitous in polymer physics due to their attractive combination of structural and chemical features that permit the realization of "environmentally responsive" systems. The conventional conceptual picture of the volume response of these systems is based on a competition between osmotic and elastic effects. We elaborate on this fundamental understanding by including ion correlations through the use of liquid-state integral equation theory. This allows for a statistical mechanical representation of the state of the system that not only surpasses traditional Poisson-Boltzmann theories but also renders structural features in a highly accurate fashion. In particular, the local ion structure is elucidated, allowing for detailed articulation of charge inversion and condensation effects in the context of gel swelling. The inclusion of correlations has a number of ramifications that become apparent, with enhanced gel collapse and excluded volume competitions that give rise to novel and ion-dependent reentrant swelling effects. We expect this rigorous theory to prove instructive in understanding any number of gelated structures, such as chromosomes or designed synthetic materials for drug delivery.

12:39PM U32.00008 Ionic Association States in Polyester Copolymer Ionomers , HANQING MASSER, SHICHEN DOU, RALPH COLBY, PAUL PAINTER, JAMES RUNT, Penn State University — A series of random copolyester ionomers were previously synthesized from poly(ethylene oxide) (PEO600) and poly(tetramethylene oxide) (PTMO650) oligomers, separated by the lithium or sodium salt of a sulfonated phthalate. PEO exhibits better solvating ability, while PTMO based ionomers have somewhat lower T_g. By changing the ratio of PEO/PTMO, the polymer's ability to solvate ions at the same ion content was varied, in order to explore the trade-off between ion solvation and lower T_g. Ionomers with different PEO/PTMO ratios were investigated by FTIR spectroscopy. The results show a systematic change in the ion association states and ion aggregation geometries with PEO/PTMO ratio and temperature. Ionomers with sodium cations have more ion pairs compared to the Lithium ionomers at the same PEO/PTMO ratio, which correspond to the higher dielectric constants in the sodium ionomers. These findings agree with previous X-ray scattering and dielectric relaxation spectroscopy results that the system microphase separates into PEO-rich and a PTMO-rich microphases and the majority of the cations reside in the PEO-rich microphase.

12:51PM U32.00009 Controlling self-assembly and transport properties of ionomer thin films , MIGUEL MODESTINO, RACHEL SEGALMAN, University of California, Berkeley and Lawrence Berkeley National Laboratory — Electrochemically active materials, such as ionomer composites, allow for both ionic and electrical conduction. Commonly, these materials involve inorganic electrocatalytic particles surrounded by ionomer thin films. This work presents insights in the effects of confinement and wetting interactions in the self-assembly and transport properties of perflourosulfonic acid ionomers thin films. Using in situ grazing-incidence X-ray scattering (GISAXS), we demonstrate that interfacial interactions and thin-film confinement can significantly affect phase separation, domain orientation and dynamics of ionomer films during water uptake. Thin-films casted on hydrophobic substrates result in parallel orientation of ionomer domains, while films prepared on SiO_2 surfaces result in isotropic orientation of these domains. These morphological characteristics, translate directly into effects on their macroscopic swelling behavior, where parallel orientation of ionomer domains limits the maximum water uptake of films. Furthermore, confinement to thickness below 10 nm hinders microphase separation of the material and results in high levels water uptake.

1:03PM U32.00010 Effect of Morphology on Ion Transport in Polymerized Ionic Liquid Block Copolymers , JAE-HONG CHOI, Department of Materials Science and Engineering, University of Pennsylvania, YUESHENG YE, YOSSEF ELABD, Department of Chemical and Biological Engineering, Drexel University, KAREN WINEY, Department of Materials Science and Engineering, University of Pennsylvania — We investigate the impact of morphology on ion transport in single-ion conductor polymerized ionic liquid (PIL) diblock copolymers. The morphology for two types of PIL block copolymers with different degrees of miscibility between blocks was studied using small angle X-ray scattering (SAXS) and transmission electron microscopy (TEM). For poly(methyl methacrylate-b-1-[(2-methacryloyloxy)ethyl]-3-butylimidazolium-bis(trifluoromethylsulfonyl)imide) (MMA-b-MEBIm-TFSI) PIL diblock copolymers, the partial miscibility between the MEBIm-TFSI and MMA blocks resulted in a weakly microphase-separated morphology without long-range order. In poly(styrene-b-1-[(2-acryloyloxy)ethyl]-3-butylimidazolium-TFSI) (S-b-AEBIm-TFSI) PIL block copolymers, a variety of self-assembled nanostructures including hexagonally packed cylinders, lamellae, and coexisting lamellae and network morphologies were observed by varying PIL composition. A comparison of ionic conductivity between PMMA- and PS-based PIL block copolymers suggests that strong microphase separation with well-defined structures can improve ionic conductivity. The local ion concentration and connectivity of the conducting microdomains also play an important role in ion conduction in these PIL block copolymers.

1:15PM U32.00011 Diffusion of polyelectrolyte chains within layer-by-layer films: a combined FRAP and neutron reflectometry study , VIKTAR SELIN, LI XU, Stevens Institute of Technology, Department of Chemistry, Chemical Biology and Biomedical Engineering, Hoboken, New Jersey 07030, JOHN F. ANKNER, Spallation Neutron Source, Oak Ridge National Laboratory, Oak Ridge, Tennessee 37831, USA, SVETLANA A. SUKHISHVILI, Stevens Institute of Technology, Department of Chemistry, Chemical Biology and Biomedical Engineering, Hoboken, New Jersey 07030 — We report a comparative study of the diffusion of polyelectrolyte chains of various types and various molecular weights within polyelectrolyte layer-by-layer (LbL) films. To that end, we used a combination of fluorescence recovery after photobleaching (FRAP) and neutron reflectometry (NR) to probe chain diffusion in directions parallel and perpendicular to the substrate, respectively. LbL films were assembled using poly(methacrylic acid) (PMAA) as a polyanion and poly-2-(dimethylamino)ethyl methacrylate (PDMA) or quaternized PDMA (QPDMA) as a polycation. Fluorescently labeled and/or deuterated PMAA chains were incorporated within films as marker layers in FRAP and NR experiments, respectively. We found that in solutions of 0.2-0.6 M NaCl, chain diffusion was enhanced, with significantly faster chain motion in the direction parallel to the substrate. We will also discuss the effects of pH, salt concentration and polyelectrolyte type and molecular weight on mobility of polyelectrolyte chains within LbL films.

1:27PM U32.00012 Origins of Symmetry in Polymer Ionic Liquid Phase Diagrams[1] , JANE LIPSON, RONALD WHITE, Dartmouth College — Recent experimental work [Lee et al. *Macromolecules* **45**, 3627 (2012)] reveals rather symmetric looking coexistence curves for poly(ethylene oxide) in [EMIM][BF_4]. This is in marked contrast to solutions involving non-ionic solvents, which show a characteristic and strong asymmetry, correlated with the molecular weight disparity between the two components. Using our simple theoretical approach we show that the special character of this systems derives from two thermodynamically-based properties. First, we find that the ionic solvent has a considerably stronger cohesive energy densities than non-ionic counterparts. In addition, we propose that aggregation in the ionic liquid has a significant impact on the entropy of mixing, typically a strong driving force for miscibility in polymer solutions. In this talk we explain how each of these features serves to drive the critical composition to the middle of the phase diagram.

1:39PM U32.00013 Ordered and Disordered Polymerized Ionic Liquid Block Copolymers: Morphology and Ionic Conductivity , SHARON WANG, Materials Science and Engineering, University of Pennsylvania, YUESHENG YE, YOSSEF ELABD, Chemical and Biological Engineering, Drexel University, KAREN WINEY, Materials Science and Engineering, University of Pennsylvania — We systematically studied the influence of temperature and relative humidity on morphology and ionic conductivity in polymerized ionic liquid block copolymers (PIL BCP). Poly(methyl methacrylate-*b*-1-[2-(methacryloyloxy)ethyl]-3-butylimidazolium-X^-) block copolymers (X^- = OH^-, Br^-) were characterized by SAXS, dynamical mechanical analysis, and electrochemical impedance spectroscopy. At 25 $^\circ$C, weak microphase separation was observed for the PIL BCP with ϕ_{PIL} = 0.38 and X^- = OH^-. Upon increasing the relative humidity to 90%, this polymer exhibited an order-disorder transition (ODT). The ODT was further studied in the PIL BCPs with X^- = OH^- and 0.11 $<\phi_{\mathrm{PIL}}<$0.38 over a range of temperatures and %RH. In contrast, the PIL BCP with ϕ_{PIL} = 0.38 and X^- = Br^- formed strongly microphase separated lamellae at all investigated T and %RH. At elevated temperature and 90 %RH, ionic conductivities of 30 and 6 mS/cm were observed for ϕ_{PIL} = 0.38 and X^- = OH^- and Br^-, respectively, surpassing the conductivities of the corresponding PIL homopolymer. By selecting the counterion and relative humidity, we significantly impact the morphology and ionic conductivity of these PIL block copolymers.

1:51PM U32.00014 Morphology, Modulus, and Ionic Conductivity of a Triblock Terpolymer/Ionic Liquid Electrolyte Membrane , LUCAS D. MCINTOSH, TIMOTHY P. LODGE, University of Minnesota — A key challenge in designing solid polymer electrolytes is increasing bulk mechanical properties such as stiffness, without sacrificing ionic conductivity. Previous work has focused on diblock copolymers, where one block is a stiff, glassy insulator and the other is a flexible ion conductor. Disadvantages of these systems include difficulty in achieving network morphologies, which minimize dead-ends for ion transport, and the necessity to operate below both the T_g of the glassy block and the order-disorder temperature. We have investigated the triblock terpolymer poly[isoprene-*b*-(styrene-*co*-norbornenylethyl styrene)-*b*-ethylene oxide] because it self-assembles into a triply-continuous network structure. SAXS and TEM revealed the bulk morphology of INSO to be disordered but strongly correlated after solvent casting from dichloromethane. This apparent disordered network structure was retained after chemical crosslinking and addition of the ionic liquid 1-ethyl-3-methylimidazolium bis(trifluoromethylsulfonyl)amide. Impedance spectroscopy confirmed the expected conductivity for ions confined to continuous PEO channels. The mechanical response before and after crosslinking showed an increase in the material modulus.

2:03PM U32.00015 Decoupling of charge transport from structural dynamics in protic ionic liquids , JOSHUA SANGORO, Oak Ridge National Laboratory, ALEXEI SOKOLOV, Oak Ridge National Laboratory and University of Tennessee, FRIEDRICH KREMER, University of Leipzig, MARIAN PALUCH, University of Silesia — Broadband dielectric spectroscopy, differential scanning calorimetry and rheology are employed to investigate charge transport and dynamics in protic and aprotic ionic liquids. While the structural α-relaxation rates and the characteristic charge diffusion rates coincide for aprotic ionic liquids, the latter is found to be more than 100 times for the protic ionic liquids studied. Moreover, the analysis of protic ionic liquids revealed a decoupling of temperature dependence of ionic transport from that of structural relaxation with the degree of decoupling increasing with fragility of the liquid. The potential technological impact of these results will be discussed.

Session U33 DMP: Focus Session: Organic Electronics and Photonics - Organic Photovoltaics I - Theory and Processing 341 - Michael Chabinyc, University of California at Santa Barbara

11:15AM U33.00001 David Adler Lectureship Award in the Field of Materials Physics Lecture , JEAN-LUC BREDAS, Georgia Institute of Technology — We first review the current state-of-the-art in the field of organic electronics and then focus on organic solar cells, which we define as solid-state cells in which the semiconducting materials between the electrodes are organic, be them polymers, oligomers, or small molecules. We describe the optical and electronic processes that take place in such cells and turn our attention briefly to: (i) optical absorption and exciton formation; (ii) exciton migration to the electron donor – electron acceptor interface; (iii) exciton dissociation into charge carriers, resulting in the appearance of holes in the donor component and electrons in the acceptor component; (iv) charge carrier mobility; and (v) charge collection at the electrodes [1-3]. In the second part of the presentation, we underline the complexity of the processes taking place at the nanoscale at the donor/acceptor interfaces and highlight the molecular understanding that comes from a computational approach combining electronic-structure theory calculations, molecular mechanics / molecular dynamics simulations, and Monte Carlo simulations [4-6].

11:51AM U33.00002 An ab initio approach to organic photovoltaics , VINCENT GOSSELIN, NICOLAS BÉRUBÉ, JOSIANE GAUDREAU, MICHEL CÔTÉ, Univ of Montreal — Within the recent years, we have witnessed continual improvements in the Power Conversion Efficiencies (PCE) of organic photovoltaic devices. These improvements have been achieved by the discovery of new polymers which are being syntesised and their performance assessed experimentally. Scharber has introduced a simple model which determines the desired properties of polymers in order to achieve high PCE. An appealing alternative to the lengthy process of polymer synthesis consists in using ab initio calculations in order to predict the electronic structure of polymer candidates and evaluate the relevant properties in the determination of their PCE. In this work, Density Functional Theory (DFT) is being used to compute the optical band gap and HOMO / LUMO levels which, in conjunction with Scharber's model, allows to predict the efficiency of various polymer - fullerene blends. In order to assess the quality of such calculations and the validity of the model, we first compare the predictions with experimental device performances. We find that the model offers an indication as to what one should expect in terms of the maximum efficiency attainable experimentally. Lastly, we present new unsynthesised polymers which have shown promising results within this framework.

12:03PM U33.00003 First principles modeling of donor materials for organic solar cells: where theory complements experiment , ANDRIY ZHUGAYEVYCH, SERGEI TRETIAK, Los Alamos National Laboratory, GUILLERMO BAZAN, University of California, Santa Barbara — We discuss the predictive power and accuracy of first principles modeling of small-molecule crystalline donors for organic solar cells. First of all, in order to understand where the theory can help us in improving the performance of photovoltaic devices, we clarify what factors constituting power conversion efficiency needed to be improved. We argue these are short circuit current and fill factor, rather than bandgap and open circuit voltage. This implies that the optimization of intramolecular properties (e.g. HOMO/LUMO), which is best suitable for theoretical search, will not give the anticipated gain in efficiency. The intermolecular properties are amenable to first principles modeling on a single-crystallite scale and we discuss some challenges in this avenue. As an example of how theory can provide design rules for architecturing small-molecule crystals we analyze the dependence of charge carrier mobility on the intermolecular geometry of a pi-stack. In the other case study we show that changes in device performance due to small changes in chemical composition can be well tracked by the theory. Finally, we analyze the performance of commonly used density functionals for typical molecular systems used in organic electronics (oligomers, polymers, dimers, crystals).

12:15PM U33.00004 A Dynamic Monte Carlo Model with an Improved Charge Injection Mechanism for the Photocurrent Generation of Organic Solar Cells , DYLAN KIPP, VENKAT GANESAN, The University of Texas at Austin — Previous dynamic Monte Carlo studies have made great strides in connecting organic solar cell device microstructure to final properties. One challenge still remaining is to capture the full illuminated and dark current-voltage curves and their dependencies on the charge injection mechanism. By modifying the injection mechanism of previous algorithms, we have developed an improved model for the simulation of photocurrent generation in organic solar cells. We include and utilize an injection rate prefactor to control the portion of dark current attributed to each of 4 kinds of charge injection. By shifting the dark current between electrode-polymer pairs, the injection timescales are aligned even when modeling ohmic contacts. Using our model, we are able to generate charge density and potential profiles that better agree with theory and better reproduce experimental results as compared to previous dynamic Monte Carlo methods. We are able to demonstrate how charge accumulation and band bending effects the shape and placement of the various current-voltage regimes. Finally, we are able to demonstrate how various parameters influence the current-voltage characteristics.

12:27PM U33.00005 Computational materials design for bulk heterojunction solar cells , XI LIN, YONGWOO SHIN, Boston University — The adapted Su-Schrieffer-Heeger Hamiltonian is further developed in this work to predict the optical bandgaps of more than 200 different π-conjugated systems. Insights on the structure-property relationship of these π-conjugated systems lead to guiding rules for new photovoltaic materials design. A copolymer of parallel and perpendicular benzodithiophenes, differing only in sulfur atom locations, is proposed as a candidate to achieve the optimal 1.2 eV donor optical gap for organic photovoltaics. The charge transfer mechanisms and the exciton and charge carrier mobilities are computed and compared for various bulk-heterojunction structures to improve the overall power convention efficiency.

12:39PM U33.00006 New way of polymer design for organic solar cells using the quinoid structure , NICOLAS BERUBE, JOSIANE GAUDREAU, MICHEL COTE, Universite de Montreal — Research in organic photovoltaic applications are receiving a great interest as they offer an environmentally clean and low-cost solution to the world's rising energy needs. Controlling the device's active polymer optical bandgap is an important step that affects its absorption of the solar spectrum, and ultimately, its power conversion efficiency. The use of fused heterocycles that favors the polymer's quinoid structure has been a known method to lower the bandgap, for example, with isothianapthene, but there is a lack of quantifiable data on this effect. Density functional theory (DFT) calculations were done on over 60 polymers with bandgaps between 0.5 eV and 4 eV. They clearly show that low bandgaps are observed in copolymers that carefully stands between their quinoid and aromatic structures. Such balance can be obtained by mixing monomer units with quinoid characteristics with aromatic ones. Time-dependant DFT results also links low bandgaps with lower reorganization energy, which means that polymers with this structural form could possess higher charge mobilities. This link between the geometrical structure and the bandgap is compatible with a vast variety of polymers and is more convincing than the commonly used donor-acceptor method of polymer design.

12:51PM U33.00007 Morphology-property insights into high-performance organic photovoltaics[1] , SETH DARLING, Argonne National Laboratory — Organic solar cells have attracted increasing attention as potential low-cost alternatives to traditional inorganic photovoltaic (PV) technologies. Additional advantages of OPVs include the use of earth-abundant materials, mechanical flexibility, light weight, rapid energy payback time, and the option for tunable coloring for aesthetic architectural installation. Key to their low-cost is solution-based high-throughput processing. Power conversion efficiency (PCE) of organic photovoltaics (OPVs) has steadily improved, with PTB series polymers exhibiting some of the highest PCEs. Using a suite of advanced characterization techniques, it is possible to decipher the morphology of OPV active layers across length scales from the molecular to the mesoscopic. Correlating these structural features with optoelectronic function leads to morphology-performance relationship insights, which in turn can be utilized as the foundation for a rational design of improved performance in OPV devices. Initial results from this methodology are encouraging, suggesting a viable alternative to the traditional Edisonian approach to device performance improvement.

1:27PM U33.00008 The impact of miscibility on organic solar cell performance and stability , BRIAN A. COLLINS, Noth Carolina State University and National Institute of Standards and Technology, JOHN R. TUMBLESTON, North Carolina State University, JON A. BARTELT, MICHAEL D. MCGEHEE, Stanford University, CHRISTOPHER R. MCNEILL, Monash University, HARALD ADE, North Carolina State University — The recent demonstration of molecular miscibility/solubility between polymers and fullerenes [1] has revealed a much more complex picture of nanostructure, charge dynamics, and device stability – aspects that are all entangled. Here we show that miscibility is important in several ways that depends on the particular material blend. For example, recent absolute measurements on domain size and composition [2] have revealed nanostructure in PTB7:$PC_{71}BM$ blends that is controlled by miscibility and that well-mixed regions likely hinder charge separation in this system. On the other hand, PBDTTPD:$PC_{61}BM$ blends rely on high levels of mixing for electron percolation [3]. Such evidence leads to a complex interplay between charge separation, electron trapping, and percolation. Miscibility, a thermodynamic parameter, can, furthermore, determine the thermal stability of device active layers, which we show varies widely between materials systems. This suggests tailoring of the molecular interactions between donor and acceptor materials in solar cells may be the key to high-performing, highly stable and, therefore, economically viable organic electronics technologies. Energy Materials DOI: 10.1002/aenm.201200637

1:39PM U33.00009 An Alternative Processing Strategy for Polymer-Fullerene Organic Photovoltaic Devices Using Supercritical Carbon Dioxide , JOJO AMONOO, Applied Physics, University of Michigan, EMMANOUIL GLYNOS, Material Science and Engineering, University of Michigan, CHELSEA CHEN, Macromolecular Science and Engineering, University of Michigan, ANTON LI, Material Science and Engineering, University of Michigan, BONG-GI KIM, Macromolecular Science and Engineering, University of Michigan, JINSANG KIM, PETER GREEN, Material Science and Engineering, University of Michigan — Bulk heterojunction thin film polymer solar cells based on poly(3-hexylthiophene) (P3HT)/phenyl-C61-butyric acid methyl ester ($PC_{61}BM$) donor/acceptor blends have received extensive attention in recent years. Well-established processing protocols, such as heating to elevated temperatures, have been employed to obtain optimum three-dimensional nano-scale morphologies critical for enhanced device performance. We show for the first time that supercritical carbon dioxide ($scCO_2$) processing provides a viable alternative strategy to achieve same or better power conversion efficiencies and short circuit currents compared to high temperature thermal annealing. Furthermore, energy-filtered transmission electron microscopy, and electron energy loss spectroscopy studies show that the same nano-scale morphologies are achieved using $scCO_2$, at an optimized temperature and pressure as those achieved using thermal annealing. Photoconductive atomic force microscopy revealed that the higher efficiency devices possessed larger fractions of photoactive regions throughout the active layer.

1:51PM U33.00010 Optimization of low band gap polymer photovoltaics through structure modification[1] , FENG LIU, YU GU, ALEJANDRO BRISENO, THOMAS RUSSELL, University of Massachusettes-Amherst, CHENG WANG, Lawrence Berkeley National Lab — In BHJ-type solar cells, the ability to control and optimize the active layer morphology is a critical issue to improve device efficiency, and this is usually achieved by optimizing the processing conditions, eg. using varied annealing procedures and choosing the right solvent additive. In this work, we shown that device performance of DPP based low band gap polymers should be optimized both in processing and structural optimization approach. Without the use of chemical additive in blended thin film preparation, large size-scaled phase separation, up to several hundred of nanometers exist. This morphology is due to the surface aggregation of phenyl-C71-butyric acid methyl ester (PCBM), which forms large oval structures and then buried by a polymer-PCBM mixture thin film. In this process, the miscibility of polymer matrix plays an important role. While using chemical additive processing method can tune the general morphology to a more fibril network texture, fine-tuning of fibril dimensions and domain size needs delicate chemical structure modification. Through this modification, a 30% device performance enhancement was observed, which mostly came from an enhancement of short circuit current, thus strongly related to the morphological details. Besides conventional morphology characterizations, an initiative effort of understanding the domain interface structure was also carried out by using polarized soft x-ray scattering, in which we observed polymer crystal orientation plays an important role.

2:03PM U33.00011 Relating Organic Solar Cell Fabrication Methods to Internal Electronic Properties Using Impedance Spectroscopy , JAMES BASHAM, The Pennsylvania State University, National Institute of Standards and Technology, DAVID GUNDLACH, National Institute of Standards and Technology, THOMAS JACKSON, The Pennsylvania State University — We report on the use of impedance spectroscopy to quantify the effect of processing on an array of important OPV device metrics. Interestingly, extract modeled mobilities over the range of $2x10^{-3}$ to $1x10^{-2}$ cm^2/Vs by changing the spinning recipe. We find fast carrier relaxation times of $1x10^{-4}$ s for 3% efficiency cells vs $3x10^{-6}$ s for a 1.8% efficiency cell, possibly demonstrating reduced recombination in more efficient devices. Devices made via slowly dried films exhibit repressed recombination compared to quickly dried films. Measurements are taken across a bias range of -1 to 1 volt with illumination intensities spanning .001 to 3 suns, in order to test under conditions which are most relevant to real device operation. Impedance spectra are analyzed through the use of a 5 element compact model based upon the work of Bisquert et al [1,2]. We report an array of device metrics measured via impedance spectroscopy including shunt resistance, effective carrier lifetime, mobility, and capacitance for P3HT:PCBM devices with efficiencies of 3.5% to <1%, fabricated via several common recipes, in an effort to elucidate the varied and complex interplay between processing and device physics, and the overall effect on solar cell efficiency. Session U34 DPOLY: Thin Films, Surfaces and Interfaces I 342 - Mesfin Tsige, The University of Akron

11:15AM U34.00001 Comparison of experimental and computational estimation of non-freezing interfacial molecules[1] , RAHMI OZISIK, NIHAT BAYSAL, DENIZ RENDE, Rensselaer Polytechnic Institute, SAMUEL AMANUEL, Union College — Recently, we have estimated that about 2.14 +/- 0.14 nm of interfacial cyclohexane molecules do not participate in phase transition. This estimation was determined from calorimetric measurements of physically confined cyclohexane in silica nanopores. In agreement with previous work, melting and freezing temperatures of the confined cyclohexane were lower than that of the bulk cyclohexane, and the apparent heat of fusion changed with silica pore size. Correcting for the layers of molecules at the interface that do not participate in the phase transition keeps the heat of fusion independent of the confined size scale. In the current study, we used molecular dynamics simulations to investigate the behavior of the cyclohexane molecules at the interface and compared their behavior to those in the bulk (away from the interface).

11:27AM U34.00002 A molecular view of latex-water interfaces[1] , ZIFENG LI, KRISTEN FICHTHORN, SCOTT MILNER, Department of Chemical Engineering, Pennsylvania State University, FANG YUAN, RONALD LARSON, Department of Chemical Engineering, University of Michigan — Latex paints and coatings are colloidal suspensions, in which amorphous polymer particles are dispersed in an aqueous phase. The polymer-water interface plays a key role in the stability and rheology of the suspension. To obtain a molecular level view of this interface, atomistic simulations were performed for a slab of poly(methyl methacrylate)-poly(butyl acrylate) random copolymer in water, focusing on polymer and water density profiles, the hydrogen bonding of water with polymer carbonyl groups, and surface tension. The carbonyl groups at the interface were found to orient significantly towards water. We also calculated the temperature dependence of the surface tension between the polymer/water and polymer/ vacuum interfaces, including tail corrections for cut-off dispersion interactions, and we predict the contact angle of a water droplet at room temperature.

11:39AM U34.00003 Pathways and Time Scales for Water Movement to a Metal/Polymer Interface[1] , HYUNGJIN LEE, University of Akron, BULENT AKGUN, Center for Neutron Research, National Institute of Standards and Technology, JIM BROWNING, Spallation Neutron Source, ORNL Neutron Science, MARK FOSTER, University of Akron — The movement of water underneath polymer films is important in the process of corrosion of metals protected by polymer coatings. Here the ingress of water to such an interface is studied with Neutron Reflectometry (NR), which allows the measurements to be done in situ. We have shown that water incursion along the interface between an epoxy hybrid coating and aluminum is fast compared to incursion through the face of the coating. With a more highly crosslinked coating, after a small amount of water has entered along the interface, water incursion slows dramatically. When the sample is once again in a dry environment, swelling of the coating caused by water is not fully reversible, but is reduced slowly over a period of a month.

[1]This material is based upon work supported by the Department of Defense.

11:51AM U34.00004 Desorption Kinetics of Water from Poly (methyl methacrylate) Films and other Polymer Films , CAROLINA ILIE, THORIN KANE, Physics Department, SUNY Oswego, ROSS NETUSIL, Chemistry Department, SUNY Oswego, ANASTASIA YORKE, Physics Department, SUNY Oswego — We present herein the water desorption from the dipole oriented poly (methyl methacrylate) PMMA. Water desorption from PMMA presents the "ice species" at 150 K and a bulk peak at about 280 K. We note that the desorption peak temperature does not vary greatly with increasing coverage. The energy of desorption is obtained by employing the Arrhenius and Polany-Wigner equations. The comparison with previous thermal desorption spectra of water from two ferroelectric polymers is also discussed. [1] Dowben, P.A., Rosa, Luis G., Ilie, C.C., Zeitschrift für Physikalische Chemie 222 (2008) 755-778. [2] Ilie, C.C., Rosa, L.G., Poulsen, M., Takacs, J., Integrated Ferroelectrics (2011) 125:1, 98-103.

12:03PM U34.00005 A Molecular Dynamics Simulation Study on the Wetting Behavior of Water on Oxidized and Non-Oxidized atactic Polystyrene Surface[1] , SELEMON BEKELE, MESFIN TSIGE, Department of Polymer Science, The University of Akron, Akron, Ohio — All-Atomistic Molecular dynamics simulations have been carried out to study the wetting of oxidized and non-oxidized atactic polystyrene (aPS) thin films by water droplets. The dependence of the contact angle on droplet size has been studied using spherical and hemispherical water droplets of varying sizes. The effect of oxidation of the aPS surface on the contact angle has been studied as a function of oxygen concentration. Oxidation of the aPs has been achieved by randomly replacing the ortho and/or meta hydrogen on the phenyl rings within 1 nm of the aPS surface by oxygen until the desired concentration of oxygen on the surface is reached. The simulated contact angle is found to decrease monotonically with oxygen concentration consistent with recent experimental results. We will present results on the variation of water contact angle with oxygen concentration on the aPS surface. In addition, the effect of oxidization on the roughness of the polystyrene surface, the ordering of the phenyl rings and the water molecules and the number of hydrogen bonding between water molecules and the polystrene at the interface have been investigated and will be presented.

[1]This work is supported by the NSF (DMR0847580).

12:15PM U34.00006 Wetting of star-shaped macromolecules[1] , EMMANOUIL GLYNOS, BRADLEY FRIEBERG, University of Michigan, GEORGIOS SAKELLARIOU, University of Athens, PETER GREEN, University of Michigan — We show that the equilibrium contact angles and line tensions of macroscopic droplets of star-shaped polystyrene (PS) macromolecules of functionality, f, and degree of polymerization per arm, Narm, on oxidized silicon substrates, may be as much as one and two orders of magnitude, respectively, smaller than their linear analogs, depending on f and Narm. The dewetting characteristics of the linear and star polymers also differ. Thin film of LPS and SPS dewet SiOx substrates due to destabilizing long-range intermolecular forces. However, while macroscopic droplets surrounded by droplets of nanoscale dimensions characterize the late-stage dewetting morphology of the LPS system, the macroscopic droplets of the SPS molecules reside on a stable layer of molecules adsorbed to the substrate. The thickness of the adsorbed layer depends on both f and Narm. We provide evidence that the wetting/dewetting characteristics of the SPS macromolecules are largely determined by the competition between interfacially attractive conformational entropic effects and steric repulsion effects, for molecules of sufficiently large f and small Narm.

12:27PM U34.00007 The Role of Acid-Base Interactions in Controlling Interfacial Segregation in Polymer Blends[1] , HE ZHU, SHISHIR PRASAD, ANISH KURIAN, ILA BADGE, ALI DHINOJWALA, The University of Akron — We have studied segregation of polymethylmethacrylate (PMMA)/polystyrene (PS) blends next to solid surfaces using interface sensitive infrared-visible sum frequency generation (SFG) spectroscopy. We have monitored the SFG spectra as a function of blend compositions and used the shift in the surface hydroxyl peak, due to acid-base interactions, to determine the concentration of PMMA groups next to the sapphire substrate. A quantitative connection between the extent of interfacial segregation and the strength of the acid-base interactions will be discussed.

[1]National Science Foundation

12:39PM U34.00008 Measurement of monolayer viscosity using non-contact microrehology , ALEX LEVINE, ARTHUR EVANS, UCLA, ROIE SHLOMOVITZ, University of Washington, THOMAS BOATWRIGHT, MICHAEL DENNIN, UCI — Microrheological studies of phospholipid monolayers, bilayers, and other surfactant monolayer systems present a particularly useful avenue for studying the flow properties of fragile, complex fluid systems. Unfortunately, in some cases microscopic particle tracking methods disagree with macroscopic flow methods by several orders of magnitude. This "missing modulus" problem has been speculated to originate in the heterogeneity of the monolayer under study, as well as the unknown boundary conditions and uncertainty in particle position intrinsically associated with coupling the tracer bead to the monolayer. In this talk we discuss an alternative method for performing microrheology experiments, where the tracer bead is submerged a known depth beneath the monolayer. Using both theory and experiment, we demonstrate that despite the weaker coupling between the tracer and the monolayer, the well-characterized hydrodynamics between the bulk sub-phase and the surface allows for the calculation of particle response functions and recovery of the "missing modulus" for several model monolayer systems.

12:51PM U34.00009 Evidence of Phase Separation during Vapor Deposition Polymerization , RAN TAO, MITCHELL ANTHAMATTEN, University of Rochester — Initiated chemical vapor deposition (iCVD) is a solventless, free radical technique predominately used to deposit homogeneous films of linear and crosslinked polymers directly from gas phase feeds. We are developing multicomponent iCVD techniques to induce phase separation during film growth. Small molecule porogens and crosslinkers are introduced into the iCVD process during film growth of poly(glycidyl methacrylate). Analogous to well established polymerization induced phase separation (PIPS) processes, porogens, such as dimethyl phthalate, are well mixed at the growing gas-film interface but are immiscible with high molecular weight polymer. Polymerization, crosslinking and PIPS are intended to occur simultaneously on the substrate, resulting in a vitrified microstructure. A series of films were grown by varying deposition rate, porogen type, and reagent flowrates. Deposited films were studied by electron microscopy and spectroscopic techniques. Experiments are compared to Cahn-Hilliard theory predictions that relate the length and time scale of the phase separation to the polymer-porogen interaction energy, the rate of polymerization and the species mobility.

1:03PM U34.00010 Surface phase separation between polythylene oxide of different molecular weight[1] , RUI CHEN, JINGFA YANG, JIANG ZHAO, Institute of Chemistry, Chinese Academy of Sciences — In-plane phase separation of polyelethylene oxide of different molecular weight has been observed. A systematic investigation on a broad range of Mw show that the process is originated from the conformatinal entropy for a polymer confined on a surface (thin film).

1:15PM U34.00011 Understanding diblock copolymer colloidal particle anisotropy , DEBRA AUDUS, SE GYU JANG, DANIEL KROGSTAD, University of California, Santa Barbara, ALEXANDRE CAMERON, Ecole Normale Superieure, SANG-WOO KIM, KRIS DELANEY, University of California, Santa Barbara, SU-MI HUR, University of Chicago, EDWARD KRAMER, CRAIG HAWKER, GLENN FREDRICKSON, University of California, Santa Barbara — Colloidal particles are formed by emulsifying a mixture of PS-*b*-P2VP, nanoparticles and chloroform in water with surfactant and then evaporating the chloroform. With the addition of a sufficient number of nanoparticles, the colloids form prolate ellipsoids with lamellae oriented along the major axis. These colloidal particles are of interest for potential applications such as photonic materials and drug delivery. In order to explain the colloidal particle anisotropy and its dependence on colloidal particle size, a theoretical model that balances internal and external surface tension was developed. Agreement between the model and experimental results suggests that thermodynamic factors control the particle anisotropy.

1:27PM U34.00012 Multiblock copolymer adsorption on a hydrophobic surface: A Monte Carlo simulation study , MAX KOLB, Laboratoire de Chimie, Ecole Normale Supérieure de Lyon, F-69364 Lyon, France, VIRGINIE HUGOUVIEUX, Sciences pour l'Oenologie, INRA, F-34060 Montpellier, France — Dilute solutions of long multiblock copolymers with alternating hydrophilic and hydrophobic segments in contact with a hydrophobic surface have been investigated by Monte Carlo simulation in order to characterize the structure of the adsorption layer. Its properties are determined as a function of the bulk hydrophobicity, the surface hydrophobicity and the monomer concentration. The influence of the copolymer length and its block structure is also investigated. Interesting features appear close to the bulk critical micelle concentration: surface micelles, a secondary surface layer of bulk micelles, depletion effects. Depending on the interaction strengths the surface layer consists of individually adsorbed hydrophobic segments or of surface micelles, at equilibrium with bulk micelles, as found in a previous study of the bulk properties [1]. At higher surface coverage the surface micelles form a regularly spaced layer of hydrophilically connected micellar cores. For sufficiently long copolymers a layer of bulk micelles is hydrophilically attached to the layer of surface micelles.

1:39PM U34.00013 Capillary Levelling of Stepped Polymer Films - A Nanofluidic Probe of the Slip Boundary Condition , OLIVER BAEUMCHEN, JOSHUA D. MCGRAW, Department of Physics & Astronomy and the Brockhouse Institute for Materials Research, McMaster University, Hamilton, ON, Canada, L8S 4M1, THOMAS SALEZ, MICHAEL BENZAQUEN, Laboratoire de Physico-Chimie Theorique, UMR CNRS Gulliver 7083, ESPCI, Paris, France, PAUL FOWLER, Department of Physics & Astronomy and the Brockhouse Institute for Materials Research, McMaster University, Hamilton, ON, Canada, L8S 4M1, ELIE RAPHAEL, Laboratoire de Physico-Chimie Theorique, UMR CNRS Gulliver 7083, ESPCI, Paris, France, KARI DALNOKI-VERESS, Department of Physics & Astronomy and the Brockhouse Institute for Materials Research, McMaster University, Hamilton, ON, Canada, L8S 4M1 — For flows on small length scales, the hydrodynamic boundary condition of a liquid at a solid surface plays an enormous role. In recent years much has been learned about this slip boundary condition from flows that are driven by internal, capillary, forces such as dewetting of thin liquid films. For the case of dewetting, holes in the film grow, driven by exposing the underlying substrate. Here, we present the opposite approach: We show that the capillary levelling of initially curved surfaces, in our case stepped polymer films, is sensitive to the nano-rheological properties of the liquid and the dependence on the slip boundary condition at the buried liquid/substrate interface. A thin film model which includes the slip boundary condition enables us to quantify the boundary condition at the buried interface and the dependence of slip on the molecular weight of the polymers used.

1:51PM U34.00014 Relaxation of non-equilibrium entanglement networks in thin polymer films , PAUL FOWLER, JOSHUA MCGRAW, MELISSA FERRARI, KARI DALNOKI-VERESS, Department of Physics & Astronomy and the Brockhouse Institute for Materials Research, McMaster University, Hamilton, ON, Canada, L8S 4M1 — It is well established that polymer films, prepared by spincoating, inherit non-equilibrium chain conformations which can affect macroscopic film properties. Here we present the results of crazing measurements that elucidate the non-equilibirum chain configurations in spin-cast films. Furthermore, we find that the entanglement network equilibrates on a time scale comparable to one reptation time. In a second set of experiments, we confine polymers to films with thickness comparable to the molecular size. By stacking two such films at room temperature, a glassy bilayer film with a buried entropic interface is created. According to Silberberg's reflection principle, such an interface has an entropic cost associated with the restricted configurations of molecules that cannot cross the mid-plane of the bilayer. In the melt, the interface heals as chains from the two layers mix and entangle with one another. Crazing measurements reveal that it takes less than one bulk reptation time for a bilayer to become indistinguishable from a single film.

2:03PM U34.00015 Ion Dispositions in Polyelectrolyte Multilayer Films[1] , DAVID HOAGLAND, Polymer Sci. & Eng. Dept., Univ. of Massachusetts Amherst, ZHAOHUI SU, XINGJIE ZAN, TIAN WANG, Changchun Institute of Applied Chemistry — Polyelectrolyte multilayers (PEMs) fabricated from sodium chloride-containing solutions of poly(diallyldimethylammonium chloride) (PDDA) and poly(styrene sulfonate) (PSS) were examined by various techniques to determine the dispositions of polyelectrolytes and counterions across the PEM thickness. The key technique was dry film QCM, which quantified incremental mass depositions during PEM assembly. Counterion dispositions depended strongly on salt concentration, and three salt regimes were identified: zero to near zero salt ([NaCl] less than 0.1M), low salt ([NaCl] between 0.1M and 0.75M), and high salt ([NaCl] greater than 0.5M]). The first two are associated with linear PEM growth while the latter is associated with exponential PEM growth. At zero salt, no counterions are present in the PEM bulk (middle), while at low salt, an excess of PDDA charge across the bulk coincides with an excess of counteranions. Differently, at high salt, deposited PSS permeates the PEM bulk, conveying an excess of countercations. At all salt concentrations, the PEM surface charge alternates according to the capping polyelectrolyte's identity. Accumulations of small ions in the bulk can be ascribed to as yet poorly understood property asymmetries between the two deposited polyelectrolytes.

Session U35 DMP: Focus Session: Search for New Superconductors III

343 - Jochen Mannhart, Max-Planck Institute for Solid State Physics, Stuttgart, Germany

11:15AM U35.00001 Designing heterostructures – a route towards new superconductors[1] , THILO KOPP, University of Augsburg, Center for Electronic Correlations and Magnetism — By now it has become technologically feasible to grow controllably transition metal oxides layer by layer. In effect, the achieved progress allows to design heterostructures with optimized electronic properties. The talk will specifically address scenarios for interface superconductivity and the possibility to raise the transition temperature of bulk superconductors by layer design. Heterostructures offer a complexity beyond that of bulk materials. The nature of the superconducting states formed in layered materials and at interfaces is a fascinating topic of recent research which will be in the focus of this presentation.

11:51AM U35.00002 Reversible Superconductivity in Electrochromic Indium-Tin Oxide Films , ALI ALIEV, Alan G. MacDiarmid NanoTech Institute, University of Texas at Dallas, Richardson, TX, 75083, MIRON SALAMON, Department of Physics, University of Texas at Dallas, Richardson, TX, 75083 — Transparent conductive indium tin oxide (ITO) thin films, electrochemically intercalated with sodium or other cations, show tunable superconducting transitions with a maximum T_c at 5 K. The transition temperature and the density of states, $D(E_F)$ (extracted from the measured Pauli susceptibility χ^P) exhibit the same dome shaped behavior as a function of electron density. Optimally intercalated samples have an upper critical field $\approx$ 4 T and $\Delta/k_B T_c \approx 2.0$. Accompanying the development of superconductivity, the films show a reversible electrochromic change from transparent to colored and are partially transparent (orange) at the peak of the superconducting dome. This reversible intercalation of alkali and alkali earth ions into thin ITO films opens new opportunities for tunable, optically transparent superconductors.

12:03PM U35.00003 Molecule/Surface Interactions and the Control of Electronic Structure In Epitaxial Charge Transfer Salts[1]

GEOFFREY ROJAS, P. GANESH, SIMON KELLY, BOBBY SUMPTER, Oak Ridge National Laboratory, JOHN SCHLUETER, Argonne National Laboratory, PETRO MAKSYMOVYCH, Oak Ridge National Laboratory, CENTER FOR NANOPHASE MATERIALS AND SCIENCES TEAM, CHEMISTRY AND MATERIALS SCIENCE DIVISION TEAM — The two-dimensionality of the fulvalene-based superconducting charge transfer salts has lead to an increasing interest in the epitaxial growth and local probe analysis of monolayer CTS films. Curiously, these studies have shown remarkable differences in both the electronic structure and topography of the monolayers grown on metals, suggesting that the organic/metal interactions introduced by epitaxial growth strongly influence the resulting structures. Through recent experiments on monolayer films of the CTS $(ET)_2SF_5CH_2CF_2SO_3$ and the bare fulvalene ET grown on Ag(111), we illustrate what effect the metal-molecule interaction has on the electronic structure and 2D charge transport of epitaxial CTS and how this differs from the bare fulvalene. Through a comparative analysis of the differences in stoichiometry and topography of these and heretofore published systems, the relative roles of ionic bonding, surface chemisorption, and hybridization for the preparation of this and future compounds are explored.

12:15PM U35.00004 Search for Very High-T_c Superconductivity in Modified Compositions of Strontium Ruthenates[1]

ARMEN GULIAN, VAHAN NIKOGHOSYAN, Advanced Physics Laboratory, Chapman University — In 2004-2007 we discovered unusual properties in laser-processed crystals of strontium ruthenates (including resistive and magnetic transitions) pointing towards superconductivity at 200K and higher [1]. Being interested in understanding and reproducing their properties we explored their composition further. We obtained, via Auger-analysis, the presence of sulfur in the explored sample. The appearance of iron-based superconductors further enhanced our interest, since compositionally our materials turned out to be close to some of these new materials. If our reported observations [1] have been caused by superconductivity that may mean that one can get T_c as high as 200-250K or even higher with these materials at proper processing. We undertook systematic research of ceramic materials Sr_2RuO_4 with sulfur and other dopants. Data on resistive, magnetic and other physical properties, as well as preparation techniques are reported. [1] A.M. Gulian, V.R. Nikoghosyan, Unusual properties of laser-processed strontium ruthenates, in: T. Frias, V. Maestas (Eds.), Bulk Materials: Research, Technology and Applications, Nova Science Publishers, Inc., NY, 2010, Ch. 9 (see also arXiv: cond-mat/0509313 and cond-mat/0705.0641).

12:27PM U35.00005 Structural instability and superconductivity in (Ir,Pt)Te2: an optical spectroscopic study

A.F. FANG, G. XU, T. DONG, P. ZHENG, N.L. WANG, Beijing National Laboratory for Condensed Matter Physics, Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China — $Ir_{1-x}Pt_xTe_2$ is an interesting system showing competing phenomenon between structural instability and superconductivity. Due to the large atomic numbers of Ir and Te, the spin-orbital coupling is expected to be strong in the system which may lead to nonconventional superconductivity. We grew single crystal samples of this system and investigated their electronic properties. In particular, we performed optical spectroscopic measurements, in combination with density function calculations, on the undoped compound $IrTe_2$ in an effort to elucidate the origin of the structural phase transition at 280 K. The measurement revealed a dramatic reconstruction of band structure and a significant reduction of conducting carriers below the phase transition. We elaborate that the transition is not driven by the density wave type instability but caused by the crystal field effect which further splits/separates the energy levels of Te (p_x, p_y) and Te p_z bands.

12:39PM U35.00006 Superconductivity in electron-doped LnOBiS$_2$ Compounds[1]

DUYGU YAZICI, KEVIN HUANG, BEN WHITE, SOOYOUNG JANG, ALAN CHANG, AARON FRIEDMAN, BRIAN MAPLE, University of California, San Diego — We present observations of superconductivity in electron-doped LnOBiS$_2$ compounds (Ln = La, Ce, Pr, Nd, Yb). Polycrystalline samples were synthesized by a two step solid-state reaction and characterized by x-ray diffraction. The parent compounds, LnOBiS$_2$, exhibit a non-metallic ground state. Superconductivity with T_c in the range 1.9 K - 5.4 K was induced by electron doping these compounds via the substitution of F for O. Prior to the onset of superconductivity, the electrical resistivity of the electron-doped LnOBiS$_2$ compounds exhibit semiconductor like behavior, similar to the behavior observed in the parent compounds.

[1]Sample synthesis was funded by the US AFOSR-MURI Initiative Grant FA9550-09-1-0603 and sample characterization and physical properties measurements were supported by the US DOE Grant DE-FG02-04-ER46105.

12:51PM U35.00007 Characterization of superconductivity in electron-doped LnOBiS$_2$ compounds with specific heat measurements[1]

BENJAMIN WHITE, DUYGU YAZICI, KEVIN HUANG, ALAN CHANG, AARON FRIEDMAN, M. BRIAN MAPLE, University of California, San Diego — Superconductivity has been reported recently in $Bi_4O_4S_3$ and electron-doped LnOBiS$_2$ compounds with Ln = La, Ce, Pr, Nd, Yb. These materials share a similar crystal structure composed of superconducting BiS_2 layers, which are separated by oxide blocking layers. Early studies have concentrated primarily on the electrical transport properties and magnetic susceptibility measurements of these systems. We present results from specific heat measurements, which were performed in order to study and characterize the superconducting and normal-state properties of several electron-doped LnOBiS$_2$ systems.

[1]Sample synthesis was supported by the US AFOSR MURI grant FA9550-09-1-0603 and heat capacity measurements were conducted under the auspices of the US DOE grant DE-FG02-04-ER46105.

1:03PM U35.00008 Crystal growth of Pt-doped $IrTe_2$

SUNSENG PYON, Okayama University (present affiliation: The University of Tokyo), KAZUTAKA KUDO, MINORU NOHARA, Okayama University — $IrTe_2$, a layered compound with a triangular iridium lattice, exhibits a structural phase transition at approximately 250 K. Electric resistivity and magnetic susceptibility exhibit anomalies at the transition with hysteresis [1]. Charge-orbital density wave or orbitally induced Peierls effect, a crystal field effect are suggested as candidates of the origin of the transition [2-4]. On the other hand, superconducting phase emerges when the structural phase transition is suppressed by chemical substitution or intercalation [2,5]. Analysis of physical property using single crystal should be helpful to clarifying the relation between the ground states of $IrTe_2$ and superconductivity. Recently, Fang *et al.* reported the growth of single crystal of parent compound [4]. However, single crystal of superconducting sample had not been reported yet. For these reason, we studied superconductivity and the structural transition in platinum doped $IrTe_2$ single crystals. We successfully synthesized several composition of the $Ir_{1-x}Pt_xTe_2$ single crystal by flux method. From magnetization and transport measurement, we confirm the suppression of structural phase transition and emergence of superconductivity. Detail of the experiment will be discussed.

1:15PM U35.00009 Enhanced Upper Critical Fields in a New Quasi-one-dimensional Superconductor $Nb_2Pd_xSe_5$, SEUNGHYUN KHIM, BUMSUNG LEE, KI-YOUNG CHOI, BYUNG-GU JEON, Department of Physics and Astronomy, Seoul National University, Seoul 151-747, Republic of Korea, EUN SANG CHOI, Natioanl High Magnetic Field Laboratory, Florida State University, Tallahassee, Florida 32310, USA, KEE HOON KIM, Department of Physics and Astronomy, Seoul National University, Seoul 151-747, Republic of Korea, CENTER FOR NOVEL STATES OF COMPLEX MATERIALS RESEARCH TEAM, NATIONAL HIGH MAGNETIC FIELD LABORATORY COLLABORATION — We report a discovery of superconductivity with T_c = 5.5 K in $Nb_2Pd_xSe_5$ in which one-dimensional (1D) Nb-Se chains exist along the b-direction and each conducting chain is hybridized to form the conducting *bc** planes. Magnetic susceptibility and heat capacity data in both single- and poly-crystals constitute evidences of bulk superconductivity and BCS-type pairing mechanism. The zero temperature upper critical fields, $H_{c2}(0)$, of a single crystal are found to be 10.5, 35 and 22 T for a', b and c* directions respectively. $H_{c2}(0)$ is clearly much larger than the expected Pauli limiting field $1.84T_c \approx 9$ T along the b and c*-direction. We will discuss the possible explanations of such enhancement of H_{c2} via suppression the Pauli limiting effect, based on the large spin-orbit scattering and the quasi-1D nature of electronic structure in analogy to an organic superconductor $(TMTSF)_2X$ ($X = PF_6$, ClO_4) and a purple bronze $Li_{0.9}Mo_6O_{17}$.

1:27PM U35.00010 Quantum Oscillations and Superconductivity in Subband Quantized $SrTiO_3$ Bilayer Delta-Doped Structures[1] , HISASHI INOUE, GLAM, Stanford University, MINU KIM, Department of Physics and Astronomy, Seoul National University, CHRISTOPHER BELL, YASUYUKI HIKITA, SIMES, SLAC National Accelerator Laboratory, HAROLD HWANG, GLAM, Stanford University & SIMES, SLAC National Accelerator Laboratory — $SrTiO_3$ delta-doped structures show two-dimensional (2D) Shubnikov de-Haas oscillations (SdH) and 2D superconductivity (SC) [1]. Lightly doped systems, with clear SdH signals are ideal to study the link between 2D single electron states and SC [2]. The subbands (SB) should strongly influence SC: their splitting is larger than the superconducting gap. However, the similar spatial extent of the SB in single delta-layers prohibits the detection of SB modulated SC. Growing two delta-layers (DL) in parallel with varying interlayer (IL) thickness d, we can spatially separate the SB and identify their contributions to SC and SdH. For small d, all SB spread over the DL and the IL. For larger d only lower SB are confined around the DL. From the angular-dependence of the main SdH frequency we find a 2D to three-dimensional crossover for $\sim 60 < d <\sim 100$ nm, hence the SdH originate from the upper SB. At the same time the SC layers are found to be decoupled, both showing 2D character with thicknesses comparable to the DL width. This implies that the lower SB contribute more to the SC. These results provide insights into the role of SB in 2D SC. [1] Y. Kozuka *et al.*, *Nature* **462**, 487 (2009). [2] M. Kim *et al.*, *Phys. Rev. Lett.* **107**, 106801 (2011).

1:39PM U35.00011 Search for new phases in the Praseodymium-Silicon system[1] , JOSE DE LA VENTA, ALI C. BASARAN, University of California San Diego, TED GRANT, University of California Irvine, J. GALLARDO-AMORES, Universidad Complutense, J.G. RAMIREZ, University of California San Diego, M.R. SUCHOMEL, Advanced Photon Source, Argonne National Laboratory, M.A. ALARIO-FRANCO, Universidad Complutense, ZACHARY FISK, University of California Irvine, IVAN K. SCHULLER, University of California San Diego — We searched for new superconducting and magnetic phases in the Pr-Si system using high-pressure high-temperature and conventional arc melting syntheses. High pressure synthesis is a unique technique which allows incorporation of elements into compounds which otherwise cannot be synthesized at ambient pressure Both high and low Si concentration areas of the phase diagram were explored. To investigate the high Si concentration compounds, $PrSi_2$ with an excess of Si was subjected to HP-HT synthesis. To explore the high Pr concentration binary compound Pr_5Si_3, we have synthesized undoped Pr_5Si_3 as well as different samples doped with C or B. High resolution X-ray powder diffraction, Magnetic Field Modulated Microwave Spectroscopy and magnetic characterization found that the addition of C gave rise to multiple previously-unknown ferromagnetic phases. Furthermore, X-ray refinement of the undoped samples confirmed the existence of the so far unconfirmed Pr_3Si_2 phase.

[1]Work supported by AFOSR MURI #F49550-09-1-0577 dedicated to Search for New Superconductors for Energy and Power A . Use of the Advanced Photon Source at ANL was supported by the U. S. DoE, Office of Basic Energy Sciences, Contract No. DE-AC02-06CH11357.

1:51PM U35.00012 Superconductivity in Bundles of Double-Wall Carbon Nanotubes[1] , ZHE WANG, WU SHI, The Hong Kong University of Science and Technology, QIUCEN ZHANG, Princeton University, YUAN ZHENG, CHAO IEONG, MINGQUAN HE, ROLF LORTZ, YUAN CAI, NING WANG, TING ZHANG, HAIJING ZHANG, ZIKANG TANG, PING SHENG, The Hong Kong University of Science and Technology, HIROYUKI MURAMATSU, YOONG AHM KIM, MORINOBU ENDO, Shinshu University, PAULO T. ARAUJO, MILDRED S. DRESSELHAUS, Massachusetts Institute of Technology — We will present electrical and thermal specific heat measurements that show superconductivity in double-wall carbon nanotube (DWCNT) bundles. Clear evidence, comprising a resistance drop as a function of temperature, magnetoresistance and differential resistance signature of the supercurrent, suggest an intrinsic superconducting transition below 6.8 K for one particular sample. Additional electrical data not only confirm the existence of superconductivity, but also indicate the Tc distribution that can arise from the diversity in the diameter and chirality of the DWCNTs. A broad superconducting anomaly is observed in the specific heat of a bulk DWCNT sample, which yields a Tc distribution that correlates well with the range of the distribution obtained from the electrical data. As quasi one dimensionality of the DWCNTs dictates the existence of electronic density of state peaks, confirmation of superconductivity in this material system opens the exciting possibility of tuning the Tc through the application of a gate voltage.

2:03PM U35.00013 Microwave absorption across phase transitions[1] , JUAN GABRIEL RAMIREZ, ALI BASARAN, J. DE LA VENTA, JUAN PEREIRO, I.K. SCHULLER, University of California San Diego — Magnetic Field Modulated Microwave Spectroscopy (MFMMS) is a high-sensitivity technique capable of detecting superconducting phases in volumes as small as 10^{-11} cm^3 even in discontinuous samples. This method measures the temperature dependence of the reflected microwave power from a sample in an oscillating magnetic field. The signature of superconductivity appears as a peak in the reflected microwave power at the transition temperature. However, the absorption mechanism is still unclear. We present an exhaustive number of measurements of known superconductors as well as other materials that undergo phase transitions to test different microwave absorption mechanisms. MFMMS measurements in micro-patterned superconducting structures were performed in order to determine the detection limit of the superconducting volume.

Session U36 DCMP: Electron Phonon Superconductivity and Isotope Effect 344 - Roxanna Margine, Binghamton University - SUNY

11:15AM U36.00001 Fermiology and Superconductivity of $LaNiGa_2$[1] , DAVID J. SINGH, Oak Ridge National Laboratory — $LaNiGa_2$ has been identified as a possible centrosymmetric triplet superconductor based on observations of time reversal symmetry breaking in μSR experiments. Here we report calculations of the Fermiology and related properties. In spite of the seemingly layered crystal structure, the Fermi surface has several large sheets and is only moderately anisotropic, so that the material is best described as a three dimensional metal. These include sections that are open in the in-plane direction as well as a section that approaches the zone center. The density of states is high and primarily derived from Ga p states, which hybridize with Ni d states. Comparing with experimental specific heat data, we infer a superconducting $\lambda \leq 0.55$, which implies that this is a weak to intermediate coupling material. Ni occurs in a nominal d^{10} configuration in this material, which places the compound far from magnetism. The implication is that this is most likely a standard electron phonon mediated s-wave superconductor.

[1]Work supported by DOE, BES, Materials Sciences and Engineering Division.

11:27AM U36.00002 Electron-phonon coupling in potassium-doped superconducting picene , MICHELE CASULA, MATTEO CALANDRA, FRANCESCO MAURI, CNRS and Université P. et M. Curie — We explore the properties of electron-phonon couplings in K_3Picene, in the framework of density functional theory (DFT). By exploiting the maximally localized Wannier function formalism, we identify the contribution of the intra- and intermolecular phonon vibrations and the role of local and non-local electronic states in determining the electron-phonon coupling. Despite the molecular nature of the crystal, we find that the purely molecular contributions account for only 20% of the total electron-phonon interaction λ. In particular, the Holstein-like contribution to λ are four times smaller than those computed for an isolated neutral molecule, as they are strongly screened by the metallic bands of the doped crystal. The major contribution (80%) to λ in K_3Picene comes from non-local couplings due to phonon modulated hoppings. We show that the crystal geometry together with the molecular picene structure leads to a strong 1D spatial anisotropy of the non-local couplings. Finally, we propose a lattice model of the electron-phonon couplings in K3Picene that gives 90% of the λ obtained in first principles calculations [1].

11:39AM U36.00003 First-principles study of cobalt pnictide $SrCo_2N_2$, ANDREW O'HARA, ALEXANDER DEMKOV, The University of Texas at Austin — With the recent discovery of high temperature superconductivity in $BaFe_2As_2$, there has been renewed interest in other members of the AT_2X_2 family (A = alkaline earth element or lanthanide, T = transition metal, X = an element of groups IIIB-VIB) and in particle isovalent members of the 122 family. In this work, we describe a hypothetical cobalt pnictide, SrCo2N2, using density functional theory (DFT) in the local density approximation (LDA) with a Hubbard U correction. In this work, we determine both the lattice and chemical stability of $SrCo_2N_2$ as well as explore how the substitutions affect the electronic and magnetic properties in comparison to $BaFe_2As_2$ and 122 rare-earth cobalt phosphides.

11:51AM U36.00004 Dynamical Jahn-Teller effect in Cs_3C_{60} superconductors , LIVIU CHIBOTARU, NAOYA IWAHARA, None — The Cs_3C_{60} shows a superconducting critical temperature of 38K which is one of the highest among phonon-mediated superconductors. Recent infrared spectroscopy data of insulating Cs_3C_{60} apparently support the presence of Jahn-Teller dynamics in this fulleride [1]. To check this possibility, we have performed the DFT calculations of vibronic constants and multiplet splitting parameters, and have calculated from the first principles the spectrum of low-lying vibronic states on C_{60}^{3-} sites by diagonalizing the full vibronic Hamiltonian in a large vibrational basis. The splitting of the t_{1u}^3 shell into degenerate multiplets and their vibronic mixing has been fully taken into account, as well as the effect of the environment on the local vibrations. The results show that in the insulating phase an unhindered dynamical Jahn-Teller effect takes place at each C_{60} site. Using Gutzwiller approach in combination with LDA band structure, we demonstrate that the Jahn-Teller instability also persists in the metallic phase for a wide range of values of intrasite repulsion energy (U).

[1] G. Klupp, P. Matus, K. Kamaras, A.Y. Ganin, A. McLennan, M.J. Rosseinsky, Y. Takabayashi, M.T. McDonald, K. Prassides, *Nat. Comm.* **2012**, *3*, 912.

12:03PM U36.00005 Repulsive interaction helps superconductivity in fullerides , SATOSHI YAMAZAKI, YOSHIO KURAMOTO, Tohoku University — Alkali metal (A) doped fullerides (A_3C_{60}) show not only superconductivity (SC) with high transition temperature Tc up to about 40K, but also antiferromagnetism (AF) with A=Cs. In view of nearby presence of the AF state, the Coulomb repulsion should play a significant role in the SC state. However, various experimental evidences point to a fully symmetric s-wave SC state being realized. In the conventional theory, the s-wave state is unfavorable in the presence of Coulomb repulsion. Then the fundamental question remains why the Tc in fullerides is so high. As a step toward the complete understanding, we study a purely repulsive interaction model with the characteristic band structure derived by degenerate molecular orbitals in fullerides. We calculate SC coupling constants for various symmetries of SC pairs by using the second order perturbation theory We find that even with the repulsive interaction model, the s-wave pair can be formed. With the electron-phonon interaction combined, it is likely that the s-wave pair becomes the most stable. According to our result, we propose that the cooperation between Coulomb repulsion and electron-phonon interaction is responsible for the high Tc.

12:15PM U36.00006 Phonon Vibrations and Superconductivity of a Bi-based Superconductor , JOOSEOP LEE, University of Virginia, MATTHEW STONE, Oak Ridge National Laboratory, TANER YILDRIM, NIST Center for Neutron Research, ASHFIA HUQ, GEORG EHLERS, Oak Ridge National Laboratory, YOSHIKAZU MIZUGUCHI, Tokyo Metropolitan University, SEUNGHUN LEE, University of Virginia, UNIVERSITY OF VIRGINIA TEAM, OAK RIDGE NATIONAL LABORATORY TEAM, NIST CENTER FOR NEUTRON RESEARCH TEAM, TOKYO METROPOLITAN UNIVERSITY TEAM — Elastic and Inelastic neutron scattering experiments have been carried out on polycrystalline samples of the newly discovered layered superconductor LaO0.5F0.5BiS2, and its nonsuperconducting parent compound LaOBiS2 to determine their crystal structures and lattice vibrational modes. The Bragg peaks from the superconducting sample shows large broadening in width in the powder diffraction pattern. For the lattice vibrations, significant difference was observed upon F doping. Using the density functional perturbation theory, we identified all phonon modes, and show the major change in the phonon spectrum comes mainly from the change in the Oxygen mode. Even though strong electron phonon coupling constant was estimated, no significant difference in the phonon spectrum from BiS2 superconducting layer was found above and below Tc.

12:27PM U36.00007 Intercalant dependent electronic structure studies on alkali metal intercalated graphite compounds[1] , WONSHIK KYUNG, YEONGKWAN KIM, GARAM HAN, CHOONSHIK LEEM, CHUL KIM, Yonsei University, Korea, YEONGWOOK KIM, JUNSUNG KIM, Postech, Korea, CHANGYOUNG KIM, Yonsei University, Korea, YONSEI UNIVERSITY TEAM, POSTECH COLLABORATION — We present electronic structure study results on various alkali-metal intercalated graphite compounds (GIC) using angle-resolved photoemission spectroscopy(ARPES). There are two competing theories on where the superconductivity occurs in this material; intercalant metal or charge doped graphene layer. To elucidate this issue, we measured electron doping amount of each alkali-metal intercalated GICs. In addition, there are some mysterious problems that can't be explained with current theories.

[1]Superconducting graphite intercalation compounds studies with ARPES

12:39PM U36.00008 Strong Variation of Density of States and Anomalous Isotope Effect in Low and High Tc Superconductors , GUANG-LIN ZHAO, Southern University and A&M College — In this work, first-principles density functional theory (DFT) calculations of electronic structures are integrated into the fundamental formalism of many-body physics for superconductivity in Zr, Nb_3Sn, and YBa2Cu3O7. It is shown that the electronic structures of the transition metals and compounds such as Zr, Nb_3Sn, and YBa2Cu3O7 are very complex. The electron densities of states around their Fermi levels possess sharp variations that have a large contribution to the anomalous isotope effect in these superconductors. The work was funded in part by NSF LASIGMA Project (Award No. EPS-1003897, NSF92010-15-RII-SUBR), AFOSR (FA9550-09-1-0367), and NSF project CBET-0754821.

12:51PM U36.00009 Charge density wave transport in heterogeneously doped $NbSe_3$ single crystals by masked ion (B^+, Li^+) implantation , KALYAN SASMAL, ASANGA WIJESINGHE, DHARSHANA WIJESUNDERA, Department of Physics and TCSUH, University of Houston, Houston, TX 77204, USA, ZHONGJIA TANG, ARNOLD GULOY, Department of Chemistry and TCSUH, University of Houston, Houston, TX 77204, USA, WEI-KAN CHU, JOHN H. MILLER, Department of Physics and TCSUH, University of Houston, Houston, TX 77204, USA, ION BEAM LAB DEPARTMENT OF PHYSICS,UH COLLABORATION, DEPARTMENT OF CHEMISTRY, UH COLLABORATION — Charge-density wave is competing electron spectrum instability of superconductivity (SC). CDW transport vs. SC with boundary between CDWs and SC are well known examples of correlated transport of macroscopic numbers of electrons.CDW superconductors include layered dichalcogenides, $NbSe_3$. On selective area medium energy ion (B^+, Li^+) implantation was used to create irradiated/unmodified/irradiated CDW heterostructures with well-defined interfaces on single $NbSe_3$ crystal. The effects of impurities go beyond simply increasing CDW pinning (J.P.McCarten.et.al J.Phys.IV France 9,1999).The dV/dI vs. bias at several temperatures, and zero-bias resistance vs. temperature, where two voltage contacts straddle the interface (near the boundary between B^+/ Li^+-implanted and unimplanted regions) are well studied. Injected charge B^+/Li^+ is a non-isoelectronic impurity. The results of ongoing investigations of similar studies of boron- and lithium-doped $NbSe_3$ will be discussed.

1:03PM U36.00010 A Time-Domain Susceptibility Model for a BCS Superconductor in FDTD Calculations[1] , G.L. CARR, XIAOXIANG XI, Photon Sciences, Brookhaven National Laboratory, - COLLABORATION — We have developed a simple time-domain electric susceptibility model for a BCS type superconductor, valid for the spectral range spanning the optical energy gap frequency $\hbar\omega \sim 2\Delta$ and $T \ll T_C$. The expression can be used in Finite Difference Time Domain (FDTD) calculations for propagating electromagnetic waves through systems containing superconductor materials, including meta-materials. Since the energy gap appears explicitly, it can be varied as a function of time to describe non-linear and non-equilibrium effects as observed in microwave experiments. We use the expression in a FDTD calculation for the transmission through and reflection from a thin film of NbN on a substrate, and compare with both conventional frequency domain calculations as well as actual experimental results.

1:15PM U36.00011 Influence of the interplay between de Gennes boundary conditions and cubicity of Ginzburg-Landau equation on the properties of superconductors[1] , OLEG OLENDSKI, King Abdullah Institute for Nanotechnology, King Saud University — Solutions of the Ginzburg-Landau (GL) equation for the film subjected to the de Gennes boundary conditions (BCs) with extrapolation length Λ are analyzed with emphasis on the interaction between Λ and the coefficient β of the cubic GL term and its influence on the temperature T of the strip. Very substantial role is played also by the carrier density n_s. Physical interpretation is based on the n_s-dependent effective potential $V_{eff}(\mathbf{r})$ created by the nonlinear term and its influence on the lowest eigenvalue of the corresponding Schrödinger equation. For the large cubicities, the temperature T becomes Λ independent linearly decreasing function of the growing β since in this limit the BCs can not alter very strong V_{eff}. The temperature increase produced in the linear GL regime by the negative de Gennes distance is wiped out by the growing cubicity. In this case, the decreasing T passes through its bulk value T_c at the unique density $n_s^{(0)}$ only, and the corresponding $\Lambda_{T=T_c}$ is an analytical function of β. For the large cubicities, the concentration $n_s^{(0)}$ transforms into the density of the bulk sample. Other analytical asymptotics are analyzed too.

1:27PM U36.00012 Numerical study of the magnetic and pair binding properties in aromatic hydrocarbon superconductors[1] , ZHONGBING HUANG, Department of Physics, Hubei University, CHAO ZHANG, HAIQING LIN, Beijing Computational Science Research Center — We performed a systematic numerical study of the magnetic and pair binding properties in recently discovered aromatic hydrocarbon superconductors, by using exact diagonalization and quantum Monte Carlo methods. The π-electrons on the carbon atoms of a single molecule are modelled by the one-orbital Hubbard model, which takes into account the energy difference between carbon atoms with and without hydrogen bonds. Our results show that the spin polarized ground state is realized for charged molecules in the physical parameter region. This provides a reasonable explanation of local spins observed in experiments. In alkali-metal-doped picene and phenanthrene, the pairing binding energy is always negative for different electron doping densities, suggesting that electron correlation has no contribution to the formation of Cooper pairs. However, a positive pair binding energy for the charged dibenzopentacene molecule with one or three added electrons indicates that electron correlation may produce an effective attraction between electrons.

Session U37 DMP DCOMP: Focus Session: Fe-based Superconductors: Tunneling Spectroscopy 345/346 - Laura Greene, University of Illinois

11:15AM U37.00001 STM on LiFeAs - Momentum Resolved Superconducting Gap Structure, Electron-Boson Interactions and Charge Susceptibilities in a Prototypical Iron-Based Superconductor , A.W. ROST, Univ. of St Andrews, M.P. ALLAN, Cornell Univ., T.-M. CHUANG, Institute of Physics, Academia Sinica, Taipei, F. MASSEE, K. LEE, M. FISCHER, Y. XIE, Cornell Univ., K. KIHOU, C.-H. LEE, A. IYO, H. EISAKI, AIST, Tsukuba, A.P. MACKENZIE, Univ. of St Andrews, E.-A. KIM, Cornell Univ., D.J. SCALAPINO, Univ. of California, Santa Barbara, J.C. DAVIS, Cornell Univ. — Tunneling spectroscopy on strong coupling superconductors has been one of the key experiments confirming the phonon-mediated mechanism of superconductivity. In the last two decades it has become possible using STM to access this information in real space with atomic resolution. One of the most important aspects of these developments is the ability to extract momentum space resolved information from Fourier-Transform STM measurements. Here we will demonstrate using our recent data on LiFeAs how this technique allows access to a range of fundamental properties of the electronic excitation spectrum. In particular I will show that it is now in principle possible to access momentum space resolved information not only on the superconducting gap structure but also on quantities such as electron-boson interactions and geometric information on 'nesting' vectors giving rise to peaks in the charge susceptibility. The resulting 'fingerprint' of the mechanism driving superconductivity goes well beyond the information obtained in traditional tunneling experiments and has the potential of being a key experimental tool in the study of the mechanism of unconventional superconductors.

11:27AM U37.00002 Tunneling Spectroscopy in Iron Pnictides to Track Orbital Splitting and Spin Density Waves , NACHUM PLONKA, Stanford University, SLAC National Laboratory, Stanford Institute for Materials and Energy Sciences, ALEXANDER KEMPER, Lawrence Berkeley National Laboratory, THOMAS DEVEREAUX, Stanford University, SLAC National Laboratory, Stanford Institute for Materials and Energy Sciences, SIEGFRIED GRASER, ARNO KAMPF, Augsburg University, Augsburg, Germany — In iron-based superconductors, nematicity has been reported in transport measurements and a broad range of spectroscopies, including angle-resolved photoemission, neutron scattering, and scanning tunneling spectroscopy (STS). Several theories have attributed these observed anisotropies of broken tetragonal symmetry to either pure spin physics or unequal occupation of the iron d-electron orbitals, referred to as orbital ordering. We use realistic multi-orbital tight-binding Hamiltonians and T-matrix formalism to explore the effects of non-magnetic impurities in an orbitally split and spin density wave (SDW) state. In each of these, the local density of states around the impurity in both position space and Fourier-transformed quasiparticle interference (QPI) have very specific signatures that may be observable in STS. These allow one to identify and track the evolution of orbital splitting and SDW gaps in regimes that have not previously been explored.

11:39AM U37.00003 Electronic Inhomogeneity and Vortex Disorder in Superconducting $Sr_{0.75}K_{0.25}Fe_2As_2$[1] , CAN-LI SONG, YI YIN, MARTIN ZECH, TESS WILLIAMS, MICHAEL YEE, Department of Physics, Harvard University, Cambridge, MA 02138, USA, GEN-FU CHEN, JIAN-LIN LUO, NAN-LIN WANG, Beijing National Laboratory for Condensed Matter Physics and Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China, ERIC W. HUDSON, Department of Physics, The Pennsylvania State University, University Park, PA 16802, USA, JENNIFER E. HOFFMAN, Department of Physics, Harvard University, Cambridge, MA 02138, USA — We characterize the surface structure, superconducting, and vortex properties in the hole-doped superconductor $Sr_{0.75}K_{0.25}Fe_2As_2$ (underdoped, T_c =32 K) by scanning tunneling microscopy. A 1 × 2 surface reconstruction and inhomogeneous superconducting gap with clear coherence peaks are universally found on the dominant Sr/K-terminated surfaces. Rarer patches of As termination show no reconstruction and no gap. The superconducting gap energy Δ anti-correlates with both the zero bias conductance and coherence peak strength with a characteristic length scale of $\sim$ 3 nm. Isotropic single-quantum vortices with short-range hexagonal order are imaged at 9 T magnetic field. By fitting the vortex-induced subgap density of states, the coherence length $\xi \sim 2.8$ nm is found to be comparable to the length scale of Δ variations. We suggest that the vortices are strongly pinned by nanoscale electronic inhomogeneity arising from K clustering.

[1]This work was supported by the Air Force Office of Scientific Research under grant FA9550-05-1-0371, and the U.S. National Science Foundation under grant DMR-0508812. C. L. S was supported by the Golub Fellowship at Harvard University.

11:51AM U37.00004 Visualizing the microscopic coexistence of spin density wave and superconductivity in underdoped $NaFe_{1-x}Co_xAs$, PENG CAI, XIAODONG ZHOU, WEI RUAN, Tsinghua University, AIFENG WANG, XIANHUI CHEN, University of Science and Technology of China, DUNG-HAI LEE, University of California at Berkeley, YAYU WANG, Tsinghua University — Although the origin of high Tc superconductivity in the iron pnictides is still under debate, it is widely believed that magnetic interactions or fluctuations play an important role in triggering Cooper pairing. Because of the relevance of magnetism to pairing, the question of whether long range spin magnetic order can coexist with superconductivity microscopically has attracted strong interests. The available experimental methods used to answer this question are either bulk probes or local ones without control of probing position, thus the answers range from mutual exclusion to homogeneous coexistence. In this talk we present STM studies of the local electronic structures of an underdoped $NaFe_{1-x}Co_xAs$ near the spin density wave (SDW) and superconducting (SC) phase boundary. Spatially resolved spectroscopy directly reveal both the SDW and SC gap features at the same atomic location, providing compelling evidence for the microscopic coexistence of the two phases. The strengths of the SDW and SC features are shown to anti correlate with each other, indicating the competition of the two orders. The microscopic coexistence clearly indicates that Cooper pairing occurs when portions of the Fermi surface are already gapped by the SDW order. [1]P. Cai, et al., arxiv:1208.3842(2012)

12:03PM U37.00005 Conductance spectra of the Fe111 compounds in the normal and superconducting states , HAMOOD ARHAM, W.K. PARK, L.H. GREENE, University of Illinois at Urbana, D.Y. CHUNG, D. BUGARIS, M.G. KANATZIDIS, Argonne National Laboratory — We use quasiparticle scattering spectroscopy (QPS), also known as point contact spectroscopy, to study Co doped NaFeAs. A conductance enhancement is observed in the normal state of NaFeAs with an onset temperature $\sim$ 95 K. Our previous work on the electron and hole doped Fe122 compounds revealed that a conductance enhancement in the normal state is only observed for those compounds that have an in-plane resistive anisotropy. This enhancement is caused by the non-Fermi liquid behavior of these compounds due to orbital fluctuations. (Arham et al. PRB 85, 214515 (2012); Lee et al. arXiv:1110.5917). Our initial results indicate that the same conditions hold true for the Fe111 compounds as well. QPS is effective in detecting strong electron correlations (hybridization gap, Fano resonance, orbital fluctuations) in the normal state of a variety of strongly correlated electron systems that exhibit the ubiquitous 'domed' phase diagram. The need for some kind of a microscopic theory that explains how QPS detects strong electron correlations will be discussed. This work is supported by the Center for Emergent Superconductivity, an Energy Frontier Research Center funded by the US DOE, Office of Science, Award No. DE-AC0298CH1088.

12:15PM U37.00006 Doping dependence of the gap of cobalt doped $BaFe_2As_2$ from Point Contact Spectroscopy[1] , JOHN TIMMERWILKE, Department of Physics, University of Florida, Gainesville, FL 32611, BRENDAN FAETH, Department of Physics, University of Florida, Gainesville, J.S. KIM, G.R. STEWART, AMLAN BISWAS, Department of Physics, University of Florida, Gainesville, FL 32611 — Point-contact spectroscopy (PCS) is a unique method which has been used for investigating the gap/s of various superconductors including the iron based superconductors. PCS measurements are capable of systematically identifying the size and number of gaps in a superconductor, certain features of various gap symmetries and gap anisotropy. We have performed a-b plane point contact measurements on single crystal $Ba(Fe_{1-x}Co_{x)2}As_2$ samples in the under, optimal, and over-doped cases. Previously we had shown clear evidence of two full gaps in the optimally-doped case. The under and over-doped crystals do not show such definitive evidence of two gaps. The changes in anisotropy and weight of the gaps for these dopings will be presented.

[1]NSF DMR-0804452, DE-FG02-86ER45268

12:27PM U37.00007 Similarities in the Tunneling Spectral Dip in FeAs-based and Cuprate Superconductors , JOHN ZASADZINSKI, LIAM COFFEY, OMID AHMADI, Physics Department, Illinois Institute of Technology, KEN GRAY, DAVID HINKS, Materials Science Division, Argonne National Lab, IIT/ANL COLLABORATION — Recent STS measurements on LiFeAs revealed an above-gap spectral dip feature in the superconducting state that diminished in size with increasing T and disappeared at Tc. We argue that such a feature mimics conventional strong coupling effects and bears a striking resemblance to dip features found in cuprates such as Bi2212. In all cases, the estimated boson energy, Ω, lies within the superconducting gap, 2Δ, suggesting a spin exciton, and is $\sim 5k_BTc$, consistent with the resonance mode found in neutron scattering. The doping dependence of the dip in Bi2212 break junctions is reviewed and it is shown that fits of the tunneling data can be achieved using an Eliashberg formalism. The electron-boson spectral function is dominated by a sharp peak at Ω. These results indicate that the two classes of superconductors have a similar pairing interaction of electrons coupled to a spin fluctuation spectrum renormalized by superconductivity.

12:39PM U37.00008 Temperature-concentration phase diagram and multigap superconductivity revealed by soft point-contact spectroscopy in $(Ca_{1-x}La_x)_{10}(Pt_3As_8)(Fe_2As_2)_5$, NI NI, Los Alamos National Lab, EUNSUNG PARK, Los Alamos National Lab & Department of Physics, Sungkyunkwan University, WARREN E. STRASZHEIM, Department of Physics and Astronomy, Iowa State University, XIN LU, DARRICK J. WILLIAMS, Los Alamos National Lab, MAKARIY A. TANATAR, RUSLAN PROZOROV, Department of Physics and Astronomy, Iowa State University, ERIC D. BAUER, FILIP RONNING, JOE D. THOMPSON, Los Alamos National Lab, ROBERT J. CAVA, Department of Chemistry, Princeton University — Sizable single crystals of the superconducting iron-pnictide system $(Ca_{1-x}La_x)_{10}(Pt_3As_8)(Fe_2As_2)_5$ (x=0 to 0.182) have been grown and characterized by X-ray, microscopic, resistivity, Hall coefficient, susceptibility and specific heat measurements. Features in magnetic susceptibility, specific heat and two kinks in the derivative of the electrical resistivity around 100 K in the x=0 compound support the existence of decoupled structural and magnetic phase transitions. With La doping, the structural/magnetic phase transitions are suppressed and a dome of superconductivity with a maximal T_c up to 23 K is observed in the temperature-concentration phase diagram. Soft point-contact spectroscopy was performed on the optimally doped sample of x=0.145. By fitting the multigap Blonder-Tinkham-Klapwijk(BTK) model to the data, three gaps with Δ_1 =1 meV, Δ_2 =8 meV and Δ_3 =27 meV are revealed. Acknowledgement: Work at Los Alamos was performed under the auspices of the US DOE.

12:51PM U37.00009 Surface investigation of $Ca_{1-x}Pr_xFe_2As_2$ by scanning tunneling microscopy , DENNIS HUANG, ILIJA ZELJKOVIC, CAN-LI SONG, Harvard University, BING LV, CHING-WU CHU, University of Houston, JENNIFER E. HOFFMAN, Harvard University — Rare-earth-doped $CaFe_2As_2$ exhibits small volume-fraction superconductivity up to 49 K of unknown origin [1,2]. We use scanning tunneling microscopy to locally probe possible sources of this phase in $Ca_{1-x}Pr_xFe_2As_2$. We encounter three kinds of surface morphologies and infer their chemical identities with local work function measurements. We also image Pr^{3+} dopants as positive-energy resonances in tunneling conductance and examine their relationship with an observed inhomogeneous spectral gap. [1] B. Lv, L. Denga, M. Goocha, F. Weia, Y. Suna, J. K. Meena, Y.-Y. Xuea, B. Lorenza, and C.-W. Chu, Proc. Nat. Acad. Sci. 108, 15705 (2011). [2] S. R. Saha, N. P. Butch, T. Drye, J. Magill, S. Ziemak, K. Kirshenbaum, P. Y. Zavalij, J. W. Lynn, and J. Paglione, Phys. Rev. B 85, 024525 (2012)

1:03PM U37.00010 Identification of surface terminations of iron pnictides with low-temperature STM/STS , JIHUI WANG, ANG LI, JIHUA MA, ZHENG WU, JIAXIN YIN, BING LV, C.W. CHU, Department of Physics and Texas Center for Superconductivity, University of Houston, A. SEFAT, M. MCGUIRE, B. SALES, Oak Ridge National Laboratory, D. MANDRUS, CHENGLIN ZHANG, PENGCHENG DAI, University of Tennessee, RONGYING JIN, JIANDI ZHANG, E.W. PLUMMER, Department of Physics and Astronomy, Louisiana State University, GENFU CHEN, HONG DING, Institute of Physics, Chinese Academy of Sciences, SHUHENG H. PAN, Department of Physics and Texas Center for Superconductivity, University of Houston, and Institute of Physics, Chinese Academy of Sciences — The alkaline-earth metal iron pnictide superconductor AEFe2As2 (AE=Ca, Sr, Ba) have been studied extensively with modern surface techniques, such as scanning tunneling microscopy/spectroscopy (STM/STS) and Angle Resolved Photoemission Spectroscopy (ARPES). Yet the surface termination upon cleaving is still controversial. Hence, the interpretation of those results of STM/STS and reconcile with results of other surface techniques tend to be challenging. We have performed a systematic low-temperature STM/STS study on a series of (Ca,Na)Fe2As2, (Ba,K)Fe2As2, Ba(Fe,Co)2As2, and BaFe2(As,P)2. We found that, with cryogenic cleaving method, all three crystalline atomic layers can be revealed and identified. We will discuss their identities and their implications.

1:15PM U37.00011 Observation of orbital governed surface selection of superconducting gap in iron Pnictides with low temperature STM/S , JIAXIN YIN, Institute of Physics, Chinese Academy of Sciences, ANG LI, ZHENG WU, JIHUI WANG, JIAN LI, CHIN-SEN TING, Department of Physics and Texas Center for Superconductivity, University of Houston, CHENGLIN ZHANG, PENGCHENG DAI, Physics Department, University of Tennessee, CHANGQING JIN, HONG DING, Institute of Physics, Chinese Academy of Sciences, SHUHENG H. PAN, Institute of Physics, Chinese Academy of Sciences.Department of Physics and Texas Center for Superconductivity, University of Houston — The strong anisotropy of orbitals plays important roles in strongly correlated electron systems. For iron pnictides, due to their layered structure, overlaping of iron 3d with arsenic 4p orbitals is essential in the pairing mechanism. To reveal such physics, Ba(K)Fe2As2 and LiFeAs are the ideal candidates owing to their integrity in the Fe-As layer. We have used low temperature scanning tunneling microscopy/spectroscopy (STM/STS) to investigate the orbital physics in Ba0.6K0.4Fe2As2 and LiFeAs at atomic level. By comparing the STM/S results on these two materials and referring to the results of angle resolved photoemission spectroscopy (ARPES), we found the phenomenon of surface dependent selection of superconducting gaps. We discuss the implications of these observations with the orbital physics in these materials.

1:27PM U37.00012 (1x2) Surface Reconstruction for $Ca(Fe_{1-x}Co_x)_2As_2$: Spin-Charge-Lattice-Coupling[1] , GUORONG LI, Dept. of Physics and Astronomy, Louisiana State University, Baton Rouge, LA 70803, LIANGBO LIANG, Department of Physics, Applied Physics, and Astronomy, Rensselaer Polytechnic Institute, New York 12180, V.B. NASCIMENTO, XIAOBO HE, A.B. KARKI, YIMIN XIONG, Dept. of Physics and Astronomy, Louisiana State University, Baton Rouge, LA 70803, VINCENT MEUNIER, Department of Physics, Applied Physics, and Astronomy, Rensselaer Polytechnic Institute, New York 12180, RONGYING JIN, JIANDI ZHANG, E.W. PLUMMER, Dept. of Physics and Astronomy, Louisiana State University, Baton Rouge, LA 70803 — Low energy electron diffraction (LEED) and density functional theory (DFT) have been utilized to investigate the surface structure for the stripe 1x2 phase of $Ca(Fe_{1-x}Co_x)_2As_2$ iron pnictides, for x = 0 and x = 0.075. Quantitative structural analysis of LEED-I(V) using the fractional spots of the 1x2 phase on both parent and doped samples gives a similar surface structure with a termination layer of half Ca atoms. The surface Ca layer has a large inward relaxation about 0.5 Angstrom and the underneath As-Fe-As layer displays a buckling distortion of about 0.07 Angstrom. DFT calculations show significant charge rearrangements at the surface, which is driven by spin charge coupling, verified by freezing the structure and reducing the magnetic moment to zero. The role of spin-charge coupling in determining the surface reconstruction will be elucidated by self-consistent calculations of the structure as a function of the magnetic moment.

[1]Research is supported by NSF DMR-1002622.

1:39PM U37.00013 Surface structure and electronic properties in $Ca_{10}(Pt_4As_8)(Fe_2As_2)_5$[1] , JISUN KIM, GUORONG LI, AMAR KARKI, JIANDI ZHANG, RONGYING JIN, E.W. PLUMMER, Department of Physics and Astronomy, Louisiana State University, Baton Rouge, LA 70803 — Among Iron-based superconductors, a new family of $Ca_{10}(Pt_nAs_8)(Fe_2As_2)_5$ with n= 3 ("10-3-8") or n=4 ("10-4-8") is unique owing to the existence of Pt_nAs_8 layer. This sets them with different electronic properties than the rest of Iron-based superconductors. By cleaving 10-4-8 single crystals ($T_c \sim 34$ K) in the ultra-high vacuum, we are able to observe three surfaces: Ca layer, FeAs layer, and Pt_4As_8 layer. Scanning tunneling microscope (STM) reveals both the topology and electronic density of individual layers. We discuss the implications of our results with the combination of bulk electronic properties.

[1]NSF DMR-1002622

1:51PM U37.00014 Multi-band model analysis of transport properties of $Ba(FeAs)_2$, HUYNH KHUONG, YOICHI TANABE, TAKAHIRO URATA, SATOSHI HEGURI, Department of Physics, Graduate School of Science, Tohoku University, TAKANORI KIDA, MASAYUKI HAGIWARA, Center for Quantum Science and Technology under Extreme Conditions (KYOKUGEN), Osaka University, KATSUMI TANIGAKI, Department of physics, Graduate school of science & WPI-Advanced Institute for Materials — In iron pnitides, unique energetic band topology and interband antiferromagnetic scatterings are the main sources of rich physics, including multiband superconductivity and Dirac cones quantum states [1, 2]. Despite its importance, the band structure of iron pnictides is not fully understood, especially in terms of transport phenomena. In this meeting, we present that the tranport properties of $Ba(FeAs)_2$, a typical iron pnictide compound, are strongly affected by the shape of Fermi surfaces and the high mobility (μ) in the Dirac cones. From magnetic-field (B) dependencies of the conductivity tensor under $B < 50$ T, we successfully extracted a spectrum of carrier number as a function of μ. Whereas the hole side of the spectra is purely characterized by parabolic hole pockets, the electron side shows interesting effects originating from partly concave Fermi pockets as well as the very high μ (50,000 $cm^2V^{-1}s^{-1}$) of the Dirac carriers. Our observations are also in a good agreement with the first principles band calculations and experimental spectroscopic observations on its Fermi surface [3, 4]. [1] K. Kuroki et al, PRL 101 (2008) [2] Ran et al, PRB 79 (2009) [3] Yin et al, Nat.Phys. 7 (2011) [4] T. Shimojima, PRL 104 (2010)

Thursday, March 21, 2013 11:15AM - 2:15PM –

Session U38 GERA DPOLY DCOMP: Novel Photophysics and Transport in NanoPV II 347 - Richard Wiener, Research Corporaton

11:15AM U38.00001 Hybrid passivated colloidal quantum dot solids for photovoltaics[1] , SUSANNA M. THON, ALEXANDER H. IP, SJOERD HOOGLAND, OLEKSANDR VOZNYY, DAVID ZHITOMIRSKY, RATAN DEBNATH, LARISSA LEVINA, LISA R. ROLLNY, GRAHAM H. CAREY, ARMIN FISCHER, KYLE W. KEMP, ILLAN J. KRAMER, ZHIJUN NING, ANDRÉ J. LABELLE, Department of Electrical and Computer Engineering, University of Toronto, KANG WEI CHOU, ARAM AMASSIAN, Physical Sciences and Engineering Division, King Abdullah University of Science and Technology (KAUST), EDWARD H. SARGENT, Department of Electrical and Computer Engineering, University of Toronto — Colloidal quantum dot (CQD) films are an attractive photovoltaic material due to their large-area-compatible solution processing and bandgap tuning through the quantum size effect. However, the large internal surface areas make CQD films prone to high trap state densities, leading to recombination of charge carriers. We quantify the density of midgap trap states in PbS CQD solids and show that the current photovoltaic performance is limited by these states. We develop a robust hybrid passivation scheme that involves introducing halide anions during the end stages of the synthesis process, which can passivate trap sites that are inaccessible to much larger standard organic ligands, and combine this with an organic crosslinking strategy to form the film. We use our hybrid passivated CQD solid to fabricate a solar cell with a certified efficiency of 7.0%, which is a record for a CQD photovoltaic device.

[1]This work is supported by an award (KUS-11-009-21) from KAUST, by the Ontario Research Fund Research Excellence Program and by the Natural Sciences and Engineering Research Council of Canada.

11:27AM U38.00002 Elimination of deep surface traps in charged colloidal PbS and CdSe quantum dots , OLEKSANDR VOZNYY, SUSANNA THON, ALEX IP, EDWARD SARGENT, University of Toronto — Colloidal quantum dots (CQDs) offer a promising path towards high efficiency, scalable, solution and room processed photovoltaics and electronics. Their promise is curtailed today by difficulty of doping, inefficient transport, nonradiative recombination, and blinking, all generally attributed to electronic trap formation. Using first-principles simulations on off-stoichiometric colloidal quantum dots, we show that preparing a CQD free of traps is possible. However, self-compensating defects can form deep electronic trap states in response to charging or doping even in the most idealized CQDs. Surface traps arise from atomic dimers whose energy levels reside within the bandgap. The same states can also form upon photoexcitation, providing an atomistic mechanism for blinking. We show that avoiding the trap formation upon doping is possible by incorporation of select cations on the surface which shift the dimer energy levels above the quantum-confined bandedge.

11:39AM U38.00003 High pressure core structures of Si nanoparticles for solar energy conversion[1] , S. WIPPERMANN, Dep. of Chemistry, University of California, Davis, M. VOROS, Dep. of Atomic Physics, Budapest University of Technology and Economics, Budapest, D. ROCCA, Dep. of Chemistry, University of California, Davis, A. GALI, Dep. of Atomic Physics, Budapest University of Technology and Economics, Budapest, G. ZIMANYI, Dep. of Physics, University of California, Davis, G. GALLI, Dep. of Chemistry, University of California, Davis — Multiple exciton generation (MEG) in semiconductor nanoparticles (NPs) is a promising path towards surpassing the Shockley-Queisser limit in solar energy conversion efficiency. Recent studies demonstrate MEG to be more efficient in NPs than in the bulk, including Si [1]. However, the increased efficiencyis observed only on a relative energy scale in units of the gap: quantum confinement (QC) effects believed to be responsible for efficient MEG in NPs, also increase their optical gap, swiftly shifting the MEG threshold beyond the solar spectrum. Device applications require NPs with low gaps despite the QC enhanced Coulomb interaction. We propose that Si NPs with a core structure resembling that of high pressure Si phases, especially Si-III/BC8, exhibit significantly lower optical absorption thresholds than Si-I NPs, while retaining efficient MEG. The existence of such NPs was recently demonstrated [2]. Our predictions [3] are based on density functional and many body perturbation theory calculations of the electronic, optical and impact ionization properties of hydrogenated Si NPs with high pressure core structures. 11:51AM U38.00004 Exploring the Influence of the Chemical Passivation on Electron Relaxation in Silicon Quantum Dots Using First-Principles Surface Hopping Methods , YOSUKE KANAI, KYLE REEVES, University of North Carolina at Chapel Hill, ANDRE SCHLEIFE, Lawrence Livermore National Laboratory — The generation of hot carriers in nano-materials is an exciting phenomenon that could potentially increase the efficiency of photovoltaic and photo-electrochemical cells significantly. The electron relaxation dynamics of a system is related to both the electronic and phononic contributions. Given that both of these contributions are ultimately derived from the electronic structure of a system, chemical substitutions may play a significant role in augmenting and controlling the electron relaxation dynamics in nano-materials. With greater insight into the phenomenon from the first-principles theory, engineering new nano-materials with novel opto-electronic properties via a chemical functionalization of its surface becomes a more realistic avenue. A first-principles surface hopping approach based on density functional theory calculations is used to elucidate the relaxation dynamics in silicon quantum-dots. We explore how varying the passivating species on silicon quantum dots influences the electron relaxation dynamics in the system. The two systems considered here are hydrogen-passivated and fluorine-passivated silicon quantum dots. We present a detailed analysis of the electron relaxation dynamics in these nano-materials.

12:03PM U38.00005 Germanium nanoparticles for solar energy conversion[1] , MÁRTON VÖRÖS, Budapest University of Technology and Economics, STEFAN WIPPERMANN, DARIO ROCCA, GIULIA GALLI, University of California - Davis, ADAM GALI, Wigner Research Center for Physics, Hungarian Academy of Sciences, GERGELY ZIMANYI, University of California - Davis — We propose a strategy to enhance the efficiency of solar energy conversion by elemental germanium, by using Multiple Exciton Generation (MEG) in Ge nanoparticles with a ST12 core structure. The latter is the structure of a high pressure phase of solid Ge. MEG is more efficient in bulk Ge in the diamond phase than in several other semiconductors, e.g. Si. In principle it may be further improved at the nanoscale, due to an increased effective Coulomb interaction. However the electronic energy gap of semiconducting nanoparticles may be too large compared to the visible solar spectrum and their density of states (DOS) too low for efficient solar energy conversion. Using ab initio calculations we found that ST12 Ge nanoparticles of $\sim$1-2 nm exhibit high impact ionization rates and thus presumably efficient MEG, as well as a gap of $\sim$2 eV and a sizable DOS in the low energy part of the spectrum. Therefore these nanoparticles appear to be promising materials for solar energy conversion exploiting MEG.

12:15PM U38.00006 Temperature-Dependent Electron Transport in Si and Ge Nanoparticle Photovoltaics , DEREK PADILLA, CARENA CHURCH, University of California, Santa Cruz, ELAYARAJA MUTHUSWAMY, SUSAN KAUZLARICH, University of California, Davis, SUE CARTER, University of California, Santa Cruz — We have studied both Si and Ge nanoparticle-based photovoltaic (PV) devices fabricated in a layered structure via spin-coating of the colloidal Si or Ge solution. With the low toxicity and high abundance of these group IV elements, combined with the relatively low costs of manufacturing via solution deposition, large-scale device processing offers high dollar-per-Watt opportunities as efficiencies continue to improve. To that end, we previously reported temperature effects of solution-processed PbS quantum dot (QD) PVs, wherein the capping ligand's thermal properties were shown to have strong effects on device performance. Here we show similar ligand effects in group IV QD devices. Current-voltage (I-V) measurements at temperatures from 100 to 360 K under dark conditions were fit to the ideal diode equation revealing the electron transport mechanism, with fit parameters matching transport models. The illuminated I-V data provide insight into each device's built-in potential, carrier mobility, and activation energy. In addition, modulating the illumination intensity gives the ideality factors of the solar cells. We show how these variations with temperature and light-intensity can be used to increase device performance for future studies.

12:27PM U38.00007 Carrier Multiplication Effects Between Interacting Nanocrystals for Solar Cell Applications[1] , IVAN MARRI, MARCO GOVONI, STEFANO OSSICINI, University of Modena and Reggio Emilia, Department of Science and Methods for Engineering, via Amendola 2, 42122 Reggio Emilia, Italy — Carrier multiplication is a carrier relaxation process that results in the generation of multiple electron-hole pairs after absorption of a single photon. Such effect can potentially increase power conversion efficiency in solar cells by minimizing effects induced by thermalization loss processes.The possibility of increasing carrier multiplication efficiency by exploiting nanocrystals interplay have been recently demonstrated in both PbSe [2] and Silicon [3] [4] strongly coupled nanocrystals. In this talk we will analyze the role played by nanocrystal-nanocrystal interaction on carrier multiplication dynamics considering a system of interacting silicon nanoparticles. Using first-principles calculations, quantum cutting energy-transfer processes will be quantified and a new carrier multiplication effect, defined by us Coulomb driven Charge Transfer, will be introduced. Conditions that maximize effects induced by nanocrystals interplay on Carrier Multiplication dynamics will be pointed out and the role played by wavefunctions delocalization will be clarified [5].

12:39PM U38.00008 Monte Carlo modeling of charge transport in nanocrystalline PbSe films , IAN CARBONE, University of California, Santa Cruz, GERGELY ZIMANYI, University of California, Davis, SUE CARTER, University of California, Santa Cruz — The electronic properties of three-dimensional nanocrystalline (NC) PbSe materials are of particular interest for next generation solar energy conversion technologies. With size-tunable optical and electronic properties, solution processing, and multiple exciton generation, these materials could represent an exciting new class of cost-effective and efficient solar cells. Two models, a multiple trapping random walk(MTRW) and a hopping model, were developed to simulate electron and hole transport in films of PbSe nanoparticles crosslinked with ethane dithiol ligands. This Monte Carlo code could easily be adapted to model solar cell current-voltage characteristics and variety of experimental conditions and device structures. In both simulations, films are represented by a regular cubic lattice, transport is carried out as a series of hopping events between neighboring nanocrystals, and electrons occupy energetic states determined by the particle size of the PbSe nanocrystals. We find that the hopping model represents a simpler parameter set and a better match to experimental measurements. This presentation will discuss the two transport mechanisms and the effects of particle size, energetic disorder, and coulomb blockade effects on electron and hole mobilities.

12:51PM U38.00009 3D engineering of potential profile by charged quantum dots for effective photovoltaic conversion[1] , ANDREI SERGEEV, NIZAMI VAGIDOV, VLADIMIR MITIN, University at Buffalo, KIMBERLY SABLON, U.S.Army Research Laboratory, Adelphi — Charging of quantum dots (QDs) is an effective tool for managing of potential profile at micro- and nanoscales. Without radiation, QDs are charged as electrons from the dopants fill QDs. Filling of QDs under solar radiation is determined by the condition of equality of electron and hole capture rates. Because of strong difference in effective masses of electrons and holes, an electron level spacing in QDs substantially exceeds a level spacing for holes. Therefore, QDs play a role of deep traps for electrons, but they are just shallow traps for holes. The holes trapped in QDs may be excited by thermal phonons, while excitation of localized electrons requires IR radiation. Therefore, n-doping of QD structures is strongly preferable for photovoltaic applications. Optimized selective n-doping of QD medium provides micro- and nanoscale potential profiles favorable for effective photovoltaic conversion.

1:03PM U38.00010 Toward an Impurity Band PV: Dynamics of Carriers Generated via Sub-band gap Photons , JOSEPH SULLIVAN, CHRISTIE SIMMONS, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA, AUSTIN AKEY, MICHAEL AZIZ, Harvard School of Engineering and Applied Sciences, Cambridge, Massachusetts 02138, USA, TONIO BUONASSISI, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA — Intermediate band solar cells are a pathway to cells that surpass the Shockley-Queisser limit by enabling the utilization of sub-band gap photons. A proposed method for fabricating an intermediate band material is to use impurities that introduce electronic levels within the band gap. At sufficiently high dopant concentrations, band formation may lead to a suppression of Shockley-Reed-Hall recombination, an idea known as "lifetime recovery" [1]. We investigate a proposed intermediate band material, silicon hyper-doped with sulfur. This material system exhibits strong sub-band gap optical absorption and metallic conductivity at sufficiently high sulfur concentrations [2], which makes it a strong candidate for an impurity-band material. We employ low-temperature photoconductivity using sub-band gap light to estimate the trapping rate of electrons in the conduction band. We vary the sulfur concentration near the critical value for the metal-insulator transition to test the idea of "lifetime recovery" in the S:Si system.

1:15PM U38.00011 Intermediate Band Performance of GaSb Type-II Quantum Dots Located in n-Doped Region of GaAs Solar Cells , ARA KECHIANTZ, ANDREI AFANASEV, George Washington University — The intermediate band (IB) electronic states assist sub-bandgap photons in generation of additional photocurrent in single-junction solar cells. Such non-linear effect of resonant two-photon absorption of concentrated sunlight attracts much attention because it promises up to 63% conversion efficiency in IB solar cells. The main obstacle to achieving high performance is involvement of IB-states in electron-hole recombination that is drastically increasing the dark current and reducing the open circuit voltage of IB solar cells. The IB-states can be composed of quantum dots (QDs). Concentration of sunlight limits recombination through type-II QD IB-states located outside of the depletion region. In this work we model GaAs solar cell with strained GaSb type-II QDs separated from the depletion region. The focus is on type-II QDs located in n-doped region of p-n-junction. Our calculation shows that photovoltaic performance can be essentially improved by concentration of sunlight, and that this improvement is highly sensitive to the doping of materials and the shape of potential barriers surrounding type-II QDs. For instance, strained GaSb type-II QDs may increase the performance of GaAs solar cell by 20% compared to the reference GaAs solar cell without QDs.

1:27PM U38.00012 Single Element n-p Co-doped Wide Band-gap Semiconductors as Candidate Materials for Intermediate-Band Solar Cells[1] , GUANGFEN WU, CHUNLEI YANG, GUOHUA ZHONG, Shenzhen Institutes of Advanced Technology,China, XUDONG XIAO, Shenzhen Institutes of Advanced Technology,China and The Chinese Univ. of Hong Kong, Hong Kong, China, ZHENYU ZHANG, University of Science and Technology of China — Non-compensated n-p codoping by different element combinations has proven to be an effective approach to introduce intermediate bands in wide band-gap semiconductors. In this approach, the electrostatic attraction within an n-p dopant pair helps to enhance both the thermodynamic and kinetic solubilities of the dopants. Here we present a conceptually new and appealing approach to achieve non-compensated n-p codoping by substitutionally occupying the anionic and cationic sites in the host materials with a single element. The validity of this approach is demonstrated using first-principles calculations, showing that half filled energy bands are created within the forbidden gaps of the semiconductors because of the non-compensated nature of the codpants. Moreover, the electrostatic attraction between the neighboring dopant pairs enhances their thermodynamic and kinetic solubilities in the host semiconductors. Efforts on experimental confirmation of the single element n-p co-doping concept will also be discussed.

1:39PM U38.00013 Optical conductivity of GaP alloys studied by hybrid-density functional theory , YOSHIHIRO GOHDA, SHINJI TSUNEYUKI, The University of Tokyo — Highly-mismatched semiconductor alloys are promising to produce multiple gaps utilizing wider frequency range of the solar spectrum. Quantitative first-principles calculations of the optical conductivity, which is of importance to access the performance of solar cells, are out of reach for the standard generalized gradient approximation (GGA) in density functional theory (DFT) due to well-known underestimation of the band gap. To overcome this problem, hybrid-DFT scheme is quite useful, which incorporates nonlocality of the exchange interaction reducing the self-interaction error in the GGA. In this work, highly-mismatched GaP alloys are studied as candidates for intermediate-band solar cells, where the optical conductivity is calculated on the basis of hybrid-DFT combined with time-dependent perturbation theory. Thanks to the practical computational costs of hybrid-DFT compared with the GW approximation, structures with realistic dopant concentrations are handled with 216-site supercells. Ideal composition of alloys in the sense of active optical transition energies and the formation energy are compared, where calculated results propose that the optimal doping condition is Mg-O co-doping [Y. Gohda and S. Tsuneyuki, Appl. Phys. Lett., in press.]

1:51PM U38.00014 Study of vertical correlation in type-II ZnCdTe/ZnCdSe submonolayer quantum dots for efficient intermediate band solar cells.[1] , SIDDHARTH DHOMKAR, IGOR KUSKOVSKY, Department of Physics, Queens College and the Graduate Center, CUNY, NY 10016, UTTAM MANNA, ISMAIL NOYAN, Department of Applied Physics and Applied Mathematics, Columbia University, NY 10027, MARIA TAMARGO, Department of Chemistry, City College and the Graduate Center, CUNY, NY 10016 — Intermediate band solar cells (IBSCs), having an intermediate band (IB) of states within the bandgap of the host semiconductor that enhances the light absorption without reducing the open circuit voltage, are substantially more efficient than single-gap devices. The IB, in principle, can be fabricated using quantum dots (QDs) embedded in the host semiconductor; however, there are many growth and material issues related to fabricating practical devices. We tackle some of these problems by growing the type-II ZnCdTe/ZnCdSe submonolayer QD system that lack the wetting layer. We present results of high resolution x-ray diffraction based reciprocal space map studies, complemented by photoluminescence, showing that this material system is an excellent candidate for IBSCs. Specifically, we found that the sample with larger Te fractions has larger QDs with increased vertical correlation. The vertical correlation is particularly important to have sufficient overlap of the hole wavefunctions, to facilitate the IB formation in this material system.

2:03PM U38.00015 Multiple Exciton Generation in Colloidal Si Nanocrystals at the Energy-Conservation-Limit[1] , M. SAGAR DODDERI, NREL, JIHUA YANG, UWE KORTSHAGEN, University of Minnesota, ERIN WHITNEY, OCTAVI SEMONIN, NREL, ARTHUR NOZIK, CU-Boulder, MATHEW C. BEARD, NREL, M.C. BEARD TEAM, UWE KORTSHAGEN COLLABORATION — Silicon covers more than 90% of photovoltaic cell production and is the 2nd most Earth-abundant element. In a Bulk Silicon solar cell about half of the total absorbed energy is lost as heat, following the detailed balance Shockley-Queisser (SQ) analysis. Generating multiple excitons (MEG) in quantum confined Nanocrystals per absorbed high energy photon is a route to circumvent some of the heat losses and thereby enhance photoconversion efficiency. However, to utilize the absorbed excess energy for MEG and to break the SQ limit it is desirable to establish MEG threshold as close as possible to 2 x E_g. Using femtosecond transient absorption spectroscopy, we demonstrate for the first time the generation of multiple excitons *right at the energy-conservation-limit (2 x E_g)* in colloidal Si nanocrystals. The observed 'near hard MEG-onset' is independent of the size of the nanocrystals studied (2.8 nm and 3.5 nm dots). Unlike Lead chalcogenides, the effect of photocharging on MEG yield is not observed in Si nanocrystals even at moderate pump-photon fluences ($\sim$ 10 nJ), much higher than the fluence typically used to measure MEG ($<$ 1nJ). The efficient MEG and the observation of 'near hard MEG-onset' at 2 x E_g in an indirect band gap semiconductor is extremely promising and has strong implications for third generation photovoltaics and is expected to enhance photoconversion efficiencies.

Session U39 DCMP: Metals: Alloys and Actinide Compounds 348 - Lin-Lin Wang, Ames Laboratory

11:15AM U39.00001 Statistical Mechanics of Nanoscale Metallic Materials Based on Thermodynamic Availability , ROBERT CAMMARATA, Johns Hopkins University — When characterizing the equilibrium behavior of small metallic systems, capillary effects can strongly influence the thermal behavior and need to be taken into account in a complete thermodynamic analysis. Although a variety of approaches have been offered to incorporate these effects, they sometimes invoke certain intensive thermodynamic quantities (e.g., chemical potentials) that are not well-defined when dealing with a physically and/or chemically inhomogeneous interfacial region.It has been proposed that many of these difficulties can be resolved by employing the thermodynamic availability function rather than the conventional free energy potentials [R.C. Cammarata, Phil Mag. 88, 927 (2008); R.C. Cammarata, Sol. State Phys. 61, 1 (2009)]. When applied to statistical mechanical calculations, capillary effects on nanoscale system behavior can be obtained in a natural and rigorous way. This procedure will be briefly reviewed and then applied to nanoscale metallic fluid and solid systems. Important issues contrasting the thermodynamic differences between fluid and solid surfaces and how they need to be included in order to obtain physically meaningful results will be discussed. Applications to gas adsorption and nucleation will be presented.

11:27AM U39.00002 Grain Rotation and Growth in Nanocrystalline Silver and Silver/Copper Alloys , MICHAEL CHANDROSS, SHENGFENG CHENG, Sandia National Laboratories — Grain rotation and growth play important roles in nanotribology and the plastic deformation of nanocrystalline metals and alloys. It is difficult, however, to study these processes with full atomistic detail experimentally. We used molecular dynamics simulations to investigate the grain rotation, coalescence, and growth in pure silver and silver/copper alloys after imposing various modes of deformation, including stretch, compression, and shear. Our results show that the degree of grain rotation and growth in pure silver depends on the state of stress in the sample and is most significant under shear deformation, where very large grains are observed after substantial shear. However, in silver/copper alloys, almost no grain growth was found even under strong shear. The presence of atoms with different lattice constants in alloys stabilizes the grain boundaries and makes grain coalescence less energetically favorable. The implications of these results on nanotribology of pure metals and alloys are discussed. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

11:39AM U39.00003 Temperature-driven Phase Transformation in Y_3Co: Neutron Scattering and DFT Studies[1] , A. PODLESNYAK, G. EHLERS, H. CAO, M. MATSUDA, Neutron Sciences Directorate, ORNL, Oak Ridge, TN 37831, USA, M. FRONTZEK, O. ZAHARKO, Laboratory for Neutron Scattering, Paul Scherrer Institut, CH-5232, Switzerland, V.A. KAZANTSEV, A.F. GUBKIN, N.V. BARANOV, Institute for Metal Physics RAS, 620041 Ekaterinburg, Russia — The effects of a crystal structure deformation due to subtle atomic displacements have attracted much attention because they can result in colossal changes of the electronic and magnetic properties of solids. The R_3Co binary intermetallic systems exhibit a number of complicated phenomena, including field-induced magnetic phase transitions (R=Er, Ho, Tb), giant magnetoresistance (R=Dy), a substantial magnetocaloric effect (R=Gd) and superconductivity (R=La). Contrary to previous studies that defined the ground state crystal structure of the entire R_3Co series as orthorhombic Pnma, we find that Y_3Co undergoes a structural phase transition upon cooling around Tc 160K. Density functional theory calculations reveal a dynamical instability of the Pnma structure of Y_3Co. Employing inelastic neutron scattering measurements we find a strong damping of the (00ξ) acoustic phonon mode below the critical temperature Tc. We suggest that some other members of the R_3Co series (or even all of them) have ground state crystal symmetry lower than reported Pnma. This raises a question about the true magnetic structures and hence the influence of magnetic properties of the entire R_3Co series.

11:51AM U39.00004 Optical Absorption Spectrum of Gold from First Principles[1] , JAMAL MUSTAFA, University of California at Berkeley, Lawrence Berkeley National Lab, EMMANOUIL KIOUPAKIS, University of Michigan, STEVEN LOUIE, University of California at Berkeley, Lawrence Berkeley National Lab — Phonon-assisted optical absorption is an important optical process in metals for photons in the visible part of the spectrum. Developments in first-principles computational methods have enabled the calculation of phonon-mediated optical absorption spectra of materials. The use of Maximally Localized Wannier Functions enables the interpolation of the GW quasiparticle band structure, along with the optical and electron-phonon coupling matrix elements, to very fine meshes in the Brillouin zone, which are needed for the calculation of the phonon-assisted absorption coefficient. We present calculations on gold that include the quasiparticle band structure and lifetimes, phonon dispersion, Wannier functions, and the phonon-assisted absorption spectrum. Since indirect absorption is a second-order process, the lifetime of the virtual intermediate state is of central importance. The results are compared to experimentally determined optical constants.

12:03PM U39.00005 Less than perfect C_{2v} symmetry: loss of mirror plane symmetry in angle-resolved photoemission , THOMAS SCOTT, University of Nebraska, Lincoln, KEISUKE FUKUTANI, Department of Physics, University of Nebraska, Lincoln, 68588, USA, HIROKAZU HAYASHI, Graduate School of Science, Hiroshima University, Higashi-Hiroshima 739-8526, Japan, TULA PAUDEL, Department of Physics, University of Nebraska, Lincoln, 68588, USA, EIKE SCHWIER, Hiroshima Synchrotron Radiation Center, Hiroshima University, 2-313 Kagamiyama, Higashi-Hiroshima 739-0046, Japan, TAIKI HORIKE, YORITO NAGATA, Graduate School of Science, Hiroshima University, Higashi-Hiroshima 739-8526, Japan, JIAN JIANG, HIDEAKI IWASAWA, KENYA SHIMADA, Hiroshima Synchrotron Radiation Center, Hiroshima University, 2-313 Kagamiyama, Higashi-Hiroshima 739-0046, Japan, EVGENY TSYMBAL, Department of Physics, University of Nebraska, Lincoln, 68588, USA, YAROSLAV LOSOVYJ, Department of Chemistry, Indiana University, E.Kirkwood Ave Bloomington, IN 47405, PETER DOWBEN, Department of Physics, University of Nebraska, Lincoln, 68588, USA — The effects of lack of in-plane C_2 invariance of the crystal on the angle-resolved photoemission spectra are investigated for Mo(112). The results indicate that, for Mo(112), the absence of C_2 symmetry gives rise to noticeable asymmetry in the ARPES band mapping along the $<1\ 1\ \text{-}1>$ direction. The apparent differences in the experimental band structure in +k versus –k wave vectors can be understood quantitatively in terms of the asymmetries in the electronic bulk band structure, photoelectron diffraction as well as the initial state contribution to the photoemission matrix elements.

12:15PM U39.00006 Prediction of dislocation junction strength in hexagonal close-packed crystals[1] , CHI-CHIN WU, PETER CHUNG, Army Research Laboratory, COMPUTATIONAL MATERIALS SCIENCE RESEARCH TEAM — Determination of dislocation junction strengths in *hcp* crystals is important in order to understand and control the fundamental mechanisms in plastic deformation in new lightweight metals and to reduce the density of deleterious dislocations in wide band-gap wurtzite semiconductors. The many factors that may be involved, such as combinations of available slip systems, native material properties, and local morphology due to growth conditions, make systematic investigations via combinatorial experimental approaches challenging. Utilizing discrete dislocation (DD) simulations, we determine yield surfaces comprised by loci of critical stresses required to unzip junctions. Then, using a comparative study of different binary junctions formed by non-coplanar dislocations using different pairs of Burgers vectors on different intersecting planes in Mg and Be crystals, we find that the shape and orientation of yield surfaces are most sensitive to the planes on which the junction forms but independent of the elastic properties. The latter only appears to affect the size of yield surface which is consistent with known behavior in fcc crystals. This work particularly detects similarities and differences in dislocation junctions in hcp crystals.

12:27PM U39.00007 Phonon Engineering in Metals from First Principles , NICHOLAS LANZILLO, J. THOMAS, E.B. WATSON, M. WASHINGTON, SAROJ K. NAYAK, Rensselaer Polytechnic Institute — The electron-phonon interaction in metallic systems controls the electronic transport properties, including both electrical and thermal resistivity. The effect of compressive strain on the electron-phonon interaction in metals is investigated using first-principles density functional theory, and we propose various ways to "engineer" this interaction for various technological applications. In particular, we show that by applying compressive strain on the FCC crystals of Al, Cu, Ag and Au, the net electron-phonon scattering rate decreases and likewise the electrical resistivity decreases with increasing pressure. This trend is corroborated by experimental measurements of the resistance of a 0.5 mm diameter high-purity Al wire pressurized up to 2 GPa in a solid-media pressure apparatus at room temperature. The rate of the decrease in electrical resistivity as a function of pressure as determined by experiment is matched by the rate predicted by theory. Our simulations show that Al nanowires have the same response to strain as the bulk crystal; the net electron-phonon scattering can be reduced through compressive strain. Modifying the electron-phonon interaction in metallic structures shows great promise for future nano-electronic devices.

12:39PM U39.00008 Density-functional study of U-TRU-Zr and U-TRU-Mo alloys , ALEXANDER LANDA, PER SODERLIND, PATRICE TURCHI, Lawrence Livermore National Laboratory — The U-Zr and U-Mo alloys proved to be very promising fuels for liquid metal fast breeder reactors. The optimal composition of these alloys is determined from the condition that the fuel could remain stable in the bcc phase (γ-U) in the temperature range of stability of α-U phase. In other words, both Zr and Mo play a role of "γ-stabilizers" helping to keep U in the metastable bcc phase upon cooling. In the present study we perform KKR-ASA-CPA and EMTO-CPA calculations of the ground state properties of γ-U-Zr and γ-U-Mo alloys and compare their heats of formation with CALPHAD assessments. Though the U-Zr and U-Mo alloys can be used as nuclear fuels, a fast rector operation on a closed fuel cycle will, due to the nuclear reactions, contain significant amount of TRU elements (Np, Pu, and Am). Above mentioned density-functional theory techniques are extended to study ground-state properties of the bcc-based X-Zr and X-Mo (X = Np, Pu, Am) solid solutions. We discuss how the heat of formation correlates with the charge transfer between the alloy components, and how magnetism influences the deviation from Vegard's law for the equilibrium atomic volume. This work was performed under the auspices of the US Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344. Work at LLNL was funded by the Laboratory Directed Research and Development Program under project tracking code 12-SI-008.

12:51PM U39.00009 Thermal properties of UO_2 single crystal , K. GOFRYK, S. DU, A.D. ANDERSSON, C.R. STANEK, R. SCHULZE, D. SAFARIK, B. MIHAILA, J.C. LASHLEY, J.L. SMITH, Los Alamos National Laboratory — For decades UO_2 has been the most widely studied actinide oxide because of its technological importance as fuel material for nuclear reactors. Therefore there is a large interest in understanding its thermal, transport and thermodynamic properties. We present recent experimental results for the thermal conductivity and thermal expansion of high quality UO_2 single crystal, obtained for different crystallographic directions, and compare with results of molecular dynamics simulations. We will discuss the implications of this study.

1:03PM U39.00010 ABSTRACT WITHDRAWN –

1:15PM U39.00011 Imaging electronic hot spots in the spectral function of the actinide $UCoGa_5$[1] , MATTHIAS J. GRAF, TANMOY DAS, TOMASZ DURAKIEWICZ, JIAN-XIN ZHU, JOHN J. JOYCE, JOHN L. SARRAO, Los Alamos National Laboratory — We performed self-consistent GW-like calculations within the intermediate Coulomb-U coupling regime to investigate dynamic correlation effects in the intermetallic actinide $UCoGa_5$. This material is often used to contrast anomalous behavior in other U-115 and Pu-115 compounds, because it is presumed to be a conventional Fermi liquid that resembles a "vegetable." First-principles electronic structure calculations were used as input, combined with the spin-fluctuation exchange approximation, to compute self-consistently the many-body self-energy responsible for dynamic correlation effects. We validated theory by angle-resolved photoemission spectroscopy (ARPES). The occurrence of electronic hot spots in the spectral function, accompanied by kinks and abrupt breaks in the slope of the quasiparticle dispersion were detected both at low (130 meV) and high (1 eV) binding energies below the Fermi energy. In conclusion, we found that dynamic correlation anomalies are adequately described by coupling between itinerant fermions and spin fluctuations arising from the particle-hole continuum of the spin-orbit-split 5f states of uranium.

1:27PM U39.00012 Probing the f-state configuration of αU and URu_2Si_2 with RXES , SCOTT MEDLING, CORWIN H. BOOTH, Lawrence Berkeley National Lab, RYAN BAUMBACH, ERIC D. BAUER, Los Alamos National Lab — We directly probed the electronic configuration of several uranium compounds using Resonant X-ray Emission Spectroscopy (RXES). Previous investigations by several groups into the magnetic properties of uranium compounds (such as URu_2Si_2) suggested that some are multiconfigurational. RXES is particularly useful for probing the configurations because measuring the energies of both the incident and scattered photons reveals information about both the empty and occupied electronic states. We collected data for several uranium samples (αU, UO_2, and URu_2Si_2) which indicate that in some of these compounds the uranium is multiconfigurational, with a mixture of f^1,f^2, and f^3 occupancies. The degree of intermediate valence that this implies will be related to electronic and magnetic properties of the compound.

1:39PM U39.00013 Towards a Density Functional Theory Exchange-Correlation Functional able to describe localization/delocalization , ANN E. MATTSSON, Sandia National Laboratories, JOHN M. WILLS, Los Alamos National Laboratory — The inability to computationally describe the physics governing the properties of actinides and their alloys is the poster child of failure of existing Density Functional Theory exchange-correlation functionals. The intricate competition between localization and delocalization of the electrons, present in these materials, exposes the limitations of functionals only designed to properly describe one or the other situation. We will discuss the manifestation of this competition in real materials and propositions on how to construct a functional able to accurately describe properties of these materials. I addition we will discuss both the importance of using the Dirac equation to describe the relativistic effects in these materials, and the connection to the physics of transition metal oxides. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

1:51PM U39.00014 Actinide electronic structure based on the Dirac equation and density functional theory , JOHN M. WILLS, Los Alamos National Laboratory, Los Alamos, NM 87545, USA, ANN E. MATTSSON, Sandia National Laboratories, Albuquerque, NM 87185, USA — Density functional theory (DFT) provides a formally predictive basis for predicting the structural properties of actinides. Although available approximations to the exchange/correlation functional provide accurate predictions for many materials, they fail qualitatively and sometimes quantitatively when applied to actinides. Major contributors to this deficiency are an inadequate treatment of confinement physics and an incomplete treatment of relativity in the underlying equations. The development of a functional correctly incorporating confinement physics with a proper treatment of relativity would provide definitive, internally consistent predictions of actinide properties. To enable the development of such a functional and quantify the predictions of currently available functionals, we have developed an efficient first-principles electronic structure method based on the Dirac equation. Results are compared with current methods, and the implications for relativistic density functionals discussed. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

Session U40 DAMOP: Non-equilibrium Cold Atom Systems 349 - Marcos Rigol, Pennsylvania State University

11:15AM U40.00001 Emergence of an effective thermal correlation length in the course of prethermalization , REMI GEIGER, MAXIMILIAN KUHNERT, TIM LANGEN, MICHAEL GRING, BERNHARD RAUER, Atominstitut, TU Wien (Vienna University of Technology), TAKUYA KITAGAWA, EUGENE DEMLER, Harvard University, DAVID ADU-SMITH, JOERG SCHMIEDMAYER, Atominstitut, TU Wien (Vienna University of Technology) — Understanding non-equilibrium processes in many-body quantum systems is an important unsolved problem in many areas of physics. Here, we study the relaxation dynamics of a coherently split one-dimensional Bose gas by measuring the full probability distribution functions of matter-wave interference. After splitting, the system rapidly relaxes to a thermal-like quasi-steady state retaining partial information about the initial conditions. We observe this state to be independent on the initial temperature before splitting and associate the relaxation dynamics with prethermalization. Observing the system on different length scales allows us to probe the dynamics of excitations on different energy scales, revealing two distinct length-scale dependent regimes of relaxation. We measure the crossover length-scale separating these two regimes and identify it with the prethermalized phase-correlation length of the system. Our work provides a direct vizualization of prethermalization and multimode dynamics in a one-dimensional many-body quantum system.

11:27AM U40.00002 Quasi-universal transient behavior of a nonequilibrium Mott insulator driven by an electric field , KARLIS MIKELSONS, JIM FREERICKS, Georgetown University, H.R. KRISHNAMURTHY, Indian Institute of Science, Bangalore — We use a self-consistent strong-coupling expansion for the self-energy (perturbation theory in the hopping) to describe the nonequilibrium dynamics of strongly correlated lattice fermions. We study the three-dimensional homogeneous Fermi-Hubbard model driven by an external electric field showing that the damping of the ensuing Bloch oscillations depends on the direction of the field, and that for a broad range of field strengths, a long-lived transient prethermalized state emerges. This long-lived transient regime implies that thermal equilibrium may be out of reach of the time scales accessible in present cold atom experiments, but shows that an interesting new quasi-universal transient state exists in nonequilibrium governed by a thermalized kinetic energy, but not a thermalized potential energy. In addition, when the field strength is equal in magnitude to the interaction between atoms, the system undergoes a rapid thermalization, characterized by a different quasi-universal behavior of the current and spectral function for different values of the hopping.

11:39AM U40.00003 Quench Dynamics in the Presence of a Bath , ADAM RANCON, James Franck Institute, ANDREAS GLATZ, IGOR ARANSON, Argonne National Laboratory, KATHY LEVIN, James Franck Institute — Feshbach resonance are now widely used to tune the interaction strength in cold atoms. This allows one to experimentally study the out-of-equilibrium dynamics of a quench associated with instantaneously changing the strength of the interactions between fermionic and bosonic atoms. Previous theoretical studies based on standard time dependent Bogoliubov or BCS theory (for bosons and fermions) have not included the presence of a thermal bath. This bath is essential for ultimate equilibration. In this talk we show how to include the bath following a Leggett-Caldeira type approach. We point out some of the important differences in the quench dynamics between bosonic and fermionic superfluids.

11:51AM U40.00004 Many-body analysis of a quasi-disordered integrable lattice system after a quench , LEA SANTOS, Yeshiva University, MARCOS RIGOL, Penn State University — It has been recently argued that the transition between a delocalized and a localized regime in a quasi-disordered integrable lattice system affects the dynamics and description of one-body observables after relaxation following a quench [1]. Specifically, the generalized Gibbs ensemble description was found to be applicable in the delocalized phase, but to break down in the localized phase. Here we present a many-body analysis of those quenches. We discuss how the expectation values of one-body observables in the many-body eigenstates behave in both regimes, and provide a microscopic understanding of the results in Ref. [1].

12:03PM U40.00005 When Is a Bath a Bath? Relaxation Dynamics and Thermalization in a Fermionic Chain , NICHOLAS SEDLMAYR, JIE REN, TU Kaiserslautern, FLORIAN GEBHARD, Marburg University, JESKO SIRKER, TU Kaiserslautern — We study thermalization in a one-dimensional quantum system consisting of a non-interacting fermionic chain with each site of the chain coupled to an additional bath site. Using a time-dependent density matrix renormalization group algorithm we investigate the time evolution of observables in the chain after a quantum quench. For a weakly interacting bath and low densities we show that the dynamics can be quantitatively described by a system of coupled equations of motion. For higher densities our numerical results show equilibration for local observables and a thermalization to the canonical ensemble independent of the initial state. In particular, we find a Fermi momentum distribution in the chain in equilibrium in spite of the seemingly oversimplified bath in our model.

12:15PM U40.00006 Quench dynamics in the one-dimensional sine-Gordon model: Quantum kinetic equation approach[1] , MARCO TAVORA, ADITI MITRA, New York University — We study dynamics after a quantum quench in the one-dimensional sine-Gordon model in its gapless phase. We construct the Dyson equation to leading (quadratic) order in the cosine potential and show that the resulting quantum kinetic equation is atypical in that it involves multi-particle scattering processes. We also show that using an effective action, which generates the Dyson equation by a variational principle, the conserved stress-momentum tensor can be constructed. We solve the dynamics numerically by making a quasi-classical approximation that makes the quantum kinetic equation local in time while retaining the multi-particle nature of the scattering processes. We find that the boson distribution function reaches a steady-state characterized by an effective temperature in the long-wavelength limit. We present an analytic argument for the value of the effective temperature and the time-scales to reach this steady-state.

12:27PM U40.00007 Thermalization in isolated quantum many-body systems and dependence on initial states , EDUARDO TORRES-HERRERA, LEA SANTOS, Yeshiva University — We study the viability of thermalization in isolated quantum many-body systems described by one-dimensional Heisenberg spin-1/2 models. We show that the onset of thermal equilibrium depends on the interplay between initial states, observables and regimes. Our numerical studies are based on the spectrum analysis of the system and on its long-time evolution after a quench.

12:39PM U40.00008 Initial-state dependence of the quench dynamics in integrable quantum systems at finite temperature , KAI HE, Georgetown University, MARCOS RIGOL, Georgetown University, Penn State University — We study properties of isolated integrable quantum systems after a sudden quench starting from thermal states. We show that, even if the system is initially in equilibrium at finite temperature, the diagonal entropy after a quench remains a fraction of the entropy in the generalized ensembles introduced to describe integrable systems after relaxation. The latter is also, in general, different from the entropy in thermal equilibrium. Furthermore, we examine the difference between the distribution of conserved quantities in the thermal and generalized ensembles after a quench and show that they are also, in general, different from each other. This explains why these systems fail to thermalize in the usual sense. A finite size scaling analysis is presented for each quantity, which allows us making predictions for thermodynamically large lattice sizes.

12:51PM U40.00009 Non-Equilbrium Behavior and Thermalization in 1D Bose Gases , ROBERT KONIK, Brookhaven National Lab, JEAN-SEBASTIEN CAUX, University of Amsterdam — Using a new numerical renormalization group based on exploiting an underlying exactly solvable nonrelativistic theory, we study the equilibrium properties and out-of-equilibrium dynamics of interacting many-body quantum systems. Focusing on the example of the Lieb-Liniger model we study quantum quenches with a focus on protocols in which the gas is released from a parabolic trap. Our method allows one not only to accurately describe the equilibrium state of the gas in the trap, but also to track the post-quench dynamics all the way to infinite time. Exploiting integrability, we are also able to exhibit a general protocol for the explicit construction of the generalized Gibbs ensemble, which is a candidate to govern the equilibriation of the trapped gas after its release. This construction does not rely on the underlying Hamiltonian being quadratic and works for arbitrary initial conditions. By comparing the predictions of equilibration from this ensemble against the long time dynamics observed in our method, we find that it is considerably more accurate than the effective grand canonical ensemble. See J.S. Caux and R. M. Konik, PRL 109, 175301 (2012).

1:03PM U40.00010 How Long Does it Take for a Non-Equilibrium System to Reach a Quasi-Thermal State? , HERBERT F. FOTSO, KARLIS MIKELSONS, JAMES K. FREERICKS, Department of Physics, Georgetown University — We study the relaxation of an interacting system driven out of equilibrium by a constant electric field using Non-Equilibrium Dynamical Mean Field Theory. We use on the one hand a DMFT method which solves the steady state problem directly in frequency space, and on the other hand, a DMFT method that follows the transient time evolution of the system on the Keldysh contour. The system is described by the Falicov Kimball model which we follow across the metal - insulator transition. We find that the retarded Green's function quickly approaches that of the steady state while the lesser Green's function and, as a result the distribution function, slowly approach that of a steady state with an increased temperature due to the additional energy transferred to the system by the electric field. Analyses of this type can help understand the results of some experiments involving ultracold atomic gases.

1:15PM U40.00011 Probing thermalization and dephasing using the Kibble-Zurek mechanism , MICHAEL KOLODRUBETZ, Boston University, BRYAN CLARK, Microsoft Station Q, ANUSHYA CHANDRAN, SHIVAJI SONDHI, DAVID HUSE, Princeton University — The Kibble-Zurek mechanism was introduced to describe defect creation after ramping through critical points. Recent work has extended this concept to a full non-equilibrium scaling theory, described by the same low-energy critical exponents as in equilibrium. In this talk, I will discuss applying Kibble-Zurek analysis and its extensions to probe open questions in non-equilibrium dynamics, specifically working to understand thermalization or – in the case of integrable systems – dephasing to a generalized Gibbs ensemble. The major advantage of investigating these questions within the Kibble-Zurek scaling regime is that the results are universal in the renormalization group sense, i.e., insensitive to microscopic details that often confound analyses of thermalization. I will describe both analytical and numerical (TEBD) approaches to address the problem, with an emphasis on understanding the long-time behavior after a slow ramps and small quenches.

1:27PM U40.00012 Dynamics of Large Quantum Systems: Equilibration, Thermalization and Interactions , DVIRA SEGAL, University of Toronto, MANAS KULKARNI, Princeton University, KUNAL TIWARI, McGill University — The question of how/whether large quantum systems equilibrate and/or thermalize when prepared in an out-of-equilibrium state has been of enormous interest given recent experimental progress. We address this question in fermionic [1,2] and bosonic [3] systems, by following the dynamics of the full density matrix. We particularly study the case of two large-twin systems connected by a weak link (a quantum impurity), and we show that the total system equilibrates and thermalizes when the weak link is susceptible to incoherent and inelastic processes. We thus provide an experimentally feasible prescription for equilibrating and thermalizing large finite quantum systems. Our calculations are based on extending methods originally developed to treat subsystem dynamics (such as impurity), namely, the quantum Langevin equation method, the well known fermionic trace formula, and an iterative path integral approach. We also explore the role of interactions. While the fermionic system [1,2] shares many common features with the bosonic analog [3], we will describe certain crucial differences that arise as a result of different statistics.

1:39PM U40.00013 Quench Dynamics of the Interacting Bose Gas in one Dimension[1] , NATAN ANDREI, DEEPAK IYER, Department of Physics, Rutgers University — We obtain an exact expression for the time evolution of the interacting Bose gas following a quench from a generic initial state using the Yudson representation for integrable systems. We study the evolution of the density and noise correlation for a small number of bosons and their asymptotic for any number. We show that for any value of the coupling, as long as it is repulsive, the system asymptotes towards a strongly repulsive gas, while for any value of an attractive coupling long time behavior is dominated by the maximal bound state. This occurs independently of the initial state and can be viewed as an emerging "dynamic universality".

1:51PM U40.00014 Quantum Quenches of Ultracold Atoms in the Presence of Synthetic Gauge Fields[1] , MATTHEW KILLI, STEFAN TROTZKY, ARUN PARAMEKANTI, University of Toronto — Motivated by the experimental realization of synthetic gauge fields for ultracold atoms in optical lattices, we consider quantum quenches in such gauge field backgrounds. We show that the density dynamics following sudden anisotropic quenches can be used as a probe of equilibrium mass currents of atoms. We show, using diverse examples of Bose superfluids and normal Fermi fluids, that bulk equilibrium currents produced by the background gauge fields can be uncovered using this method. Such quenches are also shown to provide an effective route to probing the edge currents in topological states such as quantum Hall or quantum spin Hall insulators.

2:03PM U40.00015 Thermalization Processes in Quantum Mechanics , VAN NGO, STEPHAN HAAS, University of Southern California — In quantum mechanics, the emergence of thermalization processes from unitary evolution has remained one of the greatest challenges. The two outstanding theories of this issue by Srednicki and Tasaki cannot address the concepts of temperature, heat, and work. Here, we present a theory using multiple quenches to examine the thermalization processes to advance thermodynamics concepts. To perform multiple quenches, one can vary one single control parameter (λ) in a series of time evolutions, which create a set of density operators. The average of these density operators results into a diagonal operator with probability distribution function that can describe the emerging ensembles. Measuring probability distribution functions of key physical observables, temperature, equal to the derivative of energy with respect to entropy, can be easily measured. Therefore, simulations via multiple quenches can mimic dynamics in open quantum systems with much cheaper computational cost. They allow (1) tuning of temperature and entropy via λ, (2) measuring work distribution functions from distributions of a reaction coordinate, and (3) computing free-energy changes via Jarzynski's Equality. We hope that this approach can provide a new foundation and open up new directions for studying control of quantum systems.

Thursday, March 21, 2013 11:15AM - 2:15PM –

Session U41 GQI DAMOP: Quantum Simulation in Hybrid Systems (and Nano/Optomechanics IV) 350 - Aashish Clerk, McGill University

11:15AM U41.00001 Quantum Dynamics of Photon Condensates , PETER KIRTON, JONATHAN KEELING, University of St Andrews — Recent experiments have, for the first time, been able to observe the Bose condensation of a gas of weakly interacting photons. We develop a full out-of-equilibrium quantum mechanical treatment of the dynamics of this system. Our model consists of a series of photon modes coupled to the background dye molecules which we simply treat as two-level systems in which each level is separated into a ladder of rovivibration states. We find that the behavior of the photon field is very much like that of a two-level laser in which there is an asymmetry between the effective pump and decay rates induced by the rovivibrational states of the dye. This motivates us to use techniques based on those for the inversionless two-level laser. We are able to calculate the coherence properties of the photons as well as giving insights into the thermalization processes which equilibrate the populations of the various photon modes.

11:27AM U41.00002 Excitations of a driven condensate in a cavity: dynamics of the roton-like mode , BARIS OZTOP, MANAS KULKARNI, HAKAN TURECI, Princeton University — Recent experiments have demonstrated the superfluid-supersolid quantum phase transition (PT) of an optically driven Bose-Einstein condensate (BEC), via the observation of a roton-like softening of a mode in the Bogoliubov excitation spectrum [1,2]. This phenomenon is usually studied within two-mode approximation for the BEC which results in Dicke-like effective model. In this system, the long-range interactions between the atoms are mediated by cavity photons and the strength of the interactions is controlled by pump power. In this work, we investigate the effect of including the full spectrum of atomic modes. We find a finite lifetime for the roton-like mode below the threshold that is strongly pump-dependent. The corresponding decay rate and critical exponents for the PT are calculated.

11:39AM U41.00003 Quantum optomechanics in the strong-driving, strong-coupling regime , MARC-ANTOINE LEMONDE, WEI CHEN, AASHISH CLERK, McGill University, Ca, Qc — There is considerable interest in trying to develop quantum optomechanical systems where the coupling is appreciable at the level of a single photon and single phonon. Theoretically, such strongly-coupled optomechanical systems have been largely studied using a polaron transformation in the regime of very weak optical driving. We present here a theoretical approach based on the Keldysh technique that describes single-photon strong coupling physics in an optomechanical system in the presence of a strong optical drive. We show that strong driving can be used to dramatically enhance the effects of the single-photon nonlinearity, leading to striking modifications to the usual linearized optomechanical theory. We discuss the resulting strong modifications of the optomechanically-induced transparency (OMIT) spectrum, a quantity easily accessible in experiment.

11:51AM U41.00004 Quantum many body systems with qubits and phonons in the solid state , Ö.O. SOYKAL, University of Maryland, CHARLES TAHAN, Laboratory for Physical Sciences — We previously proposed a nano-mechanical system where phonons trapped in an acoustic cavity can strongly hybridize with impurity qubit states in silicon (forming a so-called cavity-phoniton). Here, we extend the idea to the quantum many-body limit by investigating the physics of phonon-tunnel-coupled arrays of such components. The silicon qubit cavity phoniton system potentially offers advantages in this regime over purely optomechanical systems where the optomechanical coupling is still quite small. First, single phonons in a crystal can have large effective de Broglie wavelengths (microns). Second, as we have previously shown, qubit-phonon coupling can be quite large, easily allowing the system to enter the strong coupling regime and enabling phonon-blockade. Such arrays can be fabricated in semiconductor heterostructures or in on-chip, optomechanical crystals. We calculate the parameter regime where the Mott-Superfluid quantum phase transition occurs in realizable devices. We also demonstrate the emergence of super-splitting, phonon anti-bunching, and phonon blockade through the non-equilibrium density matrix master equation approach in few cavity systems.

12:03PM U41.00005 Quantum Dynamics of Optomechanical Arrays , MAX LUDWIG, University of Erlangen-Nuremberg, FLORIAN MARQUARDT, University of Erlangen-Nuremberg and Max Planck Institute for the Science of Light — Optomechanical system are typically composed of a single mechanical and a single optical mode interacting via radiation pressure. In this talk, we will introduce an array of optomechanical cells, and discuss our theoretical results on the nonlinear quantum dynamics of such a setup. In particular, we have discovered a phase transition between incoherent mechanical oscillations and a collective phase-coherent mechanical state. We describe how quantum fluctuations drive this transition at low temperatures. We will also discuss the prospects of observing these non-equilibrium dynamics in an experimental implementation based on currently available setups.

12:15PM U41.00006 Signatures of nonlinear optomechanics and engineering of nonclassical mechanical steady states[1] , KJETIL BORKJE, Niels Bohr Institute, University of Copenhagen — Motivated by recent improvements in coupling strength between light and mechanical motion, we study the strong coupling regime of cavity optomechanics theoretically. We focus on the regime where the optomechanical coupling rate is still small compared to the mechanical resonance frequency, but where the mechanically induced Kerr nonlinearity is significant. The response of the system to an optical drive is characterized. The average photon number in the cavity as a function of drive detuning can feature several peaks due to multi-photon transitions. Furthermore, we show that by optically driving the system at multiple frequencies, multi-photon transitions can facilitate the engineering of nonclassical steady states of the mechanical oscillator.

[1]The author acknowledges financial support from The Danish Council for Independent Research under the Sapere Aude program.

12:27PM U41.00007 Nonlinear Quantum Relaxation and Generation of Non-classical States in Duffing Oscillators , AURORA VOJE, ALEXANDER CROY, ANDREAS ISACSSON, Chalmers University of Technology — The dissipative quantum dynamics of an anharmonic oscillator is theoretically investigated in the context of carbon-based nano-mechanical systems. In the short-time limit, it is known that macroscopic superposition states appear for such oscillators[1]. Linear and non-linear dissipation leads to decoherence of such non-classical states in the long-time limit. However, as a result of two-vibron losses at zero temperature, the quantum oscillator eventually evolves into a non-classical stationary state – a qubit-like state. The relaxation of the qubit due to thermal excitations and one-vibron losses is numerically and analytically studied. The possibility of verifying the occurrence of the qubit is discussed and signatures of the non-classicality arising in a ring-down setup are presented. Additionally, the generation of entanglement between two coupled oscillators in presence of strong two-vibron losses is discussed.

12:39PM U41.00008 Parametric feedback squeezing of an opto-electromechanical device below 3dB , MENNO POOT, HONG TANG, Dept. of Electrical Engineering, Yale University — Parametric squeezing can reduce the uncertainty in one quadrature of the position of a mechanical resonator, even below the standard quantum limit, and it can improve measurement sensitivity. Here we demonstrate squeezing of the thermal motion of a 570 kHz opto-electromechanical resonator made out of high-stress SiN by modulating its spring constant at twice the resonance frequency. Parametric and direct actuation are achieved by applying a.c. voltages between strongly coupled electrodes on the resonator and a fixed one. It is well know that using this method the motion of one quadrature cannot be decreased more than 3 dB below the undriven case before instabilities kick in. However, by measuring the phase-space trajectory of the resonator and adjusting the phase of the parametric drive in real-time we achieve a stationary reduction in both quadratures that is far beyond this limit. Finally, due to the strong coupling between the drive electrodes, the nonlinearity of the resonator can be tuned all the way from a stiffening spring to a softening one.

12:51PM U41.00009 Non-classical correlations of scattered photons in a one-dimensional waveguide with multiple atoms[1] , DIBYENDU ROY, Theoretical Division and Center for Nonlinear Studies, Los Alamos National Laboratory, Los Alamos, New Mexico 87545, USA — We study the scaling of photon-photon correlations mediated by resonant interactions of photons with atoms in a one-dimensional photonic waveguide. Recently a new theoretical approach based on the Bethe-ansatz technique has been developed to study transport in an open quantum impurity. Here we generalize the approach to study multiple atoms. We derive the exact solution of single and two-photon scattering states, and the corresponding photon transmission through the atomic ensemble. We show how various two-photon nonlinear effects, such as spatial attraction and repulsion between photons as well as background fluorescence can be tuned by changing the number of atoms and the coupling between atoms (controlled by the separation). Finally we propose a simple scheme for nonreciprocal optical transmission in the waveguide by placing different atoms. Our fully quantum-mechanical approach provides a better understanding of cascaded optical nonlinearity at the microscopic level.

1:03PM U41.00010 Recent theoretical advances on superradiant phase transitions , ALEXANDRE BAKSIC, PIERRE NATAF, CRISTIANO CIUTI, Laboratoire MPQ, Université Paris Diderot-Paris 7 and CNRS — The Dicke model describing a single-mode boson field coupled to two-level systems is an important paradigm in quantum optics. In particular, the physics of "superradiant phase transitions" in the ultrastrong coupling regime is the subject of a vigorous research activity in both cavity and circuit QED. Recently, we explored the rich physics of two interesting generalizations of the Dicke model: (i) A model describing the coupling of a boson mode to two independent chains A and B of two-level systems [1], where chain A is coupled to one quadrature of the boson field and chain B to the orthogonal quadrature. This original model leads to a quantum phase transition with a double symmetry breaking and a fourfold ground state degeneracy. (ii) A generalized Dicke model with three-level systems [2,3] including the diamagnetic term. In contrast to the case of two-level atoms for which no-go theorems exist, in the case of three-level system we prove that the Thomas-Reich-Kuhn sum rule does not always prevent a superradiant phase transition.

1:15PM U41.00011 Light-induced phase transition in a quantum spin chain: Breakdown of the Haldane phase by circularly polarized laser , SHINTARO TAKAYOSHI, Department of Applied Physics, University of Tokyo, HIDEO AOKI, Department of Physics, University of Tokyo, TAKASHI OKA, Department of Applied Physics, University of Tokyo — We theoretically propose a new category of non-equilibrium phase transitions in quantum spin systems that can be induced by the magnetic component of strong lasers. As an example, we consider a Haldane chain with single ion anisotropy radiated by circularly polarized light. We study the spin dynamics by combining the numerical infinite time-evolving block decimation method and an analytical calculation via the Floquet theory, and demonstrate that the laser can magnetize even an antiferromagnet quantum mechanically. It is also shown that the string order is broken by the magnetization, which indicates that a photo-induced breakdown of the Haldane phase has occurred. This phenomenon can be realized using strong THz lasers.

1:27PM U41.00012 Testing Kibble-Zurek mechanism in ion traps , RAMIL NIGMATULLIN, Imperial College London, ADOLFO DEL CAMPO, T4 and Center for Nonlinear Studies, Los Alamos National Laboratory, GABRIELE DE CHIARA, Centre for Theoretical Atomic, Molecular and Optical Physics, Queen's University Belfast, GIOVANNA MORIGI, Theoretical Physics, University of Saarland, MARTIN PLENIO, Institute of Theoretical Physics, Ulm University, ALEX RETZKER, The Racah Institute of Physics, Hebrew University of Jerusalem — A quench through a critical point of a second order phase transition results in the formation of topological defects in the system. Kibble-Zurek (KZ) theory predicts the scaling of a number of defects as a function of quench rate. This scaling depends on the critical exponents of the phase transition, and hence the study of the defect density reveals something about the nature of phase transition itself. There are a number of proposals to test KZ theory experimentally. In this talk, we discuss the possibility of studying defect formation in ion traps. A linear ion chain confined in a Paul trap undergoes a continuous phase transition to a zigzag chain when the confining potential is lowered. If the chain is in a ring trap then the zigzag chain can be in a helical configuration with a nonzero winding number. Using molecular dynamics simulations we show that the scaling of the average winding number of the resulting helical chain is consistent with KZ theory.

1:39PM U41.00013 Space-Time Crystals of Trapped Ions , TONGCANG LI, University of California, Berkeley, ZHE-XUAN GONG, University of Michigan, Ann Arbor, ZHANG-QI YIN, Tsinghua University, H. T. QUAN, University of Maryland, College Park, XIAOBO YIN, PENG ZHANG, University of California, Berkeley, L.-M. DUAN, University of Michigan, Ann Arbor, XIANG ZHANG, University of California, Berkeley — Spontaneous symmetry breaking can lead to the formation of time crystals, as well as spatial crystals. Here we propose a space-time crystal of trapped ions and a method to realize it experimentally by confining ions in a ring-shaped trapping potential with a static magnetic field. The ions spontaneously form a spatial ring crystal due to Coulomb repulsion. This ion crystal can rotate persistently at the lowest quantum energy state in magnetic fields with fractional fluxes. The persistent rotation of trapped ions produces the temporal order, leading to the formation of a space-time crystal. We show that these spacetime crystals are robust for direct experimental observation. We also study the effects of finite temperatures on the persistent rotation. The proposed space-time crystals of trapped ions provide a new dimension for exploring many-body physics and emerging properties of matter.

1:51PM U41.00014 Electromagnetic induced transparency and slow light in strongly correlated atomic gases , HSIANG-HUA JEN, BO XIONG, ITE A. YU, DAW-WEI WANG, National Tsing Hua University, PHYSICS DEPARTMENT, NATIONAL TSING HUA UNIVERSITY TEAM, FRONTIER RESEARCH CENTER ON FUNDAMENTAL AND APPLIED SCIENCES OF MATTER,NATIONAL TSING HUA UNIVERSITY TEAM, PHYSICS DIVISION, NATIONAL CENTER FOR THEORETICAL SCIENCES TEAM — We develop the quantum theory for the electromagnetic induced transparency (EIT) and slow light property in ultracold Bose and Fermi gases. It shows a very different property from the classical theory which assumes frozen atomic motion. For example, the speed of light inside the atomic gases can be changed dramatically near the Bose-Einstein condensation temperature, while the presence of the Fermi sea can destroy the EIT effect even at zero temperature. This quantum EIT property is mostly manifested in the counter-propagating excitation schemes in either the low-lying Rydberg transition or in D2 transition with a very weak coupling field.
Using linear response theory, we further derive an exact and universal form for the EIT spectrum, which applies even in strongly correlated systems of ultracold atoms. We find that the spectrum is closely related to the single particle Green's function, which is not easily observable in most experimental technique. As an example, we show results of 1D Luttinger liquid, Mott-insulator state, and BCS pairing phase, and compare to the results of standard classical theory. Our theory therefore paves the way to measure strongly correlated physics of ultracold atoms via the state-of-art manipulation of light propagation inside the quantum gases.

2:03PM U41.00015 Orbital Angular Momentum as Manifestation of Photonic Zitterbewegung , BASIL DAVIS, Tulane University — The phenomenon of photonic orbital angular momentum has received considerable attention since its theoretical prediction by Allen et al in 1992. It has been established theoretically and experimentally that laser beams with a Laguerre Gaussian profile possess angular momentum in addition to their intrinsic spin angular momentum. A parallel development has been the renewed interest in zitterbewegung, first predicted for relativistic electrons by Schrodinger. It is now known that zitterebewegung is a property of all particles, regardless of spin, charge or rest mass, since it is basically a quantum mechanical phenomenon. Recently there has arisen an interest in photonic zitterbewegung. This paper shows that photonic orbital angular momentum is one experimentally observable manifestation of photonic zitterbewegung.

Session U42 DCP: Focus Session: Supercooled and Nanoconfined Water III Hilton Baltimore Holiday Ballroom 3 - Anders Nilsson, SLAC

11:15AM U42.00001 Phase transitions of liquid water at nanoscale , CHRISTIANE ALBA-SIMIONESCO, Laboratoire Léon Brillouin, CEA-CNRS, Saclay — The behaviour of fluids confined within nanometric pores significantly differs from that of the bulk. The effect of confinement, surface forces, and reduced dimension is to shift the phase transitions of the confined fluid (condensation, freezing and crystallisation). By postponing or avoiding the inconvenient crystallization process it is often suggested that confinement allows a deeper penetration into the supercooled regime and helps in the understanding the glass formation; in the case of water, confinement might helps to extend the liquid state into the so-called "no-man's land." However below confining conditions of about 10σ, σ being the size of the molecule, water or van der Waals liquids are strongly perturbed by the presence of a surface. Thus a question always remains whether the confined liquid, water or any other fluid, is an extension of the "bulk" supercooled regime or refers to specific behavior controlled by external parameters such as the size and the surface interactions imposed to the system. Despite the obvious fundamental interest in understanding bulk water, this situation corresponds to most of the cases in biological and geological systems and deserves particular attention per se. However a prerequisite is to understand and quantify how pores are filled and how much; so we studied the processes of entrance and saturation to a pore (adsorption, imbibition and intrusion) in connection with the structure and the local dynamics of liquid water. Then, we will present new experimental results on the thermodynamic, structural and vibrational properties of water confined within nanometric pores (size of a few molecular diameters).

11:51AM U42.00002 How does confinement affect the structure and dynamics of water and other liquids? , ANATOLI MILISCHUK, BRANKA LADANYI, Department of Chemistry, Colorado State University, Fort Collins, Colorado 80523-1872 — We studied the effects of confinement on static and dynamical properties of liquids including water, acetonitrile, and benzene in amorphous silica nanopores in equilibrium with the bulk liquid at ambient conditions. The model pores are approximately cylindrical, with diameters ranging from 20 to 40 Å. The filled pores are prepared using grand canonical Monte Carlo simulation and molecular dynamics simulation is used to calculate liquid structure and dynamics. Our studies of dynamics included translational mean squared displacements, orientational time correlations, and survival probabilities in interfacial shells. We also studied polarizability anisotropy time correlations that are related to experimentally observed optical Kerr effect response functions. We found that there is layering and preferential orientational ordering of solvent molecules in the interfacial region. Molecular translational and rotational mobility is reduced in the layers near the interface. Confinement leads to slowdown of the polarizability anisotropy relaxation in agreement with experimental findings.

12:03PM U42.00003 Strongly Anisotropic Dielectric Response of Confined Water , CUI ZHANG, Department of Chemistry, University of California, Davis, FRANCOIS GYGI, Department of Computer Science, University of California, Davis, GIULIA GALLI, Department of Chemistry, Department of Physics, University of California, Davis — We carried out atomistic simulations of water within hydrophobic surfaces, which revealed remarkable modifications of the dynamics and dielectric relaxation of the liquid under confinement. We found that dipolar fluctuations are modified by the presence of surfaces up to strikingly large distances, i.e., tens of nanometers. Fluctuations are suppressed by approximately an order of magnitude in the z direction, perpendicular to the interface, and are enhanced in the x-y plane, giving rise to strong anisotropies in the components of the dielectric response. Our findings are consistent with recent terahertz and ultrafast infrared pump-probe spectroscopy experiments. Work supported by DOE-CMSN DE-SC0005180.

12:15PM U42.00004 Dynamics of the fast component of nano-confined water under electric field , SOULEYMANE DIALLO, EUGENE MAMONTOV, ANDREY PODLESNYAK, GEORG EHLERS, Oak Ridge National Laboratory — We have investigated the diffusion of water molecules confined in the pores of folded silica materials (FSM), by means of quasielastic neutron scattering in the time range of 1 picosecond and 65 picoseconds. The measurements were performed on the direct geometry time-of-flight instrument CNCS at the Spallation Neutron Source, for temperatures between 220 K and 245 K, and at two electric field values, 0kV/mm and 2kV/mm. The goal was to investigate the effects of moderate electric field on the previously observed fast component of nano-confined water. In contrast to our earlier observation on the slow dynamics (at longer times) [1], the present results indicate a less drastic effect of applied electric field on the fast dynamics.

[1] S.O. Diallo, E. Mamontov, S. Inagaki, Y. Fukushima, and N. Wada, "Enhanced Translational Dynamics of Water under Electric Field" Phys. Rev. E 86, 021506 (2012).

12:27PM U42.00005 The structure of water in bulk and in confinement by total neutron and x-ray scattering , ALAN SOPER, ISIS Facility, STFC Rutherford Appleton Laboratory, UK — In the past decade or so there has been a significant worldwide effort to try to obtain a consistent set of radial distribution functions for water. Exactly how those distribution functions should be interpreted in terms of the local order in water remains a somewhat open question – whether for instance they imply water has a degree of heterogeneity in its local structure or whether it is in fact a uniform fluid with normal statistical fluctuations in density and structure. However combining a number of different x-ray and neutron data sets together is now indicating a rather consistent view of the local distribution functions in water. This consistency is achieved partly as a result of different researchers applying state-of-the-art data analysis methods to their data, both neutron and x-ray, but partly also by the application of computer simulation methods of structure refinement which help to eliminate some of the artifacts that can be introduced by uncertainties in that data analysis. The situation as regards confined water is much less clear. However it is possible to investigate water near a surface using radiation total scattering methods in the case where the pores which contain the water, whether sheet-like, cylindrical, or spherical, have a regular arrangement in the material. This is because the Bragg peaks arising from that regular arrangement are strongly affected depending on how the fluid is distributed within the pore. This talk will focus on the MCM41 silicas which have cylindrical pores on a hexagonal lattice. Combining the scattering data with computer structure refinement in the same way that is done for the bulk liquid is leading to unprecedented insight into how water is organized near the silicate surface. This work is aimed at clarifying the underlying processes that may have lead to recent observations of fragile to strong transitions in these materials.

1:03PM U42.00006 Fluctuating confinement of water in aqueous organic nanodroplets[1] , GERALD WILEMSKI, FAWAZ HRAHSHEH, Missouri University of Science and Technology — Supercooled and nano-confined water occurs frequently as nanometer-sized aqueous-organic aerosol droplets that are ubiquitous in the atmosphere and in many industrial processes. Nanodroplet structure is important because it influences droplet growth and evaporation rates, heterogeneous reaction rates, and radiative properties. We use classical molecular dynamic simulations to study the structure of ternary water-butanol-nonane nanodroplets for several temperatures and droplet sizes. We study the effects of butanol on the wetting of the water/butanol core-shell droplet by the nonane lens. At low concentrations, butanol acts as a surfactant to significantly enhance the wetability of the water droplet by nonane. At 250 K, with sufficient butanol and nonane, perfect wetting (thin film formation by nonane) occurs. Perfect wetting also occurs at higher temperatures, 270 K to 300 K, but this wetting state is progressively destabilized at higher temperature. All of the nanodroplets studied undergo distinct transitions between partial dewetting and perfect wetting states due to isothermal fluctuations in the local distribution of butanol on the surface of the water core. These fluctuations favor the wetted state at lower temperatures and the dewetted state at higher temperatures.

1:15PM U42.00007 The Effect of Contact Angle on the Depletion Layer when Water Meets a Hydrophobic Surface , ADELE POYNOR, Allegheny College — By definition hydrophobic substances hate water. Water placed on a hydrophobic surface will form a drop in order to minimize its contact area. What happens when water is forced into contact with a hydrophobic surface? One theory is that an ultra-thin low-density depletion layer forms near the surface. We investigate the effect of contact angle on depletion layer formation using the surface sensitive technique of Surface Plasmon Resonance.

1:27PM U42.00008 ABSTRACT WITHDRAWN –

1:39PM U42.00009 The dynamical relaxation: a key to understand Water Anomalies. Results from bulk and confined water , FRANCESCO MALLAMACE, Università di Messina — The anomalous behavior of thermodynamic response functions is an unsolved problem in the physics of water. The mechanism that causes the apparently indefinite increase in the heat capacity, the compressibility, and the coefficient of thermal expansion, inside the supercooled regime, is unknown. We explore this problem by analyzing both new and old experimental data coming out from the power spectrum S(Q,), on bulk and confined water at ambient pressure. On decreasing the temperature, we find that the liquid undergoes a structural transformation with the onset of an extended hydrogen bond network.Such a structure is at the basis of the marked viscoelastic behavior observed as a well defined frequency and wave vector dependence of the water sound velocity, and thus of the water response functions. All these observed properties appear consistent with the water polymorphism. We stress that, under these conditions, the thermal response functions and their corresponding fluctuations remain finite at ambient pressure. From the observation that the water density maximum dominating the system thermodynamics under ambient conditions is strongly P-dependent and disappears at a crossover pressure (P_{cross} 1.8kbar) we have studied such a variable in a wide area of the T-P phase diagram. On these basis we have considered new and old data of both the isothermal compressibility $_T$(T,P) and the coefficient of thermal expansion $_P$(T,P). In the first case the main observation is that $_T$(T) shows a minimum located at the same temperature (T_{MC} 315$\pm$5K) for all the studied pressures. As in the $_T$(T) case, also the behavior of $_P$ is surprising: all the $_P$(T) curves measured at different P cross at T_{MC}; specifically, the experimental data show a "singular and universal expansivity point" at T_{MC} 315K and $_P$(T_{MC}) 0.44 $10^{-3}K^{-1}$. Moreover, on the contrary of other water singularities we stress that such temperature has a precise thermodynamical consistence lying in the relationship connecting the two studied response functions.

Session U43 DCP: Molecules, Clusters, and Complexes Hilton Baltimore Holiday Ballroom 2 - Jeff Cina, University of Oregon

11:15AM U43.00001 Terahertz Spectroscopy of Water Vapors, Chemical Vapors and Ionized Air

, BENJAMIN GRABER, US. Naval Research Laboatory, RONGJIA TAO, Temple University, DONG HO WU, US. Naval Research Laboatory — In the past, a few research groups have demonstrated that terahertz spectroscopy could be a useful tool for the identification of chemicals. However most of those demonstrations have been done with solid-phase or liquid-phase chemicals. There are little demonstrations for the detection and identification of chemicals in the gas-phase, as it is very difficult in part due to the presence of water-absorption lines in the terahertz frequency range. As the water absorption lines predominate in the 0.1 - 2THz spectral range, and can interfere with already weak terahertz signatures generated by chemical vapors, it is often very hard to obtain meaningful terahertz spectrum of chemical vapor. Regardless we recently have been able to obtain some terahertz spectra of chemical vapors and ionized air produced by several different ionization sources, including corona discharge and nuclear isotopes. Throughout data analysis we learned that water molecules, nitrogen and oxygen molecules play very important roles in these terahertz spectra. In this presentation we will discuss our experiments and the roles of these molecules.

11:27AM U43.00002 Radiative electron attachment to molecules of astrophysical interest. Benchmark study of CN^- [1]

, VIATCHESLAV KOKOOULINE, Department of Physics, University of Central Florida, Orlando, FL, NICOLAS DOUGUET, SAMANTHA FONSECA DOS SANTOS, Department of CHMS, University of California at Davis, Davis, CA, OLIVIER DULIEU, MAURICE RAOULT, Laboratoire Aime Cotton, CNRS, Universite Paris 11, Orsay France, ANN OREL, Department of CHMS, University of California at Davis, Davis, CA, ? COLLABORATION — We have developed a first-principles approach to study the process of radiative electron attachment (REA) to linear molecules of astrophysical interest Mol $+e^- \rightarrow$ Mol$^-$ $+\hbar\omega$. (Mol$^-$ = C$_n$H$^-$, C$_n$N-). The approach is based on accurate ab initio calculations of electronic bound and continuum states of the negative ion. The electronic continuum states are obtained with the complex-Kohn variational method. The benchmark calculation for the formation of the simplest observed ion, CN-, by REA has produced a low rate coefficient, 5×10^{-17}cm^3/s at 30 K. We will present also a preliminary result for the C_4H^- formation by REA. For this molecule, the REA rate coefficient is expected is larger by about a factor of 10 due to a larger transition dipole moment. This study suggests that the negative molecular ions, recently observed in the interstellar medium, can hardly be formed by the process of radiative electron attachment.

11:39AM U43.00003 Stability and Meta-stability of Clusters in a Reactive Atmosphere: Theoretical Evidence for Unexpected Stoichiometries of Mg_MO_x [1]

, SASWATA BHATTACHARYA, SERGEY V. LEVCHENKO, LUCA M. GHIRINGHELLI, MATTHIAS SCHEFFLER, Fritz Haber Institute of the Max Planck Society — Applying genetic algorithm and replica exchange molecular dynamics in a cascade approach we calculate structure and composition of Mg_MO_x clusters at realistic temperatures and oxygen pressures. The cascade starts with force field and goes up to density functional theory with exact exchange plus correlation in the random phase approximation[2]. The stable compositions are identified using *ab initio* atomistic thermodynamics. We find that at realistic environmental conditions small clusters (M = 1-5) are in thermodynamic equilibrium when $x > M$. Non-stoichiometric clusters are found to have in general higher spin multiplicity than stoichiometric ones. This suggests a possibility of tuning magnetic properties by changing environmental conditions.

11:51AM U43.00004 First Observation of the $2^1\Pi$ state of NaH [1]

, CHIN-CHUN TSAI, Department of Physics, National Cheng-Kung University, Taiwan, HSIEN-YU HUANG, TSAI-LIEN LU, THOU-JEN WHANG, Department of Chemistry, National Cheng-Kung University, Taiwan — The upper levels (to the last bound vibrational level) of NaH $2^1\Pi$ state have been observed for the first time by using pulsed optical-optical double resonance fluorescence depletion spectroscopy. About 20 rovibrational energy levels, v=2-5 and J=1-9, were assigned to this electronic state by comparing the successive rotational spectra through selected intermediate levels of the $A^1\Sigma^+$ state. A decreased background fluorescence on the recorded spectra near the atomic asymptotic of Na(3*d*)+H(1*s*) indicates that the dissociation limit of $2^1\Pi$ state is approaching. Compared with the eigenvalues solved from the potential of Aymer's *ab* initial calculations, the vibrational quantum numbers were assigned. Un-observed lower levels (v=0 and 1) are due to the lack of Franck-Condon factor under accessible intermediate levels of the $A^1\Sigma^+$ state.

[1]We gratefully acknowledge the financial support of this work by the National Science Council, Taiwan.

12:03PM U43.00005 Probing the Electronic Structure of Small Metal-Nitride Clusters using Anion Photoelectron Spectroscopy

, CUNEYT BERKDEMIR, K.D. DASITHA GUNARATNE, SHIBO CHENG, The Pennsylvania State University, Department of Chemistry, A.W. CASTLEMAN, JR., The Pennsylvania State University, Department of Chemistry and Physics — Gas-phase spectroscopic studies have greatly enhanced our understanding of the electronic structure and chemical bonding in metal-nitrides and oxides as well as metal-halides. While photoelectron spectroscopy of negatively charged clusters is a useful technique, spectroscopic investigations concerning metal-nitrides are still scarce. To gain insights into the electronic structures of select metal-nitrides, we have investigated the structures, ground electronic states and electron affinities of niobium and tantalum mono and dinitrides by obtaining their electron binding energies and photoelectron angular distributions via a Wiley-McLaren time-of-flight mass spectrometer coupled with a velocity map imaging apparatus. The metal-nitride anions are formed by laser ablation of niobium and tantalum metal rods with a buffer gas consisting of N2 in excess argon. The formation of anionic NbNx and TaNx (x=1,2) species have been confirmed via isotopic distributions of the respective molecules. DFT calculations are performed to predict the structures, vibrational frequencies and electron affinities of the observed anions and their neutral counterparts. As an analogy, we compared the electronic properties of NbN/ZrO and TaN/WC diatomics because they have the same number of valence electron.

12:15PM U43.00006 Ab Initio Study of KCl and NaCl Clusters

, CLIFTON BROWNRIGG, AJIT HIRA, JOSE PACHECO, JUSTIN SALAZAR, Northern New Mexico College — We continue our interest in the theoretical study of molecular clusters to examine the chemical properties of small K_nCl_n and Na_nCl_n clusters (n = 2 - 15). The potentially important role of these molecular species in biochemical and medicinal processes is well known. This work applies the hybrid ab initio methods of quantum chemistry to derive the different alkali-halide (M_nH_n) geometries. Of particular interest is the competition between hexagonal ring geometries and rock salt structures. Electronic energies, rotational constants, dipole moments, and vibrational frequencies for these geometries are calculated. Magic numbers for cluster stability are identified and are related to the property of cluster compactness. Mapping of the singlet, triplet, and quintet, potential energy surfaces is performed. Calculations have been performed to examine the interactions of these clusters with some atoms and molecules of biological interest, including O, O2, and Fe. The potential for design of new medicinal drugs is explored.

12:27PM U43.00007 Structural and thermodynamic properties of Au_{2-58} clusters , YI DONG, MICHAEL SPRINGBORG, University of Saarland, INGOLF WARNKE, University of California, Irvine — The geometries and electronic properties of the isolated neutral Au_{2-58} are studied theoretically using a parametrized density-functional tight-binding method combined with genetic algorithms. Various descriptors are used in analyzing the structural and electronic properties. In addition, the temperature dependence of the vibrational heat capacities of the optimized clusters will be presented, which allow to study the low temperature properties of the clusters. We find that the vibrational heat capacity of the Au clusters is strongly size dependent in particular at low temperatures.

12:39PM U43.00008 Quantum Theoretical Study of Palladium and Silver Clusters , AJIT HIRA, JUSTIN SALAZAR, JOSE PACHECO, Northern New Mexico College — We continue our interest on the chemisorption of different atomic and molecular species on small clusters of metallic elements, by examining the interactions of H, O and F atoms with Pd_n and Ag_n clusters (n = 2 thru 12). Transition-metal clusters can be useful for the study of quantum size effects and for formation of metallic states, and are ideal candidates for catalytic processes. Hybrid ab initio methods of quantum chemistry (particularly the DFT-B3LYP model) are used to derive optimal geometries for the clusters of interest. We compare calculated binding energies, bond-lengths, ionization potentials, electron affinities and HOMO-LUMO gaps for the clusters of the two different metals. Of particular interest are the comparisons of binding strengths at the three important types of sites: edge (E) sites, hollow sites (H) site and on-top (T) sites. Effects of crystal symmetries corresponding to the bulk structures for the two metals will also be investigated. The implications for the molecular dissociation of the H_2 and O_2 species will be considered.

12:51PM U43.00009 First principles NEXAFS simulations of N-donor Uranyl complexes , C.D. PEMMARAJU, Molecular Foundry, LBNL, R. DUAN, Peking University, China, R. COPPING, Chemical Sciences Division, The Glenn T. Seaborg Center, LBNL, B. JEON, Computational Research Division, LBNL, S.J. TEAT, Advanced Light Source, LBNL, M. JANOUSCH, Laboratory for Synchrotron Radiation, Paul Scherrer Institute, Switzerland, T. TYLISZCZAK, Advanced Light Source, LBNL, A. CANNING, N. GRØNBECH-JENSEN, Computational Research Division, LBNL, D.K. SHUH, Chemical Sciences Division, The Glenn T. Seaborg Center, LBNL, D. PRENDERGAST, Molecular Foundry, LBNL — The synthesis and study of soft-donor uranyl complexes can provide new insights into the coordination chemistry of non-aqueous $[UO]2^+$ Recently, the tunable N-donor ligand 2,6-Bis(2-benzimidazyl)pyridine (BBP) was employed to produce novel uranyl complexes in which the $[UO]2^+$ cation is ligated by anionic and covalent groups with discrete chemical differences. In this work we investigate the electronic structure of the three such uranyl-BBP complexes via near-edge X-ray absorption fine structure (NEXAFS) experiments and simulations using the eXcited electron and Core-Hole (XCH) approach [1]. The evolution of the structural as well as electronic properties across the three complexes is studied systematically. Computed N K-edge and O K-edge NEXAFS spectra are compared with experiment and spectral features assigned to specific electronic transitions in these complexes. Studying the variations in spectral features arising from N K-edge absorption provides a clear picture of ligand-uranyl bonding in these systems. References: [1] D. Prendergast and G. Galli, X-ray absorption spectra of water from first-principles calculations, Phys. Rev. Lett., 215502 (2006).

1:03PM U43.00010 Electronic structure and charge transfer states of a multichromophoric heptad[1] , LUIS BASURTO, RAJENDRA ZOPE, TUNNA BARUAH, University of Texas at El Paso — A multichromophoric Heptad molecule containing Zn-tetraphenyl porphyrin, BDPY dye, bisphenyl anthracene, and C_{60} attached to a hexaphenyl -benzene core was synthesized by Gust et al. (J. Phys. Chem. B, 113, 7147 (2009)). The snowflake like molecule behaves like an antenna capturing photons at different wavelengths and transferring the energy to the porphyrin. We present a DFT based study on the ground state of the complex and also on the lowest two charge transfer (CT) states of the complex carried out using a perturbative delta-SCF method. The calculations, done using a mixed all-electron and pseudo-potential approach, show that the ionization potential of porphyrin and the electron affinity of C_{60} in the complex changes significantly from isolated molecules. Our calculated value of the lowest CT state is within 0.2 eV of the experimental estimate. This CT state contains a hole on porphyrin HOMO and a particle on the C_{60} LUMO. A comparison of the energetics with experiment indicates that the process probably involves excitation from the HOMO-1 of porphyrin to the porphyrin LUMO followed by electron transfer and hole bubbling up resulting in a CT state with the hole on porphyrin HOMO and particle on C_{60} LUMO.

1:15PM U43.00011 The effect of structural conformations and solvent effects in a light-harvesting Carotenoid-diaryl-Porphyrin-C_{60} (CPC_{60}) molecular triad on the charge transfer excitation energies[1] , TUNNA BARUAH, MARCO OLGUIN, RAJENDRA ZOPE, University of Texas at El Paso — We present a detailed study of charge transfer (CT) excited states for a large number of structural conformations in a light-harvesting Carotenoid-diaryl-Porphyrin-C_{60} (CPC_{60}) molecular triad. The molecular triad undergoes a photinduced charge transfer state exhibiting a large excited state dipole moment, making it suitable for application as a molecular-scale optoelectronic device. One important consideration is that the conformational flexibility of the CPC_{60} triad impacts its dynamics in solvents. Since many experimental photochemical measurements for the traid are made in solution, studying the effect of conformational changes on the CT energy furthers the understanding of its photoconversion properties. We have calculated a few low lying CT excited state energies for a series of triad conformers, where the conformers were generated by incrementally scanning a 360 degree torsional (dihedral) twist at the C_{60}-porhyrin linkage and the porphyrin-cartotenoid linkage. The CT excitation energy was calculated at each 45 degree dihedral increment. Addtionally, several different CPC_{60} conformations were taken from molecular dynamics simulations of the triad in water and other solvents of varying polarity. Our calculations show that structural change

1:27PM U43.00012 Chemical Nonlinearities and Radical Pair Lifetime Estimation , GREGORY ROBINSON, University of Colorado Boulder — Much attention has recently developed around chemical reactions that depend on applied static magnetic fields as weak as earth's. This interest is largely motivated by experiments that implicate the role of spin-selective radical pair recombination in biological magnetic sensing. Existing literature uses a straightforward calculation to approximate the expected lifetime of coherent radical pairs as a function of the minimum RF amplitude that is observed to disrupt magnetic navigation, apparently by decohering the radical pair via electronic Zeeman excitations. But we show that chemical nonlinearities can preclude direct computation of coherent pair lifetime without considering the cellular signalling mechanisms involved, and discuss whether it can explain the surprising fragility of some animals' compass sense. In particular, we demonstrate that an autocatalytic cycle can introduce threshold effects on the disruption sensitivity to applied oscillatory magnetic fields. We will show examples in the mean-field limit and consider the consequences of noise and fluctuations in the Freidlin-Wentzell picture of perturbed dynamical systems.

1:39PM U43.00013 Analysis of direct and indirect phonon-mediated bond excitation in the explosive RDX , BRENT KRACZEK, PETER W. CHUNG, US Army Research Laboratory — Understanding detonation pathways is essential to controlling the sensitivity of high energy explosives. Central to these pathways is initiation, the initial chemical reactions that lead to detonation. Phonons play an active role in initiation caused by compressive wave energy, such as those caused by shock loading, by converting the wave energy to thermal energy that causes bond-breaking. In the conventional model for phonon-mediated initiation energy follows an indirect route, in which the wave energy excites low-frequency phonons which in turn excite higher-frequency vibrons that break the key initial bonds in the chemical decomposition pathways. Using lattice dynamics calculations of α-RDX (the crystalline α-phase of cyclotrimethylene trinitramine), we find that a direct route of energy transfer is more likely. We have calculated the total energy available to different phonon modes and the fractions of the mode energies that go into the bonds of the material. This enabled approximation of the maximum and minimum energy exciting the bonds due to different phonon modes throughout thermal relaxation. We find that low-frequency modes provide significantly more energy than high-frequency modes to the key bonds, implying that the direct pathway is responsible.

1:51PM U43.00014 The first-principles study on the electronic and optical properties of $(Ga_{1-x}Zn_x)(N_{1-x}O_x)$ from many-body perturbation theory , HIROKI KAWAI, GIACOMO GIORGI, The University of Tokyo, MAURIZIA PALUMMO, The University of Rome "Tor Vergata", KOICHI YAMASHITA, The University of Tokyo — Gallium zinc oxynitride $(Ga_{1-x}Zn_x)(N_{1-x}O_x)$ is one of the promising candidates as overall water-splitting photocatalyst under visible light. In 2005, the high photocatalytic activity was reported on the GaN-rich alloys[1] and nowadays, the ZnO-rich ones with the higher visible-light absorption were also synthesized by some groups[2, 3]. Thus the further improvement of the photocatalytic water splitting is being expected. In spite of such a huge potential of this material, the origin of the visible-light absorption is not well understood. The first-principles methods based on many-body perturbation theory (MBPT), GW approximation and Bethe-Salpether equation, combining with density functional theory, enable us to do reliable analysis of the electronic and optical properties. On this meeting, we will discuss the origin of visible-light absorption of $(Ga_{1-x}Zn_x)(N_{1-x}O_x)$ by MBPT results focusing on the non-isovalent character. [1]K. Maeda. et al. *J.Am.Chem.Soc.* 127, 8286 (2005), [2]H. Chen. et al. *J.Phys.Chem.C*, 114, 1809 (2010), [3]K. Lee. et al. *Nano Lett*, 12, 3268 (2012)

2:03PM U43.00015 ABSTRACT WITHDRAWN –

Thursday, March 21, 2013 11:15AM - 2:15PM –

Session U44 DBIO: Focus Session: Physics of Single-Cell Heterogeneity Hilton Baltimore Holiday Ballroom 1 - Wolfgang Losert, University of Maryland College Park

11:15AM U44.00001 Single-molecule RNA observation in vivo reveals dynamics of co-transcriptional splicing , M.L. FERGUSON, A. COULON, NIH, Bethesda, MD, V. DE TURRIS, Albert Einstein College of Medicine, Bronx, NY, M. PALANGAT, C.C. CHOW, NIH, Bethesda, MD, R.H. SINGER, Albert Einstein College of Medicine, Bronx, NY, D.R. LARSON, NIH, Bethesda, MD — The synthesis of pre-mRNA and the splicing of that pre-mRNA to form completed transcripts requires coordination between two large multi-subunit complexes (the transcription elongation complex and the spliceosome). How this coordination occurs in vivo is unknown. Here we report the first experimental observation of transcription and splicing occurring at the same gene in living cells. By utilizing the PP7/MS2 fluorescent RNA reporter system, we can directly observe two distinct regions of the nascent RNA, allowing us to measure the rise and fall time of the intron and exon of a reporter gene stably integrated into a human cell line. The reporter gene consists of a beta globin gene where we have inserted a 24 RNA hairpin cassette into the intron/exon. Upon synthesis, the RNA hairpins are tightly bound by fluorescently-labeled PP7/MS2 bacteriophage coat proteins. After gene induction, a single locus of active transcription in the nucleus shows fluorescence intensity changes characteristic of the synthesis and excision of the intron/exon. Using fluctuation analysis, we determine the elongation rate to be 1.5 kb/min. From the temporal cross correlation function, we determine that splicing of this gene must be co-transcriptional with a splicing time of $\sim$100 seconds before termination and a $\sim$200 second pause at termination. We propose that dual-color RNA imaging may be extended to investigate other mechanisms of transcription, gene regulation, and RNA processing.

11:27AM U44.00002 Cellular volume is a global controller of mRNA abundance , OLIVIA PADOVAN-MERHAR, University of Pennsylvania, Department of Physics and Astronomy, ARJUN RAJ, University of Pennsylvania, Department of Bioengineering — Many researchers have observed large variability in the numbers of RNA and protein molecules from cell to cell, a phenomenon thought to result from random bursts of transcription. These findings hold even for genes involved in core cellular processes, raising questions as to how cells can function in the presence of such molecular noise. However, biochemical processes typically depend on concentrations of cellular constituents rather than absolute numbers, so we use RNA fluorescence in situ hybridization to measure mRNA counts and cellular volume in single cells. We find that while both mRNA numbers and volume vary widely between cells, mRNA density does not. Thus, for many genes, mRNA abundance is precisely controlled to match the volume of the cell, as though the genes know how big the cell is. We measure transcription on a global and single-gene scale, and find that transcriptional activity scales with volume, suggesting that density is regulated at a transcriptional level. We present a mathematical model explaining which transcriptional bursting parameters account for the presence or lack of density conservation. Our findings suggest that global properties of RNA dynamics require a reassessment of our understanding of cellular heterogeneity and stochastic gene expression.

11:39AM U44.00003 Protocols for discriminating sources of intrinsic noise in gene expression , NIRAJ KUMAR, RAHUL KULKARNI, Department of Physics, University of Massachusetts Boston, Boston, MA 02125 — The intrinsic stochasticity of gene expression leads to heterogeneity of protein levels across a population of cells. Different molecular mechanisms have been proposed that contribute to this variability in protein levels. Among these are Poissonian fluctuations of mRNAs, promoter fluctuations based on a random telegraph process, and general waiting-time distributions ("gestation") for the arrival of mRNAs. Given these different sources, an important problem in the field is the development of protocols for discriminating the dominant molecular mechanisms giving rise to the observed noise. Considering the "burst" limit (for which mRNA lifetimes are much shorter than protein lifetimes) we develop protocols for discriminating the sources of intrinsic noise based on accessible experimental measurements. Computational validation of these protocols indicates that they could lead to promising experimental approaches for discriminating the sources of intrinsic noise in gene expression.

11:51AM U44.00004 Relating Single Cell Heterogeneity To Genotype During Cancer Progression , SATWIK RAJARAM, Green Center For Computational and Systems Biology, Department of Pharmacology, University of Texas Southwestern Medical Center — Progression of normal cells towards cancer is driven by a series of genetic changes. Traditional population-averaged measurements have found that cell signalling activities are increasingly altered during this progression. Despite the fact that cancer cells are known to be highly heterogeneous, the response of individual pathways to specific genetic changes remains poorly characterized at a single cell level. Do signalling alterations in a pathway reflect a shift of the whole population, or changes to specific subpopulations? Are alterations to pathways independent, or are cells with alterations in one pathway more likely to be abnormal in another due to crosstalk? We are building a computational framework that analyzes immunofluorescence microscopy images of cells to identify alterations in individual pathways at a single-cell level. A primary novelty of our approach is a "change of basis" that allows us to understand signalling in cancer cells in terms of the much better understood patterns of signalling in normal cells. This allows us to model heterogeneous populations of cancer cells as a mixture of distinct subpopulations, each with a specific combination of signalling pathways altered beyond the normal baseline. We used this framework to analyze human bronchial epithelial cell lines containing a series of genetic modifications commonly seen in lung cancer. We confirmed expected trends (such as a population-wide epithelial mesenchymal transition following the last of our series of modifications) and are presently studying the relation between the mutational profiles of cancer cells and pathway crosstalk. Our framework will help establish a more natural basis for future investigations into the phenotype-genotype relationship in heterogeneous populations.

12:27PM U44.00005 Mapping chromatin modifications in nanochannels , SHUANG FANG LIM, ALENA KARPUSENKO, ROBERT RIEHN, North Carolina State University — DNA and chromatin are elongated to a fixed fraction of their contour length when introduced into quasi-1d nanochannels. Because single molecules are analyzed, their hold great potential for the analysis for the genetic analysis of material from single cells. In this study, we have reconstituted chromatin with histones from a variety of sources, and mapped the modification profile of the chromatin. We monitored methylation and acetylation patterns of the histone tail protein residues using fluorescently labelled antibodies. Using those, we distinguished chromatin reconstituted from chicken erythrocytes, calf thymus, and HeLa cells. We discuss prospects for profiling histone modifications for whole chromosomes from single cells.

12:39PM U44.00006 What is Growth? Concurrent determination of a bacterial population's many shades of growth , GUILLAUME LAMBERT, University of Chicago, EDO KUSSELL, New York University — One of the most exciting developments in the study of the physics of microbial life is the ability to precisely monitor stochastic variations of gene expression in individual cells. A fundamental question is whether these variations improve the long-term ability of a population to adapt to new environments. While variations in gene expression in bacteria are easily measured through the use of reporter systems such as green fluorescent proteins and its variants, precise determination of a cell's growth rate, and how it is influenced by its immediate environment, remains challenging. Here, we show that many conflicting and ambiguous definitions of bacterial growth can actually be used interchangeably in E. coli. Indeed, by monitoring small populations of E. coli bacteria inside a microfluidic device, we show that seemingly independent measurements of growth (elongation rate and the average division time, for instance) agree very precisely with one another. We combine these definitions with the population's length and age distribution to very precisely quantify the influence of temperature variations on a population's growth rate. We conclude by using coalescence theory to describe the evolution of a population's genetic structure over time.

12:51PM U44.00007 Noise in Exponential Growth , SRIVIDYA IYER-BISWAS, James Franck Institute, UChicago, CHARLES WRIGHT, JON HENRY, STAS BUROV, Univ of Chicago, YIHAN LIN, Caltech, SEAN CROSSON, Univ of Chicago, AARON DINNER, NORBERT SCHERER, James Franck Institute, UChicago — The interplay between growth and division of cells is has been studied in the context of exponential growth of bacterial cells (in suitable conditions) for decades. However, bulk culture studies obscure phenomena that manifest in single cells over many generations. We introduce a unique technology combining microfluidics, single-cell imaging, and quantitative analysis. This enables us to track the growth of single Caulobacter crescentus stalked cells over hundreds of generations. The statistics that we extract indicate a size thresholding mechanism for cell division and a non-trivial scaling collapse of division time distributions at different temperatures. In this talk I shall discuss these observations and a stochastic model of growth and division that captures all our observations with no free parameters.

1:03PM U44.00008 From Molecules to Cells to Organisms: Understanding Health and Disease with Multidimensional Single-Cell Methods , JULIÁN CANDIA, University of Maryland (College Park & Baltimore) — The multidimensional nature of many single-cell measurements (e.g. multiple markers measured simultaneously using Fluorescence-Activated Cell Sorting (FACS) technologies) offers unprecedented opportunities to unravel emergent phenomena that are governed by the cooperative action of multiple elements across different scales, from molecules and proteins to cells and organisms. We will discuss an integrated analysis framework to investigate multicolor FACS data from different perspectives: Singular Value Decomposition to achieve an effective dimensional reduction in the data representation, machine learning techniques to separate different patient classes and improve diagnosis, as well as a novel cell-similarity network analysis method to identify cell subpopulations in an unbiased manner. Besides FACS data, this framework is versatile: in this vein, we will demonstrate an application to the multidimensional single-cell shape analysis of healthy and prematurely aged cells.

1:39PM U44.00009 Stochastic Cell Fate Progression in Embryonic Stem Cells[1] , LING-NAN ZOU, ADELE DOYLE, SUMIN JANG, SHARAD RAMANATHAN, FAS Center for Systems Biology, Harvard University — Studies on the directed differentiation of embryonic stem (ES) cells suggest that some early developmental decisions may be stochastic in nature. To identify the sources of this stochasticity, we analyzed the heterogeneous expression of key transcription factors in single ES cells as they adopt distinct germ layer fates. We find that under sufficiently stringent signaling conditions, the choice of lineage is unambiguous. ES cells flow into differentiated fates via diverging paths, defined by sequences of transitional states that exhibit characteristic co-expression of multiple transcription factors. These transitional states have distinct responses to morphogenic stimuli; by sequential exposure to multiple signaling conditions, ES cells are steered towards specific fates. However, the rate at which cells travel down a developmental path is stochastic: cells exposed to the same signaling condition for the same amount of time can populate different states along the same path. The heterogeneity of cell states seen in our experiments therefore does not reflect the stochastic selection of germ layer fates, but the stochastic rate of progression along a chosen developmental path.

1:51PM U44.00010 Exact protein distributions for stochastic models of gene expression , RAHUL KULKARNI, Department of Physics, UMass Boston, HODJAT PENDAR, Department of Engineering Science and Mechanics, Virginia Tech, THIERRY PLATINI, Department of Applied Mathematics, Coventry University, UK — Stochasticity in gene expression gives rise to variations in protein levels across a population of genetically identical cells. Such fluctuations can drive phenotypic variation in clonal populations, hence there is considerable interest in quantifying noise in gene expression using stochastic models. However, obtaining exact analytical results for protein distributions has been an intractable task for all but the simplest models. We develop a novel mapping that significantly simplifies the analysis of stochastic models of gene expression. Using this mapping, we derive exact analytical results for steady-state and time-dependent protein distributions for the basic 2-stage model of gene expression. Considering extensions of the basic model, we obtain exact protein steady-state distributions for models that include the effects of post-transcriptional and post-translational regulation. The approach developed in this work is widely applicable and can contribute to a quantitative understanding of stochasticity in gene expression and its regulation.

2:03PM U44.00011 An Experimental Determination of Static Magnetic Fields Induced Noise in Living Systems , MEGAN BRADY, CRAIG LARAMEE, Binghamton University — Living systems are constantly exposed to static magnetic fields (SMFs) from both natural and man-made sources. Exposures vary in dose and duration ranging from geomagnetic ($\sim$50μT) to residential and industrial ($\sim$10s of mT) fields. Efforts to characterize responses to SMFs have yielded conflicting results, showing a dependence on experimental variables used. Here we argue that low to moderate SMF exposure is a sub-threshold perturbation operating below thermal noise, and assays that evaluate statistical characteristics of a single cell may identify responses not consistently found by population averaging approaches. Recent studies of gene expression show that it is a stochastic process capable of producing bursting dynamics. Moreover, theoretical and experimental methods have also been developed to allow quantitative estimates of the associated biophysical parameters. These developments provide a new way to assess responses of living systems to SMFs. In this work, we report on our efforts to use single molecule fluorescence *in situ* hybridization to assess responses of NIH-3T3 cells to SMF exposure at flux densities ranging from 1 to 440 mT for 48 hours. Results will contribute to determining mechanisms by which SMF exposure influences gene expression.

Thursday, March 21, 2013 11:15AM - 2:15PM –

Session U45 DBIO: Focus Session: Cell Mechanics II Hilton Baltimore Holiday Ballroom 4 - Helim Aranda-Espinoza, University of Maryland

11:15AM U45.00001 Regulation of Cellular Tension in Adherent Cells , PATRICK OAKES, University of Chicago — Cells generate stress on their surrounding extracellular matrix (ECM) via myosin II motor generated forces which are transmitted through the actin cytoskeleton. The mechanisms in the cell which regulate the magnitude and spatial distribution of these stresses, however, remain unknown. Consistent with previous reports, we find that the total magnitude of traction force exerted on the ECM scales with cell size. Such scaling is observed across numerous cell types and reflects an inherent cellular tension determined by the level of myosin II activity. Surprisingly, while stiffness modulates the cellular spread area, we find this scaling relationship to be independent of ECM stiffness. To identify the biophysical mechanisms regulating the generation of tension, we utilize micro-patterning to isolate cell spread area from cell geometry and to spatially control the distribution of stress on the ECM. We find that traction stress magnitude is dependent on the local curvature of the cell. Changes in cell geometry result in a redistribution of local stresses, but little change in the total stress applied to the ECM. Finally, for a constant geometry, we find that both the total stress and the average stress exerted on the ECM increase with cell area. Together these data suggest that the cell can be modeled as a uniformly contracting mesh, where the magnitude of tension is regulated by the cell spread area, and the distribution of tension is regulated by local geometry.

11:51AM U45.00002 Mechanical Coupling of Smooth Muscle Cells Using Microengineered Substrates and Local Stimulation[1] , CRAIG COPELAND, DAVID HUNTER, LESLIE TUNG, The Johns Hopkins Universty, CHRISTOPHER CHEN, University of Pennsylvania, DANIEL REICH, The Johns Hopkins Universty — Mechanical stresses directly affect many cellular processes, including signal transduction, growth, differentiation, and survival. Cells can themselves generate such stresses by activating myosin to contract the actin cytoskeleton, which in turn can regulate both cell-substrate and cell-cell interactions. We are studying mechanical forces at cell-cell and cell-substrate interactions using arrays of selectively patterned flexible PDMS microposts combined with the ability to apply local chemical stimulation. Micropipette "spritzing", a laminar flow technique, uses glass micropipettes mounted on a microscope stage to deliver drugs to controlled regions within a cellular construct while cell traction forces are recorded via the micropost array. The pipettes are controlled by micromanipulators allowing for rapid and precise movement across the array and the ability to treat multiple constructs within a sample. This technique allows for observing the propagation of a chemically induced mechanical stimulus through cell-cell and cell-substrate interactions. We have used this system to administer the acto-myosin inhibitors Blebbistatin and Y-27632 to single cells and observed the subsequent decrease in cell traction forces. Experiments using trypsin-EDTA have shown this system to be capable of single cell manipulation through removal of one cell within a pair configuration while leaving the other cell unaffected.

12:03PM U45.00003 Contractile Film Model for Polymorphism in Adherent Cells , SHILADITYA BANERJEE, Department of Physics, Syracuse University, LUCA GIOMI, International School for Advanced Studies (SISSA), Trieste, Italy — The optimal shapes attained by contractile cells on elastic substrates are determined by the crosstalk between intracellular forces and extracellular forces of adhesion. We model an adherent stationary cell as a contractile film bounded by an elastic cortex and connected to the substrate via elastic links. When the adhesion sites are continuously distributed, optimal cell shape is constrained by the adhesion geometry, with a spread area sensitively dependent on the substrate stiffness and contractile tension. For discrete adhesion sites, equilibrium cell shape is convex at weak contractility, while developing local concavities at intermediate values of contractility. Increasing contractility beyond a critical value, controlled by substrate stiffness, cell contour undergoes a discontinuous transition to a star-shaped configuration with cusps and protrusions, accompanied by a region of bistability and hysteresis.

12:15PM U45.00004 Unidirectional Contact guidance via surface nanotopography[1] , WOLFGANG LOSERT, XIAOYU SUN, MEGHAN DRISCOLL, CAN GUVEN, JOHN FOURKAS, University of Maryland — Unidirectional cell migration plays a key role in many critical physiological processes. Guidance of cells in a preferred direction has been explored in the context of chemotaxis and durotaxis. However, a stable field of gradient within a dynamic range needs to be maintained to achieve persistent unidirectional guidance. Hence the spatial extent of gradient sensing is limited. Contact guidance on the other hand can be achieved on surfaces with large spatial extent without changes in guidance efficiency. However, contact guidance is generally bidirectional. Here we demonstrate that unidirectional guidance efficiency is achievable by nanofabrication of asymmetrically shaped surfaces. We analyze cell velocity and orientation, as well as the dynamic changes in cell shape in response to surface topography.

12:27PM U45.00005 Biphasic cell responses on laterally mobile films[1] , ANDREAS KOUROUKLIS, Chemical Eng., Umass- Amherst, RONALD LERUM, HARRY BERMUDEZ, Polymer Science and Eng., Umass- Amherst — The engineering of polymer surfaces or matrices that are capable of controlling cell adhesion has been widely explored. In nearly all of these works, the polymer chains (and ligands) are chemically attached to the underlying substrate, and therefore these systems are inherently static. By contrast, cellular environments such as the extracellular matrix (ECM) are dynamic and remodeled by biochemical reactions and biophysical forces. Borrowing this concept from Nature, we created polymer films by an interfacial self-assembly process, whereby individual chains can exhibit lateral mobility (in-plane diffusive motion). NIH 3T3 fibroblasts seeded on such RGD-presenting polymer films show biphasic responses in spreading and adhesion strength to lateral mobility, with a minimal response for intermediate mobility values. Futhermore, preliminary immuno-staining experiments reveal that the total area of focal adhesions demonstrates a similar biphasic trend to the cellular-scale behaviors. In contrast, actin filaments or stress fibers appear to be unaffected by the substrate lateral mobility. These results show that lateral mobility is an important, although not fully explored aspect of mechano-sensing by cells, and can potentially give new perspectives on cell-ECM interactions.

12:39PM U45.00006 Remote, In-Plane Mechanosensing by Cells on Thin Floating Collagen Matrices[1] , HAMID MOHAMMADI, University of Toronto, PAUL JANMEY, University of Pennsylvania, CHRISTOPHER MCCULLOCH, University of Toronto — The mechanical properties of the extracellular matrix impact many cellular functions but little is known about the contribution of matrix deformations to cellular mechanosensing that extends beyond the immediate cell-matrix interface. We examined remote mechanosensing by developing a cell culture model that employs collagen gels circumferentially supported by nylon mesh frames that float on culture medium. This approach obviates mechanical interference from the underlying rigid foundation of tissue culture plastic and enables assessment of remote, in-plane mechanosensing. With this model we found that 3T3 cells rapidly formed cellular processes whose lengths and number per cell depended on the frame opening size. When the opening sizes were increased (from 200 μm to 1700 μm widths) mean cell extension length, mean number of extensions per cell, and the sum of cell extension lengths significantly decreased (40-60%; $p < 0.0001$). In grids of 200 μm and 500 μm widths, cells sensed the presence of nylon frames because cell-generated deformation fields extended to the grid boundaries while this did not occur in grids of 1700 μm width. This new model demonstrates the ability of cells to sense remotely, variations of matrix stiffness in the absence of a rigid underlying substrate.

12:51PM U45.00007 The Crawling Cell as a Brownian Inchworm , MOUMITA DAS, Rochester Institute of Technology, J.M. SCHWARZ, Syracuse University — Cell migration is integral to several physiological processes such as immune response, wound healing, tissue formation, fertilization etc. Previous studies, both theoretical and experimental, have attempted to model different aspects of cell migration, including adhesion, protrusion and retraction at the level of single cells, and collective motion at the multicellular level. The entire motility process of a single cell and its ability to navigate a landscape containing obstacles is, however, not well understood. We attempt to address this issue by modeling a single moving cell as a Brownian inchworm composed of two beads attached by a spring that can sense and respond to the mechanical properties and architecture of its environment. The elastic interaction between inchworm and the substrate is modeled by molecular clutches. We study the dynamics of this inchworm in a corrugated potential. In particular we focus on the interplay between confinement and adhesion in the motility of this inchworm. This model may provide important insights on cell movement through a biological maze of other cellular and extracellular structures.

1:03PM U45.00008 Frequency- dependent cell responses to an electromagnetic stimulus[1] , TOLOO TAGHIAN, ABDUL SHEIKH, DARIA NARMONEVA, ANDREI KOGAN, University of Cincinnati — External electric field (EF) acting on cells in the ionic environment can trigger a variety of mechanical and chemical cell responses that regulate cell functions, such as adhesion, migration and cell signaling; thus manipulation of EF can be used in therapeutic applications. To optimize this process, realistic studies of EF interaction with cells are essential. We have developed a combined theoretical-experimental approach to study cell response to the external EF in the native configuration. The cell is modeled as a membrane-enclosed hemisphere which is cultured on a substrate and is surrounded by electrolyte. Maxwell's equations are solved numerically (ANSYS-HFSS) to obtain 3D EF distribution inside and near the cell subjected to an external EF. Theoretical results indicate that the cell response is frequency dependent, where at low frequency EF is excluded from the cell interior while EF penetration into the cell increases for higher frequencies. In both regimes the spatial distribution and strength of induced EF in membrane varies with frequency. Experimental results are consistent with theoretical predictions and show frequency-dependent cell response, including both membrane-initiated and intracellular pathway activation and growth factor release.

1:15PM U45.00009 Measuring and modeling cellular contact guidance through dynamic sensing of nanotopography , CAN GUVEN, MEGHAN DRISCOLL, XIAOYU SUN, JOHN FOURKAS, WOLFGANG LOSERT, University of Maryland — We investigate the shape dynamics of the amoeba Dictyostelium discoideum on nanotopographical gratings. Multiple studies have previously implicated the patterning of focal adhesion complexes (FACs) in contact guidance. However, we observe significant contact guidance of Dictyostelium along ridge-shaped nano- and microtopographic surface features, even though Dictyostelium lacks FACs. We measure the surface contact guidance efficiency, which we calculate from the statistics of cell orientations, as a function of the distance between parallel ridges. Ridges with a spacing of about 1.5 μm lead to the greatest contact guidance efficiency. We previously observed that Dictyostelium cells exhibit oscillatory shape dynamics. Therefore, we model contact guidance as a resonance between the cell oscillations and the nanogratings. In particular, we model cells as stochastic cellular harmonic oscillators that couple to the periodicity of the ridges. The spatial and temporal scales of the oscillations that best couple to the surface are consistent with those of protrusive dynamics. Our results suggest that the coupling of protrusive dynamics, which are governed by actin dynamics, to surface topography is one possible mechanism for contact guidance.

1:27PM U45.00010 Interaction of mechanical and electrical oscillations and sensitivity in a model of sensory hair cell , RAMI M. AMRO, ALEXANDER B. NEIMAN, Department of Physics and Astronomy/Ohio University — Sensory hair cells are the first stage in conveying the mechanical stimuli into the electrical signals in auditory and vestibular organs of vertebrates. Experiments showed that hair cells rely on active processes in hair bundles to achieve high selective sensitivity, e.g. due to myosin molecular motors inside stereocilia. In lower vertebrates these active processes result in spontaneous oscillations of hair bundles which can be accompanied by oscillations of the cells' membrane potentials. We use modeling to study how the dynamics of both the membrane potential and the hair bundle interact to produce coherent self-sustained oscillations and how this interaction contributes to the cell's sensitivity to external mechanical perturbations. The model incorporates a mechanical stochastic hair bundle system coupled to a Hodgkin-Huxley type system for the membrane potential. We show that oscillatory regimes result in enhanced sensitivity and selectivity to harmonic stimuli.

1:39PM U45.00011 Polyacrylamide scaffolds for studying cellular response to substrate stiffness in three dimensions , KENG-HUI LIN, Institute of Physics, Academia Sinica, Taipei, Taiwan — Recent developments in two-dimensional (2D) culture substrates with tunable stiffness and patterned adhesion ligands have demonstrated that biochemical and mechanical cues regulate the biological functions of living cells. We have extended these cell culture platforms into three dimensions (3D), as in complex biological systems, by producing highly ordered scaffolds of polyacrylamide coated with extracellular matrix proteins. We characterized parameters for the scaffold fabrication. We then grew individual fibroblasts in the identical pores of our scaffolds, examing cellular morphological, cytoskeletal, and adhesion properties. We have observed rich variety of morphologies and anchoring strategies assumed by cells growing on our tunable 3D polyacrylamide scaffolds to demonstrate the richness of cell-mciroenvironment interactions when cell adhesions are not confined to 2D surfaces.

1:51PM U45.00012 Cell migration under ultrasound irradiations in micrometer scale , SHINYA MURAKAMI, YO OTSUKA, Graduate school of Bioscience, Aoyamagakuin University, YUSUKE OSHIMA, Translational Research Center, Ehime University Hospital, ATSUHIKO HIKITA, Graduate School of Medicine, Ehime University, TOSHIYUKI MITSUI, Graduate school of Bioscience, Aoyamagakuin University — Cell movements, migration play an important role in many physiological processes including cell proliferation and differentiation. C2C12, a line of mouse myoblasts is known to differentiate into osteoblast under appropriate conditions. Therefore, C2C12 cells can be chosen for the differentiation studies. However, the movement of the C2C12's has not been fully investigated although the movements may provide a better understanding of the healing processes of bone repair, regeneration and differentiation. In addition, low intensity ultrasound has been thought and used to promote bone fracture healing although the microscopic mechanism of this healing is not well understood. As a first step, we have investigated single cell migration of C2C12 under optical microscopy with and without ultrasound irradiations. The ultrasound is irradiated from an apex of a sharp needle. The frequency is 1.5 MHz and the power intensity is near 24 mW/cm^2. These values were similar to the ultrasound treatment values. In this conference, we will show the influence of the ultrasound irradiation on the cell movement by plotting the mean squared displacement and the velocity autocorrelation function as a function of time.

2:03PM U45.00013 Scaffold-independent Patterning of Cells using Magnetic Nanoparticles , SUVOJIT GHOSH, Department of Engineering Science and Mechanics, Virginia Tech, MOANARO BISWAS, SUBBIAH ELANKUMARAN, Department of Biomedical Sciences and Pathobiology, Virginia-Maryland Regional College of Veterinary Medicine, ISHWAR PURI, Department of Engineering Science and Mechanics, Virginia Tech — Spatial patterning of cells in vitro relies on direct contact of cells on to solid surfaces. Scaffold independent patterning of cells has never been achieved so far. Patterning of cells has wide applications including stem cell biology, tissue architecture and regenerative medicine besides fundamental biology. Magnetized cells in a suspension can be manipulated using an externally applied magnetic field enabling directed patterning. We magnetized mammalian cells by internalization of superparamagnetic nanoparticles coated with bovine serum albumin (BSA). A magnetic field is then used to arrange cells in a desired pattern on a substrate or in suspension. The control strategy is derived from the self-assembly of magnetic colloids in a liquid considering magnetostatic interactions. The range of achievable structural features promise novel experimental methods investigating the influence of tissue shape and size on cell population dynamics wherein Fickian diffusion of autocrine growth signals are known to play a significant role. By eliminating the need for a scaffold, intercellular adhesion mechanics and the effects of temporally regulated signals can be investigated. The findings can be applied to novel tissue engineering methods.

Session U46 GIMS: Focus Session: Advances in Scanned Probe Microscopy 2: High Frequencies and Optical Techniques Hilton Baltimore Holiday Ballroom 5 - Robert McMichael, NIST

11:15AM U46.00001 Edge mode imaging in magnetic nanodisks using ferromagnetic resonance force microscopy , FENG GUO, National Institute of Standards and Technology, University of Maryland — Edge modes are trapped spin wave modes that can form at film edges. The spontaneous localization of edge modes makes them fine probes of edge properties and test objects for magnetic resonance imaging. We use ferromagnetic resonance force microscopy (FMRFM) to study the edge modes in magnetic nanodisks with an improved resolution of less than 100 nm. In this presentation we will describe imaging and spectroscopy of the normal modes in Permalloy disks, manipulation of edge modes to characterize the disk edges, and the disk-diameter dependence of the spectrum. Micromagnetic modeling of a 500 nm diameter, 25 nm thick disk predicts a main mode that is nearly uniform across the sample and three edge modes with higher resonance fields. The spectra measured with various tip positions are consistent with the modeling results. Besides the broad center mode, three distinct edge modes are observed and appear when the tip is near the disk edge. However, in contrast to the symmetric edge behavior predicted by the modeling, the measured left and right edge modes are detected at different resonance fields, suggesting inhomogeneity of the edge properties. By rotating the applied field, we are able to move the localized edge mode along the edge of a single structure and thus probe the inhomogeneity in edge properties. The fundamental edge mode with the highest resonance field is most sensitive to the edge inhomogeneity while the center mode is relatively isotropic. The disk size dependence of the edge mode is also investigated for disk diameters ranging from 100 nm to 750 nm. The number of trapped edge modes reduces with decreasing disk size in agreement with micromagnetic modeling.

11:51AM U46.00002 Magnetic imaging with shallow spins in nitrogen delta-doped diamond[1] , BRYAN A. MYERS, JENS BOSS, Physics Department, University of California, Santa Barbara, KENICHI OHNO, Materials Department, University of California, Santa Barbara, PREETI OVARTCHAIYAPONG, DAVID D. AWSCHALOM, ANIA C. BLESZYNSKI JAYICH, Physics Department, University of California, Santa Barbara — Nitrogen-vacancy (NV) electronic spins in diamond are atomic-size sensors of magnetism at the nanoscale. Shallow NVs with long spin coherence times (T_2) are desirable for ultrasensitive magnetometry. However, T_2 tends to decrease for shallow NVs, which couple most strongly to external spins. To optimize magnetic sensitivity, it was recently shown that delta-doping nitrogen during chemical vapor deposition of single-crystal diamond (SCD) can produce films with a < 5 nm thick layer of NVs that retain long T_2 [1]. Here, using a magnetic field gradient produced by a scanning probe, we investigate optically-detected magnetic resonance measurement protocols to simultaneously determine the relative and absolute depths of the NVs in SCD films containing multiple doped layers separated by a few nm. A consistent comparison of NV properties, such as T_2, versus depth is important for engineering spin placement. Furthermore, this magnetic field gradient technique enables sub-diffraction imaging of NV centers, which itself will be explored for high resolution NV-based magnetometry. [1] K. Ohno et al., Appl. Phys. Lett. 101, 082413 (2012).

12:03PM U46.00003 Nanoscale Fourier-transform magnetic resonance imaging , JOHN NICHOL, TYLER NAIBERT, WILLIAM ROSE, University of Illinois at Urbana-Champaign, ERIC HEMESATH, LINCOLN LAUHON, Northwestern University, RAFFI BUDAKIAN, University of Illinois at Urbana-Champaign — Magnetic resonance force microscopy is a promising technique for nanoscale magnetic resonance imaging, but the detection sensitivity must still be improved to reach the single proton level. Multiplexed imaging schemes, such as Fourier encoding, are used in clinical magnetic resonance imaging for sensitivity enhancement. Here, we report a method for Fourier encoding nanoscale samples, where statistical fluctuations dominate the spin polarization. The protocol uses periodic encoding pulses to create correlations in the spin fluctuations. We demonstrate this technique using a silicon nanowire mechanical oscillator as a force sensor to image ^{1}H spins in a polystyrene sample. The sample is encoded using pulsed magnetic field gradients generated by a nanoscale current-carrying wire. We reconstruct a 2-dimensional projection of the proton density in the sample with 10 nm resolution.

12:15PM U46.00004 On infrared and terahertz imaging of surface plasmons in high-Tc superconductors , H.T. STINSON, Z. FEI, University of California - San Diego, A.S. RODIN, Boston University, A.S. MCLEOD, M.M. FOGLER, D.N. BASOV, University of California - San Diego — Recent scattering-mode scanning near-field optical microscopy (s-SNOM) experiments have imaged surface plasmons in graphene at infrared frequencies.[1] The scanning probe launches surface plasmons and detects their standing-wave interference pattern upon reflection from the sample edge. The surface plasmon dispersion relation directly relates the standing wave fringe separation and amplitude decay to the optical constants of the sample. We have modeled surface plasmon s-SNOM imaging for high-Tc superconductor (HTSC) thin films. Our results indicate that surface plasmons can be imaged in HTSCs at frequencies near or below the superconducting gap. This would allow for a direct measurement of HTSC optical constants below the gap. For known HTSCs such as YBCO, this is in the far-IR or terahertz range. Our simulations show that this method can also distinguish between superconducting and normal states at the nanoscale.

12:27PM U46.00005 Quantifying the Stochastic Dynamics of the Elastic Probe used in Cavity Optomechanical Force Micropscopy , STEPHEN EPSTEIN, MARK PAUL, Virginia Tech — Atomic force microscopy has revolutionized surface science and is now as essential tool for micro and nanoscale studies in science and engineering. Cavity optomechanical force microscopy consists of an atomic force microscopy probe that is placed in close proximity to a microfabricated optical cavity. The interaction between the probe and the optical cavity is used to quanitfy the probe dynamics. Cavity optomechaincal force microscopy extends conventional atomic force microscopy by being more sensitive with increased frequency resolution. In many situations of interest the probe operates while immersed in a viscous fluid which can strongly affect the probe dynamics. In this talk we quantify the stochastic dynamics of the elastic probe when driven by Brownian motion where the dominant source of dissipation is the surrounding viscous fluid. We use deterministic finite-element numerical simulations with the fluctuation-dissipation theorem to quantify the stochastic dynamics of the probe for the precise conditions and geometries used in current experiments.

12:39PM U46.00006 Enhanced Electroluminescence from A Nanocavity Due to Dynamical Coupling of Plasmonic and Molecular Emissions[1] , XIAOGUANG LI, Fudan University, GONG CHEN, ZHENCHAO DONG, Univ. of Sci. and Tech. of China, JIAN SHEN, Fudan University, ZHENYU ZHANG, Univ. of Sci. and Tech. of China — We investigate the electroluminescence from a nanocavity formed by a luminescent molecule within the tip-substrate junction of a scanning tunneling microscope. The light emissions from the molecular luminescence and plasmonic radiation are evaluated using respectively a density matrix approach and classical electromagnetic theory. The molecular luminescence is described in two different components: the radiation associated with the excited states effectively pumped by the tunneling electrons and the spontaneous emission enhanced by the plasmonic field. In particular, by explicitly treating the near field of the plasmons, we explore in detail the dynamical coupling between the plasmonic and molecular emissions, and identify conditions for enhanced electroluminescence. We discuss these results in comparison with experiments.

[1]Supported by NSF and MOST of China

12:51PM U46.00007 Measurement of optical force in plasmonic resonant cavities using dynamic mode AFM , DONGSHI GUAN, ZHIHONG HANG, Department of Physics, The Hong Kong University of Science and Technology (HKUST), ZSOLT MARCET, Department of Physics, University of Florida, HUI LIU, Department of Physics, Nanjing University, IVAN KRAVCHENKO, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, CHETING CHAN, HOBUN CHAN, PENGER TONG, Department of Physics, HKUST* — We report an experimental study of the optical force induced by a plasmonic resonance mode in metallic cavities using dynamic mode atomic force microscopy (AFM). The plasmonic cavity is made of a (upper) gold coated glass sphere and a (lower) quartz substrate patterned with an array of gold disks, whose diameter d varies from 250 to 750 nm. The gold coated sphere is glued to an AFM cantilever, by which we measure the optical force acted on the sphere using AFM and phase-sensitive lock-in amplifier. With this technique the sensitivity of the force measurement is significantly increased to $\sim$0.1 pN, which may have many applications in precise force measurement. The measured optical force is found to have a strong resonance dependence on the cavity separation r, as well as the diameter of gold disk d. The conventional optical force obtained in the far-field (r>3μm) for different values of d agrees well with the measured transmission. In the near-field (r<0.5μm), resonance is excited in the plasmonic cavity and the induced force by an infrared laser is found to be increased by an order of magnitude compared with the photon pressure generated by the same laser light. *Work supported by the Research Grants Council of Hong Kong SAR.

1:03PM U46.00008 Nano-FTIR: infrared spectroscopic chemical identification of materials at the nanoscale , FLORIAN HUTH, Neaspec GmbH, Martinsried, Germany, ALEXANDER GOVYADINOV, CIC Nanogune Consolider, Donostia-San Sebastian, Spain, SERGIU AMARIE, Neaspec GmbH, Martinsried, Germany, WIWAT NUANSING, CIC Nanogune Consolider, Donostia-San Sebastian, Spain, FRITZ KEILMANN, Dept. of Physics and CeNS, LMU Munich, Garching, Germany, RAINER HILLENBRAND, CIC Nanogune Consolider, Donostia-San Sebastian, Spain — Recently, we applied the principles of FTIR to scattering-type Scanning Near-field Optical Microscopy (s-SNOM). s-SNOM employs an externally illuminated sharp metallic tip to create a nanoscale hot-spot at its apex which greatly enhances the near-field interaction between the probing tip and the sample. The light backscattered from the tip transmits the information about this near-field interaction to the far zone where the FTIR spectra can be recorded. The result is a novel nano-FTIR technique, which is capable to perform near-field spectroscopy and imaging with nanoscale resolution. Here we demonstrate nano-FTIR with a coherent-continuum infrared light source. We show that the method can be used to determine the fingerprint IR absorption spectrum of organic samples with a spatial resolution of 20 nm. Corroborated by theory, the nano-FTIR absorption spectra correlate well with conventional FTIR absorption spectra, as experimentally demonstrated with PMMA samples. Nano-FTIR can thus make use of standard infrared databases of molecular vibrations to identify organic materials in ultra-small quantity and at ultrahigh spatial resolution.

1:15PM U46.00009 Broadband vibrational nano-spectroscopy with a synchrotron infrared source[1] , HANS A. BECHTEL, Lawrence Berkeley National Laboratory, ROBERT L. OLMON, ERIC A. MULLER, BENJAMIN POLLARD, MARKUS B. RASCHKE, University of Colorado, Boulder, MICHAEL C. MARTIN, Lawrence Berkeley National Laboratory — Scattering-scanning near-field optical microscopy (s-SNOM) is capable of providing chemical contrast with deep sub-wavelength spatial resolution of a few 10's of nanometers. Unfortunately, the wide applicability of the technique has been hindered by the lack of suitable broadly-tunable or broadband IR sources that can provide the necessary high spectral irradiance. Here, we demonstrate broadband, Fourier-transform infrared spectroscopic s-SNOM using infrared synchrotron radiation from the Advanced Light Source (ALS). We show near-field spectra spanning the full mid-infrared, including the fingerprint absorption region (700 cm^{-1} — 4000 cm^{-1}) and spectroscopic multi-modal imaging in combination with laser-based IR sources. We discuss the potential of the approach for a wide range of soft and hard matter nanoscale spectroscopic applications.

[1]The Advanced Light Source is supported by the Director, Office of Science, Office of Basic Energy Sciences, of the U.S. Department of Energy under Contract No. DE-AC02-05CH11231.

1:27PM U46.00010 The Lightning Rod Model: a Genesis for Quantitative Near-Field Spectroscopy , ALEXANDER MCLEOD, University of California San Diego, GREGORY ANDREEV, Bruker Nano Surfaces Division, GERARDO DOMINGUEZ, California State University San Marcos, MARK THIEMENS, MICHAEL FOGLER, D.N. BASOV, University of California San Diego — Near-field infrared spectroscopy has the proven ability to resolve optical contrasts in materials at deeply sub-wavelength scales across a broad range of infrared frequencies. In principle, the technique enables sub-diffractional optical identification of chemical compositions within nanostructured and naturally heterogeneous samples. However current models of probe-sample optical interaction, while qualitatively descriptive, cannot quantitatively explain infrared near-field spectra, especially for strongly resonant sample materials. We present a new first-principles model of near-field interaction, and demonstrate its superb agreement with infrared near-field spectra measured for thin films of silicon dioxide and the strongly phonon-resonant material silicon carbide. Using this model we reveal the role of probe geometry and surface mode dispersion in shaping the measured near-field spectrum, establishing its quantitative relationship with the dielectric properties of the sample. This treatment offers a route to the quantitative determination of optical constants at the nano-scale.

1:39PM U46.00011 Interferometric Scanning Microwave Microscope for Nanotechnology Application[1] , NICOLAS CLEMENT, THOMAS DARGENT, IEMN-CNRS (France), HASSAN TANBAKUCHI, Agilent Santa Rosa (US), KATSUHIKO NISHIGUCHI, NTT Basic Research Labs (Japan), RAGAVENDRAN SIVAKUMARASAMY, FEI WANG, IEMN-CNRS (France), AKIRA FUJIWARA, NTT Basic Research Labs (Japan), DAMIEN DUCATTEAU, GILLES DAMBRINE, DOMINIQUE VUILLAUME, BERNARD LEGRAND, DIDIER THÉRON, IEMN-CNRS (France) — Scanning probe microscopes (SPMs) allow scientists to image, characterize and even manipulate material structures at exceedingly small scales including features of atomic dimensions. Although most microelectronics devices operate at high frequency, SPMs have mainly been used with electrical excitation at DC (Conducting Atomic Force Microscope) or kHz (Electric Force Microscope, Kelvin Force Microscope). The main reason is that at GHz frequency, nanoscale objects are far from the standard impedance of 50ohms and almost all the signal is reflected. Here we show, using an interferometer to enable extraction and amplification of the signal of interest, that Scanning Microwave Microscopes (SMM) are ideal tools for tiny capacitances imaging. We demonstrate applications in several fields of nanotechnology with capacitance evaluation down to aF of nanoscale integrated capacitors, biased nanotransistors, molecular junctions and biomolecule flow in a nanofluidic channel. The frequency range of excitation varied from 2 GHz to 20 GHz. With a finite element analysis, we discuss the limits of such microscope.

[1]Support from Agilent University grant, CPER CIA, Equipex Excelsior.

1:51PM U46.00012 Highly enhanced green emission of ZnO via plasmonic resonance of a tungsten tip , HUIQI GONG, XIAODONG GUO, LI DONG, Beijing National Laboratory for Condensed-Matter Physics and Institute of Physics, Chinese Academy of Sciences, NAN XIE, Photonics Center, College of Physics Science, Nankai University, SHICHAO YAN, XINYAN SHAN, YANG GUO, JIMIN ZHAO, Beijing National Laboratory for Condensed-Matter Physics and Institute of Physics, Chinese Academy of Sciences, QIAN SUN, Photonics Center, College of Physics Science, Nankai University, XINGHUA LU, Beijing National Laboratory for Condensed-Matter Physics and Institute of Physics, Chinese Academy of Sciences — We present a systematic investigation of the photoluminescence of a single crystal ZnO with the aid of a metallic tungsten tip in a pulse laser assisted scanning tunneling microscope. When excited with 740nm laser pulses and as the tip approaches ZnO surface up to the tunneling region ($\sim$ 1nm), an enhancement in green emission (centered at 560nm), up to a factor of 70, is observed. The photoluminescence is a two-photon excitation process, which is evident by the observation of the second-harmonic peak of excitation light and the up-converted luminescence. By measuring the green emission intensity as a function of incidence power, wavelength, and tip-sample distance, we illustrate the critical role of plasmonic resonance of the tungsten tip for the enhanced green emission. The observed broad plasmonic response (680nm to 1080nm) implies possible applications in designing novel solar cells with the aid of tungsten plasmon.

2:03PM U46.00013 Single & Multiprobe Apertureless Thermal Imaging of Electromagnetic Excitation Over A Wide Range of Wavelengths , RIMMA DEKHTER, Nanonics Imaging Ltd., AARON LEWIS, Hebrew University of Jerusalem, Dept of Applied Physics & Benin School of Engineering & Computer Science, SOPHIA KOKOTOV, PATRICIA HAMRA, BOAZ FLEISCHMAN, HESHAM TAHA, Nanonics Imaging Ltd. — Near-field optical effects have generally been detected using photodetectors. There are no reports on the use of the temperature changes caused by electromagnetic radiation using thermal sensing probes for scanned probe microscopy. In this paper we apply our development of such probes to monitor the effects of electromagnetic radiation at a number of different wavelengths using the heating caused in a sample by specific wavelengths and their propagation. The paper will catalogue effects over a wide spectrum of wavelengths from the near to mid infrared. The thermal sensing probes are based on glass nanopipettes that have metal wires that make a contact at the very tip of a tapered glass structure. These probes are cantilevered and use normal force tuning fork methodology to bring them either into contact or near-contact since this feedback method has no jump to contact instability associated with it. Data will be shown that defines the resolution of such thermal sensing to at least the 32 nm level. In addition the probes have the important attribute of having a highly exposed tip that allows for either optical sensing methodologies with a lens either from directly above or below or heat sensing with a single or additional probe in a multiprobe scanning probe system.

Session U47 DBIO GSNP: Invited Session: Controlling Biological Networks Hilton Baltimore Holiday Ballroom 6 - Albert-Laszlo Barabasi, Northeastern University/Harvard Medical School

11:15AM U47.00001 Hard limits on control in fluctuating systems , JOHAN PAULSON, Systems Biology, Harvard University — All intracellular processes involve components present in low numbers, creating spontaneous fluctuations that in turn can enslave the components present in high numbers. The mechanisms are often complex, with reaction rates that depend nonlinearly on concentrations, indirect feedback loops, and distributed delays. Most systems are also sparsely characterized, with a few steps known in detail but many important interactions not even identified. I will present exact analytical mathematical frameworks for deriving limits on behavior in such systems, for example showing how hard it is to tightly control processes that involve bursts, delays, or finite signaling rates - regardless of the nature of the downstream chemical networks. I will also discuss various ways of designing experiments to rigorously exploit conditional independences in fluctuations to infer underlying mechanisms, without having to guess the nature of feedback loops or interacting processes.

11:51AM U47.00002 Controllability and observability of biological systems , YANG-YU LIU, Northeastern University and Dana-Farber Cancer Institute — The ultimate proof of our understanding of complex biological systems is reflected in our ability to control them. Although control theory offers mathematical tools for steering engineered systems towards a desired state, a framework to control complex biological systems is lacking. In this talk I will show that many dynamic properties of complex biological systems can be quantitatively studied, via a combination of tools from control theory, network science and statistical physics. In particular, I will focus on two dual concepts, i.e. controllability and observability, of general complex biological systems. Controllability concerns our ability to drive the system from any initial state to any final state within finite time, while observability concerns the possibility to deduce the system's internal state from observing its input-output behavior. I will show that by exploring the underlying network structure of complex biological systems one can determine the driver (or sensor) nodes that with time-dependent inputs (or measurements) will enable us to fully control (or observe) the whole system.

12:27PM U47.00003 Epigenetics and Why Biological Networks are More Controllable than Expected , ADILSON MOTTER, Northwestern University — A fundamental property of networks is that perturbations to one node can affect other nodes, potentially causing the entire system to change behavior or fail. In this talk, I will show that it is possible to exploit this same principle to control network behavior. This approach takes advantage of the nonlinear dynamics inherent to real networks, and allows bringing the system to a desired target state even when this state is not directly accessible or the linear counterpart is not controllable. Applications show that this framework permits both reprogramming a network to a desired task as well as rescuing networks from the brink of failure, which I will illustrate through various biological problems. I will also briefly review the progress our group has made over the past 5 years on related control of complex networks in non-biological domains.

1:03PM U47.00004 Control of cancer-related signal transduction networks , REKA ALBERT, Pennsylvania State University — Intra-cellular signaling networks are crucial to the maintenance of cellular homeostasis and for cell behavior (growth, survival, apoptosis, movement). Mutations or alterations in the expression of elements of cellular signaling networks can lead to incorrect behavioral decisions that could result in tumor development and/or the promotion of cell migration and metastasis. Thus, mitigation of the cascading effects of such dysregulations is an important control objective. My group at Penn State is collaborating with wet-bench biologists to develop and validate predictive models of various biological systems. Over the years we found that discrete dynamic modeling is very useful in molding qualitative interaction information into a predictive model. We recently demonstrated the effectiveness of network-based targeted manipulations on mitigating the disease T cell large granular lymphocyte (T-LGL) leukemia. The root of this disease is the abnormal survival of T cells which, after successfully fighting an infection, should undergo programmed cell death. We synthesized the relevant network of within-T-cell interactions from the literature, integrated it with qualitative knowledge of the dysregulated (abnormal) states of several network components, and formulated a Boolean dynamic model. The model indicated that the system possesses a steady state corresponding to the normal cell death state and a T-LGL steady state corresponding to the abnormal survival state. For each node, we evaluated the restorative manipulation consisting of maintaining the node in the state that is the opposite of its T-LGL state, e.g. knocking it out if it is overexpressed in the T-LGL state. We found that such control of any of 15 nodes led to the disappearance of the T-LGL steady state, leaving cell death as the only potential outcome from any initial condition. In four additional cases the probability of reaching the T-LGL state decreased dramatically, thus these nodes are also possible control targets. Our collaborators validated two of these predicted control mechanisms experimentally. Our work suggests that external control of a single node can be a fruitful therapeutic strategy.

1:39PM U47.00005 Controllability of Complex Systems , JEAN-JACQUES SLOTINE, Nonlinear Systems Laboratory and Departments of Mechanical Engineering; Brain and Cognitive Science, Massachusetts Institute of Technology — We review recent work on controllability of complex systems. We also discuss the interplay of our results with questions of synchronization, and point out key directions of future research.

Work done in collaboration with Yang-Yu Liu, Center for Complex Network Research and Departments of Physics, Computer Science and Biology, Northeastern University and Center for Cancer Systems Biology, Dana-Farber Cancer Institute; and Albert-László Barabási, Center for Complex Network Research and Departments of Physics, Computer Science and Biology, Northeastern University; Center for Cancer Systems Biology, Dana-Farber Cancer Institute; and Department of Medicine, Brigham and Women's Hospital, Harvard Medical School.

V1.00004 Examining Stratocumulus Properties over the Southeast Pacific , ISABEL MCCOY, New Mexico Tech, ANDREAS MUHLBAUER, JISAO, ROBERT WOOD, University of Washington — Variability in Stratocumulus (Sc) clouds is important to the planetary albedo and radiation budget because of the resulting range in reflection of incoming shortwave radiation back to space, thereby cooling the atmosphere differently. Understanding more of their micro and macro physical properties is essential to reduce uncertainty in global climate model prediction and add confidence in future climate predictions. Sc clouds have been characterized into four main categories based on their morphology and level of mesoscale organization (Wood and Hartmann, 2006). Working with satellite data from NASA's CloudSat and Goes 10 in combination with these occurrence identifications, we developed statistics on the microphysical characteristics for each cloud type. Comparisons are drawn between our results and aircraft data sampling the region of interest (the VOCALS Regional Experiment over the Southeast Pacific in 2008). We conclude that this is a feasible method of characterizing satellite data to derive pertinent results about Sc clouds.

V1.00005 Man-Made "Global Warming/Climate Change": A Critical Analysis of some of the Scientific and Methodological Approaches

, LAURENCE I. GOULD, University of Hartford — Many arguments have been made that – as a result of human activities which emit greenhouse gases (mainly carbon dioxide) – there is a trend of increasing global temperatures so as to result in such physical events as melting glaciers, rising sea levels, and increased storms. This presentation will examine some of the arguments given for such a trend in the light of corresponding counter-arguments [1].

[1] The 2011 Interim Report from the Nongovernmental International Panel on Climate Change – http://www.nipccreport.org/reports/2011/2011report.html (most of the research reported here appears in peer-reviewed science journals)

V1.00006 METALS AND METALLICS ALLOYS —

V1.00007 Atomistic analysis of short range interaction and local chemical order in LPSO structures of Magnesium alloys

, MARCO FRONZI, HAJIME KIMIZUKA, KAZUKI MATSUBARA, SHIGENOBU OGATA, Osaka University — Magnesium alloys have been object of interest as lightweight material with high strength weight ratio. In particular Long Period Stacking Ordered (LPSO) structure phases show to have a strong influence in enhancing mechanical properties of such kind alloys. However the chemical order of the interacting atomic species in the Mg lattice has not been fully understood. We perform first principles Density Functional Theory (DFT) calculation to compute formation energies as well as interaction energies of the doping atoms in both Faced Centered Cubic (FCC) and Hexagonal Close Packed (HCP) Mg lattices. In particular we consider the Mg-Al-Gd and Mg-Zn-Y ternary systems. We also calculate activation energies for vacancy assisted doping atoms diffusion in order to perform a further analysis of the kinetics of the process. In order to describe short range interaction and cluster formation in the Mg matrix, we build an on lattice potential based on first principles DFT interaction energies. By means of these inter-atomic potentials, we perform Monte Carlo simulations to analyze the chemical order occurring in LPSO Mg-Al-Gd structures.

V1.00008 Measurement of semi-rigid coaxial cables at cryogenic temperature -thermal conductance and attenuation-

, SOICHI KASAI, COAX CO., LTD., AKIHIRO KUSHINO, Asahikawa National College of Technology — We are developing semi-rigid coaxial cables for low temperature experiments which require fast readout with low noise. Coaxial cables used at low temperature are made of low thermal conductivity materials, such as stainless-steel, cupro-nickel and polytetrafluoroethylene to suppress heat penetration through cables. As the thermal conductivity of such alloys is affected by the thermal and mechanical treatment in forming process, we have to measure thermal property of coaxial cables after forming. The low thermal conductance of 5.5 cm specimen was measured by the steady-state heat-flow method with 1m long and thin niobium-titanium wiring for thermometers and heaters. Signal attenuation of coaxial cables was measured at 3K stage of an adiabatic demagnetization refrigerator. In order to cool center electrical conductor, the cables with 1m long length were coiled, and surrounded by copper blocks then attached to 3K stage. We successfully observed superconducting transition of center conductor of superconducting niobium-titanium coaxial cables with this method.

V1.00009 Analytical Expression for a Pseudo-Potential in Alkali Metals

, GREGORIO RUIZ-CHAVARRIA, Universidad Autonoma Chapingo — In previous works [1-3] using a local first principles pseudo-potential, have been calculated inter-ionic potential and thereafter different properties have been obtained from simple metals as phonon dispersion curves, phonon spectra, specific heats properly. The pseudo-potential is constructed from the electron density, which is previously calculated by the density functional theory. All this process is carried out numerically. The pseudo-potential has a similar behavior in the alkali metals and then we propose an analytical expression for it, which depends on the parameter rs, the atomic number and two additional parameters. This analytical pseudo-potential is used to calculated phonon dispersion curves, which are in good agreement with existing experimental reports, it is expected that the other properties calculated based on this pseudo-pontencial match with the experimental results.

V1.00010 Measurement of Optical, Mechanical and Transport properties of the hexagonal closed packed 4H polytype of metallic silver

, INDRANI CHAKRABORTY, Tata Institute of Fundamental Research, Mumbai, India, SHARMILA N. SHIRODKAR, JNCASR, Bangalore, India, SMITA GOHIL, Tata Institute of Fundamental Research, Mumbai, India, UMESH WAGHMARE, JNCASR, Bangalore, India, PUSHAN AYYUB, Tata Institute of Fundamental Research, Mumbai, India — Optical, mechanical and transport property measurements were done on the hexagonal closed packed (hcp) 4H polytype of Ag with stacking sequence ABCBABCB.. grown as bulk films on Al_2O_3 substrates. Diffused reflectance measurements done on the 4H films showed a general loss of reflectivity amounting to a decrease of 35% as compared to normal fcc (3C) Ag near 500 nm with a blueshift of 5nm in the bulk plasmon frequency, possibly due to the modified electronic structure of the hcp form. Raman spectroscopic measurements showed the appearance of a peak at 64.3 cm^{-1} at 4K which underwent "Mode softening," that is shifted to lower wave numbers with increase of temperature and disappeared above 350K. Low temperature transport measurements done on 4H films gave the in-plane resistivity value to be 39 times higher than that of a similarly synthesized fcc Ag film at 295 K. Vicker's microhardness measurements done on the 4H films showed that the 4H samples to be almost 5 times harder than the 3C Ag. Density functional theory simulations were done to obtain the phonon dispersion, band structure and nature of Fermi surface for the 4H Ag which corroborated with the experimental observations. The 4H form appears to be a much less metallic, darker and harder form of Ag.

V1.00011 Molecular Dynamics Simulation Of The Energetic Reaction Between Ni And Al Nanoparticle Aggregates

, JACOB SPARKS, TAKUMI HAWA, The University of Oklahoma — Molecular Dynamics simulations are used to simulate the energetic reaction of Ni and Al particles at the nanometer scale. The effect of particle size and structures on reaction time and temperature for Ni and Al separate nanoparticles has been considered. The differences in melting temperature and phase change behavior between Al and Ni are expected to produce differing results for the nanoparticle aggregates systems. Simulation results show that the sintering time increases with increasing mass of the aggregates and with decreasing the fractal dimension of the aggregate. The final temperature of the systems increases with decreasing the primary particle sizes when mass of the aggregates remains unchanged. The phenomenological model is a power law including a dependence on the number of particles in an aggregates and fractal dimension is also developed.

V1.00012 Electronic structure and high-temperature lattice dynamics of B2-ordered FeTi

, JORGE MUNOZ, LISA MAUGER, California Institute of Technology, MATTHEW LUCAS, Air Force Research Laboratory, BRENT FULTZ, California Institute of Technology — FeTi is a brittle, non-magnetic B2-ordered (CsCl-type) intermetallic alloy with an electronic structure similar to that of Cr. The Fermi level lays in a deep pseudo-gap and therefore, the bonding and anti-bonding orbitals are well separated. Inelastic neutron and x-ray scattering were used to measure the phonon spectra at temperatures up to 1035 K. Complementary measurements up to pressures of 47 GPa were used to obtain quasi-harmonic Grüneisen parameters. Ab-initio calculations of the force constants and Born-von Kármán fits to the data show that the bonds between second nearest neighbors are much stiffer than that those between first nearest neighbors, but the rate of softening with temperature is higher for the second nearest neighbors. A comparison with the high-pressure data shows this softening to be anharmonic. A simple model relating the symmetry of the orbitals to that of the crystal structure is presented to explain the stiffness of the bonds between second nearest neighbors, while the decrease in the asphericity of the orbitals due to thermal electronic excitations is used to explain the discrepancy in the rate of softening with temperature.

V1.00013 COMPLEX STRUCTURED MATERIALS, INCLUDING GRAPHENE –

V1.00014 Electric-field-dependent plasmons in AA-stacked bilayer graphene , YING-CHIH CHUANG, JHAO-YING WU, MING-FA LIN, Department of Physics, National Cheng Kung University, Tainan 701, Taiwan, CMPL TEAM — The collective excitations in AA-stacked bilayer graphene for a perpendicular electric field are investigated analytically within the tight-binding model and the random-phase approximation. Such a field destroys the uniform probability distribution of the four sublattices. This drives a symmetry breaking between the intralayer and interlayer polarization intensities in the intrapair band excitations. A field-induced acoustic plasmon thus emerges in addition to the strongly field-tunable intrinsic acoustic and optical plasmons. At long wavelengths, the three modes show different dispersions and field dependence. The definite physical mechanism of the electrically inducible and tunable mode can be expected to also be present in other AA-stacked few-layer graphenes.

V1.00015 Radicals in Graphene Oxide: Formation and Relaxation Properties , DONALD HIRSH, LYLE NOLASCO, The College of New Jersey, MICHELE VITTADELLO, KAMIL WORONOWICZ, Medgar Evers College of CUNY, MANISH CHHOWALLA, Rutgers - The State University of New Jersey — Unpaired electron spins are observed in both graphene and graphene oxide but their origins remain uncertain. We apply electron paramagnetic resonance (EPR) spectroscopy to the study of graphene oxide produced by modified Hummer's method. A narrow radical signal easily saturated at cryogenic temperatures is observed. Treatment of graphene oxide with mild reductant results in the production of additional radicals of the same linewidth and g-value. We propose that radicals are generated when epoxide rings adjacent to graphene islands open through one-electron reduction and provide preliminary data in support of this claim. The EPR spectra and relaxation properties of graphene oxide in the solid-state and dispersed in water are also compared. This comparison suggests the presence of exchange coupling between radicals on adjacent graphene oxide particles in the solid state.

V1.00016 Plasmonic heat transfer between graphene and dielectric substrate , DAN YOU, SLAVA V. ROTKIN, Physics Department and Center for Advanced Materials and Nanotechnology, Lehigh University — This work focuses on the near-field heat transfer between graphene monolayer and a dielectric substrate by taking into account the coupling of the surface plasmon- and phonon-polaritons in graphene and in the substrate respectively. The surface plasmon and phonon polaritons are coupled to the bulk optical phonons in the substrate and in graphene that constitute thermal reservoirs, to which the surface modes are strongly coupled. We assume that the reservoirs are large and have a short relaxation time scale. The surface modes are affected by coupling to reservoir, and their energy is irreversibly dissipated into the reservoir. The frequency-dependent relaxation rate of the surface plasmon and phonon polaritons is further derived within the nonequilibrium Green's function method. Finally the calculation of the heat conductance between graphene and substrate is presented.

V1.00017 Synthesis of phosphorous-doped graphene by ambient pressure chemical vapor deposition , ANUPAMA GHOSH, RUITAO LV, NESTOR PERERA LOPEZ, AYSE BERKDEMIR, ANA LAURA ELÍAS, HUMBERTO TERRONES, Department of Physics, The Pennsylvania State University, MAURICIO TERRONES, The Pennsylvania State University, Shinshu University — Although theoretical calculations have demonstrated that phosphorous (P) doping of graphene could open the largest band gap and could possess excellent properties to become an ideal toxic gas sensor, it has not been synthesized experimentally. We have successfully synthesized large-area, monolayered P-doped graphene by an ambient pressure chemical vapor deposition (AP-CVD). In particular, triphenyl phosphene (TPP) dissolved in hexane with different concentrations of TPP has been used as phosphorous-carbon precursor. Raman spectroscopy is used extensively for characterizing the different synthesized materials. The intensity ratio of D, D', 2D and G bands and their associated shifts provide information related the nature and doping levels. The strong D-band and a prominent D'-band confirms the occurrence of doping by P-substitution. The doped graphene sheets have also been characterized by high-resolution transmission electron microscopy (HRTEM) and X-ray photoelectron spectroscopy (XPS). In addition, results on the use of these P-doped graphene in molecular sensing will be discussed.

V1.00018 Adsorption of ammonium on a pyridine-like nitrogen-doped graphene layer decorated with a monovalent atom , LUIS FERNANDO MAGANA, JUAN M. RAMIREZ, GERARDO JORGE VAZQUEZ, Instituto de Fisica, UNAM — Density functional theory and molecular dynamics were used to study the interaction of an NH_4 molecule with a pyridine-like nitrogen-doped (PNG) surface. The surface is decorated with an impurity taken from the first row of the periodic table. In this way, we considered six different atoms: H, Li, Na, K, Rb and Cs, to decorate the system. We found two final configurations. One, is with the NH_4 molecule physisorbed around the impurity. In the second situation, one hydrogen atom of the ammonium molecule, is adsorbed around a nitrogen atom of the surface. The remaining NH_3 molecule stays physisorbed on the system. The final configuration depends on the initial position of the NH_4 molecule. In all decoration cases, the system was allowed to follow an evolutionary process using molecular dynamics at 300 K, and atmospheric pressure.

V1.00019 Interaction of ammonium with a pyridine-like nitrogen-doped graphene (PNG) surface , LUIS FERNANDO MAGANA, JUAN M. RAMIREZ, GERARDO JORGE VAZQUEZ, Instituto de Fisica, UNAM — We used density functional theory, with the local density approximation, and molecular dynamics, within the Born-Oppenheimer approximation. We considered the initial position of ammonium just above the PNG vacancy, at 300 K. We performed our calculations using the Quantum Espresso code. The unit cell we considered has one vacancy per twenty-eight carbon atoms, with three nitrogen atoms, and one ammonium molecule. It is found that the PNG vacancy adsorbed strongly one hydrogen atom from the ammonium molecule. Afterwards, the remaining ammonia molecule desorbs.

V1.00020 Cracking Large-Area Gragphene into Controlled Patterns , XUANHE ZHAO, Duke University — Fracture of single atomic layers, especially graphene, has attracted increasing interests in physics and engineering over recent years. While existing studies are mainly focused on cases with individual cracks, fracture patterns in single atomic layers have been rarely explored. Here, we present a combined experimental and theoretical study on fracture and fragmentation of single-atomic-layer graphene on substrates. Our *in situ* observations show that deforming the substrates can crack large-area graphene films into patterns of long ribbons and rectangular fragments with controlled sizes. We use the shear-sliding theory to characterize the stress and deformation of graphene on substrates and carry out Monte Carlo simulations of the fragmentation process. The theoretical model matches consistently with experimental results. Our study further provides a simple method to obtain large amounts of data for statistical strengths of graphene and graphene-polymer interfaces. These properties are of fundamental importance to graphene-based materials and devices, yet extremely challenging to be measured with existing methods.

V1.00021 Anisotropic etching effect in graphene for its nanostructure engineering and defect detection , RONG YANG, ZHIWEN SHI, SHUANG WU, DONGXIA SHI, GUANGYU ZHANG, Institute of Physics, Chinese Academy of Sciences — We report a highly anisotropic dry etching technique for graphene. The etching depends strongly on its crystal orientation, resulting in zigzag-edge formation. The etching rates can be precisely controlled to several nm/min by plasma intensity and temperature. The etching only starts at defect sites and the quality of graphene can be preserved. This simple technique is compatible with existing semiconductor processing technology, thus it is useful for large-scale graphene tailoring and defect detection. We have fabricated graphene nanoribbons (GNRs) along designed crystallographic directions, which have shown high nobilities and smooth zigzag edges with localized metallic edge state. Besides, we have directly identified the structural defects in graphitic materials (for example HOPG, Kish graphite, CVD graphene, SiC epitaxial graphene, etc) through defect etching magnifying technique. Rich information on their structural disorders including the defects types, defect densities, lattice orientations, stacking disorders, grain sizes and grain boundaries were extracted.

V1.00022 Controlling magnetism in graphene by molecular doping , RAHUL RAVEENDRAN NAIR, I-LING TSAI, MARGHERITA SEPIONI, ANDRE K. GEIM, IRINA V. GRIGORIEVA, School of Physics and Astronomy, University of Manchester — Graphene, the first truly two dimensional crystal, continues to attract intense interest due to its extraordinary properties. The possibility to induce magnetism in graphene, despite the absence of d- or f-electrons, has been a subject of great excitement but is still poorly understood experimentally and the possibility of magnetic coupling remains controversial. Our recent experiments provided the first definitive proof that point defects in graphene – adatoms and vacancies – carry magnetic moments, giving rise to paramagnetism that dominates graphene's magnetic response at low temperatures [1]. In this contribution we show that one can control magnetism in graphene by using chemical doping. In order to vary the carrier concentration n, we used molecular (hole) doping of graphene laminates by NO_2 or nitric acid and were able to vary n between $\sim$5x10^{11} to $\sim 10^{13}$ cm^{-2} as estimated by Raman spectroscopy and Hall effect measurement. This had a pronounced effect on the magnetisation of graphene laminates, which was measured using SQUID magnetometry. Our results show that both para- and diamagnetic response of graphene can be controlled precisely and reversibly by the doping level, which opens up a new avenue of tuneable magnetism in graphene.

[1] R.R. Nair *et al.*, Nature Physics **8**, 199 (2012).

V1.00023 Origin Of Magnetism in Graphene Nanostructures[1] , WEN YING RUAN, School of Physics, Georgia Institute of Technology, Atlanta 30332, USA, YIYANG SUN, SHENG-BAI ZHANG, Department of Physics, Applied Physics, and Astronomy, Rensselaer Polytechnic Institute, Troy, NY 12180, USA, MEI-YIN CHOU, School of Physics, Georgia Institute of Technology, Atlanta 30332, USA, and IAMS, Academia Sinica, Taipei, Taiwan — The magnetic orderings of traditional magnetic materials originate from their partially filled d- or f-electron bands. Surprisingly, theoretical and experimental studies show that graphene nanostructures which contain only s and p electrons can also exhibit magnetic ground states. On the basis of the bonding properties of pi-electrons, we propose a theoretical model to explain the origin of magnetism in graphene nanostructures. Our theory is justified via examples ranging from nanoflakes to nanoribbons. Our theory also provides a simple physical insight into Lieb's theorem about the ground state magnetic momentum of a bipartite system.

[1]Supported by DOE, award No. DEFG02-97ER45632 and DE-SC0002623

V1.00024 Surface Vibrational Modes in Multilayer Graphene , GREGORY COARD, JIA-AN YAN, Department of Physics, Astronomy, and Geosciences, Towson University, 8000 York Road, Towson, MD 21252 USA — The surface vibrational modes in multilayer graphene are studied based on both density-functional theory and the force constant model. It is found that these modes are mainly localized on the surface layers. The relationship between these modes and the stacking order as well as the layer number will be discussed.

V1.00025 Electron diffraction studies on CVD grown bi-layered graphene , KIRAN LINGAM, MEHMET KARAKAYA, RAMAKRISHNA PODILA, Dept. of Physics and Astronomy, Clemson University, Clemson, SC USA 29634, HAIJUN QUIN, Advanced Materials Research Laboratories, Clemson University, Anderson, SC USA 29625, APPARAO M. RAO, Dept. of Physics and Astronomy, Clemson University, Clemson, SC USA 29634, DEPT. OF PHYSICS AND ASTRONOMY, CLEMSON UNIVERSITY, CLEMSON, SC USA 29634. TEAM, ADVANCED MATERIALS RESEARCH LABORATORIES, CLEMSON UNIVERSITY, ANDERSON, SC USA 29625 COLLABORATION — Graphene has generated enormous interest in the scientific community due to its peculiar properties like electron mobility, thermal conductivity etc. Several recent reports on exfoliated graphene emphasized the role of layer stacking on the electronic and optical properties of graphene in case of bi-layered and few layered graphene and several synthesis techniques like chemical vapor deposition (CVD) on Copper foils are employed to prepare graphene for applications at a large scale. However, a correlated study pertinent to the stacking order in CVD grown graphene is still unclear. In this work, using a combination of Raman spectroscopy and selected area electron diffraction analysis we analyzed the preferred misorientation angles in a CVD grown bi-layered graphene and also the role of Cu crystal facets on the graphene stacking order will be presented.

V1.00026 Multifunctional Crumpling and Unfolding of Large-Area Graphene , XUANHE ZHAO, Duke University — Crumpled graphene films of atomic thickness are used in diverse applications including electronics, energy storage, composites, and biomedicine. While it is known that the degree of crumpling strongly affects the properties of graphene and the performance of graphene-based devices and materials, in existing technology it is not possible to fold and unfold crumpled graphene films in a controlled manner. Here we present a new approach, investigated by joint experiment, atomistic simulation and theory, to control reversible crumpling and unfolding of large-area graphene, achieved by harnessing mechanical instabilities of graphene adhered on highly pre-strained polymer substrate. By relaxing the pre-strain in the substrate in a particular order, we crumple graphene films into tailored self-organized hierarchical structures that mimic super-hydrophobic leaves. The degree of crumpling in graphene is controlled by stretching/relaxing the substrate. The reversible crumpling and unfolding of graphene films enables us to fabricate large-area conductive coatings and electrodes capable of giant stretchability, high transparency, super-hydrophobicity, and tunable wettability. We further demonstrate the use of novel graphene-polymer laminates as artificial muscles.

V1.00027 Fabricating graphene devices from graphite intercalation compounds , RYUTA YAGI, MIDORI SHIMOMURA, FUMIYA TAHARA, SEIYA FUKADA, Graduate School of Advanced Sicneces of Matter, Hiroshima University — We report a method of making few-layer graphene flakes by mechanically exfoliating $SbCl_5$-graphite intercalation compounds (GICS). The number of exfoliated graphene flakes had a peculiar distribution relevant to the stage structure of GICs. The carrier doping of the few-layer graphene flakes was about two orders of magnitude smaller than that expected from the stoichiometry of the GICs. The measured electric mobility was comparable to that made from pristine graphite. The EPMA measurement showed that inhomogeneous distribution of dopant near the surface of GIC was responsible for obtaining the virtually undoped graphene. Deintercalation of dopant would expand interlayer distance of each graphene layer, and thereby layer-number of exfoliated graphene depended stage number of GIC.

V1.00028 Valley beam splitter device based on giant lateral shift in strained Graphene , NEETU AGRAWAL, Indian Institute of Tecnnology - Delhi, MANISH SHARMA, SANKALPA GHOSH, Indian Institute of Technology - Delhi — The prospect of strain engineering to control electronic properties has opened up new directions for graphene research. Strain essentially can be considered as a perturbation to the in-plane hopping amplitude, which induces a gauge potential in the effective Hamiltonian which has opposite signs in the two valleys. Thus, strain can induce a valley-dependent magnetic field. We investigate the combined effect of commensurate scalar and vector potentials on a pair of region of uniform uniaxial strain. The strained region induces opposite gauge potentials leading to a valley dependence of the transverse velocity of incident valley unpolarised beam, while quasibound states arising due to well formation between the double unit structure give rise to giant lateral shifts. Thus lateral displacement of transmitted beams from K and $K^{'}$ valleys together with their difference can be enhanced to a very large extent thereby enabling a highly efficient valley beam splitting. The wide tunability of proposed device is facilitated due to the presence of external vector potential. This vector potential acts in a similar way at the two valleys, thereby providing a handle to manipulate the net effect of strain.

V1.00029 Light-matter interaction in a microcavity-controlled graphene transistor , RALPH KRUPKE, MICHAEL ENGEL, Karlsruhe Institute of Technology, MATHIAS STEINER, IBM Thomas J. Watson Research Center, ANTONIO LOMBARDO, ANDREA FERRARI, University of Cambridge, HILBERT V. LOEHNEYSEN, Karlsruhe Institute of Technology, PHAEDON AVOURIS, IBM Thomas J. Watson Research Center — Graphene has extraordinary electronic and optical properties and holds great promise for applications in photonics and optoelectronics. Demonstrations including high-speed photodetectors, optical modulators, plasmonic devices, and ultrafast lasers have now been reported. more advanced device concepts would involve photonic elements such as cavities to control light-matter interaction in graphene. Here we report the first monolithic integration of a graphene transistor and a planar, optical microcavity. We find that the microcavity-induced optical confinement controls the efficiency and spectral selection of photocurrent generation in the integrated graphene device. A twenty-fold enhancement of photocurrent is demonstrated. The optical cavity also determines the spectral properties of the electrically excited thermal radiation of graphene. most interestingly, we find that the cavity confinement modifies the electrical transport characteristics of the integrated graphene transistor. our experimental approach opens up a route towards cavity-quantum electrodynamics on the nanometre scale with graphene as a current-carrying intra-cavity medium of atomic thickness.

V1.00030 Dynamic Charge Transfer at the C_{60}/Graphene Interface , RUI WANG, XIAOWEI WANG, SHENGNAN WANG, ZHIHAI CHENG, XIAOHUI QIU, National Center for Nanoscience and Technology, China — The charge transfer dynamics between C_{60} molecules and graphene was studied using scanning probe microscopy, micro-Raman spectroscopy and transport measurement. Electrons inject from graphene to C_{60} molecules due to the hybridization of energy band was observed. The charged C_{60} molecules act as local electrical gates, which are thermally switching and induce the current or resistance fluctuations (such as 1/f noise) in graphene active channel. The thermally activated carrier trapping/detrapping process was found to be a dominant source for the 1/f noise at room temperature. As temperature decreased, Coulomb scattering from charged C_{60} molecules became a primary influence on the current flow in graphene transistors.

V1.00031 Magnetotransport through a graphene quantum ring , DAMIEN CABOSART, SEBASTIEN FANIEL, FREDERICO MARTINS, THANH NHAN BUI, CRISTIANE NASCIMENTO SANTOS, VINCENT BAYOT, BENOIT HACKENS, Universite catholique de Louvain, IMCN/NAPS, Belgium, JESSICA CAMPOS DELGADO, Universite catholique de Louvain, ICTEAM/ELEN, Belgium — We report on four-leads electrical resistance measurements in graphene quantum rings (QRs) at low temperature. Our samples were fabricated by exfoliating natural graphite on SiO_2 to form graphene monolayers. The graphene sheets have been located and characterized by optical contrast and Raman spectroscopy. The QRs were patterned by e-beam lithography and oxygen plasma etching. The graphene devices were electrically contacted thanks to Ti/Au (5nm/60nm) pads, obtained after lithography and lift-off. The measurements were performed down to 20 mK in the coherent and diffusive regime of electron transport. A back gate allowed us to manipulate the carrier concentration in the graphene layer. We measured Universal Conductance Fluctuations (UCFs) by tuning the back gate voltage as well as the magnetic field applied perpendicular to the ring. Analyzing the UCFs, we obtain invaluable information on the dynamics of phase coherent transport inside our QRs.

V1.00032 Noise properties of graphene films , NAN SUN, XINYU LIU, GERALD ARNOLD, STEVEN RUGGIERO, University of Notre Dame, DEPARTMENT OF PHYSICS TEAM — We present results for the noise characteristics of graphene flakes on SiO_2 as a function of gate bias. Our results are in accord with a new tunnel/trap model based on the interaction of graphene carriers with the underlying substrate, which incorporates trap position, energy, and barrier height for tunneling into a given trap, along with the band-structure of the graphene. We will also discuss recent work on the properties of MBE-grown GaAs on graphene, in the context of noise in spin transport.

V1.00033 Oxide-on-graphene field effect biosensors , BEI WANG, Physcis Department, Penn State University, KRISTI LIDDELL, Chemistry Department, Penn State University, JUNJIE WANG, BRANDON KOGER, Physcis Department, Penn State University, CHRISTINE KEATING, Chemistry Department, Penn State University, J. ZHU, Physcis Department, Penn State University — Nanoelectronics-based detection schemes offer fast and label-free alternatives to bioanalysis. Here we report on the design, fabrication, and operation of ion-sensitive field-effect biosensors using large-area graphene sheets synthesized by chemical vapor deposition. The graphene transducer channel has a high carrier mobility of approximately 5000cm^2/Vs. Our oxide-on-graphene design uses thin HfO_2 and SiO_2 films to passivate the graphene channel and electrodes from electrolyte and uses the top SiO_2 surface for sensing and linker chemistry. The pH sensitivity of the bare SiO_2 is measured to be 46mV/pH, in good agreement with literature results. We demonstrate the silanization of the SiO_2 surface with aminopropyl-trimethoxysilane (APTMS). The pH sensitivity of the APTMS-functionalized SiO_2 is measured to be 43mV/pH. By applying the solution gate voltage in pulse, we eliminate hysteresis in the transfer curve of the graphene channel, which is a common challenge in achieving high-solution detection using nanostructure-based field effect sensors. The amine-functionalized SiO_2 surface can be further functionalized with bio-probes to perform the detection of specific binding events such as DNA hybridization.

V1.00034 Fabrication of Single-layer Graphene Nanomechanical Oscillators by Deep-UV Lithography on Poly(methyl methacrylate) (PMMA) , JEN-FENG HSU, SHONALI DHINGRA, BRIAN D'URSO, Department of Physics and Astronomy, University of Pittsburgh — Graphene is well-known for its conductivity and high mechanical strength. Its lightness and stiffness can be exploited for oscillation devices. It also makes promising candidates for quantum nano-mechanical device. And since it's a conductive material, the oscillator can be driven electrically. Here we present a simple and scalable graphene patterning technique for suspended nanomechanical oscillator (NMO) in various geometrical shapes, including doubly clamped beams, circular drums and rectangular drums, in sizes of $\approx$ 2 - 4 μm. The graphene in this work is synthesized by chemical-vapor deposition (CVD) on $\approx$ 2mm thick copper substrates which is later thinned down by single-point diamond turning for transfer. The patterning method employs deep-UV (240-310nm) lithography to expose the PMMA layer on top of the graphene layer. Oxygen plasma may be used to transfer patterns onto the graphene film. The PMMA layer further acts as clamping material for drum devices. This method avoids any metal or contamination and devices in different shapes have unique advantages such as torsional modes (beams) and higher quality factors (drums).

V1.00035 ABSTRACT WITHDRAWN –

V1.00036 Ethane adsorption on as-produced nanohorns[1] , BRICE RUSSELL, ALDO MIGONE, Department of Physics Southern Illinois University, MASAKO YUDASAKA, SUMIO IIJIMA, Japan Science and Technology Corp., NEC Corporation, Tsukuba 305-8501, Japan — We report on an ongoing adsorption isotherm study of ethane on as-produced (closed) single-walled carbon nanohorns. We have completed measurements at two temperatures: 130 K and 140 K. Steps in the logarithmic plots of the isotherms indicate the presence of two different groups of binding energy sites, which we interpret as corresponding to different sized pore regions in the nanohorn aggregates. We will present results of the application of the point B method for the determination of the effective monolayer capacity and for the effective specific surface area values at each temperature. The isosteric heat as a function of sorbent loading will be obtained from the isotherm data. The results obtained for ethane on the closed nanohorn aggregates will be compared to those previously obtained for ethane adsorbed on bundles of closed single-walled carbon nanotubes.

[1]This work was supported by the NSF through grant # DMR -1006428.

V1.00037 Recording Single Molecule Dynamics and Function using Carbon Nanotube Circuits , YONGKI CHOI, PATRICK SIMS, ISSA MOODY, TIVOLI OLSEN, BRAD L. CORSO, O. TOLGA GUL, GREGORY A. WEISS, PHILIP G. COLLINS, Departments of Physics and Astronomy, Molecular Biology and Biochemistry, and Chemistry, University of California Irvine, Irvine, CA 92697 — Nanoscale electronic devices like field-effect transistors (FETs) have long promised to provide sensitive, label-free detection of biomolecules. In particular, single-walled carbon nanotubes (SWNTs) have the requisite sensitivity to detect single molecule events, and have sufficient bandwidth to directly monitor single molecule dynamics in real time. Recent measurements have demonstrated this premise by monitoring the dynamic, single-molecule processivity of three different enzymes: lysozyme, protein Kinase A, and the Klenow fragment of polymerase I. Initial successes in each case indicate the generality and attractiveness of SWNT FETs as a new tool to complement other single molecule techniques. Furthermore, our focused research on transduction mechanisms provides the design rules necessary to further generalize this SWNT FET technique. This presentation will summarize these rules, and demonstrate how the purposeful incorporation of just one amino acid is sufficient to fabricate effective, single molecule nanocircuits from a wide range of enzymes or proteins.

V1.00038 Hydrogen Adsorption in Carbon nanoparticles[1] , A.L. CABRERA, S. ROJAS, D.E. DIAS-DROGUETT, H. BHUYAN, Pontificia Universidad Catolica de Chile, N. AOMOA, M. KAKATI, Institute for Plasma Research, Assam, India — We have studied hydrogen adsorption in carbon nanoparticles using a quartz crystal microbalance. The carbon nanoparticles were synthesized from a thermal plasma jet at different pressure (*15 – 263 torr*) of the reactants and different current (*50 – 250 A*) to generate the plasma. The as-prepared carbon nanoparticles were directly deposited on top of the gold electrode of a quartz crystal and we monitored in-situ the changes in resonance frequency while the chamber was pressurized at different hydrogen pressures. These changes enabled determination of absorbed hydrogen mass in order to get H/C mass ratio curves as a function of H_2 pressure. Adsorption curves obtained in some carbon nanoparticles indicated the formation of hydrogen monolayer inside the pores of the carbon nanoparticles. Using the value of the jump due to the formation of a H_2 monolayer, a surface area was estimated between 40-60 m^2/g for hydrogen adsorption. In other carbon samples, hydrogen uptake curves indicated that H_2 was filling the sample's pores when pore volume was large. These observations will be discussed in detail for several carbon nanoparticles samples.

V1.00039 Electronic structure of carbon-boron nitride nanotubes , RAÚL SANGINÉS-MENDOZA, EDGAR MARTINEZ, Universidad Autónoma de Nuevo León — Structures of carbon and boron nitride nanotubes (CNTs, BNNTs) are quite similar, conversely, electronic properties are radically different from each other. Carbon nanotubes, whose electronic properties can be either metallic or semiconducting depending on their chiral structure, boron nitride nanotubes are always semiconductors with bandgaps over 4 eV. We have looked to hybrid systems, to predict a new kind of nanostructures with novel electronic properties. In this way, we explore the electronic properties of C-BN nanotubes. In particular, we studied the electronic structure of armchair C-BN nanotubes. The calculations were performed using the pseudopotential LCAO method with a Generalized Gradient Approximation for the exchange-correlation energy functional. The band structure of most of these systems have semiconductor character with an indirect gap smaller than its analogous BNNTs. In addition, the most prominent feature of these systems is the existence of flat bands both at the valence band top and at the conduction band minimum. Such flat bands results in sharp and narrow peaks on the total density of states. The behavior of these flat bands mainly indicates that electrons are largely localized. Thus, a detailed analysis on the electronic band structure shows that hybridization between those orbitals on the interfaces is responsible to exhibit localization effects on the hybrid systems.This research was supported by Conacyt under Grant No. 133022.

V1.00040 Efficiency enhancement in encapsulated thermoacoustic projector based on carbon nanotubes , ALI ALIEV, Alan G. MacDiarmid NanoTech Institute, University of Texas at Dallas, Richardson, TX, 75083, USA, YURI GARTSTEIN, Department of Physics, University of Texas at Dallas, Richardson, TX, 75083, RAY BAUGHMAN, Alan G. MacDiarmid NanoTech Institute, University of Texas at Dallas, Richardson, TX, 75083, USA — Carbon nanotubes (CNT) can generate sound by means of thermoacoustics over a wide frequency range (1-10^5 Hz). However, the low sound generation efficiency of open CNT films at low frequencies ($\eta \propto f^2$), where the demands for large size and flexible sound projectors is high, is frustrating. The nanoscale thickness of CNT film, high sensitivity to the environment and high surface temperatures required for TA sound generation are another drawbacks suggesting an efficient protection of free-standing CNTs, demonstrated in this work by means of encapsulation in inert gases. We analyze the effect of different thermodynamic regimes on fundamental efficiency of thermoacoustics sound generation for closed system using first principle calculation and experimental investigation of encapsulated sound projector's performance. The observed sound pressure level for argon gas encapsulated transducers Q times higher than for open system, where Q is a resonant quality factor of thin vibrating plates. Moreover, the sound generation efficiency for encapsulated system is increased toward low frequencies ($\eta \propto 1/f^2$). The acoustical and geometrical parameters of resonant system for further increase of efficiency and transduction performance are discussed.

V1.00041 Dopants as Morphology Promoters: a Fundamental Study of the Role of Boron and Sulfur in the Formation of MWNT Junctions , LAKSHMY PULICKAL RAJUKUMAR, ANA LAURA ELIAS, AMBER D. MCCREARY, The Pennsylvania State University, ARAVA LEELA MOHANA REDDY, KAUSHIK KALAGA, Rice University, NESTOR PEREA-LOPEZ, MARTHA E. AUDIFFRED, DAVID SWANSON, The Pennsylvania State University, HUMBERTO R. GUTIERREZ, University of Louisville, ROBERT VAJTAI, PULICKEL M. AJAYAN, Rice University, HUMBERTO TERRONES, MAURICIO TERRONES, The Pennsylvania State University, MURI3D COLLABORATION — We have synthesized CNT-based hierarchical structures via an aerosol assisted CVD process. Our experiments consist of pyrolyzing a solution containing C and Fe sources together with small amounts of B and S sources (800-900C, Ar atmosphere). The resulting structures consist of micron-size fibers decorated with short multi-walled carbon nanotubes that resemble "nanotentacles." The materials have been characterized by SEM, HRTEM, EELS, TGA, XRD, XPS and Raman spectroscopy. Finally, these materials have been tested for its possible application in batteries and supercapacitors.

V1.00042 Large-area tungsten diselenide atomic layers on an insulator substrate grown by vapor phase chemical deposition , KWONJAE YOO, National Nanofab Center (NNFC), Korea Advanced Institute of Science and Technology (KAIST), Daejeon 305-806, Republic of Korea, IL-SUK KANG, YEHOON PARK, CHI WON AHN, NNFC, KAIST, Daejeon 305-806, Republic of Korea, JONGWOO SHIN, DAE YOOL JUNG, BYUNG JIN CHO, SUNG-YOOL CHOI, Dept. of Electrical Engineering, KAIST, Daejeon 305-701,, HONGKYW CHOI, Dept. of Advanced Device Technology, UST, Daejeon, Korea, 305-333 — Group IV transition metal dichalcogenides such as WS2 and WSe2 are one of attracting material classes which have a physical two dimension of one atomic layer and atomically thin layers like graphene. These materials have interesting features such as an indirect bulk gap makes a transition to a direct band gap in monolayer. Recent research results of FETs showed that a high effective hole mobility of 250 cm^2 /V s with subthreshold swing of 60 mV/dec from an exfoliated monolayer. Indeed it is natural to think that artificial large area synthesis is needed for practical applications. Here we report the large-area tungsten diselenide layers on SiO2 substrate using vapor phase deposition method. Selenium source was evaporated from certain distances to a tungsten thin film on SiO2/Si wafer. Nitrogen gas was flowed during all processes as a carrier gas. Growth was performed at 700 $\sim$ 900 Celsius degree. The size of atomic tungsten diselenide layers simply depends on a wafer and quartz tube size. Good qualities of selected tungsten diselenide layers were investigated by AFM/EFM, SEM/TEM, and Raman spectroscopy. FET and PL data also will be presented.

V1.00043 Ferroelectric Tuning of Photocatalytic Water Splitting on Epitaxially-Strained $TiO_2/SrTiO_3$ Hetero-Structure , JUN HEE LEE, ANNABELLA SELLONI, Department of Chemistry, Princeton University, Princeton, New Jersey 08544, USA — Using first-principles density functional theory (DFT) calculations, we show that the electric-dipole moment and epitaxial strain in heterostructures of TiO_2 with polar oxides such as $SrTiO_3$ can be used as control parameters to tune the activity of TiO_2 toward water splitting. Specifically, we find that the ferroelectric dipole of strained $SrTiO_3$ rigidly shifts the band-edge-energy positions of epitaxial TiO_2 films and affects the adsorption of relevant species (OH, H) on the TiO_2 surface. By varying the magnitude of the electric dipole moment and epitaxial strain, this effect can facilitate the oxygen evolution reaction and hydrogen production on TiO_2. In particular, our results show that a positive electric dipole pointed toward TiO_2 and compressive epitaxial strain can strongly reduce the barrier for oxygen evolution and thus significantly enhance the photocatalytic efficiency of TiO_2.

V1.00044 Computational modeling of mechanical response of dual cross-linked polymer grafted nanoparticle networks , BALAJI IYER V S, VICTOR YASHIN, University of Pittsburgh, ISAAC SALIB, Intel, TOMASZ KOWALEWSKI, KRZYSTOF MATYJASZEWSKI, Carnegie Mellon University, ANNA BALAZS, University of Pittsburgh, ANNA BALAZS COLLABORATION, KRZYSTOF MATYJASZEWSKI COLLABORATION — We develop a hybrid computational model for the behavior of a network of cross-linked polymer-grafted nanoparticles (PGNs). The individual nanoparticles are composed of a rigid core and a corona of grafted polymers that encompass reactive end groups. With the overlap of the coronas on adjacent particles, the reactive end groups can form permanent or labile bonds, which lead to the formation of a "dual cross-linked" network. To capture these multi-scale interactions, our approach integrates the essential structural features of the polymer grafted nanoparticles, the interactions between the overlapping coronas, and the kinetics of bond formation and rupture between the reactive groups on the chain ends. We investigate the mechanical response of the dual-cross linked network to an applied tensile deformation. We find that the response depends on the bond energies of the labile bonds, the fraction of permanent bonds in the network, and thickness of the corona. This model provides a powerful tool for the computational design of dual cross-linked PGN's by predicting how the structural features of the system affect the mechanical performance.

V1.00045 Stable, Single-Layer MX_2 Transition-Metal Oxides and Dichalcogenides in a Honeycomb-Like Structure , CAN ATACA, HASAN SAHIN, SALIM CIRACI, UNAM-National Nanotechnology Research Center, Bilkent University, Ankara 06800, Turkey — Recent studies have revealed that single-layer transition-metal oxides and dichalcogenides (MX_2) might offer properties superior to those of graphene. So far, only very few MX_2 compounds have been synthesized as suspended single layers, and some of them have been exfoliated as thin sheets. Using first-principles structure optimization and phonon calculations based on density functional theory, we predict that, out of 88 different combinations of MX_2 compounds, several of them can be stable in free-standing, single-layer honeycomb-like structures. Our analysis of stability was extended to include in-plane stiffness, as well as ab initio, finite-temperature molecular dynamics calculations. Some of these single-layer structures are direct- or indirect-band-gap semiconductors, only one compound is half-metal, and the rest are either ferromagnetic or nonmagnetic metals. Because of their surface polarity, band gap, high in-plane stiffness, and suitability for functionalization by adatoms or vacancies, these single-layer structures can be utilized in a wide range of technological applications, especially as nanoscale coatings for surfaces contributing crucial functionalities. In particular, the manifold WX_2 heralds exceptional properties promising future nanoscale applications.

V1.00046 Crystalline α-samarium sesquisulfide nanowires: structure and electronic properties of an unusual intrinsically degenerate semiconductor , CHRIS MARIN, JOSEPH BREWER, CHIN LI CHEUNG, Department of Chemistry, University of Nebraska-Lincoln, Lincoln, NE 68588, LU WANG, WAI-NING MEI, Department of Physics, University of Nebraska at Omaha, Omaha, NE 68182 — We report that α-phase samarium sesquisulfide (α-Sm2S3) intrinsically takes on an electronic structure similar to that of a heavily degenerate p-type semiconductor by means of UV-Vis absorption spectroscopy and first-principles calculations. When prepared by chemical vapor deposition, these samples were found to have a tendency to crystallize as bundles of nanowires. Additional characterizations using high-resolution electron microscopy, along with selected area electron diffraction and X-ray diffraction, were applied to verify the matching of the modeled structure of α-Sm2S3 to that of the experimentally measured material. We expect this compound to be intrinsically well suited for potential applications in the p-type elements of diode devices such as in photovoltaic devices and thermo-electric converters.

V1.00047 Structural and Oxygen Storage Properties of Hexagonal Manganites , CASTRO ABUGHAYADA, Northern Illinois University, BOGDAN DABROWSKI, Argonne National Laboratory, Northern Illinois University, STAN KOLESNIK, Northern Illinois University, OMAR CHMAISSEM, Argonne National Laboratory, Northern Illinois University, NIU TEAM — Complex oxides exhibiting superior reversible oxygen absorption/release capacities have been generating a great deal of interest due to their critical role in the development of energy related technologies, such as oxy-fuel and chemical looping combustion. Based on our previous studies of tolerance factor, we have successfully synthesized hexagonal ($P6_3cm$) $RMnO_{3+\delta}$ manganites (R=Dy, Ho, Y) for which we discovered a large reversible oxygen storage/release capacities (within the range of oxygen content 3.0 - 3.4) at unusually low temperatures near 300 °C which make them excellent candidates for air separation and production of high purity oxygen. Resistivity, structural, magnetic, and thermal expansion properties are correlated with the oxygen content $3+\delta$ for these compounds. Work supported by NIU Great Journey Assistantship.

V1.00048 Temperature Dependence of the Raman Spectra of Mechanically Exfoliated Monolayer MoS_2 , A. GLEN BIRDWELL, FRANK J. CROWNE, TERRANCE P. O'REGAN, PANKAJ B. SHAH, MADAN DUBEY, U.S. Army Research Laboratory, Sensors and Electron Devices Directorate, 2800 Powder Mill Rd, Adelphi, MD 20783, USA, LILI YU, HAN WANG, TOMAS PALACIOS, Department of Electrical Engineering and Computer Science, Massachusetts Institute of Technology, Cambridge, MA, USA, RUSEN YAN, HUILI GRACE XING, Department of Electrical Engineering, University of Notre Dame, Notre Dame, IN 46556, USA — We investigated the temperature dependence of the E^1_{2g} and A_{1g} peaks in the Raman spectra of monolayer MoS_2 prepared by mechanical exfoliation (ME) onto Si/SiO_2 substrates. Micro-Raman spectroscopy was carried out using the 532 nm laser excitation over the temperature range from 30 to 175 °C. Extracted values of the temperature coefficient for these modes will be presented in conjunction with the effect of excessive laser power on these measurements. These results suggest power densities as low as $\approx 275\ \mu W/\mu m^2$ can still cause local heating in ME-MoS_2 monolayer samples.

V1.00049 Ultrafast photocurrents and THz generation in single InAs-nanowires[1] , ALEXANDER HOLLEITNER, NADINE ERHARD, GERHARD ABSTREITER, GREGOR KOBLMULLER, Technical University Munich, Walter Schottky Institut and Physics Department — Conventional scanning photocurrent microscopy experiments on semiconductor nanowires are typically limited to timescales exceeding 10 ps. Yet, it is known from optical experiments that carrier relaxation and transport processes can occur on much faster timescales in such wires. We therefore apply a recently developed pump-probe photocurrent spectroscopy based on coplanar striplines [1] to investigate the photocurrent dynamics of single GaAs- and InAs-nanowires with a picosecond time-resolution [2]. The ultrafast photocurrent response of the nanowires is sampled in the time-domain with the help of Auston switches. We discuss data on single InAs-nanowires which are interpreted in terms of a photo-thermoelectric current and the transport of photogenerated holes to the electrodes as the dominating ultrafast photocurrent contributions. Moreover, we show that THz radiation is generated in the optically excited InAs-nanowires, which we interpret in terms of a dominating photo-Dember effect [3]. The results are relevant for nanowire-based optoelectronic and photovoltaic applications as well as for the design of nanowire-based THz sources. [1] L. Prechtel, et al. Nature Communications 3, 646 (2012). [2] L. Prechtel, et al. Nano Letters . 12, 2337 (2012). [3] N. Erhard, et al. (2013).

[1]Financial support by the ERC grant NanoREAL is acknowledged.

V1.00050 Ab-initio study of field emission characteristics of single-walled ZnO nanotubes , WEI-CHIH CHEN, FENG-CHUANG CHUANG, ZHI-QUAN HUANG, Natl. Sun Yat-Sen Univ., Taiwan, WAN-SHENG SU, Natl. Center for High-Performance Computing, Taiwan — We employed first-principles calculations to investigate the field emission characterictics of infinite-length single-walled ZnO nanotubes (SWZONTs) in the either armchair or zigzag conformations. Both armchair and zigzag SWZONTs are found to be direct-bandgap semiconductors. Moreover, our calculations demonstrated that work functions of armchair and zigzag tubes decrease from about 5.70 to 5.25 eV with an increasing tube diameter, and it eventually approaches to the work function value of a ZnO sheet with a diameter close to an infinite limit. Finally, the direct computations on file emission factors of both nanotubes will be presented. Our findings provide an insight into the ZONT field-emission properties as well as contribute to developing procedures to produce an efficient ZONT field emitter.

V1.00051 Co-adsorptions of Hydrogen and Oxygen Molecules in Armchair Silicon Nanotubes[1] , HAOLIANG CHEN, ASOK RAY, University of Texas at Arlington — A systematic study of the interactions of hydrogen and oxygen molecules with armchair silicon nanotubes using the finite cluster approximation and the Gaussian09 suite of software is presented. Hydrogen and oxygen molecules have been adsorbed from both inside and outside of the nanotube. The admolecules were placed initially perpendicular to the tube axis in four different adsorption sites- normal bridge, zigzag bridge, hollow and on-top sites. After adsorption, the two hydrogen molecules maintained their original diatomic linear structure and the most preferred site is the on-top site, with the highest adsorption energy being 3.714eV. For adsorption of two oxygen molecules, complete dissociation, partial dissociation and non-dissociation were noted, with the highest adsorption energy being 7.659eV. We propose several precursor (or metastable) states, such as the Si-O-O-Si peroxide structure, which has a lower ground state energy than dissociative adsorption. For the co-adsorption of one hydrogen molecule with one oxygen molecule, the oxygen molecule dissociated into oxygen atoms and hydrogen molecule prefers to stay in on-top site, the highest adsorption energy being 5.563eV.

[1]Work partially supported by the Welch Foundation. (Grant No. Y-1525)

V1.00052 Exploring epitaxial relationships between InAs nanowires and shaped Au nanoparticles , DEBOSRUTI DUTTA, University of South Florida, R. MOHAN SANKARAN, XUAN GAO, Case Western Reserve University, VENKAT R. BHETHANABOTLA, University of South Florida — The high electron mobility and strong spin-orbit interactions make InAs nanowires (NWs) an excellent material for the micro-electronics industry. However, our inability to precisely control their structural properties like defects, crystalline orientation, etc pose a significant obstacle to their widespread usage. Recent evidence in the literature suggests an epitaxial relationship exists between the structural properties of a NW and, the size and shape of the metal seed nanoparticle (NP) from which it is grown. In this work, we have explored the epitaxial relationship between H-terminated [111] zinc blende (ZB) and [0001] wurtzite (WZ) InAs NW fragments with the (111) & (100) facets of Au NP using density functional theory calculations. The binding energies suggest greater stability of ZB [111] over WZ [0001] fragments on Au surface facets with both fragments being more stabilized by Au (111) than Au (100) surface. This suggests that shaped Au NPs with a higher number of Au (111) facets should produce higher yields of InAs NWs, with (111) growth directions. A chemical potential based Arrhenius model that takes into account these binding strengths, is used to compare the relative thermodynamic stability of these NW-NP interactions.

V1.00053 ABSTRACT WITHDRAWN –

V1.00054 Chirality Distribution Measurements of the NIST Single-Wall Carbon Nanotube Reference Material Using Resonance Raman Spectroscopy , KEVIN MEAD, JEFF SIMPSON, LOGAN SCHEEL, Towson University, JEFF FAGAN, ANGELA HIGHTWALKER, National Institute of Standards & Technology — The ability to rapidly and easily determine the chiral vector distribution within a nanotube population remains a key measurement need for carbon nanotube processing and applications. We report Resonance Raman Spectroscopy (RRS) measurements of a SWCNT reference material from NIST. The SWCNT samples were synthesized using the CoMoCat method, dispersed in aqueous solutions by wrapping in deoxycholate surfactant, and separated by length using ultracentrifugation. We measure Raman spectra over a wide range of excitation wavelengths from 457 nm to 850 nm using a series of discrete and continuously tunable laser sources coupled to a triple-grating spectrometer with a liquid-nitrogen-cooled detector. The spectra reveal Raman-active vibrational modes including the low-frequency radial breathing mode and higher-order modes. Chirality distributions are determined from the Raman spectra, specifically the RBM frequency and energy excitation profiles, together with input from theoretical models. RRS is sensitive to both major and minor chiral species in the sample. We will compare the resulting chirality distribution obtained from RRS with those obtained from other orthogonal measurement techniques.

V1.00055 Kondo effect in a dissipative environment[1] , CHUNG-TING KE, Duke University, HENOK MEBRAHTU, Micron Tech. Inc. , YURIY BOMZE, Duke University, ALEX SMIRNOV , North Carolina State University, GLEB FINKELSTEIN, Duke University — In this work, we study the competition between two many body-effects: Kondo effect and tunneling with dissipation. We work with nanotube quantum dots contacted by resistive leads, resulting in controlled dissipative environment for the tunneling electrons. Previously, we have demonstrated the existence of the quantum phase transition in a resonant level coupled to the dissipative environment in the spinless case. Here, we demonstrate that the Kondo effect can survive under weak enough dissipation strength.

V1.00056 Plasma excitations and self energy for gapped graphene in strong magnetic fields , ANDRII IUROV, GODFREY GUMBS, Hunter College, CUNY — The collective plasma excitations of gapped graphene such as may be induced by optically dressed Dirac electrons or by an underlying substrate have been calculated in the presence of a uniform perpendicular magnetic field. The polarization function was obtained using the random phase approximation (RPA). By varying the intensity and frequency of the polarized light, we may tune the energy gap E_g between the conduction and valence bands. The value of E_g may reach values by far exceeding that caused by spin-orbit coupling or that caused by a substrate. We report the magnetoplasmon dispersion relations for various energy gaps and for Coulomb coupled double layers with various separations between the graphene layers.

V1.00057 Edge-Saturation Effect on Finite Size 0-D Carbon Nano-Ribbons — a Density Functional Theory Study , LI CHEN, Massachesetts College of Pharmacy and Health Sciences, LOUIS CIRELLO, Rhode Island College — Using computational simulation and Density Functional Theory, we have studied the absorption of various foreign molecular/atomic groups saturated at the edge of semi-conducting, finite-size armchair carbon nano-ribbons (ACNR). The effect of this edge-saturation was studied in terms of its impact on HOMO-LUMO gap, electronic structure and spin distribution. A comparison was made between the non-saturated pristine ACNRs and saturated ones, as well as, between different saturation species, different doping sites, different doping concentration and ACNR length. Our results suggest that the type of elements play a more important role than the concentration and/or doping sites in terms of the change in HOMO-LUMO gap, which leads to the possibilities of using CNBs as nano-scale chemical sensors. The doping of some elements also introduces a spin distribution different from the pristine CNBs.

V1.00058 Theoretical study of static magnetic properties for the chiral and reconstructed graphene nanoribbons[1] , SUK-YOUNG PARK, Department of Physics, Yonsei Univ., JUN-WON RHIM, Korea Institute for Advanced Study, KYUNGSUN MOON, Department of Physics, Yonsei Univ. — Recent theoretical study of the chiral graphene nanoribbons(CGNR) has demonstrated the magnetic ordering of the edge states below a certain chiral angle[1]. Based on the Hubbard model for the CGNR, we study the static properties of the magnetic edge states such as the intra-edge and inter-edge spin stiffness, which are the two crucial parameters to control the thermodynamics of the effective magnetic hamiltonian. For the systematic study of the anti-ferromagnetic inter-edge spin correlations, we calculate the inter-edge spin stiffness as a function of ribbon width and transverse electric field. We also attempt to calculate the electronic and magnetic properties for the other edge geometries such as a reconstructed edge geometry, which has been experimentally confirmed as an edge shape other than zigzag or armchair nanoribbon[2] 1. V1.00059 Ab initio study of boron nitride lines on graphene , BERENICE MATA-CARRIZAL, RAÚL SANGINÉS-MENDOZA, EDGAR MARTINEZ, Universidad Autónoma de Nuevo León — Graphene has unusual electronic properties which make it a promising material for electronic devices. Neverthless, the absence of a band gap sets limitations on its practical applications. Thus, it is crucial to find methods to create and tune the band gap of systems based on graphene. In this way, we explore the modulation of the electronic properties of graphene through doping with boron nitride lines. In particular, we studied the electronic structure of graphene sheets doped with boron nitride lines armchair and zigzag type. The calculations were performed using the pseudopotential LCAO method with a Generalized Gradient Approximation (GGA) for the exchange-correlation energy functional. We found that both doping lines type induce a bandgap and that the energy gap increases as the length of doping lines increases. Accordingly to our DFT calculations, we found that the energy gap on graphene doped with armchair and zigzag lines is due to a two different mechanisms to drain charge from pi- to sigma- orbitals. Thus, we found that doping graphene with boron nitride lines is a useful way to induce and modulate the bandgap on graphene. This research was supported by Consejo Nacional de Ciencia y Tecnología (Conacyt) under Grant No. 133022.

V1.00060 Phonon bottleneck in graphene-based Josephson junctions at millikelvin temperatures.[1] , IVAN BORZENETS[2], ULAS COSKUN, HENOK MEBRAHTU[3], YURIY BOMZE, Duke University, ALEX SMIRNOV, North Carolina State University, GLEB FINKELSTEIN, Duke University — We examine the nature of the transitions between the normal and the superconducting branches of superconductor-graphene-superconductor Josephson junctions. We attribute the hysteresis between the switching (superconducting to normal) and retrapping (normal to superconducting) transitions to electron overheating. In particular, we demonstrate that the retrapping current corresponds to the critical current at a higher temperature, where the heating is caused by the retrapping current itself. The superconducting gap in the leads suppresses the hot electron outflow, allowing us to further study electron thermalization by phonons at low temperatures ($T < 1$K). The relationship between the applied power and the electron temperature was found to be $P \propto T^3$, which we argue is consistent with cooling due to electron-phonon interactions.

V1.00061 Magneto-electronic properties of multilayer graphenes , JEI WANG, JHAO-YING WU, Department of Physics, National Cheng Kung University, CHEN-PENG CHANG, Center for General Education, Tainan University of Technology, MING-FA LIN, Department of Physics, National Cheng Kung University — We develop the generalized Peierls tight-binding model to study the low-energy electronic properties of multilayer graphenes (MLGs) in a uniform perpendicular magnetic field. The Landau levels (LLs) in MLG can be categorized into some groups according to their wavefunction distributions among different sublattices. Their dispersions strongly depend on the field strength, layer number and stacking configuration. The level degeneracies in even number of layers are the same with those in monolayer graphene, i.e., four-fold degeneracy. However, in odd number ones, most LLs are doubly degenerate because the spatial inversion symmetry is broken. There exist LL crossings or anti-crossings during the variation of magnetic field, a feature that may reflect in transport experiments. The carrier density distribution in zero fields is also included, which provides an alternative way to understand the grouped LLs.

V1.00062 Pinning of the electronic bands at the graphene and wet contact Ti junction , TOBIAS BOTHWELL, WEI REN, SALVADOR BARRAZA-LOPEZ, University of Arkansas — Pinning of electronic bands has been observed at the junction of graphene and Ti contacts. Density functional theory is used to study this junction by analyzing the electronic bands of two systems. We study graphene atop a BN gate as well as Ti contacts atop the graphene and BN. Varying electric fields are applied in the vertical axis to study how the electronic bands shift. Contributions of each material to the bands are also analyzed. Calculations are performed using the Vienna Ab initio simulation package (VASP).

V1.00063 Bandgap opening in graphene templates on Ru(0001) from subsurface hydrogen effects studied by STM, LEED, and DFT[1] , MAXWELL GRADY, University of New Hampshire, BOGDAN DIACONESCU, Sandia National Laboratory, DARREN VALOVCIN, University of New Hampshire, FRANK HAGELBERG, East Tennessee State University, KARSTEN POHL, University of New Hampshire — Graphene has aroused tremendous interest due to its remarkable electronic and mechanical properties. Graphene's optical properties, conductance, and the fact that it can be transferred to many substrates make it an ideal candidate for use in nanoelectronic devices and organic photoelectric devices. The lack of a bandgap, however, causes a serious challenge for implementing graphene as a material for electrical switches and therefore creative ways of inducing this bandgap are needed. We will present a STM/LEED/DFT study of the single layer graphene on Ru(0001) system in the presence of hydrogen. Structural studies show arrays of moiré superlattices with sizes ranging from 0.9 to 3.0 nm in the presence of hydrogen on the compact surface of ruthenium. First principle calculations help explain the appearance of these arrays of graphene reconstructions driven by the H presence at the Ru(0001) interface, and furthermore, predict the appearance of a bandgap with values correlated with the moiré superstructure sizes in the presence of hydrogen. Control over moiré superstructure size can aid in future work using graphene as a nanotemplate for self assembled growth of nanoelectronic devices an organic photovoltaics.

V1.00064 Heat Confinement in Graphene Devices Using Superconducting Contacts[1] , CHRIS MCKITTERICK, Yale University, Department of Physics, HELI VORA, XU DU, Stony Brook University, Department of Physics, BORIS KARASIK, Jet Propulsion Laboratory, California Institute of Technology, DANIEL PROBER, Yale University, Department of Physics — Many groups have proposed the use of graphene as a photon detector due to its very small heat capacity and thermal conductivity. We describe predictions of device performance taking into account the effect of device heating from incident photons using reported results [1]. To test the achievability of these predictions, we performed Johnson noise thermometry measurements of graphene samples fabricated at Stony Brook University. These measurements probe the electron-phonon behavior of graphene on SiO_2 at very low temperatures. Because the electron-phonon coupling is weak in graphene, this requires the use of superconducting contacts to confine the hot electrons and prevent their outdiffusion. To that end, NbN leads with a $T_c \approx 11$ K are used to contact the graphene. The large energy gap present in these contacts prevents diffusive cooling for low electron temperatures. We present thermal conductivity measurements of these devices.

V1.00065 Effects of periodic scatter potential on the Landau quantization and ballistic transport of electrons in graphene , PAULA FEKETE, Department of Physics and Nuclear Engineering, US Military Academy at West Point, GODFREY GUMBS, Department of Physics and Astronomy, Hunter College at the City University of New York, DANHONG HUANG, Air Force Research Laboratory, Kirtland Air Force Base — The energy spectrum of graphene is calculated in the presence of a perpendicular magnetic field as well as a two-dimensional square array of scatterers. The potential modulation is simulated by a cosine function whose amplitude and period may be varied. This permits investigation of the effect that variation of the strength of and spacing between scattering centers has on the ballistic transport. We include both K and K' valleys as well as sublattices A and B to compute the four-component wave function. Additionally, based on our eigenenergy spectrum calculations, we determine the electron density of states for this system.

V1.00066 The effects of the layer number in optical excitations of AA-stacked graphenes , YUAN-CHENG HUANG, Center for General Education, Kao Yuan University, 821 Kaohsiung, Taiwan, CHIH-WEI CHIU, MING-FA LIN, Department of Physics, National Cheng Kung University, 701 Tainan, Taiwan — The band structures and the optical properties of AA-stacked multilayer graphenes are calculated by the tight-binding mode and the gradient approximation. For monolayer graphene, there are one pair of linear bands intersecting at Fermi level, and one pair of saddle points at $\pm\alpha_0$. As for the AA-stacked systems, n_L-layer graphenes own the n_L-pair energy bands. The energy dispersions of each pair are similar to those of the monolayer graphene, but shift upwards or downwards. The spacing of the conduction and valence bands in the same pair are slightly different among the different pairs. The threshold energy of the single-particle excitations (ω_s) of the odd-layer graphene is much lower than those for the even-layer graphene, since there is one intersecting point much close to Fermi level only for the odd-layer graphene. When the layer number increases to 80, the effects of the odd-even layers vanish Furthermore, the features of the loss spectra of the multilayer graphene close to those of bulk graphite when n_L increases more than 50 gradually.

V1.00067 Responsive Polymer Brushes on Graphene Oxide and Their Application as pH and Temperature Sensor , K. PAEK, H. YANG, KAIST, J. BANG, Korea Univ., B.J. KIM, KAIST — Light emitting responsive polymer brushes were synthesized and grafted on grapheme oxide (GO), and their pH and thermal responses were quantitatively investigated by photoluminescence (PL) quenching efficiency from fluorophores in polymer brushes to GO. First, GO was functionalized with pH responsive poly(acrylic acid) (PAA)-pyrene coated CdSe/ZnS quantum dots (QDs) by pi stacking interaction between pyrene and GO. The FRET from QDs to GO was controlled through manipulation of the conformational features of the PAA chains that respond to pH changes in solution. The PL intensity of QDs was gradually increased in the decreasing of pH value. As another example, temperature responsive GO was synthesized with poly(coumarine)-b-poly(N-isopropylacrylamide)-b-poly(azidostyrene) (PCou-b-PNIPAM-b-PSN3) by covalent bonding between PSN3 and GO. The PL of poly(coumarine) was completely quenched at the temperatures above LCST of PNIPAM due to the collapse of the PNIPAM spacer. Therefore, their temperature response can be demonstrated and monitored by the PL quenching efficiency, exhibiting reversible, well-defined on-and-off switching behavior.

V1.00068 Ultrafast collinear scattering and carrier multiplication in graphene , MARCO POLINI, NEST, Istituto Nanoscienze-CNR and Scuola Normale Superiore, I-56126 Pisa, Italy — Graphene is emerging as a viable alternative to conventional optoelectronic, plasmonic, and nanophotonic materials. The interaction of light with graphene creates a non-equilibrium carrier distribution, which first relaxes on an ultrafast timescale to a hot Fermi-Dirac distribution and then cools via phonon emission. While the slower relaxation mechanisms have been extensively investigated, the very initial stages of relaxation, ruled by fundamental electron-electron interactions, still pose a challenge. In this talk I will discuss recent results based on a pump-probe experiment featuring extreme temporal resolution (sub-10 fs) and broad spectral coverage. By comparing these results with a microscopic theory based on the Boltzmann equation I will shed light on the physical mechanisms that control the non-equilibrium dynamics of hot carriers in graphene. Reference: D. Brida, A. Tomadin, C. Manzoni, Y. J. Kim, A. Lombardo, S. Milana, R. R. Nair, K. S. Novoselov, A. C. Ferrari, G. Cerullo, and M. Polini, arXiv:1209.5729.

V1.00069 Optical absorption in trilayer graphene , XIAO LI, Department of Physics, The University of Texas at Austin, FAN ZHANG, Department of Physics and Astronomy, University of Pennsylvania, QIAN NIU, Department of Physics, The University of Texas at Austin — We use a low energy effective model to analyze the optical responses of trilayer graphene samples. We first show that optical absorption of the ABA-stacked trilayer has strong dependence on both the Fermi energy and optical frequency, which is in sharp contrast to that of ABC-stacked trilayer graphene. Secondly, we are able to determine the possible existence of trigonal warping effects in the bandstructure of ABC-stacked trilayer graphene by a divergence in the absorption spectra at around 10 meV. In addition, we can partially distinguish the vairious broken symmetry states driven by electron-electron interactions in ABC-stacked trilayer graphene. In particular, the quantum anomalous Hall (QAH) state is sensitive to the polarization of the incident light, giving a way to detect its possible existence.

V1.00070 Asymmetric scattering of Dirac like electrons and holes[1] , JANICE WYNN GUIKEMA, ATIKUR RAHMAN, NINA MARKOVIC, Johns Hopkins University — We have studied magnetotransport and noise characteristics of dual-gated graphene p-n junction devices. The observed noise amplitude decreases rapidly with increasing temperature and its origin is related to the time-dependent quantum interference corrections. By comparing the results from the series and parallel p-n junctions, we show that the noise amplitude depends on the gate voltage and that the origin of the noise is not related to the fluctuation of resistance at the p-n junction interface. From the temperature and gate voltage dependence of resistance and noise characteristics, we show that the contribution from both short-range and long-range impurity determines the noise behavior and that the electrons and holes are asymmetrically scattered by the impurities.

V1.00071 Tunneling Effect across a Graphene Barrier

, FELIX MARIN, Retired — We investigate a model of two macroscopic reservoirs which are separated by a graphene sheet. The sheets remain perpendicular to the reservoirs such that electrical conduction in the reservoirs is a three dimensional phenomena while graphene electrical conduction occurs perpendicular to the reservoirs. It means, as usual, that graphene electrical current is a bidimensional phenomena. We discuss the global electrical current as a function of the initial chemical potential of this system. The analysis include variations due to temperature and due to applied potentials to the reservoirs and to the graphene sheet.

V1.00072 Enhanced quantum coherence in graphene by Pd cluster absorption and its Golubev-Zaikin zero-temperature saturation[1]

, FENGQI SONG, JUNHAO HAN, SHANYUE WANG, BAIGENG WANG, GUANGHOU WANG, Nanjing University — The absorption of functional impurities has been vastly proposed to mediate novel quantum coherent states, including quantum spin/anomalous Hall effects and Kondo effect etc, on graphene where the surface carriers dominate. However, such surface impurities will simultaneously introduce additional electronic scattering and suppress the electronic coherence of the Dirac fermions. This may eventually disable the expected quantum states. We report the increase of the dephasing lengths of the graphene sheet after the deposition of Pd nanoclusters, as demonstrated by the measurement of weak localizations. The dephasing lengths are found to reach some saturated values with the decreasing temperatures, essentially the zero-temperature decoherence. Detailed analysis is carried out on the temperature-dependent and saturated decoherence periods. The competition between the surface scattering and electrical field screening leads to the final improvement of quantum coherence. Our data agree well with the predication of Golubev and Zaikin, where such zero-temperature decoherence is induced by local fluctuations of the electrical fields near disorders.

V1.00073 Quantum Hall Effect near the charge neutrality point in graphene[1]

, JORGE A. LEON, GUENNADII M. GUSEV, Instituto de Física, Universidade de São Paulo, FLAVIO O. PLENTZ, Departamento de Física, Universidade Federal de Minas Gerais — The Quantum Hall effect (QHE) of a two-dimensional (2D) electron gas in a strong magnetic field is one of the most fascinating quantum phenomena discovered in condensed matter physics. In this work we propose to study the transport properties of the single layer and bilayer of graphene at the charge neutrality point (CNP) and compare it with random magnetic model developed in theoretical papers in which we argue that at CNP graphene layer is still inhomogeneous, very likely due to random potential of impurities. The random potential fluctuations induce smooth fluctuations in the local filling factor around $\nu = 0$. In this case the transport is determined by special class of trajectories, "the snake states", propagating along contour $\nu = 0$. The situation is very similar to the transport of a two-dimensional particles moving in a spatially modulated random magnetic field with zero mean value. We especially emphasize that our results may be equally relevant to the composite fermions description of the half-filled Landau level.

V1.00074 Semiclassical Analysis of Landau levels Near the van Hove Singularity in Twisted Bilayer Graphen[1]

, CHI-KEN LU, HERBERT FERTIG, Physics Department, Indiana University, Bloomington, Indiana 47405, USA — We investigate the energy spectrum for electrons in twisted bilayer graphene in the presence of a weak magnetic field. Twisted bilayers host Dirac points from each layer that are near one another in the Brillouin zone, and are coupled through low energy saddle points. In the absence of a field these lead to a low energy van Hove singularity in the density of states. With the field, in a semiclassical picture, electrons orbit in momentum space on contours of constant band energy which may approach the saddle points. The orbits undergo an interesting change in topology as the energy passes from below to above the van Hove singularity energy, going from loops that separately surround each Dirac point to a single loop surrounding *neither*. This contrasts with the more standard situation in which the latter orbit surrounds both low energy orbit centers. The consequences for the Landau level spectrum of this unusual topological transition will be discussed.

V1.00075 SUPERLATTICES, NANOSTRUCTURES, AND OTHER ARTIFICIALLY STRUCTURED MATERIALS –

V1.00076 Quantum plasmon resonances and coupling of small nanoparticles

, ZAPATA-HERRERA MARIO, FLOREZ JEFFERSON, CAMACHO ANGELA, Universidad de los Andes — In this work, we propose to extend a theoretical quantum approach to describe the behavior of the optical response as a function of both size and shape of small metal nanoparticles. By using classical models as well as quantum approaches we also want to study the nanoparticle's permittivity in the whole range of nanometers in order to define the different regimes at the nanoscale. In particular, we are interested in examining size and shape effects on the enhancement field factor and the absorption spectra for comparing with possible experiments. We study the role played by Localized Surface Plasmon Resonance in the coupling of small metal nanoparticles pairs by varying the distance between them by using an analogy between molecular electronic states and plasmonic excitations as a function of particle size and shape. We pay special atention on tunnelling and multipolar effects in order to predict the regime of dimer formation. The main interest in understanding the plasmon resonances of small nanoparticles lies in the applications in biology, catalysis and quantum optics.

V1.00077 Optical and Magnetic Properties of WS_2: Single Layers, Clusters, and Nanoribbons

, FLORENTINO LOPEZ-URIAS, Advanced Materials Department, IPICYT, Camino a Presa San Jose 2055, Col. Lomas 4a Sección, San Luis Potosí, México, HUMBERTO R. GUTIERREZ, Department of Physics and Astronomy, University of Louisville, Louisville, KY 40292 USA., NESTOR PEREA-LOPEZ, ANA LAURA ELIAS, AYSE BERKDEMIR, Department of Physics, The Pennsylvania State University, University Park, PA 16802, USA, ANDRES CASTRO-BELTRAN, Facultad de ingeniera Mecanica y Electrica, Universidad Autonoma de Nuevo Leon, Avenida Universidad s/n Ciudad Universitaria, C.P.66450, San Nicolas, RUITAO RU, HUMBERTO TERRONES, Department of Physics, The Pennsylvania State University, University Park, PA 16802, USA, MAURICIO TERRONES, Pennsylvania State University and Research Center for Exotic Nanocarbons (JST), Shinshu University, Wakasato 4-17-1, Nagano 380-8553, Japan — Transition metal chalcogenides are layered materials, similar to graphite. Inspired in recent experiments on the synthesis and photoluminesce enhancement of single-layer WS_2 sheets and triangular islands, in the present work, first-principles density functional theory calculations are carried out on different WS_2 nanostructures. In addition, we have studied WS_2 clusters with different 2-D morphologies, nanoribbons with zigzag and armchair edges, as well as single- and few-layered WS_2. The electronic density of states, scanning tunneling microscopy simulations, structural and magnetic ordering stability, and edge chirality are studied. Bethe-Salpeter equation for the electron-hole two particle Green function has been solved in order to calculate the in-plane polarized optical spectrum and exciton wave functions. In addition, the role of spin-orbit coupling on the electronic properties of single layer WS_2 is discussed.

V1.00078 Lithographically defined tapered waveguides for transformation optics device applications[1]

, TODD ADAMS, KURT ERMER, ALEX PIAZZA, DAVE SCHAEFER, VERA SMOLYANINOVA, Towson University, IGOR SMOLYANINOV, University of Maryland — Recent progress in metamaterials and transformation optics (TO) give rise to such fascinating devices as perfect lenses, invisibility cloaks, etc., which are typically achieved with metamaterials. Realization of these devices using electromagnetic metamaterials would require sophisticated nanofabrication techniques. Recently we have demonstrated that the same effect may be achieved by much simpler means. By tapering a waveguide, one can literally "bend" optical space and achieve the same result. Our approach leads to much simpler designs, which require conventional lithographic techniques and readily available dielectric materials. Here we report fabrication of low cost TO devices, such as analogues of metamaterial lenses and invisibility cloaks. Their broadband properties will be demonstrated and performance for light of different polarization will be discussed.

V1.00079 Radiation rate enhancement in multilayered photonic and plasmonic nanopillars

, NATE LAWRENCE, LUCA DAL NEGRO, Department of Electrical Engineering, Boston University — We have systematically studied arrays of multilayered nanopillars composed of both metal and dielectic materials and shown that they can be used to enhance the radiative properties of active materials through modification of the local density of states (LDOS). Using an extension of the multipolar expansion method in two dimensions, we are able to calculate modifications in the radiation rate of emitters and power radiated to the far field. We show multi-resonant confinement of light to sub-wavelength gap regions inside nanopillars composed of alternating layers of metal and dielectric materials, forming a circular metal-insulator-metal (MIM) device. Sub-wavelength light confinement of 1.55μm radiation is also demonstrated in purely dielectric nanopillars with reduced optical losses using alternating layers of high and low refractive index materials. In both cases, we find that the LDOS can be strongly increased, modifying the radiative rate and the internal quantum efficiency of emitters. Using top-down electron beam lithography, reactive ion etching and sputtering deposition we have created for the first time high-aspect ratio, light emitting, multilayered nanopillar structures consisting of alternating Si and Er:SiNx layers. Using dark-field scattering and photoluminescence decay spectroscopy we have experimentally characterized the fabricated nanostructures and demonstrated ability to control their radiation properties. These results are important to enable novel Si-based optical cavities and light emitting structures with nanoscale light confinement for optical communications and sensing.

V1.00080 Characterizing FeOOH Nanorice in Solution Using Polarized and Depolarized Light Scattering

, PHIL DEE, Cleveland State University, OLGA DEMENT'EVA, VICTOR RUDOY, Frumkin Institute of Physical Chemistry and Electrochemistry, KIRIL STRELETZKY, Cleveland State University — Characterizing spindle-shaped (nanorice) particles of iron(III) oxyhydroxide (FeOOH) within their native solution environment is essential for understanding their properties for specific applications such as targeted synthesis of core/metal nano-shell structures. The combination of Dynamic Light Scattering (DLS), Static Light Scattering (SLS) and carefully designed Depolarized Dynamic Light Scattering (DDLS) allows to measure translational and rotational dynamics, structure, and size distribution of nanorice *in situ*. In addition, DLS/SLS/DDLS provides sampling of a large number of nanorice particles as opposed to a few particles typically probed by the imaging techniques. The prolate ellipsoid and solid cylinder models were used to deduce FeOOH nanorice dimensions. The ellipsoidal model generally produced nanoparticle lengths and aspect ratios within 10-20% of the transmission electron microscopy (TEM) results. The cylinder model performed slightly worse. The effects of number concentration of FeOOH nanoparticles in solution on their dynamics were also studied to understand the degree of coupling between the rotational and translation diffusion under different conditions.

V1.00081 Modeling of Au Nanoparticles and Semiconductor Nanowires for Nanodevice Applications[1]

, A. MAKEPEACE, J.M. YARRISON-RICE, Miami University of Ohio, P. KUMAR, M. FICKENSCHER, L.M. SMITH, H.E. JACKSON, University of Cincinnati, Y.-J CHOI, G.-J. PARK, Korea Institute of Science and Technology, C. JAGADISH, The Australian National University — Semiconductor nanowires with and without plasmon enhancement are being studied for nanodevice applications ranging from chemical sensors to medical monitors and photovoltaics. Semiconductor nanowires can incorporate materials with different bandgaps and can be p- or n-doped. Growths come in different morphologies and geometries (bare, axial or radial heterostructures); all of which expands the design parameters for photocurrent based devices. When Au nanoparticles are attached to nanowires, the local electric field can be enhanced by orders of magnitude, thus increasing their absorption and photocurrent. Using an FDTD Maxwell solver, we simulate local electric fields and absorption characteristics of semiconductor nanowires and Au nanoparticles. We report on spherical, cylindrical and bipyramidal Au nanoparticles with local electric field enhancements that increase with nanoparticle asymmetry and sharp features. The Au nanoparticle modeling data is also in good agreement with experimental absorption data. Initial investigations of 275 nm InP nanowires exhibit internal mode structure under illumination with both polarizations, and absorption coefficients as a function of wavelength. These results provide insight into our experimental investigations of nanowire device applications.

[1]Financial support through NSF DMR grants 0806572 and 1105121.

V1.00082 UV Photodetectors using Vertically-aligned GaN n-core/p-shell Arrays

, JONG-YOON HA[1], SERGIY KRYLYUK[2], DIPAK PARAMANIK, RATAN DEBNATH[3], ALBERT V. DAVYDOV, Materials Science and Engineering Division, NIST, Gaithersburg, MD 20899, MATTHEW KING, Northrop Grumman ES, Linthicum, MD 21090, ABHISHEK MOTAYED[4], Materials Science and Engineering Division, NIST, Gaithersburg, MD 20899 — The fabrication methods of GaN nanostructures, such as vertically aligned core-shell nano- and micro- pillar arrays, are critical for device applications. We have demonstrated dense arrays of vertically-oriented, individual GaN core-shell structures realized by a combination of top-down etching of the n-type pillars and subsequent p-shell epitaxial growth using selective CVD. The patterned samples were then etched in an inductively coupled plasma system to form GaN pillars. Mg-doped p-type GaN shells were then epitaxially grown over the n-GaN pillars in a custom-built horizontal hot-wall halide vapor phase epitaxy (HVPE) reactor. Room-temperature photoluminescence and Raman spectroscopy measurements indicate strain-relaxation in the etched pillars compared to the as-grown GaN film. Complete devices have been fabricated using dielectric planarization Detailed device characterization was correlated with TEM microstructural analysis.

V1.00083 The absorption and optical properties of nanocomposite systems[1]

, IRINA BARIAKHTAR, Boston College, YURI DEMIDENKO, Institute of Semiconductor Physics, National Academy of Sciences of Ukraine, VALERI LOZOVSKI, Taras Shevchenko National University of Kyiv, Ukraine — An approach to describe the excitation and propagation of the surface plasmon polaritons along the surface with the nanodiscs that are located above it is proposed. In the framework of the proposed approach, the dissipative function is calculated for the different geometry of the systems with the discs. The Fano-like antiresonance curves of absorption profiles have been obtained. The antiresonance absorption characteristics have been explained by the interaction between the surface plasmon polariton with the continuous spectrum and localized plasmon polaritons at the nanodisks or nanocylinders with the discrete spectrum. The localized plasmon polariton can be used, for example, in solar cells for absorbing and enhancement of the solar radiation. The obtained result is similar to the well-known Fano effect.

V1.00084 Induction of Magnetization in Zig-Zag Graphene Nanoribbons by Bending , NABIL ALAQTASH, RENAT SABIRIANOV, University of Nebraska at Omaha — We study the induced magnetization in the zig-zag terminated graphene nanoribbon (ZGNR) by applying strain gradient. In-plane sinusoidal gradient is shown to produce measurable magnetization localized around the location with the largest strain gradient. We discuss it from the point of view of flexomagnetic effect. By symmetry, the magnetization induction is forbidden in infinite system. However, it appears in the finite system due to the removal of the time-reversal symmetry. We performed ab initio Density Functional Theory (DFT) calculations for 4-ZGNR and show that local magnetic moments are decreased at the edges with inward curvature and increase at the edges with outward curvature. Due to antiferromagnetic arrangement of magnetization of two edges a net magnetization is induced by strain. We estimate an average magnetization of $\sim$ 3.3 μB that produced from the bending of nanoribbon with the sinusoidal profile δx=Asin(2πz/L) with A= 3Å and L=87.4 Å (z=0..L/2, i.e. the half of the period). The appearance of net local magnetization is due to asymmetry of magnetic moments induced at two edges when nanoribbon is subjected to non-uniform deformation, i.e. the presence of the strain gradient. The magnetic moments vary as function of local curvature due to the charge redistribution on the curved edges.

V1.00085 Spin-Dependent Smoluchowski effect , OLEG STEPANYUK, Faculty of Physics, Moscow State University, Moscow, Russia(1), MARCO CORBETTA, Max-Planck-Institut für Mikrostrukturphysik, Halle (Saale), Germany(2), OLEG POLYAKOV, (1), HIROFUMI OKA, (2), ALEXANDER SALETSKY, (1), DIRK SANDER, VALERI STEPANYUK, JÜRGEN KIRSCHNER, (2) — Surface defects, such as steps, nanoclusters, stripes or wires can significantly perturb the electronic structure of a surface. More than 70 years ago, Smoluchowski showed that electrons will not follow the sharp discontinuity of an atomic structure at step edges, instead, redistribution or "smoothing" of the electron cloud at surface protrusions should occur [1]. A charge redistribution process involves charge flow from the top of the step to the bottom and results in formation of local dipoles that are antiparallel to the surface dipoles of flat surfaces. We present a combined ab initio and experimental study of spin-dependent effects at the edges of magnetic nanoislands. Our results give clear evidence of the existence of a spin-dependent Smoluchowski effect which leads to spin, spatial and energy dependent charge flow at surface corrugations. Striking changes in the spin-polarization at the edge of Co islands on Cu(111) are predicted by calculations and revealed by the spin-polarized STS. We concentrate on a single Co nanoislands on Cu(111)[2]. Our results demonstrate that the spin-dependent Smoluchowski effect can strongly influence the tunneling magnetoresistance at the edges of magnetic nanostructures on metal surfaces.

V1.00086 Fabrication of Submicron Devices on the (011) Cleave Surface of a Cleaved-Edge-Overgrowth GaAs/AlGaAs Crystal[1] , HAO ZHANG, Duke University, LOREN PFEIFFER, KENNETH WEST, Princeton University, ALBERT CHANG, Duke University — We describe the fabrication of submicron devices on the (011)cleave surface of a GaAs heterostructure crystal, in which this surface is extremely narrow. Special purpose devices are produced, which take advantage of the unique characteristics of Cleaved-Edge-Overgrowth. The successful fabrication relies on understanding the surface tension of the electron beam PMMA resist, the workable degree of variation in resist thickness, and on gluing the crystal onto a backing substrate to increase structural strength. We demonstrate a functional gate-controlled point contact constriction placed 9 um from one edge of the cleave surface. This technique may enable the study of fractional quantum Hall fluid in a novel structure.

V1.00087 Vibrational mode mediated electron transport in molecular transistors , DEBORAH SANTAMORE, Department of Physics, Temple University, Philadelphia, PA, NEILL LAMBERT, FRANCO NORI, Advanced Science Institute, RIKEN, Japan — We investigate the steady-state electronic transport through a suspended dimer molecule coupled to leads. When strongly coupled to a vibrational mode, the electron transport is enhanced at the phonon resonant frequency and higher-order resonances. The temperature and bias determines the nature of the phonon-assisted resonances, with clear absorption and emission peaks. The strong coupling also induces a Frank-Condon-like blockade, suppressing the current between the resonances. We compare an analytical polaron transformation method to two exact numerical methods: the Hierarchy equations of motion and an exact diagonalization in the Fock basis. In the steady-state, our two numerical results are an exact match and qualitatively reflect the main features of the polaron treatment. Our results also indicate the possibility of compensating the current decrease due to the thermal environment.

V1.00088 Propagation of long-lifetime polaritons in a semiconductor microcavity[1] , GERMAN V. KOLMAKOV, OLEG L. BERMAN, ROMAN YA. KEZERASHVILI, the New York City College of Technology, the City University of New York — We study propagation of polaritons in a high-quality microcavity. The polaritons are formed by the cavity photons coupled with the excitons in a semiconductor quantum well. We focus on the long-lifetime polaritons ($\sim$ 100 ps), which can spread in a semiconductor structure over a few mm distance before they damp. The case where the polaritons form a non-equilibrium Bose-Einstein condensate is considered. We discuss the changes in the spatial polariton distribution if the polaritons are accelerated by a constant force in the wedge-shaped microcavity.

V1.00089 Characterization of patterns produced by AFM Nano-Lithography on thin films of Lanthanum Barium Manganese Oxide, $La_{0.7}Ba_{0.3}MnO_3$, E. KEVIN TANYI, PARUL SRIVASTAVA, CHRISTOPHER STUMPF, KEVIN SCHENNING, TYLER GOEHRINGER, RAJESWARI KOLAGANI, DAVID SCHAEFER, Towson University — AFM Nano-lithography is a process that uses a bias voltage between the tip of an atomic force microscope (AFM) and a sample placed beneath the tip, to produce patterns on the sample through electro-chemically induced surface modification. AFM nanolithography has been demonstrated on Silicon as well as on thin films of several perovskite metal oxides. Most of the previous research in AFM nanolithography on thin films has focused on the effects of humidity, tip voltage, contact force and the scan rate on the nanolithography processes. Little attention has been paid to the possible role of substrates on which these films have been grown. We have observed that the substrate characteristics (type of substrate, substrate thickness and surface termination) have an impact on the characteristics of the patterns produced by AFM nanolithography. In this work, we present nanolithography studies on (100) SrTiO3 (alias STO) and (100) silicon substrates before and after the deposition of thin films of $La_{0.7}Ba_{0.3}MnO_3$ (LBMO). The characteristics of the patterns produced will be discussed in an effort to fully understand how the patterns depend on sample thickness (substrate or film), sample composition (STO, Si, LBMO), voltage and scan rate. Analysis of these results is expected to shed light on the chemical and physical changes responsible for AFM nanolithography.

V1.00090 Nanoscale Effects on Charge Transport due to Surface-Plasmon Induced Quantum Image Forces , CHARLES CHERQUI, CNLS, Theoretical Division, Los Alamos National Laboratory, and Department of Physics & Astronomy, University of Mew Mexico, ANDREI PIRYATINSKI, Theoretical Division, Los Alamos National Laboratory, DAVID DUNLAP, Department of Physics and Astronomy, University of New Mexico — We examine the motion of a charge carrier in a carbon nanotube in the presence of a metal nanosphere. We show that the system can be reduced to that of a free particle moving in an effective potential consisting of a classical attractive image potential and a repulsive quantum correction. Charge carrier transport in this representation results in a resonance tunneling through the effective potential. We analyze the transmtion coefficent as a function of distance from the surface of the metal nanoparticle to the nanotube. This device setup could be used as the basis for a nanoscale filed effect transitor.

V1.00091 Ab initio investigation of thermoelectric properties of AlN nanowires under axial stress[1]

GEORGE ALEXANDRU NEMNES, TUDOR LUCA MITRAN, ADELA NICOLAEV, University of Bucharest, Faculty of Physics, "Materials and devices for Electronics and Optoelectronics" Research Center, CAMELIA VISAN, Horia Hulubei National Institute of Physics and Nuclear Engineering, The Department of Computational Physics and Information Technologies, LUCIAN ION, STEFAN ANTOHE, University of Bucharest, Faculty of Physics, "Materials and devices for Electronics and Optoelectronics" Research Center — Small diameter nanowires, down to a few lattice constants, are structurally and electronically different from bulk, due to the large surface-to-volume ratio and the effects of the surface states, which has consequences in the optical absorption and in the electrical/thermal transport. It has been recently established that AlN nanowires can suffer a stress induced phase transition from a wurtzite to a graphite-like phase [1]. The thermopower of atomic-sized wurtzite AlN wires coupled to Al(111) bulk contacts is investigated at low temperatures using Green-Keldysh formalism. We ?nd that the conduction of the wide bandgap semiconductor wire is essentially enhanced by the presence of surface states. We show that the evanescent coupling to the surface states is strong enough to render thermopower of a few tens of micro-V/K, which may be enhanced by controlling the position of the surface states. [2]. We also investigate the changes in the thermopower under applied axial stress, comparatively analyzing the nanowires in the wurtzite and graphite-like configurations. [1] T.L. Mitran, Adela Nicolaev, G.A. Nemnes, L. Ion, S. Antohe, Comput. Mat. Sci. 50, 2955 (2011) [2] G.A. Nemnes, C. Visan, S. Antohe, Physica E 44, 1092 (2012)

V1.00092 Nanoscale Phonon Transport as Probed with a Microfabricated Phonon Spectrometer for the Study of Nanoscale Energy Transport

RICHARD ROBINSON, OBAFEMI OTELAJA, JARED HERTZBERG, MAHMUT AKSIT, Department of Materials Science and Engineering, Cornell University, DEREK STEWART, Cornell Nanoscale Science and Technology Facility — Phonons are the dominant heat carriers in dielectrics and a clear understanding of their behavior at the nanoscale is important for the development of efficient thermoelectric devices. In this work we show how acoustic phonon transport can be directly probed by the generation and detection of non-equilibrium phonons in microscale and nanoscale structures. Our technique employs a scalable method of fabricating phonon generators and detectors by forming Al-Al_xO_y-Al superconducting tunnel junctions on the sidewalls of a silicon mesa etched with KOH and an operating temperature of 0.3K [1]. In the line-of-sight path along the width of these mesas, phonons with frequency ∼100 GHz can propagate ballistically The phonons radiate into the mesa and are observed by the detector after passing through the mesa. We fabricated silicon nanosheets of width 100 to 300 nm along the ballistic path and observe surface scattering effects on phonon transmission when the characteristic length scale of a material is less than the phonon mean free path. We compare our results to the Casimir-Ziman theory. Our methods can be adapted for studying phonon transport in other nanostructures and will improve the understanding of phonon contribution to thermal transport. The work was supported in part by the National Science Foundation under Agreement No. DMR-1149036.

V1.00093 Phonon Engineering of ZnO nanowires with controlled chemical doping

JAIME BOHORQUEZ-BALLEN, THUSHARI JAYASEKERA, Southern Illinois University Carbondale — Using the first principles density functional theory (DFT) calculations, we have investigated electronic and dynamical properties of ZnO nanowires in [001] direction with different diameters in the presence of impurities such as Mg, Al, and Ga. As the impurity concentration is varied, electrical and thermal conductivities of nanowires change. In this way, nanowires can be engineered to reduce the thermal transport, such that their thermoelectric properties can be enhanced.

V1.00094 Thermoelectric properties of the ReCN[1]

A. REYES-SERRATO, Centro de Nanociencias y Nanotecnologia UNAM, Ensenada, BC, 22800 Mexico, JORGE SOFO, Department of Physics, The Pennsylvania State University, University Park, Pennsylvania 16802, USA — We present thermoelectric properties of the new material, ReCN. Combining first principles band structure calculation with semi classical model analysis; we obtained the Seebeck coefficient as well as the electrical conductivity as a function of the relaxation time for the electrons. The results indicate the potential of the ReCN as a good thermoelectric material in the low region of the temperature.

[1]A. Reyes-Serrato wishes to acknowledge to Professor Jorge O Sofo and Department of Physics, The Pennsylvania State University, for the support during the sabbatical year.

V1.00095 III/V Nanowire-based Devices for Thermoelectrics

VALENTINA TRONCALE, PHILIPP MENSCH, SIEGFRIED KARG, HEINZ SCHMID, PRATYUSH DAS KANUNGO, EMANUEL LOERTSCHER, UTE DRECHSLER, VOLKER SCHMIDT, HEIKE RIEL, BERND GOTSMANN, IBM Research GmbH, Saumerstrasse 4, CH-8830, Rueschlikon, Switzerland, NANOSCALE ELECTRONICS TEAM[1] — The thermophysical properties of one-dimensional semiconductor nanostructures make them suitable for high ZT thermoelectric devices. Theoretical studies indicate that III/V nanowires (NWs) are eligible for ZT enhancement, due to increased phonon scattering resulting in thermal conductivity (k) suppression, without affecting the electrical conductivity (s). We address the thermoelectric properties of III/As NWs grown by selective-area MOVPE on Si (111) substrates, transferred onto micro-fabricated MEMS-based devices, optimized for direct thermal transfer measurements. The NWs were positioned across the gap between adjacent symmetric SiNx membranes, structured on Si. Platinum resistive heaters/thermometers connected to leads, and contacts to the NWs were realized by electron beam lithography and lift-off technique. The structures were then under-etched. For InAs NWs, we compared the k measured by both the direct method and the self-heating technique. Heat loss to the substrate and contact resistance were evaluated by finite elements simulations and compared for different fabrication techniques. We discuss alternative solutions to the technical challenge of precise NW positioning.

V1.00096 Electronic Structure and Thermoelectric properties of (LaO)x(MCh)y

HIROKI FUNASHIMA, HIROSHI KATAYAMA-YOSHIDA, Department of Materials Engineering Science, Graduate School of Engineering Science, Osaka Univ. — (LaO)MCh (M=Cu,Ag,Au, Ch=S,Se,Te) are known as transparent narrow gap p-type semiconductor, which give an excitonic absorption/emission near the band edge even at room temperature. These compounds have P4/nmm structure and can oxide natural superlattice semiconductor. In this paper at first, we calculated band structure for these compounds, using FLAPW based on LDA/DFT. In our results, these compounds have large anisotropy k_z direction. On Λ, V, and W axises, dispersion curves are very flat. W analyze the electronic structure by group theory. Secondly, we calculated conductivity tensor and Seebeck coefficient using Bloch-Boltzmann Equation semi-classically. Bloch-Boltzmann equation shows that in small dispersion so-called flat band structure, shape of Fermi-surface increase as temperature increase, dramatically, in the result these compounds have large Seebeck-coefficient. As mentioned, we showed that because these compounds have flat-band structure in a direction toward k_z, these compounds have large Seebeck coefficient. At the same time, these compounds have a small hole-pocket in valence band, thus these compounds have good electric conductivity. Finally, we changed chalcogen Ch(=S, Se,Te) and will suggest new-generation high-efficie

V1.00097 Approach to Exchange Bias Effect in $La_{2/3}Ca_{1/3}MnO_3/BiFeO_3$ and $BiFeO_3/La_{2/3}Ca_{1/3}MnO_3$ Bilayers[1]

, CLARIBEL DOMINGUEZ, JOHN E. ORDONEZ, SANDRA DIEZ, MARIA E. GOMEZ, Thin Film Group, Department of Physics, Universidad del Valle, Cali, Colombia, STEFAN GUÉNON, IVAN K. SCHULLER, Department of Physics and Center for Advanced Nanoscience, University of California-San Diego, USA — We have grown bilayers of ferromagnetic $La_{2/3}Ca_{1/3}MnO_3$ (LCMO) and multiferroic $BiFeO_3$ (BFO) on (100) $SrTiO_3$ (STO) substrates, by DC- and magnetron RF -sputtering technique, respectively, at high-oxygen pressures. We maintain constant the thickness of the layers (t_{BFO}=72nm; t_{LCMO}=80nm). Temperature dependence of the resistivity indicates that the MI-transition temperature of the manganite in the BFO/LCMO/STO is affected by the presence of the BFO layer in comparison with T_{MI} for the single LCMO layer. Furthermore, temperature dependence of magnetization shows that the BFO/LCMO/STO bilayer has higher Curie temperature than that for LCMO/BFO/STO, indicating a strong structural dependence of the LCMO layer with magnetic response. The dependence of the magnetic moment with magnetic field after field cooling gives indication of the existence of Exchange Bias effect in the LCMO/BFO/STO bilayer. Isothermal loops also display dependence of the Exchange Bias magnitude with field cooling.

V1.00098 ABSTRACT WITHDRAWN –

V1.00099 ABSTRACT WITHDRAWN –

V1.00100 Electronic structure of catalytically active gold clusters supported on cerium oxide

, NEIL LAWRENCE, YUNYUN ZHOU, JOSEPH BREWER, VIVIANNA LAWRENCE, CHIN LI CHEUNG, YI GAO, XIAO CHENG ZENG, Department of Chemistry, University of Nebraska-Lincoln, Lincoln, NE 68588, LU WANG, WAI-NING MEI, RENAT SABIRIANOV, Department of Physics, University of Nebraska at Omaha, Omaha, NE 68182, LINGMEI KONG, JING LIU, PETER DOWBEN, Department of Physics and Astronomy, University of Nebraska-Lincoln, Lincoln, NE 68588, TAI-SING WU, YUN-LIANG SOO, National Synchrotron Radiation Research Center, National Tsing Hua University, Taiwan — The high catalytic activity of gold nanoclusters when compared to that of the bulk counterpart has been an intensively-studied phenomenon using both chemical and computational experiments in the last two decades. Due to the complexity of these systems and their size- and substrate-dependent activities, different explanations discussed in the literature for these unusual activities are still under debate. Since all these proposed reasons can lead to changes in the electronic structures of the resulting gold clusters, it is necessary to resolve the details of these potential changes in catalytically active systems. Here we report our findings on some features in the electronic structures of catalytically active gold clusters supported on cerium oxide investigated by resonance photoemission spectroscopy. Particularly, the d-band of the examined gold clusters was found to be incompletely filled. These results corroborate the computed electronic structures of our computed planar and non-planar gold cluster models on cerium oxide support.

V1.00101 Dimensional crossover of a fermion gas within periodic structures

, PATRICIA SALAS, M.A. SOLIS, Instituto de Fisica, UNAM — We report the thermodynamic properties of an interactionless Fermi gas immersed in periodic structures such as penetrable multilayers or multitubes created by one (planes) or two perpendicular (tubes) external Dirac comb potentials, allowing fermions to move freely in the remaining directions. The chemical potential μ, as a function of temperature and of the planes impenetrability P_0, shows a anomalous behavior when the tubes wall impenetrability reaches a critical value while keeping the cross section constant. The specific heat of fermions inside tubes, as a function of temperature, shows two very noticeable dimensional crossovers as the system behavior goes from 3D to 2D and latter to 1D as P_0 is increased.

V1.00102 ABSTRACT WITHDRAWN –

V1.00103 Landau Quantization of a 2D Antidot Lattice

, N.J.M. HORING, S. BAHRAMI, Stevens Institute of Technology, Hoboken, NJ 07030, VASSILIOS FESSATIDIS, Fordham University, Bronx, NY 10458 — We derive the Schrödinger eigen-energy dispersion relation for a two dimensional sheet of electrons in a one dimensional periodic lattice of quantum antidot potential barriers, with a perpendicular quantizing magnetic field. This system is in the nature of a Krönig-Penney model with a high magnetic field present and we construct the appropriate Green's function which we use to formulate the dispersion relation for the energy spectrum.

V1.00104 Landau Quantization of an Asymmetric Double-Quantum-Dot

, N.J.M. HORING, S.L. HORTON, Stevens Institute of Technology, Hoboken, NJ 07030, V. FESSATIDIS, Fordham University, Bronx, NY 10458 — We examine the subband energy eigenstates of a two-dimensional asymmetric quantum double-dot system embedded in a two dimensional host sheet subject to Landau quantization. The dispersion relation for the asymmetric quantum double-dot subband energies is formulated and examined by analyzing the frequency poles of the appropriate Green's function with Landau-quantization-like splintering of the levels by a magnetic field. The effects of the asymmetry of the quantum dots in regard to their potential well depths are analyzed as functions of the well depth difference and dot separation.

V1.00105 Magnetotransport Properties of Co_2FeAl Nanowires[1]

, KESHAB R. SAPKOTA, P. GYAWALI, BISHNU DAHAL, R. DULAL, I.L. PEGG, JOHN PHILIP, The Catholic University of America — Co_2FeAl (CFA) nanowire (NW) exhibit interesting magnetic behavior with temperature, which arises from the granular structure.[2] To understand the magnetotransport properties, single CFA NW devices were fabricated using standard electron beam lithography. The magnetoresistance measurements of single CFA NW device were carried out at different temperatures. The magnetoresistance measurements show oscillations as a function of applied external magnetic field.

[2]Keshab R Sapkota *et.al,* J. Appl. Phys. Vol. **111**, Issue 12, 123906 (2012); http://dx.doi.org/10.1063/1.4729807

V1.00106 Electron-Energy-Loss Spectra of Free-Standing Silicene[1] , LUIS M. PRIEDE, CIDS-IC BUAP, LILIA MEZA-MONTES, Instituto de Física BUAP, E. GOMEZ-BAROJAS, CIDS-IC BUAP — Silicene, the silicon-based counterpart of graphene, is increasingly getting attention because it is a semi-metal material with Dirac cones and thus, in principle, has similar electronic properties [1, 2]. In this work we calculated the Electron Energy Loss Spectrum (EELS) of ideal free-standing silicene. Dielectric function is obtained by using a discretization method as suggested by Delerue, et al. [3]. Tight-binding method is applied considering 2nd Nearest Neighbors with sp^2 orbitals, the Slater-Koster parameterization [4] and the Harrison's rule. This has been done for plane and buckled silicon sheets, in the latter case with a structure based on DFT calculations [2]. The resulting dielectric function is compared to those of bulk silicon and graphene. Spectra of EEELS are contrasted for plane and buckled silicene, particularly the plasmon frequency as a function of the z displacement of buckled silicene.

V1.00107 Elementary electronic excitations in quantum wires made up of vertically stacked quantum dots , M.S. KUSHWAHA, Rice University — We report on the theoretical investigation of the elementary electronic excitations in a quantum wires made up of vertically stacked self-assembled InAs/GaAs quantum dots. The resultant quantum wire is characterized by a two-dimensional harmonic confining potential in the x-y plane and a periodic (Kronig-Penney) potential along the z (or the growth) direction within the tight-binding approximation. Since the wells and barriers are formed from two different materials, we employ the Bastard's boundary conditions in order to determine the eigenfunctions along the z direction. These wave functions are then used to generate the Wannier functions, which, in turn, constitute the legitimate Bloch functions that govern the electron dynamics along the direction of periodicity. Thus the Bloch functions and the Hermite functions together characterize the whole system. We discuss the behavior of the eigenfunctions, band-widths, density of states, Fermi energy, single-particle and collective excitations, and finally size up the importance of studying the inverse dielectric function in relation with the quantum transport phenomena. It is remarkable to notice how the variation in the barrier- and well-widths can allow us to tailor the excitation spectrum in the desired energy range...

V1.00108 Heavy-hole light-hole mixing mechanisms and optical polarization in semiconductor QDs , ALEX ZUNGER, CU Boulder, USA, GABRIEL BESTER, Max-Planck-Institut für Festkörperforschung, Germany, JUN-WEI LUO, NREL, USA — The symmetry of epitaxially grown semiconductor QDs was often overestimated to be D_{2d} in which case the [110] and [1-10] directions are equivalent. Under D_{2d} symmetry the underlying bulk HH and LH states belong to two different irreducible representations, Γ_7 and Γ_6 respectively, forbidding HH-LH mixing. Experimentally found HH-LH mixing in strained InAs/GaAs QDs was attributed to symmetry breaking induced by strain. In strain-free GaAs/AlGaAs QDs, one expects such HH-LH mixing to be vanishing. However, the HH-LH mixing experimentally observed in strain-free GaAs/AlGaAs QDs is comparable with the one observed in strained InAs/GaAs QDs. The origin of this mixing was assumed to originate from dot shape anisotropy. Using the atomistic pseudopotential method we find that the HH-LH mixing exists even in overall shape symmetric strain-free GaAs/AlGaAs QDs with a magnitude even larger than in the case of strained InAs/GaAs QDs. We will analyze the relative importance of the following mechanisms: (i) the intrinsic nonequivalence of the [110] and [1-10] directions, which lowers the QDs symmetry to C_{2v}; (ii) shape anisotropy induced symmetry breaking; (iii) built-in non-uniform strain; (iv) alloying effects in either dot material or dot barrier, and (v) C_{2v} interfaces in QDs. We also demonstrated that the intrinsic crystal induced optical anisotropy could be washed out by other factors, such as dot shape anisotropy, which indicates that HH-LH mixing is not the only mechanism responsible for optical anisotropy.

V1.00109 Sub-250nm room temperature optical gain from AlGaN materials with strong compositional fluctuations , EMANUELE FRANCESCO PECORA, WEI ZHANG, HAIDING SUN, A. YU. NIKIFOROV, JIAN YIN, ROBERTO PAIELLA, THEODORE D. MOUSTAKAS, LUCA DAL NEGRO, Boston University — Compact and portable deep-UV LEDs and laser sources are needed for a number of engineering applications including optical communications, gas sensing, biochemical agent detection, disinfection, biotechnology and medical diagnostics. We investigate the deep-UV optical emission and gain properties of $Al_xGa_{1-x}N/Al_yGa_{1-y}N$ multiple quantum wells structure. These structures were grown by molecular-beam epitaxy on 6H-SiC substrates resulting in either homogeneous wells or various degrees of band-structure compositional fluctuations in the form of cluster-like features within the wells. We measured the TE-polarized amplified spontaneous emission in the sample with cluster-like features and quantified the optical absorption/gain coefficients and gain spectra by the Variable Stripe Length (VSL) technique under ultrafast optical pumping. We report blue-shift and narrowing of the emission, VSL traces, gain spectra, polarization studies, and the validity of the Schalow–Townes relation to demonstrate a maximum net modal gain of 120 cm^{-1} at 250 nm in the sample with strong compositional fluctuations. Moreover, we measure a very low gain threshold (15 $\mu J/cm^2$). On the other hand, we found that samples with homogeneous quantum wells lead to absorption only. In addition, we report gain measurements in graded-index-separate-confined heterostructure (GRINSCH) designed to increase the device optical confinement factor.

V1.00110 UV-VIS regime band gap in a 3-d photonic system , MING YIN, FOUZI ARAMMASH, Benedict College, Columbia, SC, TIMIR DATTA, University of South Carolina, RAY TSU, University of North Carolina-Charlotte — Synthetic opals are self-organized bulk, close packed systems that are three-dimensionally ordered with periodicity determined by the sphere diameter. These materials have been used as templates for nano devices with novel properties. For example, in carbon inverse opals show quantum hall effect and related magneto electric responses. Inverse are also reported to show photonic band gap. It is expected that devices based on these materials will be an alternative to electronic devices. These opal specimens were hexagonal or face centered cubic crystals with silica sphere diameter ranging between 220 nm and 270nm. Here we will present results of structural and imaging studies such as SEM, AFM and XRD. In addition results of the (UV-VIS) optical behavior will be provided. The optical response will be analyzed in terms of photonic band gaps in the sub-micrometer optical and UV regime.

V1.00111 Optical absorption of magnesium nanoblades , GEORGE MARSHALL, KEN PODOLAK, SUNY Plattsburgh — Hydrogen cars are not widely distributed due primarily because there are no viable options for long term storage. Magnesium nanoblades may solve this problem, which are smaller than the width of a human hair. These formations can potentially store more than double the amount of hydrogen than current standards. Nanoblades are unique due to their rechargeable nature, which allows it to store and release hydrogen over wide temperature ranges. Also, there is a large surface area which allows a maximum amount of hydrogen to store. In advancement of this field, I examined how visible light interacted with the nanoblades over the entire angular spectrum. This experiment successfully developed a relationship between the angle of light's approach and the nanoblade's absorption of the light, indicating the deposited angle of the nanoblade influences the nanoblade's optical properties. This experiment proves light can be used as a mechanism to store/release hydrogen from the nanoblades, providing a possible energy efficient method to make hydrogen storage more cost effective.

V1.00112 Dynamical changes in plasmon behavior of transition metal alloys , KEN PODOLAK, SUNY Plattsburgh, JAMIE SMITH, Washington University St. Louis, DANIEL STOWE, SUNY Plattsburgh — A plasmon is as a ray of light bound onto a surface of a conducting metal, propagating among the surface and presenting itself as an electromagnetic field. The ability to control or manipulate these plasmons in subwavelength volumes is recently become of interest to improve functionality and performance of optical devices. Furthermore, plasmons can be used to monitor interactions in a biospecific surface on a metal layer. The plasmon waves of light occur at the interface between the metal and dielectric, measurable by absorption peaks in the UV or visible light. A thin top layer of gold or copper are utilized with alloys of metals underneath composed of nickel, iron, or manganese. A Cary-OLIS spectrophotometer measures the optical absorption of these samples where surface and bulk plasmon energy peaks are identified. The full width half maximum of the plasmon peaks appears to broaden over a range of alloys, which represents a change in the strength of the resonance. Further discussion of this will be presented. [ref] K.R. Podolak, S.B. Wagner, and J.A. Smith, "Manganese doping influence on the plasmon energy of nickel films," Surface Science 606, 996 (2012).

V1.00113 Hermitian Two-band Model for One-dimensional Plasmonic Crystals , YUJI KITAMURA, SHUICHI MURAKAMI, Department of Physics, Tokyo Institute of Technology — Surface plasmon polaritons form band structure when the metal surface is periodically corrugated. Such a microscopic structure of metal surface is called the plasmonic crystal. We theoretically study the plasmonic band structure of 1D plasmonic crystals. Although a similar work was reported previously, the eigenvalue equation is non-hermitian. Such a non-hermitian eigenvalue equation has essential difficulties because their eigenvalues may be complex, and we cannot apply the perturbation theory. To avoid such difficulties, we started from the plane wave solution of the Maxwell's equation and consider the small corrugation as a perturbation to the lowest two bands. In this manner, the eigenvalue equation is derived from the matching conditions for electromagnetic fields at the interface. We show that the derived eigen equation is hermitian and analogous to the usual two-band model for electrons. We also show that the wave number and corrugation dependences of the solution behave like the band theory of electrons in solids.

V1.00114 Electronic and optical properties of TiN_x from first-principles calculations , FAISAL MEHMOOD, RUTH PACHTER, Air Force Research Laboratory, Materials & Manufacturing Directorate, Wright-Patterson Air Force Base, Ohio 45433 — We present a systematic study of the structural, electronic and optical properties of bulk phases of TiN_x and its (111) surface for mimicking thin films, which are of interest technological in applications such as coatings. Time-dependent density functional theory and the GW approximation have been applied. In the first stage, a comparison between experimental ellipsometry data and the calculated optical absorption spectra, for example, for a surface upon changing stoichiometry, has been undertaken. The results demonstrate applicability of the methods in prediction of optical excitations for titanium nitride thin film, deposited with varying nitrogen flow rates.

V1.00115 Current and shot noise of a QPC coupled to an oscillator , NIKHILESH VAIDYA, DEBORAH SANTAMORE, Temple University — We study the dynamics and noise power spectrum of a quantum point contact (QPC), which is coupled to a vibration mode. We obtain the non-Markovian unconditional master equation for the reduced density matrix of the system. Using both the analytical and numerical quasi-Monte Carlo method, we calculate the current through. The modified current due to the QPC-oscillator coupling consists of the terms that depend on the oscillator variables, namely, position, momentum and their moments. We find that one of the current terms, which arise from the symmetrized product of the position and momentum operators of the oscillator, has a substantial contribution to the total current in the non-Markovian case. Both the current and the equations of motion of the oscillator reduce to the Markovian forms under the appropriate limits, namely, the long time limit, which makes the coefficients time independent, and the wide band limit. We also calculate the spectral density of the coupled system. The noise spectra show that the resonant peaks depict the backaction between the QPC and the oscillator. The interplay between the noise and the backaction may have some practical applications such as amplification of the oscillators. Our results agree with the experimental evidence.

V1.00116 Fabrication of nanoporous TiO2 filters using organic–inorganic nanocomposites[1] , MEHMET BURAK KAYNAR, SNTG Lab. Physics Engineerin Dept. Hacettepe Uni. Turkey, RYAN DELPERCIO, EMRE YASSITEPE, Department of Materials Science and Engineering, University of Delaware, Newark, DE 19716, United States, SADAN OZCAN, SNTG Lab. Physics Engineerin Dept. Hacettepe Uni. Turkey, S. ISMAT SHAH, Department of Materials Science and Engineering, University of Delaware, Newark, DE 19716, United States — Nanoporous TiO2 filters with 50 nm mean pore size is synthesized by using commercial TiO2 nanoparticles and polyvinylpyrrolidone with an easy and low cost route that did not involve any solvent. Crystal's structure and surface morphologies are studied by X-ray diffraction (XRD) and scanning electron microscopy (SEM), respectively. X-ray photoelectron microscopy (XPS) is used to confirm the filtering process by analyzing pre- and post-filter affluent containing nanoparticles to simulate the filtration of micrometer (bacteria) and nanometer (virus) species. Greater than 85% filtering efficiency is obtained during the filtering of a mixture of water and 30 nm mean crystallite size of iron oxide nanoparticles.

V1.00117 Second-harmonic generation in substoichiometric silicon nitride layers , EMANUELE FRANCESCO PECORA, Boston University, ANTONIO CAPRETTI, GIOVANNI MIANO, Universita degli Studi di Napoli Federico II, LUCA DAL NEGRO, Boston University — Harmonic generation in optical circuits offers the possibility to integrate wavelength converters, light amplifiers, lasers, and multiple optical signal processing devices with electronic components. Bulk silicon has a negligible second-order nonlinear optical susceptibility owing to its crystal centrosymmetry. Silicon nitride has its place in the microelectronic industry as an insulator and chemical barrier. In this work, we propose to take advantage of silicon excess in silicon nitride to increase the Second Harmonic Generation (SHG) efficiency. Thin films have been grown by reactive magnetron sputtering and their nonlinear optical properties have been studied by femtosecond pumping over a wide range of excitation wavelengths, silicon nitride stoichiometry and thermal processes. We demonstrate SHG in the visible range (375 - 450 nm) using a tunable 150 fs Ti:sapphire laser, and we optimize the SH emission at a silicon excess of 46 at.% demonstrating a maximum SHG efficiency of 4×10^{-6} in optimized films. Polarization properties, generation efficiency, and the second order nonlinear optical susceptibility are measured for all the investigated samples and discussed in terms of an effective theoretical model. Our findings show that the large nonlinear optical response demonstrated in optimized Si-rich silicon nitride materials can be utilized for the engineering of nonlinear optical functions and devices on a Si chip.

V1.00118 Irreversibility and carriers control in two-dimensional electron gas at $LaTiO_3/SrTiO_3$ interface

, N. BERGEAL, J. BISCARAS, S. HURAND, C. FEUILLET-PALMA, J. LESUEUR, ESPCI ParisTech-CNRS, A. RASTOGI, R.C. BUDHANI, IIT kanpur, N. REYREN, E. LESNE, UMR Thales-CNRS, D. LEBOEUF, C. PROUST, LNCMI — It has been shown recently that a two-dimensional electron gas 2DEG could form at the interface of two insulators such as $LaAlO_3$ and $SrTiO_3$ [1], or $LaTiO_3$ (a Mott insulator) and $SrTiO_3$ [2-3]. We present low temperature transport measurements on $LaTiO_3/SrTiO_3$ and $LaAlO_3/SrTiO_3$ hetero-structures, whose properties can be modulated by field effect using a metallic gate on the back of the substrate [4]. Here we show that when the carrier density is electrostatically increased beyond a critical value, the added electrons escape into the $SrTiO_3$ leading to an irreversible doping regime where all the electronic properties of the 2DEG saturate (carrier density, resistivity, superconducting transition...). The dynamic of leakage was studied using time resolved measurement. Based on a complete self-consistent description of the confinement well, a thermal model for the carriers escape has been developed, which quantitatively accounts for the data [5].

V1.00119 MAGNETISM II –

V1.00120 Origin of martensitic transition in NiMnIn alloys[1]

, RENAT SABIRIANOV, NABIL AL-AQTASH, University of Nebraska at Omaha, LE ZHANG, ANDREI SOKOLOV, University of Nebraska Lincoln — We have performed density functional theory calculationsof the effect of the martensitic transition on the electronic structure of Ni_2MnIn system. We find that both the cubic and tetragonally distorted (martensite) phases are ferromagnetic. The cubic phase has lower total energy than that of the tetragonal phase by ΔE=0.3eV/f.u. Larger relative concentration of Mn in $Ni_2Mn_{1.5}In_{0.5}$ change the relative stability in favor of martensitic phase. Calculated local magnetic moment is $3.2\mu_B$ for Mn, while only $0.3\mu_B$ for Ni. The total minority densities of states exhibit a pronounced feature at Fermi level (related mainly to Ni3d states) that is sensitive to the local environment of Ni sites. The increase of the Mn content, where Mn substitutes for In sites and orders antiferromagnetically to the magnetization of the regular Mn sites, causes substantial modification in $N(E_F)$ affecting the transport properties upon the phase transition.The band structure analysis reveals that the tetragonal distortion changes the Fermi velocity at the Fermi level that may result in substantial change in resistance upon martensitic transition. We compare our results with the magnetic and transport measurements performed on the thin films of $Ni_{50}Mn_{35}In_{15}$ grown by laser-assisted molecular beam epitaxy deposition. Magnetic and transport measurements reveal the existence of martensite-austenite phase transition on tensile stressed films and co-existance of both phases at room temperature for compressively strained films. Thin films and experimental results were obtained in close collaboration with group of N. Ali, SIUC.

V1.00121 Calculated Magnetic Properties of Zigzag Boron Nitride Nanoribbon[1]

, J. RUFINUS, Science Division, Widener University — Substantial theoretical and experimental efforts have been made in the quest to find the candidates for future spintronics devices. Recently, the search for new spintronics materials has also included two-dimensional graphene-based materials due to the theoretical prediction that this type of material may show the half-metallic property. We present the results of an ab-initio density functional theory within a generalized gradient approximation study of zigzag Boron Nitride Nanoribbon (ZBNNR). Our results show different magnetic orderings. However, we found that, in general, narrow zigzag BN nanoribbon prefers a magnetic state depending on the shape and thus the orientation of the atoms on its edges. These results are especially noticeable for very narrow ZBNNR.

[1]Work partially supported by Widener University grants

V1.00122 Temperature Dependence of Magnetic Nanoparticles for Metamaterials[1]

, QUINCY WILLIAMS, NATALIA NOGINOVA, Norfolk State University, PAGNAGIOTIS DALLAS, EMMANUEL GIANNELIS, Cornell University, NORFOLK STATE UNIVERSITY COLLABORATION, CORNELL UNIVERSITY COLLABORATION — Commonly, metamaterials are systems with engineered electric response, based on optimized spatial arrangement of sub-wavelength sized metal and dielectric components. We explore alternative methods based on use of magnetic inclusions, such as magnetic nanoparticles, which can allow microwave permeability of a composite to be tuned from negative to positive at the range of magnetic resonance. Several systems with magnetic nanoparticles of different size were experimentally tested for estimate their potential as building blocks for metamaterials. Magnetic resonance studies were performed in the limits of diluted non-interacting solutions of superparamagnetic nanoparticles in liquid form and high concentrations of particles in solids at different temperatures. Broadening of the EMR signal was observed upon increase in the particle size and concentration, due to effects of anisotropy and dipolar interaction. Microwave permeability was estimated in solid composites. In dense systems with 5 nm iron oxide nanoparticles it can be tuned from –0.8 to 2 by the external magnetic field.

[1]NSF META-PREM # D MR 1205457, AFOSR # FA9550-09-1-0456, NSF IGERT # DGE-0966188, and subcontract from UTC #10-S567-001502C4.

V1.00123 Micromagnetic studies of Full Huesler alloy, Co2FeAl, nanostructures[1]

, PATRICIA YORITOMO, The Catholic University of America, NICHOLAS MECHOLSKY, PARSHU GYAWALI, KESHAB SAPKOTA, I.L PEGG, JOHN PHILIP, Vitreous State Laboratory-The Catholic University of America — Co2FeAl (CFA) is a full Huesler alloy with interesting magnetic behavior and very high Curie temperature. We have carried out micromagnetic simulations on CFA nanopillars using a program, NMAG, with various dimensions and spacing. The micromagnetic simulations are compared with the experimental results that we have obtained. Nanopillars are produced using the liftoff technique after electron beam lithography. The CFA nanopillars are grown using electron beam deposition of Co, Fe and Al in the stoichiometric ratio and by further annealing at 850 K for one hour. We have simulated the magnetic behavior of CFA nanopillars ranging from 30 to 90 nm in diameter and with a height of about 115 nm. Preliminary results show the simulated coercivities are 700 Oe and 2400 Oe for 60 and 30 nm pillars. These are comparable to the experimental results that we have obtained. Magnetic behavior of polycrystalline nanowires of varying diameters is also simulated using NMAG. We will present the simulation and experimental results of nanopillars and polycrystalline nanowires in detail.

V1.00124 Evidence for Multicritical Behavior in Nanostructured Mn-intercalated TaS_2[1]

PAUL SHAND, COREY COOLING, ZACHARY GRIFFITH, TIMOTHY KIDD, LAURA STRAUSS, University of Northern Iowa — Nanostructured Mn-intercalated TaS_2 was prepared with a nominal Mn concentration of 25%. The sample consisted of nanotube structures with diameters between 30 nm and 300 nm. X-ray diffraction measurements indicated that the Mn was incorporated into intercalation sites between the TaS_2 layers. The sample exhibited Curie-Weiss behavior virtually all the way down to the Curie-Weiss temperature of 91 K, demonstrating the absence of significant chemical clustering and short-range order in the paramagnetic regime. Magnetization versus temperature measurements indicated a ferromagnetic transition at ∼90 K, which is somewhat higher than that for bulk crystalline $Mn_{0.25}TaS_2$. An Arrott plot confirms the ferromagnetic transition at 87 K, with critical exponents close to mean-field values. However, ac susceptibility measurements in the presence of a dc bias field suggest the presence of another transition at 81 K, with critical exponents much larger than mean-field values. A scaling plot using these unusual exponents exhibited excellent collapse of the data. We interpret this behavior in terms of a nearby multicritical point, with the system exhibiting re-entrant cluster-glass behavior.

V1.00125 Tuning Magnetism and Electronic Phase Transitions by Strain and Electric Field in Zigzag MoS2 Nanoribbons[1]

LIANGZHI KOU, Bremen center of computational materials science, Germany — Effective modulation of physical properties via external control may open various potential nanoelectronic applications of single-layer MoS2 nanoribbons (MoS2NRs). We show by first-principles calculations that the magnetic and electronic properties of zigzag MoS2NRs exhibit sensitive response to applied strain and electric field. Tensile strain in the zigzag direction produces reversible modulation of magnetic moments and electronic phase transitions among metallic, half-metallic, and semiconducting states, which stem from the energy-level shifts induced by an internal electric polarization and the competing covalent/ionic interactions. A simultaneously applied electric field further enhances or suppresses the strain-induced modulations depending on the direction of the electric field relative to the internal polarization. These findings suggest a robust and efficient approach to modulating the properties of MoS2NRs by a combination of strain engineering and electric field tuning.

V1.00126 Mössbauer spectroscopy investigation of lithium oxide-hematite solid solution

VASILII BUSHUNOW, MONICA SORESCU, Duquesne University — Lithium oxide-doped hematite $x$$Li_2O$ $_*$ (1-x) α-Fe_2O_3(x = 0.1-0.7) solid solutions were prepared via ball milling. Samples were taken at 0, 2, 4, 8, and 12 hours ball milling time (BMT). Parameters for the obtained Mössbauer spectra were determined by least-squares fitting using NORMOS-90 software. For all initial Li_2O concentrations, partial substitution of Fe^{3+} in the Li_2O lattice and vice versa was seen beginning at two hours BMT. For $x = 0.1$, 0.3, and 0.5, spectra were fit with one or two sextets and one quadrupole-split doublet. For $x = 0.7$, all spectra were fit with a single sextet and one quadrupole-split doublet. With increased BMT, the abundance of the doublet increased, irrespective of initial Li_2O concentration. For example, the abundance of the doublet increased from 2.3% at 2 h BMT to 11.1% at 12 h BMT for $x = 0.1$. The increasing abundance of the doublet indicates greater substitution of Li^+ by Fe^{3+} in the Li_2O lattice. Increasing the initial concentration of Li_2O for constant BMT did not consistently increase the abundance of the doublet. The results of this experiment demonstrate the feasibility of forming solid solutions by purely mechanical methods, e.g. ball milling.

V1.00127 ABSTRACT WITHDRAWN –

V1.00128 Interplay between intrinsic and stacking-fault magnetic domains in bi-layered manganites

M.A. HOSSAIN, MARK H. BURKHARDT, S. SARKAR, SIMES, SLAC National Accelerator Laboratory, Menlo Park, California 94025, USA, H. OHLDAG, Stanford Synchrotron Radiation Lightsource, Menlo Park, California 94025, USA, Y.-D. CHUANG, A. SCHOLL, A.T. YOUNG, A. DORAN, Advanced Light Source, Lawrence Berkeley National Laboratory, Berkeley, California 94720, USA, D.S. DESSAU, Department of Physics, University of Colorado, Boulder, Colorado 80309, USA, H. ZHENG, J.F. MITCHELL, Materials Science Division, Argonne National Laboratory, Argonne, Illinois 60439, USA, H.A. DÜRR, SIMES, SLAC National Accelerator Laboratory, Menlo Park, California 94025, USA, J. STÖHR, Linac Coherent Light Source, SLAC National Accelerator Laboratory, Menlo Park, California 94025, USA — We present a low temperature x-ray photoemission electron microscopy study of the bi-layered manganite compound $La_{1.2}Sr_{1.8}Mn_2O_7$ (BL-LSMO) to investigate the influence of stacking faults, which are structurally and magnetically different from the bi-layered host [1]. In BL-LSMO, small magnetic moment persists to $T^* = 300$ K, well above the Curie temperature of 120 K (T_C). Our magnetic images show that 3D stacking faults are responsible for the T^* transition. Furthermore, close to T_C, stacking faults are well coupled to the bi-layered host with latter magnetic domains controlling the spin direction of the stacking faults. Contrary to recent reports, we find that stacking faults do not seed magnetic domains in the host via an exchange spring mechanism and the intrinsic T_C of the BL-LSMO is not lower than 120 K. [1] Appl. Phys. Lett. 101, 132402 (2012)

V1.00129 Structural, AFM, MFM and magnetic studies of $LaMnO_3$ thin films prepared by atomic layer deposition method

MUKESH CHANDRA, HIMANI KHANDURI, National Institute of Chemical Physics and Biophysics, Tallinn-12618, Estonia, S. VASALA, Department of Chemistry, Aalto University School of Chemical Technology, Finland, S. LEINBERG, R. LOHMUS, Institute of Physics, Faculty of Science and Technology, University of Tartu - 51014, Tartu, Esonia, J. KRUSTOK, Tallinn University of Technology, Tallinn- 19086, Estonia, MAARIT KARPPINEN, Department of Chemistry, Aalto University School of Chemical Technology, Finland, RAIVO STERN, National Institute of Chemical Physics and Biophysics, Tallinn-12618, Estonia — Structural, microstructural and magnetic properties of the thin films of $LaMnO_3$ have been investigated and will be presented in this paper. Thin films were deposited by atomic layer deposition method on silicon (100) substrates. Effect of varying thickness, annealing atmosphere and temperature has been studied on $LaMnO_3$ thin film. Films annealed in a temperature range 700-800 °C show single phase perovskite crystal structure, which was confirmed from the X-ray diffraction and Raman spectra. SEM/AFM studies show uniform and high quality films with grains mostly in 20-100 nm depending on preparation conditions. MFM images measured at 65K, show different magnetic domains in films annealed in N_2 and O_2 environments. Stoichiometry, microstructure and magnetic properties are strongly dependent on films annealed in N_2 and O_2 environments; however there was no change in crystal structure. Curie transition temperature in these LMO thin films annealed in N_2 were found to be around 200K, while for the films annealed in O_2 atmosphere was around 250K. Enhanced Curie temperatures from ideal value (∼140 K) can be related to non-stoichiometry in our LMO films.

V1.00130 The colossal magnetoresistance response of EuO_{1-x} thin films[1]

L. HELLWIG, C. BECKNER, M. EBLEN-ZAYAS, Carleton College — Phase inhomogeneity is one of the fundamental features of CMR physics in the perovskite manganites. In addition to direct imaging of phase inhomogeneity, indirect manifestations of phase inhomogeneity in the manganites include slow dynamics and persistent memory of low magnetic fields. We are investigating whether phase inhomogeneity is also a relevant model for thin films of europium-rich europium oxide (EuO_{1-x}). EuO_{1-x} thin films display typical CMR behavior, including a semiconductor to metal transition associated with the onset of ferromagnetism. We have fabricated CMR EuO_{1-x} films by deposition of metallic Eu on fused silica substrates and subsequent oxidation of these Eu films. However, initial characterization of the EuO_{1-x} films indicate that these samples do not show the indirect evidence of phase-inhomogeneous behavior that is typical of CMR manganite films.

V1.00131 An In Situ Electric Field Study of Magnetoelectric Coupling in PZT-LSMO Thin Film Heterostructures Using Polarized Neutron Reflectometry and Transmission Electron Microscopy

, STEVEN SPURGEON, JENNIFER SLOPPY, Drexel University, ESTHER HUANG, RAMA VASUDEVAN, University of New South Wales, SAMUEL LOFLAND, Rowan University, VALERIA LAUTER, Oak Ridge National Laboratory, NAGARAJAN VALANOOR, University of New South Wales, MITRA TAHERI, Drexel University — The development of "spintronics" devices based on charge and spin transport has signaled a paradigm shift in the design of data storage and computing technologies. Magnetoelectric materials, which exhibit intrinsic coupling between electronic and magnetic order, are ideal for these applications. Unfortunately, single-phase magnetoelectrics are exceedingly rare in nature and attention has turned to composite heterostructures that display coupled functionalities at interfaces. A promising system in which to explore this coupling is a thin film oxide heterostructure of the piezoelectric Pb(Zr0.2Ti0.8)O3 (PZT) and the half-metal La0.7Sr0.3MnO3 (LSMO). We show that it is possible to construct a capacitor-type device structure from these materials that may form the basis for an electrically-switched magnetic memory. We conduct polarized neutron reflectometry (PNR) measurements and measure changes in the magnetization depth profile throughout the composite under the reversal of an in situ electric field. We then correlate these PNR results to local strain and chemistry using transmission electron microscopy (TEM). We find that a combination of charge doping and strain mechanisms governs coupling in this system.

V1.00132 Antiferromagnetic phase in ultrathin La2/3Sr1/3MnO3 films probed by exchange bias effect

, YUJUN SHI, DI WU, Physics Departmen, Nanjing University — Understanding the magnetic and electronic properties of the interfaces between two different perovskite oxides has gained significant attention in recent years. An important case is the interface between manganite La2/3Sr1/3MnO3 (LSMO) and SrTiO3 (STO). Grown on STO, ultrathin LSMO acts as a ?dead layer? with strongly depressed magnetization and insulating properties below a critical thickness. Since the electronic and magnetic properties of the interfaces between two oxides are sensitive to epitaxial strain, chemical stoichiometry, and polarity discontinuity, the magnetic state of LSMO dead layer is still not well understood. Here we utilize the exchange bias (EB) effect, which generally occurred in the FM/AFM bilayers. We deposited a very thin layer of Co on ultrathin LSMO films epitaxially grown on STO(001) substrates. We observed strong EB effects and coercivity enhancement for LSMO thicknesses below 3 unit cells (u.c.). The observed effects reveal the presence of AFM phase in ultrathin LSMO. The EB effect rapidly disappears with increasing temperature. Furthermore, the observation of EB down to one u.c. LSMO demonstrates the C-type AFM ordering structure other than A-type. The EB provides an easy way to study the magnetic states of ultrathin oxide films.

V1.00133 Magnetic tunnel junction based on $Mn_{2-x}Co_{2x}Ni_{1-x}O_4$ Mixed valent manganite spinels[1]

, JING WU, ZHIMING HUANG, JUNHAO CHU, Shanghai Institue of Technical Physics, Chinese Academy of Science — $Mn_{2-x}Co_{2x}Ni_{1-x}O_4$ ($0 \leq x \leq 1$) (MCNO), developing basically from the prototype of Mn_3O_4, which are spinel-structure mixed-valent manganites and electrical and magnetic properties are closely linked with interactions among spin, orbit and lattice. The electrical conduction mechanism in MCNO is small polarons hopping between localized Mn3+ and Mn4+ octahedral sites. As we known, the magnetic orders of spinel-structure transition metal oxide are commonly ferrimagnetic with antiferromagnetic exchange between tetrahedral and octahedral sites. The conductive electron i.e. e_g orbital electron hopping between octahedral Mn^{3+} and Mn^{4+} sites tends to be totally spin polarized due to the strong ferromagnetic couple between octahedral sites. Vice versa, the hopping electron enhanced the ferromagnetic couple between Mn^{3+} and Mn^{4+} sites by RKKY indirect exchange interaction. This feature of MCNO is very potential for developing MTJ due to the totally spin polarized conductive electrons. MTJs based on MCNO have been constructed by Magnetron Sputtering method. The performance of these MTJs is under studying at present.

V1.00134 Current-induced domain wall motion in the presence of spin Hall effect

, JISU RYU, PCTP and Department of Physics, Pohang University of Science and Technology, Kyungbuk 790-784, Korea, KYUNG-JIN LEE, Department of Materials Science and Engineering, Korea University, Seoul 136-701, Korea, HYUN-WOO LEE, PCTP and Department of Physics, Pohang University of Science and Technology, Kyungbuk 790-784, Korea — Recently, traces of the spin Hall effect-induced spin transfer torque (SHE-STT) on a domain wall motion (DWM) are observed.[1] While the magnetization reversal of a single domain by SHE-STT [2] can be understood rather intuitively, SHE-STT effect on a DWM is indistinct. This issue is theoretically investigated [3] in ideal nanowires, where extrinsic pinning centers are absent. In practical situations, however, the DWM can be largely affected by the pinning centers such as nanowire defects. Here, we theoretically study SHE-STT effects on a DWM in the presence of extrinsic pinning centers. We first calculate the threshold current density J_C, above which a DW can escape from a pinning center. We found that SHE-STT can significantly reduce J_C of a DW with certain chirality. Secondly we examine a DWM direction. In ideal nanowires [2] SHE-STT can induce a DWM against electron flow in a certain current density range. We found that this reversed DWM can be prohibited for the pinning strength larger than certain threshold value. From this feature, we suggest one way to distinguish SHE-STT and the Rashba spin-orbit coupling induced STT. [1] P. P. J. Haazen et al., arXiv:1209.232(2012). [2] Liu et al., Science 336, 555(2012). [3] S.-M. Seo et al., Appl. Phys. Lett. 101, 022405(2012).

V1.00135 Spectral and transport properties of ballistic quantum wire exposed to two magnetic spikes

, BERND SCHUELER, MIHAI CERCHEZ, HENGYI XU, THOMAS HEINZEL, HHU Duesseldorf — Quantum Dots (QD) in two-dimensional electron gases are typically defined by nanopatterned gate electrodes.[1] While magnetically confined QDs have been proposed theoretically to show some specific phenomena,[2] their experimental implementation is still at an early stage.[3] We have designed a ferromagnet/semiconductor hybrid structure device which allows us to form a QD by combining electrostatic potentials with localized magnetic fields in the form of two magnetic spikes at sub-micron distances. While numerical simulations of this system predict Coulomb blockade in the closed regime and Fano type resonances in the open system,[4] we observe experimentally transmission resonances in the open system which can be interpreted as signatures of zero-dimensional states weakly bound by the magnetic field profile.

V1.00136 Magnetic properties and spin transport in hybrid boron-nitrogen-carbon nanoribbons with transitional metal impurities[1]

, GEORGE ALEXANDRU NEMNES, TUDOR LUCA MITRAN, ADELA NICOLAEV, University of Bucharest, Faculty of Physics, "Materials and Devices for Electronics and Optoelectronics" Research Center, CAMELIA VISAN, Horia Hulubei National Institute of Physics and Nuclear Engineering, The Department of Computational Physics and Information Technologies, LUCIAN ION, STEFAN ANTOHE, University of Bucharest, Faculty of Physics, "Materials and Devices for Electronics and Optoelectronics" Research Center — We investigate the spin filtering effects in graphene nanoribbons, where inclusions of hexagonal boron nitride were introduced together with substitutional transitional metal impurities. It was established recently [1] that boron nitride sheets with substitutional manganese impurities can be a strong candidate for future low dimensional diluted magnetic semiconductors. Our first principle approach based on non-equilibrium Green's functions gives the polarization of the spin current for different structures and biases [2]. Several spin configurations of the magnetic impurities are considered, revealing different behaviors in the spin resolved current. Some key aspects regarding spin switching effects, i.e. the turning on and off the net spin current at different biases, are also discussed. The experimental availability of the building blocks – hybrid boron-nitrogen-carbon (BNC) materials – as well as the magnitudes of the obtained spin current polarizations indicates a strong potential of the analyzed structures for future spintronic devices. V1.00137 Quantum oscillation due to Landau subbands in bulk Ge at room temperature

, YUHSUKE YASUTAKE, SUSUMU FUKATSU, Graduate School of Arts and Sciences, The University of Tokyo — An electronic system evolves into Landau levels in strong magnetic field at low temperature unless scattering occurs. Here we attempt to observe Landau subbands at room temperature in bulk Ge. Circularly polarized photoluminescence was taken in magnetic fields up to 10 T. Quantum oscillation due to several inter-Landau level transitions in the direct valleys of Ge was clearly observed at 300 K. Individual Landau subbands are resolved as discrete peaks. The n = 0 subband showed diamagnetic shifts without optically orientation. Spin relaxation at room temperature is much faster than energy relaxation including intervalley electron-phonon scattering. Interestingly, peak separations smaller than the thermal energy were even observable, which defies the established criterion that Landau levels should develop.

V1.00138 Bilinear-biquadratic anisotropic Heisenberg model on a triangular lattice[1]

, ANTONIO PIRES, Universidade Federal de Minas Gerais — Motivated by the fact that the study of disordered phases at zero temperature is of great interest, I study the spin-one quantum Heisenberg antiferromagent with a next-nearest neighbor interaction on a triangular lattice with bilinear and biquadratic exchange interaction and a single ion anisotropy using a SU(3) Schwinger boson mean field theory.I calculate the critical properties, at zero temperature, in the disordered phase. This is, for values of the single ion anisotropy paramenter D aboce a critical value Dc where a quantum phase transition takes place to a lower D phase.

[1]CNPQ-FAPEMIG

V1.00139 Multiferroic properties in the spin-frustrated $Cu_2Te_2O_5X_2$ (X = Cl and Br)

, YU-KUAN YANG, CHIN-CHIA YEH, YI-BIN JIN, SUDIP MUKHERJEE, Department of Physics, National Sun Yat-Sen University, Kaohsiung 804, Taiwan, HELMUTH BERGER, Institutes of Physics of Complex Matter, EPFL 1015, Lausanne, Swizerland, HUNG-DUEN YANG, Department of Physics, National Sun Yat-Sen University, Kaohsiung 804, Taiwan — The geometrically frustrated spin-tetrahedral systems $Cu_2Te_2O_5X_2$ (X = Cl and Br) have been studied using magnetization, dielectric constant and temperature-dependent x-ray diffraction. It was found that a antiferromagnetic ordering and a step-jump in polarization are observed at T=18.5 K for X=Cl and T=11.5 K for X=Br, respectively. The multiferroic properties for $Cu_2Te_2O_5X_2$(X = Cl and Br) are discussed.

V1.00140 Metal doping effects on the skyrmion Cu_2OSeO_3

, DA-YE CHEN, KUO-FENG TSENG, CHIH-CHIEH CHOU, SUDIP MUKHERJEE, Department of Physics, National Sun Yat-Sen University, Kaohsiung 804, Taiwan, JIM-LONG HER, Institute for Solid State Physics, University of Tokyo, Tokyo, Japan, HELMUTH BERGER, Institutes of Physics of Complex Matter, Ecole Polytechnique Federale de Lausanne(EPFL),CH-1015 Lausanne,Switzerland, HUNG-DUEN YANG, Department of Physics, National Sun Yat-Sen University, Kaohsiung 804, Taiwan — There is a considerable research interest in skyrmion whose magnetic properties have a remarkable characteristic as a vortex-like spin orientation. Recently, neutron scattering and Lorentz transmission electron miscropy measurements showed that Cu_2OSeO_3 exists a skyrmion state. We have doped transition metals (Fe, Mn, V) in Cu_2OSeO_3 and measured dc magnetization and ac susceptibility by scaning magnetic field. The Fe and Mn doping effect on the A phase in T-H phase diagrams of Cu_2OSeO_3 has been studied. Interestingly, the doping with V is different from that with Fe and Mn. The physical significance for metal doping on the skyrmion Cu_2OSeO_3 will be discussed.

V1.00141 The Effects of Magnetic Dilution on Geometrically Frustrated Germanium Based Spinels

, JORY KOROBANIK, FEREIDOON RAZAVI, Brock University — Geometrically frustrated materials are characterized by the inability to simultaneously minimize exchange energy contributions. This causes a reduction of Neel ordering temperature. My research focuses on how magnetic dilution changes the physical properties of geometrically frustrated spinels. Magnetic and dielectric properties will be presented.

V1.00142 Spin glass behavior in the weberite related structure $Dy_{3-x}Y_xTaO_7$

, JOSE FRANCISCO GOMEZ GARCIA, Facultad de Quimica, GUSTAVO TAVIZON, Facultad de Quimica, Universidad Nacional Autonoma de México, ALEJANDRO DURAN, Centro de Nanociencias y Nanotecnologia, ROBERTO ESCUDERO, Instituto de Investigacion en Materiales, Universidad Nacional Autonoma de México — Crystalline structures with tetrahedral arrangement of magnetic cations are susceptible to present non-collinear magnetism. Dy_3TaO_7 with weberite-type crystal structure has this arrangement and could display non-conventional magnetic coupling. Previous magnetic studies on Dy_3TaO_7 have characterized this as an antiferromagnetic system with T_N of about 3 K. In this work magnetic properties of polycrystalline samples of the $Dy_{3-x}Y_xTaO_7$, with weberite structure are presented. X-Ray diffraction of our samples are single phase in all range of compositions. Magnetic properties measured from 2 - 300 K shown a typical Curie-Weiss behavior with the Dy^{3+} effective magnetic moment about 10.35 μ_B. The compositions x=0.66, 0.33, and 0.0 display a maximum in the susceptibility *vs.* temperature at 2.3, 2.7, and 3 K respectively. This behavior has been previously assigned to an antiferromagnetic transition; however our AC magnetic measurements as a function of frequency indicate a spin glass behavior. Since magnetic cations have tetrahedral arrangement for x=0, a magnetic frustrated state is anticipated for this composition.

V1.00143 Critical properties of the Kitaev-Heisenberg Model[1]

, YURIY SIZYUK, The Physics Department of UW Madsion, CRAIG PRICE, The Physics Department of Penn State University, NATALIA PERKINS, The Physics Department of UW Madsion — Collective behavior of local moments in Mott insulators in the presence of strong spin-orbit coupling is one of the most interesting questions in modern condensed matter physics. Here we study the finite temperature properties of the Kitaev-Heisenberg model which describe the interactions between the pseudospin $J = 1/2$ iridium moments on the honeycomb lattice. This model was suggested as a possible model to explain low-energy physics of AIr_2O_3 compounds. In our study we show that the Kitaev-Heisenberg model may be mapped into the six state clock model with an intermediate power-law phase at finite temperatures. In the framework of the Ginsburg-Landau theory, we provide an analysis of the critical properties of the finite-temperature ordering transitions.

[1]NSF grant DMR-1005932

V1.00144 Dynamical Band-Engineering of Spin-Polarized Edge States in Nanostructures[1]

, BINHE WU, Department of Applied Physics, Donghua University — The ability to engineer the band structure and electronic properties of nanostructures is a key step for potential applications ranging from spintronic devices to quantum information. We present theoretical results on the electronic and transport properties of a normal insulator, in form of a zigzag ribbon based on the graphene-like Kane-Mele model subjected to circularly polarized radiation. It is found that chiral edge-states can be induced in the band gap of the quasi-energy spectra under periodic driving. More interestingly, for appropriate parameters, there exists a single chiral edge state at each boundary of the sample. As a result, the conductance shows plateau structure with the step height e^2/h as we increase the ac field intensity. These observations may find their potential applications for high-efficiency non-magnetic spin injection which can be readily tuned by modulating an external ac field.

V1.00145 Tailoring spin injection and magnetoresistance in ferromagnet/graphene junctions from first principles[1]

, PREDRAG LAZIC, Rudjer Boskovic Institute, Zagreb, Croatia, GUILHERME SIPAHI, University at Buffalo/Universidade de Sao Paulo, Brazil, ROLAND KAWAKAMI, University of California, Riverside, IGOR ZUTIC, University at Buffalo — Recent experimental advances in graphene [1-3] suggest intriguing opportunities for novel spintronic applications which could significantly exceed the state-of-the art performance of their conventional charge-based counterparts[4,5]. However, for reliable operation of such spintronic devices it is important to achieve an efficient spin injection and large magnetoresistive effects. We use the first principles calculations to guide the choice of a ferromagnetic region and its relative orientation to optimize the desired effects. We propose structures which could enable uniform spin injection, one of the key factors in implementing scalable spintronic circuits. [1] C. Josza and B. V1.00146 Macroscopic quantum effects in a rotating nanomagnet

, GWANG-HEE KIM, Sejong University — We study spin tunneling in a rotational magnetic nanoparticle in the presence of sound waves. Equations of motions are derived that couple spin and mechanical degrees of freedom and the perturbative solution of these equations is obtained. We find quantum beats of magnetization which are strongly affected by the moment of inertia of the molecular magnet and its total angular momentum. The optimal condition for generating the quantum beat of magnetization with a large period is discussed.

V1.00147 High-field NMR spectroscopy of the iron based superconductor LiFeAs

, HANNES KUEHNE, A.P. REYES, P.L. KUHNS, M.J.R. HOCH, S. YUAN, Florida State University/National High Magnetic Field Laboratory, H.-J. GRAFE, S. ASWARTHAM, S. WURMEHL, B. BUECHNER, Institute for Solid State Research, Dresden, Germany — The stoichiometric compound LiFeAs is unique among the iron based superconductors. It exhibits superconductivity below 18 K without the usually necessary introduction of chemical doping. From a number of macroscopic experiments, upper critical fields of 26 T or higher for a magnetic field orientation parallel to the FeAs planes were reported. But, until now, no local probe techniques were applied for the characterization of the microscopic electronic properties in this high-field parameter regime. On our poster, we present the results of recently performed high-field (up to 30 T) NMR experiments on three high quality LiFeAs single crystals, suggesting an upper critical field much lower than 26 T. We discuss the implications of the observed, field-induced suppression of the superconducting gap in this compound and its manifestation in the temperature dependent Knight shift, nuclear spin-lattice and spin-spin relaxation rates for fields and temperatures in the normal and superconducting state.

V1.00148 SUPERCONDUCTIVITY –

V1.00149 Bromine-doping dependence of crystal structure and superconductivity in $FeSe_{1-x}Br_x$[1]

, Y.T. SHEN, S.C. CHEN, K.J. SYU, W.H. LEE, Department of Physics, National Chung Cheng University, W. H. LEE TEAM — Our experimental data indicate that the crystal structure formation in $FeSe_{1-x}Br_x$ is dependent on the amount of Br. For the samples with x between 0.18 and 0.3, the single tetragonal β-FeSe phase with space group P4/nmm could be obtained by carrying out the low-temperature (400 ^{o}C) annealing after reaction at 680 ^{o}C. As to the sample with $x = 0.1$, a heat firing at 680 ^{o}C is in favor of forming single hexagonal δ-FeSe phase with space group $P6_3/mmc$. Powder x-ray diffraction and crystallographic data provide the suggestion that the β tetragonal PbO-type phase is related to the superconducting state while the δ hexagonal NiAs-type phase has no effect on the superconductivity. Magnetization data confirm the bulk character of the superconducting state with a T_c around 5 K. Larger superconducting volume fraction appears in the single-phase sample with x near 0.2.

V1.00150 Optical investigation of $Ba(Fe_{1-x}Co_x)_2As_2$ detwinned by tunable uniaxial applied pressure

, CHIARA MIRRI, ADAM DUSZA, SANDRA BASTELBERGER, ANDREA LUCARELLI, Solid State Physics Laboratory, ETH Zurich, CH-8093 Zurich, Switzerland, HSUEH-HUI KUO, JIUN-HAW CHU, IAN FISCHER, Geballe Laboratory for Advanced Materials and Department of Applied Physics, Stanford University, Stanford, California 94305-4045, USA, LEONARDO DEGIORGI, Solid State Physics Laboratory, ETH Zurich, CH-8093 Zurich, Switzerland — The iron-pnictide superconductors are excellent materials where one can study the competition between structural, magnetic and superconducting phases. In the parent compound (i.e. x = 0%) and in the so called underdoped regime (x<6%) an antiferromagnetic transition occurs at T_N with an almost coincident tetragonal-to-orthorhombic structural distortion at $T_s \geq T_N$. The in-plane anisotropy of the orthorombic phase was found to be masked by the formation of twin domains in these compounds, which can be detwinned by applying uniaxial pressure. Here we report on an optical investigation performed with electromagnetic radiation polarized along the a and b axes of $Ba(Fe_{1-x}Co_x)_2As_2$ single crystals , for x=0, 2.5% and 4.5%, detwinned by in-situ tunable uniaxial pressure applied across the stuctural and the magnetic transitions. We show in details the experimental setup, i. e. the pressure device used to detwin the samples, and the most remarkable results. In particular we focus on the evolution of the anisotropy in the reflectivity by applying and releasing pressure at different fixed temperatures.

V1.00151 Magnetic Properties of Iron Chalcogenide Superconducting Materials for Energy Storage Applications

, DESTENIE KNOCK, KOREY POUGH, ABEBE KEBEDE, North Carolina A&T State University, DEREJE SEIFU, Morgan State University — A superconductor is characterized by its ability to conduct electricity without loss and expel magnetic flux when exposed to an external magnetic field. Additionally, the smaller the relaxation rate (S =dM/dt), the better the material for energy storage. This research focuses on the recently discovered high-quality, single-crystalline Iron-based superconductors of $FeTe_{1-x}Se_x$ (x =0.5), with a transition temperature at T_c =14.5K. Standard creep models are used to analyze the data and determine the effective pinning potential. The magnetization relaxation were measured the Superconducting Quantum Interference Device (SQUID). The relaxation rate appears to be independent of field and temperature for fields below 3T and temperatures below 7K. This result shows that the thermally activated flux motion is not as significant as in other high temperature superconductors, hence $FeTe_{1-x}Se_x$, can be a candidate for wire development to be used in Superconducting Magnetic Energy Storage systems.

V1.00152 Crystal structure and physical properties in Fe-Te-Br[1]

, C.H. HO, S.C. CHEN, K.J. SYU, W.H. LEE, Department of Physics, National Chung Cheng University, W. H. LEE TEAM — Within a spin fluctuation driven scenario of superconductivity the results indicate that FeTe with doping is a likely higher-temperature superconductor. However, $Fe_{1+x}Te$ forms the same tetragonal structure with 0.06 <y <0.17. The excess Fe (2) not only stabilizes the PbO-type crystal structure with space group P4/nmm but also is strongly magnetic as an electron donor while the deficit of Fe in $Fe_{1-x}Te$ will result in the hexagonal structure with space group $P6_3/mmc$. In this work, five single tetragonal phase samples with space group P4/nmm and three single hexagonal phase samples with space group $P6_3/mmc$ have been made in Fe-Te-Br. Magnetic and electrical properties as well as the possibility of high-T_c superconductivity in the Fe-Te-Br system investigated will be discussed.

[1]Supported by the National Science Council of Republic of China under Contract Numbers NSC-99-2112-M-194-006-MY3 and NSC-101-2811-M-194-016.

V1.00153 Thermopower as sensitive probe of electronic nematicity in iron pnictides[1]

, PHILIPP GEGENWART, I. Physikalisches Institut, Georg-August University of Goettingen — We study the in-plane anisotropy of the thermoelectric power and electrical resistivity on detwinned single crystals of isovalent substituted $EuFe_2(As_{1-x}P_x)_2$. Compared to the resistivity anisotropy the thermopower anisotropy is more pronounced and clearly visible already at temperatures much above the structural and magnetic phase transitions. Most remarkably, the thermopower anisotropy changes sign below the structural transition. This is associated with the interplay of two contributions due to anisotropic scattering and orbital polarization, which dominate at high- and low-temperatures, respectively. Preprint available at arXiv:1210.2634.

[1]in collaboration with Shuai Jiang, H.S. Jeevan and Jinkui Dong

V1.00154 Effects of pressure on T_c in $(Tl_{0.59}Cs_{0.26})Fe_{1.9}Se_2$[1]

, S.C. CHEN, K.J. SYU, H.H. SUNG, W.H. LEE, Department of Physics, National Chung Cheng University, C.C. LI, Y.Y. CHEN, Institute of Physics, Academia Sinica, W. H. LEE TEAM, Y. Y. CHEN TEAM — Hydrostatic-pressure (up to 0.96 GPa) dependence of T_c in a newly discovered Fe-based superconductor $(Tl_{0.59}Cs_{0.26})Fe_{1.9}Se_2$ is reported. The room temperature powder x-ray diffraction and crystallographic data provide the evidence for bulk superconductivity with T_c around 28 K in a tetragonal $ThCr_2Si_2$-type structure at ambient pressure. Static Magnetization measurements under pressure indicate that the linear increase in T_c is initially rapid (dT_c/dP = 9.9 K GPa^{-1}) but slows down to dT_c/dP = 2.5 K GPa^{-1} for P >0.18 GPa. The T_c of the superconducting phase is 32 K at pressure P = 0.96 GPa. The simple rigid band model may not be sufficient to account for the observations if the lattice parameters of the unit cell are linearly decreased with the hydrostatic pressure.

V1.00155 Conventional and Time-Resolved Infrared Spectroscopy of La-1111 Thin Films[1]

, XIAOXIANG XI, Photon Sciences, Brookhaven National Laboratory, Y. M. DAI, C. C. HOMES, Cond. Matter Phys. & Mat'ls Sci Dept, Brookhaven National Laboratory, M. KIDSZUN, S. HAINDL, IFW Dresden, G. L. CARR, Photon Sciences, Brookhaven National Laboratory — We have performed both conventional as well as time-resolved far-infrared spectroscopy on $LaFeAsO_{1-x}F_x$ pnictide thin films. The conventional spectroscopy results can be fit using a simple gapped superconductor + normal conductor two-component model. Absorption by quasiparticles in a gap system with nodes is a plausible explanation for the normal component [Lobo *et al.* Phys. Rev. B 82, 100506(R) (2010)]. The time-resolved study is performed by laser-pump, far-IR probe spectroscopy using synchrotron radiation at NSLS beamline U4IR. A laser pulse breaks superconducting pairs and the synchrotron probe is used to sense the recombination process. In contrast to the picosecond response observed for cuprate superconductors, we observe a nanosecond response typical of a fully gapped superconductor where phonon-bottleneck effects slow the effective recombination rate. This result suggests the presence of a full isotropic gap, as might exist at lower energies due to electronic scattering [Carbotte *et al.* Phys. Rev. B 81, 104510 (2010)].

V1.00156 Low Field Microwave Absorption in thin films of FeSe and FeTeSe deposited by PLD

, JONATHAN YUEN, AUSTIN HOWARD, Nanotech Institute, University of Texas at Dallas, LI CHEN, HAIYAN WANG, Electrical & Computer Engineering, Texas A&M University, MYRON SALAMON, ANVAR ZAKHIDOV, Nanotech Institute, University of Texas at Dallas — Our motivation is to study the 2D superconductivity of Fe-based materials deposited on different substrates - glass, STO and CNT. Pulsed laser deposition of FeSe and FeSe0.5Te0.5 films was performed. Deposition conditions including laser fluences, frequency, temperature and back pressure were optimized for different substrates. When anisotropic superconductors are confined to lower dimensions, interesting effects have been observed. Enhanced superconductivity might occur from interfacial effects, and it has been claimed that an atomic layer of FeSe may exhibit higher Tc at STO interface. LFMA (microwave absorption at low magnetic fields) is a highly sensitive tool for searching for possible higher Tc phases in FeSe based films, especially when combined with ESR, SQUID magnetometry and resistivity measurements. LFMA uses an external magnetic field to create Josephson Junction vortices, which are non-resonantly excited by MW radiation. Such vortices have strong angle dependence in 2D systems and can be used to carefully probe and understand confinement effects. The LFMA spectrum exhibits two distinct features in different temperatures: a hysteretic LFMA below 8K and non-hysteretic narrow LFMA at higher T. Angle dependences of the LFMA signals are analyzed and the origin of the higher Tc LFMA signals will be discussed.

V1.00157 Bulk superconductivity in novel $Bi_4O_4S_3$ compound , SHIVA KUMAR SINGH[1], 1,2, M. HUSAIN[2], 2, S. PATNAIK[3], 3, V. P. S. AWANA, 1 — We report here synthesis and superconductivity in BiS_2 based newly discovered $Bi_4O_4S_3$ compound. The compound is synthesized through vacuum encapsulation technique and is contaminated with small impurities of Bi_2S_3 and Bi. The compound is crystallized in tetragonal I4/mmm space group. Bulk superconductivity with superconducting transition temperature (T_C) of 4.4 K is confirmed by AC, DC magnetization and resistivity measurements. For further confirmation of intrinsic bulk superconductivity, we have heat treated Bi at same temperature and in similar condition. Bi is crystallized in rhombohedral R-3m space group (impurity phase Bi is also indexed in same space group) and is non-superconducting. This excludes any possibility of impurity driven superconductivity in the $Bi_4O_4S_3$ compound. Isothermal magnetization (M-H) measurements indicated closed loops with clear signatures of flux pinning and irreversible behavior. The magneto-transport $\rho(T, H)$ measurements showed a resistive broadening and decrease in T_C ($\rho = 0$) to lower temperatures with increasing magnetic field. The extrapolated upper critical field $H_{c2}(0)$ is around 31 kOe. In the normal state the $\rho \sim T^2$ is not indicated.

V1.00158 Magnetic property and phase diagram of single-crystalline over-doped $Ba_{1-x}K_xFe_2As_2$, YU LI, CHENGLIN ZHANG, PENGCHENG DAI, Department of Physics and Astronomy, The University of Tennessee, Knoxville — Sizable single-crystalline samples of hole-doped $Ba_{1-x}K_xFe_2As_2$ with $x > 0.4$ have been grown and characterized via magnetic measurements. Tc of our samples decreases from that of optimal doping as doping rate of K increases. Sharp transitions in M(T) curves indicate high quality of our sizable crystals which has never succeeded in over-doped region due to extreme nonhomogeneous property of this kind of material. With increasing K content, electron Fermi surface diminishing and nesting between hole FS and electron FS disappearing consequently, it is predicted that there exists a transition from s-wave superconducting state to d-wave yet without sufficient experimental evidences. Our results made it possible to further study on the hole-overdoped $Ba_{1-x}K_xFe_2As_2$ series and provide a significant platform to test and verify these current theories and understand the underlying pairing mechanism in iron-based superconductors.

V1.00159 Investigation of Gd effect on $YBa_2Cu_3O_{7-\delta}$ superconducting compounds , NEVIN SOYLU, OSMAN GORUR, AHMET VARILCI, CABIR TERZIOGLU, Department of Physics, Abant Izzet Baysal University, Bolu, 14280, Turkey — We studied the change of pinning mechanism, electrical, structural, physical, and superconducting properties of $YBa_2Cu_{3-x}Gd_xO7-\delta$ superconductor samples prepared by the conventional solid state reaction method ($x = 0, 0.025, 0.050, 0.100$ and 0.150) by use of dc resistivity, X-ray analysis (XRD),and scanning electron microscopy (SEM). The obtained results demonstrate that $T_{c,offset}$ values of the samples decrease slowly with the increase in the Gd content. The maximum $T_{c,offset}$ (92.0 K) is obtained for the pure sample prepared at 940° C for 20 h in air atmosphere while the minimum value of 83.3 K is found for the sample doped with 0.150 Gd content. Moreover, it is obtained that J_c values reduce from 132 to 34 A/cm^2 with the enhancement of the Gd level in the crystalline structure. The peak intensities belonging to Y123 (major) phase are obtained to decrease whereas the peak intensities of the minor phases such as $BaCuO_2$ and Y211 are found to enhance systematically with the increment in the Gd content in the system, illustrating that partial substitution of Cu^2+ions by Gd^3+ ions are carried out successfully.

V1.00160 ABSTRACT WITHDRAWN –

V1.00161 Study of solitons in strongly correlated systems , IRINA BARIAKHTAR, Boston College, ALEXANDER NAZARENKO, Harvard University — The aim of this paper is to draw the researchers' attention to the fact that the study of the scattering of x rays (or, incidentally, the scattering of light or electrons), together with an investigation of the neutron scattering, can give important experimental information about the properties of the solitons in solids. In this work we discuss the one-dimensional solitons that arise in two-dimensional (quasi-two-dimensional) crystals. As an example of such systems we use some high-temperature superconductor materials. In this paper we calculate the structure factors of solitons. We consider examples of solitons corresponding to the formation of a kink (fold) in a system of adatoms on the surface of a substrate. We discuss that by calculating the cross section for elastic scattering of x-rays and comparing it to experimental data one can investigate the presence and properties of solitons in such systems.

V1.00162 Flux Quantization Without Cooper Pairs , ALAN M. KADIN, Princeton Junction, NJ 08550 USA — It is universally accepted that the superconducting flux quantum h/2e requires the existence of a phase-coherent macroscopic wave function of Cooper pairs, each with charge 2e. On the contrary, we assert that flux quantization can be better understood in terms of single-electron quantum states, localized on the scale of the coherence length and organized into a real-space phase-antiphase structure [1]. This packing configuration is consistent with the Pauli exclusion principle for single-electron states, maintains long-range phase coherence, and is compatible with much of the BCS formalism. This also accounts for h/2e in the Josephson effect [2], without Cooper pairs. Experimental evidence for this alternative picture may be found in deviations from h/2e in loops and devices much smaller than the coherence length. A similar phase-antiphase structure may also account for superfluids, without the need for boson condensation.

V1.00163 Electronic origin of charge-density wave instability in underdoped YBCO , RICCARDO COMIN, G. LEVY, I. ELFIMOV, G.A. SAWATZKY, A. DAMASCELLI, Quantum Matter Institute, UBC, Vancouver, Canada — Very recent diffraction and scattering results found direct (i.e. structural) evidence for an incommensurate charge-density-wave (CDW) in underdoped YBCO ($p \sim 0.1 - 0.12$), which appears to be electronically-driven and competing with superconductivity. We have investigated the origin of this CDW-instability by analizing in detail the charge susceptibility starting from the experimentally available ARPES maps, and using an RVB-derived self-energy whose parameters are tuned to maximize comparison to ARPES data. We derive the non-interacting and full susceptibilities, which reveal how the electronic response evolves starting from the bare, uncorrelated (LDA-like) band structure to the fully dressed single-particle spectral function (incorporating both coherent and incoherent excitations). We then compare the temperature-dependent calculations to the scattering results and resolve the connection between single-particle spectroscopies and structural probes in YBCO.

V1.00164 Capillary Condensation Transitions for Various Geometries , CAROLINA ILIE, ANASTASIA YORKE, KATHARYN CHRISTIANA, MARIE ROMANO, Physics Department, State University of New York at Oswego — We explore herein the capillary condensation for planar geometry. Capillary condensation is studied in the presence of van der Waals forces. We derive the grand free energy for one planar substrate, then for two identical substrates, and we analyze the phase transitions, the absorption isotherms and the triple point. Phase transitions between full, empty and two films are investigated. Other interesting cases, for example the capillary condensation between two cylinders, may be inspected.

V1.00165 High pressure Moissanite-anvil cells for the low temperature Hall effect measurements of oxide superconductors[1]

, SHUSUKE YOMO, Tokai University, Sapporo, Japan, STANLEY W. TOZER, National High Magnetic Field Laboratory, Tallahassee, USA — The Hall effect was successfully measured for a single crystal of high temperature superconductor in a Moissanite-anvil clamp cell up to 5 GPa, with proper arrangement of lead wires and a sample. Zylon gasket, good in electrical insulation, worked well up to 5 GPa. The 30-40 % increase of the clamped pressure was observed during cooling to below 60 K. The appreciable pressure effect of the a-b plane Hall coefficient was observed and negative for $La_{2-x}Sr_xCuO_4$ with x = 0.090. The result is discussed with those for sintered samples and those studied with a different pressurizing method.

[1]Thanks are due to Visiting Scientist Program, NHMFL, and NNSA grant DE-FG52-03NA00066.

V1.00166 Finite temperature dynamical density matrix renormalization group study of high-energy optical conductivity in high-Tc cuprates

, SHIGETOSHI SOTA, RIKEN AICS, TOMONORI SHIRAKAWA, SEIJI YUNOKI, RIKEN AICS, RIKEN ASI, CREST — Synchrotron-based high-energy optical conductivity measurement has been proposed as an effective experimental means to investigate the magnetic correlations around doped carriers in strongly correlated materials. For example, very recent experiments on high-Tc cuprates have observed the surprisingly significant temperature dependence of the spectra for an energy region much higher than the value of the spin exchange ($\sim$ 125 meV) below room temperature. Motivated by these experiments, we here study the high-energy optical conductivity and its temperature dependence of an effective model for high-Tc cuprates using massively parallelized dynamical density matrix renormalization group (DMRG). To describe the Zhang-Rice singlet as well as the high-energy excitations properly, we employ a one-dimensional three-band Hubbard model describing a CuO_3 chain. Our finite-temperature dynamical DMRG calculations find the strong temperature dependence of the optical conductivity, which occurs over a wide range of the excitation energy. We attribute this anomalously strong spectral redistribution to a magnetic origin, thus indicating that the high-energy optical conductivity contains valuable information of spin dynamics.

V1.00167 Core-level Photoemission Study for Cuprates with a Dynamical Mean-Field Approach Considering Realistic Crystal Structure

, ATSUSHI HARIKI, TAKAYUKI UOZUMI, Department of Mathematical Sciences, Graduate School of Engineering, Osaka Prefecture University — Recently, remarkable experimental progress reveals some characteristic spectral features in the $2p_{3/2}$main line of Cu 2p core-level X-ray photoemission spectra (XPS)[1]. The structures show strong material dependence and drastic changes for electron or hole doping. Van Veenendaal et al., pointed out that the main line shape is strongly affected by the so-called nonlocal screening which is accompanied by a formation of a Zhang-Rice singlet (ZRS) in the XPS final state[2]. On the other hand, Taguchi et al., shows these features are reproduced by introducing an phenomenological extended impurity model[1]. We consider that this topic on 2pXPS of cuprates still remain controversial. In this study, we propose another approach based on the dynamical mean field theory(DMFT) considering the realistic crystal structure. Many-particle effects including the ZRS is appropriately embedded in the hybridization function of a single impurity Anderson model through the DMFT self-consistent cycle. Our approach reproduces experimental results and shows that the Cu $2p_{3/2}$ main line is closely related with the quasi-particle structure near the Fermi energy.

V1.00168 Monte Carlo and Langevin dynamics simulations for the steady-state and relaxation properties of magnetic flux lines in type-II superconductors[1]

, HIBA ASSI, ULRICH DOBRAMYSL, MICHEL PLEIMLING, UWE TAUBER, Department of Physics, VA Tech — We investigate the non-equilibrium relaxation properties and steady states of interacting magnetic flux lines in type-II superconductors in the presence of driving external currents and / or different types and configurations of pinning centers. We model the vortices as elastic lines, and study the competing effects of thermal fluctuations, mutual repulsion, and pinning to defects. We employ both three-dimensional Monte Carlo and more efficient Langevin molecular dynamics simulations. Comparison of the resulting data for the non-equilibrium stationary states as well as the preceding relaxation regimes allows us to validate the utilization of both algorithms in out-of-equilibrium settings. We furthermore carefully analyze finite-size effects.

V1.00169 Resistive Losses in Single-Crystal $Ba_{0.6}K_{0.4}Fe_2As_2$

, BRENDAN BENAPFL, University of Notre Dame, CHENGLIN ZHANG, PENGCHENG DAI, University of Tennessee, Knoxville, H.A. BLACKSTEAD, University of Notre Dame — Temperature- and field-dependent surface resistance measurements were conducted using Electron Spin Resonance (ESR) techniques on single-crystal $Ba_{0.6}K_{0.4}Fe_2As_2$ samples (*rf* frequency = 20.3 GHz). At a fixed temperature, field scans were performed at various angles of H_0 with respect to H_{rf}. To our knowledge, this is the first report of such studies on this material. For temperatures exceeding T_C, there was no evidence of iron ESR. In the superconducting state, the samples exhibit dissipative losses which increase monotonically as a function of applied field for fixed temperature. The level of field-dependent dissipation increases as T approaches T_C from below, and vanishes at the transition.

V1.00170 Magnetic Field Effects on Relaxation Parameters of The Hexamethylenetetramine (HMT)

, NURCAN DOGAN, Gebze Institute of Technology — The use of low magnetic field is one of the method for improvement of the signal to noise ratio (SNR) of detection of the chemical compounds by nuclear quadrupole resonance (NQR). We investigated the FID phenomenon of nuclear quadrupole resonance (NQR) from hexamethylenetetramine (HMT), $C_6H_{12}N_4$, under magnetic field. The influence of the low magnetic field (up to 30 mT) was investigated for the detection of the pulse NQR signal for HMT We detected the pure NQR FID signal of HMT with a short pulse interval. The intensity of the FID signal changed with applied magnetic field. The application of the low magnetic field produces the splitting and brodening of the NQR line. We observed T_1, T_2 and T_2^*. HMT has a long T_2^*(near 1.5ms). This one represents the suitable sample for investigation of the influence of low magnetic field for NQR detection. The application of the low magnetic field produces the splitting and brodening of the NQR line.

V1.00171 Polarizabilities of Halide Ions Co-Adsorbed on Silver Nanoparticles and Their Relationship to Increased Surface-Enhanced Raman Intensities of Rhodamine-6G and Pyridine

, MICHAEL COLE, PAUL JAGODZINSKI, Northern Arizona University — Glaspell et. al. (2004), found a linear relationship between the intensities of surface-enhanced Raman (SER) signals of selected vibrational modes of rhodamine-6G (R6G) and the polarizabilities of co-adsorbed halide ions. Furthermore, they noticed that the slopes of intensity versus time plots for R6G also exhibit a linear relationship with the halide polarizabilities. We will present similar results from the SER signals from selected vibrational modes of pyridine and the polarizabilities of co-adsorbed halide ions. In addition, we will present a plausible relationship between the adsorbates and the electric field of the induced dipole of the halide ions.

V1.00172 SQUIDs Fabrication with the Weak Links[1]

, ABDELAZIZ RAMZI, SERGE A. CHARLEBOIS, Interdisciplinary Institute for Technological Innovation (3IT) and Department of electrical and computer engineering, Université de Sherbrooke — We present a new technique to fabricate SQUIDs nanobridges as the weak links. We have shown that these chemical-mechanical polishing based process has minimal impact on Al and Nb superconducting properties as demonstrated on long microstructures. This process allows realizing "2D nanobridges" formed of the same material as the electrodes and with same thickness. The Nb nanobridges are approximately 100 nm wide and long and 20 nm thick. Similar structures have been fabricated in Ti and Al. We are working at increasing the quality of the deposited films especially in the initial phase for this is the material that remains after CMP and forms these very thin nanobridges. In these very thin structures, it is critical to have high quality material being deposited from the very start of the deposition process as it is those initial layers that are left as a device after CMP [1]. Also allows producing "3D structures" with nanobridges thinner (e.g. 20 nm) than the leads (e.g. 100 nm) in a single lithography step. In this case, we also show that the nanobridge can be made of a material other than the leads thus allow SS'S or SNS type of weak links.

V1.00173 Andreev Interferometry of Proximitized Semiconductor Nanowires

, C. CHECKLEY, D. YUVARAJ, London Centre for Nanotechnology, University College London, H. LIU, Department of Electronic and Electrical Engineering, University College London, M. SOURRIBES, M. PANFILOVA, P.A. WARBURTON, E.J. ROMANS, London Centre for Nanotechnology, University College London — By using the proximity effect to combine the spin orbit coupling of a semiconducting nanowire with a conventional superconductor it is possible to create a p_x+ip_y superconductor capable of supporting Majorana fermions [1]. We have designed a circuit in which an Andreev Interferometer is connected via superconducting leads to a proximtized InSb nanowire to investigate the presence of Majorana fermions in the nanowire. An Andreev Interferometer is a mesoscopic device consisting of a normal metal cross. One branch of the cross is placed between two superconducting electrodes while the resistance of the other branch is monitored. Phase coherent transport causes the resistance to oscillate as a function of the phase difference between the two superconductors [2]. In this way it is possible to use the interferometer as a detector of superconducting phase. A magnetic flux perpendicular to the circuit will create an external phase. If Majorana fermions are present in the nanowire, the phase around loop is distributed differently and there is a change in the magneto-resistance oscillations of the interferometer. In this paper we explain how the presence of Majorana fermions will affect the behaviour of our junction, describe our fabrication process and discuss our preliminary results. [1] R.M. Lutchyn et al., Phys. Rev. Lett. 105, 077001 (2010). [2] V.T. Petrashov et al., Phys. Rev Lett. 95, 147001 (2005).

V1.00174 Superconducting Quantum Interference Devices incorporating an InSb-Superconductor Proximity Effect Junction

, YUVARAJ DHAYALAN, CHRISTOPER CHECKLEY, London Centre for Nanotechnology, University College London, HUIYUN LIU, Electronic and Electrical Engineering, University College London, ED ROMANS, London Centre for Nanotechnology, University College London, ED ROMANS GROUP TEAM, H LIU GROUP TEAM — There have been several recent proposals for devices to detect Majorana fermions at the interfaces between conventional superconductors and semiconductors with particular types of spin-orbit coupling. One very recent proposal (Wang et al., arXiv:1204.5616 [cond-mat.supr-con]) has suggested using a novel dc superconducting quantum interference device (SQUID) comprising a conventional Josephson junction in parallel with a Majorana-carrying superconductor-semiconductor (S-Sc-S) junction. We have realised such a device using a niobium nanobridge (Dayem bridge) and an InSb-based S-Sc-S junction. The S-Sc-S junction was formed by structuring an InSb film (45 nm thick) grown by Molecular Beam Epitaxy (MBE) into a nanowire (150 nm wide) by electron beam lithography and reactive ion etching. The electrical characteristics and magnetic flux response of the device were measured at low temperature. We discuss the fabrication of the device, and the evidence for the presence of Majorana fermions in the InSb nanowire, based on the observed magnetic flux response of the SQUID.

V1.00175 Mesoscopic fluctuations of the critical current in graphene-based Josephson junctions

, MAURICIO PILO-PAIS, Duke University, IVAN BORZENETS, University of Tokyo, ULAS COSKUN, Duke University, ALEX SMIRNOV, North Carolina State University, GLEB FINKELSTEIN, Duke University — We study the critical current I_C and the normal resistance R_N in superconductor-graphene-superconductor (SGS) Josephson junctions. We observe large (close to 100%) and highly reproducible fluctuations of critical current over small scale changes in $V_{\rm gate}$. Unlike fluctuations of critical current previously seen in 1D nano-wires, the fluctuations in graphene do not necessarily track the small scale changes in normal resistance. We attribute these fluctuations to the disordered nature of our wide graphene junctions, where the critical current may be dominated by a few regions, different from those regions which determine the normal resistance.

V1.00176 Multiple Andreev Reflection in LAO/STO Heterostructure

, JIMIN CHUN, JINHEE KIM, University of Science & Technology — Electrical transport properties of LaAlO3/SrTiO3 (LAO/STO) oxide bilayer, grown by pulsed-laser deposition, was investigated. Superconducting proximity junction with an Al electrode is fabricated. Pronounced peaks in the differential conductance curve, attributed to the Multiple Andreev Reflection (MAR), was observed. From the MAR peaks, the superconducting energy gap of the LAO/STO bilayer was estimated. Unlike the conventional superconductor, the LAO/STO bilayer showed a very small superconducting gap. Experimental results also with a normal metal Au, instead of a superconductor Al, will be presented.

V1.00177 Spin fluctuation pairing in the SDW state of electron-doped cuprates[1]

, WENYA ROWE, Department of Physics, University of Florida, Gainesville, FL, ILYA EREMIN, Institute für Theoretische Physik III, Ruhr-Universität Bochum, D-44801 Bochum, Germany, P. J. HIRSCHFELD, Department of Physics, University of Florida, Gainesville, FL — The proximity of the antiferromagnetic state is considered to give rise to superconductivity in systems such as electron doped cuprates and iron-pnictide materials. We generalize the spin bag theory proposed by Schrieffer et al[2], and investigate the effects on pairing of possible electron pockets and simultaneous electron and hole pockets. We also take into account the particle-hole excitations which arise from the itinerant nature of the system and the effects of next-nearest hopping. The contributions of the charge-fluctuation channel, amplitude and orientational spin-fluctuation channels to superconductivity will be discussed.

[1]PH and WR were supported by NSF DMR-1005625

[2]J. R. Schrieffer, X. G. Wen, and S. C. Zhang, "Dynamic spin fluctuations and the bag mechanism of high-T_c superconductivity," Phys. Rev. B, 39, pp. 11663-11679 (1989).

V1.00178 Vortex states in nanosuperconductor

, LIVIU CHIBOTARU, BART DELOOF, University of Leuven, Department of Chemistry, VICTOR MOSHCHALKOV, University of Leuven, Department of Physics, DEPARTMENT OF PHYSICS TEAM — The vortex states in nanoscale superconductors are investigated within generalized Bogolubov-de Gennes theory. For symmetric (square-shaped) samples thermodynamically stable vortex phases form symmetry-consistent patterns and no transition to conventional Abrikosov-like vortex patterns occurs till T = 0K for sizes not exceeding 25 nm. For vorticity $L = 2$ a giant vortex is stabilized at temperatures in the vicinity of T_c, which transforms into a giant antivortex $L = -2$ and four normal vortices with lowering the temperature. On the other hand, the vortex pattern for vorticity $L = 3$ corresponds to an antivortex $L = -1$ and four normal vortices in the whole temperature domain.

V1.00179 Noise measurements of high temperature superconductor twin boundary junctions , LI XIANG, FANG XU, LIANG LIU, JIAN WEI, Peking University — Doubled shot noise is considered as a proof of Cooper pair tunnelling through Superconductor-Normal metal junctions. For high temperature superconductor this doubling of shot noise has yet to be observed. More interestingly, in the so called pseudogap regime, observation of doubling of shot noise can provide direct evidence of preformed Cooper pairs in the normal state. As a preliminary study, we measure the noises of single and serial of twin boundary junctions and analyse their second and third order spectra (bispectrum). The separation of low frequency noise, thermal noise, and possibly shot noise is discussed in detail.

V1.00180 UV-Ozone Treatment for Improved Contacts to Graphene , WEI LI, DAVID GUNDLACH, National Institute of Standards and Technology, Physical Measurement Laboratory, Gaithersburg, Mary — We report on the influence of UV-Ozone (UVO) treatment on the electrical properties of metal contacts formed to single layer graphene grown by CVD. Polycrystalline graphene was grown on copper foil and transferred onto a heavily doped silicon wafer with a 300 nm thick thermally grown SiO_2 insulator using the method described previously [1]. E-beam deposited Ti (20 nm)/Au (80 nm) contacts were patterned by photolithography and a lift-off process. Just prior to depositing the contacts, the substrates were UVO treated in a commercial system for times ranging from 5 minutes to 25 minutes, where only the graphene surface in the lithographically-defined openings of the resist layer were exposed to UVO. The devices were completed by oxygen plasma etching the graphene in the field regions. For comparison, we fabricated test structures in parallel without UVO treatment.

V1.00181 ABSTRACT WITHDRAWN –

V1.00182 Enhanced Tc in MgB_2 by SWCNT Dilution[1] , DANHAO MA, The Pennsylvania State University, RUWANTHA JAYASINHA, University of Louisville, KOFI ADU, The Pennsylvania State University, Altoona College, GAMINI SUMANASEKERA, University of Louisville — We report for the first time a nonsubstitutional hole-doping of the MgB_2 structure and an increase in Tc by SWCNT dilution. The SWCNT concentration was varied from 0.05wt% to 5wt%. We investigated the temperature dependence resistivity from 10K to 300K of sintered MgB_2 powder containing dilute amount of ultra-high purity single wall carbon nanotubes. Micro-Raman spectroscopy, field emission scanning electron microscope and x-ray diffraction were used to analyze the interfacial interactions between the carbon nanotubes and the magnesium diboride grains. We obtained an increase in Tc from 41.1K to 45.8K. This is attributed charge transfer: electron transfer from the MgB_2 structure to the SWCNT structure. This consequently leads to hole-doping of the MgB_2 structure and the enhancement we see in Tc. This is confirmed by micro-Raman analysis of the phonon states of the SWCNT in the composites. This is explained in terms of the interplay between impurity scattering and hole-doping. This report provides experimental alternative pathway to hole-doping of MgB_2 without appealing to elemental substitution.

V1.00183 Surface Ferromagnetism and Superconducting Properties of Nanocrystalline Niobium Nitride , SHIPRA RAI, NITESH KUMAR, A. SUNDARESAN, Jawaharlal Nehru Centre for Advanced Scientific Research, Bangalore — We report magnetic, transport (electrical) and thermal (heat capacity) properties of nanocrystalline δ-NbNx prepared by urea-nitridation method and heated at three different temperatures, 700, 800 and 900 °C respectively. Particle size and their agglomeration increases with increasing synthesis temperature. The sample prepared at 900 °C, showed the highest transition temperature, Tc(onset) = 16 K with a transition width (ΔTc) of 1.8 K, as obtained from resistivity measurement on the cold-pressed bar. Above Tc, magnetization measurements revealed the presence surface ferromagnetism that coexists with superconductivity below Tc. Heat capacity measurements confirm the bulk nature of superconductivity with strong electron -phonon coupling. These results are compared with those of the samples prepared at 800 °C with a lower Tc (10K) and 700 °C, which is non-superconducting down to the lowest temperature measured.

V1.00184 FLUIDS –

V1.00185 Using nanoparticles to control the speed of capillary filling in microchannels , YONGTING MA, OLGA KUKSENOK, University of Pittsburgh, Pittsburgh, PA 15261, AMITABH BHATTACHARYA, Indian Institute of Technology Bombay, Mumbai, 400076, DENNIS PERCHAK, Kodak Research Laboratories, Rochester, NY 14650, ANNA C. BALAZS, University of Pittsburgh, Pittsburgh, PA 15261 — Understanding the transport of multi-component fluids through porous medium is of great importance for a number of technological applications, ranging from ink jet printing, the production of textiles and enhanced oil recovery. Here, we examine the behavior of binary fluids containing nanoparticles that are driven by capillary forces to fill the microchannels. To carry out these studies, we use a hybrid computational approach that combines the lattice Boltzmann model for binary fluids and a Brownian dynamics model for the nanoparticles. We show that the nanoparticles dynamically alter both the interfacial tension between the two fluids and the contact angle in the microchannels; this, in turn, strongly affects the dynamics of the capillary filling. We demonstrate that by tailoring the properties of the nanoparticles, such as their affinity to the fluid components and their interaction with the microchannels, one can effectively control the filling velocities. Our findings provide fundamental insights into the dynamics of this complex multi-component system, as well as potential guidelines for a number of technological processes that focus on capillary filling with nanoparticles in porous media and microchannels.

V1.00186 Harnessing passive cilia arrays in ambient flow for anti-biofouling applications , ANURAG TRIPATHI, Dept. of Chemical and Petroleum Engineering, University of Pittsburgh, AMITABH BHATTACHARYA, Dept. of Mechanical Engineering, Indian Institute of Technology Bombay, Mumbai, ANNA BALAZS, Dept. of Chemical and Petroleum Engineering, University of Pittsburgh — Active cilia arrays have been predicted to propel adhesive particles away from the surface and hence, could be used for antibiofouling applications (Bhattacharya et.al. Langmuir, 2012, 28, 3217). We explore the possibility of using non-actuated, passive cilia arrays for antibiofouling applications by utilizing the arrays' response to the ambient flow conditions. Using a hybrid computational model, we simulate a sticky biofouling spherical particle moving (under the influence of an applied force) towards the ciliated surface in an ambient fluid medium. Shear flow between parallel walls was simulated to mimic the ambient fluid flow dislodging the sticky particle from the surface. We obtain the minimum shear required to propel the sticky particle from the ciliated surface for different stickiness of the biofouling particle and stiffness of the cilia. The results are contrasted with adhesion to flat, non-ciliated surfaces and the important role of the cilia's response to the ambient flow condition is emphasized.

V1.00187 Viscosity measurements of nanoscale liquid films , EDWARD KRAMKOWSKI, DAVID WILSON, Wayne State University, SHAH KHAN, University of Peshawar, ASHIS MUKHOPADHYAY, PETER HOFFMANN, Wayne State University — Measuring the viscosity of nanoscale films of liquids can be quite challenging. This difficulty has resulted in contradictory claims regarding the change in viscosity upon nanoscale confinement of liquids. Recently, we showed through a careful analysis, that in weakly interacting liquids, such as non-polar oils, the viscosity seems unchanged from the bulk value even under extreme confinement down to just a few molecular layers. Moreover, above a critical shear rate, shear thinning is observed. These measurements also have practical significance, in that traditional methods for characterizing the viscosity of solutions, while accurate, require the use of a few grams of the material being investigated. As the production methods of prototype materials becomes more costly, devising techniques that can accurately measure physical properties with much smaller volumes of material would be highly desirable. To this end, we aim to design a quick, reliable, and cost-effective method of measuring viscosity through the use of an atomic force microscope, which requires only nanograms of the sample being tested. Here we will introduce preliminary results, comparing the AFM-determined viscosity with values attained through the use of other commonly used measurement devices.

V1.00188 Measuring the effects of large scale intermittency on the small scales of turbulent flows

, CHEN-CHI CHIEN, DANIEL BLUM, GREG VOTH, Department of Physics, Wesleyan University — In standard cascade picture of 3D turbulent flows, energy is injected at a constant rate at large scales. It then is transferred to smaller scales by triad interactions that result from the non-linearity of the Navier-Stokes equation. The down-scale transfer is intermittent, and a vast literature has explored the signatures of this internal intermittency on statistics of the small scales. However, the energy injection at large scales is not constant in most real turbulent flows. We explore the signatures of this large scale intermittency on small scale turbulence statistics. Measurements were made in a flow between oscillating grids. By modulating grid frequency we introduce temporal variations in the injected energy which allows us to control the level of large scale intermittency. We find that the non-dimensional ratio of second to third order structure function depends on the degree of large scale intermittency, and we can quantitatively predict this ratio from the measured time dependence of the energy at large scales. Large scale intermittency can also be observed by conditioning Eulerian structure functions on the large scale velocity. Quantifying this dependence provides an alternative measurement of large scale intermittency which agrees with the structure function ratio.

V1.00189 A "Cyber Wind Facility" for HPC Wind Turbine Field Experiments

, JAMES BRASSEUR, ERIC PATERSON, SVEN SCHMITZ, ROBERT CAMPBELL, GANESH VIJAYAKUMAR, ADAM LAVELY, BALAJI JAYARAMAN, TARAK NANDI, PANKAJ JHA, ALEX DUNBAR, JAVIER MOTTA-MENA, BRENT CRAVEN, Penn State U., SUE HAUPT, NCAR — The Penn State "Cyber Wind Facility" (CWF) is a high-fidelity multi-scale high performance computing (HPC) environment in which "cyber field experiments" are designed and "cyber data" collected from wind turbines operating within the atmospheric boundary layer (ABL) environment. Conceptually the "facility" is akin to a high-tech wind tunnel with controlled physical environment, but unlike a wind tunnel it replicates commercial-scale wind turbines operating in the field and forced by true atmospheric turbulence with controlled stability state. The CWF is created from state-of-the-art high-accuracy technology geometry and grid design and numerical methods, and with high-resolution simulation strategies that blend unsteady RANS near the surface with high fidelity large-eddy simulation (LES) in separated boundary layer, blade and rotor wake regions, embedded within high-resolution LES of the ABL. CWF experiments complement physical field facility experiments that can capture wider ranges of meteorological events, but with minimal control over the environment and with very small numbers of sensors at low spatial resolution. I shall report on the first CWF experiments aimed at dynamical interactions between ABL turbulence and space-time wind turbine loadings. Supported by DOE and NSF.

V1.00190 Jumping-Droplet-Enhanced Condensation on Scalable Superhydrophobic Nanostructured Surfaces

, NENAD MILJKOVIC, MIT, RYAN ENRIGHT, MIT, Stokes Institute, Bell Labs Ireland, YOUNGSUK NAM, MIT, Kyung Hee University, KEN LOPEZ, MIT, Stanford University, NICHOLAS DOU, MIT, Caltech, JEAN SACK, EVELYN WANG, MIT — When droplets coalesce on a superhydrophobic nanostructured surface, the resulting droplet can jump from the surface due to the release of excess surface energy. If designed properly, these superhydrophobic nanostructured surfaces can not only allow for easy droplet removal at micrometric length scales during condensation but promise to enhance heat transfer performance. However, the rationale for the design of an ideal nanostructured surface, as well as heat transfer experiments demonstrating the advantage of this jumping behavior are lacking. Here, we show that silanized copper oxide surfaces created via a simple fabrication method can achieve highly efficient jumping-droplet condensation heat transfer. We experimentally demonstrated a 25% higher overall heat flux and 30% higher condensation heat transfer coefficient compared to state-of-the-art hydrophobic condensing surfaces at low supersaturations. This work not only shows significant condensation heat transfer enhancement, but promises a low cost and scalable approach to increase efficiency for applications such as atmospheric water harvesting and dehumidification. Furthermore, the results offer insights and an avenue to achieve high flux superhydrophobic condensation.

V1.00191 Hematocrit and flow rate regulate the adhesion of platelets to von Willebrand factor

, HSIEH CHEN, Massachusetts Institute of Technology, JENNIFER ANGERER, MATTHIAS SCHNEIDER, Boston University, ALFREDO ALEXANDER-KATZ, Massachusetts Institute of Technology — Here we present theoretical and experimental results showing that under the action of flow the adhesion probability of platelets to von Willebrand factor coated surfaces is strongly dependent on the hematocrit and flow rate. Interestingly, from experiments we observed that the actual binding forces are not markedly different, which suggest that the origin of such behavior is in the distribution of platelets. The experimental findings were solidly supported by explicit hydrodynamic simulations as well as stochastic differential equation simulations. We proposed a platelet transport model that, to our best knowledge, is the first in this field to have exact mathematical connections to the red blood cell distributions and shear rates. These findings present an important advance in understanding the dependence of blood clotting on hematocrit and can lead to advances in the treatment of vascular diseases associated with high levels of red blood cells. Furthermore, from the technological side the results presented here are important in areas where fine control of the separation of different classes of colloids is desired.

V1.00192 Numerical simulations of flagellated micro-swimmers and ciliated surfaces

, HENRY SHUM, ANURAG TRIPATHI, Department of Chemical & Petroleum Engineering, University of Pittsburgh, JULIA YEOMANS, Rudolf Peierls Centre for Theoretical Physics, University of Oxford, ANNA BALAZS, Department of Chemical & Petroleum Engineering, University of Pittsburgh — Cilia are filamentous organelles found in many organisms for achieving locomotion or for driving fluid flows within the body. Cilia-like structures can be constructed and have potential for application in microfluidics, where they may be used to locally control flow and the motion of particles in the fluid. We implement a lattice Boltzmann method to simulate fluid flows produced by externally actuated artificial cilia and explore the influence of such cilia on objects in the surrounding fluid. In particular, we show examples of interactive effects between cilia arrays and self-motile swimmers propelled by a rotating helical flagellum. Artificial swimmers mimicking the motion of flagellated bacteria in this way have been experimentally realized in recent years and our simulations produce testable predictions for the behavior of such swimmers in the presence of cilia.

V1.00193 Modeling the swimming of microbes in anisotropic fluids

, MADISON KRIEGER, Brown University, SAVERIO SPAGNOLIE, University of Wisconsin, Madison, THOMAS POWERS, Brown University — Microbes commonly swim in non-Newtonian fluids such as mucus, soil, and tissue. Some of these complex fluids are characterized by long-chain molecules which can align, leading to anisotropy. We study a simple model of swimming in an anisotropic fluid, that of an infinitely long two-dimensional sheet deforming via propagating waves and immersed in a nematic liquid crystal. The liquid crystal is categorized by the dimensionless Ericksen number, which compares viscous and elastic effects. At infinite Ericksen number, where viscous effects dominate over elastic effects and the only time scale is the period of the propagating wave, we calculate the swim- ming speed and power dissipation as a function of the anisotropic viscosities and the tumbling parameter. We also calculate the swimming speed and power dissipation at finite Ericksen number, where the orientation elasticity introduces an additional time scale, the relaxation time.

V1.00194 Development of a microfluidics model for studying migration of sperm in the female reproductive tract[1]

, CHIH-KUAN TUNG, Department of Biological and Environmental Engineering, Cornell University, FLORENCIA ARDÓN, Department of Biomedical Sciences, Cornell University, MINGMING WU, Department of Biological and Environmental Engineering, Cornell University, SUSAN S. SUÁREZ, Department of Biomedical Sciences, Cornell University — Infertility is a significant issue, both for humans and dairy cattle. In order for fertilization to happen, sperm must migrate through the female reproductive tract to reach the egg in the oviduct (fallopian tube). There is strong evidence that sperm interact with the female tract via both chemical and physical mechanisms. In this work, we focus on how the physical environment of the female tract influences the migration of bull sperm, which also serve as models for human sperm. In order for bull and human sperm to pass from the vagina into the uterus, they must swim through the cervical canal, which is lined by microchannels. Then, sperm must swim through the uterotubal junction, which also contains microchannels, in order to reach the oviduct. In both passageways, sperm must swim against a fluid flow, which would be less in the microchannels than in the central passageways. We have developed a microfluidic model for studying the sperm migration effects of the geometry of the cervix and uterotubal junction and the fluid flow within.

[1]Supported by NIH grant 1R01HD070038.

V1.00195 Swimming near a deformable interface , MARCELO A. DIAS, School of Engineering, Brown University, THOMAS R. POWERS, School of Engineering and Department of Physics, Brown University — It is a known fact that swimmers behave differently near deformable soft tissues than when near a rigid surface. Motivated by this class of problems, we investigate swimming microorganisms near flexible walls. We calculate the speed of a n infinitely long swimmer near an interface between two viscous fluids. Part of the calculation of the speed is the calculation of the shape of the free boundary. The swimming speed is controlled by the competition between surface and viscous effects, where two limits are observed. When the surface tension vanishes, we get Taylor's result for a swimmer with no walls. When the surface tension is infinite, the problem is like that of a swimmer near a rigid wall.

V1.00196 STATISTICAL AND NONLINEAR PHYSICS –

V1.00197 ABSTRACT HAS BEEN MOVED TO W30.00011 –

V1.00198 Local Elastic Fields in Granular Solids , DIETRICH WOLF, JENS BOBERSKI, LOTHAR BRENDEL, University of Duisburg-Essen — The modeling of elastic properties of disordered or granular solids requires a theory of elasticity that takes non-affine deformations into account. Using a linearized force law the non-affine elastic deformations are calculated. Base on the microscopically exact expressions for the local strain and stress fields (I. Goldhirsch, Granular Matter 12, 239 (2010)) a way to calculate maps of the local linear elastic constants for frictional granular packings is presented. The elastic constants are found to be scale and system size independent within an appropriate parameter range.

V1.00199 Pore pressure control on slope failure of a saturated granular step , YAO YOU, PETER FLEMINGS, DAVID MOHRIG, The University of Texas at Austin — Slope failure of granular sand and silt in water controls the release of sediments on the continental shelf and is an important process that delivers sand and silt into deep sea. Here we present a type of slope failure where the sediment grains are released in two modes: grain by grain release and collapsing of a slice that is a few hundred times grain diameter wide. We use flume experiments and pore pressure measurements to show that this type of slope failure is controlled by the generate and dissipation of pore pressure. The grain to grain release is associated with low pore pressure in the deposit, and collapsing of a slice occurs when the abnormally low pore pressure drains to a critical threshold. Collapsing of a slice generates pore pressure drop, which returns the mode of slope failure to grain by grain release.

V1.00200 How does money memorize social interactions? Understanding time-homogeneity in monetary systems , DIETER BRAUN, MATTHIAS SCHMITT, ANDREAS SCHACKER, Systems Biophysics, Center for Nanoscience, LMU Munich — Understanding how money shapes and memorizes our social interactions is central to modern life. There are many schools of thought on as to how monetary systems contribute to crises or boom/bust cycles and how monetary policy can try to avert them. We find that statistical physics gives a refreshing perspective [1-3]. We analyze how credit mechanisms introduce non-locality and time-heterogeneity to the monetary memory. Motivated by an analogy to particle physics, locality and time-homogeneity can be imposed to monetary systems. As a result, a full reserve banking system [4] is complemented with a bi-currency system of non-bank assets ("money") and bank assets ("antimoney"). Payment can either be made by passing on money or by receiving antimoney. As a result, a free floating exchange rate between non-bank assets and bank assets is established. Interestingly, this monetary memory allows for credit creation by the simultaneous transfer of money and antimoney at a negotiated exchange rate. We analyze this novel mechanism of liquidity transfer in a model of random social interactions, yielding analytical results for all relevant distributions and the price of liquidity under the conditions of a fully transparent credit market.

V1.00201 Why is the bulk modulus of jammed solids and granular packings much larger than the shear modulus? , ALESSIO ZACCONE, Cavendish Laboratory, University of Cambridge, DENIS WEAIRE, School of Physics, Trinity College Dublin — In granular packings and metallic glasses, the rigidity to compression is much more pronounced than with respect to shear, resulting in the bulk modulus being much larger than the shear modulus. This state of affairs becomes dramatic in marginal jammed solids which are solid-like to compression but not to shear (Ellenbroek, Zeravcic, van Saarloos, van Hecke, EPL 87, 34004 (2009)). For metallic glasses, it was argued by Weaire et al. some time ago (Acta Metall. 19, 779 (1971)) that this effect might be due to the nonaffinity of the particle displacements. These arise because the force acting on a particle upon strain as a result of the strain-induced motion of its neighbors is not balanced in the absence of local order. Hence the particles undergo nonaffine displacements to relax these forces to the expense of the elastic storage energy, leading to lower values of the elastic moduli. Using the nonaffine theory of Zaccone and Scossa-Romano (PRB, 83, 184205 (2011)) we found a conclusive solution to this long standing problem. We show that in packings and related materials the excluded volume between neighbors induces geometric correlations which significantly reduce the nonaffinity under compression but leave the nonaffinity in shear substantially unaltered.

V1.00202 Ideal strength and structural instability of aluminum at finite temperatures[1] , YI ZHANG, CHANGFENG CHEN, Department of Physics and High Pressure Science and Engineering Center, University of Nevada, Las Vegas, WEI ZHOU, HONG SUN, Department of Physics, Shanghai Jiao Tong University, China — Understanding the mechanical strength and stability of materials under different external conditions is of critical importance to material science and engineering. Despite of the extensive efforts on 0K ideal strength calculations in the past decade, the temperature effects on the ideal strength and dynamical stability have not been explored. We have calculated the ideal strength of aluminum at finite temperatures by implementing an ab initio molecular dynamics method (AIMD) that treats elastic instability, dynamic instability, and thermodynamics in a unified first-principles approach. The results reveal significant changes in fundamental mechanical properties of aluminum: (i) the ideal strength drops precipitously with increasing temperature, by as much as 60% at room temperature compared to T=0 K; (ii) the structural instability modes change qualitatively from dynamic phonon softening at low temperature to elastic failure at high temperature; (iii) the highly anisotropic low-temperature tensile strength becomes considerably more isotropic with rising temperature. Phonon calculations predict the disappearance of soft phonon modes near room temperature due to phonon anharmonic interactions, in excellent agreement with the AIMD results.

V1.00203 Composite Random Fiber Networks , CATALIN PICU, ALI SHAHSAVARI, Rensselaer Polytechnic Institute — Systems made from fibers are common in the biological and engineering worlds. In many instances, as for example in skin, where elastin and collagen fibers are present, the fiber network is composite, in the sense that it contains fibers of very different properties. The relationship between microstructural parameters and the elastic moduli of random fiber networks containing a single type of fiber is understood. In this work we address a similar target for the composite networks. We show that linear superposition of the contributions to stiffness of individual sub-networks does not apply and interesting non-linear effects are observed. A physical basis of these effects is proposed.

V1.00204 Soft-Nano-Materials: Extreme Mechanics at Extreme Length Scales , XUANHE ZHAO, Duke University — Over decades of intensive research, various technologies have been developed to manufacture large-scale nanomaterials such as nanoparticles, quantum dots, nanowires, carbon nanotubes, biomolecules, nanofilms, and graphene. Meanwhile, extraordinary properties and functionalities of nanomaterials have been demonstrated by harnessing their deformations and instabilities coupled with their small length scales. However, a grand challenge still exists on how to control the deformations and instabilities of large-scale nanomaterials for scaling-up functions and applications that can impact the society. An emerging paradigm that addresses this challenge is by using soft materials such as polymers, gels and biomaterials to assemble large amounts of nanomaterials and regulate their deformations and instabilities in controlled manners. Successful examples range from nanostructured tissues such as bones and cartilages found in nature to polymer composites with nanowire/nanotube/graphene, flexible electronics, nano-generators and nano-batteries. This talk is focused on extreme mechanics of these soft-nano-materials and systems. We will discuss large deformation, instabilities, and fractures of one-dimensional and two dimensional nanomaterials, such as nanowires and graphene, interacting with matrices of soft materials. We will further illustrate extraordinary properties and functions achieved by understanding and exploiting the extreme mechanics of soft-nano-materials and systems.

V1.00205 Radial Elasticity and Friction Properties of Multiwalled Boron Nitride Nanotubes Investigated by Atomic Force Microscopy , HSIANG-CHIH CHIU, ELISA RIEDO, School of Physics, Georgia Institute of Technology — Boron Nitride nanotube (BNNT), similar to Carbon nanotube (CNT), has a layered structure with alternating boron and nitride atoms in a honeycomb configuration. BNNTs have comparable mechanical properties with CNTs and are expected to have potential applications in Nano-Electro-Mechanical Systems (NEMS) and nanocomposites. Therefore, understanding their mechanical and frictional properties is crucial to the development of these novel applications. In this work, we study the radial elasticity and friction properties of multiwalled BNNTs by means of Atomic Force Microscopy (AFM). We find that the radial modulus of BNNT decreases nonlinearly with the inverse of its external radius,$R_{\rm ext}$, until arriving at the transverse elastic modulus of bulk hexagonal BN for larger $R_{\rm ext}$ and number of layers.[1] In addition, by sliding an AFM tip across (transverse sliding) and along (longitudinal sliding) the principal axis of the BNNT, we find a larger friction coefficient during the transverse sliding due to the transverse deformation of BNNT. The friction anisotropy, defined as the ratio of the transverse to the longitudinal friction forces per unit area, is found to increase with the nanotube-substrate contact area, estimated to be proportional to $(L_{\rm NT}R_{\rm ext})^{1/2}$, where $L_{\rm NT}$ is the length of the nanotube.[2] Our results provide a better understanding of the mechanical and frictional properties of BNNTs. [1] Appl. Phys. Lett. 101, 103109 (2012) [2] Nanotech. 23, 455706 (2012)

V1.00206 Collapse of Non-Rectangular Channels in a Soft Elastomer , DANIEL TEPAYOTL-RAMIREZ, Carnegie Mellon University, YONG-LAE PARK, Harvard University, TONG LU, CARMEL MAJIDI, Carnegie Mellon University — We examine the collapse of microchannels in a soft elastomer by treating the sidewalls as in- denters that penetrate the channel base. This approach leads to a closed-form algebraic mapping between applied pressure and cross-sectional deformation that are in strong agreement with ex- perimental measurements and Finite Element Analysis (FEA) simulation. Applications of this new approach to modeling soft microchannel collapse range from lab-on-a-chip microfluidics for pressure-controlled protein filtration to soft-matter pressures sensing. We demonstrate the latter by comparing theoretical predictions with experimental measurements of the pressure-controlled electrical resistance of liquid-phase Gallium alloy microchannels embedded in a soft silicone elas- tomer.

V1.00207 Nonlinear Geometric Effects in Bioinspired Multistable Structures[1] , ZI CHEN, Washington University in St. Louis, QIAOHANG GUO, Fuzhou University, KEVIN CHU, Serendipity Research, STEVEN SHILLIG, Virginia Technology, CHI LI, SUNY at Stonybrook, WENZHE CHEN, Fuzhou University, LARRY TABER, Washington University in St. Louis, DOUGLAS HOLMES, Virginia Technology — Nature features many thin shell structures with spontaneous curvatures, where mechanical instabilities play important roles in the morphogenesis and functioning of the organisms. However, the large deformation and instability phenomena of shells due to geometric nonlinearity, which often arise in morphogenesis and nanofabrication, remain incompletely understood. Here, we create spontaneously curved shapes with pre-strains in tabletop experiments, and study their instabilities with a minimal theory based on linear elasticity. The development of such theoretical and experimental approaches will promote quantitative understanding of the morphogenesis of growing soft tissues, and meet the emergent needs of designing stretchable electronics, artificial muscles and bio-inspired robots.

V1.00208 Mixing entropy in Dean flows , PETRU FODOR, BRIAN VYHNALEK, MIRON KAUFMAN, Cleveland State University — We investigate mixing in Dean flows by solving numerically the Navier-Stokes equation for a circular channel. Tracers of two chemical species are carried by the fluid. The centrifugal forces, experienced as the fluid travels along a curved trajectory, coupled with the fluid incompressibility induce cross-sectional rotating flows (Dean vortices). These transversal flows promote the mixing of the chemical species. We generate images for different cross sections along the trajectory. The mixing efficiency is evaluated using the Shannon entropy. Previously we have found, P. S. Fodor and M. Kaufman, Modern Physics Letters B 25, 1111 (2011), this measure to be useful in understanding mixing in the staggered herringbone mixer. The mixing entropy is determined as function of the Reynolds number, the angle of the cross section and the observation scale (number of bins). Quantitative comparison of the mixing in the Dean micromixer and in the staggered herringbone mixer is attempted.

V1.00209 Fabrication and Characterization of High Aspect Ratio PMMA Membranes for Filtering and Sensing Applications , THOMAS HOKE, James Madison University — We report on the fabrication and function of high aspect ratio membranes for filtering applications in micro fluidic devices. We describe a new technique that enables us to construct a 40-90 microns thick membrane spanning a 3mm hole in a poly methyl methacrylate (PMMA) substrate. Polydimethylsiloxane (PDMS) is used to fill the hole in the PMMA. Once a liquid monomer solution is flowed over the substrate and cured with photo-polymerization, the PDMS is then removed, leaving a thin membrane spanning the hole. Filters are made from these membranes by etching silica or nickel micro particles that are embedded in the monomer solution. One goal of this project is to quantify how variables such as particle concentration, particle size, and etch time affect the filter porosity. This was done with membranes embedded with SiO_2 by creating a series of filters with various bead sizes and etch times. SEM was used to measure the thickness and structure of the membrane, and dynamic light scattering (DLS) was used to measure the amount of particles removed from a controlled suspension. These filters could successfully filter out particles as small as 3-10 microns. We will also report on the use of Ni in the filters to filter out His-tagged proteins due to the fact that are attracted to Ni ions.

V1.00210 Dissipated work and fluctuation relations for non-equilibrium single-electron transitions , AKI KUTVONEN, JUKKA PEKOLA, TAPIO ALA-NISSILÄ, Aalto University — We discuss a simple but experimentally realistic model system, a single-electron box (SEB), where common fluctuation relations can be tested for driven electronic transitions. We show analytically that when the electron system on the SEB island is driven to a non-equilibrium state by the control parameter (gate voltage), the common fluctuation relation (Jarzynski equality) is not valid due to dissipated heat even when the system starts at thermal equilibrium and returns to it after the drive has been stopped. We perform no feedback on the system. However, an integral fluctuation relation based on total entropy production works also in this situation. We perform extensive Monte Carlo simulations of single-electron transitions in the SEB setup and find good agreement with the theoretical predictions.

V1.00212 Brain Connectivity Inference under Network Spatial Subsampling[1] , SELENE DA ROCHA AMARAL, GILSON VIEIRA, LUIZ A. BACCALA, University of Sao Paulo — Neurophysiological time series analysis using functional Magnetic Resonance Magnetic Imaging (fMRI) data can be seen as tool to investigate how the complex networks of neuronal populations interact naturally leading to brain connectivity description issues where it is desirable to process as many simultaneous structures as possible to avoid misleading interaction inferences. Here we systematically use simulations to gauge how connectivity inference is affected when only subsets of network structures are considered through exploratory tools like Partial Directed Coherence (PDC) and confirmatory methods like Dynamic Causal Modeling (DCM). PDC is based on Granger causality and uses autoregressive models to expose the direction of information flow whereas DCM was proposed to characterize neural fMRI connectivity using prior knowlegde of possible connectivity structures. SPM software was used to simulate the full network fMRI data which was subject to realistic noise levels prior to analysis of network structure subsets.

V1.00213 Synchronization of coupled oscillators in the presence of noise and communication delays , LUC ROBICHAUD, ALAIN HACHE, Universite de Moncton — The Kuramoto model of coupled oscillators has been shown to describe many collective phenomena such as synchronization in natural and artificial systems. There are many factors that determine whether a system can synchronize or not, including the coupling strength, the number and density of oscillators and their natural frequencies. In some cases, however, noise and communication delays must also be taken into account, as they can significantly limit a system's capacity to synchronize. In this work, we map the space of parameters where synchronization of an ensemble of oscillators is possible when noise and delays are present. Based on numerical results, we derive general conditions to predict the possible synchronization of any given system. The possibility and limits of using a single quantity to predict synchronization, the "quality of information", which is related only to noise and delay, is discussed.

V1.00215 Self-similarity of phase-space networks of frustrated spin models and lattice gas models[1] , YI PENG, FENG WANG, YILONG HAN, Department of Physics, Hong Kong University of Science and Technology, Clear Water Bay, Hong Kong, China — We studied the self-similar properties of the phase-spaces of two frustrated spin models and two lattice gas models. The frustrated spin models included (1) the anti-ferromagnetic Ising model on a two-dimensional triangular lattice (1a) at the ground states and (1b) above the ground states and (2) the six-vertex model. The two lattice gas models were (3) the one-dimensional lattice gas model and (4) the two-dimensional lattice gas model. The phase spaces were mapped to networks so that the fractal analysis of complex networks could be applied, i.e. the box-covering method and the cluster-growth method. These phase spaces, in turn, establish new classes of networks with unique self-similar properties. Models 1a, 2, and 3 with long-range power-law correlations in real space exhibit fractal phase spaces, while models 1b and 4 with short-range exponential correlations in real space exhibit nonfractal phase spaces. This behavior agrees with one of untested assumptions in Tsallis nonextensive statistics.

V1.00216 Classical Acoustic Echoes in Model Glasses , JUSTIN BURTON , SIDNEY NAGEL, University of Chicago — For the last 40 years, the low-temperature excitations in glasses have traditionally been explained in terms of a distribution of dilute, two-level quantum states that are created by clusters of particles tunneling between two nearly degenerate ground states. Strong evidence for this model has come from ultrasonic saturation effects and acoustic echoes [1] observed in experiments. Recently, a classical analysis of vibrational modes in model glasses has shown that at low frequencies, the modes are quasi-localized and highly anharmonic [2]. Using molecular dynamics simulations, we show that this anharmonicity can produce an acoustic echo due to the shift in the mode frequency with increasing amplitude. We observe this both in jammed packings of spherical particles with finite-range, Hertzian repulsions, and in model glasses interacting with a Lennard-Jones potential. In contrast to pulse echoes in two-level systems, a distinguishing feature of these "anharmonic echoes" is the appearance of multiple echoes after two excitation pulses, a feature also observed in experiments.

V1.00217 Electoral Susceptibility and Entropically Driven Interactions[1] , BASSIR CARAVAN, GREGORY LEVINE, Hofstra University — In the United States electoral system the election is usually decided by the electoral votes cast by a small number of "swing states" where the two candidates historically have roughly equal probabilities of winning. The effective value of a swing state is determined not only by the number of its electoral votes but by the frequency of its appearance in the set of winning partitions of the electoral college. Since the electoral vote values of swing states are not identical, the presence or absence of a state in a winning partition is generally correlated with the frequency of appearance of other states and, hence, their effective values. We quantify the effective value of states by an *electoral susceptibility*, χ_j, the variation of the winning probability with the "cost" of changing the probability of winning state j. Associating entropy with the logarithm of the number of appearances of a state within the set of winning partitions, the entropy per state (in effect, the chemical potential) is not additive and the states may be said to "interact." We study χ_j for a simple model with a Zipf's law type distribution of electoral votes. We show that the susceptibility for small states is largest in "one-sided" electoral contests and smallest in close contests.

V1.00218 Lattice Stability and Reflection Symmetry , AZITA JOVAINI, SHIGEJI FUJITA, University at Buffalo, SALVADOR GODOY, Universidad Nacional Autónoma de México, HUNG-CHEUK HO, Sincere Learning Centre, AKIRA SUZUKI, Tokyo University of Science — The basic stability condition for a general crystal lattice is the availability of parallel material planes. If this condition is met, then phonons (quanta of lattice vibrations) can be generated and can stabilize the lattice. A triclinic (TCL) lattice has three sets of material planes containing atoms subjected to restoring stresses represented by Young and rigidity moduli. Longitudinal and transverse lattice vibrations obeying one-dimensional (1D) wave equations stabilized the lattice. The phonon distribution is highly directional. There can be no spherical distribution. Earlier we show [1] that the TCL lattice has no $\mathbf{k}$-vectors for electrons and it is is an intrinsic insulator. Consider next an orthorhombic lattice. This lattice has 3D phonons obeying a 3D wave equation with a Laplacian space-derivative. The phonon distribution is over a 3D anisotropic $\mathbf{k}$-space. PACS numbers: 61.50.Ah, 72.15.Eb, 72.20.-i

V1.00219 Mechanical Stochastic Resonance , ELLIOT WAINWRIGHT, JOHN LINDNER, Physics Department, The College of Wooster — Noise and nonlinearity can produce a stochastic resonance that maximizes a system's output signal-to-noise ratio. Stochastic resonance has been observed in electronic, chemical, optical, magnetic, and biological systems. Here, we report stochastic resonance in a simple mechanical system consisting of a bistable pendulum driven by a harmonic oscillator and the broad-band noise of a flapping flag.

V1.00220 A State Dependent Potts Model[1] , GABRIELL MÁTÉ, Institute for Theoretical Physics, Heidelberg University, Germany, RONALD DICKMAN, Departamento de Fsica, ICEx, Universidade Federal de Minas Gerais, Belo Horizonte, Brazil, DIETER W. HEERMANN, Institute for Theoretical Physics, Heidelberg University, Germany — Although the resolution of conventional confocal microscopy is limited, the images provided by this technique carry a tremendous amount of information. One of the most straightforward approaches to describe these images is to model them with a Potts model. However, in many cases the detected configurations correspond to a system characterized by a temperature close to the critical point, making it almost impossible to control this model. In this work we present a modified version of the Potts model which might be useful in such situations. The modification consists in introducing arbitrary couplings between different states. We argue that in the simplest case the modified model is equivalent to the original Potts model. We investigate it numerically with respect to criticality and observe a shift of the critical point as we vary the parameters. We also show that the model is capable of exhibiting more exotic behavior.

V1.00221 Boundary Effects in Transmission through Random Media , XIAOJUN CHENG, Queens College of CUNY and The Graduate Center of CUNY, New York, CHUSHUN TIAN, Institute for Advanced Study, Tsinghua University, Beijing, AZRIEL GENACK, Queens College of CUNY and The Graduate Center of CUNY, New York — Recent measurements of the transmission matrix in disordered quasi-1D samples found the average of the logarithms of the transmission eigenvalues to be uniformly spaced. This corresponds to a single peak in the distribution of transmission eigenvalues at low values of transmission, which differs from the bimodal distribution with peaks at both high and low values. One of the reasons may be the reflectivity at the boundaries. The photon diffusion model suggests that internal reflection can be treated as extrapolation length and the average transmission behaves the same way as we change the sample length or the extrapolation length at the output, but it does not predict the impact of internal reflection on the distribution of the transmission eigenvalues. We have conducted microwave experiments and first-principles analytic calculations using the supersymmetry method to explore the role of boundary effects upon the transmission eigenchannels. Our results, however, show that the statistics of the transmission eigenchannels can be changed by reflectivity at the boundaries. The universality of the bimodal distribution breaks down in that channels with transmission close to unity are greatly suppressed when the extrapolation length is comparable to the sample length.

V1.00222 Approaching equilibrium: The evolution of CO_2 in a porous medium , YOSSI COHEN, DANIEL H. ROTHMAN, Lorenz Center and the Department of Earth Atmospheric and Planetary Sciences, MIT, Cambridge, MA, USA — Understanding the microscopic mechanisms of mineral weathering rates has motivated studies of dissolution and precipitation for decades. Many applications, including the global carbon cycle and sub- surface carbon dioxide sequestration justify the importance of a full comprehension of the mechanism. The injection of carbon dioxide into a porous medium drives the system into far-from-equilibrium conditions where forces, surface phenomena, and other processes become crucial for the long-term stability of the system. A complete physical picture able to predict the pattern formation and the structure developing within the porous medium is lacking and cannot be associated only with empirical kinetic laws. Here we propose a theoretical model that couples transport, reaction, and the intricate geometry of the rock. The model concerns the different time scales when the system is far from equilibrium and when approaching a steady state. We use analytical theory and numerical simulations to study the short and the long term behavior of the carbon dioxide as it dissolves and precipitates in a fluid-rock system.

V1.00223 Explosive percolations on a two-dimensional lattice and bond-site duality , WOOSIK CHOI, SOON-HYUNG YOOK, YUP KIM, Department of Physics and Research Institute for Basic Sciences, Kyung Hee University, Seoul 130-701, Korea — The site and bond explosive percolation models are carefully defined and studied on a square lattice. From the cluster distribution function and the behavior of the second largest cluster, it is shown that the duality in which the transition is discontinuous exists for the pairs of the site model and the corresponding bond model which relatively enhances the intra-bond occupation. In contrast the intra-bond-suppressed models which have no corresponding site models undergo the continuous transition and satisfy the normal scaling ansatz as ordinary percolation.

V1.00224 GENERAL THEORY/COMPUTAITONAL PHYSICS –

V1.00225 Photon-induced Spin Tunneling in Giant Molecules Coupled to Superconducting Resonators

, M.-Y. TSANG[1], M. SCHEFFLER, M. DRESSEL, L. BOGANI, Physikalisches Institut, Universität Stuttgart — We present a model of magnetization relaxation of Mn12-acetate strongly coupled with photonic cavity resonator in low-temperature regimes ($T \leq 1K$), a model based on photon-assisted-spin-tunnelling-induced, quartic magnetic anisotropy, on weak transverse magnetic fields and on photonic excitations. With the model, one calculates the spin-tunnelling rate as a function of the longitudinal magnetic field, whence we further determine the transition probability of a trapped photon as a function of both photon energy and external transverse magnetic field strength. This research is supported by the Sofja Kovalevskaja prize and German DFG (SFB-TRR21 and SPP1601).

V1.00226 Full Configuration Interaction Quantum Monte Carlo: The Use of Spin-pure and Non-Orthogonal Spaces

, SIMON SMART, NICK BLUNT, University of Cambridge, GEORGE BOOTH, Princeton University, ALI ALAVI, University of Cambridge — Full configuration interaction quantum Monte Carlo[1] (FCIQMC) allows for exact results to be obtained for the ground state within a finite-basis approximation of the Schrödinger equation. Working within imposed symmetry constraints permits dramatic reductions in the size of the Hilbert space considered, reducing the computational cost, as well as permitting exclusion of the natural ground-state to extract a series of excited states of the system. All converged solutions are eigenfunctions of $\hat{S}^2$ as well as the Hamiltonion and projected spin. Working within a spin-pure basis allows this property to be used in the same manner as other imposed symmetries. FCIQMC requires frequent calculation of Hamiltonian matrix elements between random pairs of basis functions. In order to make use of an efficient scheme[2] for calculating these matrix elements between spin-projected basis functions, FCIQMC has had to be extended to work in non-orthogonal (and optionally non- normalised) bases. This has consequences for our understanding of the nature of spawning and death within FCIQMC.

V1.00227 State-of-the-art molecular applications of full configuration interaction quantum Monte Carlo

, ROBERT E. THOMAS, CATHERINE OVERY, JAMES J. SHEPHERD, University of Cambridge, The University Chemical Laboratory, United Kingdom, GEORGE H. BOOTH, Department of Chemistry, Frick Laboratory, Princeton University, USA, ALI ALAVI, University of Cambridge, The University Chemical Laboratory, United Kingdom — Full configuration interaction quantum Monte Carlo (FCIQMC)[1] and its initiator adaptation (*i*-FCIQMC)[2] provide, in principle, exact (FCI) energies *via* a population dynamics algorithm of an ensemble of discrete, signed walkers in Slater-determinant space. We demonstrate that a novel choice of reference state has the potential to widen the scope of this already versatile method, and corroborate the finding that an extension of the algorithm to allow non-integer walkers can yield significantly reduced stochastic error without a commensurate increase in computational cost[3]. New applications of FCIQMC to transition-metal systems of general and biological interest are presented, many of which have, to date, posed serious challenges for traditional quantum chemical methods[4][5]. V1.00228 Measuring the Quality of Generalized Gradient Approximations in a Density Functional Theory Pseudopotential Environment for Solids

, ZACHARY NAULT, ANTONIO CANCIO, Ball State University — Much recent development in DFT has focused on improving GGAs. Two schemes are second order GGA (SOGGA) and the APBE which builds the GGA from atomic systems and not the HEG. Both of these have been tested within an all electron (AE) environment, providing the most accurate results. The focus of many simulations, however, is on large systems using pseudopotentials (PsP's). Are these PsP calculations, which rely on functionals tested in an AE environment, accurately reproducing the AE ground state properties? If not, can the deficiencies be identified? To assess this, we use the PsP generator APE, using the functional library libXC which works with the PsP package ABINIT and the AE package Elk. We generate standard Troullier-Martin PsP's based on common and new XC functionals (LDA, PBE, PBEsol, APBE, SOGGA) and test their performance in 13 solids (Na, Li, Al, C, Si, GaAs, NaCl, LiF, LiCl, Cu, Pd, Rh, and Ag). We measure how well three ground state properties (lattice constant, bulk modulus, and cohesive energy) are calculated with PsP's as compared to the corresponding AE calculations.

V1.00229 An Automatic K-Point Grid Generation Scheme for Enhanced Efficiency and Accuracy in DFT Calculations[1]

, KYLE MCGILL, TIM MUELLER, Department of Materials Science and Engineering, Johns Hopkins University — We seek to create an automatic k-point grid generation scheme for density functional theory (DFT) calculations that improves the efficiency and accuracy of the calculations and is suitable for use in high-throughput computations. Current automated k-point generation schemes often result in calculations with insufficient k-points, which reduces the reliability of the results, or too many k-points, which can significantly increase computational cost. By controlling a wider range of k-point grid densities for the Brillouin zone based upon factors of conductivity and symmetry, a scalable k-point grid generation scheme can lower calculation runtimes and improve the accuracy of energy convergence.

[1]Johns Hopkins University

V1.00230 Charge Transfer Couplings and Excitation Energies From Subsystem DFT: The Ultimate Divide and Conquer Approach to DFT

, MICHELE PAVANELLO, Rutgers University — The subsystem formulation of DFT known as Frozen Density Embedding (FDE) offers an excellent platform for studying charge transfer reactions in solvated systems, such as biosystems. I present new theory and software development for the calculation of the electronic couplings as well as the charge transfer excitations from FDE derived densities. The method presented scales linearly with the number of non-covalently bound subsystems considered in the calculation. Proof-of-principle calculations of water and ethylene clusters with up to 56 monomers are presented. In addition, DNA oligomers radical cations, including donor-acceptor, donor-bridge-acceptor, as well as a prototype of the phothosynthetic reaction center are tackled and preliminary results are presented.

V1.00231 An investigation of the internal sum convergence in the full potential multiple scattering theory[1]

, YANG WANG, Pittsburgh Supercomputing Center, AURELIAN RUSANU, G. MALCOLM STOCKS, Oak Ridge National Laboratory, J. SAM FAULKNER, Department of Physics, Florida Atlantic University — The ab initio methods based on multiple scattering theory (MST) have proved to be a very powerful technique for the electronic structure calculation for solids. The latest advances in the implementation of full potential MST have allowed us to investigate dislocations, point defects, and radiation damage effects on the physical properties of structural materials. In the conventional formulation of full potential MST, the single site wavefunctions $\phi_{l,m}$ are expanded in terms of spherical harmonics with angular momentum l up to a cutoff value ϕ-$l_{\max}$. This cutoff value defines the extension of the internal sum and is usually taken to be the same as KKR-$l_{\max}$, the cutoff value for the Bloch wave expansion (in terms of $\phi_{l,m}$) so that the single site sine and cosine scattering matrices used for calculating the t-matrix and the Green function are square matrices. In this presentation, we show a technique that allows for ϕ-$l_{\max}$ to be greater than KKR-$l_{\max}$, so to allow for converging the internal sum, while keeping the calculation of the t-matrix and the Green function tractable. We compare the results obtained from different ϕ-$l_{\max}$ values and discuss the implications of the internal sum convergence.

V1.00232 Electronic states of carbon alloy catalysts and nitrogen substituent effects on catalytic activity

, TOMOYUKI HATA, HIROSHI USHIYAMA, KOICHI YAMASHITA, Department of Chemical System Engineering, School of Engineering, The University of Tokyo — In recent years, Carbon Alloy Catalysts (CACs) are attracting attention as a candidate for non-platinum-based cathode catalysts in fuel cells. Oxygen reduction reactions at the cathode are divided into two elementary processes, electron transfer and oxygen adsorption. The electron transfer reaction is the rate-determining, and by comparison of energy levels, catalytic activity can be evaluated quantitatively. On the other hand, to begin with, adsorption mechanism is obscure. The purpose of this study is to understand the effect of nitrogen substitution and oxygen adsorption mechanism, by first-principle electronic structure calculations for nitrogen substituted models. To reproduce the elementary processes of oxygen adsorption, we assumed that the initial structures are formed based on the Pauling model, a CACs model and nitrogen substituted CACs models in which various points are replaced with nitrogen. When we try to focus only on the DOS peaks of oxygen, in some substituted model that has high adsorption activity, a characteristic partial occupancy state was found. We conclude that this state will affect the adsorption activity, and discuss on why partially occupied states appear with simplification by using an orbital correlation diagram.

V1.00233 Reflectance Anisotropy Spectroscopy(RAS) of Si(111)-(3x1)-Ag and Si(111)-c(12x2): Comparison of hybrid density functional theory and experiment[1]

, SOFIA JORGJI, JOHN MCGILP, CHARLES PATTERSON, Trinity College Dublin, Ireland — The atomic and electronic structures of the Si(111)-(3x1)-Ag surface have been investigated extensively by LEED, STM and electron spectroscopies. The atomic structure is believed to be a honeycomb chain plus channel (HCC) structure in which channels containing Ag atoms are separated by Si in honeycomb chains. Here we compare results of previous reflectance anisotropy spectroscopy (RAS) experiments with hybrid DFT simulations for the HCC structure. Results of RAS simulations are in very good agreement with RAS experiments and indicate that the HCC structure is likely to be correct. Surface state features responsible for the RAS signal are identified and the effect of dimerisation of Ag chains on the RAS spectrum is considered.

V1.00234 Theoretical study on electronic properties of 2D graphene-TiO2 nanocomposites

, YASUYUKI MASUDA, GIACOMO GIORGI, KOICHI YAMASHITA, Department of Chemical System Engineering, School of Engineering, The University of Tokyo — In recent years, bidimensional graphene-TiO2 nanocomposite materials have attracted deep interest since their potential applicability in photocatalytic and photovoltaics. It is extremely appealing, indeed, the possibility of synthesizing a composite materials able to embody both the semiconducting properties of TiO2 monolayers and the excellent transport ones of graphene.The synthetic path, similarly to the electronic and optical properties of such nanocomposites, is nowadays considered a hot-topic in materials science. However, on the theoretical side, predictive results on the properties of a so promising material with device-oriented relevance are astonishingly very scarce.In this work, we focus on the impact that the mechanical stress at the interface formed by graphene and a monolayer of anatase (001)-oriented exerts on electronic and optical properties of the final nanocomposite. In order to perform such analysis, we have modeled and optimized, by means of Density Functional Theory, several graphene-TiO2 monolayer models, examining and reporting analogies and differences between models in presence and in absence of a direct chemical bond. In this poster presentation, we report the results of these calculations and the predicted electronic properties of these nanocomposites.

V1.00235 Investigation of the liquid Pb/Si(001) interface from ab initio molecular-dynamics calculations[1]

, D.J. GONZALEZ, Universidad de Valladolid, Spain, J. SOUTO, M.M.G. ALEMANY, R.C. LONGO, L.J. GALLEGO, Universidad de Santiago de Compostela, Spain, L.E. GONZALEZ, Universidad de Valladolid, Spain — The structure of liquid Pb on an ideal Si(001) surface was studied experimentally a decade ago by means of x-ray diffraction and the results were interpreted in terms of the presence of fivefold symmetry Pb structures captured transiently by the potential created by the unreconstructed Si(001) surface. We critically analyze this interpretation in the light of the results obtained in an extensive ab initio molecular dynamics study of a system comprising 314 Pb atoms and 175 Si atoms setup in 7 (001) ideal layers (a total number of 1956 valence electrons) in a slab geometry. The structure found for the first Pb layer is very different from that of bulk Pb, mostly consisting in one-dimensional lines. However, we do observe the possibility of forming transient structures, in particular icosahedral caps.

[1]Supported by FIS2008-02490/FIS, FIS2008-04894/FIS, GR120, INCITE09E2R206033ES and INCITE08PXIB206107PR.

V1.00236 Ab initio molecular dynamics simulations of the static, dynamic and electronic properties of the liquid Bi-Pb alloy[1]

, J. SOUTO, M.M.G. ALEMANY, L.J. GALLEGO, Universidad de Santiago de Compostela, Spain, L.E. GONZALEZ, D.J. GONZALEZ, Universidad de Valladolid, Spain — We perform an ab initio molecular dynamics study of the static, dynamic and electronic properties of the liquid Bi-Pb alloy at three concentrations, including the eutectic one. This alloy is of particular technological interest for its possible use as coolant in fast reactors. Our predictions are in good agreement with the available experimental data. In particular, the computed total static structure factors reproduce accurately the neutron diffraction results, and the predicted adiabatic sound velocity and shear viscosity compare well with the experimental values. The partial dynamic structure factors exhibit clear side peaks indicative of propagating density fluctuations, and the longitudinal and transverse dispersion relations show several branches.The electronic density of states show that the liquid Bi-Pb alloy is a good metal, but with strong deviations from the free-electron parabolic curve.

[1]Supported by FIS2008-02490/FIS, FIS2008-04894/FIS, VA068A06, GR120, INCITE09E2R206033ES and INCITE08PXIB206107PR

V1.00237 Thermodynamic of cellulose solvation in novel solvent mixtures , RITANKAR DAS, University of California, Berkeley — Biomass contains abundant amounts of cellulose as crystalline microfibrils. A limiting step to using cellulose as an alternative energy source, however, is the hydrolysis of the biomass and subsequent transformation into fuels. Cellulose is insoluble in most solvents including organic solvents and water, but it is soluble in some ionic liquids like BMIM-Cl. This project aims to find alternative solvents that are less expensive and are more environmentally benign than the ionic liquids. All-atom molecular dynamics simulations were performed on dissociated glucan chains separated by multiple (4-5) solvation shells, in the presence of several novel solvents and solvent mixtures. The solubility of the chains in each solvent was indicated by contacts calculations after the equilibration of the molecular dynamics. It was discovered that pyridine and imidazole acted as the best solvents because their aromatic electronic structure was able to effectively disrupt the inter-sheet interactions among the glucan chains in the axial direction, and because perturbation of the solvent interactions in the presence of glucan chains was minimal.

V1.00238 Towards a metallic glass transition in α-Al_2O_3: A role of pressure-induced amorphization , SANJEEV K. GUPTA, Department of Physics, Michigan Technological University, Houghton, MI-49931, USA, PRAFULLA JHA, Department of Physics, Maharaja Krishnakumarsinhji Bhavnagar University, Bhavnagar-364001, India — Pressure-induced amporphization has been observed experimentally in many electrically insulating materials, including oxides. In none of the cases, the pressure-induced amorphization has been accompanied by metallic conduction. Alumina is one of the most important ceramics of the modern age and has a large band gap of at ambient conditions. In this talk, we will present the results of the study on the behavior of alumina under increasing pressure using first principles plane wave method within the linear response approach. The crystal structure and associated equilibrium lattice constants for α-Al2O3 were obtained by minimizing the calculated total energies as function of a lattice constant. Further, to calculate the entropy and other allied properties, we have used density functional perturbation theory (DFPT). The calculated results show that Al2O3 might turn to metallic glass at pressure achievable in a laboratory.

V1.00239 Nanomorphology of the interface between P3HT and SWNT , KATSUHIKO NISHIMRA, MIKIYA FUJII, RYOTA JONO, KOICHI YAMASHITA, School of Engineering, The University of Tokyo — Organic bulk-heterojunction photovoltaic devices are promising as energy harvesting device because of their mass-productivity, and shorter energy pay back time compared to silicon based solar cells. Poly-3-HexylThiophene (P3HT) and Phenyl C_{61} Butyrate Metyl (PCBM) are an early successful material pair and yield high IPCE of 60% to 80%. Instead of PCBM, Single Walled carbon Nanotubes (SWNT) has also been examined as an electron acceptor material because SWNTs have good properties such as high carrier mobility, which ended with surprisingly low efficiency compared to P3HT and PCBM pair however. According to a recent study, the low efficiency is due to ultrafast recombination of the free carriers generated on the interface. Therefore, nanomorphology of the interface is important to inhibit the recombination of free carriers. We have computationally analyzed how the nanomorphology of the interface between P3HT and SWNT is formed and how molecular orbital or other molecular properties are affected by the morphology. We are going to report how side chains on P3HT effect the nanomorphology and electronic structure around the interface.

V1.00240 Semiconductor nano-gap antennas with high quality factor , MITSUHARU UEMOTO, Graduate School of Engineering Science, Osaka University, HIROSHI AJIKI, Photonic Pioneers Center, Osaka University — Metallic islands with nano-gap structure are one of the most popular optical antennas [1]. We theoretically propose a new nano-gap antenna utilizing exciton resonance of semiconductor. A light field at the nano-gap (hot spot) formed between two CuCl islands is significantly enhanced by a factor of metallic antennas. However, the hot spot of the semiconducting antenna exhibits much higher quality factor ($Q \approx 10^4$) at $T = 40$ K than those of metallic antennas which do not exceed $Q \approx 100$. Our result suggests the semiconducting antenna would function as a new type of photonic cavity. The calculation method is based on a finite element method which can take into account exciton resonance [2]. We also systematically study the geometry dependence of the enhancement factor and Q factor. In contrast to metallic antenna, blunt edges of semiconducting islands at the gap are preferable in order to achieve high enhancement factor. This is because of the fact that exciton wave function extends near the edge for blunt geometry.

V1.00241 Cross-sectional Characterization of All Solid State Thin Film Lithium Ion Batteries by Analytical Transmission Electron Microscopy , ZHIPENG LI, SHINTARO YASUI, JOYSURYA BASU, DMITRY RUZMETOV, National Institute of Standards and Technology, ALEC TALIN, Sandia National Laboratories, ICHIRO TAKEUCHI, University of Maryland, College Park, LEONID BENDERSKY, National Institute of Standards and Technology — Recent years witnessed the fast development of microelectronic and micro energy storage devices, which require new batteries with lightweight and high energy densities. All solid state lithium ion batteries are considered as a promising candidate for power supply of such devices. In this study, all solid state thin film lithium ion batteries, consisting of a $LiLaTiO_3$ electrolyte, $Li_4Ti_5O_{12}$ anode, and $LiCoO_2$ or compositionally graded $Li(Mn/Ni)O_x$ cathodes, were fabricated by a pulsed laser deposition technique. Cross-sectional microbatteries were prepared by focus ion beam and traditional TEM sample preparation techniques. Detailed microstructures of microbatteries were performed using analytical TEM. Multilayer thin films of batteries were epitaxially grown on Nb doped SrTiO3 substrates which serve as current collectors. Microstructures of electrolyte and electrodes, and interfacial diffusions were studied before and after charge-discharge cycling. The mechanism of cycling-triggered microstructural evolution was elucidated accordingly. These findings can not only help improve the understanding of reliability of thin film battery fabrication/assembling processes, but also shed light on issues of battery degradation. This study technically lays the foundation for our ongoing work on in-situ investigation of microbattery cycling in TEM.

V1.00242 Laser-induced coherent population trapping in C_{60}[1] , GUOPING ZHANG, Department of Physics, Indiana State University, T. F. GEORGE, University of Missouri-St. Louis — Coherent population trapping and electromagnetically induced transparency represent important advancements in quantum optics and atomic physics, with broad applications from slowing and stopping light, quantum memory, photon control in quantum information processing, storage of light and information, to cancellation of Stark shifts in optical lattice clocks. In this talk, we demonstrates the possibility of generating coherent population trapping in C_{60}. Similar to a three-level Λ system, cm has a forbidden transition between the highest occupied molecular orbital (HOMO) ($|a\rangle$) and the lowest unoccupied molecular orbital (LUMO) ($|c\rangle$), but a dipole-allowed transition between HOMO and LUMO+1 ($|b\rangle$) and between $|b\rangle$ and $|c\rangle$. We employ two cw laser fields, one coupling and one probe. The strong coupling field is switched on first to resonantly excite the transition between $|b\rangle$ and $|c\rangle$. After a delay, the probe is switched on, such that the coherent interaction between the coupling and probe fields traps the population in $|a\rangle$ and $|c\rangle$. This forms a partially dark state in C_{60}, analogous to that in atomic vapors. Turning off the coupling field restores C_{60}'s absorption. Pulsed lasers

V1.00243 Shear band blocking in explosively driven collapse of corrugated Ni-Al laminate cylinder[1]

, KARL OLNEY, PO-HSUN CHIU, University of California, San Diego, ANDREW HIGGINS, MATTHEW SERGE, McGill University, GREGORY FRITZ, ADAM STOVER, Johns Hopkins University, VITALI NESTERENKO, DAVID BENSON, University of California, San Diego — Ni-Al laminate materials have been identified as a possible material system that can be used as a reactive material due to the self-sustaining reaction between Al and Ni layers. Besides traditional ignition methods, shear bands developed during mechanical loading can provide sites where ignition can occur. Corrugated Ni-Al laminate samples were created by swaging alternating layers of Ni (20 micrometers thick) and Al (30 micrometers thick) foils. The thick-walled cylinder (TWC) technique was performed on a corrugated Ni-Al laminate cylinder sample to examine shear band development in this material. Post experiment examination of the corrugated Ni-Al laminate material showed that the development of global shear bands were blocked via mesoscale mechanisms. The collapse of the corrugated laminate cylinder was simulated providing insight into these mesoscale mechanisms that were involved in blocking the development of shear bands during the experiment. Despite the shear band resistance of the material, several regions of the sample had localized reactions of Al and Ni spanning approximately 10-20 layers of laminate.

V1.00244 Ground state energy calculations of polynomial potentials based on Hamiltonian moments

, MELISSA HOFFMAN, ROBERT MURAWSKI, Drew University, JAY MANCINI, Kingsborough College of the City University of New York, VASSILIOS FESSATIDIS, Fordham University, SAMUEL BOWEN, Chicago State University — Recently, Martin et al calculated approximate energy eigenvalues for potentials of the form $V(x) = x^a + \lambda\, x^b$ by use of the multi-point quasi-rotational technique (Rev. Mex. Fis. **58**, 301 (2012)). In their paper, they considered specific values of λ and integer values of a and b. In this work, we shall apply a moments approach to study the general ground state energy of such potentials for arbitrary values of λ and for integer and non-integer values of a and b. We will compare their results against the generalized moments expansion (GMX) in terms of accuracy and computational effort. In addition, we will calculate the energy spectrum with the Lanczos tridiagonalization technique.

V1.00245 Comparing new approaches for the real and imaginary time evolution of the Hubbard model

, MICHAEL MOECKEL, University of Cambridge — Recent advances in the experimental realization and theoretical simulation of fermionic many-body systems have motivated new interest in the Hubbard model both under real and imaginary time evolution. The possibility to follow the dynamics of excited states in cold quantum gases loaded on optical lattices [1] allows to observe relaxation behavior of the Hubbard model under the influence of nonadiabatic parameter changes. On the other hand, initiator full configuration interaction quantum Monte Carlo (iFCIQMC) provides a promising new approach to an efficient sampling of the Hilbert space based on a mapping of imaginary time evolution onto a population dynamics in Slater determinant space [2]. Since characteristic features of the Hubbard model like time scale separation and long time transient behavior [3] become visible in both approaches I provide a comparison of related results.

V1.00246 Monte Carlo simulation of single-molecule recycling in a nanochannel for accurate diffusion measurements

, BO WANG, SULTAN BEHERY, LLOYD M. DAVIS, University of Tennessee Space Institute — In previous experiments on single-molecule (SM) detection in solution, we demonstrated that prolonged observation times and photon yields are achieved by actively trapping a molecule in a nanochannel. We also developed Monte Carlo simulations to optimize experimental parameters and improve real-time control algorithms. Other researchers have since shown similar advantages can be attained by alternating the flow in the nanochannel so that a SM repeatedly passes through the laser excitation focus and that variation in the times between detections provides a measure of the diffusion coefficient of the molecules. We have extended the previous simulations to study the SM recycling experiment and to compare control algorithms and measurement capabilities in which the timing of each photon is processed by an FPGA circuit, as used in our trapping experiments, with those where detected photons are first collected into 1 ms bins, as in the prior recycling experiments. We present capabilities for measuring the diffusion coefficients of SMs. Also, we compare the capability for resolving a solution containing species with differing diffusion coefficients with that of fluorescence correlation spectroscopy, which is often used for monitoring molecular interactions in pharmaceutical research.

V1.00247 Modeling of nanoscale transport using fractional exclusion statistics[1]

, GEORGE ALEXANDRU NEMNES[2], University of Bucharest, Faculty of Physics, DRAGOS VICTOR ANGHEL, Horia Hulubei National Institute of Physics and Nuclear Engineering, The Department of Theoretical Physics — In recent years, with the continuous development of nanostructured materials, many-body quantum effects were observed in the charge, spin or phonon transport. Fractional exclusion statistics (FES) has already proved to be an important tool in the study of thermodynamical properties of interacting Bose and Fermi systems, which are regarded as ideal FES gases. Recently, the transition rates for FES gases were established [1], which opens the possibility of analyzing interacting boson and fermion systems in non-equilibrium. We make here a step further and introduce a transport model based on FES, using Monte Carlo simulations. The transport model based on FES is applied on quasi-1D systems, such as core-shell structures. The statistical FES parameters are extracted from the interacting electron gas, taking into account the Coulomb interaction. We also investigate transport in systems with quenched disorder [2]. Within our approach we are able to point out some particularities of charge transport of interacting fermions in nanoscale systems with multiple interfaces.

V1.00248 Electrohydrodynamic modeling of an electrospray-based thruster in cone-jet mode

, MANISH JUGROOT, MARTIN FORGET, CECILE MALARDIER-JUGROOT, Royal Military College of Canada — Electrospray-based propulsion is an excellent candidate for small satellites due to its inherent small size and high specific impulse. The present study aims to gain an increased understanding of complex underlying physical processes namely transitions. Numerical modeling and simulations can offer insights into the flows within the electrospray and offer critical local information difficult to measure experimentally due to the small scales. A multi-component continuum-based model coupling fluid dynamics, charged species dynamics and electric field is developed. The simulations describe the charged fluid interface with emphasis on the Taylor cone formation and cone-jet transition under the effect of a electric field. The goal is to recapture this transition from a rounded liquid interface into a Taylor cone from an initial uniform distribution, without making assumptions on the behaviour, geometry or charge distribution of the system, and transition to droplet or cone-jet mode. The time evolution of the interface highlights the close interaction among space charge, coulombic forces and the surface tension, which appear as governing and competing processes in the transition. Several modes and regimes are examined and compared to experimental results. The results from the coupled formalism provide valuable insights on the physical phenomena and will be applied to tailoring a multi-beam colloid thruster.

V1.00249 Construction of adiabatic connection curve for electron-hole system using multi-component Levy-Lieb Lagrangian , JENNIFER ELWARD, BENJAMIN KAPLAN, ARINDAM CHAKRABORTY, Syracuse University — The electron-hole adiabatic connection curve (eh-ACC) is central in development of accurate correlation functional for multicomponent electron-hole density functional theory (eh-DFT). The construction of accurate eh-ACC is challenging because it requires density constrained energy minimization at different values of coupling constants. In the present work, the density constraint was avoided by defining an electron-hole Levy-Lieb Lagrangian (eh-LLL). For a given set of input electron and hole densities, the eh-LLL was constructed and expressed as a functional of the coupling constant dependent external potential. Unconstrained minimization of the eh-LLL was performed by varying the eh-wavefunction, external potential, and Lagrange's multipliers. An explicitly correlated ansatz was used for the eh-wavefunction and the search over the wavefunction was performed using variational Monte Carlo. The calculation was repeated for coupling constants in the range of 0 to 1 and the minimized wavefunction was used for construction of the eh-ACC. This study represents the first step in construction of accurate electron-hole correlation functional for eh-DFT.

V1.00250 Vacuum State Energies of Anharmonic Potentials by Method of Undetermined Amplitudes , SAMUEL P. BOWEN, Chicago State University, JAY D. MANCINI, Kingsborough College of CUNY, VASSILIOS FESSATIDIS, Fordham University — This is an examination of the applications of a method of undetermined amplitudes to the quantization of polynomial potentials leading to the determination of the exact vacuum state energies for several important potentials. The potentials studied include the simple harmonic oscillator (SHO) x^2, x^4, x^{2n}, $\pm x^2+x^4$, $\pm x^2+x^6$, $\pm x^2+x^{10}$ and others. The ground state and vacuum state energies are determined analytically and all have branch point singularities as functions of the coupling parameters and thus cannot be reached by perturbative series expansions. The excited state spectrum must usually be determined numerically, but is determined exactly for the systems where Bohr-Sommerfeld integrals can be solved for the energy.

V1.00251 Automatic sorting of point pattern sets using Minkowski Functionals , JOSHUA PARKER, Institute for Research in Electronics and Applied Physics, University of Maryland, EILON SHERMAN, National Cancer Institute, The National Institutes of Health, MATTHIAS VAN DE RAA, Institute for Nanotechnology, University of Twente, LARRY SAMELSON, National Cancer Institute, The National Institutes of Health, WOLFGANG LOSERT, Institute for Research in Electronics and Applied Physics, University of Maryland — Point patterns arise in many different areas of physical and applied research, often resulting in sets of patterns that may or may not be fundamenally different. We introduce here a automatable numerical taxonomy procedure for clustering point pattern sets using their approximated Minkowski functionals. We demonstrate that this procedure outperforms current methods, even when the patterns are drawn from very similar processes. We highlight the use of this routine for automatically analyzing sets of patterns, and in particular super-resolution images of fluorescently labeled proteins. Overall, we find that this routine is a robust method for sorting point pattern sets, and provides meaningful insight regarding the homogeneity of spatial processes.

V1.00252 Test of Relativity Theory Using Spinning Bodies in Low-Earth Orbit , RYAN EVERETT, JAMES OVERDUIN, Towson University — Using measurements of geodetic precession around the Earth from Gravity Probe B, we constrain departures from Einstein's General Relativity for a spinning test body in Kaluza-Klein gravity with one additional space dimension. We consider two of three known time-independent, spherically symmetric solutions of the 5D field equations and obtain new constraints on the values of the free parameters associated with each metric.

V1.00255 POST-DEADLINE ABSTRACTS –

V1.00256 Laser Induced Fluorescence Spectroscopy of a Langmuir Monolayer of C-16 Fluorescent Dipyrrinone Liquid Crystal

, CHRISTIAN STRUEBING[1], GIOVANNI DELUCA[2], CHANDRA PRAYAGA, AARON WADE, University of West Florida Physics Department, MICHAEL HUGGINS, AMY RENAUD[3], REBECCA CHANDLER[4], University of West Florida Chemistry Department — A C-16 Fluorescent Dipyrrinone Liquid Crystal synthesized by the Chemistry department, University of West Florida, has been prepared in a Langmuir monolayer using a Nima Langmuir-Blodgett Trough. DeLuca et al. [1] studied how the length of the hydrocarbon tail influences the behavior of the pressure-area isotherm of the Langmuir film. The C-16 Fluorescent Dipyrrinone Liquid Crystal film produced a stable film at 20 mN/m and a stable, optical quality film at 40 mN/m. We present a study of the fluorescence properties of the C-16 fluorescent dipyrrinone liquid crystal film. Once the monolayer is compressed the sample is excited using a 410 nm wavelength laser and the fluorescence is measured using an Oriel MS260i 1/4 m Spectrograph.

V1.00257 Electric-field-induced destruction of quasi-Landau levels in AA-stacked bilayer graphene nanoribbons[1]

, HSIEN-CHING CHUNG, YU-MING WANG, MING-FA LIN, Department of Physics, National Cheng Kung University, Tainan 70101, Taiwan — The magneto-electronic properties of AA-stacked bilayer zigzag graphene nanoribbons are investigated by the Peierls tight-binding method. In the presence of magnetic fields, Landau quantization leads to the partial dispersionless subbands, which are called quasi Landau levels (QLLs). For bilayer zigzag nanoribbons, there are two groups of QLLs with two pairs of partial flat subbands. A perpendicular electric field, serving as the top gate, is expected to push these QLLs to higher state energies and to split the flat subbands. Wave functions, providing more information on the electronic states, are employed to analyze the mixing Landau and localized states on the flat subbands. And the electron distributions of Landau subbands are also be presented. The density of states are discussed at last in detail. The aforementioned predicted properties could be verified through optical spectroscopy and scanning tunneling spectroscopy.

V1.00258 Role of Dirac cones in magneto-transport properties of REFeAsO (RE=rare earth) oxypnictides[1]

, FABIO BERNARDINI, CNR-IOM and University of Cagliari, 09042 Monserrato (CA), Italy, ILARIA PALLECCHI, FEDERICO CAGLIERIS, ANDREA PALENZONA, GIANRICO LAMURA, CNR-SPIN and University of Genoa, Via Dodecaneso 33, 16146 Genova, Italy, SANDRO MASSIDDA, CNR-IOM and University of Cagliari, 09042 Monserrato (CA), Italy, MARINA PUTTI, CNR-SPIN and University of Genoa, Via Dodecaneso 33, 16146 Genova, Italy — Dirac cone (DC) states are one of the most intriguing issues in condensed matter physics. Abrikosov showed that DC states can be identified by the low temperature behavior of the magneto-resistance. In additon to the usual quadratic dependence of $(\rho(H)-\rho(H=0))/\rho(H=0)$ on magnetic field, a linear dependence appears in the presence of DC states. Such a behavior was discovered in experiments of magneto-resistance in BaFeAs and Pr(Ru,Fe)AsO supporting the existence of DC states in other iron-pnictides superconductors too. Here we investigate the issue of DC states in iron oxypnictides of composition REFeAsO (RE=rare earth). We carry out both ab-initio calculations of the band structure, which evidence the presence of mildly anisotropic Dirac cones along the Y-Γ and Z-R directions of the reciprocal space and we explore transport behavior by means of resistivity, Hall resistance and magneto-resistance measurements, which confirm the dominant role of Dirac cones. By combining our theoretical and experimental approaches, we extract information on effective masses, scattering rates and Fermi velocities for different rare earth elements.

V1.00259 Vortex String in Electric Dipole Radiation near a Mirror

, ZACHARY SCHULZ, XIN LI, Millersville University, HENK ARNOLDUS, Mississippi State University — When an atom, molecule or nanoparticle is irradiated by a laser beam, it will emit radiation, either as scattered light or resonance fluorescence. When the small particle is located near an interface, the emitted radiation will interfere with the reflected radiation, and this alters the radiation pattern. This problem was already studied by Sommerfeld in the 1950's, when he considered the effect of the Earth on the radiation pattern of dipole radiation emitted by an antenna. Many experimental and theoretical efforts have been devoted to this problem since, including quantum effects leading to alterations of the lifetime of atomic levels due to the presence of the interface. With the rapid progress of nanophotonics, where phenomena on the scale of an optical wavelength or less are of interest, this area of research has attracted renewed attention. It was recently shown that when dipole radiation is emitted near an interface, the mechanism of emission is drastically different from emission in free space. In addition, the flow pattern of the energy can be rather complicated, and it contains singularities and vortices as a result of the interference between the emitted light and the light reflected by the interface.

V1.00260 Factors Influencing the 2D Elastic Moduli of Self-Assembled Nanoparticle Monolayers[1]

, SIHEN YOU, ROSSEN RASHKOV, PONGSAKORN KANJANABOOS, IGNAVIO CALDERON, MATI MERON, HEINRICH JAEGER, BINHUA LIN, University of Chicago — Nanoparticles with hydrophobic capping ligands are found to self-assemble into monolayer films when deposited on the air/water interface. Different nanoparticle monolayers exhibit a rich morphology of wrinkling, folding and buckling behavior that indicates interesting elastic properties. We obtain the 2D bulk and shear moduli of several different nanoparticle films by measuring the anisotropic stress response of the film under uniaxial compression using a Langmuir trough, a method previously applied to lipid and protein membranes. We find that the elastic properties of the nanoparticle film are affected by size distribution of the nanoparticles and the properties of their capping ligands. Higher polydispersity results in a greater number of packing defects that weaken the assembled film. The ligands mediate the particle-particle interaction, acting like elastic springs that join together hard spheres. The strength of such "springs" is determined by the degree of interdigitation of ligands between neighboring nanoparticles as well as the shapes of the capping ligands. These results suggest that the elastic moduli of nanoparticle films can be tuned through careful alteration of size distribution and capping ligand's shape and density.

V1.00261 Multiscale simulation for non-isothermal polymeric flow between parallel plates[1] , SHUGO YASUDA, University of Hyogo, RYOICHI YAMAMOTO, Kyoto University — A multiscale simulation method for non-isothermal polymeric flow is developed based on the local stress sampling strategy and applied to the flows of a polymer melt in the simple creep motion of the parallel plates. In our multiscale modeling, the macroscopic quantities, e.g., density, velocity and temperature, are calculated by using a usual lattice-mesh based computational fluid dynamic (CFD) simulation, but, instead of using any constitutive equations, the local stresses are generated by performing the molecular dynamics (MD) simulations associated with each mesh interval of the CFD calculation according to the local macroscopic quantities. It is found that, at a rapid creep velocity, the distinct regimes in the velocity field appear between the vicinity and intermediate of the plates because the local viscosity drastically varies due to the temperature variation generated by the local viscous heating. The effect of density variation due to the thermal expansion and compressible flow on the flow field is also investigated.

V1.00262 Soft X-ray Scattering for Soft Materials at ALS , CHENG WANG, ALEXANDER HEXEMER, ANTHONY YOUNG, HOWARD PADMORE, Lawrence Berkeley National Laboratory — The function and properties of organic and biological soft-condensed matter systems are largely determined by their nano- and mesoscopic chemical morphology. The understanding and rational use of such systems thus require that this structure be known. Using x-ray energies close to the absorption edge of constituent atoms, soft x-ray scattering is a combination of conventional x-ray scattering with x-ray absorption spectroscopy that yields both elemental and chemical sensitivity. The strong resonance enhancement of the scattering contrast offers large scattering signal for thin organic films with only tens of nanometers thick. The enhanced scattering and tunable sensitivity for organic materials can be achieved without any chemical modifications. Various scattering geometries including specular reflectivity, transmission, and grazing incidence with soft x-ray scattering make it a great complimentary tool for the study of soft material thin films. By taking advantage the unique features including elemental/chemical sensitivity, mesoscale probing size, large coherence length, and molecular orientation sensitivity with the polarization of the beam of photons, an inherent characteristic of synchrotron sources, soft x-ray scattering provides yet another key to unlock structure-property relationships that will lead to better materials. A dedicated soft x-rays scattering instrument optimized for soft materials has been constructed at Beamline 11.0.1.2 at the ALS. Some recent results on organic PV, block copolymer thin films will be presented.

V1.00263 Self-assembly of ABC miktoarm star peptides and kinetic evolution of the supramolecular morphology , YI-AN LIN, YU-CHUAN OU, ANDREW CHEETHAM, HONGGANG CUI, Johns Hopkins University — Amphiphilic peptides are versatile building blocks to engineer well-defined nanostructures. A great deal of work has shown the use of peptides to construct structures such as micelles, nanofibers, nanoribbons, or nanotubes through the rational design of peptide primary sequences. Despite amphiphilic peptides undergoing rapid self-assembly to form thermodynamically stable micellar structures, the resulting assembled morphologies are often found to slowly evolve over time. Here we report our rational design of an ABC miktoarm star peptide which comprises three immiscible domains: 1) a β-sheet adopting peptide segment with overall hydrophilicity 2) a hydrophobic hydrocarbon and 3) a hydrophobic and lipophobic fluorocarbon segment. In aqueous solution, this designed peptide can spontaneously associate into one-dimensional structures such as twisted-ribbons and helical ribbons. Transmission electron microscopy has been used to directly visualize the structural evolution with time from narrow structures into higher hierarchical large assemblies.

V1.00264 Photo-excited charge separation in CuPc/GaAs investigated by pump-probe second harmonic generation , HEUNGMAN PARK, Columbia University, MARLENE GUTIERREZ, University of Texas at Austin, XIAOXI WU, Columbia University, JEONG WON KIM, Korea Research Institute of Standards and Science (KRISS), XIAOYANG ZHU, Columbia University — We report photo-excited charge carrier separation between copper phthalocyanine (CuPc) and p,n-GaAs (001) probed by time-resolved second harmonic generation (SHG). Electric field induced SHG measurements show that when GaAs is excited by 1.55 eV photons, charge carriers are initially separated by GaAs surface band bending, and then holes are injected into CuPc from GaAs regardless of doping type. The interfacial band alignment between CuPc and GaAs is determined by ultraviolet photoelectron spectroscopy and supports the hole injection from GaAs to CuPc.

V1.00265 ABSTRACT HAS BEEN MOVED TO N20.00007 –

V1.00266 Dynamic Light Scattering in Network-Forming Oxide Melts: Ties Between Structure and Dynamics[1] , TRI TRAN[2], STANLEY SCHNELL, DAVID SIDEBOTTOM, Creighton University — We report results from a series of dynamic light scattering studies of network-forming oxide glasses obtained using photon correlation spectroscopy. These studies focus specifically on how the dynamics of these viscous melts are influenced by systematic changes in the chemical structure of the oxide network and include studies of both sodium phosphate and sodium aluminophosphate melts. The fragility, a dynamical property of the liquid near the glass transition point, is determined from these measurements and seen to decrease with increases in the average density of bridging oxygen bonds regardless of the alkali content. Moreover, this dependence of the fragility on bond density is shown to be identically reproduced in both alkali borate melts and chalcogenide glasses, provided accommodations are made for the presence of structural entities in the borate system that contribute to their intermediate range order. The universal pattern that emerges suggests a significant tie between network structure and dynamics that is consistent with predictions for a rigidity transition near an average bond number of 2.4 and within the framework of a simple two-state bond model, may be traced to a common dependence of the configurational entropy on connectivity.

V1.00267 Role of proton ordering in adsorption preference of polar molecule on ice surface , ZHAORU SUN, Peking University, Beijing, P.R. China, DING PAN, University of California, Davis, CA, LIMEI XU, ENGE WANG, Peking University, Beijing, P.R. China — Adsorption of polar monomers on ice surface, relevant to the physical/chemical reaction in ice clouds as well as growth of ice, remains an open issue partially due to the unusual surface characteristics with protons at the top layer of ice. Using first-principle calculations, we explore the adsorption properties of ice surface in terms of a surface proton order parameter, which characterizes the inhomogeneity of the dangling atoms on ice surface. We show that, due to an effective electric field created by dangling OH bonds and lone pairs of water molecules not only directly neighboring but also further away from the adsorbed polar molecule on the ice surface, the adsorption energy of polar monomer on ice surface exhibits large variance and a strong correlation with the proton order parameter of ice surface. Our results about the positive correlation between the inhomogeneity of ice surface and adsorption energies suggest that the physical/chemical reactions as well as the growth of ice may prefer to occur firstly on surfaces with larger proton order parameter.

V1.00268 Frequency-dependent cavity lifetime and apparent superluminality in Fabry-Perot-like interferometer , HSIN-YU YAO, NAI-CHING CHEN, TSUN-HSU CHANG, National Tsing Hua University, HERBERT G. WINFUL, University of Michigan — Extraordinary group delays shorter than the transit time of light propagating at c through an equal distance have been experimentally demonstrated in single-Fabry-Perot (FP) waveguide systems and cascaded-FP structures under off-resonant conditions. These "superluminal" phenomena are well explained by the multiple-reflection destructive interference that reduces the intracavity stored energy when operating off resonances. Excellent agreement between theory and experiment is obtained when the dispersive effects of reflective boundaries are considered. These results provide further insight into the nature of apparent superluminality in regions of allowed propagation.

V1.00269 Angular resolved photoionization of C_{60} by femtosecond laser pulses , HUI LI, ZHENHUA WANG, Kansas State University, FREDERIK SUESSMANN, SERGEY ZHEREBTSOV, Max-Planck Institut for Quantumoptik, SLAWOMIR SKRUSZEWICZ, JOSEF TIGGESBAEUMKER, THOMAS FENNEL, KARL-HEINZ MEIWES-BROER, University of Rostock, C. LEWIS COCKE, Kansas State University, MATTHIAS KLING, Kansas State University and Max-Planck Institut for Quantumoptik, JRM LABORATORY, KANSAS STATE UNIVERSITY TEAM, UNIVERSITY OF ROSTOCK COLLABORATION, MAX-PLANCK INSTITUT FOR QUANTUMOPTIK COLLABORATION — Neutral C_{60} molecules are ionized by intense femtosecond laser pulses around the wavelength of 800 nm with pulse durations 4 fs and 30 fs. We measure photoelectrons utilizing velocity-map imaging (VMI) and analyze the photoelectron angular distributions. For particular photoelectron energies, these distributions might reflect the excitation and ionization of superatomic molecular orbitals (SAMOs) which have been theoretically predicted and only recently experimentally observed. SAMOs arise from the hollow core spherical structures of the C_{60} molecules and differ from Rydberg states of C_{60} by their potential to exhibit electron density within the C_{60} cage. We have recorded the carrier envelope phase (CEP) dependence of the electron emission for 4 fs pulses using single shot CEP-tagging. The CEP-dependent asymmetry in the electron emission is observed to strongly depend on the laser polarization. Furthermore, the amplitudes and phases of the CEP-dependent electron emission are analyzed and show that thermal electron emission can be avoided enabling a more direct comparison to theory.

V1.00270 Violation of Cauchy-Schwarz inequalities by spontaneous Hawking radiation in resonant boson structures[1] , FERNANDO SOLS, JUAN R.M. DE NOVA, IVAR ZAPATA, Universidad Complutense de Madrid — The violation of a classical Cauchy-Schwarz (CS) inequality is identified as an unequivocal signature of spontaneous Hawking radiation in sonic black holes. This violation can be particularly large near the peaks in the radiation spectrum emitted from a resonant boson structure forming a sonic horizon. As a function of the frequency-dependent Hawking radiation intensity, we analyze the degree of CS violation and the maximum violation temperature for a double barrier structure separating two regions of subsonic and supersonic condensate flow. We also consider the case where the resonant sonic horizon is produced by a space-dependent contact interaction. In some cases, CS violation can be observed by direct atom counting in a time-of-flight experiment. We show that near the conventional zero-frequency radiation peak, the decisive CS violation cannot occur.

V1.00271 Implementation of squeezing jump operators , ROLAND CRISTOPHER CABALLAR, GENTARO WATANABE, Asia Pacific Center for Theoretical Physics, SEBASTIAN DIEHL, University of Innsbruck, HARRI MÄKELÄ, Aalto University — We present a method to construct phase andnumber squeezed states using dissipation. Our method makes use of a gas of ultracold bosonicatoms trapped in a narrow double well embedded in a wide harmonic oscillator, with the atoms Raman coupled to the first two energyeigenstates of the harmonic oscillator. The whole system is then immersed in a background BEC to allow for dissipation from the harmonicoscillator states back to the double narrow wellstates.

V1.00272 A study on the magnetic and dielectric behavior of nanostructured $YCrO_3/Al_2O_3$ composite ceramics[1] , A. DURAN, H. TIZNADO, J.M. ROMO-HERRERA, Centro de Nanociencias y Nanotecnologia-UNAM, E. VERDIN, UNISON, J. SIQUEIROS, Centro de Nanociencias y Nanotecnologia-UNAM, R. ESCUDERO, IIM-UNAM — Ferroelectric core-shell particles are promising architectures as functional bulk composites for potential use as dielectric resonators, supercapacitors, or multiferroic based devices. The core-shell architecture in ferroelectrics acts as barrier layer localizing electronic and ionic space charges, increasing thus the capacitance density. In bulk multiferroics, the barrier layer improves the grain boundary interface and leads to increased functionality, that is, higher charge storage and lower dielectric losses. In $YCrO_3$, large dielectric losses and changes in the activation energy have shown to be very dependent on the synthesis route as well as in the size, and chemical state of the starting grains. Increase of the conductivity and dielectric losses are associated to loose charge leaking out through the grain boundaries. Here we added an alumina shell-layer of 5, 30 or 90 nm to cover the $YCrO_3$ grains, using an atomic layer deposition (ALD) technique, followed by a sintering step to produce a multiferroic capacitor. The powder samples were characterized by XRD, XPS, SEM and TEM. Also, the magnetic and dielectric properties were evaluated and compared to bulk nanostructured ceramics of the same composition, but without the alumina shell.

V1.00273 Quasiparticle Dynamics in Reshaped Helical Dirac Cone of Topological Insulators , DONG QIAN, MIAO LIN, JINFENG JIA, Shanghai Jiao Tong University, ZHENGFEI WANG, FENG LIU, University of Utah — Topological insulators (TIs) and graphene present two unique classes of materials which are characterized by spin polarized (helical) and non-polarized Dirac-cone band structures, respectively. The importance of many-body interactions that renormalize the linear bands near Dirac point in graphene has been well recognized and attracted much recent attention. However, renormalization of the helical Dirac point has not been observed in TIs. Here, we report the experimental observation of the renormalized quasiparticle spectrum with a skewed Dirac cone in a single Bi bilayer grown on Bi2Te3 substrate, from angle-resolved photoemission spectroscopy. First-principles band calculations indicate that the quasi-particle spectra are likely associated with the hybridization between the extrinsic substrate-induced Dirac states of Bi bilayer and the intrinsic surface Dirac states of Bi2Te3 film at close energy proximity. Without such hybridization, only single-particle Dirac spectra are observed in a single Bi bilayer grown on Bi2Se3, where the extrinsic Dirac states Bi bilayer and the intrinsic Dirac states of Bi2Se3 are well separated in energy. The possible origins of many-body interactions are discussed. Our findings provide a means to manipulate topological surface states.

V1.00274 Converting an engine driven by non-uniform temperature to one driven by load[1] , MULUGETA BEKELE, TOLASA ADUGNA, TATEK YERGOU, Department of Physics, Addis Ababa University — Consider a Brownian particle moving in a symmetric ratchet potential (barrier height U_0, period L) and in an equally periodic alternate hot (T_h) and cold (T_c) temperature background along the same space coordinate (case I). Under steady state condition, the particle will attain a constant average velocity. On the other hand, if we replace the non-uniform temperature background by a uniform temperature (T_c) with a load (f) keeping the same ratchet potential (case II), the particle will attain a constant average velocity down the load at steady state. In this work, we evaluate the amount of load for case II that gives identical value of average velocity to that of the non-uniform temperature background of case I. We, in general, explore the condition under which both cases have equivalent particle velocities by varying the barrier height of the ratchet.

[1]We acknowledge the support we get from the International Science Programme, Uppsala, Sweden

V1.00275 Effect of chemical and heat treatment on the superconducting properties of niobium used in superconducting radiofrequency cavity fabrication , PASHUPATI DHAKAL, GIANLUIGI CIOVATI, GANAPATI RAO MYNENI, Jefferson Lab, Newport News VA — Niobium is the material of choice for the fabrication of the superconducting radiofrequency (SRF) cavities used in particle accelerator. In the last four decades, much work has been done to push the performance of SRF cavity to its theoretical limits of the accelerating gradient and high quality factor. One of the issues towards achieving those limits is the high residual loss and occurrence of a sharp increase of the RF losses (decrease in quality factor) when the peak magnetic field reaches about 100 mT, consequently limiting the operational accelerating gradient of SRF cavities. We present the result on the effect of the surface and heat treatment on ac and dc superconducting properties to explore the limiting factors of the SRF cavity performance.

V1.00276 Novel spin-liquid behaviour in some Ir-based oxide systems[1] , A.V. MAHAJAN, T. DEY, Department of Physics, Indian Institute of Technology Bombay, Powai, Mumbai 400076, India, P. KHUNTIA, M. BAENITZ, Max Planck Institute for Chemical Physics of Solids, 01187 Dresden, Germany, B. KOTESWARARAO, F.C. CHOU, Center for Condensed Matter Sciences, National Taiwan University, Taipei 10617, Taiwan, A.A. OMRANI, H.M. RONNOW, Laboratory for Quantum Magnetism, Ecole Polytechnique Federale de Lausanne (EPFL), CH 1015, Switzerland — The 5d-transition metal based oxide systems are of current interest due to the prominence of spin-orbit coupling driving them to a Mott insulating state in spite of a small Coulomb repulsion energy U. We have recently investigated Ba3IrTi2O9 and Ba3YIr2O9 systems (with hexagonal arrangement of Ir) using x-ray diffraction, magnetization, heat capacity, and NMR. With a power-law temperature dependence of the low-T magnetic heat capacity, we find evidence of spin-liquid behavior in the former. Whereas the latter is magnetically long-range ordered below 4 K, it transforms to a cubic structure when reacted at 1273 K under a pressure of 8GPa. The high-pressure (HP) prepared sample, though with semiconductor-like resistivity, has (in addition to the phonon term) a T-linear heat capacity term with $\gamma = 10$ mJ/mol K^2 and a T-linear ^{89}Y NMR spin-lattice relaxation rate. We conclude that the HP phase exhibits spin-liquid behavior.

V1.00277 Effect of Surface Morphology on Adhesion of Graphene , CHANGGU LEE[1], DAE-HYUN CHO, JIN-SEON KIM, TAIYU JIN, JINYOUNG KANG, RENLONG LIU, YOUNGCHAN KIM, Sungkyunkwan University, LEI WANG, GWAN-HYOUNG LEE, JAMES HONE, Columbia University — The friction of graphene on various substrates, such as SiO2, h-BN, graphite, and mica, was investigated to characterize the adhesion level between graphene and the underlying surface. The friction of graphene on SiO2 decreased with increasing thickness and converged around the penta-layers due to incomplete contact between the two surfaces. However, the friction of graphene on an atomically flat substrate, such as h-BN and graphite, was low and comparable to that of bulk-like graphene. In contrast, the friction of graphene folded onto graphite was indistinguishable with that of mono-layer graphene on SiO2 despite the ultra-smoothness of the graphite. The characterization of the graphene's roughness before and after folding showed that the corrugation of graphene induced by SiO2 morphology was preserved even after it was folded onto an atomically flat substrate. In addition, graphene deposited on mica, when folded, preserved the same corrugation level as before the folding event. We found that graphene, once exfoliated from the bulk crystal, tends to maintain its corrugation level even after it is folded onto an atomically flat substrate and that ultraflatness in both graphene and the substrate is required to achieve the intimate contact necessary for strong adhesion.

V1.00278 Coupling the valley degree of freedom to antiferromagnetic order , XIAO LI, TING CAO, QIAN NIU, JUNREN SHI, JI FENG, Peking University — Conventional electronics are based invariably on the intrinsic degrees of freedom of an electron, namely, its charge and spin. The exploration of novel electronic degrees of freedom has important implications in both basic quantum physics and advanced information technology. Valley as a new electronic degree of freedom has received considerable attention in recent years. In our paper, we develop the theory of spin and valley physics of an antiferromagnetic honeycomb lattice. We show that by coupling the valley degree of freedom to antiferromagnetic order, there is an emergent electronic degree of freedom characterized by the product of spin and valley indices, which leads to spin-valley dependent optical selection rule and Berry curvature-induced topological quantum transport. These properties will enable optical polarization in the spin-valley space, and electrical detection/manipulation through the induced spin, valley and charge fluxes. The domain walls of an antiferromagnetic honeycomb lattice harbors valley-protected edge states that support spin-dependent transport. Finally, we employ first principles calculations to show that the proposed optoelectronic properties can be realized in antiferromagnetic manganese chalcogenophosphates ($MnPX_3$, X = S, Se) in monolayer form.

V1.00279 Probing the transport properties of graphene nanostructures produced by local anodic oxidation , NILS FREITAG, II. Institute of Physics B, RWTH Aachen and JARA-FIT, Otto-Blumenthal-Strasse, 52074 Aachen, AVIRAL VAID, Dept. of Materials Science and Engineering, Indian Institute of Technology Kanpur, India 208016, MARCUS LIEBMANN, FELIX JEKAT, THERESA HECKING, ALEXANDER NENT, MARKUS MORGENSTERN, II. Institute of Physics B, RWTH Aachen and JARA-FIT, Otto-Blumenthal-Strasse, 52074 Aachen — Graphene flakes exfoliated on 300 nm SiO_2/Si and contacted by Indium soldering are modified by local anodic oxidation in an atomic force microscope (AFM). By varying voltage, tip velocity and contact pressure, we produced either cuts or areas appearing as elevations in AFM. The width of the cuts and elevations ranged down to 15 nm and 35 nm respectively. However, the cuts are mostly surrounded by additional elevations. The elevations are insulating at room temperature with an areal resistance of several TΩ and exhibit a D and a 2D peak in Raman spectroscopy. Transport studies on an Aharanov-Bohm ring with a diameter of 600 nm showed magnetooscillations with a visibility of 0.2% at 300 mK and a strong peak around 0 T attributed to weak localization within the ring. Transport measurements on a Quantum Dot structure with a diameter of 60 nm and several side gates showed several Coulomb diamonds, however, with addition energies not compatible with the structured dot area. Nevertheless, the plunger gate was six times more effective than the back gate and charge rearrangements were seldom observed.

V1.00280 Fabrication of sub-20 nm metal lines on Si substrates , YUKTA P. TIMALSINA, ZONGHUAN LU, LIANG CHEN, KIM LEWIS, TOH-MING LU, Center of Integrated Electronics, Rensselaer Polytechnic Institute, Troy, NY 12180, USA — As line width decreases below 15 nm, the diffusion barriers used in copper (Cu) technology in high performance integrated circuits significantly increase the overall resistivity of interconnects. In this work, we argue that the performance of pure W and Mo lines with line widths smaller than 15 nm could be better than that of Cu lines with barriers. We, herein, present a process of creating Cu, W and Mo metal nanolines on Si substrates using the combination of e-beam lithography (SUPRA 55 Scanning electron microscopy), oblique angle deposition, and lift-off techniques. The integrity of the sub-15 nm nanolines, including the line edge roughness, will be quantified. We shall also report our attempts to measure the resistivity of these nanolines using four point probe techniques. The relative contributions of phonon scattering versus surface scattering will be discussed. The effect of line edge roughness to the overall resistivity will also be presented.

V1.00281 Fabrication of canonical nanoporous templates by variational anodic oxidation of aluminum , ATAUR CHOWDHURY, PATRICK WALLACE, University of Alaska Fairbanks — The interesting effects of quantum confinement critically depend on the shape and size of the nanocrystals. Preliminary results of an experimental study of production of templates with conical profiles are presented here. These templates will be ideal for fabrication of nanocrytals with the same profile. Templates were fabricated in aluminum with the anodic oxidation process by carefully controlling the anodization parameters to control the shape of the resulting templates. Different combinations of theses parameters such as electrolyte, pH of the solution, applied voltage, and current density were studied to ascertain the right condition of growth for conically porous templates. The most dominant parameter was the applied voltage and the voltage was continuously changed slowly during the process of growth. Attempt was made to control the pore diameter to a size less than 20 nm with an aspect ratio of about 1.0. Structural and morphological studies were done with AFM and SEM. The details of the results will be presented.

V1.00282 Design study of the Low Energy Beam Transport system at RISP[1] , JUNGBAE BAHNG, EUNSAN KIM, YONGHWAN KIM, IN-SEOK HONG, Kyungpook Nat'l Univ. — We present the design status of LEBT for the RISP that consists of two 90 degree dipoles, a multi-harmonic buncher, pair solenoids, electrostatic quadrupoles and a high voltage platform. After ECR-IS with an energy of 10 keV/u, heavy-ion beams are selected by achromatic bending systems and then be bunched in the LEBT. A multi-harmonic buncher is used to achieve a small longitudinal emittance in the RFQ. We show the results on the optics design by using the TRANSPORT code and the beam tracking of two-charge beams by using the code IMPACT. We present the results and issues on beam dynamics simulaitons in the designed LEBT system.

[1]For heavy ion beams in the low energy system, we have to separate and select desire beam. we also transport beam from ECR to RFQ with high transmission.

V1.00283 Accelerating Molecular Dynamics Simulation on the Many Integrated Core (MIC) Platform , HONGSUK YI, HOGYUN JEONG, SEUNGMIN LEE, KISTI — Graphics processing units and Intel Many Integrated Core (MIC) architectures have emerged as alternative computational strategy in computational physics that can significantly speed up high performance computing algorithms. In this paper, we present early experiences on the MIC platform, focusing on porting of molecular dynamics (MD) kernels with the Tersoff potentials for carbon covalent crystals. In particular, we implement our MD code on heterogeneous computing platform consisting of Intel Xeon processors and Intel MIC architecture co-processors, using offload and OpenMP. The fully optimized MIC version achieves about 8 times speedup over the original CPU version. Furthermore, explicit vectorization on the MIC with 512-bit wide vector registers is found to be critical to achieving good performance of this algorithm in this type environments.

V1.00284 Efficient quantification of experimental evidence against local realism , YANBAO ZHANG, University of Colorado Boulder, and National Institute of Standards and Technology, SCOTT GLANCY, EMANUEL KNILL, National Institute of Standards and Technology — It is highly desirable to have reliable experimental demonstrations of violations of Bell inequalities for rejecting local realism. A potential problem is that due to statistical fluctuations, a finite set of data points generated by a local realistic model can violate a Bell inequality. In order to statistically quantify the evidence against local realism in an experiment, one needs to compute an upper bound of the probability according to local realism of a violation at least as high as that observed. Such bounds not only help to reliably demonstrate violations of local realism, but also help to prove the security of quantum key distribution or certify the generation of genuine randomness. We describe an efficient protocol for computing such a bound from any set of Bell inequalities for any number of parties, measurement settings, or outcomes. The bound depends on the choice and number of Bell inequalities, and generally, more inequalities make the bound asymptotically tighter. We find that even trivial Bell inequalities such as no-signaling conditions can improve the tightness of the bound. In addition, this protocol can be adapted to any test with linear witnesses, such as tests for entanglement or system dimensionality, without a full analysis of the relevant probability space.

V1.00285 Low-temperature metallic liquid hydrogen: an ab-initio path-integral molecular dynamics perspective , JI CHEN, XIN-ZHENG LI, QIANFAN ZHANG, ICQM and School of Physics, Peking University, MATTHEW PROBERT, Department of Physics, University of York, CHRIS PICKARD, Department of Physics and Astronomy, University College London, RICHARD NEEDS, Theory of Condensed Matter Group, Cavendish Laboratory, University of Cambridge, ANGELOS MICHAELIDES, London Centre for Nanotechnology and Department of Chemistry, University College London, ENGE WANG, ICQM and School of Physics, Peking University — Experiments and computer simulations have shown that the melting temperature of solid hydrogen drops with pressure above about 65 GPa, suggesting that a low temperature liquid state might exist. It has also been suggested that this liquid state might be non-molecular and metallic, although evidence for such behaviour is lacking. Using a combination of ab initio path-integral molecular dynamics and the two-phase methods, we have simulated the melting of solid hydrogen under finite temperatures. We found an atomic solid phase from 500 to 800 GPa which melts at $<$ 200 K. Beyond this and up to pressures of 1,200 GPa a metallic atomic liquid is stable at temperatures as low as 50 K. The quantum motion of the protons is critical to the low melting temperature in this system as ab initio simulations with classical nuclei lead to a considerably higher melting temperature of $\sim$300 K across the entire pressure range considered.

V1.00286 Modeling brittle material failure under high velocity impact conditions: From experiments to simulations , ANDREW TONGE, K.T. RAMESH, The Johns Hopkins University — Brittle materials have a deviatoric strength that is highly dependent on the applied pressure. To successfully model impact events involving brittle materials it is important to capture both the hydrostatic response, which is dominated by the equation of state, and the deviatoric response witch is dominated by the activation of microcracks within the material. The behavior of microcracks within the material is strongly affected by the applied pressure and gives rise to a material strength that is rate, size, and pressure dependent. In this work we present a material model that is based on an experimentally motivated micromechanics damage growth model coupled with a Mie-Gruneisen equation of state. We use this material model to simulate quarter inch glass spheres impacting a basalt cube at 2.2 km/s.

V1.00287 Ionic Transport and Structural Characterization of the Lithium-Rich Anti-Perovskite Li3OCl , JOHN HOWARD, University of Nevada - Las Vegas, LUKE DAEMEN, MONIKA HARTL, JERZY CHLISTUNOFF, Los Alamos National Laboratory, YUSHENG ZHAO, University of Nevada - Las Vegas — We will discuss the structural and electrochemical characterization of the newly synthesized lithium-rich anti-perovskite, Li_3OCl. The crystal structure of this compound was solved using x-ray diffraction techniques, and the electronic and ionic conductivities were measured using electrochemical impedance spectroscopy. This material has an ionic conductivity ranging approximately from 10^{-4} S/cm to 10^{-1} S/cm over the temperature range $25°$C to $270°$C (room temperature to just below the melting point). The high ionic conductivity of this lithium-rich electrolyte demonstates strong promise that this material is an ideal candidate for solid state battery applications.

V1.00288 Free-standing Conductive Fe_3O_4/Graphene/CNT Film As Anodes for Lithium-Ion Batteries , YUE CAI, YINGWEN CHENG, SONGTAO LU, HONGBO ZHANG, Duke University, Durham, NC, 27708, C.V. VARANASI, Army Research Office, Research Triangel Park, NC 27709, JIE LIU, Duke University, Durham, NC, 27708, ARMY RESEARCH OFFICE, RESEARCH TRIANGEL PARK, NC 27709 COLLABORATION — Fe3O4 is known as a material for lithium-ion battery anodes due to its high theoretical specific capacity. But it has limitations, such as low conductivity and poor cyclic performance etc. To address these problems, free-standing Fe3O4/Graphene/Carbon nanotube(CNT) films were prepared via hydrothermal reaction methods. The synergistic effect of graphene and CNTs provide a flexible matrix for Fe3O4. A series of experiments were performed to determine important processing factors such as carbon ratio and annealing treatments, which influenced the overall LIB performances. Currently the best film had a sheet resistance of 23 ohm/sq and a BET surface area of 132 m2/g. In addition, the lightweight films were directly tested as lithium-ion battery anodes without using a current collector or a binder, eliminating unnecessary weight in the overall devices. This metal oxide loaded carbon film had both excellent conductivity and strong mechanical strengths. The discharge capacity was found to reach 880 mAh/g at 200 mA/g current density and 580 mA/g at 400 mA/g. The rate capability tests (from 200 mA/g up to 1200 mA/g) also indicated that the lab prepared Fe3O4 loaded films have much better performance as compared to the samples made by using commercial Fe3O4.

V1.00289 A Three-Dimensional reduced Graphene Oxide/Nickel Oxide Composite in a Thin, Porous Carbon Framework to serve as a Supercapacitor Electrode

, GYEONGHEE LEE, Prof. Jie Liu Laboratory, Department of Chemistry, Duke University, C.V. VARANASI, Army Research Office, Research Triangle Park, JIE LIU, Department of Chemistry, Duke University — In recent years, environmental problems and the depletion of fossil fuels have encouraged intense research to discover ways to store energy such as supercapacitors. NiO is considered as a highly promising candidate for electrodes in supercapacitors due to its high theoretical capacitance, superior stability in alkaline electrolytes and low cost. However, the poor conductivity of NiO limited its capacitance to low value. In this work, NiO coated reduced graphene oxide (rGO) network in a conductive carbon matrix was synthesized. A porous carbon paper (CP) was utilized as a conductive framework on which initially $Ni(OH)_2$ was vertically grown via solvothermal reaction. Graphene oxide (GO) hydrogel was formed on the $Ni(OH)_2$ coated carbon paper through the dissolution of $Ni(OH)_2$. Controlling the uniformity of $Ni(OH)_2$ coating on the carbon paper was a key factor to homogeneous loading GO onto the carbon paper. $Ni(OH)_2$ was loaded again on GO hydrogel formed on the carbon paper (CP-GO-$Ni(OH)_2$) as NiO precursor. After annealing, CP-rGO-NiO composite exhibited a high specific capacitance and excellent cycle stability compared to the electrochemical performance of rGO-NiO composite connected to a carbon paper using binder. The structural and electrochemical properties of CP-rGO-NiO composite will be presented.

V1.00290 Lagrangian Approach to Study Catalytic Fluidized Bed Reactors[1]

, HOSSEIN MADI, EPFL, HOSSEIN MADI TEAM, MARCELO KAUFMAN RECHULSKI COLLABORATION, CHRISTIAN LUDWIG COLLABORATION, TILMAN SCHILDHAUER COLLABORATION — Lagrangian approach of fluidized bed reactors is a method, which simulates the movement of catalyst particles (caused by the fluidization) by changing the gas composition around them. Application of such an investigation is in the analysis of the state of catalysts and surface reactions under quasi-operando conditions. The hydrodynamics of catalyst particles within a fluidized bed reactor was studied to improve a Lagrangian approach. A fluidized bed methanation employed in the production of Synthetic Natural Gas from wood was chosen as the case study. The Lagrangian perspective was modified and improved to include different particle circulation patterns, which were investigated through this study. Experiments were designed to evaluate the concepts of the model. The results indicate that the setup is able to perform the designed experiments and a good agreement between the simulation and the experimental results were observed. It has been shown that fluidized bed reactors, as opposed to fixed beds, can be used to avoid the deactivation of the methanation catalyst due to carbon deposits. Carbon deposition on the catalysts tested with the Lagrangian approach was investigated by temperature programmed oxidation (TPO) analysis of ex-situ catalyst samples. This investigation was done to identify the effects of particles velocity and their circulation patterns on the amount and type of deposited carbon on the catalyst surface.

V1.00291 Tangential Relations between Distorted Acute Angles vs. Original Acute Angles of a Traveling Right Triangle in Special Relativity

, FLORENTIN SMARANDACHE, The University of New Mexico — Let's consider a traveling right triangle ΔABC ($\angle A = \pi/2$), with the speed v, and one of its legs AB along the motion direction on the $x-$axis. After contraction of the side AB with the factor C(v), and consequently contraction of the oblique side BC with the oblique-contraction factor

$$OC(v,\theta) = \sqrt{C(v)^2 \cos^2\theta + \sin^2\theta},$$

one gets the right triangle $\Delta A'B'C'$ with the following tangential relations between distorted acute angles vs. original acute angles of the right triangle:

$$\tan B' = \frac{\tan B}{C\,(v)},$$

$$\tan C' = \tan C \cdot C\,(v)\,,$$

where $C(v) = \sqrt{1 - \frac{v^2}{c^2}}$ is the Lorentz contraction factor, and c is the speed of light in vacuum.

V1.00292 Distinction between *Clock* and *Time*, and a Suggested Experiment with Different Types of Clocks in GPS

, FLORENTIN SMARANDACHE, The University of New Mexico — The clock is an instrument for measuring the time, instrument that may not run perfectly (accurately) under certain conditions (like, say, in strong electromagnetic field, in strong gravitational field, in extremely high or low temperature, pressure, etc.), but this does not mean that time itself runs slower or faster as Einstein's Theory of Relativity asserts. We are referring to an absolute time, i.e. time measured not with respect to ether or non-ether, but with respect to an absolute mathematical reference frame. Several types of clocks could run at a more slowly rate in a moving frame of reference than other types of clocks; it depends on the construction material and functioning principle of each **type of clock**. Relativists say that "gravity slows time". This is incorrect, since actually *gravity slows today's types of clocks*. And one type of clock is slowed more or less than another type of clock. Not only gravity but other (electric, magnetic, etc.) fields or various medium composition elements or structures may slow or accelerate clocks that are in that medium. The clocks used today in the satellites for the GPS necessitate a correction with respect to the Earth clocks. But in the future, when new types of clocks will be built based on different construction material and functioning principle, the correction of the GPS clocks would be different. In order to make the distinction between "clock" and "time", we suggest a **Experiment # 1** with different types of clocks for the GPS clocks, in order to prove that the resulted dilation and contraction factors are different from those obtained with today's cesium atomic clock.

V1.00293 A Study of Energetics and Molecular Dynamic Simulations of Ag Nanoclusters

, MELIHAT MADRAN, MINE KONUK, Istanbul Technical University, SONDAN DURUKANOGLU, Sabanci University — We present results of molecular static and molecular dynamic calculations for the energetics of adatom and small cluster dynamics on the facets of truncated octahedral silver nano-particles. To identify the governing diffusion mechanisms during growth of the cluster the diffusion barriers on the various facets are calculated using nudged elastic band method based on the potentials extracted from embedded atom method. We also performed calculations to examine the possible influence of geometry on the diffusion dynamics of a single atom or a cluster on the facets of the nano-particles. Our growth simulations show that the energy barriers for diffusions between the different facets of truncated octahedral of silver remarkably reduced in the presence of the small aggregates on the facets. Using the results of energetic calculations and molecular dynamic simulations we further discuss the possible mechanisms for structural transition in a growth on truncated octahedral silver nano-particles. This work is supported by TUBITAK under Grand no. TBAG-109T105.

V1.00294 Free Energy Landscapes of DNA Stretching Using Crooks Fluctuation Theorem[1]

, ERIC FREY, CHING-HWA KIANG, Rice University — Free energy landscapes can be reconstructed from nonequilibrium, single-molecule manipulation by using nonequilibrium work theorems. Previous studies have reconstructed landscapes of the unfolding of RNA, DNA hairpins, and proteins. Such landscapes have thus far exhibited one single pathway, or the free energy is that of the combined molecule-plus-force-probe system used in the experiments. Here we reconstruct a multiple-pathway, branched free energy landscape of poly(dA), as a function of molecular end-to-end extension, from nonequilibrium single-molecule measurements. We show that the Crooks fluctuation theorem can be used to reconstruct the landscape of poly(dA) stretching.

[1]We thank NSF DMR-0907676, Welch Foundation No. C-1632, NASA/DOE DE-FG02-08ER64712, and Nanobiology Interdisciplinary Graduate Training Program NIBIB T32EB009379 for support.

V1.00295 Simulations of adsorption of CO2 and CH4 in MOFs: effect of the size and charge distribution on the selectivity

, SIDI MAIGA, SILVINA GATICA, Department of Physics, Howard University — Using the method of Grand Canonical Monte Carlo we have computed the adsorption of CO2 and CH4 in MOFs with a periodic cubic structure. We used a model of the MOF that allows systematic variations in the charge distribution, size and LJ parameters. We estimated the selectivity of CO2 over CH4 for different temperatures in MOFs with various sizes and charge distributions. The results show that inserting dipoles at the corners of the MOF's unit cell would increase the selectivity of CO2; on the other hand adding quadrupoles to the structure is ineffective. The size of the cell strongly affects the adsorption of CO2 and selectivity: compressing the cell in only 10% significantly increases the selectivity; expanding the cell by 20% reduces it. Regarding thermal effects, we estimated that the selectivity drops from 250 to 2 when the temperature rises from 140K to 300K. Although this model is inspired by the IRMOF-1, which has a cubic unit cell, it can be adapted to represent other MOFs with noncubic structures by modifying the geometry accordingly. This work implies that MOFs suit gas separation.

V1.00296 Label-free electrical detection of ovarian cancer biomarker CA-125 with a novel nanoscale coaxial array[1]

, MICHELLE ARCHIBALD, BINOD RIZAL, DONG CAI, TIMOTHY CONNOLLY, MICHAEL J. BURNS, MICHAEL J. NAUGHTON, THOMAS C. CHILES, Boston College — Technologies to detect early stage cancer would provide significant benefit to cancer disease patients. Clinical measurement of biomarkers offers the promise of a noninvasive and cost effective screening for early stage detection. We have developed a novel 3-dimensional nanocavity array for the detection of human cancer biomarkers. This all-electronic diagnostic sensor is based on a nanoscale coaxial array architecture that enables molecular-level detection. Each individual sensor in the array is a vertically-oriented coaxial capacitor, whose capacitance is measurably changed when target molecules enter the coax annulus. The coaxial array facilitates electrical-based detection in response to antibody or molecular imprint based recognition of a specific cancer biomarker, thereby providing a label-free, non-optical measurement. Here, we describe this nanoscale 3D architecture and its application to the detection of the ovarian cancer biomarker CA-125. We report our efforts on the development of molecular detection of CA-125 based on antibody-functionalized nanocoax arrays as well as molecular imprints. The results demonstrate the feasibility of using these arrays as ultrasensitive devices to detect a wide range of molecular targets, including disease biomarkers.

V1.00297 Inductional Effects in a Halbach Magnet Motion Above Distributed Inductance

, YVES TCHATCHOUA, ARY CONROW, DONG KIM, DANIEL MORGAN, WALERIAN MAJEWSKI, ZAEEMA ZAFAR, Northern Virginia Community College, Annandale, VA — We experimented with attempts to levitate a linear (bar) Halbach array of five 1" Nd magnets above a linear inductive track. Next, in order to achieve a control over the relative velocity, we designed a different experiment. In it a large wheel with circumferentially positioned along its rim inducting coils rotates, while the magnet is suspended directly above the rim of the wheel on a force sensor. Faradays Law with the Lenz's Rule is responsible for the lifting and drag forces on the magnet; the horizontal drag force is measured by another force sensor. Approximating the magnet's linear relative motion over inductors with a motion along a large circle, we may use formulas derived earlier in the literature for linear inductive levitation. We measured lift and drag forces as functions of relative velocity of the Halbach magnet and the inductive "track," in an approximate agreement with the existing theory. We then vary the inductance and shape of the inductive elements to find the most beneficial choice for the lift/drag ratio at the lowest relative speed.

V1.00298 Physical Models of a Toroidal Dipole

, DUKE FORSYTH, KIARASH AKHLAGHI, MARTIN AZIR, VIKRAM SARKHEL, WALERIAN MAJEWSKI, Northern Virginia Community College, Annandale, VA — We are investigating two models of the third (after well-known electric and magnetic dipoles) elementary dipole - the toroidal dipole. Its electric model is a toroidal coil connected to a DC or AC voltage, its magnetic version is a circumferentially magnetized ring of neodymium, at rest or rotating. DC electric and magnetic toroids produce only inner magnetic field, and interact directly with a curl of the external magnetic field, that is - with a conductive current density or with a displacement current. Toroidal dipole moment was measured in interaction with the external current and compared with a calculated theoretical value. Rotating magnetic toroid or the AC electric toroid should each act as an electric dipole antenna and produce electric dipole radiation. We are attempting to detect and measure their near-zone electromagnetic fields, as well as an integrated value of the external magnetic vector potential A.

V1.00299 Experiments on Inductive Magnetic Levitation with a Circular Halbach Array

, IAN BEAN, DOUG GONCZ, AUSTIN RAYMER, JASON SPECHT, RICARDO ZALLES, WALERIAN MAJEWSKI, Northern Virginia Community College — Using a ring Halbach array, we are investigating a repulsive levitating force and a drag force acting on the magnet from a ring of inductors rotating below the magnet. After measuring induced currents, voltages and magnetic fields in the individual inductors (in the form of short solenoids), we investigated the dependence of lift/drag forces on the speed of relative rotation. The ratio of lift to drag increases with the angular velocity, as expected from a related theory of the induction effects in a linear motion. We are experimenting with the shape and density of inductors, and their material, in an attempt to maximize the lift at a minimal velocity of rotation. Eventually this design could have applications as frictionless bearings or as frictionless gear in a wide range of systems, especially in machinery that cannot be easily accessed.

V1.00300 An Experimental Study of a Nonlinear Phased Array Interacting with Solid Media

, PAUL ANZEL, CARLY DONAHUE, CHIARA DARAIO, California Institute of Technology — We present results in our development of a nonlinear phased array capable of focusing highly compact waves in solid media. The phased array consists of parallel chains of spherical particles in contact. When the chains are excited by an impulse, the nonlinear Hertzian force between elastic spheres allows for the formation and propagation of a solitary wave: a localized collective motion of the spheres, which maintains its shape over a long length of travel and carries a significant amount of mechanical energy. Unlike in linear media, the speed of these solitary waves can be tuned by applying a compressive force to the chain. The different pre-strain applied to the chains induces a signal delay in the system. When the phased array is placed adjacent to a medium of interest, it can focus the transmitted pulses of energy to a chosen location in the medium, creating a "sound bullet". Here, we present results in system repeatability and we investigate the limitations of the system to off axis focusing. We compare experimental results to numerical values and analytical predictions.

V1.00301 Long Working Distance Fluorescence Detection and Lifetime Imaging through Stimulated Emission[1]

, FU-JEN KAO, National Yang-Ming University, PO-YEN LIN, Academia Sinica — Stimulated emission is a newly developed modality that has found increasing applications in advanced optical microscopy. Its utilization offers a variety of advantages over spontaneous one, including stimulated emission depletion microscopy (STED) for sub-diffraction limited resolution and stimulated emission detection for dark fluorophores. In this presentation, we are demonstrating the unique aspects of spatial coherence as a result of stimulated emission, which is applied for long working distance fluorescence detection and lifetime imaging. When compared spontaneous emission, stimulated emission based detection does not require high numerical aperture optics to collect signal efficiently. The characterization of fluorescence lifetime and anisotropy measurement through stimulated emission are investigated and summarized succinctly in this presentation.

[1]Support of National Science Council, Taiwan is greatly appreciated.

V1.00302 Suspended MoS2 devices

, TAIYU JIN, JINYOUNG KANG, RENLONG LIU, YOUNGCHAN KIM, CHANGGU LEE, Sungkyunkwan University — Single or a few layer MoS2 sheets have been reported to have high electric mobility and current on/off ratio comparable to those of silicon due to its semiconductor properties with bandgap of 1.3 $\sim$ 1.9eV. However, its extremely high surface to volume ratio and low thickness prohibits it from reproducing its electronic properties on SiO2 substrates possibly because of charge scattering by surface charges and phonons. In order to investigate these surface effects, we fabricated MoS2 devices suspended from the SiO2 and characterized their electronic transport properties. We exfoliated single or a few layer MoS2 on SiO2 substrates first, and fabricated field effect transistors using e-beam lithography. After that, we suspended MoS2 sheets by etching SiO2 with hydrofluoric acid. We measured mobility and current on/off ratio before and after the etching process. We found that mobility of MoS2 devices increased by factor of 5-10 after etching for all devices. However, on/off ratio did not show significant variation. Our measurements suggest that atomically thin MoS2 devices are significantly affected by substrate surface and environment.

V1.00303 Scalable patterning of one-dimensional dangling bond chains on hydrogenated Si(001) surfaces

, FRANCOIS BIANCO, MARIA LONGOBARDI, University of Geneva, DPMC - MaNEP Quai Ernest-Ansermet 24, 1211 Geneva 4, DAVID R. BOWLER, University College London, London Centre of Nanotechnology, JAMES H.G. OWEN, CHRISTOPH RENNER, University of Geneva, DPMC - MaNEP Quai Ernest-Ansermet 24, 1211 Geneva 4 — Silicon dangling bonds exposed on monohydride silicon (001) surface are highly reactive, and enable site selective absorption of atoms and single molecules into specific patterns designed into Si(001):H surfaces through the controlled removal of hydrogen atoms. Current implementations of such hydrogen lithography rely on painstaking removal of hydrogen atoms using the tip of a scanning probe microscope. Here, we present a scalable thermal process that yields very long chains of dimer wide silicon dangling bonds to self-assemble atoms and molecules into one-dimensional structures of unprecedented length on Si(001):H.

V1.00304 Diffusion with traps as the mechanism behind the retentivity relaxation of the resistive state on bipolar RRAM devices

, ALEJANDRO SCHULMAN, University of Buenos Aires and IFIBA (Conicet), MARCELO J. ROZENBERG, Laboratoire de Physique des Solides, UMR8502 Université Paris-Sud, Orsay, France, CARLOS ACHA, University of Buenos Aires and IFIBA (Conicet) — The relaxation of the remnant resistance state obtained immediately after the electric-pulse switching process on metal/complex oxide interfaces [(Au, Pt) / (YBCO, LSMO)] has been studied. We have found that resistance relaxes following a stretched exponential law, with a temperature and applied switching power independent exponent. More interesting and unlike ordinary thermal diffusion processes, we observe that the characteristic relaxation time increases with increasing temperature and applied power. This anomalous dependence of the characteristic time gave us the opportunity to find an interesting physic process related to the oxygen diffusion on complex oxides, like superconducting cuprates or colossal magnetoresistant manganites: We argue that the observed behavior, common for both complex oxide interfaces, points to a generic phenomenon that can be understood as due to the diffusion of oxygen ions (or oxygen vacancies) moving on a 2D surface (grain boundaries) with a temperature dependent density of trapping centers.

V1.00305 Monte Carlo simulation of highly oxidized oligopyrroles in condensed phases[1]

, WEIXIAO JI, CLIFFORD HALL, ESTELA BLAISTEN-BAROJAS, Computational Materials Science Center, George Mason University, Fairfax, VA — We present a new classical model potential for the simulation of oxidized oligopyrroles. The novel potential treats the monomers as rigid bodies interacting through covalent, bending, torsion, dipole-dipole, anti-coiling, excluded volume and coulomb interactions. The potential contains 24 parameters fitted on a database of energy points calculated at the density functional theory quantum approach. Studies include structural and mechanical properties of condensed phase systems composed of 1188 pyrrole oligomers with 12 monomers each and 4752 electronegative atoms yielding a 33% dopant concentration. The mechanical equilibrium density is determined by isothermal-isobaric Monte-Carlo. The equilibrium configurations at various temperatures are studied in the canonical ensemble and our Adaptive Tempering Monte Carlo (ATMC), a multi-canonical ensemble method, finds the global minimum of the energy. Binding energy, end-to-end distance, radius of gyration, vector and orientation order parameters, and pair correlation functions are reported at 300K and 1000K.A new computational algorithm in CUDA allows a significant computer acceleration using GPUs. With this novel implementation we obtain speedup of a 45-factor faster than CPU at sufficiently large system sizes.

V1.00306 Effect of the Pattern Curvature on Thin Film Stability

, GUIDUK YU, Seoul National University, JUNE HUH, Yonsei University, KYUSOON SHIN, KOOKHEON CHAR, Seoul National University — By taking advantage of mesoscopically concave and convex patterns, we investigated the effect of pattern curvature on the stabilities of polystyrene (PS) films. The PS thin films were found to rupture on the patterns driven by the Laplace pressure. The dewetting of PS films was found to start from the peaks of each pattern, followed by the underfills in the valleys. In spite of the similar rupture behavior at the early stage, the dewetting morphologies at the later stage exhibited the pattern curvature dependence. The films placed on the substrates with concave patterns mostly wetted the substrates whereas PS films transferred to the substrates with convex patterns accompanied the micron-scale ruptures by exposing most area of the patterns to air. By scratch experiments, the film rupture was analogously observed to be localized in the vicinity of scratches on the concave patterns while propagating in much wider area in the case of the convex patterns. The dissimilar behavior based on the pattern curvature was found to originate from the opposite gradient of each pattern, associated with the local contact instability of dewetted films.

V1.00307 Inducing extended line defects in graphene by linear adsorption of C and N atoms

, YU LI, RUIQIN ZHANG, City University of Hong Kong, ZIJING LIN, University of Science and Technology of China, MICHEL A. VAN HOVE, Hong Kong Baptist University, USTC-CITYU JOINT ADVANCED RESEARCH CENTRE, SUZHOU 215123, CHINA COLLABORATION, INSITITUTE OF COMPUTATIONAL AND THEORETICAL STUDIES, HONG KONG BAPTIST UNIVERSITY COLLABORATION, GROUP OF RUI-QIN ZHANG TEAM — We propose a possible approach for controlled formation of various 585 (containing pentagonal and octagonal carbon rings) extended line defects (ELDs) by linear adsorption of various kinds of atoms (C, N, B, O) on a graphene substrate, based upon density functional theory and molecular-dynamics (MD) simulations. We find out that the C and N atoms spontaneously transform to 585 ELDs while other elements find specific stable configurations. To confirm the feasibility of forming the ELD from line adsorption, investigation of the critical transformation conditions of the 585 ELD is involved based upon various adsorption models and adsorption densities.

V1.00308 Fast-Shock Ignition: A New Concept to Inertial Confinement Fusion , SEYED ABOLFAZL GHASEMI, AMIR HOSSEIN FARAHBOD, Research Center of Laser and Optics, LASER PLASMA INTERACTION TEAM — A new concept for inertial confinement fusion called fast-shock ignition (FSI) is introduced to obtain high target gain. In the proposed model, the separation of fuel ignition into two successive steps, under the suitable conditions, reduces required ignitor energy. The main procedure in FSI concept is at first, compressing the fuel up to stagnation. Then, two high intensity short pulse laser spikes with energy and power lower than those required for shock ignition (SI) and fast ignition (FI) with a proper delay time launched at the fuel which increases the central hot-spot temperature and complete the ignition of the pre compressed fuel. The introduced semi-analytical model indicates that with fast-shock ignition, the total required energy for compression and ignition of the fuel can be slightly reduced in comparison with pure shock ignition. Furthermore, for fuel mass greater than 2mg, the target energy gain increases up to 15 percent and the contribution of fast ignitor could be decreased about 20 percent over pure fast ignition. The FSI scheme is beneficial from technological considerations for the construction of short pulse high power laser drivers. The general advantages of fast-shock ignition over pure shock ignition can be better than 1.3.

V1.00309 Excitonic probing of magnetic spin states and their temperature evolution in semi-insulating CdMnTe spin-glasses , YURIY GNATENKO, PETRO BUKIVSKIJ, Institute of Physics of National Academy of Sciences — Spin glass (SG) formation is one of the most complex and exciting problems in the condensed matter physics. In spite of the intensive theoretical and experimental investigations of SG systems, a number of issues still remain open. In particular, the relative concentrations (RCs) of "loose" (single) spins and various magnetic spin clusters in SGs is one of the important unanswered questions. Another problem is lack of detailed quantitative information on how these microscopic magnetic spin states (MMSSs) evolve with temperature. Here, we have investigated (MMSSs) {"loose spins, finite superparamagnetic, "locked" and infinite clusters} both above and below the freezing temperature in $Cd_{0.70}Mn_{0.30}Te$ SG. We used the localized exciton magnetic polarons (LEMPs), which we observed in the photoluminescence spectra, as a probe of these state. This makes it possible for the first time to estimate the MMSS's RCs and to study their temperature evolution and thus to elucidate one of the most important issues in this field of research. Furthermore, the findings described here may encourage researchers for more detailed studies of freezing process in various inhomogeneous magnetic glassy systems, especially, in dilute magnetic semiconductors – a very promising materials for spintronics. This also opens intriguing prospects for further studies of spin freezing and frozen states in these systems, especially under influence of extrinsic factors (magnetic field, pressure, ultrasound etc).

V1.00310 Nanoscintillators based on the emission of self-trapped excitons in layered PbI_2 nanoclusters , YURIY GNATENKO, ANATOLI BUKIVSKII, YURIY PIRYATINSKI, Institute of Physics of National Academy of Sciences — We studied the dynamics of excitons excited in layered semiconductor PbI_2 nanoclusters (NCLs), embedded in CdI_2 crystal matrix, using time-resolved photoluminescence (TRPL) spectroscopy. TRPL spectra reveal formation of self-trapped excitons (STEs) in nanosecond scale. The effective energy transfer from the small to the larger semiconductor NCLs, which arises from dipole-dipole intercluster interactions, takes place in sub-nanosecond scale. We demonstrate that the STEs are stable states and they define effective photoluminescence and radioluminescence of the investigated $Pb_{1-X}Cd_XI_2$ alloys. Thus, the $Pb_{1-X}Cd_XI_2$ alloys can be considered as new scintillator materials, where the radioluminescence is determined by the emission of STEs in the layered semiconductor NCLs, and can be named bulk-nanostructured scintillators (or nanoscintillators). It should be noted that these nanoscintilators are strongly radiation-resistant. Our results may pave the way towards a new class of effective scintillator materials based on the emission of the STEs in the semiconductor NCLs. The further increase of the emission intensity of such nanoscintillator materials is possible by optimizing the size distribution of NCLs in the $Pb_{1-X}Cd_XI_2$ alloys and by means of thermoelectric cooling.

V1.00311 Commensurate solid phases of Krypton in carbon nanotubes , MAMADOU MBAYE, SILVINA GATICA, Department of Physics, Howard University — Recent experiments (Wang et al., 2010) have found evidence of phase transitions of gases adsorbed on a single carbon nanotube. Previous grand canonical Monte Carlo simulations of this system, for the cases of Ar and Kr on zigzag and armchair nanotubes with radius R = 0.7 nm have resembled the experimental results in the case of Ar. However, the prominent, ordered phase found for Kr in both simulations and (classical) energy minimization calculations di_ers from that deduced from the experimental data. A tentative explanation of the apparent discrepancy is that the experiments involve a nanotube of rather large radius (>1.5 nm). We have extended our simulations to nanotubes of larger radius (1-3 nm), zigzag or armchair. In our simulations we found the formation of a layer of the same density than in the experiment, but we believe the layer is not a commensurate solid.

V1.00312 Enhanced thermoelectric figure of merit (ZT) of Te-doped $FeSb_2$ nanocomposite , MANI POKHAREL, HUAIZHOU ZHAO, MACHHINDRA KOIRALA, ZHIFENG REN, CYRIL OPEIL, Department of Physics, Boston College, Chestnut Hill MA 02467 — FeSb2 is considered as a potential candidate for Peltier cooling applications because of its colossal value of Seebeck coefficient (45,000 μVK^{-1}) at around 10 K. Our earlier works [1,2] showed that the ZT values of undoped $FeSb_2$ nanocomposites could not be improved significantly despite of the drastic reduction in thermal conductivity which we attributed to the suppression of phonon-drag effect due to increased scattering of phonons off the grain-boundaries in nanocomposites. In this work, we demonstrate that combining nanostructuring approach with Te-doping further improves the thermoelectric properties to yield an enhanced ZT value in $FeSb_2$ nanocomposites.

V1.00313 Simulations of Concentrated Antibody Solutions and Comparison with Small-Angle Scattering Experiments , MAX WATSON, NICHOLAS CLARK, JOSEPH CURTIS, National Institute of Standards and Technology — We have performed atomically detailed Monte-Carlo simulations of hundreds of antibodies in concentrated solutions. In order to compare our simulations with experiments, we developed a novel method for explicitly calculating the scattering intensity of these large systems. At various salt conditions and pH levels, the simulations are found to be in good agreement with small-angle X-ray scattering measurements for antibody concentrations exceeding 100 mg/mL.

V1.00314 Influence of spin correlations in the transport properties of a double quantum dot system , IGNACIO HAMAD, PUC Rio de Janeiro, 22452-970 , Brazil, LAERCIO COSTA RIBEIRO, Centro Federal de Educacao Tecnologica Celso Suckow da Fonseca (CEFET-RJ/UnED-NI), RJ, 26041-271, Brazil, GUILLERMO CHIAPPE, Departamento de Fisica Aplicada Universidad de Alicante, San Vicente del Raspeig, Alicant 03690, Spain, ENRIQUE VICTORIANO ANDA, PUC Rio de Janeiro, 22452-970 , Brazil — In this work we study the influence of spin correlations in the transport properties of a system consisting of two quantum dots (QDs) with high Coulomb interaction U which are interconnected through a chain of N non-interacting sites and individually coupled to two metallic leads. Using both the finite U slave boson mean field approach (FUSBMFA) and the Logarithmic-discretization-embedded-cluster approximation (LDECA) we studied the system in different regions of the parameter space for which we calculate many physical quantities, namely local density of states, conductance, total spin, spin correlations, in addition to the renormalization parameters associated with the FUSBMFA. The results reveled a very rich physical scenario which is manifested by at least two different Kondo regimes, the well-known spin s = 1/2 and some other type of Kondo effect which appears as a result of the coupling between the QDs and the non-interacting central sites. We also consider the possibility of accessing some kind of Kondo box effect due to the discrete nature of the central chain and study how this regime is affected by the magnetic interaction between the local spins of the QD's and by the interaction between these spins and the spins of the conduction electros in the leads.

V1.00315 Effect of Magnon-induced dephasing on spin transfer torque in magnetic tunnel junctions[1]

, FARZAD MAHFOUZI, BRANISLAV K. NIKOLIC, Department of Physics and Astronomy, University of Delaware, Newark, DE — In this work we investigate the effect of Electron-Magnon interaction on the spin transfer torque in magnetic tunnel junctions. We use Keldysh Green's function method and consider self consistent Born approximation (SCBA) with finite biased voltage to perform the calculation. We show that in some cases, excitation of the Magnons in the ferromagnet (FM) can enhance the spin transfer torque which is in addition to the increase of the switching rate due to existence of magnons in LLG equation.

[1]F. M. and B. K. N. were supported by DOE Grant No. DE-FG02-07ER46374.

V1.00316 Electronic properties of core-multishell semiconductor quantum wires

, JUSCIANE SILVA, Departamento de Ciências Exatas e Naturais, Universidade Federal Rural do Semi- Árido, ANDREY CHAVES, GIL FARIAS, Departamento de Física, Universidade Federal do Ceará, Caixa Postal 6030, Campus do Pici, 60455-900 Fortaleza, Ceará, Brazil, ROBSON FERREIRA, Laboratoire Pierre Aigrain, Ecole Normale Superieure, Université Paris Diderot, 24 rue Lhomond, F-75005 Paris Diderot, Paris, France — The effect of eccentricity distortions in the otherwise circular geometry of core-multishell quantum wires on their excitonic transitions is theoretically investigated. Within the effective mass approximation, the Schrödinger equation is numerically solved for electrons and holes in systems with single and double radial heterostructures, whereas the resulting exciton binding energy is calculated by means of a variational approach. Our results demonstrate that for a single shell heterostructure, in-plane electric fields applied in different directions produce qualitatively different energy spectra, which can be used to identify the eccentricity of the system. For a double heterostructure, the eccentricities of the inner and outer shells play an important role on the excitonic binding energy and on the oscillator strength. Our results also show that for a single shell heterostructure with a type-II confinement, i.e. with spatially separated electrons and holes, one of the carriers exhibits either a ring-like or a dot-like energy spectrum, depending on the radius of the system. In this case, a shell-to-core confinement transition for the electron can be induced also by an external magnetic field.

V1.00317 Stochastic models for cell division

, EVGENY STUKALIN, SEAN SUN, Department of Mechanical Engineering, The Johns Hopkins University, Baltimore, MD 21218 — The probability of cell division per unit time strongly depends of age of cells, i.e., time elapsed since their birth. The theory of cell populations in the age-time representation is systematically applied for modeling cell division for different spreads in generation times. We use stochastic simulations to address the same issue at the level of individual cells. Our approach unlike deterministic theory enables to analyze the size fluctuations of cell colonies at different growth conditions (in the absence and in the presence of cell death, for initially synchronized and asynchronous cell populations, for conditions of restricted growth). We find the simple quantitative relation between the asymptotic values of relative size fluctuations around mean values for initially synchronized cell populations under growth and the coefficients of variation of generation times. Effect of initial age distribution for asynchronous growth of cell cultures is also studied by simulations. The influence of constant cell death on fluctuations of sizes of cell populations is found to be essential even for small cell death rates, i.e., for realistic growth conditions. The stochastic model is generalized for biologically relevant case that involves both cell reproduction and cell differentiation.

V1.00318 Effects of Concentration of Precursor and Annealing Temperature on the Optical Properties of Nanostructured Al- doped Zinc Oxide (AZO) Thin films Prepared by Sol-Gel Spin Coating Technique[1]

, GBADEBO T. YUSUF, Osun state Polytechnic, Iree, AYODEJI O. AWODUGBA, Ladoke Akintola University of Technology Ogbomoso, ADEPOJU M. RAIMI, HEZEKIAH O. EFUNWOLE, TIMOTHY O. FAMILUSI, Osun state Polytechnic, Iree — This work investigates the effects of concentration of precursor and annealing temperature on the optical properties of nanostructured Al-doped (AZO) zinc oxide thin films prepared by sol-gel spin coating technique. The sols were prepared using concentration of zinc acetate dehydrate which was varied between 0.1 and 1.4 mole/liter. Aluminium chloride was used as dopant while the annealing temperature of 400° to 650° was chosen. The results show that the concentration between 0.3 to 0.6 moles/liter zinc acetate dehydrate in solution resulted in good thin films with high preferential c-axis orientation and optical transmission reveal a good transmittance within the visible wavelength spectrum region while the concentrations that fall outside this range did not yield films with good c-axis orientation. The films deposited at annealing temperatures 500° and 650° showed surface structures much smaller than 400°. The Spin coating technique creates ZnO films with potential for application as transparent electrodes in optoelectronic devices such as solar cell.

[1]The Authors would like to Acknowledge the encouragement and financial support from the Management of Osun state Polytechnic, Iree.

V1.00319 Topological surface states on high-index Bi_2Se_3 epifilms grown by molecular-beam epitaxy on InP(001)

, XIN GUO, ZHONGJIE XU, Phys. Dept.,The University of Hong Kong, MENGYU YAO, Key Laboratory of Artificial Structures and Quantum Control (Ministry of Education), Dept. of Phys., Shanghai Jiaotong University, HONGTAO HE, Phys. Dept., Hong Kong University of Science and Technology, LIN MIAO, Key Laboratory of Artificial Structures and Quantum Control (Ministry of Education), Dept. of Phys., Shanghai Jiaotong University, LU JIAO, Phys. Dept.,The University of Hong Kong, HONGCHAO LIU, JIANNONG WANG, Phys. Dept., Hong Kong University of Science and Technology, DONG QIAN, JINFENG JIA, Key Laboratory of Artificial Structures and Quantum Control (Ministry of Education), Dept. of Phys., Shanghai Jiaotong University, WINGKIN HO, MAOHAI XIE, Phys. Dept.,The University of Hong Kong — We use MBE to successfully grow a high-index Bi_2Se_3 (221) epifilm on InP(001) substrate. To facilitate growth of Bi_2Se_3 (221) on InP(001), the substrate has to undergo a careful thermal treatment. XRD and LEED measurements affirm the film to be of Bi_2Se_3 (221).The ARPES experiments on such a Bi_2Se_3(221) sample reveal unambiguously the linear dispersed surface states. In addition, the Fermi surface is elliptical rather than the more symmetrical one on Bi_2Se_3(111). Electrical transport studies of such (221) Bi_2Se_3 samples also show an anisotropy in two perpendicular directions in the plane of the surface. The longitudinal resistivity along the "transverse" direction is 1.9 $\sim$ 4.4 times higher than that along the "parallel" direction, and their ratios also depend on temperature from 2K to 300K. Hall resistances show non-linear field dependence at high temperature, implying multiband conduction.

V1.00320 Single Domain Bi_2Se_3 Films Grown on InP(111)A by Molecular-Beam Epitaxy

, X. GUO, Z.J. XU, Phys. Dept.,The University of Hong Kong, H.C. LIU, Phys. Dept., Hong Kong University of Science and Technology, B. ZHAO, X.Q. DAI, College of Physics and Information Engineering,Henan Normal University, H.T. HE, J.N. WANG, Phys. Dept., Hong Kong University of Science and Technology, H.J. LIU, W.K. HO, M.H. XIE, Phys. Dept.,The University of Hong Kong — We report the growth of single domain Bi_2Se_3(111) thin films by MBE on InP(111) substrate. On singular and vicinal substrate surfaces, we observe the 2D growth mode, as implied by the streaky RHEED patterns and the RHEED intensity oscillations. In the 2D step-flow growth mode, the epitaxial Bi_2Se_3 film is found to be diminished of twin and rotation domains, as inferable from both the unidirectional mounds seen by STM and by the three-fold LEED patterns. Such films show relatively low background doping ($\sim 1 \times 10^{18}$ cm^{-3}) and high low-temperature electron mobility (3500 $cm^2V^{-1}s^{-1}$). Magnetoresistance measurements unveil SdH oscillations at different sample tilting angles. Ab initio total energy calculations suggest the existence of strong chemical interaction between atoms at the hetero-interface. Therefore, the growth does not proceed by the vdW epitaxy process. The additional chemical interaction between P and Bi atoms at steps would facilitate step-flow mode of growth, making the steps to offer an effective guide to the lattice of epitaxial Bi_2Se_3.

V1.00321 Ab-initio study of structural and electronic properties of thin film and bulk forms of Bi_2Q_3 (Q= Se, Te) as topological insulators

AHMAD RANJBARDIZAJ, HIROSHI MIZUSEKI, YOSHIYUKI KAWAZOE, Institute for Materials Research, Tohoku University, Sendai 980-8577 — Bi_2Q_3 (Q=Se, Te) are the best-known bulk thermoelectric materials, which have been demonstrated to be topological insulators (TI). TI's are insulators with conductive surface states consisting of a single Dirac cones. These materials have layered structures consisting of stacked quintuple layers (QL), with relatively weak coupling between the QL's. Therefore, it might be easy to prepare the Bi_2Q_3 in the form of thin films with particular thicknesses using the available experimental techniques. In this study, the electronic and structural properties of bulk Bi_2Se_3 are investigated using density functional theory. Our results show that the Bi_2Se_3 is an indirect semiconductor with energy gap of $\approx$ 0.27 eV. Additionally, the electronic structure dependence of Bi_2Se_3 to the thicknesses of thin films (n-QL's with n=1,2...9) is considered. It is observed that the electronic structure of this kind of thin films depends on the number of QL's. For n-QL's with n larger than three, the thin film has a bulk band gap and has protected conducting states on its surface. Moreover, the effect of number of layers (n) on band-gap energy is studied. Similar calculations and discussions are carried out for Bi_2Te_3 and the results are compared to the Bi_2Se_3 case and also the available theoretical and experimental results.

V1.00322 Creation of massive entanglement with optimized multiple spin squeezing[1]

CHAO SHEN, LUMING DUAN, University of Michigan-Ann Arbor — Quantum entanglement is an important resource in many areas such as precision measurement, quantum information processing and quantum computation. Controlled creation of quantum entanglement between a large number of particles is a goal to which significant theoretical and experimental efforts have been devoted. For a large collection of spins, spin squeezing is an experimentally relevant approach to entanglement creation. Two-axis spin squeezing was shown to achieve the Heisenberg limit for phase sensitivity, which scales as 1/N and N is the particle number. However the required Hamiltonian H=(Sy^2-Sx^2) is usually not readily available in experimental systems. Here we propose an optimized control scheme to approach the Heisenberg limit with only a single-axis spin squeezing Hamiltonian combined with an external magnetic field. Essentially the scheme consists of multiple spin squeezing with optimized parameters. And squeezing parameter achieved seems even better than two-axis squeezing. Moreover this scheme can be employed to prepare the —S, Sz= 0 > Dicke state.

V1.00323 Effect of Stabilization and End Group Induced Charge Transfer on Frontier Molecular Orbital Reorganization - Applications to Molecular Thermoelectrics

JANAKIRAMAN BALACHANDRAN, Graduate Student, Univ. of Michigan, Ann Arbor, MI, PRAMOD REDDY, Assistant Professor, Univ. of Michigan, Ann Arbor, MI, BARRY DUNIETZ, Assistant Professor, Kent State University, Kent, OH, VIKRAM GAVINI, Assistant Professor, Univ. of Michigan, Ann Arbor, MI — Endgroups play an important role in determining the thermopower and nature of transport across molecular junctions. In this work, we analyze the electronic structure of phenyl molecules coupled to gold electrodes through five different end groups. Accordingly we find that the direction of charge transfer is strongly correlated to the degree of reorganization of frontier molecular orbitals (FMOs) and in turn on the thermopower of molecular junctions. In particular, isocyanide, nitrile, and amine end-group molecular junctions, with charge (electron) transfer out of the molecule, exhibit a strong overall downward shift in the energies of frontier molecular orbitals, whereas thiol and hydroxyl end-group molecular junctions, with charge transfer into the molecule, exhibit a smaller overall downward shift. Two dominant factors namely (i)the stabilization effect due to contact with Au cluster and (ii) the change in electron-electron interactions due to charge transfer, determine the FMOs reorganization. We also provide a good estimate of the shift individually caused by each of these factors by performing a perturbation analysis.

V1.00324 Polarization Rotation by Multilayered Chiral Metamaterial[1]

YUMIN ZHANG, Southeast Missouri State University, NATHAN BURFORD COLLABORATION — Traditionally, negative permittivity was realized by plasma resonance of the metallic structures, and negative permeability was achieved by a resonant LC circuit. Chiral metamaterial is another route to achieve negative permittivity and permeability, and such structures were investigated at different frequency domains. Recently, it was demonstrated that a two-dimensional lattice of three-dimensional gold spirals can effectively block circular polarized light with the same handedness for a frequency range exceeding one octave. From the point of view of applications, metamaterials must be fabricated easily and cheaply, and one way to achieve this goal is planarization. We designed a multiple-layer quasi-helix PCB structure and had it fabricated. The sample was tested with automated free space microwave material measurement system at X-band. These layers of PCB can be arranged in two different configurations: left-handed or right- handed helix. We found that the polarization plane is rotated in the opposite direction for the left- and right-handed samples, and the measured S-parameters agree with the simulation result relatively well.

V1.00325 Fault tolerant quantum random number generator certified by Majorana fermions[1]

DONG-LING DENG, LU-MING DUAN, Department of Physics, University of Michigan, Ann Arbor — Braiding of Majorana fermions gives accurate topological quantum operations that are intrinsically robust to noise and imperfection, providing a natural method to realize fault-tolerant quantum information processing. Unfortunately, it is known that braiding of Majorana fermions is not sufficient for implementation of universal quantum computation. Here we show that topological manipulation of Majorana fermions provides the full set of operations required to generate random numbers by way of quantum mechanics and to certify its genuine randomness through violation of a multipartite Bell inequality. The result opens a new perspective to apply Majorana fermions for robust generation of certified random numbers, which has important applications in cryptography and other related areas.

V1.00326 Magnetic Behavior of Ni-Fe Core-Shell and Alloy Nanowires

JAGNYASENI TRIPATHY[1], Dept. of Chemistry, University of New Orleans, JOSE VARGAS[2], LEONARD SPINU[3], Dept. of Physics, University of New Orleans, JOHN WILEY[4], Dept. of Chemistry, University of New Orleans — Template assisted synthesis was used to fabricate a series of Ni-Fe core-shell and alloy nanowires. By controlling reaction conditions as well as pore structure, both systems could be targeted and magnetic properties followed as a function of architectures. In the core-shell structure coercivity increases with decrease in shell thickness while for the alloys, coercivity squareness improve with increase pore diameter. Details on the systematic studies of these materials will be presented in terms of hysteretic measurements, including first order reversal curves (FORC), and FMR data. Magnetic variation as a function of structure and nanowire aspect ratios will be presented and the origins of these behaviors discussed.

V1.00327 Nondegradative Dielectric Coating of Graphene using Thermal Evaporation of SiO[1]

, SEIYA SUZUKI, Graduate School of Engineering, Toyota Technological Institute, CHIEN-CHUNG LEE, Department of Physics, University of Colorado at Boulder, TAKASHI NAGAMORI, School of Engineering Department of Advanced Science and Technology, Toyota Technological Institute, THOMAS SCHIBLI, Department of Physics, University of Colorado at Boulder, MASAMICHI YOSHIMURA, Graduate School of Engineering, Toyota Technological Institute — Deposition of dielectrics onto graphene is a challenging technique due to the difficulties of fabricating high quality oxide on pristine graphene without introducing atomic defects. Here we report on a novel method to fabricate silicon oxide layer on graphene by vacuum thermal evaporation of silicon monoxide (SiO). Raman spectroscopy and mapping showed the present method did not degrade graphene, in contrast to the e-beam evaporated SiO_2 coating method previously reported. We fabricated graphene field effect transistor devices with four metal electrodes to measure gate voltage dependence of sheet resistance of the graphene, and deposited a top coating of SiO on the graphene channel. The electrical measurements before and after the top-coating revealed that the top coating suppressed chemical shift of the graphene from strong p-dope to nearly undoped. Since SiO is transparent for visible and infrared light, the coating can be available as a protection layer for optical devices of graphene such as photodetectors and electro-optic modulators. Since the SiO top coating is a simple vacuum evaporation, it is much easier than atomic-layer-deposition which requires additional functionalization of graphene, and compatible with industrial use.

V1.00328 Optical investigation of redox properties of amorphous V_2O_5 thin films[1]

, JONG-GUL YOON, Department of Physics, University of Suwon, Korea, TAE DONG KANG, TAE WON NOH, IBS-Center for Functional Interfaces of Correlated Electron Systems and Department of Physics and Astronomy, Seoul National University, Korea, USW COLLABORATION, RECFI COLLABORATION — We report a high sensitivity of the optical properties of amorphous V_2O_5 thin films to redox reaction. Temperature dependence of spectroscopic ellipsometry data showed that the amorphous V_2O_5 films were optically anisotropic and the optical constants of the films changed irreversibly in high vacuum at around 420-480 K. Formation of oxygen vacancies in V_2O_5 film by the reduction process may result in the anisotropic changes in the optical constants and optical band gaps. Layered structure of V_2O_5 and structural relaxation by the formation of vanadyl oxygen vacancies were attributed to the optical anisotropy and the changes in the optical properties, respectively.

V1.00329 Highly Transparent Water-Repelling Surfaces based on Biomimetic Hierarchical Structure

, SANGHYUK WOOH, JAI HYUN KOH, Seoul National University, HYUNSIK YOON, Seoul National University of Science & Technology, KOOKHEON CHAR, Seoul National University — Nature is a great source of inspiration for creating unique structures with special functions. The representative examples of water-repelling surfaces in nature, such as lotus leaves, rose petals, and insect wings, consist of an array of bumps (or long hairs) and nanoscale surface features with different dimension scales. Herein, we introduced a method of realizing multi-dimensional hierarchical structures and water-repellancy of the surfaces with different drop impact scenarios. The multi-dimensional hierarchical structures were fabricated by soft imprinting method with TiO_2 nanoparticle pastes. In order to achieve the enhanced hydrophobicity, fluorinated moieties were attached to the etched surfaces to lower the surface energy. As a result, super-hydrophobic surfaces with high transparency were realized (over 176° water contact angle), and for further investigation, these hierarchical surfaces with different drop impact scenarios were characterized by varying the impact speed, drop size, and the geometry of the surfaces.

V1.00330 SIR Fronts in Complex Networks with Metapopulation Structure

, JASON HINDES, Laboratory of Atomic and Solid State Physics, Cornell University, Ithaca, New York, SARABJEET SINGH, Theoretical and Applied Mechanics, Sibley School of Mechanical and Aerospace Engineering, Cornell University, Ithaca, New York, CHRIS MYERS, Laboratory of Atomic and Solid State Physics, Cornell University, Ithaca, New York, DAVE SCHNEIDER, Department of Plant Pathology and Plant ? Microbe Biology, Cornell University, Ithaca, NewY ork, ANALYTICAL FRAMEWORKS FOR INFECTIOUS DISEASE DYNAMICS COLLABORATION — SIR dynamics has been studied extensively on complex networks, yielding insight into the effects of heterogeneity in contact patterns on the spread of infectious diseases. Separately, metapopulations have provided a paradigm for modeling systems with extended and "patchy" organization. In this paper we demonstrate how multi-type networks can be used to combine these paradigms such that simple disease dynamics models can include heterogeneity in connectivity and multi-scale structure. We first present a multi-type generalization of the Volz-Miller mean-field approximation for SIR dynamics on multi-type random graphs. We then use this technique to study the propagation of epidemic fronts in a simple metapopulation model with population centers composed of configuration model networks coupled on a one-dimensional lattice. Using the formalism of front propagation into unstable states, we derive the effective transport coefficients of the linear spreading: asymptotic speed, characteristic perturbation size, and diffusion coefficient for the pulled fronts, and explore their dependence on the underlying graph structure. We also derive the average steady-state incidence, the equilibrium spectrum, and the threshold for invasion.

V1.00331 Electron-tunneling measurements of low-Tc single-layer Bi-2201 cuprates

, TH. JACOBS, S.O. KATTERWE, H. MOTZKAU, A. RYDH, Department of Physics, Stockholm University, Sweden, A. MALJUK, Leibniz Institute for Solid State and Materials Research IFW Dresden, Germany, T. HELM, M.V. KARTSOVNIK, WMI, Bayerische Akademie der Wissenschaften, Garching, Germany, C. PUTZKE, H. H. Wills Physics Laboratory, University of Bristol, United Kingdom, E. KAMPERT, HZDR, Hochfeld-Magnetlabor Dresden, Germany, V.M. KRASNOV, Department of Physics, Stockholm University, Sweden — The single-CuO_2 plane cuprate superconductor $Bi_{2+x}Sr_{2-y}CuO_{6+\delta}$ (Bi-2201) is characterized by a low critical temperature and a relatively low upper critical field. This allows a complete suppression of superconductivity even at low T and opens a possibility to study the normal-state properties with a relatively low interference of thermal fluctuations. Furthermore, the understanding of T_c suppression in Bi-2201 is of great significance for understanding the mechanism of high T_c in other cuprates. We present intrinsic tunneling and high magnetic field (up to 65 T) transport measurements of Bi-2201 single crystals with a T_c of only ~ 4 K. All superconducting characteristics are reduced proportional to T_c, but the corresponding c-axis pseudogap characteristics remain similar to that in high-T_c Bi-2212 and Bi-2223 compounds with 20-30 times larger T_c. This scaling disparity reveals the different origin of superconducting and pseudogap states. We also conclude that the low T_c in our Bi-2201 crystals is not caused by strong thermal fluctuations at low T, nor by crystal defects, but is the consequence of a weaker coupling, leading to a small Cooper pair energy.

V1.00332 Universal functions for the transport properties through nanostructured devices[1]

, LUCAS SALA, LUIZ N. OLIVEIRA, University of Sao Paulo — A renormalization-group analysis of the temperature-dependent transport properties of a nanostructured device will be presented. To be specific, the single-electron transistor geometry, in which a quantum dot bridges two otherwise independent electron gases, will be considered. The renormalization-group analysis will consider the equilibrium electrical and thermal conductances and the thermopower in the Kondo regime and will be based on the spin-degenerate Anderson model for the device. The three properties can be related to the three lowest energy moments $\mathcal{L}_j$ $(j = 0, 1, 2)$ of the temperature-dependent spectral density of the dot level. We will rigorously show that each moment $\mathcal{L}_j$ maps linearly onto a universal function L_j of the temperature scaled by the Kondo temperature T_K, with linear coefficients determined by the ground-state occupation of the quantum dot. Essentially exact numerical renormalization-group results for each of the three universal functions will be presented, showing that they can be related to each other at relatively high temperatures, $T > T_K$. The results will be compared to previous theoretical studies of the transport properties, and the implications concerning the interpretation of experimental data will be discussed.

V1.00333 Oscillatory Rheology near Jamming , SIMON DAGOIS-BOHY, Leiden University, BRIAN TIGHE, TU Delft, ELLAK VAN SOMFAI, University of Warwick, MARTIN VAN HECKE, Leiden University — Granular matter is known to exhibit rich mechanical features close to the jamming transition. These features have been explored extensively with quasi-static approaches in the past 10 years. We explore now the dynamical axis, and look at the form of the complex shear modulus in numerical packings of soft spheres, when submitted to a strain oscillating in time. As predicted by B. Tighe (PRL 107, 158303 (2011)) we find that close to the jamming transition, an anomalous scaling regime appears, where both storage and loss moduli grow as the square root of the frequency, and this even when inertia is taken into account. Finally, higher forcing allows to explore non-linearities in these systems, as well as complex reversibility and memory effects.

V1.00334 Dissipative Particle Dynamics Method on PH-Responsive Polymeric Drug Delivery System , YINGYING GUO, City University of HongKong — The self-assembled morphologies formed by polymer in selective solvent could be potentially used as drug-delivery vehicles and has attracted great attention recently. In our work, the drug release mechanism of polymeric delivery vehicle (polymeric microsphere) is investigated with Dissipative particle dynamics simulation. Poly (Lactic Acid)-b-polyethylene glycol (PLA-b-PEG) diblock copolymer is the carrier while IBU is selected as the model drug. A core-shell spherical micelle with drug encapsulated in the core is obtained in our simulation. By changing the medium from neutral to acid, the drugs release via a diffuse mechanism. Both the formation mechanism of the encapsulant and the release mechanism for the drugs are studied in our work. For the formation process, it can be ascribed as the coalesce of the small clusters and the disperse of the drugs; while for the drug release behavior, the process can be divided for three stages: (1) swell of the polymeric carrier, (2) drug diffuse in the carrier and some acid molecules disperse into the carrier, (3) drug release towards the acid medium. Our results might provide a mesoscopic methodology for the evaluation and prediction for polymeric self-assemblies as a carrier for pharmaceutical interest.

V1.00335 Non-thermal excitation and control of dynamic magnetization in a Fe/GaAs heterojunction by ultrafast laser pulses , YU GONG, Physics & Astronomy, Hunter College and the Graduate Center of the City University of New York, A.R. KUTAYIAH, Z. CEVHER, Physics & Astronomy, Hunter College of the City University of New York, X.H. ZHANG, J.H. ZHAO, State Key Laboratory for Superlattices and Microstructures, Chinese Academy of Sciences, Y.H. REN, Physics & Astronomy, Hunter College and the Graduate Center of the City University of New York — Control carrier injection in metal semiconductor heterojunctions and therefore their magnetic dynamics is a major challenge in modern solid-state electronic devices. We report on our recent study of non-thermally excitation and coherently control the spin reorientation by utilizing low-energy femtosecond laser pulses to induce a photo- current through a Fe/GaAs interface. The magnetization dynamics and hysteresis curves were recorded by the pump-probe differential magnetic Kerr (DMK) technique. We show that magnetization excitation and reorientation strongly depend on the polarization of pump pulses. A clear four-fold switching is identified in DMK signal when we rotate the polarization of pump pulses. Our results show that the dynamic magnetization can be induced and controlled by ultrafast laser pulses, and therefore indicate the feasibility of next generation femtosecond-switching magnetic storage devices.

V1.00336 Time reversal of optical pulses by adiabatic coupling modulation in Coupled-Resonator Optical Waveguides , CHAO WANG, CHRISTOPHER SEARCH, Department of Physics and Engineering Physics, Stevens Institute of Technology — We propose a method to time reverse optical pulses in Coupled-Resonator Optical Waveguides(CROW) by adiabatically modulating the couplings between constituent microcavities. Time reversal, also known as phase conjugation, is an inversion of the optical phase. Currently, nonlinear four-wave mixing is the primary method to realize time reversal, but the need for phase matching makes it unsuitable for broadband optical pulses and in integrated devices. Therefore time reversal of both narrow pulses and in photonic circuits are still unsolved problems. Our method to overcome these difficulties is to tune the sign of the inter-resonator evanescent couplings κ of a CROW, whose dispersion is proportional to κ. A Mach-Zehnder Interferometer inserted into the coupling region can tune κ by either electro-optic or thermo-optic modulation of the interferometer phase. For small modulations of the phase around π, time reversal is realized as a result of sign reversal of κ. The bandwidth of the pulses that can be time reversed is limited only by the resonators' Q-factor and free spectral range. Simulations based on coupled mode equations of Si microring resonators show that picosecond pulses can be time reversed with good fidelity for Q-factors as low as 10^5.

V1.00337 Nonlinear Kerr enhancement of the Sagnac effect in a coherently coupled array of optical microresonators , CHAO WANG, CHRISTOPHER SEARCH, Department of Physics and Engineering Physics, Stevens Institute of Technology — Optical gyroscopes based on the Sagnac effect are of great interest both theoretically and practically. Previously it has been suggested a nonlinear Kerr medium inserted into a ring resonator gyroscope can largely increase the rotation sensitivity due to an instability caused by the non-reciprocal self-phase and cross-phase modulations. Recently, coupled microresonator arrays such as Side-Coupled Integrated Spaced Sequence of Resonators (SCISSOR) and Coupled Resonator Optical Waveguides (CROW) have drawn interest as potential integrated gyroscopes due to the sensitivity enhancement resulting from distributed interference between resonators. Here we analyze a SCISSOR system, which consists of an array of microresonators evanescently coupled to two parallel bus waveguides in the presence of a strong intra-resonator Kerr nonlinearity. We show that the distributed interference in the waveguides combined with the nonlinearly enhanced Sagnac effect in the resonators can further improve the sensitivity compared with either a single resonator of equal footprint or SCISSOR without a Kerr nonlinearity. Numerical simulation shows that bistability in the SCISSOR occurs and the rotation sensitivity $\frac{dI_{output}}{d\omega}$ can go to infinity near the boundaries of the bistable region.

V1.00338 Refraction and reflection process in a ferromagnet/frustrated-ferromagnet junction , HIROAKI UEDA, YUTA SASAKI, Tokyo Metropolitan University — The refraction and reflection process plays an important role in controlling a propagation of spinwave. In this presentation, we study the refraction and reflection process of spinwave in the junction of the (usual) ferromagnet/frustrated ferromagnet junction. Frustration induces a nontrivial dispersion relation of spinwave even in the fully polarized ferromagnet phase. As a result, we find exotic refraction processes such as the splitting of spin waves and the negative refraction.

V1.00339 Active electromagnetic metamaterial based on spin torque oscillators , HIROAKI UEDA, GEN TATARA, KATSUHISA TAGUCHI, YUTA SASAKI, MIYUKI NISHIJIMA, AKIHITO TAKEUCHI, Tokyo Metropolitan University — We propose theoretically an active material for electromagnetic radiation with frequency of GHz by use of spin-torque oscillators. The origin of the amplification is the energy supplied to the magnetization by the injected current. We show that close to a resonance with current-driven magnetization, the imaginary part of magnetic permeability becomes indeed negative for either of the two circular polarizations, resulting in negative imaginary part of refractive index. Besides, the real part of the refractive index is also manipulated by the current. Our system thus realizes an active filter to obtain circular polarized radiation and/or an electromagnetic metamaterial having negative refractive index, both controlled electrically.

V1.00340 Nematic phase and phase separation near saturation field in frustrated ferromagnets , HIROAKI UEDA, Tokyo Metropolitan University, TSUTOMU MOMOI, Riken — We discuss effects of quantum fluctuations on magnetization process of quantum frustrated ferromagnets. It is found that, on general grounds, in a neighborhood of a ferromagnet/antiferromagnet classical 1st-order phase boundary in zero external field, a phase separation or non-classical phase must appear slightly below the saturation field in a quantum case, if the classical AF is not an eigenstate. Besides, we study the ferromagnetic J_1-J_2 $S = 1/2$ Heisenberg model ($J_1 < 0$) on the bcc lattice from the viewpoint of the magnon Bose-Einstein condensation. For $-1.50097 \leq J_1/J_2 \leq -1.389$, the nematic phase is expected and for $-1.389 \leq J_1/J_2 \leq -0.48$ the phase separation appears under high magnetic field.

V1.00341 Magnetic Tethering of Microswimmers in Microfluidic Devices , ASCHVIN CHAWAN, SAIKAT JANA, SUVOJIT GHOSH, SUNGHWAN JUNG, ISHWAR K. PURI, Engineering Science and Mechanics, Virginia Tech — Exercising control over animal locomotion is well known in the macro world. In the micro-scale world, such methods require more sophistication. We magnetize Paramecium multimicronucleatum by internalization of magnetite nanoparticles coated with bovine serum albumin (BSA). This enables control of their motion in a microfluidic device using a magnetic field. Miniature permanent magnets embedded within the device are used to tether the magnetized organisms to specific locations along a microchannel. Ciliary beatings of the microswimmer generate shear flows nearby. We apply this setup to enhance cross-stream mixing in a microfluidic device by supplementing molecular diffusion. The device is similar to an active micromixer but requires no external power sources or artificial actuators. We optically characterize the effectiveness of the mechanism in a variety of flow situations.

V1.00342 Effect of Ion Binding in Palmitoyl-Oleoyl Phosphatidylserine Monolayers , MATTHEW ECKLER, SILVINA MATYSIAK, University of Maryland - College Park — Molecular dynamics simulations of palmitoyl-oleoyl phosphatidylserine (POPS) monolayers at the air-water interface were performed with different ionic strengths with the aim of determining the specific organization and dynamics of counterion binding events. Na+ ions penetrated the monolayers into both the ester carbonyl and carboxylate regions of the phospholipids. The binding events increase with the addition of salt. Differences in lipid order parameter, headgroup orientation, and prevalence of inter- and intramolecular hydrogen bonding events between the amine group of the lipid and oxygen groups are observed depending on whether the Na+ is binding near the carboxylate or ester region of the lipid. The observed changes are explained in terms of the salting-out effect.

Thursday, March 21, 2013 2:30PM - 5:30PM –

Session W1 DCMP DMP: Invited Session: Superconductivity at High Pressure Ballroom I - Viktor Struzhkin, Carnegie Institution for Science

2:30PM W1.00001 Achieving higher $T_{\rm C}$ superconductivity in dense cuprates, iron selenides, and hydrocarbons[1] , XIAO-JIA CHEN, Geophysical Laboratory, Carnegie Institution of Washington, Washington, DC 20015 — Pressure plays an essential role in inducing or tuning superconductivity as well as shedding insight on the mechanism of superconductivity. There are much rich phase diagrams in unconventional superconductors under pressure. Finding ways to control the quantum coherence properties to have a higher critical temperature $T_{\rm C}$ than the material has remains a challenge. Here we will talk about our recent experimental efforts in achieving higher temperature superconductivity in cuprates, iron selenides, and hydrocarbons. We will show how to enhance remarkably $T_{\rm C}$ through the pressure tuning of competing electronic order in multilayer cuprates [1] and how to have superconductivity in two distinct regimes in iron selenides [2,3]. We will present a discovery of an enhancement of $T_{\rm C}$ at more than doubled ambient value in a highly compressed aromatic hydrocarbon [4]. Our results have important implications for designing and engineering superconductors with much higher $T_{\rm C}$s at ambient conditions.

3:06PM W1.00002 Elemental superconductivity at high pressure[1] , KATSUYA SHIMIZU, KYOKUGEN, Osaka University — Most of superconducting materials show a negative pressure effect in the superconducting critical temperature, T_c, however, some of simple elements show the positive effect. It has been already revealed that not a few elements that are not the superconductor at ambient pressure became superconductive under combination of low temperature and high pressure. Not only for searching higher T_c but also for understanding the fundamental mechanism of "superconductivity" systematically, we have worked on pressure effect as well as pressure-induced superconductivity especially in simple elements. Here we report two characteristic results of the high-pressure phenomena including superconductivity in calcium (Ca) and lithium (Li). The T_c of Ca increases with pressure and reaches 29 K, the highest T_c in elements, at very high pressure above 200 GPa. The lightest metal element of Li exhibits relatively high T_c at high pressure, however suddenly becomes semiconductor at 80 GPa. Recently we discovered the reentrance of the superconductivity in Li at around 120 GPa.

[1]This research is supported by JSPS through its NEXT Program (GR068).

3:42PM W1.00003 NMR Studies of Novel Electronic Phases in Low Dimensional Molecular Solids at High Pressure and Low Temperature[1] , STUART BROWN, UCLA Physics and Astronomy — Molecular superconductors are known for anisotropic electronic band structure, correlations, and a sensitivity to mechanical or chemical pressure which acts to control the relative strength of the respective kinetic and potential energies. Modest pressures, of order 1 GPa are commonly used to continuously tune from a Mott insulating ground state to a superconducting state, and NMR has been particularly successful in identifying the orders involved, and the nature of the excitations in the various phases encountered. The family of quasi-two dimensional systems κ-(BEDT-TTF)$_2$X (*e.g.*, X=Cu(NCS)$_2$, Cu[N(CN)$_2$]Cl) includes a line of first order phase transitions separating the Mott and superconducting phases, with the superconducting state exhibiting signatures for line nodes associated with an order parameter sign-change over the Fermi surface. The pressure/temperature phase diagram of the quasi-one dimensional materials (TMTSF)$_2$X, X=PF$_6$, ClO$_4$,...) includes more phases, as a consequence of effective 1/4-filling and a substantial density wave susceptibility. The SC ground state is singlet, and there is evidence for a sign-change of the order parameter over the Fermi surface. The high-conductivity normal state exhibits properties associated with two-dimensional spin fluctuations, with signatures in the relaxation rate, as well as transport that are reminiscent of behaviors observed in other correlated superconductors.

[1]Supported by the NSF under grant no. DMR-1105531

4:18PM W1.00004 Pressure effects in cuprate and iron-based superconductors studied by muon spin rotation[1] , HUGO KELLER, Physics Institute, University of Zurich, Switzerland — Pressure effect (PE) studies of physical parameters of solid state systems allow one to investigate the properties of a material as a function of tuned inter-atomic distances. Such studies are performed on the same material with well defined composition and microstructure which is often advantageous, since *e.g.* chemical tuning of material properties (chemical pressure) may give rise to a number of misleading experimental artefacts. Muon-spin rotation (μSR) is a powerful and highly sensitive tool for probing static and dynamic magnetic fields in solids on the atomic scale. In type-II superconductors the nanoscale variation of the local magnetic field in the vortex state can be detected by μSR from which the magnetic penetration depth (superfliud density) can be extracted. Furthermore, μSR is a unique microscopic technique to explore magnetic ordering phenomena and various magnetic phases in solids. At the Paul Scherrer Institute (PSI) a high-pressure set-up was realized which allows to perform μSR experiments at hydrostatic pressures up to 25 kbar and low temperatures ($\simeq 0.3$ K) [1]. Such experiments open a wide spectrum of new possibilities for investigating the superconducting and magnetic properties of novel materials, such as high-temperature superconductors and related magnetic materials. Here, we present some representative examples of such μSR pressure studies carried out at PSI: Iron-based superconductors turned out to exhibit a rich and complex phase diagram which strongly depends on pressure [2,3]. μSR pressure experiments have significantly contributed to a better understanding of these novel class of superconductors [1,2]. In a further μSR study the PE on the magnetic penetration depth in cuprate superconductors was investigated and found to exhibit an interesting relation to the observed isotope effect [4]. Very recently, we also investigated the PE on the magnetic penetration depth in the heavy fermion system $CeCoIn_5$, revealing a strong increase of the superfluid density with pressure [5].

4:54PM W1.00005 Pressure tuning of magnetic fluctuation and superconductivity in $CeCoIn_5$[1] , CARMEN ALMASAN, Kent State University — One of the greatest challenges to Landau's Fermi liquid theory – the standard theory of metals - is presented by complex materials with strong electronic correlations. The non-Fermi liquid transport and thermodynamic properties of these materials are often explained by the presence of strong quantum critical fluctuations associated with a quantum phase transition that happens at a quantum critical point (QCP). The heavy-fermion material $CeCoIn_5$ is a prototypical system for which its pronounced non-Fermi liquid behavior in the normal state and unconventional superconductivity are thought to arise from the proximity of this system to a QCP [1-5]. Previous experiments address the physics of this QCP by extrapolating results obtained in the normal state, i.e., there were no *direct* probes of antiferromagnetism and quantum criticality in the superconducting state. This motivated us to study the transport in the mixed state, thus revealing the physics of antiferromagnetism and quantum criticality of the underlying normal state [6]. In this talk I will present the results obtained in these studies by measuring the vortex core dissipation under applied hydrostatic pressure (P). The vortex core resistivity increases sharply with decreasing magnetic field (H) and temperature (T) due to quasiparticle scattering on critical antiferromagnetic fluctuations. This behavior is greatly suppressed with increasing P. Using our experimental results, we obtained an explicit equation for the antiferromagnetic boundary inside the superconducting dome and constructed an $H-T-P$ phase diagram. This work provides direct evidence for a quantum critical line inside the superconducting phase and reveals the close relationship between quantum criticality, antiferromagnetism, and superconductivity.

Session W2 DCMP: Invited Session: Theory of Interacting Topological Insulators Ballroom II - Shou-Cheng Zhang, Stanford University

2:30PM W2.00001 Simplified topological invariants for interacting insulators and superconductors[1] , ZHONG WANG, Tsinghua University — Topological invariants are precise mathematical tools characterizing the topological properties of topological insulators and superconductors. While many simple and powerful topological invariants for noninteracting insulators and superconductors have been well established, the topological invariants for interacting systems are much less investigated, despite of their great importance in studies of topological states in interacting systems. In this talk I will report some recent progress in the search of topological invariants for interacting systems. I will show that topological invariants defined in terms of zero frequency Green's function are precise and convenient tools for interacting topological insulators and superconductors. They have much simpler forms compared to earlier interacting topological invariants, and have the potential to facilitate discoveries of new topological insulators with strong electron-electron interaction.

[1]We acknowledge the support by Tsinghua University Initiative Scientific Research Program (No. 20121087986).

3:06PM W2.00002 Interaction effects on 3D topological insulators and semi-metals[1] , WILLIAM WITCZAK-KREMPA, Perimeter Institute — We discuss the effects of interactions on 3D Z2 topological insulators and related phases such as axion insulators, Weyl semi-metals and topological Mott insulators. Our analysis is motivated by the pyrochlore iridates but is of general scope. We begin by studying the effects of interactions on topological phases adiabatically connected to non-interacting Hamiltonians using both regular and dynamical mean field theories. Both the bulk and boundary topological signatures are analyzed. We then move to stronger interactions where a Mott transition from a topological insulator to a fractionalized topological Mott insulator can occur. We discuss the effects of gauge fluctuations on the transition and the resulting spin liquid.

[1]Supported by NSERC, FQRNT, the Walter Sumner Foundation, the University of Toronto and Perimeter Institute.

3:42PM W2.00003 Topological Insulator Materials with Strong Interaction[1] , HAIJUN ZHANG, Department of Physics, Stanford University — All kinds of topological insulator materials have recently been discovered in two-and three-dimensional systems with strong spin-orbit coupling (SOC) hosting helical gapless edge or surface states consisting of odd number of Dirac fermion states inside the bulk band gap. Most of these discovered topological insulators have negligible interaction. Here we theoretically predict a new class of topological insulators with strong interaction. The typical examples are PuTe and AmN, with a simple rocksalt structure, which lie on the boundary between metals and insulators. We show that the interaction can effectively enhance SOC and drives a quantum phase transition to the topological insulator phase with a single Dirac cone on the surface (001). In addition, this kind of compounds has fully or partly filled f states, which could exhibit all kinds of magnetic phases, potentially leads to the discovery of intrinsic quantum anomalous Hall effect (QAHE) and topological magnetic insulators with dynamic axion field.

[1]I acknowledge thesupport of the Army Research Office (No.W911NF-09-1-0508).

4:18PM W2.00004 Interacting topological phases and quantum anomalies , SHINSEI RYU, University of Illinois at Urbana-Champaign — Since the quantum Hall effect, the notion of topological phases of matter has been extended to those that are well-defined (or: "protected") in the presence of a certain set of symmetries, and that exist in dimensions higher than two. In the (fractional) quantum Hall effects (and in "chiral" topological phases in general), Laughlin's thought experiment provides a key insight into their topological characterization; it shows a close connection between topological phases and *quantum anomalies*. Compared to genuine topological phases, symmetry protected topological phases are more fragile and less entangled states of matter, and hence for their characterization we need to sharpen our understanding on how topological properties of the systems manifest themselves in the form of a quantum anomaly. By taking various kinds of symmetry protected topological phases as an example, I will demonstrate that quantum anomalies serve as a useful tool to diagnose (and even define) topological properties of the systems. I will also discuss quantum anomalies play an essential role when developing descriptions of these topological phases in terms bulk and boundary (effective) theories.

4:54PM W2.00005 Braiding statistics approach to symmetry-protected topological phases , MICHAEL LEVIN, University of Maryland — Symmetry-protected topological (SPT) phases can be thought of as generalizations of topological insulators. Just as topological insulators have robust gapless boundary modes protected by time reversal and charge conservation symmetry, SPT phases have boundary modes protected by more general symmetries. In this talk, I will describe a method for analyzing 2D SPT phases using braiding statistics. I will present this approach in the context of a simple example: a 2D Ising paramagnet with gapless edge modes protected by Ising symmetry. First, I will show that if the paramagnet is coupled to a Z_2 gauge field, the resulting π-flux excitations have different braiding statistics from that of a usual Ising paramagnet. This result provides a simple proof that the spin model belongs to a distinct quantum phase from a conventional paramagnet. Second, I will show that the π-flux braiding statistics directly imply the existence of protected edge modes. I will argue that this analysis can be generalized to any 2D SPT phase with unitary symmetries.

Thursday, March 21, 2013 2:30PM - 5:30PM –

Session W3 GQI: Invited Session: Quantum Foundations Ballroom III - Terry Rudolph, Imperial College London

2:30PM W3.00001 The freedom of choice assumption and its implications , RENATO RENNER, ETH Zurich — The assumption that the parameters of an experiment (e.g., those determining the basis of a quantum measurement) can be chosen freely is implicit to most considerations in physics. One may therefore ask whether it is possible to give a precise meaning to the notion of "free choice" and, if yes, study its implications. One natural approach towards defining free choice, considered already by Bell, is to specify a causal structure on the set of all physically relevant parameters and observables. A parameter may then be considered "free" if it is statistically independent of all other parameters and observations that do not lie in its causal future. Recently, it has been realized that the assumption of free choice, as defined above, has various interesting consequences. In particular, if defined relative to a causal structure compatible with relativity theory, free choice immediately implies completeness of quantum theory. This means that there cannot exist any additional (hidden) parameters that would improve the statistical predictions that quantum theory makes about the outcomes of future measurements. In this talk, I motivate and explain this definition of free choice and give an overview of the most important implications of the free choice assumption.

3:06PM W3.00002 Quantum correlations in Newtonian space and time: arbitrarily fast communication or nonlocality , NICOLAS GISIN, University of Geneva — Experimental violations of Bell inequalities using space-like separated measurements precludes the explanation of quantum correlations through causal influences propagating at subluminal speed. Yet, "everything looks as if the two parties somehow communicate behind the scene." We investigate the assumption that they do so at a speed faster than light, though finite. Such an assumption doesn't respect the spirit of Einstein relativity. However, it is not crystal clear that such "communication behind the scene" would contradict relativity. Indeed, one could imagine that this communication remains for ever hidden to humans, i.e. that it could not be controlled by humans, only Nature exploits it to produce correlations that can't be explained by usual common causes. To define faster than light hidden communication requires a universal privileged reference frame in which this faster than light speed is defined. Again, such a universal privileged frame is not in the spirit of relativity, but it is also clearly not in contradiction: for example the reference frame in which the cosmic microwave background radiation is isotropic defines such a privileged frame. Hence, a priori, a hidden communication explanation is not more surprising than nonlocality. We prove that for *any* finite speed, such models predict correlations that can be exploited for faster-than-light communication. This superluminal communication doesn't require access to any hidden physical quantities, but only the manipulation of measurement devices at the level of our present-day description of quantum experiments. Consequently, all possible explanations of quantum correlations that satisfy the principle of continuity, which states that everything propagates gradually and continuously through space and time, or in other words, all combination of local common causes and direct causes that reproduce quantum correlations, lead to faster than light communication. Accordingly, either there is superluminal communication or the conclusion that Nature is nonlocal (i.e. discontinuous) is unavoidable [Nature Physics DOI: 10.1038/NPHYS2460 (2012); arXiv:1210.7308].

3:42PM W3.00003 Three-dimensionality of space and the quantum bit: an information-theoretic approach , MARKUS MUELLER, Perimeter Institute for Theoretical Physics — It is sometimes pointed out as a curiosity that the state space of quantum two-level systems, i.e. the qubit, and actual physical space are both three-dimensional and Euclidean. In this talk, I report on joint work with Lluis Masanes [1], where we attempt an information-theoretic analysis of this relationship, by proving a particular mathematical result: suppose that physics takes place in d spatial dimensions, and that some events happen probabilistically (not assuming quantum theory in any way). Furthermore, suppose there are systems that behave in some sense as "units of direction information," interacting continuously and reversibly in time. We prove that this uniquely determines spatial dimension d=3 and quantum theory on two qubits (that is, the complex Hilbert space formalism and unitary time evolution). Moreover, we prove that it allows observers to infer local spatial geometry from probability measurements. This applies and generalizes results obtained earlier with further collaborators [2,3].

4:18PM W3.00004 Quantum correlations with indefinite causal order , CASLAV BRUKNER, Vienna Center for Quantum Science and Technology (VCQ), Faculty of Physics, University of Vienna, Boltzmanngasse 5, A-1090 Vienna, Austria — Quantum mechanics differs from classical physics in that no definite values can be attributed to unobserved physical quantities. However, the notion of time and of causal order preserves such an objective status in the theory: all operations are assumed to be ordered such that every operation is either in the future, in the past or space-like separated from any other operation. Consequently, the correlations between operations respect definite causal order: they are either signalling correlations for the time-like or no-signalling correlations for the space-like separated operations. I will present a framework that assumes only that operations in local laboratories are described by quantum mechanics (i.e. are completely-positive maps), but relax the assumption that they are causally connected. Remarkably, we find situations where two operations are neither causally ordered nor in a probabilistic mixture of definite causal orders, i.e. one cannot say that one operations is before or after the other. The correlations between the operations are shown to enable performing a communication task ("causal game") that is impossible if the operations are ordered according to a fixed background time. I will discuss experimental perspectives for observing such correlations in nature.

4:54PM W3.00005 Realism and the epistemic view of quantum states[1] , TERRY RUDOLPH, Imperial College London — The idea that quantum states reflect only an observers knowledge/beliefs/information about the world has a long history, with a wide variety of strong arguments having been proffered in its favour. The challenge for an advocate of this position, however, is to identify what we can deduce is "really going on" out there. There seem to three main paths proponents of the epistemic view have followed in trying to extract such a narrative from quantum theory. I will explain how the most naive such path–that quantum states can be associated with standard (probabilistic) uncertainty about some (arbitrary) real states of the world–is not tenable under some extremely mild assumptions about how any theory of reality must treat independent experiments. I will then overview the other two paths and what I see as the challenges they face.

Session W4 FIAP: Invited Session: Start-ups and Small Businesses: Success Stories and Tool Kits Ballroom IV - Joseph Sabol, Chemical Consultant

2:30PM W4.00001 Top 10 Steps to Business Success , GIANNA ARNOLD, Saul Ewing LLP — What does it really take to build a successful technology based company? This fast paced and interactive discussion will highlite potential missteps as well as actions that increase the likelihood of success. Topics under consideration will include: how to begin, creating an organizational structure, creating a plan, selecting a name, financing, allocating resources as efficiently as possible, building a team, protecting intangible assets, strategic alliances, obtaining revenue and transitioning from startup to growth. The primary goal of this presentation is to help you identify value-creating practices as well as wasteful practices, while providing the general nuts and bolts required to move forward.

3:06PM W4.00002 Learnings from an Entrepreneur: How to Start a Consulting Practice , DEBRA BOWES, Chevy Chase BioPartners — There are important basic learnings I have experienced in starting my own consulting practice over 7 years ago. These learnings will help you maximize your value, reduce competition and build your reputation and business income. I believe these can apply to many fields but certainly for the Life Sciences. A few of the basic I will cover are

1. Why do you want to start a consulting practice
2. Qualifications/Specialty/Experience vs the Competition
3. What is your target market vs the Competition
4. Contracts/ constructing and costing for your target market
5. Networking/Involvement in Professional Organizations

3:42PM W4.00003 The Road from University to Small Business , KIMBERLY BROWN, Amethyst Technologies, LLC — Scientists are trained to solve problems, persevere, and be innovative with a goal of improving the quality of life for others. Pursuit of science undergraduate and graduate degrees is often based on our desire to become a physician, solve a critical problem, follow in the footsteps of a family member, or satisfy an inquisitive mind. This aptitude uniquely suits us to be successful entrepreneurs who can change the world by developing high tech companies. Keys to being an entrepreneur include perseverance, innovation, and commitment. These qualities are cultivated during the rigorous process of obtaining a science degree which requires laboratory work, problem solving in team settings, innovation to answer exam questions that are sometimes abstract, and dedication to take electives and non-electives not always of one's choosing over the course of four to ten years. Taking a risk and starting a business using the core skills developed during science studies is the focus of this talk. The viewpoint is based on the path of one scientist who always dreamed of performing research and obtained a PhD in chemical engineering along the way to founding a biotechnology company.

4:18PM W4.00004 The Untapped Entrepreneurial Frontier: Transferring Innovation from the Laboratory to the Market , SHIRLEY COLLIER, Optemax, LLC — Technology transfer from federally funded research laboratories and universities into the private sector holds great promise, yet those promises are largely unfulfilled. In this session you will learn about the scope of technology transfer in our country, the barriers to successful commercialization of scientific innovations and suggestions for how the system can be fixed. You will also learn what inventors, entrepreneurs and investors can do to improve the chances of success.

4:54PM W4.00005 Identifying, Licensing, and Commercializing Technology: An Entrepreneur's View , KRIS APPEL, Encore Path, Inc — A linguist by trade, Kris Appel left government service to pursue entrepreneurship. She knew she wanted to start a company, but she did not have a business idea. After researching various technologies available for commercialization, she began to focus on a prototype medical device at the University of Maryland Medical School, which had been developed to help stroke survivors recover their arm movement. The device was based upon emerging science into brain re-training, and was backed by very convincing clinical trials. Working closely with University researchers, she licensed the rights to the device, developed a commercial version, and launched it in 2009. Today the device is used around the globe, and has helped thousands of stroke and brain injury survivors improve their arm function and way of life. Kris will tell the story of the device, and how it got from idea to prototype to successful rehabilitation product.

Thursday, March 21, 2013 2:30PM - 5:30PM –

Session W5 DCMP: Focus Session: Graphene: Transport and Optical Phenomena: Nanostructures 301 - Caio Lewenkopf, Universidade Federal Fluminense

2:30PM W5.00001 Large Scale Mesoscopic Transport in Nanostructured Graphene , HAIJING ZHANG, JIANMING LU, WU SHI, ZHE WANG, TING ZHANG, MINGYUAN SUN, YUAN ZHENG, QIHONG CHEN, NING WANG, Hong Kong University of Science and Technology, JUHN-JONG LIN, National Chiao Tung University, PING SHENG, Hong Kong University of Science and Technology — We report the observation of strong 2D Anderson localization at the charge neutrality point (CNP) in nanostructured antidot graphene samples. A localization length of 2 micron is obtained through sample size scaling up to 10 micron. Localization length is seen to increase with applied magnetic field, in accurate agreement with the theoretical prediction of Ono [Prog. Theor. Phys. Suppl. 84, 138 (1985)]. Our observation is made possible by the very large dephasing length of 10 micon, owing to the opening of a Coulomb quasigap, observable below 25 K, that suppresses the inelastic electron-electron scatterings. Such a large dephasing length is further substantiated by the observation of a crossover from the mesoscopic transport (with exponential size scaling) to diffusive transport (with size independence) at 10 micron. Large scale mesoscopic transport may provide promising future to graphene nanoelectronic device applications.

2:42PM W5.00002 Ballistic transport in nanometer-scale suspended graphene , V. TAYARI, A.C. MCRAE, S. YIĞEN, J. PORTER, J.O. ISLAND, A. R. CHAMPAGNE, Department of Physics, Concordia University, Montreal, Canada — We study electron transport in suspended ultra-short graphene transistors. We fabricate narrow bowtie gold junctions on exfoliated graphene, and use oxygen plasma to etch away the graphene crystal except under the gold junctions. We then use a wet etch to remove the SiO_2 under the junctions and suspend the devices. Finally, we use a feedback-control electromigration procedure to break the gold junctions and expose sections of graphene which are $\sim$100 nm wide, and as short as $\sim$10 nm. Using low-temperature electron transport, we observe Fabry-Perot oscillations in the conductivity as a function of charge density, as expected for ballistic transport. The conductivity is asymmetric for electron and hole gate-doping, signaling charge doping from the gold contacts and the formation of p-n junctions. At temperatures below $\approx$ 1 Kelvin, a very strong hysteresis is observed in the gate-dependence of conductivity. We study these devices as a function of charge density, temperature, magnetic field and aspect ratio.

2:54PM W5.00003 The Effects of the Mean-Field Interaction on the Anderson Localization of Graphene Nanoribbons , JACK BALDWIN, Y. HANCOCK, Department of Physics, University of York, UK — A generalized tight-binding (TB) model,[1] which includes a mean-field Hubbard-U and up to 3rd nearest-neighbor hopping terms, is applied to edge-disordered zigzag graphene nanoribbons in order to study spin-transport within the Landauer-Bütticker formalism. Edge-disorder is modeled by random perturbation of the on-site energy in the range $-E..E$ on all edge atoms, and the resulting Anderson localization lengths determined. We compared the Anderson localization lengths and spin-transport features obtained from the generalized model, an extended TB model (non-interacting) and the simplified TB model (1st nearest neighbor hopping only). Within the range $\pm E$ =0.5 eV the Anderson localization length for a single spin was found to decrease by 86.4% with the introduction of the Hubbard-U in the generalized model compared to the non-interacting models, whereas the opposite spin remained unchanged across all model types. For the range $\pm E$ =2.0 eV the Anderson localization length for both spin types decreased by 71.4% and 76.2% in the generalized model when compared to the extended TB model, and 76.5% and 80.4% when compared to the simplified TB model.

[1]Hancock *et al.* PRB **8**1, 245402 (2010).

3:06PM W5.00004 Graphene-based spaser , OLEG BERMAN, ROMAN KEZERASHVILI, New York City College of Technology of the City University of New York, YURII LOZOVIK, Institute of Spectroscopy — We propose graphene-based surface plasmon amplification by stimulated emission of radiation (spaser) formed in the graphene nanoribbon located near a semiconductor quantum dot (QD). The population inversion of the two electron levels of the QD can be achieved by applying external electric current or laser pumping. If the frequency of the dipole plasmon resonance in a graphene nanoribbon comes in the resonance with the transition frequency for the QD, it is possible to excite plasmons and generate the coherent surface plasmon states in the graphene nanoribbon. Therefore, the oscillating dipole in the QD excites coherent surface plasmons in the graphene nanoribbon. By solving the system of equations for the number of coherent localized plasmons in a graphene-based spaser the optimal design, optimal width of graphene nanoribbon and optimal regime for the graphene-based spaser are found. The minimal size and minimal threshold pumping intensity for the graphene-based spaser are obtained. The advantage of using graphene for the spaser is discussed.

3:18PM W5.00005 ABSTRACT WITHDRAWN –

3:30PM W5.00006 Shearing graphene and its transmission properties[1] , ANDRES CONCHA[2], School of Engineering and Applied Sciences, Harvard University, Cambridge, MA 02138, USA, SHENGFENG CHENG, Sandia National Laboratories, Albuquerque, New Mexico 87185, USA, L. MAHADEVAN[3], School of Engineering and Applied Sciences, Harvard University, Cambridge, MA 02138, USA — Graphene being the thinnest possible membrane is prone to deformations under slight external forcing or even under thermal fluctuations. Here, we take advantage of this proneness to deformations to manipulate transport properties of graphene ribbons. We do so by using the spontaneous pattern produced when a wide ribbon is subject to shear. The deformation of the ribbon produces pseudo-magnetic fields as well as scalar potentials, resulting in the modification of transmission properties without the need of an external gate potential. Our proposal is a concrete realization of a quantum device that takes full advantage of an elastic instability that spans from the nano to macro-scales.

3:42PM W5.00007 Optical Properties of Graphene Nanoribbons , HUGEN YAN, TONY LOW, WENJUAN ZHU, YANQING WU, IBM T. J. Watson Research Center, FRANCISCO GUINEA, Instituto de Ciencia de Materiales de Madrid. CSIC, FENGNIAN XIA, PHAEDON AVOURIS, IBM T. J. Watson Research Center — The electrical transport properties of graphene nanoribbons have been extensively studied. However, the experimental investigation of the optical properties is still lacking. In this paper, we present the infrared (IR) absorption measurement of graphene nanoribbons with width down to 50 nm. The optical response is dominated by plasmonic resonances in the mid-IR when the incident light polarization is perpendicular to the ribbon axis. By varying the width of the ribbons, we were able to determine the plasmon dispersion in graphene. Meanwhile, we revealed the important role of surface polar phonons and graphene intrinsic optical phonons in the plasmon dispersion and damping. In conjunction with theoretical analysis, we found that graphene plasmons are severely damped through the emission of an optical phonon together with an intraband electron-hole pair. Our study paves the way for graphene applications in infrared photonics and opto-electronics.

3:54PM W5.00008 The role of the disorder range and electronic energy in the graphene nanoribbons perfect transmission , LEANDRO LIMA, FELIPE PINHEIRO, RODRIGO CAPAZ, Universidade Federal do Rio de Janeiro, CAIO LEWENKOPF, Universidade Federal Fluminense, EDUARDO MUCCIOLO, University of Central Florida — Numerical calculations based on the recursive Green's function method in the tight-binding approximation are performed to calculate the dimensionless conductance g in disordered graphene nanoribbons with Gaussian scatterers. The influence of the transition from short- to long-ranged disorder on g is studied as well as its effects on the formation of a perfectly conducting channel. We also investigate the dependence of electronic energy on the perfectly conducting channel. We propose and calculate a backscattering estimate in order to establish the connection between the perfectly conducting channel (with g = 1) and the amount of intervalley scattering.

4:06PM W5.00009 First-principles calculation of the heat transport properties of strained graphene nanoribbons , CHEE KWAN GAN, Institute of High Performance Computing, Singapore, PEI SHAN EMMELINE YEO, National University of Singapore — We use density-functional theory coupled with a nonequilibrium Green function's method to calculate the characteristics of ballistic thermal transport (P.S.E. Yeo, K.P. Loh, and C.K.Gan, Nanotechnology, 2012, accepted and to appear) of tensile-strained armchair (AGNR) and zigzag (ZGNR) edge graphene nanoribbons, with widths between 3 and 50 Å. The optimized lateral lattice constants for AGNRs of different widths display a three-family behavior when the ribbons are arranged according to N modulo 3, where N represents the number of carbon atoms across the width of the ribbon. Two lowest-frequency out-of-plane acoustic modes play an important role in increasing the thermal conductance of AGNR-N at low temperatures. At high temperatures the effect of tensile strain is to reduce the thermal conductance of AGNR-N and ZGNR-N. These results could be explained by the changes in force constants in the in-plane and out-of-plane directions when strain is applied. This fundamental atomistic understanding of the heat transport in graphene nanoribbons suggests a route to controlling heat transport properties via strain at various temperatures.

4:18PM W5.00010 Optical selection rules in graphene quantum dots , ELEFTHERIA KAVOUSANAKI, KESHAV DANI, Okinawa Institute of Science and Technology, Graduate University, Okinawa 904-0495, Japan — We theoretically study the optical absorption of graphene quantum dots for different shapes, sizes and edge types. We calculate the single particle energy spectrum using the tight-binding Hamiltonian and the Dirac-Weyl equation and show that dots with zigzag edges exhibit a degenerate shell of zero energy states, in agreement with previous results. Using standard group theoretical tools, we obtain the optical selection rules for triangular and hexagonal quantum dots and discuss the role of light polarization on the absorption spectrum. Finally, we calculate the oscillator strengths and absorption spectra for different quantum dot sizes and identify the contribution of the zero energy states therein.

4:30PM W5.00011 Immense Weak Localization Effect in CVD Graphene[1] , OLESYA SARAJLIC, RAMESH MANI, Georgia State University — In this study, we report magnetoresistance (MR) measurements on graphene grown by chemical vapor deposition (CVD) on copper. CVD graphene is transferred onto SiO_2/Si substrate and Hall bar devices with Au/Ti contacts are fabricated by photo-lithography. Measurements show that the diagonal resistance R_{xx} varies logarithmically vs. temperature and magnetic field, as expected for weak localization. The interesting aspect here in CVD graphene is that weak localization effect is immense compared to the typical observation in dirty metals. At zero magnetic field, R_{xx} increased by about 7% with decreasing temperature from 110 K to 1.5 K. From the observed weak localization, we extract characteristics lifetimes and length scales, and compare the results with theoretical expections [1], and other weak localization work on CVD graphene [2,3].

4:42PM W5.00012 Conductance Fluctuation and Superconducting-to-Normal State Switching Measurements of Superconducting Graphene Devices[1] , JOSEPH LAMBERT, STEVEN CARABELLO, Drexel University, ROBERTO RAMOS, Indiana Wesleyan University — We report on gate voltage dependent conductance fluctuations (CF) in superconducting graphene devices and compare measurements in the superconducting versus normal state at temperatures down to 20 mK. The CF arise from the averaged interference of charge carrier wave functions caused by scattering in the graphene. An enhancement in the magnitude of the average CF is expected when in the superconducting state due to Andreev reflections. We fabricate devices by contacting graphene with two parallel superconducting leads that are spaced a few hundred nanometers apart. The leads are a Pd/Al or Ti/Al bilayer with the thin Pd or Ti layer providing high transparency contact to graphene. Additionally, we report on our ongoing superconducting-to-normal state switching measurements in graphene Josephson junctions. The distribution of the stochastic switching current gives insight into the dynamics of the junction such as the phase particle escape mechanisms and dissipation processes. The use of graphene as the weak link allows novel control of the critical current, and thus the dynamics of the junction. By gathering switching data, we can study the modified Josephson washboard potential in these devices (J. G. Lambert, et al., IEEE Trans. in Appl. Supercond. 21, 734 (2011)).

4:54PM W5.00013 Conductance fluctuation and dimensional crossover in hydrogenated graphene systems , DUK-HYUN CHOE, KEE JOO CHANG, KAIST, KAIST TEAM — The conductance of mesoscopic disordered systems in the localized transport regime exhibits extremely large sample-to-sample fluctuations. Thus, their transport properties must be understood in terms of the conductance distribution function. Although the distribution functions show distinctive behavior depending on the dimension of system, previous studies have been mainly focused on one, two, and three dimensional systems individually. Here, we investigate the dimensional transition from two-dimensional (2D) graphene to quasi-one-dimensional (Q1D) graphene nanoribbons and discuss the effect of the dimensional crossover on the conductance fluctuation. As a model system, we consider hydrogenated graphene systems which have attracted much attention due to the observation of a metal-insulator transition. Adopting two different strategies to examine the crossover behavior of conductance between Q1D and 2D systems, we find that a transition from 2D to Q1D is attainable by reducing the sample width, while it is not possible by increasing the length of the 2D system. Our results provide fundamental insights into the dimensionality change not only in graphene, but also in general mesoscopic systems in the localized regime.

5:06PM W5.00014 Impurity state and variable range hopping conduction in graphene , SANG-ZI LIANG, JORGE O. SOFO, Department of Physics, the Pennsylvania State University — The variable range hopping (VRH) theory is widely accepted as explaining the temperature dependence of the conductivity of doped semiconductors. However, as formulated for exponentially localized impurity states, it does not necessarily apply in the case of graphene with covalently attached impurities. We analyze the localization of impurity states in graphene using the nearest neighbor tight-binding model of an adatom-graphene system with Green's function perturbation methods. The impurity states in graphene are characterized as resonant states in the band continuum and both low energy approximations and numerical evaluation of the Green's functions indicate that the amplitude of the wave function decays as a power law with exponents depending on sublattice, direction, and the impurity species. We revisit the VRH theory in view of this result and find that considering only the overlap and energy difference of the impurity states, the conductivity obeys a power law of the temperature with an exponent related to the localization of the wave function. Other factors that were ignored in the original VRH are included due to the weaker temperature dependence, which contribute an additional exponent. We show that this relationship is in agreement with available experimental results.

5:18PM W5.00015 Gate-tuned two-channel Kondo screening in Graphene: Universal scaling of the nonlinear conductance[1] , CHUNG-HOU CHUNG, Department of Electrophysics, National Chiao-Tung University and Physics Division, National Center for Theoretical Sciences, HsinChu, Taiwan, R.O.C., TSUNG-HAN LEE, KENNETH YI-JIEH ZHANG, Department of Electrophysics, National Chiao-Tung University, HsinChu, Taiwan, R.O.C., STEFAN KIRCHNER, Max-Planck-Institut fuer Physik komplexer Systeme and Max-Planck-Institut fuer chemische Physik Stoffe, Dresden, Germany — We study the nonlinear conductance through magnetic adatoms on Graphene. In particular, we address the finite-temperature crossover from a quantum critical to the two-channel Kondo regime expected to occur in doped Graphene. Based on the non-crossing approximation, We calculate both the linear and nonlinear conductance within the two-lead single-impurity Anderson model where the conduction electron density of states vanishes in a power-law fashion $\propto |\omega - \mu_F|^r$ with $r = 1$ near the Fermi energy, appropriately for Graphene. For given gate voltage, we study the universal crossover from a 2-channel Kondo (2CK) phase to a un-screened local momemt (LM) phase. We extract universal scaling functions governing charge transport through the adatom and discuss our results in the context of a recent scanning tunneling spectroscopy (STM) experiment on Co-doped Graphene.

Session W6 DMP: Focus Session: Graphene on SiC: Synthesis and Properties 302 - Randall Feenstra, Carnegie Mellon University

2:30PM W6.00001 Spin transport in epitaxial graphene on SiC (0001) , YUCHEN DU, ADAM T. NEAL, MIKE CAPANO, PEIDE YE, Purdue University, Birck Nanotechnology Center — Graphene has been identified as a promising material for future spintronics devices due to its low spin orbit coupling and long spin diffusion lengths, even at room temperature [1-2]. However, any device application requires the use of large-area graphene compatible with wafer-scale manufacturing methods, such as graphene grown epitaxially on SiC. We study spin transport in epitaxial graphene grown on SiC (0001) as a step toward future spintronics devices. A non-local spin valve signal of 200mΩ is observed at 77K, with a signal of 50mΩ resolved at 145K. Assuming a contact polarization of 10% [1], the measured signal corresponds to a spin diffusion length of 130nm at T=77K. Hanle effect spin precession measurements are ongoing. [1] Tombros et al. **Nature** 448 571 (2007) [2] Maassen et al. **Nano Lett.** 12, 1498 (2012)

2:42PM W6.00002 Scanning tunneling microscopy/spectroscopy study of hydrogen intercalated epitaxial graphene on SiC(0001)[1] , S. RAJPUT, Y. Y. LI, M. WEINERT, L. LI, University of Wisconsin, Milwaukee — In this work, we studied the atomic structures and electronic properties of hydrogen intercalated epitaxial graphene on Si-face SiC(0001) using scanning tunneling microscopy/spectroscopy and density functional theory (DFT) calculations. Hydrogen intercalation was achieved by either annealing graphene/SiC(0001) in hydrogen gas at atmospheric pressure or in hydrogen plasma in ultrahigh vacuum. We found that while the as-grown graphene is n-type, the H-intercalated graphene is p-type, which can be attributed to the saturation of the Si dangling bonds at the interface by hydrogen atoms. These results and the origin of the p-type doping in hydrogen intercalated epitaxial graphene on SiC(0001) will be discussed at the meeting.

[1]Supported by DOE (DE-FG02-05ER46228).

2:54PM W6.00003 Scanning Tunneling Microscopy and Spectroscopy of Quasi-freestanding Graphene on SiC , TIANSHUAI GUAN, ANDREAS SANDIN, J.E. (JACK) ROWE, DANIEL DOUGHERTY, Department of Physics, North Carolina State University — Epitaxial graphene on SiC(0001) is a promising approach for industrial-scale production of very high quality graphene. Recently, it has been demonstrated by angle-resolved photoelectron spectroscopy (Riedl et al., Phys. Rev. Lett 103, 246804 (2009)) that graphene can be prepared on SiC in almost undoped form by intercalating atomic hydrogen beneath the non-graphitic carbon-rich "buffer layer." We present scanning tunneling microscopy and spectroscopy measurements of quasi-free-standing monolayer graphene on SiC(0001) obtained by atomic hydrogen intercalation. Small hydrogen-intercalated domains formed at the initial stages of quasi-free graphene nucleation exhibit a $\left(\sqrt{3} \times \sqrt{3}\right)$R30 corrugation due to the sub-surface hydrogen. Local image potential state spectroscopy on these domains is used to observe changes in local doping due to intercalation. These states show the energetic shift ($\approx$ 0.4 eV) with respect to the usual n-doped single-layer graphene on SiC(0001) that suggests that H-intercalated graphene is almost charge-neutral.

3:06PM W6.00004 Spin transport over long distance in epitaxial graphene grown on C-face SiC , PIERRE SENEOR, Unite Mixte de Physique CNRS/Thales, Palaiseau, France and Université de Paris-Sud, Orsay — Spintronics is a paradigm focusing on spin as the information vector and ranging from quantum information to zero-power non-volatile magnetism. Several spintronics evices (logic gates, spin FET, etc) are based on spin transport in a lateral channel between spin polarized contacts. However while spin is acclaimed for information storage, a paradox is that efficient spin transport as remained elusive. We will present magneto-transport experiments on epitaxial graphene multilayers on SiC showing very large spin signals and spin diffusion length in graphene in the 100μm range (as high as 285μm). In the best case, the spin transport efficiency of epitaxial graphene is found to be of 75% of the ideal channel. Graphene, could turn out as a material of choice for large scale logic circuits and the transport/processing of spin information. Understanding the mechanism of the spin relaxation, improving the spin diffusion length and also testing various concepts of spin gates are the next challenges.

3:42PM W6.00005 Imaging stacking faults in epitaxial graphene/buffer layer structures on SiC(0001) , PATRICK MENDE, GUOWEI HE, RANDALL FEENSTRA, MICHAEL WIDOM, Dept. Physics, Carnegie Mellon University, Pittsburgh, PA, IRENE CALIZO, GUANGJUN CHENG, RANDOLPH ELMQUIST, ANGELA HIGHT WALKER, National Institute of Standards and Technology, Gaithersburg, MD, MARIANO REAL, Instituto Nacional de Tecnología Industrial, San Martín, Buenos Aires, Argentina — In characterizing the structure of epitaxial graphene on SiC, the homogeneity of the number of monolayers (MLs) of graphene on the surface is important due to its substantial effect on graphene's electronic properties and, until recently, was not easily controlled. As the processing of samples continues to improve, other structural properties of the films and substrate (e.g., substrate morphology, step density, and grain area) have become important in the pursuit of improved electronic behavior. In this talk, imaging of rotational stacking faults in epitaxial graphene on SiC(0001) using low-energy electron microscopy (LEEM) is described. Using a pattern of fiducial marks on the SiC surface, we have correlated LEEM imaging of these stacking faults with micro-Raman imaging. Additionally, while stacking domains in $\geq$1ML graphene have been studied previously in LEEM [1-2], here we introduce first-principles calculations of low-energy electron reflectivity for various stacking arrangements of 1ML graphene/buffer- layer structures on SiC(0001), and compare these predictions to the reflectivity seen in LEEM.

3:54PM W6.00006 Control of epitaxial graphene growth by SiC-SiC capping[1] , ISMET KAYA, CEM CELEBI, CENK YANIK, ANIL GUNAY DEMIRKOL, Sabanci University, QUANTUM TRANSPORT AND NANOELECTRONICS LABORATORY TEAM — The growth of epitaxial graphene on the surfaces of silicon carbide is considered to be one of the most promising techniques for obtaining high quality large scale graphene for electronics applications. Although graphene grown on the C-face has high mobility, its growth under vacuum is too fast, not self limited and produces high concentration of crystalline defects. Therefore a precise control over the Si evaporation rate is required. We demonstrate a new method to reduce the growth rate and yield thin graphene layers with excellent thickness uniformity on the C-face of SiC in ultra high vacuum conditions. The sample is capped by another SiC substrate with a rectangular recess of about one micron depth on its surface which forms a partially open cavity between the surfaces. During the growth by high temperature annealing, silicon atoms sublimated from the capped sample are confined inside the cavity between the two substrates. The confined silicon vapor maintains a high partial pressure at the sample surface which significantly reduces the growth rate of graphene to an easily controllable range. We demonstrate that the growth rate linearly increases with the area of the cavity opening. We investigated the effect of Si confinement on the thickness and morphology of UHV grown epitaxial graphene on C-face SiC by Raman spectroscopy, atomic force microscopy, scanning electron microscopy and low energy electron diffraction.

4:06PM W6.00007 Growth and characterization of the graphene and its interface on the SiC (0001) face , JAMES PALMER, MING RUAN, YIKE HU, ZELEI GUO, JOHN HANKINSON, RUI DONG, JAN KUNC, Georgia Institute of Technology, CLAIRE BERGER, Georgia Institute of Technology, CNRS - Institut Neel, WALT DE HEER, Georgia Institute of Technology — The confinement controlled sublimation method [1] provides a method of producing high quality epitaxial graphene on silicon carbide by controlling the silicon evaporation rate through confinement. Here we present growth studies of the first few graphene layers on the silicon terminated face (SiC (0001)). Surface properties of the grown layers are characterized by Raman spectroscopy, AFM, EFM, ellipsometry, and LEED, along with resistivity measurements of the grown graphene. Together these characterization methods can provide information on the substrate step structure and doping of the first layers of graphene. The growth of the initial buffer layer from SiC, of graphene nanoribbons from the SiC substrate steps (e.g. sidewall growth [2, 3]), and of large-area graphene can be better understood for different growth conditions. Finally, we will present electronic transport data for these well characterized graphene layers. Ultimately, the right growth conditions provide control of the substrate steps and number of graphene layers grown, leading to quality epitaxial graphene devices. [1] PNAS 108, 16900 (2011) [2] Nature Nanotechnology 5, 727 (2010) [3] J. Phys. D: Appl. Phys. 45 154010 (2012)

4:18PM W6.00008 Studies of epitaxial graphene growth on vicinal silicon carbide , M. TIEN HOANG, DAVID B. TORRANCE, HSIN-JU WU, PHILLIP N. FIRST, School of Physics, Georgia Institute of Technology — The growth of epitaxial graphene on SiC has been shown to begin at step edges. Therefore, control of the step-edge density and step bunching on the substrate is important for the production of large-area and high-quality graphene. Additionally, recent experiments [1] have exploited the nucleation of graphene at step edges to produce graphene nanoribbons. Here we study the kinetics of graphene growth as a function of SiC step morphology by using dimple-ground SiC samples. This method of sample preparation allows for the study of a continuous range of miscut angles, prepared under identical growth conditions. Samples are annealed inside a graphite furnace with the flux of silicon controlled via physical confinement and a controlled background pressure of argon or silane. The morphology and graphene coverage of the samples are characterized in situ with LEED and Auger spectroscopy and ex-situ by AFM, SEM, and Raman spectroscopy.

[1] M. Sprinkle, M. Ruan, Y. Hu, J. Hankinson, M. Rubio-Roy, B. Zhang, X. Wu, C. Berger and W. A. de Heer, Nature Nano 5, 727 (2010).

4:30PM W6.00009 Correlating low-energy electron microscopy and micro-Raman imaging of epitaxial graphene on SiC , GUANGJUN CHENG, NIST, IRENE CALIZO, FUI, PATRICK MEADE, GUOWEI HE, Carnegie Mellon University, M.A. REAL, Instituto Nacional de Tecnología Industrial, R.E. ELMQUIST, NIST, R.M. FEENSTRA, Carnegie Mellon University, A.R. HIGHT WALKER, NIST — Several techniques exist for determining the number of graphene layers grown on SiC such as low-energy electron microscopy (LEEM) and Raman spectroscopy. The method which is arguably the most definitive for SiC-grown graphene isLEEM. Low-energy (0 – 10 eV) electrons interfere with the graphene layers, yielding minima in the electron reflectivity vs. energy curve that can be used to determine the layer number.1 LEEM also provides the means of collecting selected-area diffraction on ?m-size surface regions (micro-LEED), giving access to further useful structural information. While Raman spectroscopy is also commonly used to determine graphene layer number on SiC substrates; such measurements have no definitive calibration for large-area graphene on SiC, unlike the case of exfoliated graphene on SiO2. In this talk, results of correlated LEEM/micro-Raman imaging of large-area, mono and multilayer graphene samples are presented. These initial findings show that LEEM can show the contrast between terrace regions and step edges at particular areas of monolayer-graphene surfaces. Micro-Raman imaging of these same locations show Raman shifts in the G' (2D) band. The influence of heterogeneities on electrical behavior of graphene will be discussed. Comparative studies of multilayer graphene are in progress, and will also be reported. 1. H. Hibino, et al., Phys. Rev. B 77, 075413 (2008). 2. L. I. Johansson, et al., Phys. Rev. B 84, 125405 (2011).

4:42PM W6.00010 Electronic and Magnetic Properties of Epitaxial Graphene Sidewall Nanoribbons , JOHN HANKINSON, MING RUAN, JAMES PALMER, WENLONG YU, RUI DONG, CHAO HUAN, ZHIGANG JIANG, Georgia Institute of Technology, School of Physics, CLAIRE BERGER, Georgia Institute of Technology, School of Physics; CNRS Insitute Neel, WALT DE HEER, Georgia Institute of Technology, School of Physics — Confinement controlled sublimation growth of epitaxial graphene on silicon carbide has proven to be a viable method for the production of high quality graphene for use in nanoelectronics. However, patterning of bulk graphene using oxygen plasma leads to rough edges that cause electronic transport in nanostructures to be dominated by edge scattering through localization and quantum dot effects. To overcome this, we have developed a method to create graphene nanostructures directly during growth. For this the SiC substrate is etched to reveal sidewall facets that graphitize more readily than the SiC (0001) face. High temperature growth on such pre-patterned SiC yields graphene nanoribbons only a few tens of nanometers wide with well-controlled edges anchored to the SiC substrate. Here we present these growth techniques as well as experimental evidence showing that the resulting ribbons are metallic with unique spin transport properties.

4:54PM W6.00011 Electron flow in polycrystalline graphene on C-face SiC , CHOCKALINGAM SUBBAIAH, ABHAY PASUPATHY, Department of Physics, Columbia University, NY, JAMES HANNON, RUDOLF TROMP, FRANCES ROSS, IBM T. J. Watson Research Center, Yorktown Heights, NY, SHUAIHUA JI, IBM T. J. Watson Research Center, Yorktown Heights, NY and Department of Physics, Tsinghua University, Beijing, China — Graphene films can be grown both on the Si and C faces of SiC (0001), and the films grown have strikingly different morphologies. Previously, we have used scanning tunneling potentiometry to characterize electron flow in epitaxial graphene grown on the Si face of SiC [1]. Here we will describe recent measurements on nanoscale electronic transport in graphene films grown on the C-face of SiC. In particular, C-face graphene has several topographical features such as pleats, ridges and carbon beads, which determine the quality of the material. We use scanning potentiometry to relate these topographical features to the electron transport in these films at the nanoscale, and discuss the relative impact of different sources of scattering in the epitaxial graphene.

[1] Ji, S.-H. et al. *Nature Mat.* **2012**, 11, 114

5:06PM W6.00012 Electronic Structure of Self-Organized Graphene Nanostructures on SiC(0001)[1] , YUNTAO LI, DAVID B. TORRANCE, JAMES O. ANDREWS, PHILLIP N. FIRST, Georgia Institute of Technology — Graphene nanostructures directly grown on SiC are appealing for their potential application to nanoscale electronic devices. We use different methods to control the step morphology of the SiC(0001) surface in order to guide the growth of graphene, which initiates at step edges. "Sidewall" graphene nanoribbons can be formed on step bunches by limiting the graphene growth. We study such nanostructures via scanning tunneling spectroscopy (STS) in ultra-high vacuum. Significant features are observed in tunneling dI/dV spectra, which we interpret in terms of both strain and quantum confinement. Scanning tunneling microscopy (STM) reveals that the epitaxy between SiC and layer-zero (buffer-layer) graphene on nearby terraces determines the crystalline orientation of the sidewall nanoribbons on step-bunches. We also find a somewhat variable character to the insulating buffer layer, depending on growth conditions and air exposure.

5:18PM W6.00013 The metastable chemical gallery of the oxide of epitaxial graphene at room temperature[1] , SUENNE KIM, SI ZHOU, YIKE HU, CLAIRE BERGER, WALT DE HEER, School of Physics, Georgia Institute of Technology, ANGELO BONGIORNO, School of Chemistry and Biochemistry, Georgia Institute of Technology, ELISA RIEDO, School of Physics, Georgia Institute of Technology — Insights in the chemistry of graphene oxide and its response to external stimuli are crucial to control its electronic and optical properties, thus enabling future applications of this material. Here, we present a combined experimental and density functional theory study concerning the compositional and structural properties of the oxide of epitaxial graphene (OeG) as a function of time[1, 2] and temperature. Our result indicates that OeG synthesized by oxidizing epitaxial graphene grown on SiC via the Hummers method is a metastable material whose structure and chemistry evolve with a notable degree at room temperature. XPS studies reveal, metastable OeG reaches a nearly stable reduced O/C ratio of 0.37 with a featured relaxation time of a month. Initially the most enriched epoxide groups decrease with time while hydroxyl groups increase. In addition to this, further XPS study of OeG as a function of temperature shows heating above 120 C in air can abruptly deteriorate the OeG structure. Our calculations show that the availability of hydrogen atoms could be the key factor in tuning structural and chemical properties at relatively low temperatures. [1] S. Kim et al., Nature Materials 11, 544(2012). [2] Z. Wei et al., Science 328, 1373 (2010).

Session W7 DMP: Focus Session: Carbon Nanotubes: Optical Properties 303 -

2:30PM W7.00001 Tailoring of optoelectronic properties in nanotube-chromophore energy transfer complexes , FRIEDERIKE ERNST, Free University of Berlin, Department of Physics, TIMM HEEK, Free University of Berlin, Department of Chemistry, ANTONIO SETARO, Free University of Berlin, Department of Physics, RAINER HAAG, Free University of Berlin, Department of Chemistry, STEPHANIE REICH, Free University of Berlin, Department of Physics — The formation of nanotube-chromophore energy transfer complexes is of great interest for a number of applications, in particular for energy conversion. Certain chromophores can π - π stack on the nanotube wall: when they are radiatively excited an exciton is formed, which subsequently passes into the carbon nanotube. In the carbon nanotube it can radiatively recombine, emitting a photon characteristic for that nanotube's chirality, or, by applying a voltage, the exciton can be split into an electron and a hole, generating a photocurrent. We demonstrate that the chromophore may be incorporated directly into a surfactant molecule, which then serves two distinct purposes: constituting the photon collecting half of the energy transfer complex, and solubilizing said complexes (Ernst et al., Adv. Funct. Mat 2012). This approach results in temporally stable, biologically compatible solutions which are functional in a wide range of pHs. Alternatively, nanotubes suspended in surfactant micelles can be functionalized with dyes in organic media through micelle swelling. Both processes yield functional nanotube-chromophore complexes with tunable optoelectronic properties, paving the way for scalable optoelectronic devices.

2:42PM W7.00002 Optical transitions of small-diameter carbon nanotubes , TAKASHI KORETSUNE, KOICHIRO KATO, SUSUMU SAITO, Tokyo Institute of Technology — The optical properties for most of carbon nanotubes have been well understood based on the band structure of graphene with some curvature effects. In small-diameter nanotubes, however, it is well known that the curvature drastically affects the electronic structures. Thus, to clarify the optical properties of these small-diameter tubes from first principles, we theoretically study all the small-diameter nanotubes including chiral ones using the density-functional theory, and predict the absorption and emission properties within the single-particle picture. It is found that the wavefunction that originates from M point in the hexagonal Brillouin zone of the graphene plays an key role to understand the optical properties of small-diameter nanotubes.

2:54PM W7.00003 Probing the Free Carrier Doping Effects in Individual Carbon Nanotubes by Optical Spectroscopy , KAIHUI LIU, XIAOPING HONG, FENG WANG, Department of Physics, UC Berkeley, FENG WANG GROUP TEAM — The free carrier (electron or hole) doping in carbon nanotubes will shift their Fermi level, which has dramatically effects in the nanotube electrical transport properties. At the same time, the free carrier doping will also significantly modify the nanotube optical properties. Here we report the development of a new optical spectroscopy method to measure the field-induced change of optical transitions in individual semiconducting and metallic nanotubes. We will discuss the important role of electron-electron interactions to explain our results.

3:06PM W7.00004 Non-Adiabatic/Adiabatic Phase Transitions in Ultra-Clean Suspended Carbon Nanotubes , ROHAN DHALL, SHUN-WEN CHANG, ZUWEI LIU, STEPHEN CRONIN, University of Southern California, Los Angeles — We have recently reported pronounced electron-phonon interactions in suspended, nearly defect-free metallic carbon nanotubes, observed through a Kohn anomaly of greater strength than theoretically predicted. This Kohn Anomaly is accompanied by a gate-induced modulation of the G band Raman intensity. In a systematic study of over 20 quasi-metallic carbon nanotubes devices, we have established a quantitative correlation between the strength of the non-adiabatic Kohn anomaly and the modulation of Raman intensity, indicating that the underlying cause that leads to both these effects is the same. We find that metallic nanotubes can switch between a regime in which the non-adiabatic Kohn anomaly is clearly observed and a regime where the non-adiabatic Kohn anomaly is absent, by varying temperature. In the non-adiabatic regime, an enhancement of the Raman intensity is observed under electrostatic gating. However, in the regime where the non-adiabatic Kohn anomaly is not observed, suppression of the Raman intensity with gating is observed.

3:18PM W7.00005 The Double Resonance Raman Behavior of the Carbon Nanotube 2-D Mode Observed in Samples Enriched in a Single Chirality , STEPHEN DOORN, HAGEN TELG, JUAN DUQUE, Los Alamos National Laboratory, JANINA MAULTZSCH, Technische Universitat Berlin, XIAOMIN TU, MING ZHENG, NIST — Access to carbon nanotube samples enriched in single chiralities allows the observation of new photophysical behaviors obscured or difficult to demonstrate in mixed-chirality ensembles. Recent examples include the observation of strongly asymmetric G-band excitation profiles [1] and the unambiguous demonstration of Raman interference effects [2]. Likewise, the complex response expected for the CNT 2-D mode has not yet been clearly defined because of similar limitations. We present results on the dispersive and resonance behaviors of the 2-D mode obtained from samples enriched in a single chirality. The response will be discussed in the context of the interplay of dispersive effects and resonance with the E11 and E22 transitions. The results will be compared to simulations that include all relevant electronic and phonon bands tied to the double-resonance process. 1. J.G. Duque, et. al., ACS Nano, 5, 5233 (2011). 2. J. G. Duque, et. al., Phys. Rev. Lett., 108, 117404 (2012).

3:30PM W7.00006 Observation and Spectroscopy of a Two-Electron Wigner Molecule in Ultra-Clean Carbon Nanotubes , SHARON PECKER, Weizmann Institute of Science, Rehovot 76100, Israel, FERDINAND KUEMMETH, Niels Bohr Institute, University of Copenhagen, DK-2100 Copenhagen, ANDREA SECCHI, MASSIMO RONTANI, CNR-NANO Research Center S3, 41125 Modena, Italy, DAN RALPH, PAUL MCEUEN, Cornell University, Ithaca, New York 14853, USA, SHAHAL ILANI, Weizmann Institute of Science, Rehovot 76100, Israel — Coulomb interactions can have a decisive effect on the ground state of electronic systems. The simplest system in which interactions can play an interesting role is that of two electrons on a string. In the presence of strong interactions the two electrons are predicted to form a Wigner molecule, separating to the ends of the string due to their mutual repulsion. This spatial structure is believed to be clearly imprinted on the energy spectrum, yet to date a direct measurement of such a spectrum in a controllable one-dimensional setting is still missing. Here we use an ultra-clean suspended carbon nanotube to realize this strongly-correlated system in a tunable potential. Using tunneling spectroscopy we measure the excitation spectra of two interacting carriers, electrons or holes. Seven quantum states are identified, characterized by their spin and isospin quantum numbers. These states are seen to fall into two distinctive multiplets according to their exchange symmetries. Interestingly, we find that the splitting between multiplets is quenched by an order of magnitude compared to the non-interacting value. This quenching is shown to be a direct manifestation of the formation of a strongly-interacting Wigner-molecule ground state.

3:42PM W7.00007 Raman Studies on Chirality Purified Nanotubes: the Chirality Dependence of the G Modes in Semiconducting and Metallic Carbon Nanotubes , HAGEN TELG, JUAN G. DUQUE, Center for Integrated Nanotechnologies, Los Alamos National Laboratory, XIAOMIN TU, Polymers Division, National Institute of Standards and Technology, ERIK H. HAROZ, JUNICHIRO KONO, Department of Electrical and Computer Engineering, Rice University, MING ZHENG, Polymers Division, National Institute of Standards and Technology, STEPHEN K. DOORN, Center for Integrated Nanotechnologies, Los Alamos National Laboratory — We present results from resonant Raman experiments on nanotube samples which are highly enriched in particular chiralities (n,m). Our study includes 14 different semiconducting tube species and 5 different types of metallic armchair (n,n) carbon nanotubes. Results from G peak positions of semiconducting tubes show a significant dependence on tube diameter, chiral angle and family. Considering theoretical predictions we discuss the origin of these dependences with respect to rehybridization of the carbon orbitals, confinement, and electron-electron interactions.[1] As all armchair nanotubes have the same chiral angle and family, results from these samples are restricted to a diameter dependence, which, however, strongly deviates from the diameter dependence of semiconducting tubes. This deviation has been predicted to be associated with non-adiabatic effects and the Kohn-anomaly in metallic carbon nanotubes. We discuss the contribution of these effects on the peak positions of armchair carbon nanotubes based on electro-chemical doping experiments.

3:54PM W7.00008 Surface-enhanced Raman scattering study using metal oxide nanowires grown by chemical vapor deposition[1] , HAE-YOUNG SHIN, Department of Physics, Ewha Womans University, Seoul, 120-750, Korea, HAYOUNG JUNG, MYUNG HWA KIM, Department of Chemistry and Nano Sciences, Ewha Womans University, Seoul, 120-750, Korea, SEOKHYUN YOON, Department of Physics and Department of Chemistry and Nano Sciences, Ewha Womans University, Seoul, 120-750, Korea — We present surface-enhanced Raman scattering (SERS) results using templates made of metal oxide nanowires such as IrO_2 and RuO_2 that were grown by chemical vapor deposition. SERS has been attracting great attention due to its interesting optical behavior and great potential for applications such as chemical sensor, optoelectronic devices, etc. For promising applications utilizing SERS effect, however, there are crucial issues to be resolved. One is to find a way to systematically control 'hot spots' of enhancement and the other is to fully understand the enhancement mechanism. In addition to the well-known two dominant mechanisms, i.e., electromagnetic enhancement mechanism and charge transfer mechanism, we observed that the enhancement greatly depends on the geometry of the nanowires that could suggest another mechanism for SERS. Our results were compared to the FDTD simulations. Our finding may lead us to a way to systematically create, or control hot spots for enhancement of light field using one dimensional nanostructures.

4:06PM W7.00009 Deformations and nanomechanical energy storage in twisted carbon nanotube ropes[1] , DAVID TOMANEK, ZACHARIAS G. FTHENAKIS, Michigan State University, GOTTHARD SEIFERT, DAVID TEICH, TU Dresden — We determine the deformation energetics and energy density of twisted carbon nanotube ropes that effectively constitute a torsional spring. Due to the unprecedented stiffness and resilience of constituent carbon nanotubes, a twisted nanotube rope becomes an efficient energy carrier. Using *ab initio* and parameterized density functional calculations, we identify structural changes in these systems and determine their elastic limits. The deformation energy of twisted nanotube ropes contains contributions associated not only with twisting, but also with stretching, bending and compression of individual nanotubes. We quantify these energy contributions and show that their relative role changes with the number of nanotubes in the rope. The calculated reversible nanomechanical energy storage capacity of carbon nanotube ropes surpasses that of advanced Li-ion batteries by up to a factor of ten.

4:18PM W7.00010 Probing Mechanical Resonances in Cantilevered Coiled Carbon Nanowires , DEEPIKA SAINI, DOYL DICKEL, HERBERT BEHLOW, BALU PILLAI, KEQIN YANG, MALCOLM SKOVE, Clemson University, STEVEN SERKIZ, Savannah River National Laboratory, APPARAO RAO, Clemson University, CLEMSON UNIVERSITY TEAM, SAVANNAH RIVER NATIONAL LABORATORY TEAM — Helically coiled carbon nanowires (CCNW) and nanotubes are promising elements for use in MEMS/NEMS devices and nanorobotics, as nano-inductors and sensors, and for impact protection (e.g. Bell *et al.* 2007 IEEE International Conference, J. Appl. Phys. **100**, 064309 (2006)). Understanding and characterizing their mechanical resonance behavior is essential for the reliability in applications. In this study, we have electrically actuated an individual CCNW in a diving-board cantilever configuration inside a scanning electron microscope, and electrically detected its mechanical resonance modes. By oscillation at low frequency we confirmed the induced-charge actuation mechanism. Among the modes we observed, some appeared to have both axial and lateral components. We also observed closely spaced resonance modes which we attribute to the splitting of degenerate modes, consistent with our COMSOL simulations. We suggest that the helical morphology facilitates inter-mode coupling that results in the observed complex resonance behavior.

4:30PM W7.00011 A Novel Multidirectional, Non-Contact Strain-Sensing Nanocomposite , PAUL WITHEY, Dept. of Physics, University of Houston - Clear Lake, SRIVISHNU VEMURU, SERGEI BACHILO, SATISH NAGARAJAIAH, R. BRUCE WEISMAN, R.E. Smalley Institute for Nanoscale Science and Technology, Rice University — Single-walled carbon nanotubes (SWCNTs) have been successfully dispersed in a polymeric host resulting in the development of a novel strain-sensitive nanocomposite material with promise for scalability. Dubbed "strain paint" this new material when coated onto a surface becomes a smart-skin sensor that can detect strain through load transfer from the polymeric host to embedded SWCNTs. Strain is easily measured in a non-contact manner via laser excitation and detection of the unique near-infrared (NIR) fluorescence spectrum of semiconducting SWCNTs. When strained, each (n, m) SWCNT type exhibits a predictable shift in its NIR fluorescence peak. SWCNTs with high intensity are easily detected in the bulk fluorescence spectrum of raw, unsorted SWCNTs embedded in the polymer. Thin films of the polymer/SWCNT nanocomposite were spin-coated onto substrates, strains typically up to 1% were applied, and strain magnitudes were determined by resistive strain gauges bonded to the coating and substrate. Spectral shifts reveal a linear response to strain with little hysteresis. Two SWCNT types exhibiting opposite spectral shifts with strain were used to improve sensitivity. Strain along any direction is determined simply by adjusting the polarization of the excitation laser.

4:42PM W7.00012 Strong electromechanical coupling in ultra-short carbon nanotube quantum dots , A.C. MCRAE, V. TAYARI, J.O. ISLAND, A.R. CHAMPAGNE, Department of Physics, Concordia University — We study electromechanical coupling in suspended single-wall carbon nanotubes using low-temperature electron transport. Using a feedback-controlled electromigration method [1], we create gate-tuneable single quantum dots whose lengths range from tens of nm down to $\approx$ 3 nm. We observe current suppression of low bias stretching vibron sidebands due to the Franck-Condon blockade, and extract the electron-vibron coupling strength, g, both in the electron and hole doped regimes in the same devices. We observe strong g and are exploring its dependence on mechanical strain in the tube. Due to a positive feedback mechanism between tunneling electrons and bending mode vibrations of the nanotubes, we observe bending mode frequencies up to the 100 GHz range [2]. The bending mode frequency is found to be tuneable by a factor of two by applying electrostatic strain.

4:54PM W7.00013 Origin of Compressive Strain Induced Electromechanical Oscillations in Multiwalled Carbon Nanotubes , SWASTIBRATA BHATTACHARYYA, LAISHRAM SINGH, KARUNA NANDA, ABHISHEK SINGH, Materials Research Centre, Indian Institute of Science, Bangalore 560012, India — We show by the application of compressive strain, the electrical conductance of multiwalled carbon nanotubes can be increased monotonically. The strain induces oscillations in electrical conductance, which can have potential applications in many electromechanical nanodevices. While the monotonic increase in the conduction is due to the intra-wall interaction of the nanotubes, the oscillations are caused by the transition from sp^2 to sp^3 hybridization of the carbon atoms, promoted by the interwall interaction. A series of experimental and theoretical analyses based on density functional tight binding method were performed to confirm this finding. These results opens up a possibility of enhancing the conductance of carbon nanotubes by controlling applied strains.

5:06PM W7.00014 Movement of solid iron nanocrystal through a constriction in the multiwall carbon nanotube[1]

, SINISA COH, WILL GANNETT, ALEX ZETTL, MARVIN L. COHEN, STEVEN G. LOUIE, UC Berkeley, Lawrence Berkeley National Laboratory — It has been known for some time that iron (and some other metals) can move inside multiwall carbon nanotube under the application of an external electrical current to the nanotube (B.C. Regan et al, Nature 428, 924 (2004)). Here we report on finding that a solid piece of iron nanocrystal can move through a constriction in the multiwall carbon nanotube that has a smaller cross-sectional area than the nanocrystal itself. Furthermore, we find that during this entire process the core of the nanocrystal remains solid and that the carbon in the nanotube does not chemically interact with iron. We performed kinetic Monte Carlo simulation based on a first principles density functional theory calculation which can reproduce this experimental finding. Additionally, we discuss the nature of the movement of the iron nanocrystal in our simulation and show why the nanocrystal is able to go through a constriction. Also, we compare the dependence of the nanocrystal speed on applied current with available experimental data. From this comparison we are able to estimate the experimental temperature and infer the magnitude of the electromigration force experienced by individual iron atoms for given applied external current.

Session W8 DCMP: Topological Insulators: Theory III 307 - Maxim Dzero, Kent State University

2:30PM W8.00001 Modifying properties of Chern insulators by time dependent perturbations[1]

, BENJAMIN M. FREGOSO, VICTOR GALITSKI, Joint Quantum Institute and Condensed Matter Theory Center, University of Maryland — We study the quantum dynamics of topological Chern insulators in the presence a time dependent perturbation. We show that and under proper drive conditions they can be turned in to trivial insulators or insulators with a higher Chern number. We discuss signatures of such states in the context of non-adiabatic Thouless pumping. We argue that this provides a way to tune the properties of topological systems.

[1]funding provided by PFC

2:42PM W8.00002 Band Splitting by Period Potential and Resultant Topological Quantum Numbers

, LIANG SUN, Department of Modern Physics, University of Science and Technology of China and National High Magnetic Field Laboratory, Florida State University, KUN YANG, National High Magnetic Field Laboratory, Florida State University — When a Chern band is split into two subbands by breaking lattice translation symmetry that results in a doubled unit cell, the subbands have a set of Chern numbers whose sum has to be the same as the origin band. This, however, does not uniquely determine the Chern numbers of individual subbands. We show how the subbands Chern numbers are related to the structure of the original band, as well as the details of the periodic perturbation. We also generalize this one-to-two band splitting case to one-to-many splitting, as well as the case with time-reversal symmetry, where the Chern number is zero but the bands can carry Z2 topological quantum numbers.

2:54PM W8.00003 Using topological entanglement entropy to identify low energy effective field theories of fractional Chern Insulators

, BRYAN CLARK, Station Q, ANDREI BERNEVIG, Princeton University — The physics of quantum interacting many-body systems allow for a wide variety of phases, whose properties are governed by low energy field theories. In this talk, we write down prototypical parton Chern insulating wave-functions with chern numbers 1,2,3, and 5 and determine their corresponding low energy effective field theory by computing their topological entanglement entropy. We also discuss non-universal aspects of the entanglement entropy including the effect of changing the mass on the corner terms and the slope of the area law.

3:06PM W8.00004 Adiabatic continuity between Hofstadter and Chern insulator states[1]

, YINGHAI WU, JAINENDRA JAIN, Penn State University, KAI SUN, U of Maryland and U of Michigan — We show that the topologically nontrivial bands of Chern insulators are adiabatic cousins of the Landau bands of Hofstadter lattices. We demonstrate adiabatic connection also between several familiar fractional quantum Hall states on Hofstadter lattices and the fractional Chern insulator states in partially filled Chern bands, which implies that they are in fact different manifestations of the same phase. This adiabatic path provides a way of generating many more fractional Chern insulator states and helps clarify that nonuniformity in the distribution of the Berry curvature is responsible for weakening or altogether destroying fractional topological states.

3:18PM W8.00005 Entanglement Entropy at Generalized RK Points of Quantum Dimer Models[1]

, ALEXANDER SELEM, University of California, Berkeley, CHRISTOPHER HERDMAN, University of Vermont, K. BIRGITTA WHALEY, University of California, Berkeley — We study the $n = 2$ Rényi entanglement entropy of the triangular quantum dimer model via Monte Carlo sampling of Rokhsar-Kivelson(RK)-like ground state wavefunctions. Using the construction proposed by Kitaev and Preskill [Phys. Rev. Lett. 96, 110404 (2006)] and an adaptation of the Monte Carlo algorithm described in [Phys. Rev. Lett. 104, 157201 (2010)], we compute the topological entanglement entropy (TEE) at the RK point $\gamma = (1.001 \pm .003) \ln 2$ confirming earlier results. Additionally, we compute the TEE of the ground state of a generalized RK-like Hamiltonian and demonstrate the universality of TEE over a wide range of parameter values within a topologically ordered phase approaching a quantum phase transition. For systems sizes that are accessible numerically, we find that the quantization of TEE depends sensitively on correlations. We characterize corner contributions to the entanglement entropy and show that these are well described by shifts proportional to the number and types of corners in the bipartition.

3:30PM W8.00006 Thermal Instability of Edge States in a 1D Topological Insulator[1]

, OSCAR VIYUELA, ANGEL RIVAS, MIGUEL ANGEL MARTIN-DELGADO, Universidad Complutense de Madrid — The stability of topological phases of matter, also known as topological orders, against thermal noise has provided several surprising results in the context of topological codes used in topological quantum information. However, very little is known about the behavior of a topological insulator (TI) subjected to the disturbing thermal effect of its surrounding environment. This is of great relevance if we want to address key questions such as the robustness of TIs to thermal noise, existence of thermalization processes, use of TIs as platforms for quantum computation, etc. In this work, we have studied the dynamical thermal effects on the protected edge states of a TI when it is considered as an open quantum system in interaction with a noisy environment at a certain temperature T. Let us recall that stable edge states are a defining signature of topological insulators. Outstandingly, we find that the usual protection of edge states against quantum perturbations and randomness is lost in the case of thermal effects, despite the fermion-boson interaction with the thermal environment respects chiral symmetry, which is the symmetry responsible for the protection (robustness) of the edge states in this TI. We are able to compute decay rates for practical implementations. PRB (2012)

[1]Phys. Rev. B 86, 155140 (2012)

3:42PM W8.00007 Torsional Response, bulk-boundary correspondence, and Viscosity in Topological Insulators , TAYLOR HUGHES, ROBERT LEIGH, ONKAR PARRIKAR, University of Illinois at Urbana-Champaign — We discuss the relationship between torsion and visco-elastic response of 2D time-reversal breaking topological insulators. We connect the bulk topological response to a new anomalies in the momentum current of the chiral edge theory that we have determined. We also discuss the implications for spectral flow and the emergence of a chiral-gravity type response theory.

3:54PM W8.00008 Effect of static charge fluctuations on the conduction along the edge of two-dimensional topological insulator[1] , JUKKA VAYRYNEN, MOSHE GOLDSTEIN, LEONID GLAZMAN, Yale University — Static charge disorder may create electron puddles in the bulk of a material which nominally is in the insulating state. A single puddle – quantum dot – coupled to the helical edge of a two-dimensional topological insulator enhances the electron backscattering within the edge. The backscattering rate increases with the electron dwelling time in the dot. While remaining inelastic, the backscattering off a dot may be far more effective than the proposed earlier inelastic processes involving a local scatterer with no internal structure. We find the temperature dependence of the dot-induced correction to the universal conductance of the edge. In addition to the single-dot effect, we calculate the classical temperature-independent conductance correction caused by a weakly conducting bulk. We use our theory to assess the effect of static charge fluctuations in a heterostructure on the edge electron transport in a two-dimensional topological insulator.

[1]The work at Yale University is supported by NSF DMR Grant No. 1206612 and the Simons Foundation.

4:06PM W8.00009 Backscattering Between Helical Edge States via Dynamic Nuclear Polarization , ADRIAN DEL MAESTRO, University of Vermont, TIMO HYART, BERND ROSENOW, Institute for Theoretical Physics, University of Leipzig — We describe how the non-equilibrium spin polarization of one dimensional helical edge states at the boundary of a two dimensional topological insulator can dynamically induce a polarization of nuclei via the hyperfine interaction. When combined with a spatially inhomogeneous Rashba coupling, the resulting steady state polarization of the nuclei produces backscattering between the topologically protected edge states leading to a reduction in the conductance which persists to zero temperature. We study these effects in both short and long edges, uncovering deviations from Ohmic transport at finite temperature and a current noise spectrum which may hold the fingerprints for experimental verification of the backscattering mechanism.

4:18PM W8.00010 Symmetries in the entanglement spectrum and topological phases protected by spatial discrete symmetries , PO-YAO CHANG, SHINSEI RYU, University of Illinois at Urbana-Champaign — We study topological phases protected by spacial (non-local) symmetries using the entanglement spectrum. Exploiting the structure of the entanglement Hamiltonian that can be formulated as the supersymmetric quantum mechanics, we study how a spacial symmetry constrains the entanglement spectrum when the bipartitioning is consistent with the spatial symmetry. Specific examples we took a look at include a reflection symmetric topological insulator composed of two Chern insulators with opposite chiralities in one and two spacial dimensions. For both topological insulators, the edge states in the physical energy spectrum can be gapped while the entangling boundary remains gapless.

4:30PM W8.00011 Interfacial Protection of Topological Surface States in Ultrathin Sb Films , GUANG BIAN, Department of Physics, University of Illinois at Urbana-Champaign, XIAOXIONG WANG, College of Science, Nanjing University of Science and Technology, YANG LIU, THOMAS MILLER, TAI-CHANG CHIANG, Department of Physics, University of Illinois at Urbana-Champaign — Spin-polarized gapless surface states in topological insulators form chiral Dirac cones. When such materials are reduced to thin films, the Dirac states on the two faces of the film can overlap and couple by quantum tunneling, resulting in a thickness-dependent insulating gap at the Dirac point. Calculations for a freestanding Sb film with a thickness of four atomic bilayers yield a gap of 36 meV, yet angle-resolved photoemission measurements of a film grown on Si(111) reveal no gap formation. The surprisingly robust Dirac cone is explained by calculations in terms of interfacial interaction. Our work suggests that quantum tunneling, an intrinsic property dependent on the film thickness, and substrate bonding, an extrinsic factor amenable to interfacial engineering, can be effectively manipulated to achieve desired electronic and spintronic properties of topological thin films.

4:42PM W8.00012 ABSTRACT WITHDRAWN –

4:54PM W8.00013 Controlling topological insulating phases by tuning the coupling strength of Dirac fermions in chalcogenide ternary compounds , JEONGWOO KIM, JINWOONG KIM, SEUNG-HOON JHI, Pohang University of Science and Technology — Chalcogenide ternary compounds such as $Ge_2Sb_2Te_5$ are considered as superlattice of topological insulating layers and band insulating layers. Using first-principles methods and a model Hamiltonian, we study the topological phases of the chalcogen compounds arising from the interactions of Dirac fermionic states existing at the interfaces between the topological insulating and band insulating layers. We particularly investigate the interactions of Dirac fermions upon varying the thickness of band insulating layers or upon introducing magnetic impurities in the layers. We observe a jump of Dirac cones from one time-reversal invariant momentum to another when the thickness is changed. We also discuss the degree of freedom in the spin helicity of the Dirac fermions and how it limits the topological phases.

5:06PM W8.00014 The space group classification of topological band insulators[1] , VLADIMIR JURICIC, Lorentz-Institute for Theoretical Physics, Leiden University, ROBERT-JAN SLAGER, Lorentz-Institute for Theoretical Physics, Leiden University, The Netherlands, ANDREJ MESAROS, Department of Physics, Boston College, USA, JAN ZAANEN, Lorentz-Institute for Theoretical Physics, Leiden University, The Netherlands — The existing classification of topological band insulators(TBIs) departs from time-reversal symmetry, but the role of the crystal symmetries in the physics of these topological states remained elusive. I will discuss the classification of TBIs protected not only by time-reversal, but also by space group symmetries [1]. I find three broad classes of topological states: (a) Γ-states robust against general time-reversal invariant perturbations; (b) Translationally-active states protected from elastic scattering, but susceptible to topological crystalline disorder; (c) Valley topological insulators sensitive to the effects of non-topological and crystalline disorder. These three classes give rise to 18 different two-dimensional, and, at least 70 three-dimensional TBIs. I will show how some of these topological states can be realized in two dimensions when tight-binding M-B model, originally introduced for HgTe quantum wells, is generalized to include longer-range hoppings. Finally, experimental implications of our classification scheme with an emphasis on topological states in Sn-based materials will be discussed.

5:18PM W8.00015 Why is the bulk resistivity of topological insulators so small? , TIANRAN CHEN, BRIAN SKINNER, BORIS SHKLOVSKII, Fine Theoretical Physics Institute, University of Minnesota — As-grown topological insulators (TIs) are typically heavily-doped n-type crystals. Compensation by acceptors is used to move the Fermi level to the middle of the band gap, but even then TIs have a frustratingly small bulk resistivity. We show that this small resistivity is the result of band bending by poorly screened fluctuations in the random Coulomb potential. Using numerical simulations of a completely compensated TI, we find that the bulk resistivity has an activation energy of just 0.15 times the band gap, in good agreement with experimental data. At lower temperatures activated transport crosses over to variable range hopping with a relatively large localization length.

Session W9 DCMP DPOLY: Invited Session: Physics of Next Generation DNA Sequencing 308

- Alexander V. Balatsky, Los Alamos National Laboratory

2:30PM W9.00001 Detection and interrogation of biomolecules via nanoscale probes: From fundamental physics to DNA sequencing , MICHAEL ZWOLAK[1], Oregon State University — A rapid and low-cost method to sequence DNA would revolutionize personalized medicine [1], where genetic information is used to diagnose, treat, and prevent diseases. There is a longstanding interest in nanopores as a platform for rapid interrogation of single DNA molecules. I will discuss a sequencing protocol based on the measurement of transverse electronic currents during the translocation of single-stranded DNA through nanopores. Using molecular dynamics simulations coupled to quantum mechanical calculations of the tunneling current, I will show that the DNA nucleotides are predicted to have distinguishable electronic signatures in experimentally realizable systems. Several recent experiments support our theoretical predictions. In addition to their possible impact in medicine and biology, the above methods offer ideal test beds to study open scientific issues in the relatively unexplored area at the interface between solids, liquids, and biomolecules at the nanometer length scale [1].

3:06PM W9.00002 Single Molecule Electrical Sequencing of DNA and RNA , MASATERU TANIGUCHI, The Institute of Scientific and Industrial Research, Osaka University — Gating nanopore devices are composed of nanopores with embedded nanoelectrodes, and they are expected to be one of the core devices used to realize label-free, low-cost DNA sequencing, subsequently leading to $1000-genome sequencing technologies. The operating principle of these nanodevices is based on identifying single base molecules of single DNA passing through a nanopore using a tunneling current between nanoelectrodes. We successfully identified single base molecules of DNA and RNA using tunneling currents. To make gating nanopore devices fit for practical use, core technologies should be integrated on one device chip. One core technology is the identification of single DNA and RNA composed of many base molecules using tunneling currents. We have succeeded in the single-molecule electrical sequencing of DNA and RNA formed by 3 and 7 base molecules, respectively, using a hybrid method of identifying single base molecules via a tunnelling current and random sequencing. A method that controls the speed of a single DNA passing through a nanopore is one core technology that determines the speed and accuracy of sequencing. We successfully developed a method that controls the translocation speed of a single DNA by three orders of magnitude using a voltage between nanoelectrodes.

3:42PM W9.00003 DNA Electronic Fingerprints by Local Spectroscopy on Graphene[1] , ALEXANDER BALATSKY[2], Los Alamos National Laboratory, NORDITA — Working and scalable alternatives to the conventional chemical methods of DNA sequencing that are based on electronic/ionic signatures would revolutionize the field of sequencing. The approach of a single molecule imaging and spectroscopy with unprecedented resolution, achieved by Scanning Tunneling Spectroscopy (STS) and nanopore electronics could enable this revolution. We use the data from our group [1] and others in applying this local scanning tunneling microscopy and illustrate possibilities of electronic sequencing of freeze dried deposits on graphene. We will present two types of calculated fingerprints: first in Local Density of States (LDOS) of DNA nucleotide bases (A,C,G,T) deposited on graphene[2]. Significant base-dependent features in the LDOS in an energy range within few eV of the Fermi level were found in our calculations. These features can serve as electronic fingerprints for the identification of individual bases in STS. In the second approach we present calculated base dependent electronic transverse conductance as DNA translocates through the graphene nanopore. Thus we argue that the fingerprints of DNA-graphene hybrid structures may provide an alternative route to DNA sequencing using STS.

4:18PM W9.00004 Edge-functionalization aspects in DNA sequencing with graphene nanoelectrodes , RALPH H. SCHEICHER, Uppsala University — Slowing down DNA translocation and achieving single-nucleobase resolution are major issues for the realization of nanopore-based sequencing [see, e.g., our review in J Mater Sci 47, 7439 (2012)]. On the one hand, complex functionalization of nanopore-embedded gold electrodes with one [J Phys Chem C 112, 3456 (2008)] or two types of molecules [Appl Phys Lett 100, 023701 (2012)] might address both these issues simultaneously, but is difficult to implement in practice. On the other hand, the fabrication process of nano-gaps or -pores in graphene could readily introduce more simple edge-functionalization in the form of hydrogen atoms saturating the dangling bonds resulting from cutting the carbon network. — A range of computational tools can be used to theoretically determine the electronic structure and quantum transport properties of individual nucleotides or short DNA strands in realistic models of nanopore-based sequencing device setups. In this manner, we were able to explore the effects of the temporary formation of weak H-bonds between hydrogenated graphene edges and suitable atomic sites in the nucleotides on the dynamical [Adv Funct Mater 21, 2674 (2011)] and static [Nano Lett 11, 1941 (2011)] properties of this system. Recently also more ambitious functionalization schemes for graphene edges [arXiv:1202.3040] as well as a promising bilayer graphene setup [arXiv:1206.4199] were investigated by us. Finally, there might be a particular appeal to use graphene edges terminated with nitrogen atoms, and we have studied some of the benefits that this type of edge-functionalization could offer for the purpose of DNA sequencing. — Funding provided by the Swedish Research Council (VR), the Swedish Foundation for International Cooperation in Research and Higher Education (STINT), and the Carl Trygger Foundation for Scientific Research.

4:54PM W9.00005 Reading DNA at single-nucleotide resolution with a mutant MspA nanopore , JENS GUNDLACH, U Washington — No abstract available.

Session W10 DCMP DAMOP: Invited Session: Many Body Physics in Quantum Gases 309 - Paul Goldbart, Georgia Institute of Technology

2:30PM W10.00001 Magnetic correlations and density ordering in quantum gases , TILMAN ESSLINGER, ETH Zurich — Quantum gases provide a unique avenue to study fundamental concepts in quantum many-body physics. In our research we go beyond the class of atomic many-body systems that are governed by the interplay between kinetic energy and contact interactions. Using a tunable geometry optical lattice, we create hexagonal, dimerized or anisotropic lattice structures [1]. This allows us to control the exchange energy in a repulsive two-component Fermi gas and study the formation of magnetic correlations. In a different approach, we place a Bose-Einstein condensate into a dynamic lattice potential created by the interaction of the atoms with the vacuum field of an optical cavity. This gives rise to long-range interactions, which result in a transition to a supersolid phase with a broken discrete symmetry, preceded by a mode softening [2]. In the talk I will introduce our experiments and discuss recent results.

3:06PM W10.00002 Dissipative quantum glasses in optical cavities , PHILIPP STRACK, Harvard University — Strong light-matter interactions offer the prospects of quantum realizations of soft matter phases. We discuss how glassy phases of matter may appear with atomic ensembles in multi-mode optical cavities. Our computations show that some of these quantum optical glasses have no direct analogue in condensed matter realizations due to the photon-mediated long-range interactions and the nature of the driving and dissipation that occurs in the many-body cavity QED systems.

3:42PM W10.00003 Non-Equilibrium Dynamics of Ultra Cold Atoms and Effective Spin Models in Optical Cavities , JOE BHASEEN, King's College London — There has been spectacular progress in exploring the properties of ultra cold atoms using light. Recent experiments [1] on Bose–Einstein condensates in optical cavities have reported a novel self-organization transition of the atom-light system. This coincides with the superradiance transition in an effective non-equilibrium Dicke model, describing two-level "spins" coupled to light. The light leaking out of the cavity provides valuable information on this hybrid matter-light system, and the time-dependent nature of the experiments demands consideration of the associated dynamics. We present a rich dynamical phase diagram [2,3], accessible by quench experiments, with distinct regimes of collective dynamics separated by non-equilibrium phase transitions. These findings open new directions to study the emergent dynamics and non-equilibrium phase transitions of quantum many body systems and effective spin models.

In collaboration with J. Keeling (University of St Andrews), J. Mayoh (University of Cambridge) and B. D. Simons (University of Cambridge).

4:18PM W10.00004 Heavy Solitons in a Fermionic Superfluid , MARTIN W. ZWIERLEIN, Massachusetts Institute of Technology — Topological excitations are found throughout nature, in proteins and DNA, as dislocations in crystals, as vortices and solitons in superfluids and superconductors, and generally in the wake of symmetry-breaking phase transitions. In fermionic systems, topological defects may provide bound states for fermions that often play a crucial role for the system's transport properties. Famous examples are Andreev bound states inside vortex cores, fractionally charged solitons in relativistic quantum field theory, and the spinless charged solitons responsible for the high conductivity of polymers. However, the free motion of topological defects in electronic systems is hindered by pinning at impurities. We have created long-lived solitons in a strongly interacting fermionic superfluid by imprinting a phase step into the superfluid wavefunction, and directly observed their oscillatory motion in the trapped superfluid. As the interactions are tuned from the regime of Bose-Einstein condensation (BEC) of tightly bound molecules towards the Bardeen-Cooper-Schrieffer (BCS) limit of long-range Cooper pairs, the effective mass of the solitons increases dramatically to more than 200 times their bare mass. This signals their filling with Andreev states and strong quantum fluctuations. For the unitary Fermi gas, the mass enhancement is more than fifty times larger than expectations from mean-field Bogoliubov-de Gennes theory. Our work paves the way towards the experimental study and control of Andreev bound states in ultracold atomic gases. In the presence of spin imbalance, the solitons created in our experiment represent one limit of the long sought-after Fulde-Ferrell-Larkin-Ovchinnikov (FFLO) state of mobile Cooper pairs.

4:54PM W10.00005 Collective Dipole Oscillations of a Spin-Orbit Coupled Bose-Einstein Condensate , SHUAI CHEN, Hefei National Lab for Physical Sciences at Microscale and Department of Modern Physics, University of Science and Technology of China, Hefei, 230026 — We present an experimental study of the collective dipole oscillation of a spin-orbit coupled Bose-Einstein condensate in a harmonic trap. The dynamics of the center-of-mass dipole oscillation is studied in a broad parameter region as a function of spin-orbit coupling parameters as well as the oscillation amplitude. The anharmonic properties beyond the effective-mass approximation are revealed, such as the amplitude-dependent frequency and finite oscillation frequency at a place with a divergent effective mass. These anharmonic behaviors agree quantitatively with variational wave-function calculations. Moreover, we experimentally demonstrate a unique feature of the spin-orbit coupled system predicted by a sum-rule approach, stating that spin polarization susceptibility—a static physical quantity—can be measured via the dynamics of dipole oscillation. The divergence of polarization susceptibility is observed at the quantum phase transition that separates the magnetic nonzero-momentum condensate from the nonmagnetic zero-momentum phase. The good agreement between the experimental and theoretical results provides a benchmark for recently developed theoretical approaches.

Session W11 DPOLY FIAP: Invited Session: Polymer Based Soft Materials: Industrial Applications 310 - Miriam Rafailovich, State University of New York, Stony Brook

2:30PM W11.00001 Tuning the Photoinduced Motion of Glassy Azobenzene Polymers and Networks[1]

, R.A. VAIA, Air Force Research Laboratory — Continual innovation at the forefront of soft-matter, in areas such as liquid crystal networks, nano-composites and bio-molecules, is providing exciting opportunities to create smart materials systems that exhibit a controlled, reproducible and reversible modulation of physical properties. These material systems evoke the adaptivity of natural organisms, and inspire radical aerospace notions. A key example is photo-responsive polymers, which convert a light stimulus input into a mechanical output (work). Photoinduced conformational changes, such as within azobenzene, dictate molecular-level distortions that summate into a macroscopic strain, which often manifests as a shape change or motion. The transduction of the molecular-level response to a macroscale effect is regulated by mesoscopic features, such as chain packing, free volume, and local molecular order - factors which depend on chemical composition as well as the process history of the material. For example, physical aging increases the density of the glass, reduces local free volume, and thus decreases the minima in local conformation space which strongly influences the azobenzene photochemistry (trans-cis-trans isomerization). The subsequent change in the energy landscape of the system reduces the fraction of azobenzene able to undergo reconfiguration as well as increases the probability that those photoinduced conformations will relax back to the initial local environment. The result is a tuning of the magnitude of macroscopic strain and the ability to shift from shape fixing to shape recovery, respectively.

3:06PM W11.00002 Using Modeling to Design new Rheology Modifiers for Paints[1]

, VALERIY GINZBURG, Dow Chemical Company — Since their invention in 1970-s, hydrophobically ethoxylated urethanes (HEUR) have been actively used as rheology modifiers for paints. Thermodynamic and rheological behavior of HEUR molecules in aqueous solutions is now very well understood and is based on the concept of transient network (TN), where the association of hydrophobic groups into networks of flower micelles causes viscosity to increase dramatically as function of polymer concentration. The behavior of complex mixtures containing water, HEUR, and latex ("binder") particles, however, is understood less well, even though it has utmost importance in the paint formulation design. In this talk, we discuss how the adsorption of HEUR chains onto latex particles results in formation of complex viscoelastic networks with temporary bridges between particles. We then utilize Self-Consistent Field Theory (SCFT) model to compute effective adsorption isotherms (thickener-on-latex) and develop a rheological theory describing steady-shear viscosity of such mixtures. The model is able to qualitatively describe many important features of the water/latex/HEUR mixtures, such as strong shear thinning. The proposed approach could potentially lead to the design of new HEUR structures with improved rheological performance.

, WILSON LEE, Estee Lauder Co. — No abstract available.

4:18PM W11.00004 Starch Applications for Delivery Systems[1]

, JASON LI, Ingredion — Starch is one of the most abundant and economical renewable biopolymers in nature. Starch molecules are high molecular weight polymers of D-glucose linked by α-(1,4) and α-(1,6) glycosidic bonds, forming linear (amylose) and branched (amylopectin) structures. Octenyl succinic anhydride modified starches (OSA-starch) are designed by carefully choosing a proper starch source, path and degree of modification. This enables emulsion and micro-encapsulation delivery systems for oil based flavors, micronutrients, fragrance, and pharmaceutical actives. A large percentage of flavors are encapsulated by spray drying in today's industry due to its high throughput. However, spray drying encapsulation faces constant challenges with retention of volatile compounds, oxidation of sensitive compound, and manufacturing yield. Specialty OSA-starches were developed suitable for the complex dynamics in spray drying and to provide high encapsulation efficiency and high microcapsule quality. The OSA starch surface activity, low viscosity and film forming capability contribute to high volatile retention and low active oxidation. OSA starches exhibit superior performance, especially in high solids and high oil load encapsulations compared with other hydrocolloids.

4:54PM W11.00005 New Developments in Brominated and Halogen-Free Flame Retardants[1]

, A. DESIKAN, ICL-IP America, 430 Saw Mill Rriver Rd., Ardsley, NY, 10502, USA — With a broad portfolio of brominated, organophosphorus and inorganic flame retardants, ICL Industrial Products (ICL-IP) is engaged in the development of new flame retardants by exploiting the synergism between bromine based, phosphorus based and other halogen-free flame retardants. ICL-IP is also focusing on the development of polymeric and reactive flame retardants. This presentation will give examples of existing and new polymeric and reactive products for applications in thermoplastics, thermosets and polyurethane foam. This presentation will also show examples of phosphorus-bromine synergism allowing partial or complete elimination of antimony trioxide in many thermoplastics for electronic applications. New synergistic combinations of magnesium hydroxide with phosphorus and other halogen-free FRs will be presented.

2:30PM W12.00001 Thermoelectric performance of chemically exfoliated n-Bi_2Te_3

, POOJA PUNEET, MEHMET KARAKAYA, RAMAKRISHNA PODILA, SONG ZHU, JIAN HE, TERRY TRITT, MALCOLM SKOVE, APPARAO RAO, Department of Physics and Astronomy, Clemson University, Clemson SC, USA 29634 — Bi_2Te_3 based thermoelectric (TE) devices are of interest because of their high thermoelectric figure of merit (ZT) near room temperature, and ability to be utilized in both refrigeration and power generation modes. Recently, nano-structuring has shown promise in improving the TE performance of p-type Bi_2Te_3, however n-type counterparts are still lagging in this respect. Here, we display high ZT values ($\sim$ 0.9) in exfoliated n-Bi_2Te_3 at elevated temperatures (400– 500 K). The chemically exfoliated samples were prepared by an ultra-sonication technique with subsequent spark plasma sintering to obtain dense pellets. Our transport results showed improved compatibility and a shift in the ZT maximum towards a higher temperature ($\sim$ 430 K) than commercially available ingots. The experimental details and transport data will be discussed within the frame work of exfoliation-induced structural modifications.

2:42PM W12.00002 Room Temperature Thermoelectric Properties of Porous BiSbTe Thin Films , JANE CORNETT, ODED RABIN, University of Maryland — $Bi_{(2-x)}Sb_xTe_3$ is currently the best known room temperature p-type thermoelectric material, with a ZT value ~ 0.75. We report synthesis of $Bi_{(2-x)}Sb_xTe_3$ thin films via pulsed laser deposition using a $Bi_{0.5}Sb_{1.5}Te_3$ target. We have investigated the effect of deposition parameters, including substrate, laser power and inert gas pressure, and annealing conditions on the microstructure, composition and thermoelectric properties of the films. We find a strong dependence of film characteristics on background pressure: The Sb content of the films increases with deposition pressure. Low pressure (1-2 mTorr) depositions yield highly conducting and amorphous films deficient in Te. In addition, we will present a comparison of the thermoelectric properties of porous and dense BiSbTe films, to evaluate film porosity as a means for increasing confinement and improving the thermoelectric power factor.

2:54PM W12.00003 Thermoelectric properties of electrolessly etched silicon nanowire arrays , JYOTHI SADHU, HONGXIANG TIAN, JUN MA, KRISHNA VALAVALA, PIYUSH SINGH, SANJIV SINHA, Dept of Mechanical Science and Engg, Urbana — Patterning silicon as nanowires with roughened sidewalls enhances the thermoelectric figure-of-merit ZT by order of magnitude compared to the bulk at 300 K [1]. The enhancement is mainly achieved by the remarkable reduction in the thermal conductivity below 5 W/mK at 300 K with only a negligible effect on the power factor of these nanowires. While the focus remained on understanding the implications of surface disorder on the thermal conductivity, the phonon transport effects on the Seebeck coefficient of these wires remains largely unexplored. We developed an electroless etching technique to generate nanowire arrays (NWAs) with controlled surface roughness, morphology, porosity and doping [2]. We conduct the simultaneous device-level measurements of the Seebeck coefficient and thermal conductivity of the NWAs using frequency domain techniques. We observe that nano-structuring quenches the phonon drag [3] in NWAs thereby reducing the Seebeck coefficient by $\sim$25% compared to the bulk at degenerate doping levels. Further, we observe that the sidewall roughness greater than 3 nm roughness height lowers the thermal conductivity 75% below the Casimir limit [4] with 10% - 15% increase in Seebeck coefficient. The porous NWAs show thermal conductivity close to the amorphous limit of Si with enhancement in the Seebeck coefficient primarily due to the carrier depletion. References: [1] A. I. Hochbaum et al, Nature 451, 163-167 (2008). [2] K. Balasundaram et. al., Nanotechnology 23, 305304 (2012). [3] C. Herring, Phys. Rev. 96, 1163 (1954). [4] H. G. B. Casimir, Physica 5, 495 (1938).

3:06PM W12.00004 Low temperature phonon boundary scattering in slightly rough Silicon nanowires , MARC GHOSSOUB, KRISHNA VALAVALA, MYUNGHOON SEONG, BRUNO AZEREDO, JYOTHI S. SADHU, SANJIV SINHA, Department of Mechanical Science and Engineering - University of Illinois at Urbana-Champaign — Nanostructured materials [1-3] have lower thermal conductivities than the bulk and are promising candidates for thermoelectric applications. In particular, measurements on single silicon nanowires show a reduction in thermal conductivity below the Casimir limit. This reduction increases with surface roughness [4] but the trend and its connection to phonon boundary scattering are still elusive. Here, we measure the thermal conductivity of single silicon nanowires fabricated using metal-assisted chemical etching. High resolution TEM imaging shows crystalline wires with slightly rough surfaces. Their statistical correlation lengths (5-15 nm) and RMS heights (0.8-1.5 nm) are in a range where perturbation-based wave scattering theory is still applicable. We use the thermal conductivity data to extract the frequency dependence of phonon boundary scattering at low temperatures (10-40 K) and show agreement with multiple scattering theory. This work provides insight into enhancing the thermoelectric performance of nanostructures. 1-A. I. Hochbaum et al, Nature Lett. 451, 163-167 (2008). 2-A. J. Minnich et al, Energy Environ. Sci. 2, 466-479 (2009). 3-L. Shi, Nanoscale Microscale Thermophys. Eng. 16, 79–116 (2012). 4-J. Lim et al, Nano Lett. 12, 2475−2482 (2012).

3:18PM W12.00005 Thermal conductivity of disordered porous Silicon , GIUSEPPE ROMANO, MIT, JEFFREY GROSSMAN, Department of Materials Science and Engineering, MIT — Nanostructuring bulk materials is a promising approach for engineering high-efficiency thermoelectric devices thanks to its ability to decoupling the thermal and electrical transport. Among different approaches, porous Silicon has been attracting much attention due to its ability of strongly suppressing heat transport. Recent experimental works show that classical size effects of phonons can be further enhanced by having staggered pores, as opposed to the aligned pores case. Motivated by these results, we solve the phonon Boltzmann Transport Equation to compute heat transport across an arbitrary pores arrangement. The model has been discretized by means of the Discontinuous Galerkin method, which allows complex simulation domains. We focus on triangular, circle and square pores where the orientation is allowed to change stochastically. In order to compute the ZT, the electrical conductivity and the Seebeck coefficients are computed by means of diffusive theory. Our main finding is that pore disorder can play a crucial rule in optimizing thermoelectric materials. Indeed, in the special case of triangular pores we predict an increasing in ZT of up to ten times the value found for the aligned case.

3:30PM W12.00006 Strong suppression of near-surface thermal transport by metal-assisted chemical etching of Si , JOSEPH FESER, DAVID CAHILL, Department of Materials Science and Engineering, U. Illinois, Urbana — Recently, we reported that the thermal conductivity of Si nanowire arrays roughened by metal-assisted chemical etching (MAC-etch) is strongly correlated to both the magnitude of the roughness and a broadening of the one-phonon Raman linewidth. We hypothesized that microstructural disorder induced by the etching chemistry leads to changes in the Raman linewidth and reduced thermal conductivity. Here, we simplify the study of such effects by chemically roughening Si wafers instead of nanowires. We have studied the effects of various roughening procedures on the near-surface thermal transport properties using time-domain thermoreflectance. We find that the thermal conductance of the near-surface region is systematically reduced by the MAC-etch process, despite the expectation that pristine roughened surfaces should have increased conductance due to enhanced surface area. In addition, highly roughened surfaces show strong picosecond acoustic echoes with reflection coefficient indicative of a soft interface. These features are consistent with the presence of strong disorder or nanoporosity in the near-surface region created by the MAC-etch process.

3:42PM W12.00007 Evaluating Heat Dissipation in Si/SiGe Nanostructures using Raman Scattering , SELINA MALA, LEONID TSYBESKOV, New Jersey Institute of Technology, D.J. LOCKWOOD COLLABORATION, J.-M. BARIBEAU COLLABORATION, X. WU COLLABORATION — Bulk SiGe alloys and SiGe nanostructures exhibit relatively low thermal conductivity and have found applications in efficient thermoelectric devices. Practical measurements of thermal conductivity involve a sophisticated device design, which may not be applicable to sub-micrometer structures and devices. Raman scattering can be used to measure local temperature with a high accuracy, and it allows calculations of thermal conductivity. In this work, we present Raman data obtained for three sets of samples: partially-relaxed SiGe alloy layers with thickness close to 50 nm; planar Si/SiGe superlattices (SL) with $\sim$ 30% Ge content; and three-dimensional (3D) Si/SiGe cluster multilayers with different Ge concentration and degrees of vertical self-ordering. Despite a high signal-to-noise ratio (better than 1000 to 1), quantitative analysis of Raman spectra requires proper baseline modeling and subtraction. By measuring multi-modal Stokes/anti-Stokes Raman signals and performing base line correction, we calculate local temperatures and develop a model of heat dissipation in the different SiGe and Si/SiGe nanostructures.

3:54PM W12.00008 Probing Large-Wavevector Phonons in Silicon Nanomembranes using X-ray Thermal Diffuse Scattering

, GOKUL GOPALAKRISHNAN, University of Wisconsin - Madison, MARTIN HOLT, Argonne National Laboratory, KYLE MCELHINNY, University of Wisconsin - Madison, DAVID CZAPLEWSKI, Argonne National Laboratory, PAUL EVANS, University of Wisconsin - Madison — Phonons play a critical role in determining physical properties of crystalline materials. Phonon dispersions can be modified via nanoscale engineering, by introducing boundaries separated by distances comparable to phonon wavelengths. In free-standing nanowires and sheets, theoretical and experimental investigations have been largely restricted to studying small-wavevector phonons lying within the central 1% of the Brillouin Zone. Large-wavevector phonons, important for transport in nanostructures, cannot be modeled using continuum physics, and are difficult to probe using conventional optical techniques. Synchrotron x-ray thermal diffuse scattering (TDS) collects information from the scattering of x-rays by phonons with wavevectors spanning the entire Brillouin zone. We adopt this technique to probe the dispersion of large-wavevector acoustic phonons in the nanoscale regime. TDS measurements were performed on silicon nanomembranes, from 315 nm thick sheets exhibiting bulk Si dispersions, to membranes as thin as 6 nm, where deviations from bulk-like behavior are observed. Systematic examinations of the variation of scattered intensity with crystallographic orientation, wavevector, and membrane thickness will be presented.

4:06PM W12.00009 Atomistic Monte Carlo simulations of heat transport in Si and SiGe nanostructured materials[1]

, IVANA SAVIC[2], Department of Chemistry, University of California at Davis, Davis, USA, DAVIDE DONADIO, Max Planck Institute for Polymer Research, Mainz, Germany, EAMONN MURRAY, Department of Chemistry, University of California at Davis, Davis, USA, FRANCOIS GYGI, Department of Computer Science, University of California at Davis, Davis, USA, GIULIA GALLI, Department of Chemistry and Physics, University of California at Davis, Davis, USA — Efficient thermoelectric energy conversion depends on the design of materials with low thermal conductivity and/or high electrical conductivity and Seebeck coefficient [1]. Semiconducting nanostructured materials are promising candidates to exhibit high thermoelectric efficiency, as they may have much lower thermal conductivity than their bulk counterparts [1]. Atomistic simulations capable of handling large samples and describing accurately phonon dispersions and lifetimes at the nanoscale could greatly advance our understanding of heat transport in such materials [2]. We will present an atomistic Monte Carlo method to solve the Boltzmann transport equation [3] that enables the computation of the thermal conductivity of large systems with both empirical and first principles Hamiltonians (e.g. up to several thousand atoms in the case of Tersoff potentials). We will demonstrate how this new approach allows one to rationalize trends in the thermal conductivity of a range of Si and SiGe based nanostructures, as a function of size, dimensionality and morphology [3]. [1] See e.g. A. J. Minnich et al. Energy Environ. Sci. 2, 466 (2009). [2] Y. He, I. Savic, D. Donadio, and G. Galli, accepted in Phys. Chem. Chem. Phys. [3] I. Savic, D. Donadio, F. Gygi, and G. Galli, submitted.

4:18PM W12.00010 Thermoelectric Power Factor Engineering of Low-Dimensional and Nanocomposite Si Nanostructures

, NEOPHYTOS NEOPHYTOU, HANS KOSINA, Tecnical University of Vienna, Institute for Microelectronics — By employing nanostructured materials the thermoelectric figure of merit ZT has been raised to unprecedented large values, with a present record of ZT=2.4. Even in traditionally poor thermoelectric materials such as Si, high ZT values were achieved. The improvement was a result of the drastic reduction in the thermal conductivity, which could be suppressed close or even below the amorphous limit. Since thermal conductivity reduction is reaching its limits, additional benefits resulting from electronic structure engineering have to be investigated. In this work we theoretically provide design directions for the thermoelectric power factor (comprising Seebeck coefficient and electrical conductivity) and thermal conductivity in nanostructured Si channels. We consider 1D nanowires, 2D ultra-thin layers, and nanocomposite Si-based materials. We employ semiclassical Boltzmann transport and use both atomistic and continuum calculations for the electronic and phononic structure of the materials. This study examines how length scale can be exploited as a degree of freedom in designing the nanoscale thermoelectric material properties.

4:30PM W12.00011 Enhanced Power Factor in Strained Silicon Nanomesh Thin Film

, BINGYUAN HUANG, XIAO GUO, DUCKHYUN LEE, ANISH TUTEJA, PETER GREEN, AKRAM BOUKAI, University of Michigan - Ann Arbor — The power factor $S^2\sigma$ (S is the Seebeck coefficient and σ is the electrical conductivity) of n-type silicon thin films is increased by utilizing both tensile lattice strain and nanomesh structures. The tensile strained lattice in n-type silicon splits the six-fold degenerate conduction band, which results in reduced inter-valley scattering and consequently enhanced electron mobility. The nanomesh feature structure decreases the thermal conductivity due to increased phonon scattering. The nanomesh was patterned onto both strained and unstrained silicon on insulator (SOI) using reactive ion etching with self-assembled block copolymers as masks. The Seebeck coefficient and electrical conductivity measurements were then performed on both strained and unstrained nanomesh SOI in vacuum over a wide temperature range. Increases in S and σ were observed and an enhanced power factor was obtained.

4:42PM W12.00012 Studies on Seebeck Coefficient of Individual Bismuth Telluride Nanotube[1]

, DUKSOO KIM, Department of Electrical Engineering, The Penn State Univ., RENZHONG DU, Department of Physics, The Penn State Univ., YUEWEI YIN, SINING DONG, XIAOGUANG LI, Hefei National Laboratory for Physical Sciences at Microscale, University of Science and Technology of China, QI LI, Department of Physics, The Penn State Univ., SRINIVAS TADIGADAPA, Department of Electrical Engineering, The Penn State Univ. — We have studied on Seebeck coefficient (S) of freestanding individual Bismuth Telluride nanotubes using micro-fabricated thermoelectric workbench at the temperatures from 300 K to 25 K. The thermoelectric workbench is composed of three main elements: heater, thermocouple, and platinum pad. A polysilicon-gold thermocouple accurately measures the temperature, arising from the heat generated at the tips of the test sites from the polysilicon heater located 2 μm apart from the thermocouple. Platinum pads placed on top of the heater and thermocouple structures and electrically isolated from these constitute S measurement circuit. IPA solution containing Bi_2Te_3 nanotubes was drop-cast on the workbench and the Ebeam Induced Deposition of platinum was used to improve the electrical and thermal contacts between nanotube and platinum pads. The inner and outer diameter of nanotube is 50 nm and 70 nm, respectively. The sign of obtained S was positive which is indicating the nanotube is p-type. And the magnitude was increased compared to the bulk and nanowire types. The measured S (364 μV/K) of nanotube at T = 300 K is 1.65 times larger than that (220 μV/K) of bulk and 1.4 times larger than the previously reported value (260 μV/K) of nanowire.

[1]This work is supported by NSF MRSEC (Grant No. DMR-0820404)

4:54PM W12.00013 Signatures of 1D Electron Subbands in the Thermoelectric Properties of InAs Nanowire

, XUAN GAO, YUAN TIAN, JESSE KINDER, DONG LIANG, MICHAEL MACDONALD, RICHARD QIU, Dept of Physics, Case Western Reserve University, MOHAMMED SAKR, Faculty of Science, Alexandria University, Egypt, HONGJUN GAO, Institute of Physics,Chinese Academy of Sciences, Beijing — We report electrical conductance and thermopower measurements on InAs nanowires synthesized by chemical vapor deposition. Gate modulation of the thermopower of individual InAs nanowires with diameter around 20nm is obtained over T = 40 to 300K. At low temperatures (less than c.a.100K), oscillations in the thermopower and power factor concomitant with the stepwise conductance increases are observed as the gate voltage shifts the chemical potential of electrons in InAs nanowire through quasi-one-dimensional (1D) sub-bands. This work experimentally shows the possibility to modulate semiconductor nanowire's thermoelectric properties through the peaked 1D density of states in the diffusive transport regime, a long-sought goal in nanostructured thermoelectrics research. Moreover, we point out the importance of scattering (or disorder) induced energy level broadening in smearing out the 1D confinement enhanced thermoelectric power factor at practical temperatures (e.g. 300K). The authors acknowledge NSF CAREER Award (DMR-1151534), ACS PRF (48800-DNI10) and the NSF of China for support of this research.

5:06PM W12.00014 Thermoelectric effects in disordered branched nanowires , OLEKSIY ROSLYAK, ANDREI PIRIATINSKIY, LANL — We shall develop formalism of thermal and electrical transport in $Si_{1-x}Ge_x$ and $BiTe$ nanowires. The key feature of those nanowires is the possibility of dendrimer type branching. The branching tree can be of size comparable to the short wavelength of phonons and by far smaller than the long wavelength of conducting electrons. Hence it is expected that the branching may suppress thermal and let alone electrical conductance. We demonstrate that the morphology of branches strongly affects the electronic conductance. The effect is important to the class of materials known as thermoelectrics. The small size of the branching region makes large temperature and electrical gradients. On the other hand the smallness of the region would allow the electrical transport being ballistic. As usual for the mesoscopic systems we have to solve macroscopic (temperature) and microscopic ((electric potential, current)) equations self-consistently. Electronic conductance is studied via NEGF formalism on the irreducible electron transfer graph. We also investigate the figure of merit ZT as a measure of the suppressed electron conductance.

5:18PM W12.00015 Electrochemical Deposition of Lanthanum Telluride Thin Films and Nanowires , SU (IKE) CHI, STEPHEN FARIAS, ROBERT CAMMARATA, Department of Materials Science and Engineering, Johns Hopkins University, Baltimore, Maryland 21218, USA — Tellurium alloys are characterized by their high performance thermoelectric properties and recent research has shown nanostructured tellurium alloys display even greater performance than bulk equivalents [1-2]. Increased thermoelectric efficiency of nanostructured materials have led to significant interests in developing thin film and nanowire structures. Here, we report on the first successful electrodeposition of lanthanum telluride thin films and nanowires. The electrodeposition of lanthanum telluride thin films is performed in ionic liquids at room temperature. The synthesis of nanowires involves electrodepositing lanthanum telluride arrays into anodic aluminum oxide (AAO) nanoporous membranes. These novel procedures can serve as an alternative means of simple, inexpensive and laboratory-environment friendly methods to synthesize nanostructured thermoelectric materials. The thermoelectric properties of thin films and nanowires will be presented to compare to current state-of-the-art thermoelectric materials. The morphologies and chemical compositions of the deposited films and nanowires are characterized using SEM and EDAX analysis. References: [1] D. M. Rowe, *CRC Handbook of Thermoelectrics*, CRC Press (1995). [2] A. May *et al., Phys. Rev. B* **78**, 125205 (2008).

Thursday, March 21, 2013 2:30PM - 5:30PM –

Session W13 DCMP: Topological Insulators: Bi2Se3, Pure and Chemically Doped 315 - James Analytis, University of California, Berkeley

2:30PM W13.00001 Insulating behavior in ultra-low carrier density Bismuth Selenide single crystals , PAUL SYERS, JOHNPIERRE PAGLIONE, University of Maryland — The topological insulator material Bi_2Se_3 is well known to suffer from a non-insulating bulk due to doping caused by selenium vacancies. We present results on the synthesis and characterization of pure undoped Bi_2Se_3 crystals that exhibit nonmetallic transport behavior over the entire measured temperature range, from room temperature down to at least 2 K. Measurements of longitudinal transport and Hall effect are used to characterize the transport temperature and magnetic field dependences, carrier sign and density, and sensitivity to air exposure.

2:42PM W13.00002 THz generation and the detection on the Dirac-cone surface states in topological insulator Bi_2Se_3 , J.-Y. LIN, Institute of Physics, National Chiao Tung University, Hsinchu 30010, Taiwan, C.W. LUO, Department of Electrophysics, National Chiao Tung University, Hsinchu 30010, Taiwan — A terahertz (THz) wave is generated from the (001) surface of cleaved Bi_2Se_3 and Cu-doped Bi_2Se_3 single crystals, using femtosecond pulses of 800 nm. The generated THz power is strongly dependent on the carrier concentration of the crystals, which can be explained by considering the absorption of both surface and bulk states altogether. In particular, the Dirac-cone surface states in Bi_2Se_3 significantly affect the THz emission efficiency. Therefore, the THz radiation from topological insulators can be used to ascertain the existence and characteristics of the Dirac-cone surface states.

2:54PM W13.00003 Coexistence of Bulk and Surface Shubnikov-de Haas Oscillations in Bi_2Se_3[1] , CHI ZHANG, Peking University, FANMING QU[2], Institute of Physics, Chinese Academy of Science, RUI-RUI DU, Rice University, LI LU, Institute of Physics, Chinese Academy of Science — Topological insulator possesses insulating bulk state and spin-momentum interlocked conducting topological surface state. Among many materials, bismuth selenide (Bi_2Se_3) is an important candidate, which hosts a single Dirac cone in the surface energy spectrum. In electron transport measurements, 3-dimensional Shubnikov-de Haas (SdH) oscillations of bulk state were observed. Under a very high magnetic field, our rotating sample experimental results exhibit the coexistence of bulk and surface SdH oscillations: Hall bar shape device based on Bi_2Se_3 nano-plate was fabricated and studied at a dilution temperature with a tilted magnetic field up to 45 T. Three types of carrier, one of 3-dimensional and two of 2-dimensional, were identified by analyzing the angular dependence of SdH oscillations, which confirmed the coexistence of bulk carrier and band bending induced two-dimensional electron gas in transport experiment. The co-contributions to quantum oscillations indicated the independence of these states, without smearing out by scattering with each other, which may pave off the way for studying topological surface states with residual bulk carriers in Bi_2Se_3. The data analysis and experimental results are included in the presentation.

[1]We would like to thank National High Magnetic Field Lab (NHMFL) in Florida, in which the high magnetic field measurements were conducted.

3:06PM W13.00004 Bulk versus surface contributions to the Shubnikov-de Haas Effect[1] , E. MANIV, M. PETRUSHEVSKY, Raymond and Beverly Sackler School of Physics and Astronomy, Tel-Aviv University, Israel, E. LAHOUD, Department of Physics, Technion-Israel Institute of Technology, Israel, A. RON, I. NEDER, Raymond and Beverly Sackler School of Physics and Astronomy, Tel-Aviv University, Israel, S. WIEDMANN, V.K. GUDURU, U. ZEITLER, J.C. MAAN, High Field Magnet Laboratory, Institute for Molecules and Materials, Radboud University Nijmegen, The Netherlands, K. CHASHKA, A. KANIGEL, Department of Physics, Technion-Israel Institute of Technology, Israel, Y. DAGAN, Raymond and Beverly Sackler School of Physics and Astronomy, Tel-Aviv University, Israel — Among the bulk materials that are considered as experimental realizations of topological insulators Bi_2Se_3 is of particular interest due to its large bulk band gap and surface states with a single Dirac cone. It has been recently shown that Bi_2Se_3 can become superconducting when Cu intercalation is introduced (Hor, Y. S.; Williams, A. J. et al. *Phys. Rev. Lett.* **2010**, 104, 057001). We report on transport measurements of cleaved flakes $\sim$1$-$100 μm thick of Cu intercalated Bi_2Se_2. Clear Shubnikov-de Haas oscillations are observed. We study the temperature and angular dependence of these oscillations together with the Hall coefficient at low temperatures for various Cu concentrations. We discuss possible contributions from bulk and the protected surface states to the various transport channels.

3:18PM W13.00005 Modification of topological insulator transport properties by electron beam irradiation[1]

, ZILONG JIANG, ZHIYONG WANG, TAO LIN, JING SHI, Department of Physics and Astronomy, University of California, Riverside, CA, 92521 — Topological insulators (TI) are predicted to present a variety of interesting surface transport phenomena. However, in TI devices, the metallic bulk conduction usually overwhelms the surface transport. In this work, we first fabricate TI devices based on our high bulk resistivity material ($\sim$5 Ω.cm) $Bi_xSb_{2-x}Te_ySe_{3-y}$ using ebeam lithography. Then we expose the devices with an electron beam to introduce disorders to localize the bulk carriers. The devices are $\sim$100-200 nm in thickness and the resistivity is weakly temperature dependent. Upon initial low-energy exposures, we find that the resistance of device decreases and reaches a saturation state as the dosage increases. We attribute this decrease in resistivity to an increased electron density in the devices. As we ramp up the energy of the electron beam, the resistance starts to increase, showing the effect of additional scattering. At low temperatures, the resistance rapidly increases in a diverging trend. At 4 K, the magnetoresistance starts to display oscillatory features that are likely the Shubnikov-de Haas oscillations from the surface states. We believe that the disorders introduced by the electron beam play an important role in modifying the transport of the bulk carriers. More detailed experimental results and discussions will be presented.

3:30PM W13.00006 Topological Spin-Polarized Electron Layer above the Surface of Ca-Terminated Bi_2Se_3[1]

, XIAOXIONG WANG, College of Science, Nanjing University of Science and Technology, Nanjing 210094, China, GUANG BIAN, TOM MILLER, TAICHANG CHIANG, Department of Physics, University of Illinois at Urbana-Champaign, 1110 West Green Street, Urbana, Illinois 61801-3080, USA — Spin-polarized gapless surface states on the boundary of topological insulators are of interest for spintronic applications. First-principles calculations show that adsorption of a Ca monolayer on films of the prototypical topological insulator, Bi_2Se_3, yields a substantial enhancement of the surface-state spin polarization, despite the low atomic mass of Ca and its weak spin-orbit coupling. Much of the topological surface electron distribution is transferred outside the Ca to form a polarized electron layer out in vacuum; this spatial separation from the substrate minimizes scattering by defects in Bi_2Se_3 and is very desirable for spin transport.

3:42PM W13.00007 Strong single-ion anisotropy and anisotropic interactions of magnetic adatoms induced by topological surface states[1]

, ZHENGLU LI, JIHUI YANG, GUOHONG CHEN, Departmenf of Physics, Fudan University, M.-H. WHANGBO, Department of Chemistry, North Carolina State University, HONGJUN XIANG, XINGAO GONG, Departmenf of Physics, Fudan University — The nature of the magnetism brought about by Fe adatoms on the surface of the topological insulator Bi_2Se_3 was examined in terms of density functional calculations. The Fe adatoms exhibit strong easy-axis magnetic anisotropy in the dilute adsorption limit due to the topological surface states (TSS). The spin exchange J between the Fe adatoms follows a Ruderman-Kittel-Kasuya-Yosida behavior with substantial anisotropy, and the Dzyaloshinskii-Moriya interaction between them is quite strong with $|D/J| \approx 0.3$ under the mediation by the TSS, and can be further raised to 0.6 by an external electric field. The apparent single-ion anisotropy of a Fe adatom is indispensable in determining the spin orientation.

3:54PM W13.00008 The Fermi Surface of Highly Doped Bi_2Se_3 and the Implications for Superconductivity in $CuBi_2Se_3$

, ELIAS LAHOUD, AMIT KANIGEL, MUNTASER NAAMNEH, AMIT RIBAK, HANAN CHASKA, Technion - Israel Institute of Technology, MICHAL PETRUSHEVSKY, ERAN MANIV, YORAM DAGAN, Tel-Aviv University, KANIGEL GROUP TEAM, DAGAN GROUP TEAM — The 3D Fermi-surface (FS) mapping of Bi_2Se_3 for different samples with carrier-density ranging from 10^{17} to 10^{20} cm^{-3} was made using Angle Resolved Photoemission Spectroscopy. While in the low carrier density samples a closed FS was observed, in high carrier density superconducting $Cu_xBi_2Se_3$ samples the FS was found to be open. The open FS puts constraints on the possible order-parameters in this system.

4:06PM W13.00009 Scanning tunneling microscopy of defects and electronic fluctuations in Cu-doped Bi_2Se_3

, CHRISTOPHER MANN, University of Texas at Austin, DAMIEN WEST, Rensselaer Polytechnic Institute, IRENEUSZ MIOTKOWSKI, YONG CHEN, Purdue University, SHENGBAI ZHANG, Rensselaer Polytechnic Institute, CHIH-KANG SHIH, University of Texas at Austin — We report scanning tunneling microscopy and spectroscopy studies of the topological insulator $Cu_xBi_2Se_3$. We have identified five different atomic-resolution signatures of Cu dopant-related point defects and correlated several of them to density functional theory simulations of the defects. Most interestingly, by investigating the dI/dV images of the known Bi_{Se} antisite defects as a function of bias, we show that local electronic structure can vary substantially over a length scale of 30nm, with amplitudes as large as $\pm$50meV. The strong fluctuations appear to be caused by a variety of defects and may have consequences for the topological surface state, as revealed by quasiparticle scattering studies. Correlation of quasiparticle scattering with the various defects indicates that the surface state is robust to backscattering, though detailed analysis shows that some defects are more effective in producing stationary scattering states than others.

4:18PM W13.00010 Probing the pairing symmetry of candidate topological superconductor CuxBi2Se3 via point contact spectroscopy

, XUNCHI CHEN, CHAO HUAN, Georgia Institute of Technology, YEW SAN HOR, Missouri University of Science and Technology, CARLOS SA DE MELO, ZHIGANG JIANG, Georgia Institute of Technology — We perform point contact spectroscopy measurements on the candidate topological superconducting material, $Cu_{0.25}Bi_2Se_3$, using a normal-metal gold tip or an s-wave superconductor niobium tip. For the Au- $Cu_{0.25}Bi_2Se_3$ interface, we observe a marked zero-bias conductance peak in the point contact spectra on the superconducting area of the sample, indicative of unconventional superconducting pairing symmetry. The point contact spectra also exhibit a pronounced linear background, which we attribute to inelastic scattering at the tip-sample interface. We compare the background subtracted spectra to a single-band p-wave model. For the Nb-$Cu_{0.25}Bi_2Se_3$ interface, we observe a two-gap-like feature in the spectra, corresponding to the superconducting gap of the niobium and the sample, respectively. In addition, we find that the spectra are highly dependent on the interface barrier strength, and exhibit non-monotonic temperature dependence at zero bias, possibly owing to the incompatibility of the pairing symmetries between the Nb tip and the sample. Our results signify the unconventional superconductivity in $Cu_xBi_2Se_3$.

4:30PM W13.00011 Quantum oscillations in topological superconductor candidate $Cu_xBi_2Se_3$

, BENJAMIN LAWSON, GANG LI, Physics Dept., Univ. of Michigan, YEW SAN HOR, Physics Dept., Missouri S&T, LU LI, Physics Dept., Univ. of Michigan — In $Cu_xBi_2Se_3$, a candidate to be a 3-dimensional topological superconductor, it is of high interest to study how its bulk electronic structure differs from Bi_2Se_3, since the nature of the emergent bulk superconducting order puts constraints on the possible surface state. The de Hass-van Alphen effects is observed on a single crystals of $Cu_{0.25}Bi_2Se_3$ using sensitive torque magnetometry. Our results show that the Cu doping in Bi_2Se_3 increases the carrier density and the effective mass, without increasing the scattering rate or decreasing the mean free path. In addition, the Fermi velocity remains the same in copper doped compound as that in Bi_2Se_3. These results imply that the insertion of Cu does not change the overall band structure and that conduction electrons in Cu doped Bi_2Se_3 sit in the linear Dirac-like band.

4:42PM W13.00012 Gapped Dirac surface states in In doped topological insulator Bi_2Se_3[1] , WEIDA WU, QUANTONG SHEN, XUEYUN WANG, SANG-WOOK CHEONG, Rutgers Center for Emergent Materials & Department of Physics and Astronomy, Rutgers University, Piscataway, NJ, 08854 — Topological insulators host helical Dirac surface states which linearly disperse through bulk band gap. The unusual helical surface states are protected by time reversal symmetry, and therefore believed to be robust against disorders that do not break time reversal symmetry. It has been debated whether massive Dirac surface states (i.e. a gap at the Dirac point) are experimentally observed in doped topological insulators [1-3]. Herein, we report the observation of a spectroscopic gap of topological surface states in $Bi_{2-x}In_xSe_3$ using low temperature scanning tunneling microscopy and spectroscopy (LT-STM/STS). The tunneling spectroscopic maps suggest that the interactions between In dopants effectively change the topological class of local band structure, resulting in a nanoscale mixture of topologically trivial and nontrivial states. This electronic inhomogeneity poses a nanoscale spatial confinement to the Dirac surface states so that the long wavelength surface states near the Dirac point are suppressed, i.e. a gap is opened at the Dirac point.

4:54PM W13.00013 Topological phase transition in the $(Bi_{1-x}In_x)_2Se_3$ system investigated via STM , WENWEN ZHOU, YOSHINORI OKADA, ZHENSONG REN, DANIEL WALKUP, STEPHEN WILSON, VIDYA MADHAVAN, Boston College — Transport and photoemission measurements on $(Bi_{1-x}In_x)_2Se_3$ have shown that the system transforms from a pure (x=0) topological insulator (TI) into a topologically trivial material ($x > 0.07$) through a topological phase transition. Indium (In) substitution for heavier Bismuth is expected to have a large effect on the electronic properties of TIs and is a very sensitive way to tune spin-orbit coupling while maintaining the same lattice structure. In this talk we present scanning tunneling microscopy measurements of the surface state and electronic structure of $(Bi_{1-x}In_x)_2Se_3$ single crystals over a wide range of In concentrations. We identify the local density signature of the In impurities and use these local measurements to determine the actual doping levels. Using spectroscopy and Fourier transform maps we then trace the evolution of the topological insulator into the trivial phase, thereby providing insights into the nanoscale evolution of this process.

5:06PM W13.00014 Topological-Metal to Band-Insulator Transition in $(Bi_{1-x}In_x)_2Se_3$ Thin Films , MATTHEW BRAHLEK, NAMRATA BANSAL, NIKESH KOIRALA, Rutgers University Physics and Astronomy Department, SU-YANG XU, MADHAB NEUPANE, CHANG LIU, M. ZAHID HASAN, Princeton University Physics Department, SEONGSHIK OH, Rutgers University Physics and Astronomy Department — By combining transport and photoemission measurements on $(Bi_{1-x}In_x)_2Se_3$ thin films, we report that this system transforms from a topologically nontrivial metal into a topologically trivial band insulator through three quantum phase transitions. At $x \approx$3%–7%, there is a transition from a topologically nontrivial metal to a trivial metal. At $x \approx$15%, the metal becomes a variable-range-hopping insulator. Finally, above $x \approx$25%, the system becomes a true band insulator with its resistance immeasurably large even at room temperature. This material provides a new venue to investigate topologically tunable physics and devices with seamless gating or tunneling insulators.

5:18PM W13.00015 Theoretical study of topological phase transitions in $(Bi_{1-x}In_x)_2Se_3$ and $(Bi_{1-x}Sb_x)_2Se_3$, JIANPENG LIU, DAVID VANDERBILT, Department of Physics and Astronomy, Rutgers University — We use first-principles calculations to study the phase transition from a topological to a normal insulator with concentration x in $(Bi_{1-x}In_x)_2Se_3$ and $(Bi_{1-x}Sb_x)_2Se_3$ in the Bi_2Se_3 crystal structure. The spin-orbital coupling (SOC) strength is similar in In and Sb, which have similar atomic numbers, so that if the topological transitions in $(Bi_{1-x}In_x)_2Se_3$ and $(Bi_{1-x}Sb_x)_2Se_3$ are purely driven by the decrease of SOC strength, we would expect to see similar critical concentrations x_c in the two systems. However, based on our preliminary calculations, x_c is much lower in $(Bi_{1-x}In_x)_2Se_3$ than in $(Bi_{1-x}Sb_x)_2Se_3$, indicating that different mechanisms control the behavior in the two cases. Specifically, in $(Bi_{1-x}Sb_x)_2Se_3$ we find that the phase transition is mostly dominated by the decrease of SOC. However, for $(Bi_{1-x}In_x)_2Se_3$, the In $5s$ orbitals also play an important role, both in the phase-transition behavior and in determining the indirect bulk band gap. Finally, we discuss the accuracy of the energy-level position of the In $5s$ orbitals in $(Bi_{1-x}In_x)_2Se_3$ as predicted by density-functional theory and more advanced methods.

Session W14 GMAG DMP: Focus Session: Magnetic Domains 316 - Andrew Balk, National Institute of Standards and Technology

2:30PM W14.00001 Observation and Control of exotic magnetic domain structures in ferromagnetic $CeRu_2Ga_2B$, JEEHOON KIM, R. BAUMBACH, O. AYALA-VALENZUELA, K. BARROS, K. YASUYUKI, I. MARTIN, L. CIVALE, E. BAUER, F. RONNING, J. D. THOMPSON, R. MOSHOVICH, Los Alamos National Laboratory — The structure of magnetic domains in a single crystal of $CeRu_2Ga_2B$ was investigated using low-temperature magnetic force microscopy (MFM) over a wide range of fields and temperatures. The low Curie temperature ($T_C \approx$16 K) allows for extensive tunability, revealing a rich variety of magnetic states including branched stripes, bubble domains, and finger-like domains. In addition to the higher spatial resolution, the advantage of MFM over optical imaging techniques is the ability to manipulate magnetic domains. In particular, we are able to manipulate (move and destroy) individual circular domains with the MFM tip, which suggests that we observe unusual spherical 'bubble' domains (as opposed to cylindrical ones, with round terminations at the surface). Our results clarify the origins and illustrate the diversity of the domain structures in nearly ferromagnetic compounds.

2:42PM W14.00002 Distribution of non-adiabatic and adiabatic torques in domain wall systems , ELIZABETH GOLOVATSKI, Dept. of Physics, Luther College, MICHAEL FLATTÉ, OSTC and Dept. of Physics and Astronomy, University of Iowa — Spin torque and the subsequent motion of domain walls caused by coherent carrier transport[1] is an important aspect in the development of spintronic devices[2]. We model spin torque in Néel walls[3] in various configurations using a piecewise linear transfer-matrix method[4] and calculate the spin torque distribution[5] throughout the system. We find a large non-adiabatic component to the spin torque throughout the system, that oscillates with position in the wall, as if it would introduce an out-of-plane twist in the magnetization. This twisting effect is especially pronounced in a domain sandwiched between two domain walls, where the non-adiabatic torque increases almost linearly from a large negative value to a large positive value across the domain. We also note differences in the adiabatic torques across materials: ferromagnetic semiconductors have symmetry of the adiabatic torques around the wall center that is lost when considering a magnetic metal. Golovatski and M. Flatté, Phys. Rev. B, 84, 115210 (2011) [5] J. Xiao et al., Phys. Rev. B, 73, 054428 (2006)

2:54PM W14.00003 ABSTRACT WITHDRAWN –

3:06PM W14.00004 Large scale magnetic domain wall fluctuations in ultrathin cobalt films , ANDREW BALK[1], JOHN UNGURIS, Center for Nanoscale Science and Technology, National Institute of Standards and Technology, Gaithersburg, MD 20899 — Controlling anisotropy through ion bombardment is a convenient method for manipulating domain walls in perpendicularly magnetized films. In ultrathin (<1nm) cobalt deposited on platinum, exposure to 50eV argon ions reduces the perpendicular magnetic anisotropy until the magnetization lies in plane. Just before this in-plane transition, the domain wall energy and pinning strength are reduced such that zero-field Barkhausen-like domain wall jumps become observable at zero field and room temperature. The domain wall jumps are large enough (>100nm) to be measured optically. In this work we use magneto-optic Kerr effect to measure how these fluctuations depend on the film thickness and applied magnetic field. Furthermore, we observe magnetostatic correlations between fluctuations in nearby domain walls.

3:18PM W14.00005 Voltage Control of Domain Wall Motion in Perpendicular Magnetic Anisotropy Materials[1] , UWE BAUER, SATORU EMORI, GEOFFREY S. D. BEACH, Massachusetts Institute of Technology, Cambirdge, USA — High-performance solid-state operation of a wide variety of spintronic devices requires efficient electrical control of domain walls (DWs). In this work we examine DW dynamics in ultrathin Co films under the influence of an electric field applied across a gadolinium oxide gate dielectric. By measuring the velocity scaling with temperature, driving field, and gate voltage, we verify domain expansion via thermally-activated creep dynamics. We show that an electric field linearly modulates the activation energy barrier E_{A} that governs DW creep, leading to an exponential dependence of DW velocity on gate voltage. As a consequence, significant voltage-induced velocity enhancement can be achieved in the low-velocity regime, but the efficiency is diminished at high velocities where E_{A} is correspondingly small. We overcome this limitation by engineering novel device structures with significantly larger voltage induced effects on magnetic anisotropy and demonstrate voltage modulation of the DW propagation field by hundreds of Oe. Implementation into magnetic nanowire devices allows us to engineer gate voltage controlled DW traps which are nonvolatile and robustly switchable for many cycles.

3:30PM W14.00006 Direct Imaging the Thermally Excited Magnon Driven Domain Wall Motion in Magnetic Insulators , WANJUN JIANG, PRAMEY UPADHYAYA, YABIN FAN, JING ZHAO, ROBERT SCHWARTZ, KANG L. WANG, Electrical Engineering Department, UCLA, ELECTRICAL ENGINEERING DEPARTMENT, UCLA TEAM — Experimental demonstrations of domain wall (DW) motion induced by the thermally excited magnons in YIG are revealed by applying spatial/temporal resolved polar MOKE imaging in the presence of various temperature gradients. These results include: (1) the DW moves from the cold regime towards the hot regime (for both positive and negative temperature gradients); (2) a threshold temperature gradient (5 K/mm), $i.e.$, a minimal temperature gradient required to induce DW motion; (3) the linear relation of the average DW velocity with the (positive/negative) temperature gradients. Our results suggest that DWs in insulating magnetic materials can be effectively manipulated by a magnonic STT simply by applying small temperature gradients. Further efforts are required to understand this exciting phenomenon, such as quantifying the thermally excited spin wave spin current J_m, resolving the reflection, and transmission of J_m across the DW. Nevertheless, our observations demonstrate that, by incorporating thermal effect into DW engineering, insulating magnetic materials could potentially enable many devices for information processing and other applications in spin caloritronics.

3:42PM W14.00007 Mechanical manipulation of magnetic domains in continuous and patterned magnetostrictive FeGa thin films[1] , PARIS ALEXANDER, SEAN FACKLER, ICHIRO TAKEUCHI, JOHN CUMINGS, University of Maryland - Department of Materials Science and Engineering — The controlled and reversible switching of magnetic domains using static electric fields has been previously demonstrated via magneto-electric (ME) coupling in a multiferroic system [T. Brintlinger, Nano Lett. 10, 1219(2010)]. In these systems, enhanced magnetostriction allows for magnetic switching in response to an electrically induced deformation. Here we demonstrate the nature of magnetic switching using mechanical stress alone. Magnetostrictive iron-gallium ($Fe_{70}Ga_{30}$) thin films are deposited on flexible free-standing membranes, and patterned to square arrays. Using a mechanically manipulated tip a strain is directly applied to the film. We observe the resulting magnetization dynamics using Lorentz-force transmission electron microscopy (LTEM). The varied hysteretic behaviors under applied magnetic and strain fields will be presented for both continuous and patterned films.

3:54PM W14.00008 Magnon-induced motion of magnetic domain wall in a nanowire with non-uniaxial anisotropy , JAE-HO HAN, HYUN-WOO LEE, POSTECH — Magnons propagating along a nanowire may interact with a magnetic domain wall (DM) and shift the DW position. Often, the DW shift direction is opposite to the magnon propagation direction, which can be explained by the angular momentum conservation when the wire has only uniaxial anisotropy. We studied a nanowire with non-zero perpendicular anisotropy constant, in which the angular momentum conservation argument is broken. Additional to the term comes from the angular momentum conservation, we found new term in the DW shift which comes from the rotation of the DW plane during the magnon pass through the DW. The rotation direction gives DW shift in the opposite direction to the magnon propagation direction, and same for two types of transvers DW: head-to-head or tail-to-tail. The magnitude of this term can be comparable to that comes from the angular momentum conservation when the large perpendicular anisotropy and the small magnon wavelength compare to the DW width.

4:06PM W14.00009 Current-Induced Dynamics in Antiferromagnetic Metal: Domain Wall Dynamics and Spin Wave Excitation , RAN CHENG, QIAN NIU, Department of Physics, University of Texas at Austin — When a spin-polarized current flows through a ferromagnetic (FM) metal, angular momentum is transferred to the magnetization via spin transfer torque. However, corresponding theory is absent in antiferromagnetic (AFM) metals due to the absence of spin conservation. We solve this problem via effective gauge theory without the necessity of spin conservation. By identifying the adiabatic dynamics of conduction electrons as a non-Abelian gauge theory on degenerate band, we derive the AFM version of Landau-Lifshitz-Gilbert equation with current-induced dynamics from a microscopic point of view. Quite different from its FM counterpart, current-induced dynamics in AFM materials does not behave as a torque, but a driving force triggering second order derivative of local staggered order with respect to time. Its physical consequences are studied in two examples: 1. A domain wall is accelerated to a terminal velocity without a Walker's threshold; 2. A sufficiently large spin current will generate spin wave excitation.

4:18PM W14.00010 Domain wall propagation through spin wave emission , XIANSI WANG, Hong Kong University of Science and Technology, PENG YAN, Kavli Institute of NanoScience, Delft University of Technology, YUHUA SHEN, Hong Kong University of Science and Technology, G.E.W. BAUER, Kavli Institute of NanoScience, Delft University of Technology, X. R. WANG, Hong Kong University of Science and Technology — We theoretically study field-induced domain wall (DW) motion in an electrically insulating ferromagnet with hard- and easy-axis anisotropies. Different from the common wisdom, we prove that a DW in a dissipationless wire with a finite transverse magnetic anisotropy can propagate along the wire. The DW subjected to an external magnetic field undergoes a periodic transformation that excites SWs. The energy carried away must be compensated by the Zeeman energy that is released by DW propagation. Thus, a domain wall propagation mode through spin wave emission is revealed. The DW propagation locked into the known soliton velocity at low fields. In the presence of small damping, the usual Walker rigid-body propagation mode may become unstable for magnetic fields below the Walker breakdown.

4:30PM W14.00011 Enhanced controllability of domain-wall pinning by asymmetric control of domain-wall injection[1] , SUNG-MIN AHN, Massachusetts Institute of Technology — Recently, using magnetostatic interactions via the magnetic-charge distributions, a few ideas to effectively and selectively manipulate the DW pinning without additional alterations to the nanowire have been suggested. Even though the DW pinning via the magnetostatic interaction is locally controlled, the pinning strength is insufficient to reliably manipulate the DW propagation in the real DW-mediated device. Here, it is experimentally studied that depinning fields of domain walls (DWs) under an interaction between magnetic charges distributed at a nanobar and at a notch can be enhanced by controlling injection fields for injecting DWs into the ferromagnetic nanowire with an asymmetrical nucleation pad. The DWs injected from the asymmetrical pad show an asymmetrical dependence of the injection field on the saturation angle and are pinned by the notch with the nanobar vertical to it. We have found that the shape of the pinning potential energy experienced by the DW depends on the magnetized direction of the nanobar and the level of that is lifted by the injection field leading to an increase in the depinning field with respect to the saturation angle. This is consistent with our estimation based on micromagnetic simulation.

4:42PM W14.00012 Domain Wall Trajectory Determined by its Fractional Topological Edge Defects , AAKASH PUSHP, TIMOTHY PHUNG, CHARLES RETTNER, BRIAN HUGHES, SEE-HUN YANG, LUC THOMAS, STUART PARKIN, IBM Almaden Research Center — A domain wall in a ferromagnetic nanowire is composed of elementary topological bulk and edge defects with integer and fractional winding numbers, respectively. The spatial arrangement of the defects reflects the chiral internal structure of the domain wall. By breaking the symmetry across the width of the nanowire we show that we can control the formation of these topological defects and thereby can form domain walls of a given chirality with high fidelity. Utilizing this capability, we show that the fractional topological edge defects of the domain wall determine its trajectory in branched nanowire networks. Our results can account for the motion of domain walls in complex networks of magnetic nanowires such as "Artificial Spin Ice" systems, explaining the formation of Dirac strings, and may also lead to fault-tolerant domain wall based memory and logic devices.

4:54PM W14.00013 Dynamics of topological defects in a 2D magnetic stripe pattern , DAVID VENUS, NIDAL ABU-LIBDH, McMaster University — The magnetic stripe domain patterns formed in perpendicularly-magnetized ultrathin films are one example of pattern formation in 2D systems with short-range attractive (exchange) and long-range repulsive (dipole) interactions. Topological pattern defects (dislocations) play a key role in the evolution of the pattern. The magnetic susceptibility due to domain wall motion is very sensitive to the presence of the topological defects, and can be used to study their energetics and population dynamics. The total energy density of the domain pattern is altered by the contribution from the concentration of topological defects, changing the average domain density and magnetic "stiffness" in a characteristic way. These changes can be directly monitored in the magnetic susceptibility peak, where the peak location and shape can be related quantitatively to the defect concentration. These ideas are confirmed using recently published data for perpendicularly-magnetized Fe/ 2 ML Ni/W(110) films, and allows the extraction of the characteristic time scale, lifetime, and activation energy for the annihilation of topological defects. In addition, it is possible to quantify the proportion of the domain system energy density that is due to the topological defects.

5:06PM W14.00014 Topological defects and misfit strain in magnetic stripe domains of lateral multilayers with perpendicular magnetic anisotropy[1] , MARIA VELEZ, A. HIERRO-RODRIGUEZ, R. CID, G. RODRIGUEZ-RODRIGUEZ, J.I. MARTIN, L.M. ALVAREZ-PRADO, J.M. ALAMEDA, Dpto. Fisica, Universidad de Oviedo and CINN (CSIC-U. Oviedo-P. Asturias), Spain — Stripe domain patterns are characteristic of magnetic films with perpendicular magnetic anisotropy (PMA). In this work, PMA amorphous Nd-Co films have been nanostructured with a periodic thickness modulation that induces the lateral modulation of magnetic stripe periods and in-plane magnetization. Confinement effects of stripe domains within the nanostructured regions are combined with coupling effects between nearby elements through elastic interactions within the magnetic stripe pattern. The resulting "lateral" magnetic superlattice is the 2D equivalent of a strained superlattice controlled by interfacial misfit strain within the magnetic stripe structure and shape anisotropy: misfit dislocations appear in the stripe pattern at the boundaries between nanostructured regions and, during magnetization reversal, a 2D variable angle grain boundary is observed within the magnetic stripe pattern. Beautiful patterns appear at the point of maximum misfit strain due to the decay of dislocations in the magnetic stripe pattern into 1/2 disclination pairs. The link between topological defects in the magnetic stripe patterns and domain walls for the in-plane magnetization component allow us to tailor the whole magnetization reversal process. 5:18PM W14.00015 Current-driven domain wall dynamics in ultrathin heavy-metal/ferromagnet/oxide submicron strips[1] , SATORU EMORI, SUNG-MIN AHN, GEOFFREY BEACH, Massachusetts Institute of Technology — Recent studies have reported efficient current-driven domain wall (DW) motion and magnetization switching in out-of-plane magnetized structures consisting of an ultrathin (<1 nm) ferromagnetic Co layer embedded between a heavy-metal Pt underlayer and an oxide overlayer such as AlOx [1, 2] and GdOx [3]. These phenomena have been attributed to "spin-orbit" torques arising from the metal-oxide interface (Rashba effect) and in the heavy-metal underlayer (spin Hall effect). We investigate current-driven DW motion in submicron-wide strips of ultrathin Ta/CoFe/MgO and Pt/CoFe/MgO. DWs move in the direction of electron flow in Ta/CoFe/MgO, whereas they move against electron flow in Pt/CoFe/MgO. Measurements of the DW propagation field and velocity reveal large spin torque efficiencies exceeding 100 Oe/10^{11} A/m^2 in both structures. Because the signs of the spin Hall angles of Ta and Pt are opposite, the spin Hall effect may partially explain such efficient current-driven DW motion whose directionality differs with the heavy-metal underlayer. Session W15 GMAG DMP: Focus Session: Theory of Kagome Magnetism 317 - Oleg Tchernyshyov, Johns Hopkins University

2:30PM W15.00001 Simplex SU(3) quantum antiferromagnets on the kagome and hyperkagome lattices[1] , YURY YU. KISELEV, University of California San Diego, SIDDHARTH A. PARAMESWARAN, University of California Berkeley, DANIEL P. AROVAS, University of California San Diego — We investigate SU(3) "simplex solid" antiferromagnets on the kagome and hyperkagome lattices. The ground states of these systems are annihilated by certain local projectors acting on triples of sites, and are analogous to the valence bond solid wavefunctions constructed by Affleck, Kennedy, Lieb, and Tasaki. Using a coherent state representation, we map to a classical model of CP^2 spins with 3-spin interactions, which we analyze via single-spin Monte Carlo simulations and a cluster algorithm for the three-body interactions. We compute the static structure factor and short-range correlations encoded by the simplex solid wavefunction and rationalize the results in terms of the "order by disorder" mechanism.

[1]We acknowledge support from NSF grant DMR-1007028 (YYK and DPA) and from the Simons Foundation (SAP).

2:42PM W15.00002 Structure of dynamical correlations developing on top of an entropically designed frustrated manifold , MATHIEU TAILLEFUMIER, ITP, Goethe University, JULIEN ROBERT, LLB - CEA Saclay, F-91191 Gif-sur-Yvette cedex, France., BENJAMIN CANALS, Institut Neel - 25 avenue des Martyrs, BP 166, 38042 Grenoble cedex 9, France. d LASSP, Clark Hall, Cornell University, Ithaca, NY 1485, CHRISTOPHER HENLEY, LASSP, Clark Hall, Cornell University, Ithaca, NY 14853-2501. — By combining monte carlo and spin dynamics simulations, we investigate the precessional dynamics of the classical kagome antiferromagnet through the calculation of the dynamical structure factor $S(\mathbf{Q}, t)$. Recently, evidences for spin wave like excitations in the two distinct low temperature regimes whose temperature ranges are given by the entropically driven onset of spin plane coplanarity at $T_0/J \approx 5\ 10^{-3}$ has been given. However, only a little is known about the longer time scales describing the fluctuations around the ground-state manifold. We give more insight about this relaxationnal dynamics and establish in particular the temperature and wave-vector dependence of the lifetime of locally ordered states. Although the infinite components spins model qualitatively accounts for the dynamical properties in the cooperative paramagnetic regime, we show at lower temperature that the entropic selection (i) leads to strongly different dynamical correlations for the in- plane and out-of-plane spin components below the transition, and (ii) almost suppresses the diffusive behaviour observed in the cooperative regime in favour of mainly propagative spin transfers.

2:54PM W15.00003 DMRG Study of the $S \geq 1$ quantum Heisenberg Antiferromagnet on a Kagome-like lattice without loops[1] , R. ZACH LAMBERTY, HITESH J. CHANGLANI, CHRISTOPHER L. HENLEY, Cornell University — The Kagome quantum Heisenberg antiferromagnet, for spin up to $S = 1$ and perhaps $S = 3/2$, is a prime candidate to realize a quantum spin liquid or valence bond crystal state, but theoretical or computational studies for $S > 1/2$ are difficult and few. We consider instead the same interactions and $S \geq 1$ on the Husimi Cactus, a graph of corner sharing triangles whose centers are vertices of a Bethe lattice, using a DMRG procedure tailored for tree graphs [1]. Since both lattices are locally identical, properties of the Kagome antiferromagnet dominated by nearest-neighbor spin correlations should also be exhibited on the Cactus, whereas loop-dependent effects will be absent on the loopless Cactus. Our study focuses on the possible transition(s) that must occur with increasing S for the Cactus antiferromagnet. (It has a disordered valence bond state at $S = 1/2$ but a 3-sublattice coplanar ordered state in the large S limit [2]). We also investigate the phase diagram of the $S = 1$ quantum XXZ model with on-site anisotropy, which we expect to have three-sublattice and valence-bond-crystal phases similar to the kagome case [3]. 3:06PM W15.00004 Wannier Permanents and Featureless Bosonic Mott Insulators on the 1/3 Filled Kagome Lattice[1] , ARI TURNER, University of Amsterdam, SIDDHARTH PARAMESWARAN, ITAMAR KIMCHI, DAN STAMPER-KURN, ASHVIN VISHWANATH, UC Berkeley — We study Bose-Hubbard models on tight-binding, non-Bravais lattices, with a filling of one boson per unit cell – and thus fractional site filling. At integer filling of a unit cell, a fully symmetric insulating state is in principle allowed without triggering topological order. We demonstrate by explicit construction of a family of wavefunctions that such a featureless Mott insulating state exists at 1/3 filling on the kagome lattice. We construct Hamiltonians for which these wavefunctions are exact ground states. Such wavefunctions also yield 1/3 magnetization plateau states for spin models in an applied field. The featureless Mott states we discuss can be generalized to any lattice for which symmetric exponentially localized Wannier orbitals can be found at the requisite filling, and their wavefunction is given by the permanent over all Wannier orbitals.

[1]We acknowledge support from the Simons Foundation, the NSF Graduate Fellowship Program, and the Army Research Office via the DARPA Optical Lattice Emulator Program.

3:18PM W15.00005 Spin $1/2$ Heisenberg antiferromanget on kagome: Z_2 spin liquid with fermionic spinons[1] , ZHIHAO HAO, Department of Physics and Astronomy, University of Waterloo, Waterloo, ON, OLEG TCHERNYSHYOV, Department of Physics and Astronomy, Johns Hopkins University, Baltimore, MD — Motivated by recent numerical and experimental studies of spin $1/2$ Heisenberg antiferromagnet on kagome, we formulate a many-body model for the fermionic spinons introduced in Phys. Rev. Lett. 103, 187203. The spinons experience strong onsite attraction. They also couple with a compact U(1) gauge field. The ground state of the model is generically a Z_2 liquid. We calculate the edge of the two-spinon continuum, which can be measured in numerics and inelastic neutron scattering experiments.

3:30PM W15.00006 Symmetry-broken phases proximate to Z2 spin liquid on Kagome lattice , GIL YOUNG CHO, YUAN-MING LU, ASHVIN VISHWANATH, University of California, Berkeley — Recently, Z_2 spin liquid was proposed as the ground state of the Kagome quantum antiferromagnet [S. Yan, D.A. Huse, and S.R. White, *Science*, 332, 1173 (2011)]. We study proximate symmetry-broken phases that may appear on exiting the spin liquid phase, by tuning parameters such as further neighbor couplings. Given that the Dirac spin liquid is also a relatively low energy state, we consider models of Z_2 spin liquids that are proximate to it. Specifically we consider the s-wave paired state of an algebraic spin liquid on Kagome lattice, $Z_2[0, \pi]\beta$ state of Y.-M Lu, Y. Ran, and P.A. Lee, *Phys. Rev.* B 83, 224413 (2011)] and examine its relations with other competing states. This allows us to characterize the proximate magnetically ordered and VBS phases and criticality between them and the quantum spin liquid.

3:42PM W15.00007 A Phenomenological Theory for the Z_2 Spin-Liquid Phase of the $S = 1/2$ Kagome Heisenberg Antiferromagnet , YUAN WAN, Department of Physics and Astronomy, the Johns Hopkins University — The spin-$1/2$ kagome Heisenberg antiferromagnet is one of the most promising candidate systems for a quantum spin liquid. However, the precise nature of its ground state is still being debated. Recent density-matrix renormalization group (DMRG) calculations show evidence for a possible Z_2 spin-liquid phase, the effective description of which is a Z_2 gauge theory [1,2]. In this work, we construct a minimal Z_2 gauge Hamiltonian encapsulating the DMRG phenomenology in the $S = 0$ sector. We generalize Misguich's Hamiltonian [3] by including dynamical visons [4]. We show that our minimal model naturally produces the diamond resonance pattern observed in DMRG. Moreover, puzzling even-odd effects in kagome cylinders are easily explained by our model. We also predict the existence of edge spinons in certain cylindrical geometries.

4:18PM W15.00008 Spinon-vison interactions in kagome-lattice spin liquids , DEBANJAN CHOWDHURY, SARANG GOPALAKRISHNAN, SUBIR SACHDEV, Harvard University — Recent neutron-scattering measurements on the kagome-lattice antiferromagnet Herbertsmithite [1] suggest that the ground state is well-described by a spin liquid consisting of weakly correlated (i.e., non-dispersing) singlets. We consider how these observations can be accounted for within a Schwinger-boson mean-field theory, by including interactions between spinons (i.e., the spin-1/2 excitations of the Z_2 spin liquid) and the topological excitations known as visons. We compute the dynamic structure factor (which is measured in the experiments of Ref. [1]) as a function of a phenomenological spinon-vison coupling constant, and discuss how this coupling constant may be extracted from numerics. [1] T.H. Han et al., to appear.

4:30PM W15.00009 Dipolar order by disorder in the classical Heisenberg antiferromagnet on the kagome lattice , GIA-WEI CHERN, Theoretical Division, Los Alamos National Laboratory, RODERICH MOESSNER, Max Planck Institute for the Physics of Complex Systems, Dresden, Germany — Ever since the experiments which founded the field of highly frustrated magnetism, the kagome Heisenberg antiferromagnet has been the archetypical setting for the study of fluctuation induced exotic ordering. To this day the nature of its classical low-temperature state has remained a mystery: the non-linear nature of the fluctuations around the exponentially numerous harmonically degenerate ground states has not permitted a controlled theory, while its complex energy landscape has precluded numerical simulations at low temperature. Here we present an efficient Monte Carlo algorithm which removes the latter obstacle. Our simulations detect a low-temperature regime in which correlations saturate at a remarkably small value. Feeding these results into an effective model and analyzing the results in the framework of an appropriate field theory implies the presence of long-range dipolar spin order with a tripled unit cell.

4:42PM W15.00010 Spin Correlations in Quantum Spin Liquids on the Kagome Lattice , TYLER DODDS, YONG BAEK KIM, University of Toronto — The spin-1/2 Heisenberg kagome antiferromagnet, due to its highly frustrated nature, is considered a prime candidate to realize a spin-liquid ground state that breaks no symmetry and hosts fractionalized magnetic excitations. Recent numerical results indicate a close competition for the ground state between different spin-liquid states. We study spin correlations in competing phases, suggest possible experiments to distinguish different ground states, and discuss the application of these ideas to Herbertsmithite.

4:54PM W15.00011 p6 - Chiral Resonating Valence Bonds in the Kagome Antiferromagnet[1] , ASSA AUERBACH, Technion, SYLVAIN CAPPONI, University of Toulouse, V. RAVI CHANDRA, Institute of Physics, Bhubaneswar, MARVIN WEINSTEIN, SLAC — The Kagome Heisenberg antiferromagnet is mapped onto an effective Hamiltonian on the star superlattice by Contractor Renormalization. Comparison of ground state energies on large lattices to Density Matrix Renormalization Group justifies truncation of effective interactions at range 3. Within our accuracy, magnetic and translational symmetries are not broken (i.e. a spin liquid ground state). However, we discover doublet spectral degeneracies which signal the onset of p6 - chirality symmetry breaking. This is understood by simple mean field analysis. Experimentally, the p6 chiral order parameter should split the optical phonons degeneracy near the zone center. Addition of weak next to nearest neighbor coupling is discussed.

5:06PM W15.00012 Normal Modes of Frustrated Spins on a Kagome Lattice , ASHWATHI IYER, Cornell University, VADIM OGANESYAN, College of Staten Island, MICHAEL LAWLER, Binghamton University, Cornell University — We study the normal modes of spins in a classical kagome antiferromagnetic Heisenberg model (KAHM), seeking evidence for the canonical and gauge-like zero modes predicted by the constrained spin model of Ref. [1]. We do so by splitting the degeneracy of the low energy configuration space through the introduction of Dzyaloshinski-Moriya (DM) interactions of strength D, performing a Monte-Carlo calculation to find the new ground state configuration, expanding the Hamiltonian to quadratic order about the minimum and diagonalizing the resulting problem to obtain the normal modes. We find that the resulting spectrum splits up into modes that scale with J, the strength of the Heisenberg interactions, and modes that scale with D and D^2/J. The latter two types of modes map directly into the canonical and gauge-like modes of the constrained spin model. In addition, we find clear evidence for "edge modes," which involve the motion of the dangling triangles, in agreement with the conjecture of Ref. [1]. Our calculations shed much light on how the low energy spin dynamics of the classical KAHM behaves like a gauge theory.

5:18PM W15.00013 Monte Carlo Simulations of FCC Kagome Lattice: Competition Between Triangular Frustration and Cubic Anisotropy[1] , MARTIN LEBLANC, MARTIN PLUMER, JOHN WHITEHEAD, Memorial University of Newfoundland — The impact of an effective local cubic anisotropy [1] on the magnetic states of the Heisenberg model on the FCC kagome lattice are examined through classical Metropolis Monte Carlo simulations. Previous simulations revealed that the macroscopic degeneracy of the 2D kagome exchange-coupled co-planar spin system persists in the 3D case of ABC stacked layers [2] giving rise to a discontinuous (possibly order-by-disorder) phase transition. Local cubic anisotropy is shown to reduce this degeneracy by re-orienting the spins out of the co-planar configuration. In addition, the re-oriented states are shown to carry a uniform magnetic moment. The effect of anisotropy on the order of the phase transition will also be reported. These results are relevant to Ir-Mn alloys which have been widely used by the magnetic storage industry in thin-film form as the antiferromagnetic pinning layer in GMR and TMR spin valves [2].

Session W16 GMAG DMP: Focus Session: Biomagnetics, Magneto-Optics, and Ultrafast Effects 318 - Weigang Wang, University of Arizona

2:30PM W16.00001 GMAG PhD Dissertation Research Award Talk: Dynamic Magnetic Traps for Particle Self-Assembly and Lab-on-Chip Applications , AARON CHEN, Department of Physics, The Ohio State University — Micro-patterned Permalloy thin films serve as an excellent means to architect the spatial profile of magnetic fields with the tunable, high gradients required to manipulate objects with weak induced magnetic moments. In this presentation, I will highlight two projects carried out during my PhD studies. These findings demonstrate the functionalities achieved through carefully designed patterns of different sizes and shapes (e.g. circular, triangular, octagonal profiles): (i) By tuning a precessing magnetic field in conjunction with such Permalloy patterns, microsphere (i.e. dipole) cluster structures ranging from closely packed to frustrated and to plum-pudding-like planar lattices are stabilized. Such self-assembly of components at the micro to nanometer range not only support a rich variety of physical phenomena, but also have applications, for example, as filters or force probes and field-tunable photonic crystals. (ii) Mobile magnetic trap arrays consisting of Permalloy disks have enabled rapid transport of magnetic beads or immunomagnetically labeled cells across surfaces. Integration of these arrays with microfluidic droplet technology allows separation of labeled cells and their subsequent encapsulation into picoliter-sized droplets. The droplets serve as isolated containers for individual cells to be probed without cross-contamination. The separation-encapsulation function could become a critical component in point-of-care single-cell analysis platforms.

3:06PM W16.00002 Magnetic multicomponent nanoparticles $Cu_xMn_{1-x}Fe_2O_4$ for biomedical applications , NURCAN DOGAN, Gebze Institute of Technology — Magnetic nanoparticles (NPs) are increasingly important in many biomedical applications, such as drug delivery, hyperthermia, and magnetic resonance imaging (MRI) contrast enhancement. In this multicomponent nanoparticles $Cu_xMn_{1-x}Fe_2O_4$ (CuMnF), x= 0, 0.6, 1, were prepared by hydrothermal synthesis, sol-gel and solid state methods. To build the most effective magnetic nanoparticle systems for various biomedical applications, particle characteristics including size, surface chemistry, magnetic properties and toxicity have to be fully investigated. In this work, effects of production methods of magnetic nanoparticles for the bio-medical applications are discussed. X-ray powder diffractometry (XRD), scanning electron microscopy (SEM) and vibrating scanning magnetometer (VSM) were used to characterize the structural, morphological and magnetic properties. The particle size of samples is measured by Malvern Instruments Zeta Sizer Nano-ZS instrument. The temperature dependence of field cooled (FC) magnetization of all $Cu_xMn_{1-x}Fe_2O_4$ samples have been shown here. The data were recorded under 1k Oe and 100 Oe magnetic fields for different ratio.

3:18PM W16.00003 Detection of low-concentration superparamagnetic nanoparticles using a functional biosensor based on magneto-impedance technology[1] , JAGANNATH DEVKOTA, ALEJANDRO RUIZ, PRITISH MUKHERJEE, HARIHARAN SRIKANTH, MANH-HUONG PHAN, Department of Physics, University of South Florida, CHUNYAN WANG, SUBHRA MOHAPATRA, Department of Internal Medicine, University of South Florida — Improving the sensitivity of existing magnetic biosensors for detection of magnetic nanoparticles as biomarkers in biological systems is an important and challenging task. Here we demonstrate the possibility of combining the magneto-resistance (MR), magneto-reactance (MX), and magneto-impedance (MI) effects to develop a functional magnetic biosensor with tunable and enhanced sensitivity. A systematic study of the 7 nm Fe_3O_4 nanoparticle concentration dependence of MR, MX, and MI ratios of a soft ferromagnetic amorphous ribbon shows that these ratios first increase sharply with increase in particle concentration (0 - 124 nM) and then become unchanged for higher concentrations (>124 nM). This points to the sensitivity and limit of the detection of the biosensor. The MX-based biosensor shows the highest sensitivity. With this sensor, 2.1×10^{11} 7 nm Fe_3O_4 nanoparticles can be detected over a detection area of 2.0×10^5 μm^2, which is comparable to a SQUID biosensor that detects the presence of 1×10^8 11 nm Fe_3O_4 nanoparticles over a detection area of 6.8×10^4 μm^2.

[1]The research was supported by the Florida Cluster for Advanced Smart Sensor Technologies (FCASST) and by USAMRMC through grant numbers W81XWH-07-1-0708 and W81XWH1020101/3349.

3:30PM W16.00004 Characterization of magnetic nanoparticles using Magnetic Hyperthermia System (MHS) for the application in cancer treatment , M.E. SADAT, RONAK PATEL, DAVID B. MAST, DONGLU SHI, University of Cincinnati, SERGEY L. BUD'KO, Ames Laboratory and Department of Physics and Astronomy, Iowa State University, JIAMING ZHANG, University of Michigan, HONG XU, Med-X Institute, Shanghai Jiao Tong University, Shanghai, China — In this study, the heating profiles of various concentrations of three Fe_3O_4 magnetic nanoparticle systems were measured when the nanoparticles were exposed to alternating magnetic fields in a RF Magnetic Hyperthermia System. The Fe_3O_4 core nanoparticles of each system were approximately 10nm in diameter, but each system had different nanoparticle configurations and surface modifications. The heating profiles were used to investigate the dominant heating mechanism, the heat transfer into the surrounding fluid, and the overall effectiveness of each nanoparticle system for possible use in hyperthermia cancer treatments. Magnetization measurements showed that all samples were superparamagnetic in nature with almost zero retentivity and coercivity. For all samples, the saturation magnetization was observed to increase linearly with increasing concentration of Fe_3O_4. Five different concentrations of the three Fe_3O_4 nanoparticle samples were exposed to a 13.56 MHz alternating magnetic field with an amplitude of 4500 A/m, while the solution temperature was measured as a function of time using an optical fiber temperature probe. A correlation was observed between the heating rate, the initial susceptibility, and the type of surface modification of the Fe_3O_4 nanoparticles.

3:42PM W16.00005 Magnetization measurements of magnetic fluids , Z. BOEKELHEIDE, C. L. DENNIS, NIST — Magnetic fluids are used for damping in vehicle suspensions, as MRI contrast agents, heat transfer materials, and even in art installations. Most of these applications benefit from high quality magnetic characterization. Techniques for measuring magnetization (M) of materials, such as vibrating sample magnetometry (VSM), and superconducting quantum interference device (SQUID) magnetometry, are well-developed for small solid samples such as bulk crystals and thin films. This presentation discusses special issues that arise in measurement of fluid samples. First, the effects of the sample vessel must be taken into account. Often, the vessel must be vacuum-tight; care must be taken that the sealing process does not physically change the properties of the fluid. Then, the portion of the signal due to the sample vessel should be subtracted from the total, not a trivial subtraction as the sample vessel has a different geometry from the sample (in contrast to, e.g., a thin film sample and substrate). In addition, the sample must be centered, adding an additional degree of difficulty when the material is fluid and the center position may be a dynamic property. Our results show that incorrect centering can lead to not only incorrect values of M, but to a change in the shape of $M(H)$.

3:54PM W16.00006 Probing Brownian relaxation in water-glycerol mixtures using magnetic hyperthermia , HUMESHKAR NEMALA, Department of Physics and Astronomy, Wayne State University, Detroit, Michigan, MICHAEL MILGIE, Department of Natural Sciences,University of Michigan, Dearborn, Michigan, ANSHU WADEHRA, JAGDISH THAKUR, Department of Physics and Astronomy, Wayne State University, Detroit, Michigan, VAMAN NAIK, Department of Natural Sciences,University of Michigan, Dearborn, Michigan, RATNA NAIK, Department of Physics and Astronomy, Wayne State University, Detroit, Michigan — Generation of heat by magnetic nanoparticles in the presence of an external oscillating magnetic field is known as magnetic hyperthermia (MHT). This heat is generated by two mechanisms: the Neel relaxation and Brownian relaxation. While the internal spin relaxation of the nanoparticles known as Neel relaxation is largely dependent on the magnetic properties of the nanoparticles, the physical motion of the particle or the Brownian relaxation is largely dependent on the viscous properties of the carrier liquid. The MHT properties of dextran coated iron oxide nanoparticles have been investigated at a frequency of 400KHz. To understand the influence of Brownian relaxation on heating, we probe the MHT properties of these ferrofluids in water-glycerol mixtures of varying viscosities. The heat generation is quantified using the specific absorption rate (SAR) and its maximum at a particular temperature is discussed with reference to the viscosity.

4:06PM W16.00007 ABSTRACT WITHDRAWN –

4:18PM W16.00008 Propagation of Electromagnetic Waves in 3D Opal-based Magnetophotonic Crystals , MARTHA PARDAVI-HORVATH, The George Washington University, GALINA S. MAKEEVA, OLEG A. GOLOVANOV, Penza State University, ANATOLII B. RINKEVICH, Institute of Metal Physics Ural Branch of Russian Academy of Science — Opals, a class of self-organized 3D nanostructures, are typical representatives of photonic bandgap structures. The voids inside of the opal structure of close packed SiO_2 spheres can be infiltrated by a magnetic material, creating magnetically tunable magnetophotonic crystals with interesting and potentially useful properties at GHz and THz frequencies. The propagation of electromagnetic waves at microwave frequencies was investigated numerically in SiO_2 opal based magnetic nanostructures, using rigorous mathematical models to solve Maxwell's equations complemented by the Landau-Lifshitz equation with electrodynamic boundary conditions. The numerical approach is based on Galerkin's projection method using the decomposition algorithm on autonomous blocks with Floquet channels. The opal structure consists of SiO_2 nanospheres, with inter-sphere voids infiltrated with nanoparticles of Ni-Zn ferrites. Both the opal matrix and the ferrite are assumed to be lossy. A model, taking into account the real structure of the ferrite particles in the opal's voids was developed to simulate the measured FMR lineshape of the ferrite infiltrated opal. The numerical technique shows an excellent agreement when applied to model recent experimental data on similar ferrite opals.

4:30PM W16.00009 Ultrafast Magnetization Enhancement in Metallic Multilayers Driven by Superdiffusive Spin Current , EMRAH TURGUT, CHAN LA-O-VORAKIAT, PATRIK GRYCHTOL, HENRY C. KAPTEYN, MARGARET M. MURNANE, JILA/University of Colorado Boulder, USA, DENNIS RUDOLF, ROMAN ADAM, CLAUS M. SCHNEIDER, Peter Grünberg Institute, Jülich, Germany, MARCO BATTIATO, PABLO MALDONADO, PETER M. OPPENEER, Uppsala University, Sweden, STEFAN MATHIAS, MARTIN AESCHLIMANN, OPTIMAS/University of Kaiserslautern, Germany, JUSTIN M. SHAW, HANS T. NEMBACH, THOMAS J. SILVA, National Institute of Standards and Technology, Boulder, USA — We report on the surprising enhancement in the magnetization of iron in Ni:Fe based multilayer structures following the excitation by an ultrafast laser pulse. Few femtosecond extreme ultraviolet pulses from tabletop high harmonic generation, tuned to the M-edges of Ni and Fe, are used to probe the layer- and element- specific spin dynamics in multilayer structures of Ni/X/Fe, where X is Ru, Ta, W, or Si3N4. We find that both the Ni and Fe moments demagnetize on timescales of 100 fs when excited by an ultrafast optical pulse, for good spin scattering and insulating spacer layers consisting of Ta, W, and Si3N4. However, we also find that the Fe magnetization is enhanced by 16% for Ru spacer layers of 1.7 nm thickness, when the magnetizations of the Fe/Ni layers are initially aligned parallel. Our observations can be explained by a laser-generated superdiffusive spin current between the Ni and Fe layers, whereby a substantial current of majority spins injected into the Fe layer enhances its magnetization. [1] [1] D. Rudolf et. al. Nat. Comm. 3, 1037 (2012)

4:42PM W16.00010 A microscopic model for ultrafast remagnetization dynamics[1] , BIPLAB SANYAL, RAGHUVEER CHIMATA, ANDERS BERGMAN, Dept. of Physics and Astronomy, Uppsala University, Sweden, LARS BERGQVIST, Department of Materials Science and Engineering, KTH, Sweden, OLLE ERIKSSON, Dept. of Physics and Astronomy, Uppsala University, Sweden — In this work, we provide a microscopic model for the ultrafast remagnetization of atomic moments already quenched above Stoner-Curie temperature by a strong laser fluence. Combining first principles density functional theory, atomistic spin dynamics utilizing the Landau-Lifshitz-Gilbert equation and a three temperature model, we show the temporal evolution of atomic moments as well as the macroscopic magnetization of bcc Fe and hcp Co covering a broad time scale, ranging from femtoseconds to picoseconds. Our simulations show [1] a variety of complex temporal behavior of the magnetic properties resulting from an interplay between electron, spin and lattice subsystems, which causes an intricate time evolution of the atomic moment, where longitudinal and transversal fluctuations result in a macro spin moment that evolves highly non-linearly.

4:54PM W16.00011 Current understanding of the laser-induced ultrafast (de)magnetization process[1] , GUOPING ZHANG, MINGQIANG GU, Department of Physics, Indiana State University, M.S. SI, Department of Physics, LanZhou University, China, T.F. GEORGE, University of Missouri-St. Louis, XIAOSHAN WU, Nanjing University, China — The laser-induced ultrafast (de)magnetization process in ferromagnets is complex. There are several theories available [1], but none of these is satisfactory. In this talk, we first review several theoretical formalism for femtomagnetism and point out strengths and weaknesses of each theory [2]. In particular, we address issues associated with comparing experimental and theoretical results, which have been very challenging. Our first-principles theory includes electron correlation and electron-phonon effects along with spin-orbit coupling in metals or rare-earth compounds. Some of the newest results are presented, which are expected to tremendously enhance our understanding of the overall (de)magnetization process [3].

Session W17 DMP GMAG: Focus Session: CMR Manganites 319 - Jeffrey Lynn, NIST Center for Neutron Research

2:30PM W17.00001 Paramagnetic Spin Fluctuations in Optimally Doped CMR Manganites $La_{0.7}A_{0.3}MnO_3$ (A = Ca, Sr, Ba)

JOEL HELTON, JEFFREY LYNN, YIMING QIU, YANG ZHAO, NIST Center for Neutron Research, DMITRY SHULYATEV, YAKOV MUKOVSKII, National University of Science and Technology "MISiS", Moscow, GEORGII BYCHKOV, SERGEI BARILO, Institute of Solid State and Semiconductor Physics, Minsk — Hole doped perovskites of the form $La_{0.7}A_{0.3}MnO_3$ (where A = Ca, Sr, or Ba) display colossal magnetoresistance at a combined ferromagnetic and metal-insulator transition. The spin fluctuation spectrum of these materials develops a quasielastic spin diffusive central component that dominates the spectrum near T_C. We report inelastic neutron scattering measurements that reveal an additional and unexpected component to the spin fluctuation spectrum, in the form of anisotropic ridges of surprisingly strong quasielastic scattering running along (H 0 0) and equivalent directions. Temperature and field dependent measurements show that this scattering is most pronounced at temperatures in the paramagnetic phase and is suppressed by applied magnetic fields exceeding 10 Tesla.

2:42PM W17.00002 Role of covalency in "Charge Ordering" perovskite ferrates[1]

ANTONIO CAMMARATA, JAMES RONDINELLI, Drexel University — Transition-metal oxides (TMO) with the perovskite crystal structure exhibit strong electron–electron correlation effects and complex structural distortions. The balance of those factors determines the stability of charge ordered states in chemistries susceptible to valence instabilities. We use first-principles density functional calculations to investigate the role of symmetry-unique structural distortions on covalent bonding in the "charge-ordered" insulator $CaFeO_3$. We evaluate the electronic density distribution along the Fe–O bonds to assess the ground state stability by tracing the evolution in the oxygen environment, which appears as octahedral expansion/contractions and rotations. We show that nearly zero charge transfer occurs; the insulating phase results from a complex interplay of symmetry-lowering structural distortions and enhanced covalent interactions. Finally, we discuss possible routes to control the metal–insulator transition by fine-tuning the covalency.

2:54PM W17.00003 Magnetic, structural and magneto-resistance studies of doped $LaMnO_3$ bulk samples prepared by citrate combustion process

HIMANI KHANDURI, MUKESH CHANDRA DIMRI, National Institute of Chemical Physics and Biophysics, Tallinn-12618, Estonia, ARVO MERE, VALDEK MIKLI, JÜRI KRUSTOK, Tallinn University of Technology, Tallinn- 19086, Estonia, RAIVO STERN, National Institute of Chemical Physics and Biophysics, Tallinn-12618, Estonia — We present the structural and magnetic properties of polycrystalline samples of $La_{0.95}A_{0.05}MnO_3$ (where A = Na, Sr, Er, Dy and Ce) prepared by chemical citrate combustion method. Er substituted samples ($La_{1-x}Er_xMnO_3$ with x = 5, 10, 20 and 30%) were also investigated, because their studies lack in the literature. The pervoskite structure was confirmed from X-ray diffraction and Raman spectra in these doped samples, excluding higher Er substituted samples (x > 0.1). The grain sizes were around 2-3 micrometres for all of the sintered samples (at 1300°C), whereas it was below 100 nm for the powders calcined at 600°C, determined from the SEM images. Curie transition temperatures in those doped LMO bulk samples were found to be around 250K, which is higher than the ideal value (∼140 K) for undoped samples. The increase in the Curie temperature can be related to non-stoichiometry and cation vacancies created due to higher/lower valence substitutions for trivalent La^{3+} ions. The temperature dependence of resistivity also confirms the MIT transition in some of these samples.

3:06PM W17.00004 Theory of K-edge resonant inelastic x-ray scattering and its application for $La_{0.5}Sr_{1.5}MnO_4$[1]

T.F. SEMAN, New Jersey Institute of Technology, X. LIU, J.P. HILL, Brookhaven National Laboratory, M. VAN VEENENDAAL[2], Argonne National Laboratory, K.H. AHN, New Jersey Institute of Technology — We present a formula based on tight-binding approach for the calculation of K-edge resonant inelastic x-ray scattering spectrum for transition metal oxides, by extending the previous result [K. H. Ahn, A. J. Fedro, and M. van Veenendaal, Phys. Rev. B 79, 045103 (2009).] to include explicit momentum dependence and a basis with multiple core hole sites. We apply this formula to layered charge, orbital, and spin ordered manganites, $La_{0.5}Sr_{1.5}MnO_4$. The K-edge RIXS spectrum is found not periodic with respect to the actual reciprocal lattice, but approximately periodic with respect to the reciprocal lattice for the hypothetical unit cell with one core hole site. With experimental strcuture and reasonable tight-binding parameters, we obtain good agreement with experimental data, in particular, with regards to the large variation of the intensity with momentum. We find that the screening in $La_{0.5}Sr_{1.5}MnO_4$ is highly localized around the core hole site and demonstrate the potential of K-edge RIXS as a probe for the screening dynamics in materials.

3:18PM W17.00005 LSCO: Consistent agreement for electronic structure and experimental X-ray spectra

Y. LEE, B.N. HARMON, Ames Laboratory and Dept. Physics and Astronomy, Iowa State University, S. MEDLING, F. BRIDGES, Dept. of Physics, University of California, Santa Cruz, H. ZHENG, J.F. MITCHELL, Materials Science Division, Argonne National Laboratory, J.W. FREELAND, Advanced Photon Source, Argonne National Laboratory, AMES LABORATORY AND DEPT. PHYSICS AND ASTRONOMY, IOWA STATE UNIVERSITY COLLABORATION, DEPT. OF PHYSICS, UNIVERSITY OF CALIFORNIA SANTA CRUZ COLLABORATION, MATERIALS SCIENCE DIVISION, ARGONNE NATIONAL LABORATORY COLLABORATION, ADVANCED PHOTON SOURCE, ARGONNE NATIONAL LABORATORY COLLABORATION — We have investigated magnetic properties of $La_{1-x}Sr_xCoO_3$ (LSCO) as a function of Sr doping with X-ray absorption spectroscopy (XAS), x-ray magnetic circular dichroism(XMCD) at the O K edge and a first principles method. Experiment shows the peak of the oxygen XAS at beginning of the edge is increased with increasing Sr doping. The calculations, using supercells, are in good agreement with detailed XAS of the O K-edge as a function of doping. XMCD calculations reproduce the full experimental spectrum well, and show an increase of the magnetic moment on the oxygen with the number of Sr nearest neighbors. The calculations show that the hybridization involving Co d- and O-p electrons is the key factor for obtaining agreement with the changing XAS spectra as a function of doping. In this talk, we will discuss the XAS, XMCD results and the large external magnetic field effects on the ground state of LSCO(x=0).

3:30PM W17.00006 Crossover from Polaronic to Magnetically Phase-Separated Behavior in $La_{1-x}Sr_xCoO_3$

D. PHELAN, CEMS, University of Minnesota (UMN), S. EL KHATIB, Physics, AUS, S. WANG, CEMS, UMN, J. BARKER, NCNR, NIST, J. ZHAO, H. ZHENG, J.F. MITCHELL, MSD, ANL, C. LEIGHTON, CEMS, UMN — Dilute hole-doping in $La_{1-x}Sr_xCoO_3$ leads to the formation of "spin-state polarons" where a non-zero spin-state is stabilized on the nearest Co3+ ions surrounding a hole [1]. Here, we discuss the development of electronic/magnetic properties of this system from non-magnetic x=0, through the regime of spin-state polarons, and into the region where longer-range spin correlations and phase separation develop. We present magnetometry, transport, heat capacity, and small-angle neutron scattering (SANS) on single crystals. Magnetometry indicates a crossover with x from Langevin-like behavior (polaronic) to a state with a freezing temperature and finite coercivity. Fascinating correlations with this behavior are seen in transport measurements, the evolution from polaronic to clustered states being accompanied by a crossover from Mott variable range hopping to intercluster hopping. SANS data shows Lorentzian scattering from short-range ferromagnetic clusters first emerging around x = 0.03 with correlation lengths of order two unit cells. We argue that this system provides a unique opportunity to understand in detail the crossover from polaronic to truly phase-separated states.

3:42PM W17.00007 Energy-loss magnetic circular dichroism measurements of ferromagnetic ordering in $LaSrCoO_3$[1]

, AHMET GULEC, ROBERT F. KLIE, University of Illinois at Chicago, JOHN F. MITCHELL, The Materials Science Division at Argonne National Laboratory — Experimental results show that tuning the ferromagnetism of $LaSrCoO_3$ can be achieved at various temperatures by doping bulk sample with smaller atoms or straining thin film sample. In this work, we will use atomic-resolution Z-contrast imaging, annular bright field (ABF) imaging and electron energy-loss spectroscopy in the aberration-corrected JEOL JEM-ARM200CF in combination with in-situ heating and cooling experiments to examine the magnetic and spin-state transitions in $La_{1-x}Sr_xCoO_3$ (x=0-0.3) between 80 K and 600 K. Using energy-loss magnetic circular dichroism method, we confirm the magnetic ordering transition at room temperature with increasing doping concentrations. Differences in the O K- and Co-L-edges will be utilized to determine the Co valence of the samples. A magnetic transition is observed in 5% doped sample during in-situ cooling experiment to 95 K. Additionally, with increasing the doping concentration, a change in crystal structure is measured using ABF imaging, more specifically a distortion of the CoO_6 octahedra.

3:54PM W17.00008 Metastable low-spin character of Co^{2+} and the control of spin state transition

, BONGJAE KIM, B. I. MIN, POSTECH — We have studied different spin states of the octahedrally coordinated Co^{2+} systems. For every tested systems, we found metastable character of low-spin phase and, interestingly, the energy differences between the high-spin and low-spin phases are similar regardless of the anion (X) type, Co^{+2}-X bond lengths and CoX_6 octahedron distortion. For $CoCl_2$ as a model system, we studied pressure-induced high-spin to low-spin state transition, which is governed by J/Δ_{CF} value (J: exchange parameter, Δ_{CF}: crystal-field parameter). $CoCl_2$ shows sudden collapse of volume and spin moment at the point of spin state transition together with the insulator-to-metal transition. Unlike the other transition-metal oxides, which shows pressure-driven Mott-type transition, physics of $CoCl_2$ is determined mainly by J and Δ_{CF}, not by U and W.

4:06PM W17.00009 Pressure Effect on the Structural Transition and Suppression of the High-Spin State in the Triple-Layered T'-La4Ni3O8[1]

, J.-G. CHENG, U. Texas-Austin and ISSP, U. Tokyo, J.-S. ZHOU, J.B. GOODENOUGH, U. Texas-Austin, H.D. ZHOU, NHMFL, Tallahassee, K. MATSUBAYASHI, Y. UWATOKO, ISSP, U. Tokyo, P.P. KONG, C.Q. JIN, IOP, CAS, W.G. YANG, HPSync, ANL, G.Y. SHEN, HPCAT, ANL — We have carried out a comprehensive high-pressure study on the triple-layer T'-La4Ni3O8 with a suite of experimental probes, including structure determination, magnetic, and transport properties up to 50 GPa. Consistent with a recent ab inito calculation [1], application of hydrostatic pressure suppresses an insulator-metal spin-state transition at Pc $\sim$ 6 GPa. However, a low-spin metallic phase does not emerge after the high-spin state is suppressed to the lowest temperature. For P $>$ 20 GPa, the ambient T' structure transforms gradually to a T'-type structure, which involves a structural reconstruction from fluorite La-O2-La blocks under low pressures to rock-salt LaO-LaO blocks under high pressures. Absence of the metallic phase under pressure has been discussed in terms of local displacements of O2- ions in the fluorite block under pressure before a global T* phase is established [2]. Ref. [1] V. Pardo and W. E. Pickett, Phys. Rev. B 85, 045111 (2012). [2] J.-G. Cheng, et al. Phys. Rev. Lett. 108, 236403(2012).

4:18PM W17.00010 Lattice and transport properties of the misfit-layered oxide thermoelectric $Ca_3Co_4O_9$ from first principles

, ALEJANDRO REBOLA, ROBERT KLIE, University of Illinois at Chicago, PETER ZAPOL, Argonne National Laboratory, SERDAR OGUT, University of Illinois at Chicago — The misfit-layered oxide $Ca_3Co_4O_9$ (CCO) has recently been the subject of many experimental and some theoretical investigations due to its remarkable thermoelectric properties. CCO is composed of two incommensurate subsystems, a distorted rocksalt-type Ca_2CoO_3 layer sandwiched between hexagonal CoO_2 layers. Taking into account that the composition ratio between these subsystems is very close to the golden mean, which is the limit of the sequence of the ratios of consecutive Fibonacci numbers $F(n)$, we model CCO from first principles[1] by using rational approximants of composition $[Ca_2CoO_3]_{2F(n)}[CoO_2]_{2F(n+1)}$. In the present study, we use 3/2 and 5/3 rational approximants and PBE+U computations to calculate the *ab initio* phonon dispersion curves, related thermal properties, as well as *ab initio* electronic transport properties such as DC conductivity and thermopower within the relaxation time approximation by applying the Boltzmann transport theory. Results are compared with available experimental data and potential routes for increasing the thermopower of CCO are discussed.

4:30PM W17.00011 Magnetostructural transitions and metamagnetism induced by Ising spins in spinel-rock salt intergrowth $Co_{10}Ge_3O_{16}$

, PHILLIP BARTON, RAM SESHADRI, Materials Department and Materials Research Laboratory, University of California, Santa Barbara — $Co_{10}Ge_3O_{16}$ crystallizes in an intergrowth structure featuring alternating layers of spinel and rock salt, making it related to $GeCo_2O_4$. Variable-temperature synchrotron X-ray powder diffraction, magnetometry, and heat capacity experiments reveal a magnetostructural transition at antiferromagnetic $T_N = 205$ K. This rhombohedral-to-monoclinic transition involves a slight elongation of the CoO_6 octahedra. Curie-Weiss analysis suggests that the Co^{2+}, with $S = 3/2$ and $L = 3$, acts as a Kramer's doublet due to spin-orbit coupling. Below T_N, the Ising-like Co^{2+} causes spin reorientation at high applied magnetic field that is first seen as an upward kink in M-H near $H_C = 3.9$ T. A "butterfly" loop emerges when $T <$ 150 K, with the transition causing hysteresis at high fields while linear and reversible behavior persists at low fields. H_C decreases as temperature is lowered and the loops at positive and negative fields merge beneath $T = 20$ K. The low-temperature behavior is complicated by a field-induced first-order transition that is observed in temperature-dependent measurements for $H >$ 1000 Oe. We discuss the H-T phase diagram with reference to other measurements including neutron powder diffraction and high-field magnetometry.

4:42PM W17.00012 Anisotropy and Magnetostriction in Cobalt-Modified Magnetite: A Crystal Field Approach

, CAJETAN NLEBEDIM, Ames Laboratory, US DOE, Iowa State University, DAVID JILES, Department of Electrical and Computer Engineering, Iowa State University — The anisotropy and magnetostrictive properties of magnetite are altered by the introduction of cobalt ions into the spinel crystal lattice. 4% of Co^{2+} substituted for Fe^{2+} changes both the sign and magnitude of magnetocrystalline anisotropy coefficient. Such strong dependence can be useful for tailoring the properties of cobalt-iron oxides for applications. This is especially important, considering that cobalt ferrite materials prepared for magnetostrictive, multiferroic and other related applications often deviate from targeted or stoichiometric compositions. In this study, magnetite has been systematically modified by substitution of cobalt. The changes in anisotropy and magnetostriction have been studied and can be explained using the single ion model. The agreement between the trend observed in this experimental investigation and previous theoretical studies is noteworthy. The variation in anisotropy and magnetostriction will be presented on the basis of two competing factors; the unquenched orbital angular momentum of Co^{2+} and changes in the crystal field due to Co^{2+} substitution.

4:54PM W17.00013 Thermal expansion study of anisotropic magnetolattice coupling and antiferromagnetic transition in CuO[1] , JOHN J. NEUMEIER, ALWYN REBELLO, SAMUEL VIALL, ZACHARY C.M. WINTER, Montana State University — Transition metal oxides have been the subject of intense research over the past few decades since they form the basic building block of many materials showing exotic properties such as high temperature superconductivity, spin and charge ordering, magnetoresistance, multiferroicity etc. Recently, Kimura et al. demonstrated an intriguing coupling between electric and magnetic dipole ordering in CuO, which opened a new route for finding materials exhibiting induced multiferroic behavior.[2] Here we present results on anisotropic thermal expansion in single crystalline CuO in the temperature range $5 < T < 350$ K. Our results demonstrate anisotropic magnetolattice coupling in CuO around the two known antiferromagnetic phase transitions at T_{N1}= 230 K and T_{N2}= 213 K. We also discuss the pressure dependence of T_{N1} and critical behavior in CuO using the scaling of heat capacity and thermal expansion data.

[1]Supported by NSF Grant DMR-0907036.

5:06PM W17.00014 Ab initio study on magnetic coupling in A-site-ordered perovskite CaCu3B4O12 (B=Ti, Ge, Zr, and Sn) , MASAYUKI TOYODA, CREST, Japan Science and Technology Agency. ISIR, Osaka University, KUNIHIKO YAMAUCHI, ISIR, Osaka University, TAMIO OGUCHI, CREST, Japan Science and Technology Agency. ISIR, Osaka University — Magnetism of A-site-ordered perovskites, $CaCu_3Ti_4O_{12}$, $CaCu_3Ge_4O_{12}$, $CaCu_3Sn_4O_{12}$, and $CaCu_3Zr_4O_{12}$, is comprehensively studied by ab initio electronic structure calculations. The magnetic exchange constants between Cu spins, J_1, J_2 and J_3, are estimated via an effective Heisenberg model, which reveals relative importance of J_3 despite its long interaction length. The ground-state magnetic order is reasonably explained by combination of relatively weak ferromagnetic super-exchange interaction (J_1 and J_2) and dominant super-exchange interaction (J_3) which can be tuned by replacement of the B-site element. We will also discuss the effect of A-site-cation replacement by comparing with the results of other A-site-ordered perovskite materials.

Thursday, March 21, 2013 2:30PM - 5:30PM –

Session W18 GMAG DMP FIAP: Focus Session: Spin-Dependent Phenomena in Semiconductors - Dynamic and Nuclear Effects 320 - Vanessa Sih, University of Michigan

2:30PM W18.00001 THz Magneto-photoresponse of an InAs-based Quantum Point Contact Structure in the Region of Cyclotron Resonance , MEHDI PAKMEHR, Department of Physics, University at Buffalo (SUNY), VINCENT WHITESIDE, University of Oklahoma, NIKHIL BHANDARI, MARC CAHAY, RICHARD NEWROCK, University of Cincinnati, BRUCE MCCOMBE, Department of Physics, University at Buffalo (SUNY) — We have studied the THz magneto-photoresponse of a 2DEG in an InAs quantum well with an embedded Quantum Point Contact in the frequency/field region where electron cyclotron resonance (CR) dominates the response suing several lines from an optically pumped THz laser. The photoresponse near CR is manifested as an envelope of the amplitude of the Shubnikov-de Haas oscillations of the 2DEG with a peak near the CR field. Clear spin-splitting of the quantum oscillations is observed for B $>$ 4, while the SdH oscillations do not show resolved spin-splitting up to 10 T. Data were simulated by a model of resonant carrier heating (due to CR), and from the simulations the carrier density, the CR effective mass, scattering times and the g-factor were obtained. We find a significantly enhanced g-factor, apparently due to many-electron exchange interaction effects. The g-factor determined from fitting spin-split Landau level peaks increases with magnetic field. Work at UB was supported by NSF DMR 1008138 and the Office of the Provost; work at the University of Cincinnati was supported by NSF ECCE 1028483.

2:42PM W18.00002 Terahertz excitation and control of spin photocurrents in a semiconductor nanostructure[1] , NELSON STUDART, ANIBAL BEZERRA, Departamento de Fisica - UFSCar / DISSE - INCT, LEONARDO CASTELANO, Departamento de Fisica - UFSCar, PAULO FARINAS, Departamento de Fisica - UFSCar / DISSE - INCT, MARCELO MAIALLE, MARCOS DEGANI, Faculdade de Ciencias Aplicadas - UNICAMP / DISSE - INCT — Time dependent calculations of induced photocurrents are presented for ZnMnSe semiconductor nanostructures under the action of a static magnetic field of a few Tesla. The study shows the existence of spectral domains in the THz range for which the spin polarization in the photocurrent is strongly sensitive to static biases applied in the growth direction of the structures. For such photon frequencies, changing the bias is predicted to reverse the spin polarization quite effectively for specific absorption frequencies. This behavior suggests the possibility of conveniently simple mechanisms for switching and torque generation. The physics underlying these results is studied and understood in terms of the spin dependent profiles of the structures.

[1]Work supported by DISSE - INCT - CNPq - Brazil.

2:54PM W18.00003 Anomalous spin precession and spin Hall effect in semiconductor quantum wells , PEIRU HE, XINTAO BI, ICQD, University of Science and Technology of China, E.M. HANKIEWICZ, Universität Würzburg, R. WINKLER, Argonne National Laboratory, GIOVANNI VIGNALE, University of Missouri, DIMITRIE CULCER, ICQD, University of Science and Technology of China — We study the contributions of the anomalous position operator to the spin-Hall effect in quasi two-dimensional semiconductor quantum wells with strong band structure spin-orbit interactions. The skew scattering and side-jump *scattering* terms in the SHE vanish, but we identify two additional terms in the SHE due to the anomalous position operator. One term reflects the modification of the spin precession due to the action of the external electric field, which produces an effective magnetic field perpendicular to the plane of the quantum well. The other term reflects a similar modification of the spin precession due to the action of the electric field created by random impurities. We refer to these two effects collectively as *anomalous spin precession*. In electron systems with weak momentum scattering, anomalous spin precession due to the external electric field equals 1/2 the side-jump SHE, while the additional impurity-dependent contribution depends on the form of the band structure SO coupling. For band structure SO linear in wave vector the two additional contributions cancel. For band structure SO cubic in wave vector external electric field contribution can be detected through its density dependence. In 2D hole systems both additional contributions vanish.

3:06PM W18.00004 Electrically generated nuclear spin polarization in $In_{.04}Ga_{.96}As$, CHRISTOPHER TROWBRIDGE, BENJAMIN NORMAN, University of Michigan Department of Physics, YUICHIRO K. KATO, Institute of Engineering Innovation, School of Engineering, The University of Tokyo, DAVID AWSCHALOM, Center for Spintronics and Quantum Computation, Univ. of California Santa Barbara, VANESSA SIH, University of Michigan Department of Physics — The promises of lower power consumption and simple interfacing to magnetic storage has driven interest in the development of spintronics, in which devices could take advantage of electron spin as a means to store, move, and process data. Due to its long lifetime in moderate fields, nuclear polarization could serve as intermediate timescale data storage in both classical spintronic and quantum computation schemes. Here, we investigate the role of nuclear spins in materials with electrically driven spin polarization. The electron spin polarization generated by electrical current in a non-magnetic semiconductor is transferred via dynamic nuclear polarization to the nuclei. The resulting nuclear field is interrogated using Larmor magnetometry. We measure nuclear field as a function of current, applied magnetic field, and temperature. Polarization decay dynamics and the role of nuclei in devices are also discussed.

3:18PM W18.00005 Knight shift and quadrupolar relaxation measured by NMR in Fe/GaAs heterostructures , KEVIN CHRISTIE, CHAD GEPPERT, MUN CHAN, University of Minnesota, Minneapolis, QI HU, CHRIS PALMSTRÖM, University of California, Santa Barbara, PAUL CROWELL, University of Minnesota, Minneapolis — We report on all-electrical measurements of nuclear magnetic resonance (NMR) in epitaxial (100) Fe/GaAs heterostructures with a channel doping (Si) of $n = 5 \times 10^{16}$ cm^{-3}. By changing the electrical bias, measurements of NMR were performed as a function of spin accumulation. A Knight shift due to the presence of spin-polarized electrons is demonstrated under conditions of large (10-20%) spin polarization. The effects of nuclear quadrupole moments are also investigated. Although GaAs is cubic, strain induced field gradients split the NMR line into quadrupole multiplets. We investigate the role of nuclear quadrupole relaxation as a function of temperature. Phonon induced quadrupolar relaxation is expected to increase strongly with temperature and be more pronounced for the As nuclei. We show that the evolution of the relative magnitude of the NMR peaks as a function of temperature agrees well with a model dominated by quadrupole relaxation. Supported by NSF DMR-0804244 and DMR-1104951.

3:30PM W18.00006 Long-lived electron spins in a modulation doped (100) GaAs quantum well , JOHN COLTON, DAVID MEYER, KEN CLARK, DANIEL CRAFT, JANE TANNER, TYLER PARK, PHIL WHITE, Brigham Young University — We have measured T_1 spin lifetimes of a 14 nm modulation-doped (100) GaAs quantum well using a time-resolved pump-probe Kerr rotation technique. The quantum well was selected by tuning the wavelength of the probe laser. T_1 lifetimes in excess of 1 microsecond were measured at 1.5 K and 5.5 T, exceeding the typical T_2^* lifetimes that have been measured in GaAs and II-VI quantum wells by orders of magnitude. We observed effects from nuclear polarization, which were largely removable by simultaneous nuclear magnetic resonance, along with two distinct lifetimes under some conditions that likely result from probing two differently-localized subsets of electrons.

3:42PM W18.00007 Spin-orbit ferromagnetic resonance , ANDREW FERGUSON, University of Cambridge — In conventional magnetic resonance techniques the magnitude and direction of the oscillatory magnetic field are (at least approximately) known. This oscillatory field is used to probe the properties of a spin ensemble. Here, I will describe experiments that do the inverse [1]. I will discuss how we use a magnetic resonance technique to map out the current-induced effective magnetic fields in the ferromagnetic semiconductors (Ga,Mn)As and (Ga,Mn)(As,P). These current-induced fields have their origin in the spin-orbit interaction [2-4]. Effective magnetic fields are observed with symmetries which resemble the Dresselhaus and Rashba spin-orbit interactions and which depend on the diagonal and off-diagonal strain respectively. Ferromagnetic semiconductor materials of different strains, annealing conditions and concentrations are studied and the results compared with theoretical calculations. Our original study measured the rectification voltage coming from the product of the oscillatory magnetoresistance, during magnetisation precession, and the alternating current. More recently we have developed an impedance matching technique which enables us to extract microwave voltages from these high resistance (10 kΩ) samples [5]. In this way we measure the microwave voltage coming from the product of the oscillating magneto-resistance and a direct current. The direct current is observed to affect the magnetisation precession, indicating that anti-damping as well as field-like torques can originate from the spin-orbit interaction.

4:18PM W18.00008 Experimental demonstration of Scanned Spin-Precession Microscopy[1] , V.P. BHALLAMUDI, C.S. WOLFE, Department of Physics, The Ohio State University, V.P. AMIN, Department of Physics and Astronomy, Texas A&M University, D.E. LABANOWSKI[2], A.J. BERGER, D. STROUD, Department of Physics, The Ohio State University, J. SINOVA, Department of Physics and Astronomy, Texas A&M University, P.C. HAMMEL, Department of Physics, The Ohio State University — We present the demonstration of a new spin-microscopy tool that relies on the precessional response of spins to the spatially heterogeneous field of a micromagnet. In this first experiment, we map the spin density within an optically pumped GaAs sample by recording the variations of a global spin-photoluminescence signal as a function of a micromagnetic probe's position (relative to the pump beam). The spin density map is then obtained by deconvolving the measured signal with an experimentally or theoretically determined response of the spins to their magnetic environment. The response function is sensitive to other important properties, such as spin lifetime and gyromagnetic ratio, and thus these properties can also imaged. Further, the technique can be employed in conjunction with both optical and electrical detection schemes. In the former case it can enhance the imaging resolution while for the latter it can enable imaging. Due to the magnetic nature of coupling between the probe and the spins, this technique has the potential to be material independent and enable subsurface imaging.

4:30PM W18.00009 Spin relaxation near the metal-insulator transition: dominance of the Dresselhaus spin-orbit coupling , PABLO I. TAMBORENEA, Universidad de Buenos Aires, GUIDO A. INTRONATI, Universidad de Buenos Aires, IPCMS U. Strasbourg, CEA Saclay, DIETMAR WEINMANN, RODOLFO A. JALABERT, IPCMS U. Strasbourg — We identify the Dresselhaus spin-orbit coupling as the source of the dominant spin-relaxation mechanism in the impurity band of a wide class of n-doped zincblende semiconductors. The Dresselhaus hopping terms are derived and incorporated into a tight-binding model of impurity sites, and they are shown to unexpectedly dominate the spin relaxation, leading to spin-relaxation times in good agreement with experimental values. This conclusion is drawn from two complementary approaches: an analytical diffusive-evolution calculation and a numerical finite-size scaling study of the spin relaxation time. Reference: G. A. Intronati, P. I. Tamborenea, D. Weinmann, and R. A. Jalabert, Phys. Rev. Lett. vol. 108, 016601 (2012).

4:42PM W18.00010 X-Ray Circular Dichroism Detected Spin Populations in N Doped (100) GaAs[1] , SIOAN ZOHAR, JONG WOO KIM, PHILIP RYAN, DAVID KEAVNEY, Argonne National Laboratory — We present the x-ray absorption and reflectivity of optically injected spin populations into highly doped n:GaAs. The spin population was excited in the GaAs using a circularly polarized laser at the band gap energy and detected using synchronous methods referenced to the x-ray repetition rate and laser chopping frequency. We observe x-ray circular dichroism along the Ga L_3 and L_2 edges two orders of magnitude larger than expected from LMTO band structure calculations. This observation is explained in the context of a surface related spin dependent non-equilibrium population immediately above and below the GaAs band-gap.

4:54PM W18.00011 Mott's scattering and Spin Hall Effect modeled by means of numerical solutions of the Schrödinger equation , NAGENDRA DHAKAL, MIKHAIL EREMENTEHOUK, MICHAEL LEUENBERGER, University of Central Florida — We have developed a code for numerical solution of non-stationary Schrödinger equations based on the finite difference time-domain (FDTD) method. We model the 2 dimensional free electron gas system using perfectly matched layers for the open surrounding space. We study the effect of localized impurities on the time evolution of the electron wave function, thereby observing dephasing introduced by the impurities. Our numerical simulations show the de-coherence due to the impurities at moderate impurity densities and Anderson localization at high impurity densities. We implement the code for studying an effect of the spin orbit interaction in presence of the impurities. The clear picture of Mott's scattering gives rise to the Spin Hall Effect. Our results are important for the implementation of quantum computing, quantum communication, and spintronics.

5:06PM W18.00012 Diode Aided Geometrical Enhancement of Magnetoresistance in Semiconductors , XIAOZHONG ZHANG, CAIHUA WAN, SHAOCHU LUO, JIMING WANG, JIAOJIAO CHEN, HONGGUANG PIAO, Department of Materials Science and Engineering, Tsinghua University, China — Magnetoresistance (MR) reported in some non-magnetic semiconductors particularly silicon has triggered considerable interest owing to the large magnitude of the effect. Here we showed that MR in lightly doped n-Si can be significantly enhanced by introducing a diode in the device and proper design of the carrier path [1,2]. We designed an MR device whose room-temperature MR ratio reaching 30% at 0.065T and 20000% at 1.2T, respectively, approaching the performance of commercial MR devices. We also realized MR of over 2600% in GaAs and Ge at 1.2T [2]. The MR mechanism of our devices is: The diode helps to establish a transition from low resistance state to high resistance state. In the transition region the small change in magnetic field cause a large change in MR. Because our MR device is based on a conventional Si/semiconductor platform, it should be possible to integrate it with existing Si/semiconductor devices and so aid the development of Si/semiconductor-based magneto-electronics leading to some multifunctional devices.

5:18PM W18.00013 A spin-influenced hopping theory for transport in molecular semiconductors\fs20[1] , CHANG-QIN WU, Department of Physics, Fudan University, Shanghai 200433, China — We investigate the influence of charge carrier's spin interaction on the hopping transport in molecular semiconductors. By considering the quenching of the spin correlation after the carrier's incoherent jump between molecules, we obtain the carrier's hopping rate that contains explicitly the contribution of carrier's spin interaction. As a consequence, the rate is modulated by applied magnetic field, leading to the magnetoresistance with a general feature of a Lorentzian-shape saturation at large fields and an ultrasmall-field component, which explains well the related experiments observed in organic semiconducting materials.

Session W19 DCMP: Holography and Higgs Physics in Condensed Matter 321 - Philip Phillips, University of Illinois

2:30PM W19.00001 Spin and holographic metals[1] , VICTOR ALEXANDROV, PIERS COLEMAN, Rutgers University — We examine the spin structure of the Green's function of the holographic metal, demonstrating that the excitations of the holographic metal are "chiral," lacking the inversion symmetry of a conventional Fermi surface, with only one spin orientation for each point on the Fermi surface aligned parallel to the momentum. This implies that ferromagnetic spin fluctuations are absent from the holographic metal, leading to a complete absence of Pauli paramagnetism. The talk will discuss a possibility of going to a 3-dimensional holographic metal, where electrons should have both left- and right-handed chiralities.

2:42PM W19.00002 The Pauli exclusion principle in semi-local quantum criticality , DAVID RAMIREZ, RICHARD ANANTUA, SEAN HARTNOLL, VICTORIA MARTIN, Stanford University — A crucial consequence of the Pauli exclusion principle in weakly coupled systems is the presence of low energy degrees of freedom at finite momenta; a natural question is then to what extent does this aspect of Pauli exclusion persist at strong coupling, which may not even admit well-defined quasiparticles? We use holography to address this issue by studying the momentum space structure of low energy current-current correlation functions in finite density field theories exhibiting semi-local criticality. The semi-locally critical theories are characterized by an exponent η that determines the low temperature scaling of entropy density to be $s \sim T^{\eta}$. Despite the fact that spatial momenta do not scale in semi-locally critical theories, we find that operator dimensions can have non-trivial momentum dependence, leading to novel momentum space structure. In particular, for $0 < \eta < 2$, we find sharp discontinuities in the transverse response functions at a non-zero k_*, reminiscent of Pauli exclusion-type dynamics. Finally, we comment on the $\eta = 1$ geometry, which allowed for analytic expressions for correlation functions at finite temperature as well as interesting phenomenological properties and string theory embeddings.

2:54PM W19.00003 Superconducting Dome and Anisotropy in Holographic Striped Superconductor , JIMMY HUTASOIT, The Pennsylvania State University, SUMAN GANGULI, GEOGRE SIOPSIS, JASON THERRIEN, University of Tennessee at Knoxville — Using gauge/gravity duality, we study the properties of a strongly coupled striped superconductor with unidirectional charge density wave order. By including the effects of fluctuations, we show that there is a regime in which this holographic model exhibits a superconducting dome. Furthermore, we study the anisotropy of the optical conductivity at temperature below the critical temperature and compare it with the experimental results in cuprate.

3:06PM W19.00004 Inhomogeneous Phases in Holographic Superfluids[1] , KUBRA YETER, The University of Tennessee, Knoxville, ELEFTHERIOS PAPANTONOPOULOS, National Technical University of Athens, GEORGE SIOPSIS, The University of Tennessee, Knoxville — We discuss inhomogeneous solutions of a gravitating system consisting of two $U(1)$ gauge fields and a real scalar field. One of the $U(1)$ gauge fields determines the chemical potential, whereas the other one corresponds to a magnetic field interacting with the spin in the boundary theory. We solve the field equations and find a second-order phase transition to an inhomogeneous phase at a critical temperature which we compute. Below the critical temperature, the equations are solved perturbatively, and a spatially dependent charge density is generated. This is compatible with the generation of a charge density wave in condensed matter systems.

3:18PM W19.00005 Compressible quantum phases from conformal field theories in 2+1 dimensions , SUBIR SACHDEV, Harvard University — Conformal field theories (CFTs) with a globally conserved U(1) charge Q can be deformed into compressible phases by modifying their Hamiltonian, H, by a chemical potential $H \to H - \mu Q$. We study 2+1 dimensional CFTs upon which an explicit S duality mapping can be performed. We find that this construction leads naturally to compressible phases which are superfluids, solids, or non-Fermi liquids which are more appropriately called 'Bose metals' in the present context. The Bose metal preserves all symmetries and has Fermi surfaces of gauge-charged fermions, even in cases where the parent CFT can be expressed solely by bosonic degrees of freedom. Monopole operators are identified as order parameters of the solid, and the product of their magnetic charge and Q determines the area of the unit cell. We discuss implications for holographic theories on asymptotically AdS_4 spacetimes: S duality and monopole/dyon fields play important roles in this connection.

3:30PM W19.00006 Metal-Insulator Transition from Holography , SEAN HARTNOLL, Stanford University, ARISTOMENIS DONOS, Imperial College London — The holographic correspondence allows theoretical control of certain phases of matter that do not admit a quasiparticle description. This approach has proved helpful for the description of quantum critical transport. I will present holographic results for transport away from particle-hole symmetry. This requires explicit inclusion of lattice effects to render the conductivity finite. I will show that the holographic system undergoes a metal-insulator transition as a function of the strength of the lattice. This results implies that holography is capable of describing localization physics in strongly interacting systems. I will present results for the optical conductivity, exibiting a transition from a metallic drude peak to Mott insulating behavior.

3:42PM W19.00007 Multipoint correlators of conformal field theories: implications for quantum critical transport , PHILIPP STRACK, DEBANJAN CHOWDHURY, Harvard, SUVRAT RAJU, Bangalore, SUBIR SACHDEV, Harvard, AJAY SINGH, Waterloo — We relate three-point correlators between the stress-energy tensor and conserved currents of conformal field theories (CFTs) in 2+1 dimensions to observables of quantum critical transport. We first compute the correlators in the large-flavor-number expansion of conformal gauge theories and then do the computation using holography. In the holographic approach, the correlators are computed from an effective action on 3+1 dimensional anti-de Sitter space (AdS_4), and depend upon the co-efficient, γ, of a four-derivative term in the action. We find a precise match between the CFT and the holographic results, thus fixing the values of γ. The CFTs of free fermions and bosons take the values $\gamma = 1/12, -1/12$ respectively, and so saturate the bound $|\gamma| \leq 1/12$ obtained earlier from the holographic theory; the correlator of the conserved gauge flux of U(1) gauge theories takes intermediate values of γ. The value of γ also controls the frequency dependence of the conductivity, and other properties of quantum-critical transport at non-zero temperatures. Our results for the values of γ lead to an appealing physical interpretation of particle-like or vortex-like transport near quantum phase transitions of interest in condensed matter physics.

3:54PM W19.00008 The quasi-normal modes of quantum criticality[1] , WILLIAM WITCZAK-KREMPA, Perimeter Institute, SUBIR SACHDEV, Harvard University — We study the general features of charge transport of quantum critical points described by CFTs in 2+1D. We use an effective field theory on an asymptotically AdS spacetime, expanded to fourth order in spatial and temporal gradients. The presence of a horizon at non-zero temperatures implies that this theory has quasi-normal modes with complex frequencies. The quasi-normal modes determine the poles and zeros of the conductivity in the complex frequency plane, and so fully determine its behavior on the real frequency axis, at frequencies both smaller and larger than the temperature. We describe the role of particle-vortex or S-duality on the conductivity, specifically how it maps poles to zeros and vice versa. These analyses motivate two sum rules obeyed by the quantum critical conductivity. Finally, we compare our results with the analytic structure of the O(N) model in the large-N limit, and other CFTs.

4:06PM W19.00009 FFLO States in Holographic Superconductors , GEORGE SIOPSIS[1], University of Tennessee, JAMES ALSUP, University of Michigan - Flint, ELEFTHERIOS PAPANTONOPOULOS, National Technical University of Athens — We discuss a novel mechanism to set up a gravity dual of FFLO states in strongly coupled superconductors. The gravitational theory utilizes two $U(1)$ gauge fields and a scalar field coupled to a charged AdS black hole. The first gauge field couples with the scalar sourcing a charge condensate below a critical temperature, and the second gauge field provides a coupling to spin in the boundary theory. The scalar is neutral under the second gauge field. By turning on an interaction between the Einstein tensor and the scalar, it is shown that, in the low temperature limit, an inhomogeneous solution possesses a higher critical temperature than the homogeneous case, giving rise to FFLO states.

4:18PM W19.00010 Study of Higgs mode near quantum critical points , YEJIN HUH, SUBIR SACHDEV, Harvard University — We present a study of Higgs excitation mode in different quantum theories in 2 space dimensions. $O(N)$ theory and $CP(N)$ theory near the quantum critical points will be discussed for zero and finite temperature. Electron systems with fermi surfaces will be studied under this framework.

4:30PM W19.00011 Superconductivity in a model involving transverse gauge bosons[1] , IPSITA MANDAL, SUDIP CHAKRAVARTY, SUK BUM CHUNG, University of California Los Angeles — It has been known for some time that a system of fermions interacting with transverse gauge bosons does not behave like a Fermi liquid and provides a bona fide model for a non-Fermi liquid. Here we study superconductivity in this model Preliminary calculations show explicitly that a superconducting gap exists only for couplings greater than a threshold. It is hoped that a proper elucidation of this problem would lead to insights that may be useful in developing effective low energy theories of realistic physical problems, such as the normal state of high temperature superconductors, the state of half-filled quantum Hall systems, or the color superconductivity in the quark-gluon system, or even in the effects of disorder in a non-Fermi liquid system that could provide a new paradigm.

[1]This work is being supported by NSF under Grant number DMR-1004520

4:42PM W19.00012 Detection of Higgs mode in D-wave Superconductors , YAFIS BARLAS, CHANDRA VARMA, University of Califronia at Riverside — Higgs modes, which are collective excitations of the amplitude of the order parameter, have zero spin and no charge, do not couple directly to experimental probes. They are, however, linearly coupled to excitations which shake the ground state and therefore appear as poles or branch-cuts in their self-energy. In the superconducting state the Higgs modes can be distinguished from other excitations because they can only appear as satellites which steal all their spectral weight from excitations which promote superconductivity. This is an observable effect if such excitations and the Higgs modes are not too far separated in energy. We show that the Higgs mode in the A_{1g} Raman scattering channel appears as a sharp resonance below 2Δ in the spectral weight of excitations responsible for superconductivity in Cuprates in a class of theories. Comparison is made with existing experiments and further experiments to confirm or rule out the idea are proposed.

4:54PM W19.00013 Unified Description of Nambu-Goldstone Bosons without Lorentz Invariance , HARUKI WATANABE, University of California, Berkeley, HITOSHI MURAYAMA, Kavli IPMU; University of California, Berkeley; Lawrence Berkeley National Laboratory — We address the well-known problem that Nambu-Goldstone's theorem does not correctly predict the number of Nambu-Goldstone bosons in systems without Lorentz invariance. Using the effective Lagrangian approach, we provide a general prescription to predict the number of Nambu-Goldstone bosons and the form of their dispersion relation correctly. We trace the abnormalities in non-Lorentz invariant systems back to Nambu-Goldstone boson pairs becoming canonically conjugate–this reduces the number of Nambu-Goldstone bosons and changes the linear dispersions to quadratic. The generality of our construction clarifies the powerful approach of analyzing quantum many-body systems–including strongly coupled systems–by their symmetry breaking patterns. This will also aid our understanding of recent experiments and theoretical works on spinor BECs and lattices of topological defects. Reference: H. Watanabe, H. Murayama, PRL 108, 251602 (2012)

Session W20 DMP: Focus Session: Electron, Ion, Exciton Transport in Nanostructures: Charge Transport in Functional Nanostructures 322 - Kenji Shiraishi, University of Tsukuba

2:30PM W20.00001 Two important physical models for resistance switching phenomena , TAE W. NOH, Center for Functional Interfaces of Correlated Electron Systems, Institute of Physics, and Dept. of Physics and Astronomy, Seoul National Univ. — Resistance switching (RS) phenomena refer to reversible resistance changes between two metastable resistance states driven by an external voltage. Recently, there has been a flurry of investigations into RS due to their inherent scientific interest and potentials for memory applications. In spite of extensive efforts, the basic mechanisms of RS still remain to be elucidated. One of the reasons is that RS usually occurs in very dirty materials, where defects should play important roles. In this talk, I will present two models for RS phenomena, which are material independent and can be used to make quantitative predictions. The first model is for unipolar RS, where the corresponding current-voltage ($I-V$) curves are quite symmetric. We introduced a new kind of percolation model, called the random circuit breaker (RCB) network model, which allows reversible changes between two resistance states. This model can describe the formation of conducting channels due to dielectric breakdown and make quantitative predictions especially for scaling behaviors. We will show that collective behavior of conducting channels plays an important role in most aspects of unipolar RS, including the wide distribution of set and reset voltages, scaling behaviors, and large $1/f$ noise. The second model is for bipolar RS, where the corresponding $I-V$ curves are quite asymmetric. We introduced a quantitative model which can describe motion of mobile defects under electric field. We will show that oxygen vacancy migration near the interface region could determine important features of bipolar RS, including two switching directions of $I-V$ curves. We also showed that important aspects of these two models can be combined successfully in a unified scheme by putting interface effects into the RCB network model.

3:06PM W20.00002 Fractal dynamics in chaotic quantum transport , ESA RASANEN, Department of Physics, Tampere University of Technology, Finland, VILLE KOTIMAKI, Department of Physics, University of Jyvaskyla, Finland, HOLGER HENNIG, ERIC HELLER, Physics Department, Harvard University, USA — Despite several experiments on chaotic quantum transport, corresponding ab initio quantum simulations have been out of reach so far. Here we carry out quantum transport calculations in real space and real time for a two-dimensional stadium cavity that shows chaotic dynamics. Applying a large set of magnetic fields yields a complete picture of the magnetoconductance that indicates fractal scaling on intermediate time scales. Two methods that originate from different fields of physics are used to analyze the scaling exponent and the fractal dimension. They lead to consistent results that, in turn, qualitatively agree with the previous experimental data.

3:18PM W20.00003 Schottky Barrier Transport for Multiphase Gallium Nitride Nanowire , STEVEN HARTZ, KAN XIE, ZHUN LIU, VIRGINIA AYRES, Michigan State University — Our group has shown that gallium nitride nanowires grown by catalyst-free vapor deposition at 850^{o}C have multiple internal crystalline regions that may be zinc blende or wurtzite phase. Stability is enabled by one or more totally coherent (0001)/(111) internal interfaces. Cross-section HRTEM has further demonstrated that, while the transverse nanowire profile appears triangular, it is actually made up of two or more surface orientations corresponding to the multi-phase internal regions. We present results of a transport investigation of these multiphase nanowires within a nanoFET circuit architecture, focusing on injection from the contacts into the nanowires. Experimental results demonstrated that a variety of surface state derived Schottky barriers could be present at the contact-nanowire interfaces. Transport across the Schottky barriers was modeled using a combined thermionic emission-tunnelling approach, leading to information about barrier height, carrier concentrations, and expected temperature behavior. The experimental and theoretical results indicate that with optimal design taking surface and internal structures into account, high current densities can be supported.

3:30PM W20.00004 Non-adiabatic excitation and detection of coherent oscillations of single electrons , MATTHEW BENESH, CHRISTOPHER FORD, CRISPIN BARNES, ADAM THORN, JON GRIFFITHS, GEB JONES, IAN FARRER, DAVID RITCHIE, University of Cambridge — Surface acoustic waves (SAWs) are used to drive single-electron quantum dots along a complex depleted channel defined by various split gates. As the electron moves through this potential landscape at the SAW velocity (2800m/s), the evolution of the electron's wavefunction may be probed by detecting oscillations in the probability of tunnelling through a narrow barrier on one side of the channel. Coherent oscillations of the wavefunction are generated by non-adiabatic potential changes on a time-scale of tens of ps. We present here results of work in which this phenomenon is observed in two separate tunnelling regions, indicating a charge coherence time > 500 picoseconds. Additionally, we show that the initial state of the oscillations may be determined a significant distance from the tunnelling region through the use of suitably tuned gate voltages.

3:42PM W20.00005 Non-Radiative Energy Transfer Into Nanometer-Scale Thin Semiconducting Films , JOSEPH GORDON, YURI GARTSTEIN, University of Texas at Dallas — Non-radiative energy transfer (NRET) has gained a lot of attention recently due to its possible utility in new generations of light-emitting and photovoltaic devices. In this process, a "donor" species in an excited state transfers its excitation energy resonantly to an "acceptor" species. A classical realization of NRET is Förster ET between two point-like species. Our interest is in ET between a small donor and an ultrathin acceptor layer. The layers can be realized as planar ensembles of molecules or QDs or as a thin crystalline semiconductor slab. We use two complementary approaches to study the effects of dielectric polarization in thin layers on ET rates: (1) The classical macroscopic electrodynamics treating the acceptor layer as a continuum of certain dielectric permittivity; (2) A direct modeling utilizing planar acceptor lattices, each of the acceptors treated as a polarizable point dipole. Comparison of the results allows us to establish salient qualitative features as well as to clarify the role of local-field factors. Of particular interest is our finding a broad region of the dielectric responses where ET into thinner films *counter-intuitively* turns out to be more efficient than ET into thicker films.

3:54PM W20.00006 Quantum decrease of capacitance in a nanometer-sized tunnel junction[1]

, C. UNTIEDT, Universidad de Alicante, Spain, G. SAENZ, Universidad Nacional, Heredia, Costa Rica, B. OLIVERA, Universidad de Alicante, Spain, M. CORSO, Frei Universität Berlin, Germany, C. SABATER, Universidad de Alicante, Spain, J.I. PASCUAL, Frei Universität Berlin, Germany — We have studied the capacitance of the tunnel junction defined by the tip and sample of a Scanning Tunnelling Microscope through the measurement of the electrostatic forces and impedance of the junction. A decrease of the capacitance when a tunnel current is present has shown to be a more general phenomenon as previously reported in other systems [1]. On another hand, an unexpected reduction of the capacitance is also observed when increasing the applied voltage above the work function energy of the electrodes to the Field Emission (FE) regime, and the decrease of capacitance due to a single FE-Resonance has been characterized. All these effects should be considered when doing measurements of the electronic characteristics of nanometer-sized electronic devices and have been neglected up to date.

4:06PM W20.00007 Detecting stray microwaves and nonequilibrium quasiparticles in thin films by single-electron tunneling

, OLLI-PENTTI SAIRA, Aalto University, Olli V. Lounasmaa Laboratory, VILLE MAISI, ANTTI KEMPPINEN, Centre for Metrology and Accreditation (MIKES), MIKKO MÖTTÖNEN, Aalto University, Department of Applied Physics/COMP, JUKKA PEKOLA, Aalto University, Olli V. Lounasmaa Laboratory — Superconducting thin films and tunnel junctions are the building blocks of many state-of-the-art technologies related to quantum information processing, microwave detection, and electronic amplification. These devices operate at millikelvin temperatures, and – in a naive picture – their fidelity metrics are expected to improve as the temperature is lowered. However, very often one finds in the experiment that the device performance levels off around 100–150 mK. In my presentation, I will address three common physical mechanisms that can cause such saturation: stray microwaves, nonequilibrium quasiparticles, and sub-gap quasiparticle states. The new experimental data I will present is based on a series of studies on quasiparticle transport in Coulomb-blockaded normal-insulator-superconductor tunnel junction devices. We have used a capacitively coupled SET electrometer to detect individual quasiparticle tunneling events in real time. We demonstrate the following record-low values for thin film aluminum: quasiparticle density $n_{\rm qp} < 0.033/\mu{\rm m}^3$, normalized density of sub-gap quasiparticle states (Dynes parameter) $\gamma < 1.6 \times 10^{-7}$. I will also discuss some sample stage and chip designs that improve microwave shielding.

4:18PM W20.00008 Frequency Regimes of Kondo Dynamics in a Single-Electron Transistor[1]

, BRYAN HEMINGWAY, ANDREI KOGAN, University of Cincinnati, STEPHEN HERBERT, Xavier University, MICHAEL MELLOCH, Purdue University — It has been theoretically predicted that the Kondo temperature, T_K, serves as the intrinsic timescale for the formation of Kondo correlations between conduction electrons and local spin moments. To probe this timescale, we have measured the time averaged differential conductance, $\langle G \rangle = d\langle I \rangle / dV_{ds}$, of a single electron transistor in the spin 1/2 Kondo regime in presence of an oscillating bias voltage, $V(t) = V_{ds} + V_{AC} \sin(2\pi ft)$. We present the amplitude dependent conductance over select frequencies spanning several orders of magnitude below T_K to twice T_K ($T_K \sim 16$GHz). At frequencies above T_K, we find good agreement with theory [Kaminski, et al. Phys. Rev. B 62, 8154 (2000)] in both the low ($V_{AC} \sim T_K/10$) and high ($V_{AC} \sim 10T_K$) amplitude regimes. The onset of non-adiabatic conductance behavior occurs well below prediction, $f \sim T_K$, and becomes more apparent as the frequency nears T_K.

4:30PM W20.00009 Treatment of High Conductance Kondo Transport in Single Molecule Devices

, GAVIN D. SCOTT, Bell Laboratories, Alcatel-Lucent, 600 Mountain Ave, Murray Hill, NJ 07974, DOUGLAS NATELSON, Department of Physics and Astronomy and Department of Computer and Electrical Engineering, Rice University, 6100 Main St, Houston, TX 77005, STEFAN KIRCHNER, Max Planck Institute for the Physics of Complex Systems and Max Planck Institute for Chemical Physics of Solids, 01187 Dresden, Germany , ENRIQUE MUÑOZ , Facultad de Fìsica, Pontificia Universidad Catòlica de Chile, Casilla 306, Santiago 22, Chile — A single molecule break junction device serves as a tunable model system for probing the many body Kondo state. There are predictions of universality across many realizations of the Kondo model in which the response of the system to different perturbations is characterized by a single emergent energy scale, $k_B T_K$. Comparisons between different experimental systems have shown issues with numerical consistency. With a new constrained analysis examining the response of conductance to temperature, bias, and magnetic field perturbations simultaneously, we show that these deviations from universality can be resolved by properly accounting for background, non-Kondo contributions to the conductance that are often neglected. We clearly demonstrate the importance of these non-Kondo conduction channels by examining transport in devices with total conductances exceeding the theoretical maximum due to Kondo-assisted tunneling alone.

4:42PM W20.00010 Constrained-DFT method for energy level alignment of metal-molecule interfaces

, AMAURY DE MELO SOUZA, Trinity College Dublin, CHAITANYA DAS PEMMARAJU, Lawrence Berkeley National Laboratory, IVAN RUNGGER, STEFANO SANVITO, Trinity College Dublin — The electron transport properties of molecular junctions depend strongly on the alignment of the molecule's ionization potential (IP) and electron affinity (EA) with respect to the metal Fermi energy. It has been demonstrated experimentally[1] and theoretically **J. Neaton et al., Phys. Rev. Lett. 97, 216405 (2006).** that the IP and the EA of molecules change when they are absorbed on a polarizable substrate, due to the formation of an image charge in the surface when an electron is either removed or added to the molecule. While within the GW approximation such a renormalization can be described, the energy levels of standard density functional theory (DFT) fail to capture it. However, DFT total energy differences between charged and neutral systems can usually describe IP and EA of molecules rather well. Here we therefore apply constrained DFT (CDFT) to calculate charge transfer energies between molecules and a metallic substrate in the weak coupling limit. We present CDFT results for the IP and EA of a benzene molecule as function of molecule-surface separation, and find good agreement with GW calculations. Within the CDFT approach we also evaluate the image plane height as function of separation.

4:54PM W20.00011 Vibrationally Induced Decoherence in Single-Molecule Junctions: The Role of Electron-Hole Pair Creation Processes

, RAINER HARTLE, Department of Physics, Columbia University, MICHAEL BUTZIN, PEDRO B. COTO, Institut fur Theoretische Physik, Universitat Erlangen-Nurnberg, STEFAN BALLMANN, HEIKO B. WEBER, Lehrstuhl fur Angewandte Physik, Universitat Erlangen-Nurnberg, MICHAEL THOSS, Institut fur Theoretische Physik, Universitat Erlangen-Nurnberg — We investigate quantum interference effects and vibrationally induced decoherence in single-molecule junctions, employing nonequilibrium Green's function theory [1]. Molecular junctions often exhibit quasidegenerate electronic states that allow an electron to tunnel through the junction in different ways [2,3]. The respective outgoing wavefunctions interfere constructively or destructively, leading to an increase or decrease of the tunnel current, respectively. Interaction of the tunneling electrons with the vibrational degrees of freedom of the junction, however, gives 'which-path' information about the corresponding tunneling pathways because of the state-specific nature of electronic-vibrational coupling [2,3,4]. We demonstrate how this interplay between interference and vibrationally induced decoherence results in a strong temperature dependence of the current and highlight the role of electron-hole pair creation processes in this context [3,4]. To this end, we employ both generic models of single-molecule junctions as well as realistic models that are based on first-principles electronic structure calculations. [1] Phys. Rev. Lett. 102, 146801 (2009), [2] Phys. Rev. Lett. 107, 046802 (2011), [3] Phys. Rev. Lett. 109, 056801 (2012), [4] arXiv:1209.5619 (2012).

5:06PM W20.00012 Charge Transport in Azobenzene-Based Single-Molecule Junctions , ARAN GARCIA-LEKUE, Donostia International Physics Center (DIPC) - Ikerbasque (Spain), YOUNGSANG KIM, Department of Mechanical Engineering, University of Michigan (USA), DMYTRO SYSOIEV, Department of Chemistry, University of Konstanz (Germany), THOMAS FREDERIKSEN, Donostia International Physics Center (DIPC) - Ikerbasque (Spain), ULRICH GROTH, Department of Chemistry, University of Konstanz (Germany), ELKE SCHEER, Department of Physics, University of Konstanz (Germany) — The azobenzene class of molecules has become an archetype of molecular photoswitch research, due to their simple structure and the significant difference of the electronic system between their *cis* and *trans* isomers. However, a detailed understanding of the charge transport for the two isomers, when embedded in a junction with electrodes is still lacking. In order to clarify this issue, we investigate charge transport properties through single Azobenzene-ThioMethyl (AzoTM) molecules in a mechanically controlled break junction (MCBJ) system at 4.2 K. Single-molecule conductance, *I-V* characteristics, and IETS spectra of molecular junctions are measured and compared with first-principles transport calculations. Our studies elucidate the origin of a slightly higher conductance of junctions with *cis* isomer and demonstrate that IETS spectra of *cis* and *trans* forms show distinct vibrational fingerprints that can be used for identifying the isomer.[1]

5:18PM W20.00013 High bias shot noises measurement and electronic heating in STM style gold junctions at room temperature , RUOYU CHEN, PATRICK WHEELER, DOUGLAS NATELSON, Department of Physics and Astronomy, Rice University — Shot noise is a powerful tool in transport measurements, which encodes individual transmission channel's behavior; thus shot noise provides more information than solely conductance measurements. Using a STM-style gold break junction method, we can measure shot noise and conductance simultaneously at room temperature to study its bias-dependence and the distribution of noise and so on. Quantum suppression of shot noise remains very robust even at room temperature. The standard Landauer-Buttiker treatment of shot noise in nanoscale junctions at finite temperature assumes that the electronic temperature in the source and drain electrodes is unaffected by the applied bias. That is, the applied bias is assumed to shift the relative chemical potentials of the electrodes without broadening the electronic distributions. We perform noise measurements at biases as high as 0.5 V (an energy scale much larger than room temperature) and analyze the noise to determine if its bias dependence shows evidence of electronic heating. We will discuss the evolution of shot noise with bias voltage in detail and the role of electronic heating in this experiment.

Thursday, March 21, 2013 2:30PM - 5:42PM –

Session W21 FIAP: Optoelectronics & Photonics 323 - Leslie Cohen, Imperial College

2:30PM W21.00001 Development and Test of a Travelling Wave Tube mm-wave Source[1] , MARK FIELD, Teledyne Scientific LLC, TAKUJI KIMURA, JOHN ATKINSON, Communications and Power Industries, DIANA GAMZINA, LARRY BARNETT, JINFENG ZHAO, NEVILLE LUHMANN, University of California, Davis, ZACHARY GRIFFITH, Teledyne Scientific LLC, THOMAS REED, MARK RODWELL, University of California, Santa Barbara — We report on the fabrication and test of a Traveling Wave Tube (TWT) amplifier designed for operation over a 40 GHz bandwidth centered on 220 GHz, and producing 50 W output power. The TWT amplifier uses a slow wave structure with staggered interdigitated vanes within a waveguide [1]. Each vane is 110 micron wide situated inside a 770 micron wide waveguide, and was directly machined into copper using a 100 micron wide end mill. This structure slows radiation down to group velocity of 8.16 x 10^7 ms^{-1} where the velocity matches the speed of electrons from a 20 keV source. The TWT uses a sheet electron beam of 7:1 aspect ratio and 400 A/cm^2 charge density stabilized by a Brillouin flow magnetic field provided by an external permanent magnet. RF vacuum windows were designed and built using brazed diamond windows, providing less than 1 dB insertion loss across the full 40 GHz bandwidth. Solid state preamplifiers have been developed which provide 20 dB gain and 50 mW output power over the full bandwidth to the input of the TWT.

2:42PM W21.00002 Velocity-matching dispersion maps for zincblende and chalcopyrite terahertz sources , JOSEPH ROWLEY, West Virginia University, KEVIN ZAWILSKI, PETER SCHUNEMANN, BAE Systems, DEREK BAS, ALAN BRISTOW, West Virginia University — Pulsed terahertz radiation has been shown to be a useful diagnostic in fundamental and applied science. A common method for generating pulsed THz is by optical rectification. (110)-cut $ZnGeP_2$ was previously demonstrated as an efficient source of broadband THz radiation for near-infrared pump pulses [1], while other orientations have been modeled to show equal or greater efficiency [2]. Here we explore and compare phase-matching in $ZnGeP_2$ to that in other commonly used near-infrared THz sources including GaAs and GaP. We experimentally demonstrate that the three most efficient orientations provide distinct phase-matching configurations and thus distinct phase-matched near-infrared and THz frequencies. Our calculations also show that thin ($\sim$100 micron) crystals of ZGP may be promising sources for phase-matched and broadband THz emission out to 9 THz for 850 nm pump pulses.

2:54PM W21.00003 Modeling ultra-broadband terahertz waveguide emitters through difference frequency generation using coupled mode theory , FELIPE A. VALLEJO , L. MICHAEL HAYDEN, Department of Physics University of Maryland, Baltimore County — We use a coupled mode theory that adequately incorporates both terahertz (THz) and infrared (IR) losses, to model and design ultra-broadband terahertz waveguide emitters (0.1-15 THz) based on difference frequency generation of femtosecond IR optical pulses. We apply the theory to generic, symmetric, five-layer, metal/cladding/core waveguides using transfer matrix theory. Our expressions for the conversion efficiency and output THz power spectrum depend on the pump power, pulse width, beam waists, laser repetition rate, material optical properties, and waveguide dimensions. Using this approach we design waveguides whose active cores are composed of a poled guest-host electro-optic polymer composite DAPC, comprised of DCDHF-6-V chromophores embedded in an amorphous polycarbonate matrix host. The resulting bandwidths are greater than 15 THz and we obtain high nonlinear conversion efficiencies up to $1.2 \times 10^{-4} W^{-1}$. Our results reveal that a perfectly phase-matched structure is not necessarily the one with the highest conversion efficiency. The highest efficiency is obtained by balancing both the modal phase-matching and modal effective loss effects.

3:06PM W21.00004 Intense Nanosecond-Pulsed Cavity-Dumped Laser Radiation at 1.04 THz[1]

, THOMAS WILSON, Marshall University — We report first results of intense far-infrared (FIR) nanosecond-pulsed laser radiation at 1.04 THz from a previously described[2] cavity-dumped, optically-pumped molecular gas laser. The gain medium, methyl fluoride, is pumped by the 9R20 line of a TEA CO_2 laser[3] with a pulse energy of 200 mJ. The THz laser pulses contain of 30 kW peak power in 5 nanosecond pulse widths at a pulse repetition rate of 10 Hz. The line width, measured by a scanning metal-mesh FIR Fabry-Perot interferometer, is 100 MHz. The novel THz laser is being used in experiments to resonantly excite coherent ns-pulsed 1.04 THz longitudinal acoustic phonons in silicon doping-superlattices.

3:18PM W21.00005 Tunable terahertz detectors on GaAs substrates

, CHRISTOPHER KIM, US Naval Research Laboratory, RONGJIA TAO, Temple University, DONG HO WU, US Naval Research Laboratory — Despite considerable research activitities in terahertz science and technologies, there has not been much progress in terahertz detectors. At present, the sensitivity of room temperature detector does not exceed 10^{-9} W/(Hz)$^{1/2}$ in terms of noise equivalent power. Also most detectors are not tunable, and their response time is slow. In order to make terahertz technology practical substantial improvements should be made on the detector. Earlier, throughout research collaboration with UCSB, we have demonstrated a terahertz detector based on a Metal-Semiconductor Field Effect Transitor (MESFET) technology, which enabled us to achieve a high speed, tunable terahertz detector. The detector was tunable over the frequency range from 0.1 THz to 1.4 THz with a sensitivity of 10^{-8} W/(Hz)$^{1/2}$. Recently we have attempted to modify this earlier design in order to improve its sensitivity up to 10^{-11} W/(Hz)$^{1/2}$ and the operating frequency range from 0.07 to 2.5 THz. We employed a GaAs/AlGaAs heterostructure substrate, and drastically modified the previous MESFET design.We will present our fabrication process and experimental results.

3:30PM W21.00006 Semiconductor-core optical fibers for terahertz waveguides

, DEREK BAS, SCOTT CUSHING, JOSEPH ROWLEY, West Virginia University, JOHN BALLATO, Clemson University, ROBERT RICE, Dreamcatchers Consulting, ALAN BRISTOW, West Virginia University — Waveguiding of terahertz (THz) radiation is important for imaging and communications applications. Simulations have been performed based on a fiber optic geometric waveguide with a poly-crystalline silicon core and silica cladding [1]. High-resistivity silicon has a flat dispersion over a 0.1 – 3 THz range [2], making it viable for propagation of broadband picosecond pulses of THz radiation such as that produced by optical rectification [3]. Frequency-dependent mode indices are determined for 0.1 – 0.3 mm diameter cores. The normalized frequency parameter V is also determined and a 140 micron core is selected as the low edge of diameters that can support a THz pulse. Finite-difference time-domain simulations are performed in two-dimensions to extract the propagation dynamics and the integrated intensity, from which transverse mode profiles and absorption lengths are extracted. It is found that for this core diameter the mode partially propagates in the cladding, such that the overall absorbance is only slightly less than in bulk polycrystalline silicon. [1] J. Ballato, T. Hawkins, P. Foy, R. Stolen, B. Kokuoz, M. Ellison, C. McMillen, J. Reppert, A. M. Rao, M. Daw, S. R. Sharma, R. Shori, O. Stafsudd, R. R. Rice, and D. R. Powers, Opt. Express 16, 18675-18683 (2008) [2] D. Grischkowsky, Søren Keiding, Martin van Exter, Ch. Fattinger, J. Opt. Soc. Am. B 7, 2006 (1990) [3] J. D. Rowley, J. K. Pierce, A. T. Brant, L. E. 3:42PM W21.00007 Simulations of Brillouin Scattering in Optical Fibers[1]

, CARL MUNGAN, U.S. Naval Academy, ELIOT PETERSEN, SHUOCHEN HUANG, JEFFREY WHITE, Army Research Lab — Brillouin scattering arises when a laser beam generates density variations in a medium via electrostriction. The density variations modulate the refractive index, resulting in a grating that Bragg scatters pump light into a Stokes beam. The Stokes wave is downshifted in frequency by the Doppler effect because the grating is moving at the speed of acoustic phonons. To conserve both energy and momentum, the Brillouin photons are backscattered. This back-reflected radiation is a major factor limiting the transmission of laser power in optical fibers for practical applications. It is mathematically described by a set of coupled partial differential equations. I will describe some of the known analytic solutions of these equations, as well as how to find numeric solutions using MATLAB.

3:54PM W21.00008 Metamaterial features for a pure dielectric fiber[1]

, ADRIAN REYES CERVANTES, CARLOS MENDOZA, Universidad Nacional Autónoma de México — We consider a solid cylindrical dielectric waveguide with an extremely thin coaxial cylindrical shell of higher refraction index inserted on it. We calculate the propagation parameters and the band structure of this fiber as function of the contrast index, and show that there exist propagating modes whose transverse distribution of amplitudes are both oscillating and evanescent. The oscillating modes exhibit the usual dispersion relation of a standard wave guide, whereas the evanescent modes gives rise to regions for which the group velocity almost vanishes and with propagation direction opposed to the Poynting vector, as seen in metamaterials.

4:06PM W21.00009 Measurements of Effective Schottky Barrier in Inverse Extraordinary Optoconductance Structures[1]

, L.C. TRAN, F.M. WERNER, S.A. SOLIN, Washington University in St. Louis, ADAM GILBERTSON, L.F. COHEN, Imperial College London — Individually addressable optical sensors with dimensions as low as 250nm, fabricated from metal semiconductor hybrid structures (MSH) of AuTi-GaAs Schottky interfaces, display a transition from resistance decreasing with intensity in micron-scale sensors (Extraordinary Optoconductance, EOC) to resistance increasing with intensity in nano-scale sensors (Inverse Extraordinary Optoconductance I-EOC). I-EOC is attributed to a ballistic to diffusive crossover with the introduction of photo-induced carriers and gives rise to resistance changes of up to 9462% in 250nm devices. We characterize the photo-dependence of the effective Schottky barrier in EOC/I-EOC structures by the open circuit voltage and reverse bias resistance. Under illumination by a 5 mW, 632.8 nm HeNe laser, the barrier is negligible and the Ti-GaAs interface becomes Ohmic. Comparing the behavior of two devices, one with leads exposed, another with leads covered by an opaque epoxy, the variation in Voc with the position of the laser can be attributed to a photovoltaic effect of the lead metal and bulk GaAs. The resistance is unaffected by the photovoltaic offset of the leads, as indicated by the radial symmetry of 2-D resistance maps obtained by rastering a laser across EOC/IEOC devices.

[1]SAS has a financial interest in PixelEXX, a start-up company whose mission is to market imaging arrays.

4:18PM W21.00010 Light Intensity Influence on the Effective Schottky Barrier Height in Extraordinary Optoconductance (EOC) Structures[1] , F.M. WERNER, L.C. TRAN, S.A. SOLIN, Washington University in St. Louis — Novel micro to nanoscale metal-semiconductor-hybrid (MSH) structures capable of room temperature light detection have been previously reported and classified as Extraordinary Optoconductance (EOC) devices. The devices are square stacked structures, with a Au-Ti shunt forming a Schottky-Interface with an n-doped Ga-As mesa. Resistance measurements were taken by a 4-point van-der Pauw method to remove contact and lead resistance and eliminate DC offsets. The device's resistance changes as light incident on the surface of the structure modifies the charge density within the body of the device. The change in charge density changes the effective Schottky Barrier height and shifts the measured 4 point resistance of the heterogeneous structure. We investigate the dependence of the effective Schottky Barrier height on the incident intensity of light by measuring the open circuit voltage under various intensities of optical perturbation at room temperature. The barrier height is negligible and the interface ohmic under HeNe laser 632.8 nm illumination at a power density of 636 mW/cm^2, allowing the flow of current through the shunt. This device performance will be contrasted with that of an FET, where current does not propagate through the gate.

[1]SAS has a financial interest in PixelEXX, a start-up company whose mission is to market imaging arrays.

4:30PM W21.00011 Proposal for realization of one-way electromagnetic modes at the interface of two lossless metals[1] , MEHUL DIXIT, DAVID STROUD, Department of Physics, The Ohio State University, Columbus, OH 43210 — One-way electromagnetic waveguides are of special interest because of complete suppression of back-scattering by disorder. Such waveguides support a unique class of photonic modes that completely forbid propagation in the opposite direction. We show that a one-way electromagnetic waveguide can be realized at the interface of two dissimilar lossless metals in an external magnetic field parallel to the interface. Electromagnetic surface plasmon modes bound to the interface of the two metals and propagating parallel to it and normal to the direction of the external magnetic field, with the electric field polarized normal to the plane of the interface, support one-way electromagnetic propagation in a range of frequencies. Increasing the magnetic field increases the window of frequencies for one-way propagation. Adding damping reduces the range of frequencies. Details of the calculation and plots showing the dispersion relation will be presented.

[1]Work supported by DOE grant 60011493

4:42PM W21.00012 Pulse Shaping with Moire Volume Bragg Gratings , SERGIY MOKHOV, DANIEL OTT, BORIS ZELDOVICH, LEONID GLEBOV, CREOL - the College of Optics and Photonics, Univ. of Central Florida — Optical pulses of various temporal profiles are required for many applications but their durations and shapes are available only in limited ranges for certain laser wavelengths. For generation of pulse durations around ten ps, we proposed to reflect short pulses from volume Bragg gratings (VBGs) with few millimeter thickness. In case of VBG reflection bandwidth much narrower than incident pulse spectral width the significant loss of power occurs but such approach can be acceptable if there are no other generation processes for required pulse duration. VBGs in photo-thermo-refractive glass developed in our group are characterized by wide transparency range, small absorption and high laser damage threshold. In comparison with fiber Bragg gratings VBGs have additional spatial transverse degrees of freedom which allow not only tuning the pulse carrier wavelength but also shaping of generated pulses. Recording of two gratings with slightly different periods in the same glass wafer provides VBG with moire fringe pattern. After skew cutting of specimen with thickness of moire semi-period the longitudinal modulation VBG profile will vary in transverse direction from sine semi-period to cosine one. Reflected pulse from VBG with apodized sine profile has temporal profile close to transform limited Gaussian one while pulse reflected from transverse part of moire VBG with cosine semi-period profile has zero dip in temporal profile. At intermediate position the flat-top pulse shape is achievable.

4:54PM W21.00013 Monolithic Single-Mode DFB Laser Array with Precise Wavelength Control for Optoelectronic Integration using an Equivalent Phase Shift Method , JINGSI LI, JULIAN CHENG, University of Texas at Austin, MICROELECTRONICS RESEARCH CENTER TEAM — The integrated distributed feedback (DFB) laser array is a key component in photonic integrated circuits for wavelength-division multiplexing (WDM) system. However, it is difficult to precisely control the wavelength of individual lasers. When the rear facet of the laser is coated with a high-reflectivity mirror, a random phase change is introduced that shifts the lasing wavelength, making monolithic integration of a wavelength-controlled WDM array very difficult. To solve this problem, we propose a method to precisely control the lasing wavelength of DFB lasers over a wide range by introducing an equivalent phase shift in the cavity using sampled Bragg gratings, using wafer-scale optical lithography and requiring only coarse dimension control. The wavelength can be fine-tuned by applying different DC currents. It is shown that a WDM-DFB laser array with uniform wavelength spacing can be controlled accurately in this manner. Integrated arrays of single-mode DFB lasers for WDM systems can thus be fabricated in a low-cost manner without using low-throughput e-beam lithography, and is scalable for mass-manufacturing.

5:06PM W21.00014 Observation of Polarization Switching in Vertical-Cavity Surface-Emitting Lasers at Constant Injection Current , YU-HENG WU, YUEH-CHEN LI, WANG-CHUANG KUO, TSU-CHIANG YEN, Department of Physics, National Sun Yat sen University, DEPARTMENT OF PHYSICS, NATIONAL SUN YAT SEN UNIVERSITY TEAM — This study investigated the thermal characteristics of the polarization switching (PS) in vertical-cavity surface-emitting lasers (VCSELs) at constant injection current. The experiments were performed with a quasi-step function current experiment. A simplified temperature rate equation was used to simulate the experiment of the step function. The consistency of the experiments and simulations concludes that the thermal effect plays a major role in PS and PS's hysteresis. These results contribute to the understanding of the mechanism of VCSEL's polarization switching.

5:18PM W21.00015 Development of an image-analysis light-scattering technique , SAAD ALGARNI, HEKTOR KASHURI, GERMANO IANNACCHIONE, Physics Deparment, Worcester Polytechnic Institute, Worcester, MA — We describe the progress in developing a versatile image-analysis approach for a light-scattering experiment. Recent advances in image analysis algorithms, computational power, and CCD image capture has allowed for the complete digital recording of the scattering of coherent laser light by a wide variety of samples. This digital record can then yield both static and dynamic information about the scattering events. Our approach is described using a very simple and in-expensive experimental arrangement for liquid samples. Calibration experiments were performed on aqueous suspensions of latex spheres having 0.5 and 1.0 micrometer diameter for three concentrations of 2 X 10^{-6}, 1 X 10^{-6}, and 5 X 10^{-7} % w/w at room temperature. The resulting data span a wave-vector range of q = 10^2 to 10^5 cm^{-1} and time averages over 0.05 to 1200 sec. The static analysis yield particle sizes in good agreement with expectations and a simple dynamic analysis yields an estimate of the characteristic time scale of the particle dynamics. Further developments in image corrections (laser stability, vibration, curvature, etc.) as well as time auto-correlation analysis will also be discussed.

5:30PM W21.00016 ABSTRACT WITHDRAWN –

Thursday, March 21, 2013 2:30PM - 5:18PM –

Session W22 FIAP: Transparent Conductors, Titania, and Other Oxides 324 - Kartik Ghosh, Missouri State University

2:30PM W22.00001 The doping effect of Mn and Co ions in $PbPdO_2$, KYUJOON LEE, SEONG-MIN CHOO, Sogang University, JIHOON HWANG, JEONGSOO KANG, The Catholic University of Korea, MYUNG-HWA JUNG, Sogang University — Spintronics is a promising field in which the spin of electrons along with the charge is used for data storage and data manipulation. For spintronics application a long mean free path with high spin polarization is required. In this sense, the magnetic gapless semiconductor is a promising material since it satisfies both conditions. Here we have studied $PbPdO_2$, which is predicted to be a gapless semiconductor, and its Co and Mn doping to be a spin gapless semiconductor. We have tried to tune its electrical and magnetic properties with magnetic ions such as Co and Mn, in order to achieve the magnetic gapless semiconductors for spintronics application. A drastic change in the magnetic properties has been observed when doped with magnetic ions. The Co doping induces a weak ferromagnetic exchange, while the Mn doping induces an antiferromagnetic exchange. To investigate the electronic structures of $PbPdO_2$ we have measured the valence band photoemission spectroscopy and X-ray absorption spectroscopy. The results show Mn^{4+} and Co^{3+} states for the Mn and Co doped $PbPdO_2$, respectively. This implies that the magnetic and electrical properties of PbPdO2 can be easily tuned by chemical doping, and it leads to possible applications for spintronics.

2:42PM W22.00002 P-type K-doping of $BaSnO_3$ and its pn junctions , HOONMIN KIM, CHULKWON PARK, USEONG KIM, KOOKRIN CHAR, Department of physics, Seoul National University, MATERIALS & DEVICES PHYSICS LAB. TEAM — We have recently reported high mobility in La-doped BaSnO3 (BSO), whose transparency and chemical stability promises large potential for scientific and technical applications. The doping possibility with p-type carrier will further enhance its utility in scientific and technical endeavors. For such purpose, we will present our work in p-type doping BSO by epitaxially growing K-doped BSO by pulsed laser ablation on SrTiO3 substrates. We have found that K replaces Ba from EPMA. Although K-doped BSO exhibited rather high resistivity at room temperature, its conductivity increased dramatically at high temperature and the conductivity decreased when small amount of oxygen was removed from the thin films, consistent with the behavior of p-type doped oxides. The carrier type of K-doped BSO will be further confirmed by direct high-temperature Hall measurement. We will report on the mobility of the K-doped BSO and the performance of pn junctions fabricated by using K- and La-doped BSO.

2:54PM W22.00003 Role of annealing temperature on microstructural and electro-optical properties of ITO films produced by sputtering , ABDULKADIR SENOL, Department of Physics, Kastamonu University, MAHIR GULEN, GURCAN YILDIRIM, OZGUR OZTURK, AHMET VARILCI, CABIR TERZIOGLU, IBRAHIM BELENLI, Department of Physics, Abant Izzet Baysal University — In this study, we investigate the effect of annealing temperature on electrical, optical and microstructural properties of indium tin oxide (ITO) films deposited onto Soda lime glass substrates by conventional direct current (DC) magnetron reactive sputtering technique at 100 watt using an ITO ceramic target (In_2O_3:SnO_2, 90:10 wt. %) in argon atmosphere at room temperature. The films obtained are exposed to the calcination process at different temperature up to 700 ° C. Resistivity, Hall Effect, X–ray diffractometer (XRD), ultra violet-visible spectrometer (UV–vis) and atomic force microscopy (AFM) measurements are performed to characterize the samples. Moreover, phase purity, surface morphology, optical and photocatalytic properties of the films are compared with each other. Furthermore, mobility, carrier density and conductivity characteristics of the samples prepared are carried out as function of temperature in the range of 80-300 K at the magnetic field of 0.550 T. The results obtained show that all the properties depend strongly on the annealing temperature and in fact the film annealed at 400 ° C obtains the better optical properties due to the high refractive index while the film produced at 100 °C exhibits much better photoactivity than the other films as a result of the large optical energy band gap.

3:06PM W22.00004 Transparent oxide semiconductors (Ba,La)SnO_3 with high mobility at room temperature , HYUNG JOON KIM, USEONG KIM, TAI HOON KIM, JIYEON KIM, HOON MIN KIM, BYUNG-GU JEON, WOONG-JHAE LEE, Department of Physics and Astronomy, Seoul National University, HYO SIK MUN, Seoul National University, KWANG TAEK HONG, JAEJUN YU, KOOKRIN CHAR, KEE HOON KIM, Department of Physics and Astronomy, Seoul National University — We present our discovery of (Ba,La)SnO_3 system exhibiting electrical mobility at 300 K of 200-320 $cm^2V^{-1}s^{-1}$ in a doping range from 1.0x10^{19} to 4.0x10^{20} cm^{-3}. Moreover, their conductivity values were as large as around 10^4 S/cm, being comparable to those of indium tin oxides. The system yet shows the optical gap around 3.33 eV and only slight increase of the in-gap states, maintaining visual transparency. Several unique physical properties of (Ba,La)SnO_3 are also discussed: a superior oxygen stability evidenced by persistent transport properties under high temperature environments, a small effective mass coming from the ideal Sn-O-Sn bonding in a cubic perovskite, small disorder effects due to doping away from the main conduction channels (SnO_6 octahedra network) and reduced carrier scattering due to the high dielectric constant. (Ba,La)SnO_3 thus holds great potential for realizing transparent, high power, high temperature functional devices.

3:18PM W22.00005 Small polarons and their interaction with donor centers in Titania[1] , ANDERSON JANOTTI, Materials Department, University of California Santa Barbara, CESARE FRANCHINI, University of Vienna and Center for Computational Materials Science, JOEL VARLEY, Materials Department, University of California Santa Barbara, GEORG KRESSE, University of Vienna and Center for Computational Materials Science, CHRIS VAN DE WALLE, Materials Department, University of California Santa Barbara — The use of TiO_2 in photocatalysis, photosensitized solar cells, and memristors strongly depends on the behavior of conduction-band electrons, prompting a more profound understanding of conduction mechanisms. The reported results for the behavior of excess electrons in TiO_2 are contradictory. High carrier mobilities, characteristic of delocalized electrons, have been observed in Hall measurements, whereas optical spectra indicate the presence of localized, small polarons. Using first-principles calculations based on a hybrid functional we study the formation of small polarons, comparing it to delocalized electrons in the conduction band of TiO_2. From the calculated configuration coordinate diagram and migration energy barriers, we discuss the coexistence of small polarons with delocalized electrons, and address how the observed behavior depends on the type of experiment being conducted. The interaction of small polarons with intrinsic defects such as the oxygen vacancy and donor impurities will also be discussed.

3:30PM W22.00006 Preparation of perpendicular oriented TiO2 films via hydrothermal method: phase selection and growth control[1] , YUN GAO, MEILAN GUO, XIAOHONG XIA, University of Hubei, GUOSHENG SHAO, University of Bolton — Either rutile or anatase vertical orientated TiO_2 array films were synthesized successfully on FTO (F: SnO_2) substrate via hydrothermal method through controlling the concentration of Cl^- and SO_4^{2-}. The density of nanorods can be adjusted by varying the volume ratio of ethanol/water, and the degree of orientation and crystallinity of TiO_2 nanofilms were enhanced with increasing dosage of ethanol. Meanwhile, completely dense anatase films with [004] oriented growth appear within a very narrow concentration window when adding sulfuric acid into precursor. Besides, other alcohols such as methanol, n-propanol and n-butyl were also used as solvent to examine the role of alcohol type during hydrothermal process for both two phase films. The growth rate and degree of perpendicular orientation declined as the alkyl length of solvents increases. Hydrogen sensing characteristics of dense films of both rutile and anatase phases showed that there was a remarkable improvement of sensitivity response over reported data. It was found that rutile films have higher sensitivity while anatase films have faster response.

3:42PM W22.00007 Visible Light Sensitization of TiO_2 Films by co-doping with Nitrogen and Carbon , INCI RUZYBAYEV, EMRE YASSITEPE, University of Delaware, AWAIS ALI, ARSHAD S. BHATTI, COMSATS Institute of Information Technology, SYED ISMAT SHAH, University of Delaware — Anatase phase of TiO_2 has a band gap of 3.20 eV. Therefore, only UV light can be absorbed from the solar spectrum. Introducing defect states narrows the band gap of TiO_2 semiconductor and enhances the visible light activity. In this study, the defect states in the band gap are created by nitrogen and carbon dopants. Reactive pulsed laser deposition technique is used to prepare nitrogen and carbon co-doped TiO_2 films. Total pressures of nitrogen and methane gases are kept at 100 mTorr. Two types of co-doped samples are investigated with partial pressures of 80 mTorr nitrogen with 20 mTorr methane and 20 mTorr nitrogen with 80 mTorr methane. Undoped, control, sample is also prepared under 100 mTorr oxygen gas. All films show polycrystalline anatase structure. Nitrogen dopant is calculated from XPS high resolution scans while carbon incorporation into TiO_2 lattice is supported by XRD and FESEM analyses. Also, direct relation between oxygen vacancies and nitrogen doping concentration is observed from XPS high resolution scans of N 1s and Ti 2p regions. Band gap is calculated using absorption coefficient obtained from UV-Vis diffuse reflection spectroscopy measurements. 80 mTorr nitrogen and 20 mTorr methane co-doped TiO_2 film has the lowest band gap among all with 2.17 eV which lies near the most intense peak in the visible part of the solar spectrum. Therefore, co-doping TiO_2 with nitrogen and carbon is a possible method for visible light sensitization.

3:54PM W22.00008 the effect of electron doping in TiO2 assessed by ARPES , LUCA MORESCHINI, Advanced Light Source, Berkeley, SIMON MOSER, Institute of Condensed Matter Physics (ICMP)-EPFL-Lausanne, JACIM JACIMOVIC, Institute of Condensed Matter Physics (ICMP)-EPFL, Lausanne, OSOR BARISIC, Institute of Physics, Zagreb, HELMUT BERGER, ARNAUD MAGREZ, Institute of Condensed Matter Physics (ICMP)-EPFL, Lausanne, YOUNG JUN CHANG, KEUN SU KIM, AARON BOSTWICK, Advanced Light Source, Berkeley, LASZLO FORRO, Institute of Condensed Matter Physics (ICMP)-EPFL, Lausanne, ELI ROTENBERG, Advanced Light Source, Berkeley, MARCO GRIONI, Institute of Condensed Matter Physics (ICMP)-EPFL, Lausanne — The titanium oxide TiO2 has been object of extensive studies because of its suitability in many practical fields, ranging from photovoltaic applications, to catalysis, memristors, and others. As for many other transition metal oxides, great attention has been devoted to the impact on the electronic structure of different doping mechanisms, either extrinsic or due to the creation of oxygen vacancies. Here we report an angle-resolved photoemission (ARPES) work on TiO_2 single crystals and epitaxial films grown wIth the *in situ* pulsed-laser-deposition (PLD) system available on beamline 7.0.1 at the Advanced Light Source. We show the evolution of the electronic structure as a function of the amount of oxygen vacancies induced by the photon beam.

4:06PM W22.00009 Thermodynamic Effects on Phase Stabilities and Structural Properties of TiO2 from the First-principles[1] , YUTA AOKI, SUSUMU SAITO, Department of Physics, Tokyo Institute of Technology — Titanium dioxide (TiO2) is one of the most representative photocatalytic materials and much attention is focused on understanding and improvement of its photocatalytic activity. At the same time, TiO2 is known to be a highly polymorphic material and as many as eleven crystal phases have been identified so far. It is expected that TiO2 show various photocatalytic properties depending on crystal phases. However, relative stabilities of these identified phases are still controversial. In order to clarify the thermodynamic phase stabilities of TiO2, we obtain the free energies of its several representative phases, rutile, anatase, brookite, and TiO2-II within the framework of the density-functional theory using the pseudopotential method. We calculate both the static energy and the contribution of phonons to the free energy through the quasiharmonic approximation for each phase. It is found that treatment of semicore electrons in constructing the pseudopotential of the Ti atom significantly affects the relative phase stabilities. From the phase diagram obtained, we find that the anatase phase is the most stable at lower temperature and pressure. We also discuss the thermodynamic effects on structural properties such as thermal expansion.

4:18PM W22.00010 Properties of p-type ZnO Films co-doped with Lithium and Phosphorus[1] , TOM ODER, MICHAEL MCMASTER, ANDREW SMITH, Youngstown State University — Thin films of ZnO co-doped with lithium and phosphorus were deposited on sapphire substrates by RF magnetron sputtering. The films were sequentially deposited from ZnO and Li_3PO_4 solid targets on the substrates maintained at 500 °C. An undoped ZnO buffer layer was first deposited at a substrate temperature of 900 °C for 2 hours. Post deposition annealing was carried using a rapid thermal processor in N_2 and O_2 at temperatures ranging from 400 °C to 900 °C for 3 min. Analyses performed using low temperature photoluminescence spectroscopy measurements reveal several luminescence peaks at 3.36, 3.353, 3.317, 3.11and 2.33 eV whose relative intensities vary with annealing environments and temperatures. We will discuss the origins of these luminescence peaks and their relevance to p-type doping of ZnO films. The x-ray diffraction 2θ-scans for all the films showed a single peak at about 34.4° with FWHM of about 0.17°. Hall Effect measurements revealed conductivities that change from p-type (with concentration up to about 1.3 x 10^{17} cm^{-3}) to n-type (with concentration up to about 1.5 x 10^{19} cm^{-3}) as the annealing temperature is increased to 900 °C.

[1]The authors gratefully aknowledge the funding support from NSF.

4:30PM W22.00011 Magnetic and Optical Properties of Co-doped ZnO Nanorods , N. DAS, R. DELONG, A. WANEKAYA, K. GHOSH, Missouri State University — Transition-metal doped ZnO is considered as an ideal system for carrying out research in the field of spintronics as well as optoelectronics as they can successfully combine magnetism and electronics in a single substance. ZnO is a wurtzite-type wide-bandgap semiconductor of the II-VI semiconductor group with band gap energy of 3.37 eV. Synthesis of undoped and Co-doped ZnO nanorods is carried out using aqueous solutions of $Zn(NO_3)_2.6H_2O$, and $Co(C_2H_3OO)_2.4\ H_2O$, using NH_4OH as hydrolytic catalyst by hydrothermal process. For optimizing the nanorod growth condition, parameters such as concentration, pH, synthesis time and temperature are varied. Optimum condition for the growth of pure zinc oxide nanorods is found 0.15 M pH 9, 6 hrs and 130°C respectively. Structural, morphological, optical and magnetic properties are studied using XRD, Raman spectroscopy, SEM, UV-vis spectroscopy, PL spectroscopy and SQUID magnetometer.Detailed structural, optical, and magnetic properties will be discussed in this presentation. This work is supported by National Science Foundation (Award Number DMR-0907037).

4:42PM W22.00012 Effective Lifetimes of Atomic Layer Deposited Diffusion Barrier Films for Silver Artifacts[1] , AMY MARQUARDT, University of Maryland, Department of Materials Science and Engineering, ERIC BREITUNG, E-Squared Art Conservation Science, GLENN GATES, TERRY WEISSER, The Walters Art Museum, GARY RUBLOFF, RAY PHANEUF, University of Maryland, Department of Materials Science and Engineering — We investigated using atomic layer deposition (ALD) to create dense, transparent oxide diffusion barrier coatings to reduce the tarnishing rate for silver art objects. An elevated H_2S aging chamber was used for accelerated aging to directly compare the effectiveness of 5-100nm Al_2O_3 ALD thin films and nitrocellulose coatings, the current technique for silver preservation, at reducing the tarnishing rate of silver while minimally affecting the visual appearance of the silver. Reflectance spectroscopy and an integrated sphere spectrophotometer were used to measure the thickness of the tarnish layer and indicate the lifetimes of the ALD and nitrocellulose coatings. Electrochemical impedance spectroscopy (EIS) was used to determine the porosity and average pore size of ALD films. Failure mechanisms for the two types of films were observed, the ALD films failing in defects or pinholes in the films and the nitrocellulose failing due to non-uniform in coating thickness. Thin Al_2O_3 ALD films were found to be more porous than thick ALD films, sufficient in protecting silver five times longer and effected the overall color change of the object less than micron thick nitrocellulose films.

4:54PM W22.00013 Impact of carbon and nitrogen on gate dielectrics in metal-oxide-semiconductor devices[1] , MINSEOK CHOI, JOHN L. LYONS, ANDERSON JANOTTI, CHRIS G. VAN DE WALLE, Materials Department, University of California, Santa Barbara, CA 93106-5050 — Al_2O_3 and HfO_2 are used as alternative gate oxides in CMOS technology. Promising results have been achieved with Al_2O_3/III-V and HfO_2/Si MOS structures, which exhibit relatively low densities of interface states. However, the presence of charge traps and fixed-charge centers near the oxide/semiconductor interface still poses serious limitations in device performance. Native point defects are usually proposed as an explanation; unintentional incorporation of impurities in the gate dielectric during the deposition process has so far received less attention. Using first-principles calculations based on hybrid functionals we investigate the effects of carbon and nitrogen impurities in Al_2O_3 and HfO_2. By analyzing the position of the impurity levels with respect to the III-V and Si band edges, we determine if these impurities can act as charge traps or sources of fixed charge. Our results show that carbon can act as a charge trap and lead to leakage current through the gate dielectric. Nitrogen can act as a source of negative fixed charge, but may be effective in alleviating the problem of charge traps and fixed charges associated with Al, Hf, and O vacancies.

5:06PM W22.00014 Characterization of Er^{+3}:Y_2O_3 films made via Atomic Layer Deposition , NICHOLAS BECKER, Illinois Institute of Technology, THOMAS PROSLIER, JEFFREY KLUG, Argonne National Laboratory, JOHN ZASADZINSKI, Illinois Institute of Technology, JEFFREY ELAM, Argonne National Laboratory, CARLO SEGREY, Illinois Institute of Technology, TIGRAN SANAMYAN, MARK DUBINSKIY, Army Research Laboratory, MICHAEL PELLIN, Argonne National Laboratory — Er^{+3}:Y_2O_3 thin films with spatially-controlled Er^{+3} ion incorporation, were deposited on various substrates using Atomic Layer Deposition. By systematically varying the Erbium precursors used in the deposition of the films, a method to spatially control the Erbium has been realized. All films were polycrystalline as deposited and no appreciable change was detected after post-deposition annealing. Emission spectra for all precursors used show crystalline emission lines, similar to those grown via a melt process. Photoluminescent lifetimes up to 6.5ms have been recorded from these films, the largest to date in films deposited with Atomic Layer Deposition. Films have been characterized using XRD/GIXRD, UV-Vis spectroscopy, XAFS, RBS, HFS, SEM, TEM, and AFM. The results of these various measurements, and the influence on photoluminescent lifetime will be discussed.

2:30PM W23.00001 Line width resonance of the longitudinal optical phonon in GaAs:N , ALEKSEJ MIALITSIN, ANGELO MASCARENHAS, NREL — We extend resonant Raman scattering studies of Mascarenhas et al. [PRB68, 233201 (2003)] of $GaAs_{1-x}N_x$ to the ultra-dilute nitrogen doping concentrations, whereby we unambiguously resolve the line width resonances of the LO phonon. A discontinuity is observed in the LO phonon line width resonance energy as a function of concentration. With decreasing nitrogen concentration the E_W line width resonance energy reduces by ca. 40 meV at $x = 0.4\%$. This value corresponds to the concentration, at which the localized to delocalized transition manifests itself in the electro-reflectance signature line widths.

2:42PM W23.00002 Micro-Raman study of InAs/GaSb superlattices from front and cleaved edge[1] , HENAN LIU, YONG ZHANG, UNC-Charlotte, SHUN LIEN CHUANG, University of Illinois at Urbana-Champaign, RUSSELL DUPUIS, Georgia Institute of Technology, AMY LIU, IQE, Inc — The InAs/GaSb superlattice (SL) has a "broken-gap" type II band alignment, with its effective bandgap being able to be tuned by changing the thickness of individual layers. Therefore, it is of great interest for mid- and far-IR detection. Because the SL does not have common cation or anion at the interface, there are two types of interfacial layers: InSb and GaAs, that impact the device performance. We investigate the SLs grown on either GaSb or InAs substrate and with difference interfacial treatment using confocal micro-Raman spectroscopy on both front surface and cleaved edge of the epilayer with polarization.

2:54PM W23.00003 Raman Investigation of p-type Amorphous Silicon Thin Films[1] , KIRAN SHRESTHA, CHRISTOPHER LITTLER, VINCE LOPES, ATHANASIOS SYLLAIOS, University of North Texas Department of Physics — Thin film layers of p-type a-Si:H of differing doping concentration and hydrogen dilution were investigated by Raman spectroscopy to determine their effect on short- and mid-range order. In this study, the TA and TO peaks were used to study the microstructure of the thin films. Our analyses reveal an interesting counter-balance relationship between the boron-doping and hydrogen-dilution growth parameters. Specifically, an increase in the hydrogen dilution ratio (H_2/SiH_4) was found to cause the increase in the short-range order, as evidenced by an increase in the TO frequency and a decrease in the FWHM of the spectral peak. However, an increase in the doping concentration resulted in a decrease in the short-range order, as evidenced by a decrease in the TO frequency and an increase in the FWHM of the spectral peak. These results will be correlated with Multiple Internal Reflection Infrared Spectroscopy, electrical transport and noise in a-Si:H thin films to determine the effects of doping and hydrogen on the transport mechanisms in a-Si:H.

3:06PM W23.00004 Scanning tunneling microscope study of La- and Sb-doped $BaSnO_3$ thin films , CHAN-JONG JU, HOONMIN KIM, USEONG KIM, CHULKWON PARK, KOOKRIN CHAR, Department of Physics in Seoul National University, MATERIALS & DEVICES PHYSICS LAB. TEAM — The La-doped $BaSnO_3$(BLSO) system was found to exhibit high electron mobility and high oxygen stability along with its transparency in visible spectrum. Additionally, we recently observed a significant difference in electron mobility values between BLSO and Sb-doped BSO (BSSO) epitaxial thin films. In order to elucidate the origin of the different mobility in BLSO and BSSO thin films, we have investigated a density of states (DOS) of BLSO and BSSO by scanning tunneling microscopy and spectroscopy. Our measurements were performed at 77 K in ultra-high vacuum of $2\text{x}10^{-10}$ Torr. We will compare the DOS of the conduction band of BLSO with that of BSSO. Only in the conduction band of BSSO, we found a specific peak that can be identified as due to the localized Sb impurity states. Our results provide strong evidence for the strong influence of localized Sb impurity states on the electron mobility. We will explain our data by anisotropy of scattering on the Fermi surface by resorting to band structure calculations of BLSO and BSSO.

3:18PM W23.00005 ABSTRACT WITHDRAWN –

3:30PM W23.00006 Origin of Charge Separation in III-Nitride Nanowires under Strain , YELONG WU, GUANGDE CHEN, MOE Key Laboratory for Nonequilibrium Synthesis and Modulation of Condensed Matter, Xi'an Jiaotong University, Xi'an, Shaanxi 710049, China, SU-HUAI WEI, MOWAFAK AL-JASSIM, National Renewable Energy Laboratory, Golden, CO 80401, USA, YANFA YAN, Department of Physics and Astronomy, The University of Toledo, Toledo, OH 43606, USA — The structural and electronic properties of BN, AlN and GaN nanowires (NWs) under different strain condition are investigated using first-principles calculations. We found an anomaly of band gap change with respect to the applied external uniaxial strain. We show that this is due to the band crossing caused by the crystal field splitting at the top of the valance band. Due to the difference of the atomic relaxation at the core and surface regions of the NW, we show that electron and hole separation can be achieved when the compressive uniaxial strain exceeds the critical value $|\epsilon_c|$.

3:42PM W23.00007 Band offsets at GaN/$ZnGeN_2$ interfaces , ATCHARA PUNYA, WALTER LAMBRECHT, Department of Physics, Case Western Reserve University, Cleveland, OH-44106-7079, USA — The interfaces of GaN/$ZnGeN_2$ are of interest because of their close lattice match and hence suitability of GaN as substrate for $ZnGeN_2$ film growth. In the present work, the band offsets for various polar and non-polar interfaces between GaN and $ZnGeN_2$ are determined from full potential linear muffin-tin orbital (FP-LMTO) within the local density approximation (LDA). We determine the dipole potential formed at the interface from self-consistent supercell calculations and then add the difference between the bulk band-edges energy levels. Quasiparticle self-consistent GW corrections of the bulk band edges relative to the LDA edges are added. The strain state of the $ZnGeN_2$ is determined by assuming an unstrained GaN substrate with the $ZnGeN_2$ in-plane lattice constants matched to the substrate and the perpendicular lattice constant determined by minimizing the elastic strain energy using the known elastic constants. We find that the offset is type II, meaning staggered instead of straddled alignment, which is of interest for photovoltaic applications as holes and electrons would separate in different regions. The band offset depends slightly on interface direction. The orientation averaged valence band maximum of GaN is 0.86 eV lower than $ZnGeN_2$'s. The charge neutrality point alignment model is tested and found to give a significantly smaller band offset.

3:54PM W23.00008 Pentacene Derivatives: Electronic Structure and Spectra , ROSS NETUSIL, Chemistry Department, State University of New York at Oswego, CAROLINA ILIE, THORIN KANE, Physics Department, State University of New York at Oswego, FEHMI DAMKACI, Chemistry Department, State University of New York at Oswego — The variation in composition and structure of the substituent groups of pentacene compounds promises a broad range of electronic structures and behaviors and provides a vast and alluring field of inquiry with avenues of exploration. These include the development of synthetic schema, the process of design for novel derivatives and, in order to identify those hypothesized compounds which demonstrate the desired behavior, the identification and refinement of computational tools that make accurate predictions about the electronic behavior of theoretical compounds. Two computational techniques and six pentacene derivatives are here examined. One technique was used to predict the vibrational spectra of the compounds, in order to both acquire data about the optical conductivity of the compounds and to establish a pool of theoretical data against which experimental data will be compared. The molecular orbital energy level diagram of the same six compounds was derived using a second approach, with the same goals of discerning between valid and invalid predictive schema by comparison with pending experimental data and between hypothesized compounds which show promise and those which present little potential for use in organic semiconductor technology.

4:06PM W23.00009 Many-body physics of intersubband polaritons , LUC NGUYEN-THÊ, Laboratoire MPQ, Université Paris Diderot, France, SIMONE DE LIBERATO, University of Southampton, UK, MOTOAKI BAMBA, Osaka University, Japan, CRISTIANO CIUTI, Laboratoire MPQ, Université Paris Diderot, France — Intersubband polaritons are light-matter excitations originating from the strong coupling between an intersubband quantum well electronic transition and a microcavity photon mode. Up to now intersubband polaritons have been observed in a wide range of the electromagnetic spectrum from the mid-infrared to the THz regime. Due to their composite bosonic nature, the matter part of these excitations is responsible for a non-trivial dynamics of cavity polaritons. We studied how the Coulomb electron-electron interaction and the Pauli saturation of the electronic transitions affect the many-body physics of intersubband polaritons [1]. As a first application we calculated the efficiency of intersubband polariton-polariton scattering, paving the way to promising quantum non-linear optics especially in the THz regime.

4:18PM W23.00010 Band-gap variations in polytypes of SiC: misleading parameter "hexagonality"and proposal of new parameter , YU-ICHIRO MATSUSHITA, ATSUSHI OSHIYAMA, Dept. of Appl. Phy., The University of Tokyo — Silicon carbide (SiC) has been discovered in various polytypes. Each polytype is characterized by its stacking of atomic planes. The band gap varies substantially in each polytype from 2.40 eV to 3.33 eV in spite that the local atomic structures are identical to each other. Recently, we have clarified the mechanism of this intriguing property based on the density functional theory [1]. We have found that the Kohn-Sham orbital at the conduction-band bottom extends broadly in the internal space called channels, and thus floating in the matter. Therefore, important parameter describing the band-gap variations is the channel length, not "hexagonality," which is thought to be important for the band-gap variations.

4:30PM W23.00011 Band gap formation in tetrahedrally bonded I_3-V-VI_4 semiconductors-the role of V lone pairs[1] , S.D. MAHANTI, DAT DO, Department of Physics, Michigan State University — An interesting class of tetrahedrally coordinated ternary compounds have attracted considerable interest because of their potential as good thermoelectrics. These compounds, denoted as I_3-V-VI_4, contain three monovalent-I (Cu, Ag), one pentavalent-V (P, As, Sb, Bi), and four hexavalent-VI (S, Se, Te) atoms; and can be visualized as ternary derivatives of the II-VI zincblende or wurtzite semiconductors, obtained by starting from four unit cells of (II-VI) and replacing four type II atoms by three type I and one type V atoms. In trying to understand their electronic structures and transport properties, some fundamental questions arise: whether V atoms are indeed pentavalent and if not how do these compounds become semiconductors, what is the role of V lone pair electrons in the origin of band gaps, and what are the general characteristics of states near valence band maxima and conduction band minima. We will answer some of these questions using ab initio electronic structure calculations (density functional methods with both local and nonlocal exchange-correlation potentials). Some part of this work has been published in Dat et al, J. Phys.: Condens. Matter 24, 415502 (2012).

4:42PM W23.00012 NMR spectroscopy around filling factor three , TREVOR DAVID RHONE, LARS TIEMANN, KOJI MURAKI, NTT and ERATO-JST — We probe the spin signatures of a two-dimensional electron system, confined to a GaAs quantum well, around filling factor three ($\nu \sim 3$) using resistively detected nuclear magnetic resonance (RDNMR) spectroscopy at milliKelvin temperatures. Whereas the existence of spin textures, known as skyrmions, around filling factor one is well established, an understanding of the spin degrees of freedom for odd-integer states in higher Landau levels remains elusive. It is believed that for skyrmions to exist at $\nu \sim 3$, the Zeeman energy needs to be smaller than in the case of $\nu \sim 1$ [1]. We measured the spin-lattice relaxation time, T_1, which is sensitive to these spin textures as they trigger a rapid nuclear spin relaxation. Our T_1 measurements around $\nu = 3$ at 5 T find a small spin-lattice relaxation rate, suggesting the absence of skyrmions. In addition, our Knight shift measurements corroborate this interpretation. Furthermore, we report striking anomalies in the RDNMR spectral line shape and discuss their origin in conjunction with our findings.
[1]N. R. Cooper, Phys. Rev. B 55, R1934 (1997).

4:54PM W23.00013 Phonon-Assisted Auger Recombination in Gallium Arsenide and Gallium Nitride from First Principles[1] , DANIEL STEIAUF, Materials Department, University of California, Santa Barbara, EMMANOUIL KIOUPAKIS, Materials Science and Engineering, University of Michigan, Ann Arbor, CHRIS G. VAN DE WALLE, Materials Department, University of California, Santa Barbara — GaN and GaAs and their alloys are technologically important materials for solid-state optoelectronic devices such as light emitting diodes. The internal quantum efficiency of these devices, defined as the fraction of electron-hole pairs converted to photons, is limited by non-radiative loss mechanisms. Auger recombination is such a mechanism which decreases the efficiency at high current densities. In this process, the energy and momentum of an electron-hole pair is transferred to a third carrier. Numerically it is found that this process does not lead to relevant loss rates. However, if a phonon is emitted or absorbed at the same time, Auger loss rates increase by several orders of magnitude. We calculate the Auger recombination rate coefficients from first principles using density functional theory. Treating also the phonons from first principles allows us to analyze which modes and wave vectors contribute predominantly to Auger recombination and the non-radiative loss in these materials.

5:06PM W23.00014 Core level shift and charge transfer of Sr templates on Si(001) for epitaxial oxide growth: theoretical and experimental study , MIRI CHOI, AGHAM POSADAS, HOSUNG SEO, RICHARD HATCH, ALEXANDER DEMKOV, The University of Texas at Austin — Sub-monolayer Sr templates are used as a transition layer in the epitaxial growth of perovskite oxides on semiconductors. However, a detailed understanding of how the template enables oxide growth on Si(001) is still lacking. Sr on Si(001) shows different structural and electronic properties as a function of Sr coverage. Using a combination of *in situ* reflection high energy electron diffraction (RHEED) and *in situ* x-ray photoelectron spectroscopy (XPS), we observed both the Si 2p and Sr 3d core levels shift toward higher binding energy as Sr coverage increases up to one half monolayer. In addition, increase of Sr coverage leads to unbuckling of the Si dimer atoms as evidenced by the merging of the up and down dimer core level components as Sr donates charge to the dimer atoms. The work function of Si also shifts with Sr coverage as observed using ultraviolet photoelectron spectroscopy (UPS).

5:18PM W23.00015 Inelastic electron and light scattering from the elementary electronic excitations in quantum wells , M.S. KUSHWAHA, Rice University — The most fundamental approach to an understanding of electronic, optical, and transport phenomena which the condensed matter physics offers is generally founded on two experiments: the inelastic electron scattering and the inelastic light scattering. This work embarks on providing a systematic framework for the theory of inelastic electron scattering and of inelastic light scattering from the electronic excitations in quantum wells. To this end, we start with the Kubo's correlation function to derive the generalized dielectric function, the inverse dielectric function, and the Dyson equation for the screened potential within the framework of Bohm-Pines' random-phase approximation. This is followed by a thorough development of the theory of inelastic electron scattering and of inelastic light scattering. After trying and testing the eigenfunctions, we compute the density of states, the Fermi energy, the full excitation spectrum made up of single-particle and collective (plasmon) excitations, the loss functions for the inelastic electron scattering, and the Raman intensity for the inelastic light scattering. It is found that HREELS can be a potential alternative of the overused Raman scattering for investigating collective excitations in such nanostructures.

2:30PM W24.00001 FCIQMC algorithm development and applications , ALI ALAVI, University of Cambridge — No abstract available.

3:06PM W24.00002 Stochastic Coupled Cluster Theory , ALEX J. W. THOM, Department of Chemistry, University of Cambridge, Cambridge, UK — In an extension of the Full Configuration Interaction Monte Carlo method of Alavi et al.[1], I describe a stochastic algorithm to perform Coupled Cluster Theory[2] which represents excitation amplitudes as populations discrete excitation particles (excips) in the space of excitation operators (excitors). Re-expressing the Coupled Cluster equations as the dynamics of excips in this space, we show that a simple set of rules consisting of spawning, death, and annihilation steps suffice to evolve a distribution of in the space of excitors to sample the Coupled Cluster solution and correctly evaluate its energy. These rules are extremely simple to implement and not truncation-specific and thus this method can calculate solutions to an arbitrary level of truncation. I present results of CCSDTQ calculations on the neon atom with basis sets up to cc-pV6Z as well as calculations on the uniform electron gas beyond the capability of other present methods.

3:18PM W24.00003 Full Configuration Interaction Quantum Monte Carlo and Diffusion Monte Carlo: A Comparative Study of the 3D Homogeneous Electron Gas , JAMES J. SHEPHERD, PABLO LÓPEZ RÍOS, RICHARD J. NEEDS, University of Cambridge, UK, NEIL D. DRUMMOND, University of Lancaster, UK, JENNIFER A.-F. MOHR, University of Cambridge, UK, GEORGE H. BOOTH, Princeton University, USA, ANDREAS GRÜNEIS, GEORG KRESSE, University of Vienna, Austria, ALI ALAVI, University of Cambridge, UK — Full configuration interaction quantum Monte Carlo[1] (FCIQMC) and its initiator adaptation[2] allow for exact solutions to the Schrödinger equation to be obtained within a finite-basis wavefunction *ansatz*. In this talk, we explore an application of FCIQMC to the homogeneous electron gas (HEG). In particular we use these exact finite-basis energies to compare with approximate quantum chemical calculations from the VASP code[3]. After removing the basis set incompleteness error by extrapolation[4,5], we compare our energies with state-of-the-art diffusion Monte Carlo calculations from the CASINO package[6]. Using a combined approach of the two quantum Monte Carlo methods, we present the highest-accuracy thermodynamic (infinite-particle) limit energies for the HEG achieved to date. [1] G. H. Booth, A. 3:30PM W24.00004 Development of multicomponent semistochastic quantum Monte Carlo method for variational solution of molecular Hamiltonian without invoking the Born-Oppenheimer approximation

, BENJAMIN ELLIS, ARINDAM CHAKRABORTY, Dept. of Chemistry, Syracuse University, ADAM HOLMES, HITESH CHANGLANI, CYRUS UMRIGAR, Dept. of Physics, Cornell University — We present the multicomponent extension of the semistochastic quantum Monte Carlo (mc-SQMC) method for treating electron-nuclear correlation in the molecular Hamiltonian. All particles in the molecule are treated quantum mechanically and the variational solution is obtained with the SQMC method. The key feature of this approach is that the BO and separation-rotor approximation are not assumed. The application of the SQMC method for multicomponent systems involves many formidable challenges and this talk will focus on strategies to address these challenges including, appropriate coordinate system for the molecular Hamiltonian, separation of the center of mass kinetic energy, construction of the 1-particle basis functions for electrons and nuclei, construction of the multicomponent CI space and evaluation of connected configurations needed during propagation step in the SQMC method. Results from mc-SQMC will be presented for H_2, He_2, and H_2O systems. The H_2 system has been extensively studied using various methods, such as QMC and PIMC, making it an ideal system to test and compare the mc-SQMC implementation. The impact of the BO approximation and vibration-rotation coupling will be discussed by comparing mc-SQMC results with reported values for the weakly bound He_2.

3:42PM W24.00005 Reduced Density Matrices in Full Configuration Interaction Quantum Monte Carlo

, CATHERINE OVERY, DEIDRE CLELAND, The University Chemical Laboratory, University of Cambridge, UK, GEORGE H. BOOTH, Department of Chemistry, Frick Laboratory, Princeton University, USA, JAMES J. SHEPHERD, ALI ALAVI, The University Chemical Laboratory, University of Cambridge, UK — Reduced density matrices are a powerful construct in quantum chemistry, providing a compact representation of highly multi-determinantal wavefunctions, from which the expectation values of important physical properties can be extracted, including multipole moments, polarizabilities and nuclear forces[1,2]. Full configuration interaction quantum Monte Carlo (FCIQMC)[3] and its initiator extension (*i*-FCIQMC)[4] perform a stochastic propagation of signed walkers within a space of Slater determinants to achieve FCI-quality energies *without* the need to store the complete wavefunction. We present here a method for a stochastic calculation of the 1- and 2-body reduced density matrices within the framework of (*i*)-FCIQMC, and apply this formulation to a range of archetypal molecular systems. Consideration is also given to the source and nature of systematic and stochastic error, and regimes to effectively alleviate these errors are discussed[5]. [1] P.-O. Löwdin, Phys. Rev. 97, 1474 (1955). [2] C. A. Coulson, Rev. Mod. Phys. 32, 170 (1960). [3] G. H. Booth, A. Thom, and A. Alavi, J. Chem. Phys. 131, 054106 (2009). [4] D. Cleland, G. H. Booth, and A. Alavi, J. Chem. Phys. 132, 041103 (2010). [5] D. Cleland, PhD thesis, University of Cambridge, 2012.

3:54PM W24.00006 Evaluation of expectation values in full configuration interaction quantum Monte Carlo

, J.S. SPENCER, W.M.C. FOULKES, Imperial College London — The full configuration interaction quantum Monte Carlo (FCIQMC) method[1-3] provides access to the exact ground state energy. However, like diffusion Monte Carlo, it is hard to precisely calculate expectation values of operators which do not commute with the Hamiltonian due to the stochastic representation of the wavefunction. Following related work on diffusion Monte Carlo[4], we have formulated an approach to stochastically sample additional operators in FCIQMC by using the Hellmann-Feynman theorem and sampling pumped equations of motion coupled to the standard equation of motion used to evolve the wavefunction. Our approach requires only minor modifications to existing FCIQMC programs and can be used to evaluate expectation values of arbitrary operators. We will present example calculations on the Hubbard model and molecular systems.

4:06PM W24.00007 Improvements and Applications of Semistochastic Quantum Monte Carlo[1]

, ADAM HOLMES, HITESH CHANGLANI, Laboratory of Atomic and Solid State Physics, Cornell University, MIGUEL MORALES, Lawrence Livermore National Laboratory, M.P. NIGHTINGALE, Department of Physics, University of Rhode Island, C.J. UMRIGAR, Laboratory of Atomic and Solid State Physics, Cornell University — Fully stochastic quantum Monte Carlo (QMC) methods, such as the full configuration interaction quantum Monte Carlo (FCIQMC) [1,2] allow one to compute the ground state of a Hamiltonian in a far larger Hilbert space than is possible using deterministic iterative diagonalization techniques. However, QMC methods suffer from the sign problem and may have large statistical errors. Recently we have shown [3] that these problems can be greatly alleviated by using a semistochastic quantum Monte Carlo (SQMC) approach, wherein the iterative projector is applied deterministically for a small subset of the Hilbert space states and stochastically elsewhere. In addition, the initiator bias, which is introduced to tame the sign problem in FCIQMC, is often greatly reduced. We explore further improvements to SQMC and apply it to a subset of the G2 set of molecules [4]. [1] George Booth, Alex Thom, Ali Alavi. J Chem Phys 131, 050106, (2009). 4:18PM W24.00008 Investigating the Singlet-Triplet Gap in Tetramethyleneethane using Quantum Monte Carlo Techniques[1]

, ZACHARY POZUN, Department of Chemistry, University of Pittsburgh, JAN HERMANN, Department of Physical and Macromolecular Chemistry, Faculty of Science, Charles University in Prague, KENNETH JORDAN, Department of Chemistry, University of Pittsburgh — Tetramethyleneethane (TME) is an organic molecule composed of two allyl subunits that is the simplest disjoint diradical. The ground state according to experimental and theoretical evidence is a singlet state with ^{1}A symmetry. [2] Due to the near degeneracy of the frontier orbitals, however, this state is inherently two-configurational. As the molecule is twisted through torsional angles about the central C-C bond, we compute the singlet-triplet gap using quantum Monte Carlo (QMC). In its diffusion Monte Carlo (DMC) variant, QMC is an exact method for solving the Schrödinger equation within the bounds of the fixed-node approximation. [3] DMC calculations using a multi-configurational trial wave function produce the correct ordering of the singlet and triplet states. We also investigate an alternate approach, full configuration interaction quantum Monte Carlo (FCIQMC). We compare the FCIQMC singlet-triplet energy gap as a function of torsional angle with the different theoretical methods.

4:30PM W24.00009 Systematically improvable auxiliary-field quantum Monte Carlo for strongly correlated systems[1] , WIRAWAN PURWANTO, SHIWEI ZHANG, HENRY KRAKAUER, Department of Physics, College of William and Mary, Williamsburg, VA — The quest for an accurate and scalable many-body method for strongly correlated systems is still ongoing despite many years of efforts. The auxiliary-field quantum Monte Carlo (AFQMC) method is an exact many-body method, but it suffers from a sign problem that limits its usefulness. The phaseless AFQMC (ph-AFQMC) has been introduced[2] to control the sign problem. In this work we employ the unconstrained (exact) AFQMC method on massively parallel supercomputers to systematically improve ph-AFQMC results. Applications to strongly correlated systems, including transition-metal compounds, will be presented.

4:42PM W24.00010 Acceleration of Self Healing Diffusion Monte Carlo for nearly degenerate eigenstates[1] , FERNANDO REBOREDO, Oak Ridge National Laboratory — The Self-Healing Diffusion-Monte-Carlo method (SHDMC) recurisvely applies an evolution operation for a finite imaginary time. SHDMC and finds the full configuration interaction coefficients of the many-body ground state by projecting out excited states. The convergence of the SHDMC, being a projection method, is dictated by the energy separation between the ground and excited states. In this talk we explore methods to accelerate the convergence of SHDMC for nearly degenerate states using the dynamical information of the excited states accumulated over the recursive iterations and to compute ground and excited states simultaneously.

4:54PM W24.00011 Excited states and spectral functions within full configuration interaction quantum Monte Carlo , GEORGE BOOTH, GARNET CHAN, Princeton University — Here we consider a modified propagator in order to obtain stable convergence to excited states within the full configuration interaction quantum Monte Carlo framework.[1] By working with a Gaussian propagator, the dominant eigenstate is one which is closest to an initial guess energy for the state. Issues with the speed of convergence compared to the ground state propagator are discussed, with results presented for pilot applications, and potential improvements for the algorithm considered.

5:06PM W24.00012 Quantum Monte Carlo Study of π-bonded Transition-metal Organometallic Sandwiches[1] , IVAN STICH, LUCIA HORVATHOVA, MATUS DUBECKY, Institute of Physics, Slovak Academy of Sciences, Bratislava, Slovakia, LUBOS MITAS, North Carolina State University, Department of Physics, Raleigh — Accurate quantum Monte Carlo (QMC) calculations enabled us to determine the structure, spin multiplicity, ionization energy, dissociation energy, and spin-dependent electronic gaps of neutral and positively charged vanadium-benzene and cobalt-benzene half-sandwich and sandwich systems. The most intriguing application of these systems is as spin filters. For this purpose we have used a multi-stage combination of techniques with consecutive elimination of systematic biases except for the fixed-node approximation in QMC. The-fixed node approximation was treated at different levels from quantum chemistry (CAS-SCF) to various DFT schemes such as GGA, meta-GGA, hybrid, double-hybrid and local-hybrid functionals. While QMC results indicate a very limited predictive power of mean field DFT methods for this class of systems, QMC results are quite stable with fixed-node approximation based on several classes of DFT orbitals. Our results significantly differ from the established picture based on previous less accurate calculations and point out the importance of high-level many-body methods for predictive calculations of similar transition metal-based organometallic systems.

5:18PM W24.00013 Symmetry in Auxiliary-Field Quatnum Monte Carlo Calculations[1] , HAO SHI, SHIWEI ZHANG, physics department, College of William and Mary — We discuss how symmetry properties can be preserved rigorously to improve the accuracy and efficiency in auxiliary-field quantum Monte Carlo (AFQMC) calculations. Using the Hubbard model as an example, we study the effect of symmetry in two aspects of ground-state AFQMC calculations, the Hubbard-Straonovich transformation and the form of the trial wave function. In unconstrained calculations, the implementation of symmetry often leads to shorter convergence time and much smaller statistical errors, thereby resulting in a substantial reduction of the sign problem and allowing exact calculations for larger and more strongly correlated systems. Moreover, certain excited states become possible to calculate which are otherwise beyond reach. In calculations with constraints,[2,3] it is shown that the use of symmetry can often reduce the systematic error significantly. Results are presented for the two-dimensional repulsive Hubbard model.

2:30PM W25.00001 Hard-Disk Equation of State: First-Order Liquid-Hexatic Transition in Two Dimensions with Three Simulation Methods[1]

, MICHAEL ENGEL, JOSHUA A. ANDERSON, University of Michigan, MASAHARU ISOBE, Nagoya Institute of Technology, ETIENNE P. BERNARD, Massachusetts Institute of Technology, WERNER KRAUTH, École Normale Supérieure, SHARON C. GLOTZER, University of Michigan — We report large-scale computer simulations of the hard-disk system at high densities in the region of the melting transition [1]. Our simulations reproduce the equation of state, previously obtained using the event-chain Monte Carlo algorithm, with a massively parallel implementation of the local Monte Carlo method [2] and with event-driven molecular dynamics. We analyze the relative performance of these simulation methods to sample configuration space and approach equilibrium. Phase coexistence is visualized for individual configurations via the local orientations, and positional correlation functions are computed. Our results confirm the first-order nature of the liquid-hexatic phase transition in hard disks.

2:42PM W25.00002 Massively parallel Monte Carlo for many-particle simulations on GPUs

, SHARON GLOTZER, JOSHUA ANDERSON, ERIC JANKOWSKI, THOMAS GRUBB, MICHAEL ENGEL, University of Michigan — Current trends in parallel processors call for the design of efficient massively parallel algorithms for scientific computing. Parallel algorithms for Monte Carlo simulations of thermodynamic ensembles of particles have received little attention because of the inherent serial nature of the statistical sampling. We present a massively parallel method that obeys detailed balance and implement it for a system of hard disks on the GPU.[1] We reproduce results of serial high-precision Monte Carlo runs to verify the method.[2] This is a good test case because the hard disk equation of state over the range where the liquid transforms into the solid is particularly sensitive to small deviations away from the balance conditions. On a GeForce GTX 680, our GPU implementation executes 95 times faster than on a single Intel Xeon E5540 CPU core, enabling 17 times better performance per dollar and cutting energy usage by a factor of 10. [1] J.A. Anderson, E. Jankowski, T. Grubb, M. Engel and S.C. Glotzer, arXiv:1211.1646. [2] J.A. Anderson, M. Engel, S.C. Glotzer, M. Isobe, E.P. Bernard and W. Krauth, arXiv:1211.1645.

2:54PM W25.00003 Generalized Bond Order Parameters to Characterize Transient Crystals

, MASAHARU ISOBE, Nagoya Institute of Technology, BERNI ALDER, Lawrence Livermore National Laboratory — Higher order parameters in the hard disk fluid are computed to investigate the number, the life time and size of transient crystal nuclei in the pre-freezing phase. The methodology introduces further neighbor shells bond orientational order parameters and coarse-grains the correlation functions needed for the evaluation of the stress autocorrelation function for the viscosity. We successfully reproduce results by the previous collision method for the pair orientational correlation function, but some two orders of magnitude faster. This speed-up allows calculating the time dependent four body orientational correlation between two different pairs of particles as a function of their separation, needed to characterize the size of the transient crystals. The result is that the slow decay of the stress autocorrelation function near freezing is due to a large number of rather small crystal nuclei lasting long enough to lead to the molasses tail.

3:06PM W25.00004 Size-dependent Melting Behavior of Iron Nanoparticles by Replica Exchange Molecular Dynamics[1]

, QIANG SHU, YANG YANG, YINGTENG ZHAI, Department of Physics, Fudan University, DEYAN SUN, Department of Physics, East China Normal University, HONGJUN XIANG, XINGAO GONG, Department of Physics, Fudan University — Due to the finite size effect, nanoparticles own unique physical, chemical, and magnetic properties. Comparing with the bulk materials, the large surface/volume ratio of nanoparticles could lead to more complicate atomic and electronic behavior, thus the thermodynamical properties can be also very rich. In the last a few decades, as one of the fundamental problems in the nano science, the melting behavior of nanoparticles had been widely investigated by numerous experimental and theoretical studies. Using replica-exchange molecular dynamics method (REMD), we have investigated the size dependence of the melting behavior of iron nanoparticles. Comparing to the conventional molecular dynamics (MD), the REMD method is found to be very efficient to determine the melting point, by avoiding the superheating and undercooling phenomena. With accurate determination of the melting point, we find that the melting temperature does not follow linearly with the inverse of size. By incorporating the size dependent thickness of surface liquid layer which is observed in our simulation, we propose a revised liquid skin melting model to describe the size dependent melting temperature.

3:18PM W25.00005 Nanoindentation in Nanoporous Silica: Multimillion-Atom Molecular Dynamics Simulations

, ADARSH SHEKHAR, University of Southern California, CAMILLA N. KIRKEMO, ANDERS MALTHE-SØRENSSEN, University of Oslo, RAJIV K. KALIA, AIICHIRO NAKANO, PRIYA VASHISHTA, University of Southern California — Nanoporous silica is widely used in catalysis, chromatography, anticorrosion coatings, desalination membranes, and as drug delivery vehicles because it is easy to tune the size of pores and their morphologies and to functionalize pore surfaces with a variety of molecular moieties. We have performed multimillion-atom molecular dynamics simulations to examine the structural properties and mechanical behavior of nanoporous silica at various densities. The simulations are based on experimentally validated force field for silica. We have examined the pore size distribution, and calculated roughness exponents of pores to characterize pore morphologies. We have determined the scaling of elastic moduli, hardness and fracture toughness with porosity of nanoporous silica through nanoindentation simulations. Our calculated value of hardness (10.6 GPa) for amorphous silica at normal density agrees very well with the experimental value (10 GPa) [1].

3:30PM W25.00006 Automated generation of quantum-accurate classical interatomic potentials for metals and semiconductors[1]

, AIDAN THOMPSON, STEPHEN FOILES, PETER SCHULTZ, LAURA SWILER, CHRISTIAN TROTT, GARRITT TUCKER, Sandia National Laboratories — Molecular dynamics (MD) is a powerful condensed matter simulation tool for bridging between macroscopic continuum models and quantum models (QM) treating a few hundred atoms, but is limited by the accuracy of available interatomic potentials. Sound physical and chemical understanding of these interactions have resulted in a variety of concise potentials for certain systems, but it is difficult to extend them to new materials and properties. The growing availability of large QM data sets has made it possible to use more automated machine-learning approaches. Bartók *et al.* demonstrated that the bispectrum of the local neighbor density provides good regression surrogates for QM models. We adopt a similar bispectrum representation within a linear regression scheme. We have produced potentials for silicon and tantalum, and we are currently extending the method to III-V compounds. Results will be presented demonstrating the accuracy of these potentials relative to the training data, as well as their ability to accurately predict material properties not explicitly included in the training data.

[1]Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Dept. of Energy Nat. Nuclear Security Admin. under Contract DE-AC04-94AL85000.

3:42PM W25.00007 Database Optimization for interatomic potential model , PINCHAO ZHANG, DALLAS TRINKLE, Department of Materials Science and Engineering, University of Illinois, Urbana-Champaign — We develop a new algorithm for database optimization of interatomic potential models with Bayesian statistics. Conventional classical potential fitting schemes generates a best fit parameter set, but do not show inadequacies of the potential model nor give insight into viability of the fitting database. Our algorithm generates an ensemble of potential fits with Markov Chain Monte Carlo and make predictions based on Bayesian error estimation according to the ensemble. We consider a fitting database to be optimal when the sum of relative errors for all entries of the database is minimized. A specific objective function is proposed and an optimized database of the interatomic potential model can be obtained by modifying the relative importance (weights) of different structures in the database. We test the algorithm with a Lennard-Jones potential fitting of Ti, which shows specific limitations of this simple potential model. We also show that the derivative of the objective function with respect to weight determines whether a structure should be added to or removed from the database.

3:54PM W25.00008 A first-principles interatomic potential via perturbative theory , XINYUAN AI, CHRIS MARIANETTI, Columbia University — Here we propose a new approach for constructing a first-principles interatomic potential based upon a Taylor series expansion in clusters of the atomic displacements. While the number of clusters is very large in general, group theory can be used to generate a tractable number of clusters in materials with sufficiently high symmetry. A large dataset of perturbed structures which randomly samples the irreducible cluster phase space is constructed and computed in density functional theory. The cross validation score is then used to determine which clusters should be retained in the expansion. This method is then benchmarked on a one-dimensional atomic chain. Excellent agreement is achieved within a large range of atomic displacements in addition to large lattice strains. Additionally, one can recover the phonons as a function of strain. Further application of the method to two and three dimensional materials are also presented.

4:06PM W25.00009 A new type of interatomic potential for oxides and its applications to $BiFeO_3$ and $PbTiO_3$[1] , SHI LIU, HIROYUKI TAKENAKA, TINGTING QI, ILYA GRINBERG, ANDREW RAPPE, Department of Chemistry, University of Pennsylvania — Conventional first-principles methods are limited due to their intense computational cost. There is therefore still a strong need to develop accurate and efficient atomistic potential that could reproduce the full dynamical behaviors of metal oxides for large-scale finite-temperature simulations. We will present a new type of interatomic potential based on principles of bond-valence conservation and bond-valence vector conservation. The physical basis is justified quantum mechanically in the framework of a tight-bonding model, demonstrating that our model is formally equivalent to the bond-order potential (BOP), but is dramatically more efficient computationally. We will present an interatomic potential for $BiFeO_3$ and $PbTiO_3$, respectively. The validity of those model potentials is tested for both constant-volume and constant-pressure molecular dynamics simulations. The ferroelectric-to-paraelectric phase transitions of $BiFeO_3$ and $PbTiO_3$ are successfully reproduced. The calculated domain-wall energies using classical potentials are in satisfying agreement with DFT values. We conclude that our model potential is a promising type of force field that can have a broad application to a wide range of inorganic materials.

4:18PM W25.00010 A New Charge Model in The Valence Force Field Model for Phonon Calculations[1] , CHRISTOPHER BARRETT, University of California, Berkeley, Department of Materials Science & Enginering, LIN-WANG WANG, Lawrence Berkeley National Laboratory, Materials Science Division — The classical ball and spring Valence Force Field model is useful to determine the elastic relaxation of thousand-atom nanosystems. We have also used it to calculate the phonon spectra of nanosystems. However, we found that the conventional point charge model in the Valence Force Field model can cause artificial instability in nanostructures. In this talk, we will present a new charge model which represents the electron cloud feature of the Born charge in a real crystal. More specifically, we have two opposite-signed point charges assigned to each atom, one at its real position, another at a position determined by its neighbor atoms. This innovation allows both electrostatic charges and Born charges to be accurately represented while retaining extreme efficiency. This customized VFF method is developed to be fittable to the results of density functional theory (DFT) calculation. We will present the results of CdSe bulk, surface, and nanowire calculations and compare them with the equivalent ab-initio calculations, for both in their accuracies and their costs.

4:30PM W25.00011 Temperature-dependent classical phonons from efficient non-dynamical simulations[1] , JORGE INIGUEZ, MATHIAS P. LJUNGBERG, ICMAB-CSIC — We describe a rigorous approach to the calculation of classic lattice-dynamical quantities from simulations that do not require an explicit consideration of the time evolution. We focus on the temperature-dependent vibrational spectrum. We start from the usual moment expansion of the relevant time correlation function (position-position or velocity-velocity) for a many-body system, and show that it can be conveniently split into one-body-like contributions by using a basis in which the low-order terms are diagonal. This allows us to compute the main spectral features (e.g., position *and* width of the phonon peaks) from thermal averages readily available from any statistical simulation. We demonstrate our method with an application to a model system that presents a structural transition and strongly temperature-dependent phonons. Our theory justifies and clarifies the status of previous heuristic schemes to estimate phonon frequencies in a computationally efficient way.

4:42PM W25.00012 Density and Spectral-Density Matrices in Atomistic-Scale Models[1] , STEVEN VALONE, Los Alamos National Laboratory — Density matrices for the states of atoms appear from the construction of a model referred to as the Fragment Hamiltonian (FH) model. The FH model is not dependent on construction of one-electron as a prelude to the atomistic level. Rather a density matrix of occupation numbers of the integer charge states is composed directly from a many-electron point of view to represent the state of each atom or fragment in a molecule or material. The properties of these density matrices comply with those general density matrices. Two particular properties are explored. One property that is unique to the FH model is that the coefficients of the occupancy density matrix can be transformed into functions of more familiar variables, such as net charge and ionicity that play a central role in regulating charge flow in a molecule or material. The second property is that the concept of a spectral density matrix can be defined as an extension of the occupancy density matrix and again is utilized in a manner that is analogous to the role of that concept in one-electron theories of electronic structure. The construction and functionalities of both density matrix concepts are illustrated through examples from idealized systems such as one-dimensional chains.

4:54PM W25.00013 Atomistic Simulation Studies of the Bulk Lithiated TiO_2[1] , PHUTI NGOEPE, MALILI MATSHABA, University of Limpopo, DEAN SAYLE, University of Cranfield — TiO_2 has been confirmed as a safe anode material in lithium ion batteries due to its higher Li-insertion potential, (1.5V) in comparison with commercialised carbon anode materials. In the current study, amorphisation recrystallization method is used to produce bulk TiO_2 with a brookite structure and lithium is inserted at different concentrations. In accordance with pair distribution function experiments [1], it is found that lithiation tends to amorphise the structures. Simulated X-ray diffraction patterns are produced from such structures and compared with the experimental XRDs. Microstructures of TiO_2 are generated and are found to be highly twinned hence forming straight and zigzag tunnels. The microstructures of lithiated TiO_2 display limited twinning and tunnels with less pathways available for lithium transport. The microstructures are compared with those of nanostructural TiO_2 and suggestions for the preference of the latter in anodes are put forward.

5:06PM W25.00014 Atomistic simulations studies of the bulk cobalt pentlandite (Co_9S_8): Validation of the potential model[1] , MOFUTI MEHLAPE, University of Limpopo, STEVE PARKER, University of Bath, PHUTI NGOEPE, University of Limpopo — We investigate various forms of the cobalt pentlandite, Co_9S_8, at different temperatures, using classical atomistic simulation methods with the support of electronic structure calculations. The first interatomic potentials of Co_9S_8 based on the Born model, were derived with input data such as structure and elastic properties from experiments and electronic structure calculations respectively. The interatomic potentials were validated by running energy minimization and molecular dynamics calculations. The structure, elastic properties and phonon spectra corresponded well with those determined by electronic structure methods. The calculations further reproduced the complex high temperature transformation to high form pentlandite and the melting of Co_9S_8; as deduced from the crystal structure and radial distribution functions. The interatomic potentials can be used for studies of surfaces and nanostructures.

5:18PM W25.00015 Stable Algorithms for Modeling Thin-Film Epitaxial Growth[1] , GREG SEYFARTH, Colby College, BENJAMIN VOLLMAYR-LEE, Bucknell University — We search for stable time-stepping schemes for a phase-field model of thin film epitaxial growth. In particular, we consider a class of linear semi-implicit schemes which ensure the free energy decreases with time, a property called gradient stability. System dynamics slow at late times, so gradient stable schemes which allow adaptive time stepping are highly desirable. We perform a linear stability analysis and support it with numerical testing, revealing a region in parameter space of gradient stable semi-implicit schemes.

Session W26 GQI: Focus Session: Semiconductor Qubits - Progress in Si 328 - Charles Tahan, Laboratory for Physical Sciences, University of Maryland

2:30PM W26.00001 Robust few-electron quantum dot devices in nuclear spin engineered Si/SiGe , DOMINIQUE BOUGEARD, Universitaet Regensburg, Institut fuer Experimentelle und Angewandte Physik, Regensburg, Germany — Spins in gate-defined quantum dots are currently discussed as one of the most promising scalable qubit architecture. Since the identification of the hyperfine interaction as a dominant spin qubit decoherence mechanism, Si/SiGe heterostructures have been receiving steadily increasing attention for realizing devices almost free of nuclear spin carrying isotopes. Building Si/SiGe heterostructures from material enriched in nuclear spin-free isotopes brings new perspectives of reaching a regime of further improved decoherence times compared to Si/SiGe of natural isotope composition. In such isotopically engineered heterostructures, the decoherence is predicted to no longer be governed by the hyperfine interaction with the nuclear spin bath, but solely by dipolar interactions. In the first part of my presentation I will review the development of two-dimensional electron systems in 28Si for spin qubit applications in my group and discuss few electron double quantum dot devices based on these heterostructures. Being able to avoid hyperfine-induced decoherence then brings a second major limitation for the realization of robust spin qubits into focus. Indeed, the manipulation of such qubits relies on Coulomb interactions, enabling electronic noise to cause decoherence. Charge traps in the heterostructure may contribute to decoherence through a fluctuation of charges or through dipolar interactions of the spin degree of freedom of the trap and the qubit. In the second part of my talk I will present our recent study of charge noise in modulation-doped Si/SiGe heterostructures and discuss device and heterostructure designs which efficiently suppress charge noise.

3:06PM W26.00002 *In situ* isotopic enrichment and growth of ^{28}Si for quantum information , KEVIN DWYER, Materials Science and Engineering, University of Maryland, JOSHUA POMEROY, NIST — Starting from natural abundance silane gas, we deposit ^{28}Si films enriched *in situ* to 99.9% in support of solid state quantum information systems. Isotopically enriched materials such as ^{28}Si are known to act as a "solid state vacuum" allowing for qubits with coherence (T_2) times of minutes. Quantum coherent devices rely on long T_2 times, but nuclear spin impurities are a major cause of decoherence. Isotopically enriching materials to eliminate stray nuclear spins (such as the 4.7% ^{29}Si in natural silicon) greatly improves coherence. Our objective is to produce silicon that is not only isotopically enriched, but chemically pure and defect free. We crack and ionize a natural abundance source gas, magnetically mass filter the ions in a beam line, and deposit the enriched material hyperthermal energies. In addition to our first ^{28}Si samples assessed by SIMS to be enriched to $>$ 99.9%, we previously implanted ^{22}Ne enriched at 99.4% (9.2% natural abundance) as proof of principle and have also grown ^{12}C films enriched at $>$ 99.996% (98.9% natural abundance). To our knowledge, no other effort is actively producing enriched solid silicon directly from natural abundance silane. Ongoing improvements are leading us towards our goal of ^{28}Si enriched to $>$ 99.99% and epitaxial deposition.

3:18PM W26.00003 Coherence time of the nuclear spin of ionized phosphorus donors in ^{28}Si at liquid He and room temperature , MICHAEL L.W. THEWALT, KAMYAR SAEEDI, Dept. of Physics, Simon Fraser University, Burnaby BC V5A 1S6 Canada, STEPHANIE SIMMONS, Dept. of Materials, Oxford University, Oxford OX1 3PH, UK, JOHN J.L. MORTON, London Centre for Nanotechnology, University College London, London WC1H 0AH, UK — Remarkable coherence times have recently been reported for the nuclear spin of dilute neutral ^{31}P in highly enriched ^{28}Si [1]. For ionized ^{31}P, the removal of the hyperfine-coupled electron should result in a nuclear spin even more decoupled from the environment, and hence even longer coherence times at cryogenic temperatures. The coherence time of ionized ^{31}P was recently observed in natural Si, and while the nuclear coherence time was indeed much longer than the electron coherence time measured in the same device, it was limited to 18 ms due to both the presence of ^{29}Si as well as the readout mechanism being employed [2]. Here we report on coherence time measurements for ionized ^{31}P in the same ^{28}Si samples used for the previous [1] neutral donor study. In addition to the promise of longer cryogenic coherence times, the removal of the hyperfine-coupled electron should result in a profound change in the temperature dependence of T_2. For the neutral donor, the electron T_1 decreases very rapidly with increasing temperature, and even at 4.2 K the nuclear T_2 is limited by the electron T_1 [1]. This mechanism is absent for the ionized donor, and we will report on nuclear coherence time measurements for ionized ^{31}P at room temperature.

3:30PM W26.00004 Decoherence of Neutral ^{31}P Donor Nuclear Spins by ^{29}Si[1] , E.S. PETERSEN, A.M. TYRYSHKIN, S.A. LYON, Princeton University, J.J.L. MORTON, University College London, K.M. ITOH, Keio University, M.L.W. THEWALT, Simon Fraser University — NMR data from degenerately doped Si:P has suggested that the coherence of ^{31}P nuclear spins can be limited to a few ms in natural Si by spectral diffusion from ^{29}Si [1]. Here we report measurements of the nuclear spin coherence of neutral isolated ^{31}P donors in lightly-doped ($\sim 10^{15}$ /cm^3) Si with ^{29}Si concentrations from 1% to 50%. Pulsed ENDOR at X-band microwave frequency and a magnetic field of 0.35 T was used to measure the nuclear spins. The light doping and measurement temperature of 1.7K ensured that neither electron spin flips nor flip-flops limited the nuclear T_2. We find that the resulting echo intensity decays are nonexponential, and the time to reach 1/e is inversely proportional to the ^{29}Si density. The nuclear decoherence time for natural silicon is found to be approximately 1 second, about 2000 times longer than donor electron spins in natural Si.

3:42PM W26.00005 Spin measurement in an undoped Si/SiGe double quantum dot incorporating a micromagnet , XIAN WU, JONATHAN PRANCE[1], DANIEL WARD, JOHN GAMBLE, DONALD SAVAGE, MAX LAGALLY, MARK FRIESEN, SUSAN COPPERSMITH, MARK ERIKSSON, University of Wisconsin-Madison — We present recent measurements on a double dot formed in an accumulation mode undoped Si/SiGe heterostructure. The double dot incorporates a proximal micromagnet to generate a stable magnetic field difference between the quantum dots. By measuring the ground state and excited state spectrum of this double dot as a function of in-plane magnetic field we identify the (1,1) and (2,0) charge degeneracy point. Using single-shot readout we measure transitions between the (2,0) singlet and the (1,1) triplet states. This method enables the identification of the crossing as a function of detuning between the (1,1) triplet states (both the first and second excited states) and the (2,0) singlet state. We also present data showing that this undoped device has good charge stability and can be measured with high frequency (up to 500MHz) voltage pulses.

3:54PM W26.00006 Valley-orbit hybrid states in Si quantum dots[1] , JOHN KING GAMBLE, MARK FRIESEN, S.N. COPPERSMITH, Department of Physics, University of Wisconsin-Madison, Madison, WI 53706 — The conduction band for electrons in layered Si nanostructures oriented along (001) has two low-lying valleys. Most theoretical treatments assume that these valleys are decoupled from the long-wavelength physics of electron confinement. In this work, we show that even a minimal amount of disorder (a single atomic step at the quantum well interface) is sufficient to mix valley states and electron orbitals, causing a significant distortion of the long-wavelength electron envelope. For physically realistic electric fields and dot sizes, this valley-orbit coupling impacts all electronic states in Si quantum dots, implying that one must always consider valley-orbit hybrid states, rather than distinct valley and orbital degrees of freedom. We discuss the ramifications of our results on silicon quantum dot qubits.

4:06PM W26.00007 A new mechanism for spin and valley relaxation in silicon quantum dots , RUSKO RUSKOV, CHARLES TAHAN, Laboratory for Physical Sciences, College Park, MD 20740, U.S.A. — We consider spin and valley relaxation in imperfect silicon quantum dots with 1 to 3 electrons. Phonons, spin-orbit coupling, and the electrostatic confining potential of the dot all play roles in both the functional dependence on key parameters (say magnetic field) and the quantitative magnitude of the relaxation rate. Level mixing in the dot allows for spin relaxation via phonons and also explains anti-crossing behavior of dot levels as a function of magnetic field. We show that valley state relaxation can be fast in realistic dots and that spin relaxation can be a few orders of magnitude longer. Our results compare favorably to recent experimental data including the power dependence on magnetic field, location of relaxation hot spots, and the magnitude of the relaxation rates themselves. Some of this work is in collaboration with A. Dzurak group at the University of New South Wales, Australia.

4:18PM W26.00008 ABSTRACT WITHDRAWN –

4:30PM W26.00009 Interactions and valley-orbit coupling in Si quantum dots , LUYAO JIANG, ICQD, University of Science and Technology of China, C. H. YANG, University of New South Wales, ZHAODI PAN, ICQD, University of Science and Technology of China, ANDREA MORELLO, ANDREW DZURAK, University of New South Wales, DIMITRIE CULCER, ICQD, University of Science and Technology of China — The valley-orbit coupling in a few-electron Si quantum dot is a function of its occupation number N, and for N >1 is in principle renormalized by the electron-electron Coulomb interaction, which is known to be strong. We study the interaction renormalization of the valley-orbit coupling for $2 \leq N \leq 4$, showing that, counterintuitively, interaction effects on the valley-orbit coupling are weak. For $N = 2$ the renormalization is suppressed by valley interference, while for $N = 3$ all renormalization terms are zero due to spinor overlaps, and for $N = 4$ interaction renormalization terms cancel between different pairs of electrons. Experimental observations reveal no evidence of interaction effects on the valley-orbit coupling, consistent with these findings.

4:42PM W26.00010 Genetic Design of Enhanced Valley Splitting towards a Spin Qubit in Silicon[1] , LIJUN ZHANG, JUN-WEI LUO, National Renewable Energy Laboratory, ANDRE SARAIVA, BELITA KOILLER, Universidade Federal do Rio de Janeiro, Brazil, ALEX ZUNGER, University of Colorado — The quantum state of an electron in the Si conduction band holds exceptional promise for quantum computing, owing to its attractive spin coherence properties and adaptability to standard electronics. A paramount challenge is the orbital degeneracy of the lowest conduction band of Si, which is potentially a serious source of decoherence for spin qubits. Hence, isolating a single electron valley state by creating a sufficiently large valley splitting (VS) is a prerequisite for the realization of Si-based spin qubits. Previous explorations of Si quantum wells confined by Si-Ge alloy barriers led thus far to a limited VS of the order of 1 meV or smaller. Here we demonstrate, via an atomically resolved pseudopotential theory, that the monolayer ordering of Si-Ge barriers within reach of modern superlattice growth techniques can be harnessed to enhance the VS by up to one order of magnitude compared to disordered random alloy barriers. A biologically inspired genetic-algorithm search allowed us to identify magic atomic layer sequences of the superlattice barriers that isolate single electron valley state in Si with VS as large as $\sim$9 meV. These results may provide a roadmap for reliable spin-only quantum computing in Si.

4:54PM W26.00011 Impact of the valley degree of freedom on the control of donor electrons near a Si/SiO_2 interface[1] , ANDRE SARAIVA, IF-UFRJ, ALEJANDRA BAENA, MARIA CALDERÓN, ICMM - CSIC, BELITA KOILLER, IF-UFRJ — We analyze the valley composition of one electron bound to a shallow donor close to a Si/barrier interface as a function of an applied electric field within a multivalley effective mass model. Switching from low to high fields, the electron ground state is drawn from the donor site into the interface, leaving the donor partially ionized. Valley splitting at the interface occurs due to the valley-orbit coupling, $V_{vo}^I = |V_{vo}^I|e^{i\theta}$. At intermediate electric fields, close to a characteristic shuttling field, the electron states may constitute hybridized states with valley compositions different from the donor and the interface ground states. The full spectrum shows crossings and anticrossings as the field varies. The degree of level repulsion depends on the relative valley compositions, which vary with $|V_{vo}^I|$, θ and the interface-donor distance. We focus on the valley configurations of the states involved in the donor-interface tunneling process, given by the anticrossing of the three lowest levels. A sequence of two anticrossings takes place and the complex phase theta affects the symmetries of the eigenstates and level anticrossing gaps. Implications of our results on the practical manipulation of donor electrons in Si nanostructures are discussed.

5:06PM W26.00012 Localization of Si/SiO_2 Interface States: Properties and Physical Implications[1] , BELITA KOILLER, AMINTOR DUSKO, ANDRE SARAIVA, Physics Institute, Universidade Federal do Rio de Janeiro — Interface states (IS) form spontaneously at some semiconductor-barrier interfaces and they may improve or hinder electronic control and coherence for semiconductor-based qubits. Intrinsic Si/SiO_2 IS and its hybridization to the Si bulk states were recently investigated within tight binding (TB) models [1]. From the simplest model (1D), new insights emerge regarding the IS's energy and hybridization with the band states. In this work the 1D TB Hamiltonian is further explored, here within a Green's function formalism. The problem is solved exactly via a decimation technique based on renormalization group ideas [2]. The IS thus obtained are strictly related to the junction of two semi-infinite chains modeling the Si material and the SiO_2 barrier, excluding possible contributions from parameters (e.g. chain length) previously invoked [1]. We obtain the energy of IS as well as the exponential longer (shorter) localization lengths into the Si (barrier) material. The IS may be probed experimentally by an external electric field, which modulates the capacitance of the system, or by the spacing between the two lowest levels, related to the valley splitting [1].

Session W27 GQI: Focus Session: Superconducting Qubits: Quantum Computing Architectures

329 -

2:30PM W27.00001 Overview of a Quantum Annealing Processor , MARK W. JOHNSON, D-Wave Systems Inc. — Quantum Adiabatic Evolution algorithms have been proposed as a potentially powerful set of methods to solve computationally hard problems.[1] One example of this approach is to find the ground state configuration of an Ising spin system with a transverse field using quantum annealing (QA).[2] I will present an overview of the architecture and operation of the D-Wave One, an end-to-end computing platform that performs QA by slowly decreasing the transverse field of a programmable Ising spin system. After a brief review of quantum annealing, I will describe how superconducting flux qubits are used to construct the programmable Ising spins.[3] I will then discuss some recent experiments performed to determine whether or not the processor behaves as intended. Toward this end, it is particularly useful to be able to measure the spectrum of single and multiple coupled qubits as they progress through the annealing algorithm.[4] Finally, since the primary measure of the efficacy of such a machine is how well it solves problems, I will conclude with a discussion of system performance and scaling.

3:06PM W27.00002 Realization of three-qubit quantum error correction with superconducting circuits , SCHOELKOPF ROBERT, Department of Applied Physics, Yale University — No abstract available.

3:42PM W27.00003 Cross-Talk in Superconducting Transmon Quantum Computing Architecture[1]

DAVID ABRAHAM, JERRY M. CHOW, ANTONIO CORCOLES, MARY BETH ROTHWELL, GEORGE KEEFE, JAY GAMBETTA, MATTHIAS STEFFEN, IBM T.J. Watson Research Center, IBM QUANTUM COMPUTING TEAM — Superconducting transmon quantum computing test structures often exhibit significant undesired cross-talk. For experiments with only a handful of qubits this cross-talk can be quantified and understood [1], and therefore corrected. As quantum computing circuits become more complex, and thereby contain increasing numbers of qubits and resonators, it becomes more vital that the inadvertent coupling between these elements is minimized. The task of accurately controlling each single qubit to the level of precision required throughout the realization of a quantum algorithm is difficult by itself, but coupled with the need of nulling out leakage signals from neighboring qubits or resonators would quickly become impossible. We discuss an approach to solve this critical problem.

3:54PM W27.00004 Implementation of a two-qubit Grover algorithm using superconducting qubits[1]

MATTHIAS STEFFEN, ANTONIO CORCOLES, JERRY CHOW, JAY GAMBETTA, JOHN SMOLIN, IBM, MATT WARE, JOEL STRAND, BRITTON PLOURDE, Syracuse University — High fidelity two-qubit gates have previously been demonstrated with fixed frequency superconducting qubits and employing the cross-resonance effect generating the qubit-qubit interaction in which qubit 1 is driven at the frequency of qubit 2. The drawback of previous implementations of the cross-resonance gate is the fact that single qubit gates on qubit 2 emerge when the qubits are multi-level systems instead of strictly two-level systems. As a result, two-qubit gates must be tuned up by careful timing or by explicitly applying single-qubit correction pulses. This is a cumbersome procedure and can add overall errors. Instead, we show a refocusing scheme which preserves the two-qubit interaction but eliminates the single-qubit gates. The total gate length is only increased by the duration of two single qubit pi-pulses which is a low overhead. When tuning up this composite pulse we show an implementation of a two-qubit Grover's algorithm without applying any correction pulses. The average success probability of the algorithm is consistent with fidelity metrics obtained by independent randomized bench-marking experiments (both single and two-qubit).

[1]We acknowledge support from IARPA under contract W911NF-10-1-0324.

4:06PM W27.00005 Emulating a mesoscopic system using superconducting quantum circuits

YU CHEN, R. BARENDS, J. BOCHMANN, B. CAMPBELL, B. CHIARO, E. JEFFREY, J. KELLY, M. MARIANTONI, A. MEGRANT, J. MUTUS, C. NEILL, P. O'MALLEY, S. OHYA, P. ROUSHAN, D. SANK, A. VAINSENCHER, J. WENNER, T. WHITE, A.N. CLELAND, J.M. MARTINIS, UC Santa Barbara — We demonstrate an emulation of a mesoscopic system using superconducting quantum circuits. Taking advantage of our ReZQu-architectured quantum processor, we controllably splitted a microwave photon and manipulated the splitted photons before they recombined for detection. In this way, we were able to simulate the weak localization effect in mesoscopic systems - a coherent backscattering process due to quantum interference. The influence of the phase coherence was investigated by tuning the coherence time of the quantum circuit, which in turn mimics the temperature effect on the weak localization process. At the end, we demonstrated an effect resembling universal conductance fluctuations, which arises from the frequency beating between different coherent backscattering processes. The universality of the observed fluctuation was shown as the independence of the fluctuation amplitude on detailed experimental conditions.

4:18PM W27.00006 Speed limits for quantum gates in multiqubit solid-state systems

SAHEL ASHHAB, The Institute of Physical and Chemical Research (RIKEN), Wako-shi, Japan; and The University of Michigan at Ann Arbor, USA, PIETER DE GROOT, Delft University of Technology, The Netherlands; and Max Planck Institute for Quantum Optics, Garching, Germany, FRANCO NORI, The Institute of Physical and Chemical Research (RIKEN), Wako-shi, Japan; and The University of Michigan at Ann Arbor, USA — We derive speed limits for various unitary quantum operations in multiqubit systems under typical experimental conditions, using parameters and constraints that are commonly encountered with superconducting qubits. In particular we focus on two- and three-qubit gates. We find that simple methods for implementing two-qubit gates generally provide the fastest possible implementations of these gates. We also find that the three-qubit Toffoli gate time varies greatly depending on the type of interactions and the system's geometry, taking only slightly longer than a two-qubit controlled-NOT (CNOT) gate for a triangle geometry.

4:30PM W27.00007 Designing entangling microwave gates between fixed frequency superconducting circuits coupled by resonators[1]

SETH MERKEL, JAY GAMBETTA, JOHN SMOLIN, IBM, IBM QUANTUM COMPUTING TEAM TEAM — Many of the recent techniques for controlling superconducting quantum circuits are directly derived from the atomic theory of cavity QED, and the fixed frequency transmon provides a particularly close analogy to an "artificial atom." However, even in this case new modelling techniques are required as we engineer parameter regimes that have been previously unexplored in atomic systems. In this talk we develop the Schrieffer-Wolff transformation as a means of adiabatically eliminating high-energy subspaces in order to derive effective entangling Hamiltonians. We can use this theory to explain many of the recent, experimentally demonstrated fixed frequency gates such as the cross-resonance gate and the two-photon 00 to 11 transition. In the case of the cross-resonance gate this more detailed model predicts spurious single qubit rotations, and their rates, which can then be removed through refocusing techniques.

[1]We acknowledge support from IARPA under contract W911NF-10-1-0324.

4:42PM W27.00008 Hardware-efficient quantum memory protection[1]

ZAKI LEGHTAS, GERHARD KIRCHMAIR, BRIAN VLASTAKIS, ROBERT SCHOELKOPF, MICHEL DEVORET, Applied Physics Department, Yale University, MAZYAR MIRRAHIMI, INRIA Paris-Rocquencourt / Applied Physics Department, Yale University — We propose a new method to autonomously correct for errors of a logical qubit induced by energy relaxation. This scheme encodes the logical qubit as a multi-component superposition of coherent states in a harmonic oscillator, more specifically a single cavity mode. The sequences of encoding, decoding and correction operations employ the non-linearity provided by a single physical qubit coupled to the cavity. We layout in detail how to implement these operations in a circuit QED architecture. This proposal directly addresses the task of building a hardware-efficient and technically realizable quantum memory.

[1]This work was partially supported by the French "Agence Nationale de la Recherche" under the project EPOQ2 number ANR-09-JCJC-0070 and the Army Research Office (ARO) under the project number ARO - W911NF-09-1-0514.

4:54PM W27.00009 Engineered circuit QED with dense resonant modes[1]

FRANK WILHELM[2], DANIEL EGGER, Saarland University — In circuit quantum electrodynamics even in the ultrastrong coupling regime, strong quasi-resonant interaction typically involves only one mode of the resonator as the mode spacing is comparable to the frequency of the mode. We are going to present an engineered hybrid transmission line consisting of a left-handed and a right-handed portion that has a low-frequency van-Hove singularity hence showing a dense mode spectrum at an experimentally accessible point. This gives rise to strong multi-mode coupling and can be utilized in multiple ways to create strongly correlated microwave photons.

5:06PM W27.00010 Observing the nonequilibrium dynamics of the quantum transverse-field Ising chain in circuit QED , OLIVER VIEHMANN, JAN VON DELFT, Physics Department, ASC, and CeNS, LMU Munich, FLORIAN MARQUARDT, Institute for Theoretical Physics, FAU Erlangen-Nuremberg — Circuit QED architectures of superconducting artificial atoms and microwave resonators are currently moving towards multi-atom, multi-resonator setups with drastically enhanced coherence times, making them increasingly attractive candidates for quantum simulations of interesting interacting quantum many-body systems. Here we propose and analyze a circuit QED design that implements the quantum transverse-field Ising chain coupled to a microwave resonator for readout. Our setup can be used to study quench dynamics, the propagation of localized excitations, and other nonequilibrium features, in a field theory exhibiting a quantum phase transition, and based on a design that is feasible with current technology and could easily be extended to break the integrability of the system.

5:18PM W27.00011 Strongly-coupled Josephson junction array for simulation of frustrated one-dimensional spin models , ZHENGWEI ZHOU, LIANGHUI DU, XINGXIANG ZHOU, YONGJIAN HAN, GUANGCAN GUO, Key Laboratory of Quantum Information, University of Science and Technology of China — We study the capacitance-coupled Josephson-junction array beyond the small-coupling limit. We find that, when the scale of the system is large, its Hamiltonian can be obtained without the small-coupling approximation and the system can be used to simulate strongly frustrated one-dimensional Ising spin problems. To engineer the system Hamiltonian for an ideal theoretical model, we apply a dynamical-decoupling technique to eliminate undesirable couplings in the system. Using a six-site junction array as an example, we numerically evaluate the system to show that it exhibits important characteristics of the frustrated spin model.

Thursday, March 21, 2013 2:30PM - 5:30PM –

Session W28 GSNP: Focus Session: Soft-Matter, Biology, & Bioinspiration 336 - Carmel Majidi, Carnegie Mellon University

2:30PM W28.00001 Cavitation in trees monitored using simultaneously acoustics and optics , ALEXANDRE PONOMARENKO, OLIVIER VINCENT, PHILIPPE MARMOTTANT, LIPhy, Grenoble University, Saint-Martin-dHères, France — Under hydric stress, in dry weather conditions, the sap within trees may reach extreme negative pressures and cavitate: bubbles appear, which eventually causes an embolism in the circulation. It has been shown that cavitation is associated with short acoustic emissions, and they can be recorded in the ultrasound range. However the precise origin of each acoustic emission is still not clear. In particular, the acoustic emissions could be not only the consequence of cavitation, but also of the collapse of xylem conduits, or of fractures in the wood. Here we present an original set-up where we can simultaneously record (i) the acoustic emissions, (ii) the location of cavitation events, by imaging the sap channels under light transmission microscopy. We are then able to correlate the sounds to the visible changes in channels, such as the appearance of cavitation bubbles. We hope the results of the present study might help to better understand the acoustic signals emitted by trees, and to obtain further information in the evolution of wood under dry stress conditions.

2:42PM W28.00002 Reversible Rigidity Control Using Low Melting Temperature Alloys , WANLIANG SHAN, TONG LU, CARMEL MAJIDI, Carnegie Mellon University — Inspired by nature, materials able to achieve rapid rigidity changes have important applications for human body protection in military and many other areas. This talk presents the fabrication and design of soft-matter technologies that exhibit rapid reversible rigidity control. Fabricated with a masked deposition technique, the soft-matter composite contains liquid-phase and phase-changing metal alloys embedded in a soft and highly stretchable elastomer. The composite material can reversibly change its rigidity by three orders of magnitude and sustain large deformation.

2:54PM W28.00003 "Lock and key mechanism" for ligand binding with adrenergic receptors and the arising mechanical effects on the cell membrane[1] , LAURA LUNGHI, Department of Pharmaceutical and Applied Chemistry, Università of Siena, Italy, LUCA DESERI, Center for Nonlinear Analysis, Carnegie Mellon University — Chemicals hitting the surface of cell aggregates are known to give arise to cyclic Adenosine Mono Phosphate (cAMP), a second messenger that transduces inside the cell the effects of species that cannot get through the cell membrane. Ligands bind to a specific receptor following the so called "lock and key mechanism"; (beta)-adrenergic receptors are proteins embedded in the lipid bilayer characterized by seven transmembrane helices. Thinning and thickening in cell membranes may be initiated by conformational changes of some of three of the seven domains above. The cell response is linked to the coupling of chemical, conformational and mechanical effects. Part of the cAMP remains intracellular, whereas the remaining fractions migrates outside the cell due to membrane transporters. A new Helmholtz free energy, accounting for receptor and transporter densities, receptor conformation field and membrane elasticity is investigated. It is shown how the density of active receptors is directly related to the conformation field and it enters the resulting balance equation for the membrane stress. Balance laws for fluxes of transporters and receptors, coupled with the former because of the outgoing cAMP flux caused by the transporters, as well as for the diffusive powers must be supplied.

[1]The Center for Nonlinear Analysis through the NSF Grant No. DMS-0635983 is gratefully acknowledged.

3:06PM W28.00004 Geometrical study of the deformations of a thin spherical shell inspired by pollen grains. , ETIENNE COUTURIER, USACH, ELENI KATIFORI, MPI Göttingen, JACQUES DUMAIS, UAI Viña del Mar, ENRIQUE CERDA, USACH — Various monocotyledon pollen grains have a geometric design. They are constituted by a stiff thin shell with an n-fold rotationally symmetric softer sector. The mechanic response of these inhomogeneous shells can be approximated as an open shell. Isometric modes are known to be energetically favorable for thin shells when they are possible. Although the literature for the complete sphere, for which these modes are impossible, is extensive, analyses of the deformation of open shells whose isometric deformations are not inhibited, are much more scarce. We focus on the isometric deformation of spheres with n-fold rotationally symmetric openings. The isometric deformation means that the surface remains a constant gaussian curvature surface. Using differential geometry, we obtained an integrable family of surfaces whose gaussian curvature remains approximatively constant. We performed both simulations by tethered mesh methods and experiments with cut ping-pong balls. We observe that first the shell surface deforms without any stretching and is very well described as a part of an approximative constant gaussian curvature surface whose singularities remain outside the shell surface and get closer to the shell surface as the load increases.

3:18PM W28.00005 Hysteresis in the creasing instability of hydrogels and elastomers , DAYONG CHEN, Department of Polymer Science and Engineering, University of Massachusetts Amherst, SHENGQIANG CAI, LIHUA JIN, ZHIGANG SUO, School of Engineering and Applied Sciences, Harvard University, RYAN HAYWARD, Department of Polymer Science and Engineering, University of Massachusetts Amherst — Soft polymers placed under compressive stress can undergo an elastic creasing instability in which sharp folds spontaneously form on the free surfaces. This process can play an important role in a variety of material failure modes, but has also been harnessed to fabricate dynamic chemical and topographic patterns. Creases have been found to form by nucleation and growth, which we show reflects the influence of surface energy as a barrier for both processes. Hysteresis in the loading and unloading cycles is an important aspect of this process, but has been reported to occur to different degrees in different material systems. Through variations in interfacial energy, we show that for a model elastomeric system, it is self-adhesion within the folding region rather than plastic deformation that gives rise to hysteresis.

3:30PM W28.00006 Extreme Mechanics of Growing Matter[1] , ELLEN KUHL, Stanford University — Growth is a distinguishing feature of all living things. Unlike standard materials, living matter can autonomously respond to alterations in its environment. As a result of a continuous ultrastructural turnover and renewal of cells and extracellular matrix, living matter can undergo extreme changes in composition, size, and shape within the order of months, weeks, or days. While hard matter typically adapts by increasing its density to grow strong, soft matter adapts by increasing its volume to grow large. Here we provide a state-of-the-art review of growing matter, and compare existing mathematical models for growth and remodeling of living systems. Applications are plentiful ranging from plant growth to tumor growth, from asthma in the lungs to restenosis in the vasculature, from plastic to reconstructive surgery, and from skeletal muscle adaptation to heart failure. Using these examples, we discuss current challenges and potential future directions. We hope to initiate critical discussions around the biophysical modeling of growing matter as a powerful tool to better understand biological systems in health and disease.

4:06PM W28.00007 A micromechanical viscoelastic model for soft biological tissue , BAPTISTE COUDRILLIER, THAO D. NGUYEN, Johns Hopkins University, PROF. NGUYEN LAB TEAM — Understanding the viscoelastic behavior of soft collageneous tissue from micromechanical considerations is critical to the characterization of their physiological and pathological response. In this study, we propose to model biological tissue as an aggregate of unit cells (UC). Each UC represents two wavy parallel collagen fibrils cross-linked by intrafibrillar bridges. A fibril consists of two linear springs deforming axially, and interconnected by a linear torsional spring modeling the fibril bending rigidity. When an axial displacement is applied to the unit cell, the uncrimping and stretching of the fibrils cause the ground substance to shear and the intrafibrillar bridges to rotate. This model assumes that the time-dependent behavior of the UC is due to the viscous rotation of the bridges, which are modeled as Maxwell solids. The constitutive equation of the tissue is calculated from the orientation average of the constitutive equation of the unit cell weighted by the probability density function for unit cell distribution. The performance of the model to predict the creep response will be illustrated using the results of an inflation test performed on the human sclera.

4:18PM W28.00008 Spatially localized structure-function relations in the elastic properties of sheared articular cartilage , JESSE SILVERBERG, Department of Physics, Cornell University, LAWRENCE BONASSAR, Department of Biomedical Engineering and Sibley School of Mechanical and Aerospace Engineering, Cornell University, ITAI COHEN, Department of Physics, Cornell University — Contemporary developments in therapeutic tissue engineering have been enabled by basic research efforts in the field of biomechanics. Further integration of technology in medicine requires a deeper understanding of the mechanical properties of soft biological materials and the structural origins of their response under extreme stresses and strains. Drawing on the science generated by the "Extreme Mechanics" community, we present experimental results on the mechanical properties of articular cartilage, a hierarchically structured soft biomaterial found in the joints of mammalian long bones. Measurements of the spatially localized structure and mechanical properties will be compared with theoretical descriptions based on networks of deformed rods, poro-visco-elasticity, and standard continuum models. Discrepancies between experiment and theory will be highlighted, and suggestions for how models can be improved will be given.

4:30PM W28.00009 Highly Deformable Liquid Embedded Soft-Matter Capacitors and Inductors for Stretchable Electronics , ANDREW FASSLER, CARMEL MAJIDI, Carnegie Mellon University — We have developed a family of soft-matter capacitors and inductors that can be stretched to several times their natural length. These circuit elements are composed of microchannels of a liquid-phase Gallium-Indium-Tin alloy (Galinstan) embedded in a soft silicone elastomer (Ecoflex® 00-30). As the elastomer stretches, the embedded liquid channels deform, causing the capacitance and inductance to change monotonically. The relative changes in capacitance and inductance are experimentally measured as a function of stretch in three directions. The relationships found show potential for these devices to be used as strain sensors and tunable electronic filters. Additionally, theoretical predictions derived using finite elasticity kinematics are consistent with these experimentally found relationships.

4:42PM W28.00010 Delayed Fluid-Driven Fractures on Soft Gels , MARK SCHILLACI, JOSHUA BOSTWICK, KAREN DANIELS, NC State University — A droplet of surfactant spreading on a weak gel substrate (~ 10 Pa) can produce fractures on the gel surface, which originate at the contact-line and propagate outwards in a star-burst pattern. Experiments show that the number of arms is controlled by the ratio of the surface tension differential to the gel's shear modulus. We interpret the number of fractures formed in the context of a linear elastic model arising from the uncompensated, Young-Dupre (out-of-plane) force acting at the contact-line. However, we also observe that there is an inherent variability in both the number of fractures formed and the delay for fractures to form. In the regime where single fractures form, we observe a range of delay values consistent with a thermally-activated process. The mean delay time is set by the modulus of gel substrate, decreasing for weaker substrates. In the regime where multiple fractures form, we observe that all fractures appear simultaneously and the long delays are suppressed.

4:54PM W28.00011 Soft-Matter Resistive Sensor for Measuring Shear and Pressure Stresses , DANIEL TEPAYOTL-RAMIREZ, PETER ROBERTS, CARMEL MAJIDI, Carnegie Mellon University — Building on emerging paradigms in soft-matter electronics, we introduce liquid-phase electronic sensors that simultaneously measures elastic pressure and shear deformation. The sensors are com- posed of a sheet of elastomer that is embedded with fluidic channels containing eutectic Gallium- Indium (EGaIn), a metal alloy that is liquid at room temperature. Applying pressure or shear traction to the surface of the surrounding elastomer causes the elastomer to elastically deform and changes the geometry and electrical properties of the embedded liquid-phase circuit elements. We introduce analytic models that predict the electrical response of the sensor to prescribed surface tractions. These models are validated with both Finite Element Analysis (FEA) and experimental measurements.

5:06PM W28.00012 Manufacturing of Liquid-Embedded Elastomers for Stretchable Electronics[1] , REBECCA KRAMER, Mechanical Engineering, Purdue University, CARMEL MAJIDI, Mechanical Engineering, Carnegie Mellon University, JAMES WEAVER, Wyss Institute for Biologically Inspiring Engineering, ROBERT WOOD, SEAS, Harvard University — Future generations of robots, electronics, and assistive medical devices will include systems that are soft, elastically deformable, and may adapt their functionality in unstructured environments. This will require soft active materials for power circuits and sensing of deformation and contact pressure. As the demand for increased elasticity of electrical components heightens, the challenges for functionality revert to basic questions of fabrication, materials, and design. Several designs for soft sensory skins (including strain, pressure and curvature sensors) based on a liquid-embedded-elastomer approach have been developed. This talk will highlight new "soft MEMS" manufacturing techniques based on wetting behavior between gallium-indium alloys and elastomers with varying microtextured surface topography.

[1]Supported by Harvard MRSEC and the Wyss Institute

5:18PM W28.00013 Elastoswellability: Will it bend or will it buckle? , DOUGLAS HOLMES, ANUPAM PANDEY, Virginia Tech — Soft mechanical structures such as biological tissues and gels exhibit motion, instabilities, and large morphological changes when subjected to external stimuli. Swelling is a robust approach for inducing structural change as it occurs naturally in humid environments and can be easily adapted for industrial design. Small volumes of fluid that interact favorably with a material can cause large, dramatic, and geometrically nonlinear deformations including beam bending, plate buckling, and surface wrinkling. In this talk we address an overarching question regarding swelling-induced deformations: will the structural change occur globally, or will it be confined to the material's surface? We introduce a materials and geometry defined transition point that describes a fluid-structure's characteristic "elastoswellability" lengthscale. By locally swelling unconstrained slender beams and plates with solvents of varying solubility, we identify a transition between local surface wrinkling and global structural bending.

Session W29 GSNP: Straight-Up Jamming 337 - Scott Franklin, Rochester Institute of Technology

2:30PM W29.00001 Dynamical Heterogeneity in a Granular System Near the Jamming Transition , KARINA E. AVILA, Ohio University, USA, ANNETTE ZIPPELIUS, Georg-August-Universitaet Goettingen, Germany, HORACIO E. CASTILLO, Ohio University, USA — We investigate dynamical heterogeneity in event driven simulations of a two-dimensional bidisperse granular fluid. We study the dynamic susceptibility $\chi_4(t)$ extracted from two different correlation functions $Q(t)$ and estimate the dynamic correlation length $\xi(t)$ obtained from the four-point structure factor $S_4(q, \tau_4)$, where τ_4 is the time corresponding to the maximum of $\chi_4(t)$. We find that the dynamic correlation length grows as the volume fraction is increased to approach the jamming transition.

2:42PM W29.00002 Jamming in Emulsions and Elastic Tomography , RODRIGO GUERRA, DAVID WEITZ, Harvard University — Attempting to bridge the gap between the jamming of soft, athermal particles and soft colloids, we measure the elasticity of packings of $\sim 10\mu m$ droplets using light scattering and tomography. Droplets in this size range retain the soft, frictionless contacts of colloidal dispersions, yet are large enough to resist thermal agitation. Nearly buoyant droplets form disordered piles where the compression varies smoothly and slowly with depth. Using light scattered from different sections of the pile we measure the dependence of the shear modulus on pressure using Diffusing Wave Spectroscopy (DWS) microrheology. We find a shear modulus that is proportional to pressure down to loads corresponding to a $\sim 0.1\%$ compression. However, below a critical pressure, the shear modulus drops abruptly and the droplets exhibit what appears like glassy rearrangements: despite loads many orders of magnitude greater than $\frac{K_B T}{a^3}$.

2:54PM W29.00003 Jamming of 2D foams , ALEXANDER SIEMENS, MARTIN VAN HECKE, University Leiden — We probe the jamming of 2D wet foams by lateral compression of a bidisperse foam monolayer sandwiched between a glass plate and a fluid surface. Boundaries and residual gravitational effects prevent the foam to be truly unjammed, obstructing the observation of a jammed/unjammed transition. Instead, we find a clear transition from a "gravity jammed" to a "boundary jammed" state, where the bulk modulus jumps from essentially zero to a finite value, in agreement with theory. In addition, we probe the nonaffine bubble motion, which becomes large near this transition.

3:06PM W29.00004 Stress distributions of jammed particle clusters and the maximum entropy principle[1] , YEGANG WU, STEPHEN TEITEL, University of Rochester — Using a simple model of frictionless bidisperse disks in two dimensions, we consider the distribution of stress on finite clusters of particles, within a statically jammed granular system at fixed global stress tensor. We compare our results against recent theories of the stress ensemble [1] and force network model [2] to investigate whether the distribution of stress is well described by a maximum entropy assumption.

3:18PM W29.00005 The link between the geometric and mechanical phase transitions at jamming , PETER MORSE, ERIC CORWIN, Department of Physics and Material Science Institute, University of Oregon — We have observed a phase transition in the geometrically defined network of nearest neighbors of sphere packings as a function of packing density. By creating packings in a range of spatial dimension, from $d = 2$ to $d = 9$, we have amassed evidence suggestive of an upper critical dimension for this transition of $d \leq 3$. However, as of yet we do not have a field theory to confirm this fact. It is suggestive that the geometric transition point coincides with the mechanical jamming point in all dimensions, raising the question of how the geometry of nearest-neighbors relates to the formation of contacts necessary for mechanical stability. We present an answer to this question based on the evolution of geometric constraints as mechanical jamming is approached. In addition, we find that many of the requirements for renormalization are met by the order parameters associated with the geometric phase transition. Taking cues from traditional condensed matter systems and networking theory we explore various renormalization group approaches to this phase transition.

3:30PM W29.00006 Sedimentary Deposition and the Kinetics of Jamming , TED BRZINSKI, R. KARUNAMUNI, A. D. A. MAIDMENT, P. E. ARRATIA, D. J. DURIAN, University of Pennsylvania — We observe a dispersion of spheres sedimenting in a fluid until all grains form a packing. In a Newtonian fluid, the dispersion is roughly homogenous in space and time except at two well-defined interfaces: a dispersion-supernatant interface, and a jamming front below which grains form a jammed packing. This system is ideal for the study of jamming kinetics because the jamming front is stationary: it moves upwards with a constant speed and shape. To characterize the concentration profile at the front, we have utilized x-ray absorption to directly measure volume fraction as a function of height and time. To characterize the grain-scale dynamics across the front, we now utilize a light scattering technique, speckle-visibility spectroscopy, to directly measure fluctuations of the grain velocities as a function of height and time. In order to alter the kinetics of jamming in this model system, we perturb the hydrodynamic interactions between grains by using a viscoelastic fluid, and observe how the shape and speed of the jamming front changes.

3:42PM W29.00007 How far is the Jamming point street-lamp illuminating the real world? , OLIVIER DAUCHOT, ESPCI, UMR Gulliver CNRS, Paris, France, CORENTIN COULAIS, University of Leiden, Leiden, The Netherlands, ROBERT P. BEHRINGER, Department of Physics, Duke University, Durham, NC, USA, CEA SACLAY/SPEC/SPHYNX - DUKE UNIV. COLLABORATION, ESPCI - CEA SACLAY/SPEC/SPHYNX COLLABORATION — The jamming of soft spheres at zero temperature has been extensively studied both numerically and theoretically, thus defining a well defined location, where a street lamp has been lit up. However it has been shown [1] that even model experiments on colloids are rather far away from the scaling regime illuminated by this lamp. Is it that the J-point has little to say about real system? We investigate the statics and the dynamics of the contact network of an horizontally shaken bi-disperse packing of photoelastic discs, close to jamming, we observe a remarkable dynamics of the contact network. It exhibits strong dynamical heterogeneities, which are maximum at a packing fraction ϕ^*, distinct and smaller than the packing fraction $\phi^\dagger$, where the average number of contact per particle starts to increase. We demonstrate that the two cross-overs, one for the maximum dynamical heterogeneity, and the other for structural jamming, converge at point J in the zero mechanical excitation limit. Our grains are frictional and are far from thermal equilibrium. However we succeed in mapping these behaviors onto those observed for thermal soft spheres and demonstrate that some light of the J-point street-lamp reaches our granular universe. [1] Ikeda et al. arXiv.1209.2814(2012)

3:54PM W29.00008 Jamming of Cylindrical Grains in Featureless Vertical Channels[1]

, G. WILLIAM BAXTER, NICHOLAS BARR, SETH WEIBLE, NICHOLAS FRIEDL, Penn State Erie, The Behrend College — We study jamming of low aspect-ratio cylindrical Delrin grains falling through a featureless vertical channel. With a grain height less than the grain diameter, these grains resemble aspirin tablets, poker chips, or coins. Unidisperse grains are allowed to fall under the influence of gravity through a uniform channel of square cross-section where the channel width is greater than the grain size and constant along the length of the channel. Channel widths are chosen so that no combination of grain heights and diameters is equal to the channel width. Collections of grains sometimes form jams, stable structures in which the grains are supported by the channel walls and not by grains or walls beneath them. The probability of a jam occurring and the jam's strength are influenced by the grain dimensions and channel width. We will present experimental measurements of the jamming probability and jam strength and discuss the relationship of these results to other experiments and theories.

[1]Supported by an Undergraduate Research Grant from Penn State Erie, The Behrend College

4:06PM W29.00009 Local strain field fluctuations in quasi-two-dimensional colloidal glasses[1]

, YE XU, Laboratory for Research on the Structure of Matter, University of Pennsylvania, TIM STILL, Department of Physics and Astronomy, University of Pennsylvania, KEVIN APTOWICZ, Department of Physics, West Chester University, ARJUN YODH, Department of Physics and Astronomy, University of Pennsylvania — We investigate the local strain field fluctuations in a quasi-two-dimensional colloidal glass as a function of packing fraction as the jamming transition is approached. Using standard video microscopy and particle tracking techniques, we derive the best-fit affine strain tensor and the non-affinity for each particle in the sample; this information is obtained by analyzing the variations of local configurations around each particle due to thermal motion. The spatial and temporal distributions of this local deformation permit us to probe the mechanical properties of our colloidal systems. We study how these mechanical properties evolve as the systems approaches the jamming transition. Furthermore, we explore the connection between the mechanical heterogeneity and the onset of irreversible rearrangements.

4:18PM W29.00010 Unusual order in squeezed repulsive spheres

, WOUTER G. ELLENBROEK, Eindhoven University of Technology — The soft spheres that we have been using for years to study jamming into disordered packings can make a range of surprising ordered structures at higher densities. Monodisperse repulsive harmonic disks in two dimensions form, apart form the triangular lattice everyone would expect, a square lattice and various non-bravais lattices that can be described as a triangular lattice with a basis. The latter class includes the honeycomb structure, a chiral structure, and a structure which is best described as a tiling of pentagons and triangles. The appearance of these structures, some of which have not been previously reported, is surprising because the potential between the disks only very weakly violates the condition of complete monotonicity which has been conjectured to guarantee the triangular lattice to be the ground state structure. I will discuss how these structures come about, how they are related to tiny periodic packings of hard spheres and in what ways the resulting structures might be useful.

4:30PM W29.00011 The role of curvature in the jamming of hard spheres on the surface of a spheroid

, DONALD W. BLAIR, Department of Physics, University of Massachusetts, Amherst, MA 01003 , BADEL MBANGA, CHRISTOPHER BURKE, TIMOTHY J. ATHERTON, Department of physics and astronomy, Tufts University, Medford, MA 02155 — Using various packing protocols, we investigate numerically the jamming of spherical particles that are constrained to the surface of a larger, host spheroid. While jamming has been extensively investigated for different particle shapes and containers, the role played by curvature in the frustration that arises when spherical particles are adsorbed to curved interfaces is not yet well understood. Accordingly, we explore the dependence of the critical particle coverage fraction Φ required for jamming to occur upon the number and polydispersity of the smaller particles as well as the shape and relative size of the host spheroid. Along the way, we evaluate the relative efficiency of the numerical algorithms we employ in terms of their efficiency and their relevance to the physics of recent experiments in microfluidics and colloid deposition on curved surfaces.

4:42PM W29.00012 Thinking Inside the Box: The Optimal Filling of Shapes[1]

, CAROLYN PHILLIPS, Argonne National Laboratory, JOSHUA ANDERSAON, University of Michigan, GREG HUBER, University of California, Santa Barbara, SHARON GLOTZER, University of Michigan — We introduce a new spatial partitioning problem called filling[1,2], which combines aspects of traditional packing and covering problems from mathematical physics. Filling involves the optimal placement of overlapping objects lying entirely inside an arbitrary shape so as to cover the most interior volume. In n-dimensional space, if the objects are polydisperse n-balls, we show that solutions correspond to sets of maximal n-balls. We investigate the mathematical space of filling solutions and provide a heuristic for finding the optimal filling solutions for polygons filled with disks of varying radii. We consider the properties of ideal distributions of N disks as N approaches infinity. We discuss applications of filling to such problems as tumor irradiation, designing wave fronts and wireless networks, minimal information representations of complex shapes, and molecular modeling of nanoparticles and colloids.

4:54PM W29.00013 Jammed frictional tetrahedra are hyperstatic

, MATTHIAS SCHRÖTER, MAX NEUDECKER, STEPHAN HERMINGHAUS, Max Planck Institute for Dynamics and Self-Organization (MPIDS), STEPHAN ULRICH, Leiden University — We prepare packings of frictional tetrahedra with volume fractions ϕ ranging from 0.469 to 0.622 using three different experimental protocols under isobaric conditions. Analysis via X-ray micro-tomography reveals that the contact number Z grows with ϕ, but does depend on the preparation protocol. While there exist four different types of contacts in tetrahedra packings, our analysis shows that the edge-to-face contacts contribute about 50% of the total increase in Z. The number of constraints per particle C increases also with ϕ and even the loosest packings are strongly hyperstatic i.e. mechanically over-determined with C approximately twice the degrees of freedom each particle possesses.

5:06PM W29.00014 Packings and assemblies of hard convex polyhedra[1]

, DAPHNE KLOTSA, Department of Chemical Engineering, University of Michigan, ELIZABETH CHEN, School of Engineering and Applied Sciences, Harvard University, PABLO DAMASCENO, MICHAEL ENGEL, SHARON GLOTZER, Department of Chemical Engineering, University of Michigan — Dense packings of hard polyhedra have been studied for centuries due to their mathematical aesthetic and more recently for their applications in fields such as granular matter, amorphous matter, and biology. The spontaneous organization of hard polyhedra under compression has only recently been addressed, demonstrating a plethora of assembled complex structures. The infinite pressure dense packings and the finite pressure, thermodynamically assembled structures for a given shape, however, are often different. In this talk we investigate connections between those two limits for convex polyhedra. We discuss the possibility of predicting one limit from the other, discuss some general rules, and link with previous works.

5:18PM W29.00015 Jamming of Ordered Vortex Lattice Domains[1] , C. RASTOVSKI, M.R. ESKILDSEN, University of Notre Dame, C.D. DEWHURST, Institut Laue-Langevin, Grenoble, France, W.J. GANNON, Northwestern University, IL, USA, N.D. ZHIGADLO, J. KARPINSKI, ETH, Zurich, Switzerland — Jamming is mostly associated with granular materials, but is applicable in a variety of physical situations. Our results indicate that the vortex lattice (VL) in type-II superconductors can be used as a model system to study jamming. Previous small-angle neutron scattering (SANS) studies of the VL in MgB_2 with H $\parallel$ c found a triangular VL which undergoes a field-driven 30° reorientation transition, forming three distinct ground state phases. The low and high field phases have hexagonal VLs aligned with high symmetry directions in the crystal, whereas at intermediate fields the VL is marked by the presence of domains of vortices continuously rotating from one high symmetry direction to another. A high degree of metastability between the VL phases of MgB_2 has been observed [P. Das et al., Phys. Rev. Lett. 2012]. Our recent SANS measurements show that this cannot be understood based on the single domain free energy. We applied a transverse AC magnetic field to the sample and found the decrease in the metastable volume fraction depends logarithmically on the number of AC cycles, similar to some jamming scenarios. We propose that the origin for the VL metastability is a jamming of counter-rotated VL domains that prevents rotation to the equilibrium orientation.

Session W30 GSNP: Nonlinear Dynamics 338 - David Egolf, Georgetown University

2:30PM W30.00001 Time Reversal Experiments in Chaotic Cavities[1] , BO XIAO, EDWART OTT, THOMAS ANTONSEN, STEVEN ANLAGE, CNAM, University of Maryland — Wave focusing through a strongly scattering medium has been an intriguing topic in the fields of optics, acoustics and electromagnetics. By introducing the time reversal technique, prior knowledge about each transmission channel is no longer needed since the step of sending waves through the medium measures this information. Many approaches have been explored to achieve better focusing quality, which is influenced by several factors, such as the propagation loss. We present two methods to conduct time reversal experiments in ray-chaotic billiards or cavities. The first method uses a ray-tracing algorithm to calculate orbit information from knowledge of the cavity geometry. We then use this information to generate a synthetic signal, which is then sent into the cavity as if it's the time reversed signal in the traditional time-reversal scheme. This method tries to obtain channel information numerically but has limited accuracy due to the chaotic properties of the cavity. Another method is to utilize the transmission scattering parameter, obtained from the time domain response of the cavity between two ports. We amplify the time-reversed signal for each frequency channel in proportion to the loss it experiences during the transmission. The experimental results show that the amplitude of side lobes around the reconstructed signal is reduced significantly and the correlation between the reconstruction and the initial signal is improved from 0.8 to 0.98 in a low-mode density cavity.

[1]This work is funded by the ONR/Maryland AppEl Center, the AFOSR, and Center for Nanophysics and Advanced Materials (CNAM).

2:42PM W30.00002 Statistical fluctuations in chains of chaotic electromagnetic enclosures[1] , GABRIELE GRADONI, THOMAS ANTONSEN, STEVEN ANLAGE, EDWARD OTT, University of Maryland — Today, the statistical analysis of complex electromagnetic cavities constitutes a very active field of research in applied electromagnetics and statistical physics. The Random Coupling Model (RCM) provides a framework for predicting the statistics of scattering of radiation in complicated enclosures. RCM makes use of results from random matrix theory (RMT) to model the mode spectrum of irregular cavities. Here, we show how to use the RCM to study the scenario of two (or more) three-dimensional cavities interconnected by apertures. We imagine exciting the first cavity of the so formed chain with a small antenna, and receiving a signal in the last cavity with a similar antenna. Recently, we derived the probability distribution of the power flowing through the cavity chain. A closed form solution of the trans-impedance between the two ports is derived, and its statistics discussed. Variations of cavity losses and aperture geometry are discussed within our statistical framework, for which distribution functions are generated by the Monte Carlo method. In the high-loss limit we are able to identify self- and cavity-cavity interaction terms. The extreme case of an irregular aperture connecting to an irregular cavity is also proposed and investigated.

2:54PM W30.00003 Finding equilibrium statistical mechanics in spatiotemporal chaos[1] , C. CLARK ESTY, CHRISTOPHER C. BALLARD, JOHN A. KERIN, DAVID A. EGOLF, Department of Physics, Georgetown University — Ruelle has argued that the extensivity of the complicated dynamics of spatiotemporal chaos is evidence that these systems can be viewed as a gas of weakly-interacting regions of a characteristic size. We have performed large-scale computational studies of spatiotemporal chaos in the 1D complex Ginzburg-Landau equation and have found that histograms of the number of maxima in the amplitude are well-described by an *equilibrium* Tonks gas (and variants) in the grand canonical ensemble. Furthermore, for small system sizes, the average number of particles in the Tonks gas (with particle sizes and temperatures determined from fits to the CGL histograms) exhibits oscillatory, decaying deviations from extensivity in agreement with the deviations in the fractal dimension found by Fishman and Egolf. This result not only supports Ruelle's picture but also suggests that the coarse-grained behavior of this far-from-equilibrium system might be understood using equilibrium statistical mechanics.

[1]This work was supported by the U.S. National Science Foundation (DMR-0094178).

3:06PM W30.00004 Dynamic Scaling of Synchronization in Kuramoto-type Globally Coupled Oscillators , MEESOON HA, Chosun University, CHULHO CHOI, BYUNGNAM KAHNG, Seoul National University — We investigate the dynamic scaling behavior of the phase synchronization order parameter in the framework of the original Kuramoto model with Gaussian natural frequecies near and at the critical value of the coupling strength. The temporal behavior has been never paid attention to in the earlier studies of synhronization and its transition nature including finite-size scaling (FSS), whereas the stationary critical behavior has been widely studied. We focus on the scaling behavior of the order parameter until the system reaches its steady state from various initial conditions in the context of the dynamic scaling form at criticality. It is found that dynamic scaling of synchronization can indicate the critical valule of the coupling strength and also estimate all critical exponents of the continuous synchronization transition, based on the scaling relation of the earlier suggested FSS theory. Moreover, we figure out that the dynamic scaling analysis is quite useful even though the system does not reach its steady state, provided that the system size is not too small. Finally, we argue how the generating method of natural frequecies and the thermal effect of phases affect dynamic scaling with the change of the dynamic exponent, which are numerically confirmed.

3:18PM W30.00005 Observation of Asymmetric Transport in Structures with Active Nonlinearities , NICHOLAS BENDER, SAMUEL FACTOR, JOSH BODYFELT, HAMIDREZA RAMEZANI, FRED ELLIS, TSAMPIKOS KOTTOS, Wesleyan University — A mechanism for asymmetric transport based on the interplay between the fundamental symmetries of parity (P) and time (T) with nonlinearity is presented. We experimentally demonstrate and theoretically analyze the phenomenon using, as a reference system, a pair of coupled van der Pol oscillators, one with anharmonic gain and the other with the complementary time reversed anharmonic loss, connected to two transmission lines. An increase of the degree of the gain/loss strength or of the number of PT -symmetric nonlinear dimers in a chain, increases the non-reciprocality effect.

3:30PM W30.00006 Wave scattering from cavities with both regular and chaotic ray trajectories , MING-JER LEE, THOMAS ANTONSEN, EDWARD OTT, Institute for Research in Electronics and Applied Physics (IREAP), University of Maryland, College Park — The random plane wave hypothesis has been used to characterize fields inside chaotic cavities where all ray trajectories are chaotic and visit the available phase space uniformly. We consider incident and reflected waves in channels connecting to a chaotic cavity. From Random Matrix Theory, the impedance, obtained from the scattering matrix, for pure chaotic cavities can be described as a Lorentzian random variable with predictable mean and width. For some shapes of cavities, called mixed systems, some rays are chaotic and visit subregions of phase space ergodically, while some rays are regular staying on invariant troi. We generalize the previous chaotic cavity theory to mixed systems by separating the impedance into regular and chaotic parts. We test the theory by numerically solving for eigenmodes of the Helmholtz equation in a mushroom shaped cavity where there is a clear separation between regular and chaotic regions of phase space. We compare our theoretical predictions with numerical calculations for one-port and two-ports cases with different port positions.

3:42PM W30.00007 Testing the Predictions of Random Matrix Theory in Low Loss Wave Chaotic Scattering Systems[1] , JEN-HAO YEH, THOMAS ANTONSEN, EDWARD OTT, STEVEN ANLAGE, University of Maryland — Wave chaos is a field where researchers apply random matrix theory (RMT) to predict the statistics of wave properties in complicated wave scattering systems. The RMT predictions have successfully demonstrated universality of the distributions of these wave properties, which only depend on the loss parameter of the system and the physical symmetry. Examination of these predictions in very low loss systems is interesting because extreme limits for the distribution functions and other predictions are encountered. Therefore, we use a wave-chaotic superconducting cavity to establish a low loss environment and test RMT predictions, including the statistics of the scattering (S) matrix and the impedance (Z) matrix, the universality (or lack thereof) of the Z- and S-variance ratios, and the statistics of the proper delay times of the Wigner-Smith time-delay matrix. We have applied an in-situ microwave calibration method (Thru-Reflection-Line method) to calibrate the cryostat system, and we also applied the random coupling model to remove the system-specific features. Our experimental results of different properties agree with the RMT predictions.

3:54PM W30.00008 Phase dynamics of coupled oscillators reconstructed from data , MICHAEL ROSENBLUM, Dept. of Physics and Astronomy, University of Potsdam, Germany, BJOERN KRALEMANN, Christian-Albrechts-Universitaet zu Kiel, Germany, ARKADY PIKOVSKY, Dept. of Physics and Astronomy, University of Potsdam, Germany — We present a technique for invariant reconstruction of the phase dynamics equations for coupled oscillators from data. The invariant description is achieved by means of a transformation of phase estimates (protophases) obtained from general scalar observables to genuine phases. Staring from the bivariate data, we obtain the coupling functions in terms of these phases. We discuss the importance of the protophase-to-phase transformation for characterization of strength and directionality of interaction. To illustrate the technique we analyse the cardio-respiratory interaction on healthy humans. Our invariant approach is confirmed by high similarity of the coupling functions obtained from different observables of the cardiac system. Next, we generalize the technique to cover the case of small networks of coupled periodic units. We use the partial norms of the reconstructed coupling functions to quantify directed coupling between the oscillators. We illustrate the method by different network motifs for three coupled oscillators. We also discuss nonlinear effects in coupling.

4:06PM W30.00009 The Universal α-Family of Maps , MARK EDELMAN, Stern College at Yeshiva University and Courant Institute at NYU — We modified the way in which the Universal Map is obtained in the regular dynamics to derive the Universal α-Family of Maps depending on a single parameter $\alpha > 0$ which is the order of the fractional derivative in the nonlinear fractional differential equation describing a system experiencing periodic kicks. We show that many well-known regular maps, like integer n- dimensional (area/volume preserving for $n > 1$) quadratic maps (including for $n = 1$ the Logistic Map which is not measure preserving) and n-dimensional (volume preserving for $n > 2$) standard maps (including the non-measure preserving Circle Map and the area preserving Standard Map), can be considered as particular forms of the Universal α-Family of Maps. In the case of the fractional α corresponding maps, which are maps with memory, demonstrate various types of attractors including cascade of bifurcation types trajectories. Maps with memory can be applied for modeling biological systems and circuit elements with memory.

4:18PM W30.00010 Synchronization Dynamics of Coupled Anharmonic Plasma Oscillators , JOHN LAOYE, Olabisi Onabanjo University, Ago-Iwoye, Nigeria, UCHECHUKWU VINCENT, Redeemer University, Nigeria, TAIWO ROY-LAYINDE, University of Ibadan, Nigeria — The synchronization of two identical mutually driven coupled plasma oscillators modeled by anharmonic oscillators was investigated. Each plasma oscillator was described by a nonlinear differential equation of the form: The model employed the spring-type coupling. Numerical simulations, including Poincare sections, time series analysis, and bifurcation diagram were performed using the fourth-order Runge-Kutta scheme. The numerical value of the threshold coupling Kth was determined to be approximately 0.15.

4:30PM W30.00011 Nonlinear Time-Reversal in a Wave Chaotic System[1] , MATTHEW FRAZIER, STEVEN ANLAGE, BINIYAM TADDESE, EDWARD OTT, THOMAS ANTONSEN, University of Maryland — Time reversal mirrors are particularly simple to implement in wave chaotic systems and form the basis for a new class of sensors [1-3]. The sensors make explicit use of time-reversal invariance and spatial reciprocity in a wave chaotic system to sensitively measure the presence of small perturbations to the system. The underlying ray chaos increases the sensitivity to small perturbations throughout the volume explored by the waves. We extend our time-reversal mirror to include a discrete element with a nonlinear dynamical response [4]. The initially injected pulse interacts with the nonlinear element, generating new frequency components originating at the element. By selectively filtering for and applying the time-reversal mirror to the new frequency components, we focus a brief-in-time excitation only onto the nonlinear element, without knowledge of its location. Furthermore, we demonstrate a model which captures the essential features of our time-reversal mirror, modeling the wave-chaotic system as a network of transmission lines arranged as a star graph, with the discrete nonlinearity modeled as a diode terminating a particular line. [1] Appl. Phys. Lett. 95, 114103 (2009) [2] J. Appl. Phys. 108, 114911 (2010) [3] Acta Physica Polonica A 112, 569 (2007) [4] arXiv:1207.1667

4:42PM W30.00012 Quantifying Transport in Chaotic Rayleigh-Benard Convection , CHRISTOPHER MEHRVARZI, MARK PAUL, Virginia Tech — The transport of a scalar species in a complex flow field is important in many areas of current interest such as the combustion of premixed gases, the dynamics of particles in the atmosphere and oceans, and the reaction of chemicals in a mixture. There has been significant progress in understanding transport in steady periodic flows such as a ring of vortices. In addition, transport in turbulent flow has an extensive literature. Here we focus on the transport of a scalar species in a three-dimensional time-dependent flow field given by the spiral defect chaos state of Rayleigh-Benard convection. We use a highly efficient and parallel spectral element approach to simultaneously evolve the Boussinesq equations and the reaction-advection-diffusion equation in large cylindrical domains with experimentally relevant boundary conditions. We explore the active and passive transport of a scalar species in a chaotic flow field to quantify the transport enhancement for a range of Lewis and Damkholer numbers.

4:54PM W30.00013 Quantifying Spatiotemporal Chaos in Rayleigh-Benard Convection: Using Numerics to Connect Theory and Experiment , MU XU, Virginia Tech, ALIREZA KARIMI, University of Notre Dame, JEFFREY TITHOF, Georgia Institute of Technology, MIRO KRAMAR, VIDIT NANDA, Rutgers University, MICHAEL SCHATZ, Georgia Institute of Technology, KONSTANTIN MISCHAIKOW, Rutgers University, MARK PAUL, Virginia Tech — Spatiotemporal chaos is a common and important feature of spatially-extended systems that are driven far-from-equilibrium. Many open questions remain regarding the high-dimensional chaotic dynamics that describe fluid systems for laboratory conditions. In this talk we explore the spiral defect chaos state of Rayleigh-Benard convection. Recent advances in computing algorithms and available supercomputing resources have made possible the computation of fundamentally important quantities of theoretical importance that are currently inaccessible to experiment. For example, the temporal variation of the spectrum of Lyapunov exponents, the spatial and temporal variation of the Lyapunov vectors, and the variation of the fractal dimension with system parameters. We use large-scale parallel numerical simulations to compute theoretically important diagnostics of spatiotemporal chaos, such as these, with particular interest in connecting these numerical results with experimentally accessible quantities that describe the pattern dynamics.

5:06PM W30.00014 Effect of Size Polydispersity on Diffusion Behaviors of Traces in Random Obstacle Matrices , HYUN WOO CHO, BONG JUNE SUNG, Department of Chemistry, Sogang University, Seoul 121-742, Republic of Korea, ARUN YETHIRAJ, Theoretical Chemistry Institute and Department of Chemistry, University of Wisconsin, Madison, Wisconsin 53706, USA — Diffusion behavior on random obstacle matrices has been studied extensively for several decades to explain dynamic behaviors in disordered systems, such as dynamic arrest in colloidal glass phase and anomalous diffusion in crowded biological systems. We present the effect of size polydispersity of the obstacles on diffusion behavior in two-dimensional random obstacle matrices. We generate the random matrices by randomly locating non-overlapping hard disks in two-dimensional space, and consider the diffusion behavior of the tracers. We show that the diffusion behavior is sensitive to the size polydispersity of the obstacles even though their average sizes are the same. In addition, we locate the percolation threshold of void space, and find that diffusion constant D follows scaling relation $D \sim (\varphi_c - \varphi)^{\mu-\beta}$ regardless of the size polydispersity, where φ and φ_c is the area fraction of the obstacles and its value at percolation threshold, respectively. The value of the dynamic scaling constant μ is, however, not universal. We will also discuss briefly non-universal dynamic scaling exponents of two-dimensional random obstacle matrices.

5:18PM W30.00015 Colloidal Bandpass and Bandgap Filters[1] , BENJAMIN YELLEN, 1) Duke University, 2) University of Michigan - Shanghai Jiao Tong University, Joint Institute, MUKARRAM TAHIR, Duke University, YUYU OUYANG, University of Michigan - Shanghai Jiao Tong University, Joint Institute, FRANCO NORI, Riken Institute, Japan — Thermally or deterministically-driven transport of objects through asymmetric potential energy landscapes (ratchet-based motion) is of considerable interest as models for biological transport and as methods for controlling the flow of information, material, and energy. Here, we provide a general framework for implementing a colloidal bandpass filter, in which particles of a specific size range can be selectively transported through a periodic lattice, whereas larger or smaller particles are dynamically trapped in closed-orbits. Our approach is based on quasi-static (adiabatic) transition in a tunable potential energy landscape composed of a multi-frequency magnetic field input signal with the static field of a spatially-periodic magnetization. By tuning the phase shifts between the input signal and the relative forcing coefficients, large-sized particles may experience no local energy barriers, medium-sized particles experience only one local energy barrier, and small-sized particles experience two local energy barriers. The odd symmetry present in this system can be used to nudge the medium-sized particles along an open pathway, whereas the large or small beads remain trapped in a closed-orbit, leading to a bandpass filter, and vice versa for a bandgap filter.

Session W31 DPOLY: Focus Session: Understanding Fluctuation and Correlation Effects in Polymers 339 - Amalie Frischknecht, Sandia National Laboratories

2:30PM W31.00001 Recent Developments in Field-Theoretic Polymer Simulations , GLENN FREDRICKSON, University of California, Santa Barbara — This presentation will address recent progress in methods and algorithms for conducting simulations of statistical field theory models of polymers and complex fluids beyond the mean-field approximation (as invoked, e.g., in self-consistent field theory). Topics to be discussed include regularization methods, improved stochastic integration algorithms for complex Langevin equations, techniques for locating phase boundaries, and systematic coarse-graining/renormalization techniques for multi-scale simulations. Early results on a promising "coherent state" formulation of polymer field theory will also be presented.

3:06PM W31.00002 Understanding Fluctuation/Correlation Effects on the Order-Disorder Transition of Symmetric Diblock Copolymers with a Density-Functional Theory , JING ZONG, QIANG WANG, Department of Chemical and Biological Engineering, Colorado State University — How fluctuations change the order-disorder transition (ODT) of symmetric diblock copolymers (DBC) is a classic yet unsolved problem in polymer physics.[1] Taking a model system of discrete Gaussian chains interacting with soft, finite-range repulsions as commonly used in dissipative-particle dynamics simulations we formulate a density-functional theory (DFT) based on the polymer integral equation theories,[2] which includes the system fluctuations and correlations neglected by the mean-field theory (i.e., the widely applied self-consistent field theory) and can be reduced to the latter under the mean-spherical approximation. We then unambiguously reveal the fluctuation/correlation effects on the ODT of symmetric DBC by direct comparisons among the mean-field theory, DFT, and fast off-lattice Monte Carlo simulations,[3] all using exactly the same model system (Hamiltonian) and thus without any parameter-fitting.

3:18PM W31.00003 Computational Investigation of Block Copolymer Surfactants for Stabilizing Fluctuation-Induced Polymeric Microemulsions , KRIS DELANEY, GLENN FREDRICKSON, UC Santa Barbara — High molecular weight diblock copolymers introduced into a blend of immiscible homopolymers can act as a surfactant to suppress macroscopic two-fluid phase separation. With variation of block copolymer composition, the crossover between low-temperature ordering into microphase or macrophase separated states is marked by a mean-field isotropic Lifshitz multi-critical point. Strong fluctuations close to the Lifshitz point are observed[1,2] to suppress the low-temperature ordering; a microemulsion state emerges, with large, co-continuous domains of segregated fluid lacking any long-range order. We study this phenomenon with fully fluctuating field-theoretic simulations based on complex Langevin sampling, and we attempt to design new block polymer surfactants that can produce the microemulsion state with a wider composition tolerance. 3:30PM W31.00004 Condensation of semiflexible polyelectrolytes in mixed solutions of mono- and multivalent salts[1] , AMELIA A. PLUNK, ERIK LUIJTEN, Northwestern University — The salt-dependent condensation of highly charged polyelectrolytes in aqueous solution is a topic of great biological and industrial importance that has been widely studied over the past decades. It is well established that interaction with multivalent counterions leads to the formation of bundle-like aggregates for rigid polyelectrolytes and to collapsed structures or disordered aggregates for flexible polyelectrolytes. Here, we investigate the behavior of semiflexible chain molecules, where the electrostatically induced aggregation is impeded by the intrinsic bending stiffness of the polymer. Moreover, we study the competition between monovalent and multivalent counterions in mixed solutions and establish the threshold salt concentration required for condensation. Our findings are relevant for a range of biomedical problems, including the fabrication of nanoparticles for gene delivery [1] and the packaging of DNA by histones.

3:42PM W31.00005 Rattle, restrict, and release in entangled polymer solutions , SUBHALAKSHMI KUMAR, TSANG CHI HANG BOYCE, SUNG CHUL BAE, STEVE GRANICK, University of Illinois at Urbana Champaign — The nature of entanglement release and chain fluctuation is studied in entangled solutions of high molecular weight PEG in water. Reporter fluorescent polystyrene particles of radius comparable to the entanglement length are suspended in solution and tracked individually with with nm resolution using epifluorescence microscopy. Thousands of single particle trajectories are analyzed to quantify caging and hopping dynamics. The cage relaxation time changes by orders of magnitude depending on the polymer concentration, but is faster than and therefore more accessible within experimentally accessible time scales, than for colloidal glasses.

3:54PM W31.00006 Direct imaging of fluctuations in a cross-linked biopolymer network , BO WANG, LINGXIANG JIANG, BOYCE TSANG, STEVE GRANICK, Department of Materials Science and Engineering, University of Illinois at Urbana-Champaign, STEVE GRANICK TEAM — Cross-linked networks are ubiquitous in synthetic and biological polymer systems, such as rubbers and cytoskeletons. To model cross-linked networks, several theories have been developed on the basis of different assumptions as to fluctuations in the networks. Here we put these theories to direct test. This talk will describe direct single-molecule imaging of the dynamic fluctuations of junction points in a cross-linked semiflexible polymer (F-actin) network. The actin filaments are cross linked by biotin/avidin. The junction points are selectively labeled to allow nm spatial imaging resolution. The surprising results point to limitations of the prevailing network models.

4:06PM W31.00007 Effect of Fluctuation on Order-Disorder Transition in Polydisperse Block Copolymer Melts , GUNJA PANDAV, VENKAT GANESAN, University of Texas at Austin — We examine fluctuation effects on order-disorder transition (ODT) temperature in polydisperse block copolymer melts using single chain in mean field simulations. Diblock copolymer melts having monodisperse A blocks and polydisperse B blocks with symmetric composition on an average are examined. Increase in polydispersity at constant composition resulted in change in equilibrium morphology in accordance with the mean-field theory prediction. The dependence of ODT temperature on the strength of fluctuations as characterized by Ginzburg parameter is examined and scaling prediction for fluctuation induced shift in ODT is reported. Also, the qualitative shift in ODT as a function of increasing polydispersity in asymmetric copolymers is investigated.

4:18PM W31.00008 Directed polymer liquids addressed via the two-dimensional one-component plasma: Developing the framework , ANTON SOUSLOV, Georgia Institute of Technology, D. ZEB ROCKLIN, University of Illinois at Urbana-Champaign, PAUL M. GOLDBART, Georgia Institute of Technology — The distribution of *small* density fluctuations in a directed polymer liquid is characterized by the equilibrium structure factor. By contrast, the distribution of *large* density fluctuations embodies new information about the polymer state. Physically, large density fluctuations are closely related to particle inclusions, i.e., compact regions from which polymers are excluded. The highly correlated nature of directed polymer liquids complicates a single-chain approach to such issues and, instead, we invoke a quantum many-body technique to map the three-dimensional polymer system to a two-dimensional hard-core Bose fluid. Then, by using Chern-Simons field theory, we make the standard transformation of this Bose fluid into a system of non-interacting fermions that fill a single Landau level. The density distribution of these fermions is that of a classical two-dimensional one-component plasma (2DOCP), whose properties are well understood; we invoke them to obtain the entropy cost of particle inclusions in the polymer liquid. Along the way, we examine the validity of the various approximations that have been made.

4:30PM W31.00009 Directed polymer liquids addressed via the two-dimensional one-component plasma: Implications for the density profile , D. ZEB ROCKLIN, University of Illinois at Urbana Champaign, ANTON SOUSLOV, PAUL GOLDBART, Georgia Institute of Technology — We consider the inclusion of one or more particles into a dense, three-dimensional liquid of long, directed polymers. The particles represent an excluded volume within the liquid which raises its free energy. As discussed in the accompanying talk, the statistical mechanics of such a polymer liquid can be described in terms of certain two-dimensional fluids of quantum particles and, hence, via an exactly solvable classical two-dimensional one-component plasma (2DOCP). The free energy cost of a particle inclusion is related to the probability of spontaneous formation of a large void within the quantum fluid or the plasma. We use these relationships to study the effect of particle inclusions in the polymer liquid, as well as large fluctuations of the liquid. We find that displaced polymers accumulate near the edge of the inclusion, in a manner similar to the accumulation of excess charge near the surface of a conductor. In addition, we are able to determine the equilibrium density profile for polymer liquids subject to more general constraints, e.g., ones that force some fixed number of polymers to pass through a ring.

4:42PM W31.00010 Disentangle Model Differences and Fluctuation Effects in DPD Simulations of Diblock Copolymers , DAVID (QIANG) WANG, PARAMVIR SANDHU, JING JONG, DELIAN YANG, Department of Chemical and Biological Engineering, Colorado State University, Fort Collins, CO — In the widely used dissipative particle dynamics (DPD) simulations [Hoogerbrugge and Koelman, **Europhys. Lett. 19**, 155 (1992); Groot and Warren, **J. Chem. Phys. 107**, 4423 (1997)], polymers are commonly modeled as discrete Gaussian chains interacting with soft, finite-range repulsions. In the original DPD simulations of microphase separation of diblock copolymer melts by Groot and Madden [**J. Chem. Phys. 108**, 8713 (1998)], the simulation results were compared and found to be consistent with the phase diagram for the "standard model" of continuous Gaussian chains with Dirac ?-function interactions obtained from self-consistent field (SCF) calculations. Since SCF theory is a mean-field theory neglecting system fluctuations/correlations while DPD simulations fully incorporate such effects, the model differences are mixed with the fluctuation/correlation effects in their comparison. Here we report the SCF phase diagram for exactly the same model system as used in DPD simulations. Comparing our phase diagram with that for the standard model highlights the effects of chain discretization and finite-range interactions, while comparing our phase diagram with DPD simulation results reveal without any parameter-fitting the effects of fluctuations/correlations neglected in the SCF theory.

4:54PM W31.00011 Static Correlation Functions of Polymer Concentration Fluctuations in the Presence of an Interface , CATHERINE YEH, PHILIP PINCUS, University of California, Santa Barbara — We study static correlation functions of polymer solutions using the Cahn-de Gennes square gradient theory of interfacial energies. Fluctuations are considered for good, theta, and poor solvents at repulsive and adsorbing surfaces as well as at the interface of phase separated solutions. We predict the existence of bound state fluctuations associated with an interface under certain conditions.

5:06PM W31.00012 Dynamical simulation of disordered micelles in a diblock copolymer melt with fluctuations , RUSSELL SPENCER, ROBERT WICKHAM, University of Guelph — By including composition fluctuations in our dynamical simulation of the time-dependent Landau-Brazovskii model for a diblock copolymer melt, we find that disordered micelles form above the order-disorder transition to a BCC phase. At high-temperatures, the micelle number density is effectively zero, and the melt is disordered at the molecular level. As we lower the temperature, the micelle number density increases gradually and approaches the number density in the BCC phase. If we increase the strength of the fluctuations, the temperature range over which disordered micelles exist broadens, and the onset of BCC order is suppressed. We examine the dynamics of crystallization of disordered micelles into the BCC phase. By tracking trajectories, we also investigate the dynamical behaviour of individual micelles in an environment of disordered micelles.

5:18PM W31.00013 X-ray imaging of wetting ridge on a soft solid[1] , SU JI PARK, BYUNG MOOK WEON, JI SAN LEE, JUNG HO JE, Pohang University of Science and Technology, ROBERT W. STYLE, GUY K. GERMAN, ERIC R. DUFRESNE, Yale University, STEVE WANG, Argonne National Laboratory — Softness of solids affects a microscopic deformation, called a 'wetting ridge', at a three-phase contact line. We present a direct visualization of wetting ridges by high-resolution x-ray imaging, which shows a spatial transition between elastic and fluidic wetting behaviors on a soft solid. The fluidic behavior that corresponds to Neumann's triangle occurs at the vicinity of the triple point while the elastic deformation at |x|<le (the elasto-capillary length). Real-time x-ray imaging clearly shows temporal variation of wetting ridge.

Session W32 DPOLY DFD: Focus Session: Micro/Nanofluidics I 340 - Daeyeon Lee, University of Pennsylvania

2:30PM W32.00001 Uncovering stem-cell heterogeneity in the microniche with label-free microfluidics[1] , LYDIA L. SOHN, University of California, Berkeley — Better suited for large number of cells from bulk tissue, traditional cell-screening techniques, such as fluorescence-activated cell sorting (FACS) and magnetic-activated cell sorting (MACS), cannot easily screen stem or progenitor cells from minute populations found in their physiological niches. Furthermore, they rely upon irreversible antibody binding, potentially altering cell properties, including gene expression and regenerative capacity. We have developed a label-free, single-cell analysis microfluidic platform capable of quantifying cell-surface marker expression of functional organ stem cells directly isolated from their micro-anatomical niche. With this platform, we have screened single quiescent muscle stem (satellite) cells derived from single myofibers, and we have uncovered an important heterogeneity in the surface-marker expression of these cells. By sorting the screened cells with our microfluidic device, we have determined what this heterogeneity means in terms of muscle stem-cell functionality. For instance, we show that the levels of beta1-integrin can predict the differentiation capacity of quiescent satellite cells, and in contrast to recent literature, that some CXCR4+ cells are not myogenic. Our results provide the first direct demonstration of a microniche-specific variation in gene expression in stem cells of the same lineage. Overall, our label-free, single-cell analysis and cell-sorting platform could be extended to other systems involving rare-cell subsets.

3:06PM W32.00002 Designing artificial phagocyte that selectively "ingests" solutes , ALEXANDER ALEXEEV, KATHERINE C. POLHEMUS, AYUKO MORIKAWA, Georgia Institute of Technology — We use dissipative particle dynamics to design an active composite vesicle that can controllably and selectively "ingest" solutes from the surrounding fluid. The vesicle consists of a lipid membrane that envelops a stimuli-responsive microgel particle. When the microgel swells and increases in size due to an external stimulus, the lipid membrane breaks forming pores that expose a part of the microgel to the external solvent. Solutes initially dispersed in the solvent diffuse and bind to the uncovered surface of microgel particles. After the stimulus is removed and microgel deswells to its original size, the transmembrane pores close isolating the adsorbed solutes inside the vesicle. In our simulations, we formulate the criteria for the controlled pore opening and closing, and probe how this smart vesicle can be harnessed to "ingest" specific macromolecules. Our results will be useful for developing a new class of artificial phagocytes for targeted sampling in various biomedical applications.

3:18PM W32.00003 Transient Flow Induced by the Adsorption of Particles[1] , NAGA MUSUNURI, DANIEL CODJOE, BHAVIN DALAL, IAN FISCHER, PUSHPENDRA SINGH, New Jersey Institute of Technology — When small particles, e.g., glass, flour, pollen, etc., come in contact with a fluid-liquid interface they disperse so quickly to form a monolayer on the interface that it appears explosive, especially on the surface of mobile liquids like water. This is a consequence of the fact that the adsorption of a particle in an interface causes a lateral flow which on the interface away from the particle. In this study we use the particle image velocimetry (PIV) technique to measure the transient three-dimensional flow that arises due to the adsorption of spherical particles. The PIV measurements show that the flow develops a fraction of a second after the adsorption of the particle and persists for several seconds. The fluid below the particle rises upwards and on the surface moves away from the particle. These latter PIV results are consistent with the surface velocity measurements performed in earlier studies. The strength of the induced flow, and the time duration for which the flow persists, both decrease with decreasing particle size. For a spherical particle the flow is axisymmetric about the vertical line passing through the center of the particle.

3:30PM W32.00004 ABSTRACT WITHDRAWN –

3:42PM W32.00005 Direct measurement of friction of a fluctuating contact line , SHUO GUO, Department of Physics, Hong Kong University of Science and Technology, MIN GAO, Department of Mathematics, Hong Kong University of Science and Technology, XIAOMIN XIONG, Department of Physics, Sun Yat-sen University, YONG JIAN WANG, Department of Physics, Hong Kong University of Science and Technology, XIAOPING WANG, Department of Mathematics, Hong Kong University of Science and Technology, PING SHENG, PENGER TONG, Department of Physics, Hong Kong University of Science and Technology* — What happens at a moving contact line, where one fluid displaces another (immiscible) fluid over a solid surface, is a fundamental issue in fluid dynamics. In this presentation, we report a direct measurement of the friction coefficient in the immediate vicinity of a fluctuating contact line using a micron-sized vertical glass fiber with one end glued to an atomic force microscope (AFM) cantilever beam and the other end touching a liquid-air interface. By measuring the broadening of the resonance peak of the cantilever system with varying liquid viscosity η, we obtain the friction coefficient ξ_c associated with the contact line fluctuations on the glass fiber of diameter d and find it has the universal form, $\xi_c = 0.8\pi d\eta$, independent of the contact angle. The result is further confirmed by using a soap film system whose bulk effect is negligibly small. This is the first time that the friction coefficient of a fluctuating contact line is measured. *Work supported by the Research Grants Council of Hong Kong SAR.

3:54PM W32.00006 Giant slip at liquid-liquid interfaces using a hydrophobic ball bearing , LAURENT JOLY, QUENTIN EHLINGER, OLIVIER PIERRE-LOUIS, LPMCN - Université Lyon 1, France — We suggest to build an interface where hydrophobic beads maintain a gas layer between two liquids. We show that this interface behaves as a liquid-liquid ball bearing under shear and exhibits giant slip. Such a metastable configuration reminds of pillar-based superhydrophobic surfaces, used to amplify liquid-solid slip. To the advantage of hydrophobic ball bearings, beads are able to roll, thereby reducing friction at the liquid-bead interface. However beads will always penetrate inside the liquid, inducing viscous dissipation and consequently decreasing slippage. The penetration depth being directly controlled by the wetting angle of the liquid at the bead surface, the latter is expected to have a strong influence on the efficiency of the liquid/liquid bearing. We start by quantifying analytically the influence of the wetting angle on liquid/liquid slip in this system. We then confirm the obtained scaling law by means of Molecular Dynamics (MD) simulations. Liquid-liquid bearings open new pathways for micro and nanofluidics. One major direction could be to build fluidic channels without walls, where different liquids in contact could flow independently while maintaining an extremely low interfacial friction, and preventing mixing by diffusion between the different channels.

4:06PM W32.00007 A Study of the Concentration Dependent Water Diffusivity in Polymer using Magnetic Resonance Imaging , HOWON LEE, Massachusetts Institute of Technology, JIAXI LU, JOHN GEORGIADIS, University of Illinois at Urbana-Champaign, NICHOLAS FANG, Massachusetts Institute of Technology — Hydrogel allows solvent molecules to migrate in and out of the polymer network, often in response to various environmental stimuli such as temperature and pH, resulting in significant volumetric change. Kinetics of penetrants in polymeric network determines time dependent behavior of hydrogel. However, swelling deformation resulting from the solvent uptake in turn significantly changes diffusivity of solvent, and this strong coupling makes it challenging to study dynamic behavior of hydrogels. Here we study concentration dependent diffusivity of water in poly(ethylene glycol) diacrylate (PEGDA) hydrogel using magnetic resonance imaging (MRI). Projection micro-stereolithography is used to fabricate gel samples in which a gradient of water volume fraction occurs. In situ measurement using MRI provides quantitative relationship between diffusivity and volume fraction of water in the gel. This result will help better understand interstitial diffusion behavior of solvent in polymers, which has great implication in board areas such as soft matter mechanics, drug delivery, and tissue engineering.

4:18PM W32.00008 Closing the loop in the boundary layer: water slippage, interfacial viscosity and wettability[1] , ELISA RIEDO, School of Physics, Georgia Institute of Technology, DEBORAH ORTIZ-YOUNG, School of Chemistry, Georgia Institute of Technology, HSIANG-CHIH CHIU, School of Physics, Georgia Institute of Technology, KISLON VOÏTCHOVSKY, Institute of Materials, Ecole Polytechnique Fédérale de Lausanne, SUENNE KIM, School of Physics, Georgia Institute of Technology — Understanding and manipulating fluids at the nanoscale is a matter of growing scientific and technological interest. Here, we present experiments showing that the interfacial viscosity of water depends drastically on the wetting properties of the confining surfaces. By using an atomic force microscope (AFM), we have measured the lateral viscous force experienced in water by a nano-size AFM tip while it is sheared in parallel to a smooth solid surface, as a function of the tip-surface distance. The viscous force curves, FL(d), have been measured for five surfaces with various wettabilities. In particular, the experiments indicate that in water lower forces are required to shear a tip very close to a slippery non-wetting surface, yielding to a lower effective viscosity. A modified form of the Newtonian definition of viscosity, which includes slippage, is used to successfully predict the measured shear forces in the boundary layer as a function of surface wettability, and slippage. We prove that this effect is general and can be applied in different contexts such as in explaining the relationship between dissipation and surface wettability for a nano-tip vibrating in proximity of a surface in water.

4:30PM W32.00009 Molecular Dynamic Studies of Thermal Resistance and Temperature Jumps in Confined Nanofilms , P. THOMPSON, California Instiute of Technology, MC 128-95, Pasadena, CA 91125, . ., . — In macroscale systems, it is always assumed that two adjoining materials adopt equal temperatures across the surface of contact. In fact, even in the presence of a thermal flux, the contacting boundary is believed to remain in thermal equilibrium so long as the interfacial resistance is small in comparison to that of the bulk. This has long been assumed an especially good approximation for liquid/solid (L/S) interfaces since liquids easily conform in shape to an adjacent substrate. Recent MD simulations of liquid nanofilms subject to a constant thermal gradient, however, have revealed the existence of large intrinsic temperature jumps. The magnitude of these jumps is traceable to proximity effects including the depth of the attraction potential between the liquid and solid and the degree of fluid layering near the interface. As expected, increased commensurability between the adjoining phases leads to a decrease in thermal resistance. Here we discuss how non-local effects caused by the magnitude of the overall thermal flux can lead to linear enhancement in the temperature jump. This finding suggests that temperature jumps across a liquid/solid interface depend not only on density mismatch effects but the actual rate of heat transfer in confined nanoscale films.

4:42PM W32.00010 Near-wall Brownian motion of anisotropic particles , SADAO OTA, TONGCANG LI, YIMIN LI, ZILIANG YE, ANNA LABNO, XIAOBO YIN, M-REZA ALAM, XIANG ZHANG, UC Berkeley — Anisotropic microscopic objects are ubiquitous such as biological cells, filamentous macromolecules, as well as synthesized nanomaterial. Near interfaces, the thermal motion of these objects is strongly constrained due to the hydrodynamic interactions, impacting the overall behavior of the biophysical and colloidal systems. Thus, understanding this wall-effect is a key to describe many surface-related problems. Unlike the well-studied case of spheres, however, both its experimental and theoretical studies have been elusive due to the intrinsic complexity of the system. Here we present a comprehensive experimental and computational study of the Brownian motion of silicon nanowires tethered on a substrate. A uniquely developed interference method enables the direct visualization of its microscopic rotations in three dimensions with high angular and temporal resolutions. The quantitative measurement at short time scales revealed the anisotropic reduction in their rotational diffusivities as a function of the inclined angles, resulting in the decrease more than 40-80 % at long time scales. We then developed a numerical model from a string-of-beads idealization, which implicitly simulates the complex hydrodynamic interaction and showed excellent agreement with the experimental observations. Our study provides insights into the fundamental diffusive processes, useful for understanding the anisotropic behavior of anisotropic macromolecules near interfaces. The demonstrated methods offers a systematic approach for studying the interfacial rheology of various anisotropic objects.

4:54PM W32.00011 Enhancing microscale particle deposition using actuated synthetic cilia , MATTHEW S. BALLARD, ZACHARY G. MILLS, ALEXANDER ALEXEEV, George W. Woodruff School of Mechanical Engineering, Georgia Institute of Technology, Atlanta, Georgia 30032 — We use three dimensional simulations to examine deposition of diffusive nanoscopic particles suspended in a viscous fluid onto the walls of a microchannel containing an array of actuated synthetic cilia. We model the cilia as elastic filaments attached to the channel walls and actuated by an external periodic force. We use a lattice Boltzmann model coupled with a lattice spring model to simulate the system and investigate the effects of the oscillating cilia on the rate of particle deposition. We consider the effects of variation of cilia properties and spacing, as well as the frequency and amplitude of the applied force on the deposition of particles with different diffusivity. Our findings are useful in understanding how active microscopic structures can be harnessed to design microfluidic devices and surfaces with controllable transport properties.

5:06PM W32.00012 Statics and dynamics of polymer droplets on topographically structured substrates[1] , MARCUS MUELLER, NIKITA TRETYAKOV, Georg-August University, Gottingen, Germany — Using Molecular Dynamics simulations of a polymer liquid flowing past flat and patterned surfaces, we investigate the influence of corrugation, wettability and pressure on slippage and friction at the solid-liquid interface. We devise a computational method to compute the interface potential that does not rely on grandcanonical simulation techniques and quantitatively compare droplet profiles obtained in simulations with the predictions of a thin-film equation using the independently determined interface potential. For substrates structured by one-dimensional, rectangular grooves, we observe a gradual crossover between the Wenzel state, where the liquid fills the grooves, and the Cassie state, where the corrugation supports the liquid and the grooves are filled with vapor. Using two independent flow set-ups, we characterize the near-surface flow by the slip length and the position, at which viscous and frictional stresses are balanced according to Navier's partial slip boundary condition. This hydrodynamic boundary position depends on the pressure inside the channel and may be located above the corrugated surface. In the Cassie state, we observe that the edges of the corrugation contribute to the friction.

5:18PM W32.00013 The Effect of Polarization on Structure, Dynamics and Electric Double Layer for Interfacial Water near Charged Graphene[1] , ALBERTO STRIOLO, TUAN A. HO, The University of Oklahoma, MOLECULAR SCIENCE AND ENGINEERING TEAM TEAM — A solid surface perturbs water for up to 10-20 Å. Quantifying the structural and dynamics properties of water within this interfacial layer remains crucial for a number of applications, including lab-on-chip and micro- and nano-fluidic devices, and also for designing efficient electric double layers capacitor. As graphene is finding wide applications in the energy sector (batteries and capacitors) we revisited the graphene-water interface. Because at the air-water interface it is known that accounting for the polarization of water and ions is required to properly describe the ions distribution, we conducted a parametric study in which we varied the polarization of carbon atoms on charged graphene. The polarization is described implementing a classic Drude oscillator, which is consistent with the model implemented to describe water and ions. External electric fields are represented by uniform charge distributions on the carbon atoms. The results are quantified in terms of structure and dynamics of interfacial water, as well as of structure of the electric double layer. Comparison with accurate experimental observations is provided.

Session W33 DMP: Focus Session: Organic Electronics and Photonics - Organic Photovoltaics II - Efficiency, Stability, and Interfaces 341 - Richard Lunt, Michigan State University

2:30PM W33.00001 Organic Solar Cell Efficiency Limitations and Pathways to Overcoming Them[1] , SEAN SHAHEEN, University of Denver — Organic solar cell device efficiencies are often limited by a reduced external quantum efficiency, particularly for low band gap materials used in either single- or double-junction devices. This can be attributed to loss mechanisms occurring either at the device-physics scale, in the form of carrier recombination, or at the molecular donor-acceptor scale, in the form of incomplete photo-carrier generation and/or geminate recombination. Here mechanisms at both scales are addressed, utilizing drift-diffusion models of device operation and kinetic models of photo-carrier production. At the device-physics level, the negative impact of dark carriers, commonly derived from defect states in the organic semiconductor, is demonstrated. For dark carrier densities above a typical threshold of 10^{16} cm^{-3}, depletion at one of the electrodes leads to a field-free region of the device and substantial carrier recombination. At the molecular level, the fundamental impact of the molecular reorganization energy λ on device efficiency is considered through use of a Marcus Theory-based kinetic model. It is shown that substantial gains in efficiency, to values approaching 20%, are possible for hypothetical materials in which λ has been reduced to approximately 0.3 eV. Finally, measurements of molecular alignment at interfaces are presented, and implications on the above two mechanisms are explored.

3:06PM W33.00002 Tailored exciton diffusion in organic photovoltaic cells for enhanced power conversion efficiency , RUSSELL J. HOLMES, University of Minnesota — Organic photovoltaic cells (OPVs) have the potential to become a low-cost source of renewable energy due to their compatibility with high throughput processing techniques and the demonstration of power conversion efficiencies exceeding 10%. In the simplest planar heterojunction OPVs, photoconversion is limited by a short exciton diffusion length (L_D) that restricts migration to the dissociating electron donor-acceptor (D-A) interface. Consequently, bulk heterojunctions are often used to realize high efficiency as these structures reduce the distance an exciton must travel to be dissociated. Here, we present an alternate approach that seeks to directly engineer L_D by optimizing the intermolecular separation and consequently, the photophysical parameters responsible for excitonic energy transfer. By diluting the electron donor boron subphthalocyanine chloride (SubPc) into a wide energy gap host material, we optimize the degree of interaction between donor molecules and observe a nearly 50% increase in L_D. Using this approach, we construct planar heterojunction OPVs with a power conversion efficiency of 4.4%, >30% larger than the case of optimized devices containing an undiluted donor layer. It is worth noting that this efficiency also rivals those realized in optimized, bulk heterojunction OPVs based on SubPc and C_{60}. The underlying correlation between L_D and the degree of molecular interaction has wide implications for the design of both OPV active materials and device architectures.

3:18PM W33.00003 >1.0% solar cell derived from carbon nanotube excitons , MATTHEW SHEA, MICHAEL ARNOLD, University of Wisconsin-Madison — Semiconducting single-walled carbon nanotubes (s-SWCNTs) are promising photoabsorbers for photovoltaics due to their strong optical absorptivity, tunable NIR bandgaps, fast charge transport, and solution processability. We have previously shown that electrons can be extracted from photogenerated excitons in s-SWCNTS by C_{60} with internal quantum efficiency (QE) over 90%. Here, we demonstrate s-SWCNT/C_{60} heterojunction devices with over 1.0% AM1.5G power conversion efficiency for the first time. We implemented highly monochiral (7,5) s-SWCNTs to optimize exciton diffusivity and tailored the device stack to tune the spectral response. External QE of over 35% and 20% are achieved at the E_{11} bandgap of the s-SWCNTs at 1055 nm and the E_{22} transition at 655 nm. More than 50% of the AM1.5G photoresponse is derived from the s-SWCNTs, substantially exceeding previous s-SWCNT hybrid devices in which the photoresponse has mostly originated from the organic phase. This work will lead to solar cells based on s-SWCNT photoabsorbers with higher responsivity across the solar spectrum by tailoring the s-SWCNT film morphology and blending them directly with acceptors.

3:30PM W33.00004 Towards high performance inverted polymer solar cells , XIONG GONG, The University of Akron — Bulk heterojunction polymer solar cells that can be fabricated by solution processing techniques are under intense investigation in both academic institutions and industrial companies because of their potential to enable mass production of flexible and cost-effective alternative to silicon-based electronics. Despite the envisioned advantages and recent technology advances, so far the performance of polymer solar cells is still inferior to inorganic counterparts in terms of the efficiency and stability. There are many factors limiting the performance of polymer solar cells. Among them, the optical and electronic properties of materials in the active layer, device architecture and elimination of PEDOT:PSS are the most determining factors in the overall performance of polymer solar cells. In this presentation, I will present how we approach high performance of polymer solar cells. For example, by developing novel materials, fabrication polymer photovoltaic cells with an inverted device structure and elimination of PEDOT:PSS, we were able to observe over 8.4% power conversion efficiency from inverted polymer solar cells.

3:42PM W33.00005 The Science of Making Organic Solar Cells Stable , MICHAEL MCGEHEE, Stanford University — As organic PV efficiencies exceed 10%, the science of stabilization and lifetime gains importance. We seek the origin of the exponential decrease, or "burn-in," of OPV device efficiency in the first 200 hours of operation. First, we examine an efficient polymer, PCDTBT, and demonstrate a 6.2 year lifetime. For standard PCDTBT devices, burn-in is not caused by reactions at the transport layers; rather, it is caused by photochemical traps. We hypothesize that impurities could play a role. The effect of impurities is investigated in another polymer, PBDTTPD, with an 8.3% PCE. For PBDTTPD we find that degradation correlates to the presence of small, organic impurities. We stabilize PBDTTPD, without diminishing performance, by purifying it further. We also investigate the fullerene's role in degradation using photobleaching experiments, and find that photoactive layer stability correlates with the fullerene's electron affinity. From our conclusions, we outline strategies for improving OPV device stability.

4:18PM W33.00006 Influence of MoO_x interlayer on the maximum achievable open-circuit voltage in organic photovoltaic cells , YUNLONG ZOU, RUSSELL HOLMES, University of Minnesota — Transition metal oxides including molybdenum oxide (MoO_x) are characterized by large work functions and deep energy levels relative to the organic semiconductors used in photovoltaic cells (OPVs). These materials have been used in OPVs as interlayers between the indium-tin-oxide anode and the active layers to increase the open-circuit voltage (V_{OC}) and power conversion efficiency. We examine the role of MoO_x in determining the maximum achievable V_{OC} in planar heterojunction OPVs based on the donor-acceptor pairing of boron subphthalocyanine chloride (SubPc) and C_{60}. While causing minor changes in V_{OC} at room temperature, the inclusion of MoO_x significantly changes the temperature dependence of V_{OC}. Devices containing no interlayer show a maximum V_{OC} of 1.2 V, while devices containing MoO_x show no saturation in V_{OC}, reaching a value of >1.4 V at 110 K. We propose that the MoO_x-SubPc interface forms a dissociating Schottky junction that provides an additional contribution to V_{OC} at low temperature. Separate measurements of photoluminescence confirm that excitons in SubPc can be quenched by MoO_x. Charge transfer at this interface is by hole extraction from SubPc to MoO_x, and this mechanism favors donors with a deep highest occupied molecular orbital (HOMO) energy level. Consistent with this expectation, the temperature dependence of V_{OC} for devices constructed using a donor with a shallower HOMO level, e.g. copper phthalocyanine, is independent of the presence of MoO_x.

4:30PM W33.00007 The effect of interfaces on charge transport and recombination in polymeric solar cells , RONALD OSTERBACKA, SIMON SANDEN, QIAN XU[1], OSKAR SANDBERG, MATHIAS NYMAN, JAN-HENRIK SMATT[2], Abo Akademi University, GYTIS JUSKA[3], Vilnius University — Charge-carrier transport and recombination in hybrid TiO2/P3HT:PCBM bulk-heterojunction solar cells (BHSCs) have been measured using photo-CELIV. We have fabricated hybrid devices in the form of indium tin oxide/titanium dioxide/P3HT:PCBM/Cu) to clarify the impact of the TiO_2/P3HT:PCBM interface on the charge transport using the charge extraction by linearly increasing voltage (CELIV) technique. We found that a large equilibrium charge reservoir is accumulated at negative offsets at the TiO_2/P3HT:PCBM interface leading to space charge limited extraction current (SCLC) transients. We show analytically the SCLC transient response and compare the experimental data to calculated SCLC in a linearly increasing voltage. The theoretical calculations indicate that the large charge reservoir at negative offset voltages is due to thermally generated charges combined with poor hole extraction at the ITO/TiO_2 contact, due to the hole blocking character of TiO2. In this presentation we will discuss how interfaces, both metal-organic but also organic-organic interfaces affect charge carrier transport and recombination measurements.

4:42PM W33.00008 Effect of interfacial modification of organophosphonate-based self-assembled monolayers on the performance of inverted hybrid ZnO:P3HT photovoltaic devices , LUISA WHITTAKER-BROOKS, WILL MCCLAIN, Princeton University, ARTHUR WOLL, Cornell University, JEFFREY SCHWARTZ, YUEH-LIN (LYNN) LOO, Princeton University — Hybrid organic-inorganic photovoltaics have not lived up to their promise because of our poor handle of the exciton dissociation interface. Interfacial modification based on self-assembled monolayer (SAM) adsorption provides a way of improving device performance. Here, we provide the first examples of a stepwise functionalization methodology that allows binding of phosphonic acid derivatives to ZnO nanowire arrays with minimal surface degradation and etching. We examined different adsorption methods; SAM adsorption via tethering-by-aggregation-and-growth (T-BAG) yields the most robust surface-bound monolayers. Poly(3-hexylthiophene), P3HT, infiltrated in surface modified ZnO nanowire arrays yielded functional hybrid solar cells with power conversion efficiencies as high as 2.1% due to improvements in both the short-circuit current density (Jsc) and the open-circuit voltage (Voc). The increase in Jsc can be attributed to enhanced charge transfer with surface passivation of ZnO, while the increase in Voc is attributed to the interfacial dipole introduced and improved P3HT wettability on ZnO with SAM adsorption.

4:54PM W33.00009 Anomalous charge storage exponents of organic bulk heterojunction solar cells.[1] , PRADEEP NAIR, RAAZ DWIVEDI, GOUTAM KUMAR, Dept of Electrical Engineering, IIT Bombay, DEPT OF ELECTRICAL ENGINEERING, IIT BOMBAY TEAM — Organic bulk heterojunction (BHJ) devices are increasingly being researched for low cost solar energy conversion. The efficiency of such solar cells is dictated by various recombination processes involved. While it is well known that the ideality factor and hence the charge storage exponents of conventional PN junction diodes are influenced by the recombination processes, the same aspects are not so well understood for organic solar cells. While dark currents of such devices typically show an ideality factor of 1 (after correcting for shunt resistance effects, if any), surprisingly, a wide range of charge storage exponents for such devices are reported in literature alluding to apparent concentration dependence for bi-molecular recombination rates. In this manuscript we critically analyze the role of bi-molecular recombination processes on charge storage exponents of organic solar cells. Our results indicate that the charge storage exponents are fundamentally influenced by the electrostatics and recombination processes and can be correlated to the dark current ideality factors. We believe that our findings are novel, and advance the state-of the art understanding on various recombination processes that dictate the performance limits of organic solar cells.

5:06PM W33.00010 Physical Processes in Organic Photovoltaic Devices Tuned by Ionic Double Layer Doping , ALEXANDER COOK, JONATHAN YUEN, ANVAR ZAKHIDOV, University of Texas at Dallas, NANOTECH INSTITUTE, DEPARTMENT OF PHYSICS, UNIVERSITY OF TEXAS AT DALLAS TEAM, SOLARNO INC, IRVING, TEXAS TEAM — We have recently found that Organic Photovoltaic (OPV) performance can be improved by creating p-i-n structures via doping by double layer charging. We have designed a hybrid device; an OPV attached to a supercapacitor via a common transparent carbon nanotube (CNT) electrode. We've demonstrated that photoexcitation of this hybrid results in double layer capacitive doping of the upper organic layers in the OPV and the CNT electrode. This device can also be viewed as an electrochemically gated CNT/OPV which is ionically reconfigurable either upon photoexcitation or upon application of a voltage bias to the gate electrode. We have demonstrated a two fold increase in the short circuit current and filling factor of our initial test device; an inverted P3HT:PCBM bulk heterojunction cell attached to an electrochemical microcell with a CNT anode laminated on top of the OPV functioning as a common anode. The physical processes in this ionically tuned OPV are discussed in terms of better ohmic contact with CNT electrode and formation of p-i junction in P3HT chains which contribute to better separation of photogenerated carriers and their improved collection. Optical studies of the bleaching effects in both in CNT and in P3HT independently confirm the DLC ionic doping.

5:18PM W33.00011 Correlation between magneto-photocurrent and power conversion efficiency in organic solar cells , BHOJ GAUTAM, TEK BASEL, DALI SUN, Department of Physics and Astronomy, University of Utah, Salt Lake City, UT 84112, USA, EITAN EHRENFREUND, Physics Department, Technion-Israel Institute of Technology, Haifa, Israel, Z. VALY VARDENY, Department of Physics and Astronomy, University of Utah, Salt Lake City, UT 84112, USA — In order to investigate the effect of spin 1/2 radical on the photocurrent in organic solar cells, we studied magneto-photocurrent (MPC) and power conversion efficiency (PCE) of "standard" P3HT:PCBM (1.2:1) device at various Galvinoxyl radical wt%. The MPC measurements were performed to understand the increase in Jsc and hence PCE of the OPV device with Galvinoxyl wt%. We found that the MPC reduction with Galvinoxyl wt% follows the same trend as that of the PCE enhancement. We propose that MPC in OPV blends is due to spin-mixing mechanism related with the manifold of the charge transfer (CT) state at the donor-acceptor interfaces. Our results thus demonstrate that the Galvinoxyl spin 1/2 radical additives act as spin flip initiator within this exciton manifold. This process is unraveled via MPC of the doped devices. Supported by the NSF-MRSEC program at the UoU.

Session W34 DPOLY: Thin Films, Surfaces and Interfaces II 342 - Dvora Perahia, Clemson University

2:30PM W34.00001 Photo-crosslinkable polymers for fabrication of photonic multilayer sensors , MARIA CHIAPPELLI, RYAN C. HAYWARD, University of Massachusetts Amherst — We have used photo-crosslinkable polymers to fabricate photonic multilayer sensors. Benzophenone is utilized as a covalently incorporated pendent photo-crosslinker, providing a convenient means of fabricating multilayer films by sequential spin-coating and crosslinking processes. Colorimetric temperature sensors were designed from thermally-responsive, low-refractive index poly(N-isopropylacrylamide) (PNIPAM) and high-refractive index poly(para-methyl styrene) (PpMS). Copolymer chemistries and layer thicknesses were selected to provide robust multilayer sensors which show color changes across nearly the full visible spectrum due to changes in temperature of the hydrated film stack. We have characterized the uniformity and interfacial broadening within the multilayers, the kinetics of swelling and de-swelling, and the reversibility over multiple hydration/dehydration cycles. We also describe how the approach can be extended to alternative sensor designs through the ability to tailor each layer independently, as well as to additional stimuli by selecting alternative copolymer chemistries.

2:42PM W34.00002 Diffusion of single molecules on surface tethered polymer brushes , ZHENYU ZHANG, MATT MEARS, Department of Physics and Astronomy, University of Sheffield, Sheffield, S3 7RH, UK, MARK MOXEY, NICOLAS WARREN, JEPPE MADSEN, STEVEN ARMES, Department of Chemistry, University of Sheffield, Brook Hill, Sheffield, S3 7HF, UK, ANDREW LEWIS, Biocompatibles UK Ltd., Chapman House, Farnham Business Park, Weydon Lane, Farnham, Surrey, GU9 8QL, UK, MARK GEOGHEGAN, Department of Physics and Astronomy, University of Sheffield, Sheffield, S3 7RH, UK — The interaction between polymer molecules and brush surfaces in aqueous media is a multi-dimensional problem; the polymer competes with the solvent for surface sites, and the resultant molecular conformation controls its diffusion properties. The diffusion coefficients of single fluorescence-labeled poly(ethylene glycol) (PEG) molecules on surface-immobilized PEG brushes are measured by fluorescence correlation spectroscopy, and are shown to slow down by nearly 10 times when grafting density increased from 0.11 to 0.42 chain per nm^2. This diffusion dynamics can be explained by Stokes-Einstein treatment of the surface-adsorbed polymer. Subsequently, we prepared a series of surface-grown poly(oligo(ethylene glycol) methacrylate) (POEGMA) brushes with varying grafting density. Diffusion coefficients of three types of fluorescence-labeled polymer (PEG, POEGMA, PGMA) on the POEGMA brushes were quantitatively measured. It was found that diffusion coefficient of PEG changed substantially over those POEGMA samples, with POEGMA to a small degree, and PGMA not affected. The data indicates that not only grafting density of polymer brushes, but also intermolecular interaction could affect the transport of macromolecules on polymer brushes.

2:54PM W34.00003 Molecular Dynamics Simulations of Tension Amplification in Tethered Bottle-brushes[1] , GARY M. LEUTY, MESFIN TSIGE, University of Akron, MICHAEL RUBINSTEIN, University of North Carolina, GARY S. GREST, Sandia National Laboratories — Bottle-brush polymers are grafted comb polymers in which the density of side chains grafted to the polymer backbone is large enough that steric repulsions between the side chains force the backbone to stretch and preclude it from forming random-coil configurations. Tethering one end of the bottle-brush backbone to a solid substrate restricts the conformations of the side chains near the surface and leads to side-chain repulsion that induces significant amplification of the tension along the polymer backbone. Depending on the grafting density on the substrate, the density of side chains and the length of the side chains, this tension amplification may be large enough break bonds along the bottle-brush backbone, especially at the site of the link with the substrate, where the tension is maximized. We have performed coarse-grained molecular dynamics simulations to understand the interplay between the factors affecting backbone tension amplification and whether the amplification effects can be controlled in such a way as to predict, for a given architecture and surface coverage, the maximum allowable packing of chains on the substrate surface prior to tethering failure.

3:06PM W34.00004 Fast Lattice Monte Carlo Simulations of Grafted Homopolymers under Compression , PENGFEI ZHANG, QIANG WANG, Colorado State University — Fast lattice Monte Carlo (FLMC) simulations [Q. Wang, Soft Matter 5, 4564 (2009); 6, 6206 (2010)] with multiple occupancy of lattice sites and Kronecker δ-function interactions give orders of magnitude faster/better sampling of configuration space for many-chain systems than conventional lattice MC simulations with the self- and mutual- avoiding walk and nearest-neighbor interactions. Using FLMC simulations with the novel Wang-Landau-Optimized-Ensemble sampling, we have studied homopolymers end-grafted on an impenetrable and flat substrate under the compression by another impenetrable and flat surface. Comparing various quantities (including chain dimensions, internal energy, Helmholtz free energy, and pressure) obtained from FLMC simulations with predictions from the corresponding lattice self-consistent field (LSCF) calculations, both using the same model system (Hamiltonian) and thus without any parameter-fitting, we unambiguously quantify the effects of system fluctuations and correlations neglected in LSCF theory. In particular, we find LSCF theory underestimates the pressure for compression of mushrooms in the athermal and θ-solvents and for compression of brushes in the θ-solvent, but overestimates it for compression of brushes in the athermal solvent.

3:18PM W34.00005 ABSTRACT WITHDRAWN –

3:30PM W34.00006 Low voltage switching of crease patterns on gel surfaces with topographically patterned microelectrodes[1] , BIN XU, RYAN HAYWARD, University of Massachusetts Amherst — Exercising precise control over surface instability patterns on soft hydrogels is of significant interest for applications in biological and biomedical contexts. Here, we show that patterns of surface creases can be successfully programmed on thin hydrogel layers by applying a direct current electric voltage to underlying micro-patterned electrodes. We characterize the dependence of the critical switching voltage on the swelling of the gel layer and the geometry of the electrode array, as well as the depth of creases as a function of applied voltage and the switching kinetics. We also show that introducing topographically structured electrodes lowers the critical voltage slightly, and provides better control over crease shape. To better understand the mechanism of electrically-triggered creasing, we have developed an *in situ* strain mapping technique based on bleaching of markers within the gel layer.

3:42PM W34.00007 Tunable Surface Properties from Bioinspired Comb Copolymers , WENDY VAN ZOELEN, HILDA BUSS, NATHAN ELLEBRACHT, University of California, Berkeley, RONALD ZUCKERMANN, The Molecular Foundry, Lawrence Berkeley National Laboratory, RACHEL SEGALMAN, University of California, Berkeley — A modular polymer system which incorporates multiple functionalities simultaneously while keeping an identical backbone chemistry is a useful tool in determining necessary functionalities for marine antifouling properties. We have investigated the surface properties and antifouling behavior of polypeptoids, a class of non-natural biomimetic polymers based on an N-substituted glycine backbone, that combine many of the advantageous properties of bulk polymers with those of synthetically produced proteins, including controllable chain shape, sequence, and self-assembled structure. Using thiol-ene click chemistry, thiol functionalized amphiphilic peptoid sequences consisting of hydrophilic methoxyethyl and hydrophobic heptafluorobutyl side chains were attached to polystyrene-block-poly(ethylene oxide-stat-allyl glycidyl ether), creating comb-shaped molecules. Near edge X-ray absorption fine structure spectroscopy (NEXAFS) was used to study the surface characteristics as a function of peptoid length and composition. Only 20% of fluorinated groups in the peptoid were sufficient for promoting surface display of the otherwise hydrophilic PEO/peptoid comb block. Antifouling experiments with spores of the green algae Ulva indicated an influence of sequence.

3:54PM W34.00008 Microwave-Assisted Surface-Initiated Free Radical Polymerization , ERICH BAIN, XINFANG HU, CHRISTOPHER GORMAN, JAN GENZER, North Carolina State University — We investigate microwave (μw) irradiation as a heat source for surface-initiated (SI) free-radical polymerization (FRP). First, we consider the possibility of SI controlled radical polymerization (CRP) without chemical additives, based on local heating due to microwave absorption by the substrate. A simple model is developed to predict the temperature gradient at the interface between a microwave absorbing substrate and a nonabsorbing medium. Stochastic simulations are then applied to predict the molecular weight distribution for polymerizations with decoupled kinetics of initiation, propagation, and termination due to the temperature gradient. The simulations shed light on experimental requirements for μw-induced SI-CRP, as well as general conditions for any successful CRP. Secondly, we consider whether μw irradiation may increase throughput of SI-FRP, affording either faster brush growth, thicker brushes, or both, compared with conventional heating (CH) (e.g. by an oil bath). Experimental results of μw SI-FRP are compared against CH on silicon wafers, quartz slides, particles, and in bulk. Reproducibility of heating for silicon wafers is found to depend on orientation relative to the incident irradiation.

4:06PM W34.00009 Free Volume Model of Enhanced Mobility at a Free Surface[1] , NICHOLAS B. TITO, JANE E. G. LIPSON, Dartmouth College, SCOTT T. MILNER, The Pennsylvania State University — Experiments on polymer thin films during the past two decades have revealed a number of intriguing properties as they approach the glass transition. In addition to dynamic heterogeneity, which is also characteristic of the bulk, there is a substantial body of evidence for enhanced mobility at and near a free surface, leading to local suppression of the glass transition temperature. We have developed a simple kinetic lattice model of free volume and mobility transport in a near-glassy fluid. The model qualitatively exhibits hallmarks of the glass transition in bulk fluids, e.g. power-law growth of the cooperative length scale of glassified material, and slowing global dynamics on approach to a "kinetic arrest" transition. In this talk we discuss how introducing a free surface into the model yields a gradient of mobility, the depth of which depends on proximity to the bulk glass transition.

4:18PM W34.00010 Quantification of tip-sample forces on and below resonance in tapping mode atomic force microscopy , ORSOLYA KARACSONY, TOMASZ KOWALEWSKI, Carnegie Mellon University, BRIAN CUSICK, Westinghouse Electric Company — There has been a recent resurgence of interest in multi-frequency tapping mode AFM techniques, in which quantifying the tip-sample force is crucial. In particular, knowledge of the magnitude of tip-sample force may be essential in understanding the nature of contrast in imaging soft materials such as block copolymers or novel complex macromolecular architectures. This presentation will focus on the quantitative understanding of the dependence of average tip-sample forces on imaging conditions such as set-point ratio and operating frequency. First, the derivation of an analytical expression for the average tip-sample force will be presented. Its predictions will be then shown to be in excellent agreement with the results of numerical simulations using a single degree of freedom, driven damped harmonic oscillator model of tapping mode AFM.

4:30PM W34.00011 Grazing Resonant Soft X-ray Scattering: A New Way to See Inside Mesoscale Thin Films , ELIOT GANN, ANNE WATSON, NCSU, CHENG WANG, LBNL, JUSTIN COCHRAN, UCSB, JOSHUA CARPENTER, TERRY MCAFEE, HONGPING YAN, NCSU, CHRISTOPHER MCNEILL, Monash University, MICHAEL CHABINYC, UCSB, HARALD ADE, NCSU — Thin film structures are becoming increasingly important in energy and engineering applications as functional films and specifically as thin film electronics. Often the most important structures in these thin films are the interfaces between different materials. The internal structure of thin film complex systems, particularly interfacial structure, has been difficult and often impossible to characterize with traditional characterization techniques. Existing methods either lack materials contrast necessary to distinguish different components, lack penetrating power to see structure beneath the film surface, require special sample preparation which may change important features, or are too local a probe to get statistically meaningful information. This talk highlights a new technique, Grazing Resonant Soft X-ray Scattering (GR-SOXS), capable of probing buried structures in thin film systems. GR-SOXS uses varying energy x-rays near the 1S core electron absorption peak of carbon to scatter from thin polymer films at a grazing angle. Using simulations of the electric field propagation and scattering contrast of different features in model systems as a guide, Scattered X-rays from different structures within the film can be disentangled, elucidating their internal structure.

4:42PM W34.00012 Marangoni-Driven Topographic Patterning of Polymer Thin Films , CHRISTOPHER ELLISON, JOSHUA KATZENSTEIN, DUSTIN JANES, JULIA CUSHEN, NATHAN PRISCO, NIKHIL HIRA, DANA MCGUFFIN, The University of Texas at Austin — When exposed to UV light polystyrene (PS) undergoes partial dehydrogenation of its polymer backbone, raising its surface energy. By exposing a PS thin film to UV light through a photomask, a surface energy pattern can be programmed in to the polymer film. Upon heating the film to a liquid state without the mask present, the polymer flows from the unexposed (relatively low surface energy) to exposed (relatively high surface energy) regions of the film. The driving force for this phenomenon is the Marangoni Effect, familiar to most in the 'tears' or 'legs' in a glass of wine, which describes convective mass transfer due to surface energy gradients. This flow results in three-dimensional topography reflective of the photomask used in the patterning step, which can be preserved indefinitely by quenching the film below its glass transition temperature. In this talk, this process, a preliminary model, and its kinetics will be described.

4:54PM W34.00013 Polymer Thin Films and Interfaces; a Layer-by-Layer Approach[1] , RONALD WHITE, JANE LIPSON, Dartmouth College — In this talk we discuss new ways to model polymer films and interfaces, including properties such as density and concentration gradients, interfacial tension, and surface enrichment. We build on recent work where we developed a very simple equation of state approach for polymer thin films, and successfully applied it to determine thermodynamic properties and even to make predictions for the thickness-dependent depression of the thin film glass transition temperature. In that very simplified mean field model, the film properties across the entire interface region were treated as a "whole sample" average. Here, we take the next step, and develop a layer-by-layer equation of state model wherein details of the interface region are captured by allowing properties to vary from one discretized layer (within which properties are uniform) to the next. The model can be solved by imposing hydrostatic equilibrium in each layer, which then leads to predictions for the corresponding density gradient and other key interface properties.

5:06PM W34.00014 Melting of Linear Alkanes between Swollen Elastomers and Solid Substrates[1] , ALI DHINOJWALA, The University of Akron, KUMAR NANJUNDIAH, Dow Chemical Company — We have measured the melting and freezing behavior of linear alkanes confined between a poly(dimethylsiloxane) (PDMS) elastomer and a solid sapphire substrate. For shorter alkanes (15 and 17 carbons) the interfacial layer has a higher melting temperature (T_m) than the majority of the alkane crystals inside the swollen PDMS elastomer. For longer alkanes (19, 21, and 22 carbons), a large depression in T_m was observed and the crystallization takes place outside the contact region first and then proceeds to the PDMS-sapphire boundary. In heating, the sapphire/alkane interface shows a pre-melting layer (or melts first) before the melting of a thicker alkane layer next to the sapphire surface. The observation of this unusual depression of T_m of the interfacial layers was unexpected and these findings have important implications in understanding friction and adhesion of soft elastomeric materials.

5:18PM W34.00015 Tacticity Effects on the Local Conformation and Interfacial Properties of poly (methyl methacrylate) at the Liquid-Vapor Interface , KSHITIJ C. JHA, HE ZHU, ALI DHINOJWALA, MESFIN TSIGE, Department of Polymer Science, The University of Akron — The orientation of functional groups of poly (methyl methacrylate) (PMMA) play a key role in understanding functionalities like wettability, aggregation and solvent interaction. We have studied the orientation of different functional groups such as the α-methyl, ester methyl, methylene and carbonyl groups of the PMMA chain through all atom Molecular Dynamics (MD) simulations for different chain lengths of the polymer. Through orientational correlation, and number density computations we are able to establish the identity and extent of groups coming to the surface. Surface tensions are computed to validate our PMMA model. Analysis has been carried out for all three tacticities-atactic, syndiotactic, and isotactic. Sum Frequency Generation (SFG) spectroscopy also provides insight into the orientation of various groups at the liquidvapor interface. Characterization of the SFG peaks is the point of some debate and MD simulations aim to aid in the understanding of local ordering.

Thursday, March 21, 2013 2:30PM - 5:18PM –

Session W35 DCMP: Novel Superconductors II 343 - Meigan Aronson, Brookhaven National Laboratory

2:30PM W35.00001 Evolution of superconductivity and magnetic order in $LaRu_3Si_2$ by rare earth and transition metal substitutions. , RENXIONG WANG, SHANTA R. SAHA, JOHNPIERRE PAGLIONE, Ceter for Nanophysics and Advanced Materials, Department of Physics, University of Maryland, College Park, MD 20742, DANIEL PRATT, QINGZHEN HUANG, JEFFREY W. LYNN, NIST Center for Neutron Research, Gaithersburg, MD 20899 — The recent discovery of high temperature superconductivity in iron based materials has renewed interest to condensed matter physics. Although its mechanism is not yet settled completely, it should have a close relationship with the electron correlations. The compound $LaRu_3Si_2$ shows superconductivity with a transition temperature $T_c = 7.8$ K. Recent study indicates that electron correlations play a significant role for superconductivity in this Kagome lattice of Ru and the Ru band dominates at the Fermi level, similar to Fe-band in iron-superconductors. Superconductivity in $LaRu_3Si_2$ has been found robust against the local paramagnetic moment. We will present our study on the evolution of superconductivity and magnetic order in $LaRu_3Si_2$ due to substitutions of Tm, a J=6 (J is the total angular momentum) ion with a maximum ordered moment of 7 μ_B, and transition metals by measuring magnetic, transport and Neutron scattering properties.

2:42PM W35.00002 Possible Pressure Driven Quantum Critical Point in $CaCo_2P_2$, RYAN E. BAUMBACH, XIN LU, Los Alamos National Laboratory, VLADIMIR SIDOROV, Vereschagin Institute for High Pressure Physics, Russia, Los Alamos National Laboratory, FILIP RONNING, ERIC D. BAUER, JOE D. THOMPSON, Los Alamos National Laboratory — We performed electrical resistivity measurements under pressures up to a maximum of $\approx$ 5 GPa for the d-electron antiferromagnet $CaCo_2P_2$, where we find that the Néel temperature (T_N = 106 K) is rapidly suppressed towards zero near 1.4 GPa. In the vicinity of the suppressed magnetic state, the Fermi liquid coefficient of the electrical resistivity A increases abruptly, suggesting a divergence in the effective mass of the charge carrier quasiparticles. In addition, we find that the residual resistivity ρ_0 increases abruptly at 1.4 GPa. For P >1.4 GPa, we also observe a broad hump in $\partial\rho/\partial T$ at a temperature T*, which increases with increasing P. We will compare these measurements to expectations for prototypical f-electron quantum critical point (QCP) systems (e.g., $CeRhIn_5$ and $CeRh_2Si_2$) and the iron arsenide high temperature superconductors (e.g., $CaFe_2As_2$, $SrFe_2As_2$, and $BaFe_2As_2$) and discuss implications for studying a possible d-electron QCP in the absence of superconductivity.

2:54PM W35.00003 Universal scaling relations in exotic superconductors , S.V. DORDEVIC, The University of Akron, D.N. BASOV, University of California, San Diego, C.C. HOMES, Brookhaven National Laboratory — Universal scaling relations are of tremendous importance in science, as they reveal fundamental laws of nature. Several such scaling rations have recently been proposed for superconductors, however, they are not really universal in a sense that some important families of superconductors appear to fail the scaling, or obey the scaling with different scaling pre-factors. In particular, a large group of materials called organic (or molecular) superconductors are a notable example. In this paper we show that such apparent violations are largely due to the fact that the required experimental parameters were collected on different samples, with different experimental techniques. When experimental data is taken on the same sample, using a single experimental technique, organic superconductors, as well as all other studied superconductors, do in fact follow universal scaling relations.

3:06PM W35.00004 Anomalous thermodynamic power laws in nodal superconductors[1] , JORGE QUINTANILLA, University of Kent and ISIS Facility, STFC Rutherford Appleton Laboratory, BAYAN MAZIDIAN, University of Bristol and ISIS Facility, STFC Rutherford Appleton Laboratory, JAMES F. ANNETT, University of Bristol, ADRIAN D. HILLIER, ISIS Facility, STFC Rutherford Appleton Laboratory — Unconventional superconductors are frequently identified by the observation of power law behaviour on low temperature thermodynamic properties such as specific heat. These power laws generally derive from the linear spectrum near points or lines of zeros, or nodes, in the superconducting energy gap on the Fermi surface. Here we show that, in addition to the usual point and line nodes, a much wider class of different nodal types can occur. Some of these new types of nodes typically occur when there are transitions between different types of gap node topology, for example when point or line nodes first appear as a function of some physical parameter. We derive anomalous, non-integer thermodynamic power laws associated with these new nodal types and predict their occurrence in iron pnictide superconductors and in the noncentrosymmetric system $Li_2Pd_{3-x}Pt_xB$.

[1]This works was supported by EPSRC and STFC (U.K.) J.Q. gratefully acknowledges funding from HEFCE and STFC through the South-East Physics network (SEPnet).

3:18PM W35.00005 Anomalous angular dependence of the upper critical induction of orthorhombic ferromagnetic superconductors with completely broken p-wave symmetry , CHRISTOPHER LÖRSCHER, University of Central Florida, JINGCHUAN ZHANG, QIANG GU, University of Science and Technology Beijing, RICHARD KLEMM, University of Central Florida — We calculate the angular dependence of the upper critical field, $H_{c2}(\theta, \phi, T)$, for an orthorhombic ferromagnetic superconductor with a general ellipsoidal Fermi surface with effective masses m_1, m_2, and m_3, in which we have p-wave parallel-spin pairing that is locked onto the z-axis direction. We report anomalous angular dependence of H_{c2} for fixed $3 < m_3/\left(m_1 \cos^2\phi + m_2 \sin^2\phi\right)$, for which we observe a peak in H_{c2} for some angle $0° < \theta^* < 90°$, providing a sensitive test of the order parameter symmetry in materials such as URhGe. This technique can be generalized to other order parameter symmetries. We have also made relevant predictions about the angular dependence of H_{c2} for the low-field superconducting phase of URhGe.

3:30PM W35.00006 Triplet Nodeless Superconductivity Scenario in the Quasi-One-Dimensional Layered Conductor $Li_{0.9}Mo_6O_{17}$[1] , ANDREI LEBED, OTAR SEPPER, Department of Physics, University of Arizona — We solve a theoretical problem about the upper critical magnetic field, parallel to a conducting axis of a layered quasi-one-dimensional superconductor. In particular, we consider the case, where triplet superconducting order parameter is not sensitive to the Pauli destructive effects against superconductivity and has no zeros on two quasi-one-dimensional pieces of the Fermi surface. We demonstrate [1] that in this case the orbital destructive effects against superconductivity can destroy superconducting state at magnetic fields much higher than the so-called Clogston-Chandrasekhar paramagnetic limit. Comparison of our theoretical results with the very recent experimental data [2] is in favor of a triplet superconducting pairing in the layered quasi-one-dimensional superconductor $Li_{0.9}Mo_6O_{17}$.

3:42PM W35.00007 Ferromagnetism in CuFeSb: Evidence of competing magnetic interactions in Fe-based superconductors , JIN HU, BIN QIAN, Tulane University, J. LEE, University of Virginia, GAOCHAO WANG, P. KUMAR, MINGHU FANG, TIJIANG LIU, DAVID FOBES, Tulane University, H. PHAM, L. SPINU, University of New Orleans, XIAOSHAN WU, Nanjing University, M. GREEN, National Institute of Standards and Technology, S.H. LEE, University of Virginia, ZHIQIANG MAO, Tulane University — In this talk, we will report a new layered iron-pnictide compound CuFeSb [1]. This material shares similar layered tetragonal structure with iron-based superconductors, with Fe square planar sheets forming from the edge-sharing iron antimony tetrahedral network. CuFeSb differs remarkably from Fe-based superconductors in the height of anion Z_{anion} from the Fe plane; Z_{Sb} for CuFeSb is ∼1.84 Å, much larger than Z_{As} (1.31-1.51 Å) in FeAs compounds and Z_{Te} (∼1.77 Å) in $Fe_{1+y}Te$. In contrast with the metallic antiferromagneticor superconducting state of iron pnictides and chalcogenides under current studies, CuFeSb exhibits a metallic, ferromagnetic state with T_c = 375 K. This finding provide strong experimental evidence for the competition between antiferromagnetic and ferromagneticcorrelations in layered Fe-based superconductors, and that the nature of magnetic coupling within the Fe plane is indeed dependent on the height of anion as predicted in theories [2,3].

3:54PM W35.00008 Selective d-band Participation in Magnetic and Electronic Behavior of Spin-Ladder Iron-chalcogenides , JOSEPH CARON, JAMES NEILSON, DAVID MILLER, The Johns Hopkins University, VADIM KSENOFONTOV, CLAUDIA FELSER, Johannes Gutenburg University, KATHRINE ARPINO, The Johns Hopkins University, ANNA LLOBET, Los Alamos National Laboratory, TYREL MCQUEEN, The Johns Hopkins University — The mechanism of superconductivity in the iron-based superconductors, particularly the role of magnetism and band nesting, remains controversial. The iron-based superconductors share many properties with the high-T_c cuprates, including two-dimensional layers and proximity to magnetic order. Using reduced dimensionality, as exemplified by the "spin ladder" cuprates, we attempt to understand the electronic and magnetic behavior of the AFe_2X_3 (A= alkali or alkali earth, X = chalcogenide) family of materials. These compounds have $2 \times \infty$ double-chains ("ladders") of edge-sharing FeX_4 tetrahedra, cutouts of the full two-dimensional Fe_2X_2 layers of the iron-based superconductors which provide a platform from which to understand the interplay of structure, magnetism, and electronic behavior. The unique properties of these compounds is exemplified by both the inability of DFT programs recapitulate either the underlying physical properties or the dramatic transition from block to stripe magnetic order in $Ba_{1-x}K_xFe_2Se_3$ that coincides with a change from magnetic to non-magnetic behavior of one d- orbital-derived band. I will also present the influence of pressure and chemical doping on metallic and/or superconducting behavior.

4:06PM W35.00009 Physical properties of Kx(Ni,Fe)2-ySe2 single crystal alloys1 , HYEJIN RYU, HECHANG LEI, KEFENG WANG, Brookhaven National Lab., D. GRAF, National High Magnetic Field Lab., EMIL S. BOZIN, J. B. WARREN, C. PETROVIC, Brookhaven National Lab. — We report physical properties and ground state phase diagram of Kx(Fe,Ni)2-ySe2 single crystal alloy series. The ground state evolves from a heavy-Fermion-like metal KxNi2-ySe2 (I4/mmm) to a phase separated superconducting KxFe2-ySe2 (I4/m and I4/mmm space groups). Intermediate alloys show rich variety of ground states including semiconducting magnetic spin glass as Ni is replaced by Fe. We will address magnetic, thermodynamic, electronic and thermal transport properties and their connection to relevant structural parameters. 1Work at Brookhaven is supported by the U.S. DOE under Contract No. DE-AC02-98CH10886 and in part by the Center for Emergent Superconductivity, an Energy Frontier Research Center funded by the U.S. DOE, Office for Basic Energy Science (H. L. and C. P). Work at the National High Magnetic Field Laboratory is supported by the DOE NNSA DEFG52-10NA29659 (D.G.), by the NSF Cooperative Agreement No. DMR-0654118, and by the state of Florida.

4:18PM W35.00010 Physical and magnetic properties of $LaFe_{0.6}Sb_2$[1] , JENNIFER MISURACA, J.E. GROSE, J.W. SIMONSON, C. MARQUES, J. LIU, G. SMITH, A. PURI, J. HASSINGER, Department of Physics and Astronomy, Stony Brook University, M.C. ARONSON, Department of Physics and Astronomy, Stony Brook University and Condensed Matter Physics and Materials Science, Brookhaven National Laboratory — Currently, there is a tremendous effort to grow and characterize new iron pnictide materials with the hopes of discovering the next set of novel high temperature superconductors. The previous research has been focused on iron phosphides and arsenides, with relatively little work being done on the next heavier pnictogen, antimony. In this work, single crystals of the layered iron pnictide $LaFe_{0.6}Sb_2$ have been grown with the $ZrCuSi_2$ structure with vacancies on the Fe sites as determined via x-ray diffraction and energy-dispersive x-ray spectroscopy. The DC magnetization, resistivity, and heat capacity have been measured in a range of temperatures between 300 K and 0.5 K. The susceptibility is small and shows very little anisotropy; there is a maximum at 265 K and we see no Curie-Weiss-like behavior from room temperature down to 1.8 K. This material is a good metal whose resistivity decreases by a factor of 1.4 from 300 K to 0.5 K and we see Fermi liquid-like behavior from 7 K to 20 K. Although there is no evidence of bulk superconductivity down to 0.5 K in this undoped material, a large Sommerfeld coefficient of 50 mJ/(mol Fe) K^2 suggests that this metal is very strongly correlated.

[1]Research supported by a DOD National Security Science and Engineering Faculty Fellowship via the AFOSR.

4:30PM W35.00011 Quasi-two-dimensional non-collinear magnetism in the Mott insulator $Sr_2F_2Fe_2OS_2$[1] , SHAN WU, C. BROHOLM, Johns Hopkins University, LIANG L. ZHAO, JIAKUI K. WANG, E. MOROSAN, Rice University, J.P. HODGES, Oak Ridge National Laboratory, JOHNS HOPKINS UNIVERSITY TEAM, RICE UNIVERSITY COLLABORATION, OAK RIDGE NATIONAL LABORATORY COLLABORATION — We study the magnetism of $Sr_2F_2Fe_2OS_2$ through neutron powder diffraction and thermodynamic and transport measurement. Quasi-two-dimensional magnetic order develops below T_N=106K with an in-plane correlation length exceeding 310 Å and an out-of-plane correlation length of only 17(3) Å. The data are well described by a two-k structure with k_1=(1/2,0,1/2) and k_2=(0,1/2,1/2). The ordered moment is 3.3(1) μ_B oriented along the in-plane components of k. This structure is composed of orthogonal AFM chains intersecting at super-exchange mediating O sites. The Density Function Theory (by Liang L.Zhao, Jiakui K. Wang, etc.) also leads to this structure and a narrower Fe 3d band than for the iron pnictides from which electronic correlations produce a Mott insulator.

[1]This research was supported by the U.S. DoE under award DE-FG02-08ER46544 and contract DEAC05-00OR22725 with UT-Battelle, LLC. The work at Rice University was supported by AFOSR-MURL.

4:42PM W35.00012 Functional interfaces in $La_{2/3}Ca_{1/3}MnO_3$/ $YBa_2Cu_3O_{7-x}$ heterostructures[1] , TRA VU THANH, Institute of Physics, National Chiao Tung University, Hsinchu 30010, Taiwan, YING-JIUN CHEN, HONG-JI LIN, National Synchrotron Radiation Research Center, Hsinchu 30010, Taiwan, JIUNN-YUAN LIN, Institute of Physics, National Chiao Tung University, Hsinchu 30010, Taiwan, YING-HAO CHU, Department of Materials Science and Engineering, National Chiao Tung University Hsinchu 30010, Taiwan — Interfaces have emerged as one of the focal points of current condensed matter science. In complex, correlated oxides, heterointerfaces provide a powerful route to create and manipulate the charge, spin, orbital, and lattice degrees of freedom. In this study, epitaxial bilayers of ferromagnetic of $La_{2/3}Ca_{1/3}MnO_3$(LCMO) and superconducting $YBa_2Cu_3O_{7-x}$ (YBCO) with two distinct interfaces have been fabricated to understand the effects of these two distinct interfaces. X-ray absorption near edge spectroscopy (XANES) was applied to characterize the interfaces and also provided direct evidence of the charges transfer at these interfaces. The studies of the macroscopic properties, such as the transport and magnetic properties, established the connection between macroscopic properties and the interface structures. This present study opens new venue to design the functional interfaces.

4:54PM W35.00013 Superconducting interface in cuprate p-n heterostructures[1] , MAXIME DION, LAURENT OLIVIER, GUILLAUME HARDY, SÉBASTIEN GODIN-PROULX, PATRICK FOURNIER, Université de Sherbrooke — In this explorative work, we combined two kinds of non-superconducting cuprates : over-doped $Pr_{2-x}Ce_xCuO_4$ and under-doped $La_{2-x}Sr_xCuO_4$ in the same p-n heterostructures in order to generate new behaviors through the interplay between the two materials. We will show that a thin superconducting layer (< 10 nm) arise at the interface between these two compounds. We will discuss its actual location, its unexpected occurrence and its origin which is partly compatible with a charge transfer scenario that takes place in similar p-p cuprate heterostructures [1,2].

5:06PM W35.00014 Electron Doping by Charge Transfer at $LaFeO_3/Sm_2CuO_4$ Epitaxial Interfaces , JACOBO SANTAMARIA, F.Y. BRUNO, GFMC. Dpt. Applied Physics. U. Complutense, M. VARELA, Materials science and Technology Div. Oak Ridge National Laboratory. Tn 37831-6071, J. GARCIA-BARRIOCANAL, A. RIVERA, R. SCHMIDT, C. LEON, GFMC. Dpt. Applied Physics. U. Complutense, P. THAKUR, J.C. CEZAR, N.B. BROOKES, European Synchrotron Radiation Facility (ESRF)B.P. 220 Grenoble Cedex 38043 France, M. GARCIA HERNANDEZ, Instituto de Ciencia de Materiales ICMM CSIC 28049 Madrid, E.R. DAGOTTO, S.J. PENNYCOOK, Materials science and Technology Div. Oak Ridge National Laboratory. Tn 37831-6071 — We examine the interfacial charge transfer in epitaxial heterostructures formed between Mott insulating Sm_2CuO_4 (SCO) and charge transfer insulator $LaFeO_3$ (LFO) in LFO/SCO superlattices. High resolution EELS measurements at the O-K edge have provided evidence for 0.09+/-0.01 extra electrons in the SCO d- band as revealed by a reduction of the Cu oxidation state. The transfer of electrons from LFO to SCO is further supported by the spectroscopic signature of Cu^{1+} as obtained from XAS measurements. Transport measurements have evidenced a metallic state at the interface between two nominally insulating materials. Dielectric spectroscopy measurements have allowed ascribing the metallic state to the LFO/SCO interfaces, consistent with DC measurements. When lowering the temperature a metal to insulator transition occurs at 120 K, indicating, in accordance with the phase diagram, an insufficient doping level to enter a superconducting state.

Thursday, March 21, 2013 2:30PM - 5:30PM –

Session W36 DMP DCOMP: Focus Session: Fe-based Superconductors: Synthesis and Characterization 344 - Cedomir Petrovic, Brookhaven National Lab

2:30PM W36.00001 Preparation and characterization of annealed single crystals of $Ba(Fe_{1-x}Co_x)_2As_2$ at and near optimally doped, $0.07 \leq x \leq 0.095$[1] , G.R. STEWART, B.D. FAETH, J.S. KIM, G.N. TAM, Department of Physics, University of Florida — Using self flux single crystal growth and long term annealing in the presence of an As vapor source, we report resistivity, magnetic susceptibility and specific heat characterization of optimized samples at and near to optimally doped $Ba(Fe_{1-x}Co_x)_2As_2$. The ultimate achievable T_c in 122 $BaFe_2As_2$ doped on the Fe layers will be discussed, along with the variation with composition on a very fine scale of the linear T term in the resistivity and the discontinuity in the specific heat, $\Delta C/T_c$, on both the overdoped and underdoped (coexistent with magnetism) sides of optimally doped.

[1]Work supported by the US DOE, contract no. DE-FG02-86ER45268

2:42PM W36.00002 Properties of epitaxial $Ba(Fe_{1-x}Co_x)_2As_2$ thin films on different substrates , Q.Y. LEI, M. GOLALIKHANI, A. RAFTI, J. QIU, M. HAMBE, Department of Physics, Temple University, F. WILLIAMS, Q. YANG, D. TEMPLE, Applied Research Center, Center for Materials Research, Norfolk State University, E.D. BAUER, F. RONNING, Q.X. JIA, Materials Physics and Applications, Los Alamos National Laboratory, X.F. WANG, X.H. CHEN, Hefei National Laboratory for Physical Sciences at Microscale and Department of Physics, University of science and Technology of China, J.D. WEISS, E.E. HELLSTROM, Applied Superconductivity Center, National High Magnetic Field Laboratory, Florida State University, X.X. XI, Department of Physics, Temple University — We have grown epitaxial, optimally-doped superconducting $Ba(Fe_{0.92}Co_{0.08})_2As_2$ films on $SrTiO_3$, (La, Sr)(Al, Ta)O_3 and $LaAlO_3$ substrates, which have a range of lattice mismatch, and studied the strain effect on the structural and transport properties of the films. We found that the superconducting transition temperature increased as the c lattice constant decreased and a lattice constant increased. The thickness dependence of the superconducting transition temperature was studied, which was related to the strain and strain relaxation. A zero-resistance T_c of 21.7 K was obtained in the 120 nm-thick $Ba(Fe_{0.92}Co_{0.08})_2As_2$ film on $SrTiO_3$ substrate.

2:54PM W36.00003 Combined effects of annealing/quenching and transition metal substitution on physical properties of $CaFe_2As_2$[1] , SHENG RAN, SERGEY BUD'KO, PAUL CANFIELD, Ames Laboratory U.S. DOE and Department of Physics and Astronomy, Iowa State University — Our previous work on $CaFe_2As_2$ single crystals grown out of FeAs flux has shown that a process of annealing and quenching can be used as an additional control parameter which can tune the ground state of $CaFe_2As_2$ systematically, in a manner similar to applied pressure. With combined effect of annealing/quenching and transition metal substitution, $CaFe_2As_2$ system offers ready access to the salient low-temperature states associated with Fe-based superconductors: antiferromagnetic/orthorhombic, superconducting, and nonmagnetic/collapsed tetragonal. In this talk we will present systematic studies of the combined effects of annealing/quenching and chemical substitution with various transition metals (Co, Ni, Rh) on the physical properties of $CaFe_2As_2$ and construct phase diagrams for different substitution levels and different annealing/quenching temperatures.

[1]Supported by the U.S. Department of Energy Basic Energy Sciences under Contract No. DE-AC02-07CH11358.

3:06PM W36.00004 Superparamagnetism and interfacial superconductivity in rare earth Pr-doped Ca122[1] , L.Z. DENG, B. LV, F.Y. WEI, Y.Y. XUE, C.W. CHU[2], Texas Center for Superconductivity and department of Physics, University of Houston, Houston, TX 77204-5002 — To better understand the origin of the non-bulk superconductivity with an unusually high onset-T_c (49 K) and its superconducting behavior in the rare earth Pr-doped Ca122 [$(Ca_{1-x}Pr_x)Fe_2As_2$], detailed chemical analyses and magnetization measurements on both the as-synthesized and annealed single crystals were carried out. A small but non-negligible As-deficiency and superparamagnetic clusters (SPCs) were detected in the superconducting as-synthesized crystals, suggesting that the SPCs originate from the As vacancies. The magnetic moment of the SPC were found to be insensitive to the doping level x, while the SPC density (n) is zero for $x < 0.05$ in the non-superconducting region and increases monotonically with x for $x > 0.1$ in the superconducting region. The superconducting volume fraction (f) was shown to be very closely related with n. Noticeable inter-cluster interactions, from antiferromagnetic for $x < 0.05$ (non -SC region) to weakly ferromagnetic for $x > 0.1$ (SC region) were found, suggesting that the defects are ordered. Systematically annealing the crystals over 500-920° simultaneously suppress both n and f. Therefore, we propose that the ordered vacancies, and the associated interfaces, are responsible for the rather high onset-T_c.

3:18PM W36.00005 Evidence of Interface-Enhanced T_c in Rare-Earth Doped Ca122 , C.W. CHU, BING LV, LIANGZI DENG, FENGYAN WEI, YU-YI XUE, MELISSA GOOCH, BERND LORENZ, Texas Center for Superconductivity, University of Houston — Nonbulk superconductivity with an onset-T_c up to 49 K has been observed in single crystalline rare-earth doped $CaFe_2As_2$ [$(Ca_{1-x},RE_x)122$] recently. Such a T_c is more than $\sim$ 20 K higher than any known compounds that consist of one or more of the Ca, RE, Fe and As elements at ambient or under high pressures. The unusually high onset-T_c has therefore been attributed to interface effect. We have made systematic magnetic, transport, calorimetric and structural studies. They show: a chemically homogeneity of $\Delta x < 0.005$ over a 1μm; less than 5 % of a bulk superconducting volume fraction; a doping-insensitive onset-T_c in samples with or without the "collapsed phase", varying from $\sim$ 42 K for RE = Nd to 49 K for RE = Pr with a doping sensitive superconducting volume fraction, suggesting that the high onset-T_c cannot be due to chemical doping or the effect of the "collapsed phase"; an unusually high magnetic anisotropy up to 200, in contrast to the value of 4 from the sample geometric anisotropy, suggesting that the superconducting body has a very high aspect ratio; several steps in the magnetic susceptibilities along both the c- and ab-directions in the field range between 10^{-3} to 10^{+3} Oe, demonstrating the sample consisting of Josephson-Coupled superconducting islands imbedded with nano-scale interfaces; and the presence of superparamagnetic clusters associated with minute As-vacancies, consistent with theoretical calculations. The present studies therefore present the strongest evidence for interface-enhanced T_c to date.

3:30PM W36.00006 Films of Iron-Chalcogenide Superconductors and Applications , QIANG LI, WEIDONG SI, Brookhaven National Lab, BROOKHAVEN NATIONAL LAB TEAM — Iron chalcogenides are of great interest for both basic physics and applications. Although their superconducting transition temperatures are typically lower than those of iron pnictides, iron chalcogenides exhibit lower anisotropies with very high upper critical field slopes near the superconducting transition temperatures. In this presentation, I will discuss recent progress in the superconducting thin films and coated conductors of iron chalcogenides. The very high upper critical fields and critical current densities of these films suggest that they are prospective candidates for high field and energy applications. - Reference: Qiang Li, Weidong Si, and Ivo Dimitrov, "Films of Iron-Chalcogenide Superconductors," Rep. Prog. Phys. **74** 124510 (2011)

3:42PM W36.00007 Plused Laser Deposition growth of iron chalcogenide with tunable structural and physical properties , WANGDONG KONG, JUN MA, LEI YAN, HONG DING, Institute of Physics, CAS — Since the discovery of iron superconductor in 2008, plenty of spectroscopic experimental and theoretical works have been done to explore the mechanism of superconductivity. In parallel, much effort is devoted to thin film growth with the aim to fabricate high quality samples with tunable structural and physical properties,as well as for the development of new functional devices. Here we apply the Plused Laser Deposition (PLD) method to obtain iron chalcogenide superconductor thin films. By adjusting the growth parameters and procedure, we can modulate the structure and properties of the thin films. One of the main results is the enhancement of Tc. We are constructing a new system combining ARPES and PLD for in-situ measurements which will surely shed interesting light on the mechanism of superconductivity.

3:54PM W36.00008 Effects of Oxygen Annealing in Fe(Te,Se) Single Crystals , TSUYOSHI TAMEGAI, YUE SUN, TOSHIHIRO TAEN, YUJI TSUCHIYA, Department of Applied Physics, The University of Tokyo, ZHIXIANG SHI, Department of Physics, Southeast University — Iron-chalcogenide superconductor Fe(Te,Se) has the simplest structure among all iron-based superconductors. Yet, its superconducting properties except for T_c are not very much reproducible. This is partly due to the fact that the as-grown crystals of Fe(Te,Se) is not superconducting, and post-annealing is important to induce superconductivity. We found that the annealing in a controlled oxygen atmosphere is very important to induce superconductivity in this system. Upon annealing in oxygen atmosphere, the content of excess iron in the crystal decreases. We will demonstrate the dynamics of the oxygen annealing process by changing the annealing time and temperature. We also compare the effect of different annealing conditions, such as vacuum annealing, with that of oxygen annealing. Finally, physical properties of well-characterized Fe(Te,Se) crystals are discussed together with the vortex physics in this system.

4:06PM W36.00009 The mechanism of alcoholic beverage induced superconductivity in Fe-chalcogenide compounds , KEITA DEGUCHI, SATOSHI DEMURA, HIROYUKI OKAZAKI, SALEEM DENHOLME, MASAYA FUJIOKA, TOSHINORI OZAKI, TAKAHIDE YAMAGUCHI, HIROYUKI TAKEYA, YOSHIHIKO TAKANO, National Institute for Materials Science — We have clarified the mechanism of alcoholic beverage induced superconductivity in Fe-chalcogenide compounds. Previously we reported that the bulk superconductivity in Fe-based compounds Fe(Te, Se) and Fe(Te, S) is achieved by heating in alcoholic beverages [1,2]. However, the exact mechanism of how they act to enhance the superconductivity in the compounds remains unsolved. To understand the effect of alcoholic beverage treatment, we investigated the mechanism using a technology of metabolomic analysis [3]. We found that weak acid in alcoholic beverages has the ability to deintercalate the excess Fe, which is not in favor of superconductivity. In this presentation, we will discuss the systematic mechanism to induce superconductivity in Fe-chalcogenide compounds. [1] K. Deguchi et al., Supercond. Sci. Technol. 24 (2011) 055008. [2] K. Deguchi et al., arXiv: 1210.5889. [3] K. Deguchi et al., Supercond. Sci. Technol. 25 (2012) 084025.

4:18PM W36.00010 Improved growth of Ln1111 superconducting crystals from NaAs/KAs flux , NIKOLAI D. ZHIGADLO, Laboratory for Solid State Physics, ETH Zurich, Switzerland, S. WEYENETH, Physik-Institut der Universitat Zurich, Switzerland, S. KATRYCH, P.J.W. MOLL, Laboratory for Solid State Physics, ETH Zurich, Switzerland, K. ROGACKI, Institute of Low Temperature and Structure Research, Wroclaw, Poland, S. BOSMA, Physik-Institut der Universitat Zurich, Switzerland, R. PUZNIAK, Institute of Physics, Warsaw, Poland, J. KARPINSKI, B. BATLOGG, Laboratory for Solid State Physics, ETH Zurich, Switzerland — Single crystals of the LnFeAsO (Ln1111, Ln = Pr, Nd, and Sm) family with lateral dimensions up to 1 mm were grown from NaAs and KAs flux using the cubic anvil high-pressure and high-temperature technique. The crystals become superconducting when O is partially substituted by F ($PrFeAsO_{1-x}F_x$ and $NdFeAsO_{1-x}F_x$) or when Fe is substituted by Co ($SmFe_{1-x}Co_xAsO$). In $SmFe_{1-x}Co_xAsO$ the maximum T_c is 16.3 K for x = 0.8. From transport and magnetic measurements we estimate the critical fields and their anisotropy, and we find these superconducting properties to be quite comparable to the ones in $SmFeAsO_{1-x}F_x$ with a much higher T_c of $\approx$ 50 K. The magnetically measured critical current densities are as high as 10^9 A/m^2 at 2 K up to 7 T, with indications of the usual "fish tail" effect.

4:30PM W36.00011 Synthesis methods and character of iron-based mixed-anion superconductor with suppression of the amorphous FeAs impurity phase , MASAYA FUJIOKA, TOSHINORI OZAKI, HIROYUKI OKAZAKI, DENHOLME SALEEM, KEITA DEGUCHI, SATOSHI DEMURA, HIROSHI HARA, TOHRU WATANABE, HIROYUKI TAKEYA, TAKAHIDE YAMAGUCHI, HIROAKI KUMAKURA, YOSHIHIKO TAKANO, National Institute for Materials Science — To obtain the high superconducting properties of polycrystalline $SmFeAsO_{1-x}F_x$, we investigated the following three synthesis methods: a high pressure synthesis, a low temperature synthesis with gradual cooling and a metal added synthesis. Generally, polycrystalline $SmFeAsO_{1-x}F_x$ is composed of superconducting grains and a little amorphous FeAs compounds. These areas randomly co-exist and amorphous areas are located between the superconducting grains. Therefore, we suggest that the superconducting current is prevented by the amorphous areas. In fact, although the single crystal of this material shows a large critical current density of 10^6 A/cm^2, polycrystalline $SmFeAsO_{1-x}F_x$ shows a significant depression of critical current density due to this grain boundary blocking effect. To obtain a high global critical current density, it is important to investigate how to remove the amorphous FeAs. It is found that the impurity phase of amorphous FeAs is decreased by using the above three synthesis methods.

4:42PM W36.00012 Hydrostatic and chemical pressure tuning of $CeFeAs_{1-x}P_xO$ single crystals: The intriguing interaction between $3d$- and $4f$-correlations[1] , M. NICKLAS, K. MYDEEN, E. LENGYEL, A. JESCHE[2], C. GEIBEL, Max Planck Institute for Chemical Physics of Solids, Dresden, Germany — We present a combined P-substitution and hydrostatic pressure study on $CeFeAs_{1-x}P_xO$ single crystals in order to investigate the peculiar relationship of the local moment magnetism of Ce, the ordering of itinerant Fe moments, and their connection with the occurrence of superconductivity [1,2]. Our results evidence a close relationship between the weakening of Fe magnetism and the change from antiferromagnetic to ferromagnetic ordering of Ce moments at $p^* = 1.95$ GPa in $CeFeAs_{0.78}P_{0.22}O$. The absence of superconductivity in $CeFeAs_{0.78}P_{0.22}O$ and the presence of a narrow and strongly pressure sensitive superconducting phase in $CeFeAs_{0.70}P_{0.30}O$ and $CeFeAs_{0.65}P_{0.35}O$ indicate the detrimental effect of the Ce magnetism on superconductivity in P-substituted CeFeAsO.

4:54PM W36.00013 Raman spectroscopic analysis for grain boundary of Superconducting polycrystalline $SmFeAsO_{1-x}F_x$, HAJIME SHINOHARA, Department of Applied Physics and Physico-Informatics, Keio University, MASAYA FUJIOKA, Nano Frontier Materials Group, National Institute for Materials Science (NIMS), HIROKI TANIGUCHI, MITSURU ITOH, TOSHIYUKI ATOU, Materials and Structures Laboratory, Tokyo Institute of Technology, YOSHIHIKO TAKANO, Nano Frontier Materials Group, National Institute for Materials Science (NIMS), HIROAKI KUMAKURA, National Institute for Materials Science (NIMS), MASANORI MATOBA, YOICHI KAMIHARA, Department of Applied Physics and Physico-Informatics, Keio University — The observation of grain boundary structures is essential technique to fabricate high-T_c superconducting wires. Spatial crystal distribution analysis for grain boundary of superconducting polycrystalline $SmFeAsO_{1-x}F_x$ is demonstrated by Raman Spectroscopy. Polycrystalline $SmFeAsO_{1-x}F_x$ samples were synthesized using two-step solid state reaction described elsewhere [New J. Phys.**12**, 033005 (2010)]. Samples' surface and their structures were checked by microscopic optical measurement and electron beam backscattering diffraction (EBSD) analysis. The Raman spectroscopy was performed at the range from 150 cm^{-1} to 500 cm^{-1}. F contents (x) were 0, 0.019, 0.037, 0.045, 0.069, 0.075. Although our several spectra are similar to which had been reported [Hadjiev, et al, Phys. Rev. B. **77**, 220505 (2008)], our results indicate that grain boundary structures are mixtures of small single crystalline $SmFeAsO_{1-x}F_x$ and amorphous-FeAs. Details of the Raman spectra will be presented at the conference.

5:06PM W36.00014 Synthesis and characterization of whisker crystals of iron-based superconductor[1] , JUN LI, JIE YUAN, HUA-BING WANG, KAZUNARI YAMAURA, Superconducting Properties Unit, National Institute for Materials Science, Tsukuba, Japan — Single-crystal superconducting whiskers of $Ca_{10}(Pt_4As_8)(Fe_{1.8}Pt_{0.2}As_2)_5$ were grown in a Ta capsule in an evacuated quartz tube by a flux method [J. Li, *et al.* J. Am. Chem. Soc. 134, 4068−4071 (2012)]. This technique can be potentially useful for growth of other whiskers containing toxic elements, although the growth mechanism is not understood well. The $Ca_{10}(Pt_4As_8)(Fe_{1.8}Pt_{0.2}As_2)_5$ whiskers were confirmed to have excellent crystallinity with T_c of 33 K, $\mu_0 H_{c2}$ of 52.8 T, and J_c of 6.0 × 10^5 A/cm^2 (at 26 K). The T_c value is comparable with that of the bulk material. Since cuprate high-T_c superconducting whiskers are fragile ceramics, the present intermetallic superconducting whiskers with high-T_c have better opportunities for device applications. In addition, we studied the $Ca_{10}(Pt_4As_8)(Fe_{2-x}Pt_xAs_2)_5$ superconducting whiskers consisting of several grains. With current tunneling across the grain boundaries, current-voltage characteristics show the behavior of Josephson tunnel junction effect with pronounced hysteresis. In this talk, we review the growth of the superconducting whiskers and shows progress of studies of the Josephson junction using the whiskers.

5:18PM W36.00015 Annealing and doping effects of Fe-based superconductors with thick perovskite-type blocking layers , HIRAKU OGINO, AKIYASU YAMAMOTO, KOHJI KISHIO, JUN-ICHI SHIMOYAMA, The University of Tokyo — After the discovery of superconductivity in LaFeAs(O,F), several types of Fe-based superconductors were developed. In particular, iron-based superconductors having extremely thick perovskite-type blocking layers, such as (Fe2As2)(Ca5(Sc,Ti)4Oy) and (Fe2As2)(Ca4(Mg,Ti)3Oy) were discovered[1]. Interlayer Fe-Fe distances of these compounds are from 2 to 3 nm, which are much longer than other iron-based superconductors. Antiferromagnetic ordering or structural transition is not observed in these compounds, and superconducting transitions appear without intentional carrier doping. In this study, we have investigated carrier doping and annealing effect of these compounds. Relationship between crystal structure, chemical compositions and physical properties will be discussed. Thursday, March 21, 2013 2:30PM - 5:30PM –

Session W37 DMP DCOMP: Focus Session: Fe-based Superconductors: General Theory 345/346

- Rafael Fernandes, University of Minnesota

2:30PM W37.00001 Gap symmetry and nodal structure of iron-based superconductors[1] , MAXIM KHODAS, University of Iowa — We first analyze the gap symmetry in iron chalcogenides with only electron pockets. Previously, two competing alternatives for the gap symmetry were considered. In the first scenario the order parameter has opposite sign on two pockets which gives rise to a d-wave symmetry. In the second scenario the order parameter has a constant sign, resulting in an s-wave symmetric state. Experimentally, the d-wave is excluded by ARPES, while s-wave scenario is inconsistent with the spin resonance as seen by neutrons. We present the third alternative agreeing with both ARPES and neutron scattering. In contrast to the earlier theories we suggest that the pairing of electrons at different pockets is equally or more important than the usual intra-pocket pairing. The inter-pocket pair momentum (π, π) is supplied by the lattice via the inter-pocket hybridization processes. When the hybridization amplitude exceeds the threshold set by the pocket ellipticity the system is brought into an $s^{\pm}$ state. In this state both intra- and inter-pockets pair condensates are present. We argue that $s^{\pm}$ state is consistent with experiments. We next argue that the hybridization is crucial for the nodal structure of iron pnictides. In these superconductors with both electron and hole pockets the hybridization causes the nodal lines to form a closed nodal loops. This is consistent with ARPES, penetration depth and specific heat measurements.

[1]University of Iowa

3:06PM W37.00002 S+iS superconductivity in hole-doped Fe-pnictides , SAURABH MAITI, ANDREY CHUBUKOV, University of Wisconsin-Madison — The extended s-wave (s+-) symmetry proposed for Fe-pnictides requires flipping of the phase of the superconducting order parameter (the gap) on at least two pockets. In optimally doped BaK-122, the phase is flipped between the hole and electron gaps-but have the same phase on the hole gaps (e.g., both are +). But in the strongly hole doped sample only hole pockets remain, and ARPES experiments were interpreted as evidence for s+- symmetry. This requires flipping of the phase on a pair of hole pockets (one gap is + and another is -). We address this issue of ++ to +- transition of the hole gaps as doping is changed. We find that such a transition occurs via an intermediate phase of s+is type, in which time reversal symmetry is broken (TRSB state). The ++ and +- states are two end points of the s+is state. We show that TRSB state emerges at a single point at T_c, but the parameter range over which it exists widens as we go down in temperature down to $T = 0$. We investigate the structure of collective phase and amplitude gap fluctuations in the TRSB state and analyze the sensitivity of this state to the angular anisotropy of the interaction. We find that anisotropy-driven accidental gap nodes can survive in s+is state, unlike in s+id state (proposed for electron doped pnictides).

3:18PM W37.00003 Enhancement of the London penetration depth in pnictides at the onset of SDW order under superconducting dome , ALEX LEVCHENKO, Department of Physics and Astronomy, Michigan State University, East Lansing, Michigan 48824, USA, MAXIM VAVILOV, DUSHKO KUZMANOVSKI, Department of Physics, University of Wisconsin, Madison, Wisconsin 53706, USA, MAXIM KHODAS, Department of Physics and Astronomy, University of Iowa, Iowa City, Iowa 52242, USA, ANDREY CHUBUKOV, Department of Physics, University of Wisconsin, Madison, Wisconsin 53706, USA — Recent measurements of the doping dependence of the London penetration depth $\lambda(x)$ in clean samples of isovalent $BaFe_2(As_{1-x}P_x)_2$ at $T \ll T_c$ [Hashimoto et al., Science 336, 1554 (2012)] revealed a sharp peak in $\lambda(x)$ near optimal doping $x = 0.3$. This observation points to the existence of the quantum critical point beneath the superconducting dome. We show that quantum magnetic fluctuations, associated with the emerging spin-density-wave order give rise to the observed feature. The effect comes from the dynamic renormalization of the effective mass m^*, which is related to λ as $\lambda \propto \sqrt{m^*}$. We show that the effective mass has a maximum at the onset of the spin-density-wave order. We argue that the case of pnictides is conceptually different from a one-component Galilean invariant Fermi liquid, for which correlation effects do not cause the renormalization of the London penetration depth at $T = 0$.

3:30PM W37.00004 Prediction for fingerprints of bosonic modes through self-energy effects in LiFeAs , KYUNGMIN LEE, MARK FISCHER, EUN-AH KIM, Department of Physics, Cornell University, Ithaca, NY — The role of bosonic modes has been of great interest in the research of Fe-pnictides. We aim at identifying fingerprints of specific bosonic modes in the spectral properties of the multi-orbital superconductor LiFeAs. For this, we contrast the lowest order contributions to the self energy of Bogoliubov quasiparticles from two bosonic modes: antiferromagnetic(AF) fluctuation and E_g phonon. Focusing on the largest hole pocket in LiFeAs, we find that E_g phonon leads to an almost completely isotropic self energy. In contrast, AF mode leads to a pronounced angle dependent self energy. We predict signatures of such self-energy in ARPES and quasiparticle interference measured by spectroscopic imaging STM.

3:42PM W37.00005 Quantum Monte Carlo study of a dominant s-wave pairing symmetry in iron-based superconductors , TIANXING MA, Department of Physics, Beijing Normal University/ Beijing Computational Science Research Center, HAI-QING LIN, Beijing Computational Science Research Center, JIANPING HU, National Laboratory for Condensed Matter Physics, Institute of Physics, CAS, China/Department of Physics, Purdue University USA — We perform a systematic quantum Monte Carlo study of the pairing correlation in the S_4 symmetric microscopic model for iron-based superconductors. It is found that the pairing with an extensive s-wave symmetry robustly dominates over other pairings at low temperature in reasonable parameter region regardless of the change of Fermi surface topologies. The pairing susceptibility, the effective pairing interaction and the $(\pi, 0)$ antiferromagnetic correlation strongly increase as the on-site Coulomb interaction increases, indicating the importance of the effect of electron-electron correlation. Our non-biased numerical results provide a unified understanding of superconducting mechanism in iron-pnictides and iron-chalcogenides and demonstrate that the superconductivity is driven by strong electron-electron correlation effects.

3:54PM W37.00006 Magnetic and superconductivity structures near the twin boundaries in low doped Fe-pnictides , BO LI, JIAN LI, KEVIN BASSLER, CHIN-SEN TING, University of Houston — The spatial distributions of the magnetic, superconducting (SC) and charge orders near twin boundaries (TBs) in slightly electron-doped $Ba(Ca)(FeAs)_2$ superconductors are investigated. Two different types of TBs, which respectively correspond to the 90-degree lattice rotation and asymmetrically placement of As atoms, are considered. We find that the domain walls, which spatially separate different magnetic regions, can be formed under a relatively small Coulomb interaction due to the existence of TBs. We show that the SC is enhanced on the TBs of the first type, while on the TBs of the second type, the SC is always suppressed.

4:06PM W37.00007 Oriented gap opening in the magnetically ordered state of Iron-pnicitides: an impact of intrinsic unit cell doubling on the Fe square lattice by As atoms , NINGNING HAO, Department of Physics, Purdue University, West Lafayette, Indiana 47907, USA., YUPENG WANG, Beijing National Laboratory for Condensed Matter Physics and Institute of Physics, Chinese Academy of Sciences, P. O. Box 603, Beijing 100190, China, JIANGPING HU, Department of Physics, Purdue University, West Lafayette, Indiana 47907, USA. — We show that the complicated band reconstruction near Fermi surfaces in the magnetically ordered state of iron-pnictides observed by angle-resolved photoemission spectroscopies (ARPES) can be understood in a meanfield level if the intrinsic unit cell doubling due to As atoms is properly considered as shown in the recently constructed S4 microscopic effective model. The (0,pi) or (pi,0) col-linear antiferromagnetic (C-AFM) order does not open gaps between two points at Fermi surfaces linked by the ordered wave vector but forces a band reconstruction involving four points in unfolded Brillouin zone (BZ) and gives rise to small pockets or hot spots. The S4 symmetry naturally chooses a staggered orbital order over a ferro-orbital order to coexist with the C-AFM order. These results strongly suggest that the kinematics based on the S4 symmetry captures the essential low energy physics of iron-based superconductors.

4:18PM W37.00008 Local Quantum Criticality in an Iron-Pnictide Tetrahedron[1] , TZEN ONG, Department of Physics & Astronomy, Rutgers University, PATRICK SEMON, ANDRÉ-MARIE TREMBLAY, Department of Physics, University of Sherbrooke, PIERS COLEMAN, Center for Materials Theory Department of Physics & Astronomy, Rutgers University — The iron-based superconductors display a close experimental relationship between the Tc values and the tetrahedral bond angle of the As-Fe-As layer, with optimal Tc clustering close to the ideal tetrahedron geometry. This motivates a study of the local physics of an Fe atom within an As tetrahedron, and we find a strong interplay between spin and orbital degrees of freedom. The d-orbitals are crystal field split, and the lower eg orbitals have an SU(2) $\times$ SU(2) symmetry with both a spin and orbital Kondo interaction. The spin Kondo coupling is strongly reduced by the Hund's coupling; hence the system flows to an over-screened orbital Kondo state. A perturbative RG analysis of the strong-coupling fixed point is done using a Majorana fermion representation of the SU(2) $\times$ SU(2) symmetry. The low-temperature physics, and the possibility of a Marginal Fermi Liquid ground state, is carefully studied using the CTQMC method, taking into account the effect of Hund's coupling on the Kondo physics.

4:30PM W37.00009 Cooper Pair Formation from Quantum Magnetism in Iron-Pnictide High-Tc Superconductors[1] , JOSE RODRIGUEZ, California State University at Los Angeles — We study how spin fluctuations mediate the formation of Cooper pairs in iron-pnictide high-T_c superconductors via a Schwinger-boson-slave-fermion analysis of a two-orbital t-J model for a square lattice of iron atoms that includes magnetic frustration and Hund's Rule coupling. The starting point is a hidden half-metal state across the two-orbitals that recovers correct nested Fermi surfaces at a quantum-critical transition with a commensurate spin density wave (cSDW) metal [1]. A mean-field approximation indicates that hidden spinwaves at zero 2D momentum [2] result in an s-wave Cooper-pair instability on the hole Fermi surface pockets centered at 2D momentum $(0, 0)$. Proximity to the quantum-critical transition results, additionally, in a simultaneous s-wave Cooper-pair instability on the electron Fermi surface pockets centered at 2D momenta $(\pi, 0)$ and $(0, \pi)$, but with a sign change. This mean-field prediction will be checked by extracting the amplitude for such s_{+-} pairing from exact numerical diagonalizations of the two-orbital t-J model over the 4×4 lattice with two holes.

4:42PM W37.00010 Anisotropic Superconducting Gap in a Multiorbital t-J_1-J_2 Model for Iron Pnictides , RONG YU, QIMIAO SI, Department of Physics and Astronomy, Rice University, Houston, TX77005 — We study the anisotropy of the superconducting gaps in the iron pnictides within a five-orbital t-J_1-J_2 model. We show that the interplay between the multiorbital nature and the magnetic frustration can give rise to an anisotropic superconducting gap with the A_{1g} pairing symmetry. We have also calculated the dynamical spin susceptibility in the superconducting state, and find that the anisotropic gap structure affects the spin dynamics by showing two resonance peaks. We further discuss the connections between our results and recent ARPES and inelastic neutron scattering measurements.

4:54PM W37.00011 Detecting pairing symmetry in Fe-based superconductors: Solitons and proximity patch[1] , VICTOR VAKARYUK, Johns Hopkins University, VALENTIN STANEV, Argonne National Laboratory, WEI-CHENG LEE, University of Illinois at Urbana-Champaign, ALEX LEVCHENKO, Michigan State University — We suggest a mechanism which promotes the existence of a phase soliton – topological defect formed in the relative phase of superconducting gaps of a two-band superconductor with s_{+-} type of pairing. This mechanism exploits the proximity effect with a conventional s-wave superconductor which favors the alignment of the phases of the two-band superconductor which, in the case of s_{+-} pairing, are π-shifted in the absence of proximity. In the case of a strong proximity such effect can be used to reduce soliton's energy below the energy of a soliton-free state thus making the soliton thermodynamically stable. Based on this observation we consider an experimental setup, applicable both for stable and metastable solitons, which can be used to distinguish between s_{+-} and s_{++} types of pairing in the iron-based multiband superconductors.

5:06PM W37.00012 Intersoliton forces and magnetic response of three band superconductors with broken time reversal symmetry[1] , JOHAN CARLSTROM, JULIEN GARAUD, EGOR BABAEV, KTH, University of Massachusetts — The recent discovery of iron pnictide superconductors has resulted in a rapidly growing interest in multiband models with more than two bands. The three-band Ginzburg-Landau model does in part of the parameter space exhibit broken time reversal symmetry and degenerate ground states. As was shown in Phys. Rev. Lett. 107, 197001 (2011) these systems possess topological defects in the form of bound states of fractional vortices that are different from ordinary vortices, and lack rotational symmetry. We discuss intersoliton forces, and show that they exhibit a strong orientational dependence and thus can results in nontrivial structures appearing in an applied external field. Such structures can be detected by surface magnetic probes such as scanning SQUID, magnetic force microscopy etc.

5:18PM W37.00013 Chiral CP^2 skyrmions in three-band superconductors and layered superconducting structures[1] , JULIEN GARAUD, University of Massachusetts, Amherst, JOHAN CARLSTROM, KTH, University of Massachusetts, EGOR BABAEV, University of Massachusetts Amherst and KTH Stockholm, MARTIN SPEIGHT, University of Leeds — Recently discovered iron-based superconductors and well as multilayer structures involving $s_{\pm}$ superconductors can exhibit a spontaneous breaking of the time reversal symmetry. This raises the question of experimental manifestations of this additional broken symmetry. We demonstrate that it can result in formation of experimentally detectable nontrivial flux-carrying excitations which are topologically different conventional vortices. This new kind of solitons can provide an experimental signature of the breaking of time reversal symmetry.

Session W38 GERA DPOLY DCOMP: Focus Session: Novel Photophysics and Transport in NanoPV III 347 - Zhigang Wu, Colorado School of Mines

2:30PM W38.00001 Novel Low-Loss Plasmonic Waveguides to Create HE PV from Ultra-Thin Organic and Low-Purity Earth Abundant Inorganic Layers , JANELLE LEGER, Western Washington Univ — No abstract available.

3:06PM W38.00002 Embedded metal nanopatterns for near-field scattering-enhanced optical absorption , MICHAEL J. BURNS, FAN YE, AARON H. ROSE, MICHAEL J. NAUGHTON, Boston College, Department of Physics, 140 Commonwealth Avenue, Chestnut Hill, MA, 02467 — Simulations of metal nanopatterns embedded in a thin photovoltaic (PV) absorber show significantly enhanced absorbance within the semiconductor, with a more than 300% increase for $\lambda = 800$ nm. Integrating with AM1.5 solar irradiation, this yields a 70% increase in simulated short circuit current density and thus power conversion efficiency (single junction $\eta = 13\%$) in a 60 nm amorphous silicon film. Embedding such metal patterns inside an absorber maximally utilizes enhanced electric fields that result from intense, spatially organized, near-field scattering in the vicinity of the pattern. Appropriately configured (i.e., with a thin insulating coating), this optical metamedium architecture may be useful for increasing PV efficiency in thin film solar cells, including offering prospects for realistic ultrathin hot electron cells.

3:18PM W38.00003 Improved electrical response of photovoltaic devices by photonic structuring , JEREMY MUNDAY, University of Maryland — We describe the use of dispersion engineered photonic materials to develop a new photovoltaic technology that can achieve much higher efficiencies than traditional devices through the modification of spontaneous emission. The limiting efficiency of photovoltaic energy conversion was determined by Shockley and Queisser using the theory of detailed balance, which described the balance between absorption and emission of photons. However, when the solar cell is formed from a photonic crystal or a similar material is placed on top of a solar cell, both the absorption and emission of photons is modified, a fact not considered in the original formalism. Here we show that photonic crystal structuring can improve the cell efficiency by either effectively modifying the semiconductor bandgap energy or reducing the spontaneous emission within the device, leading to higher carrier concentrations and hence higher open circuit voltages.

3:30PM W38.00004 Optical absorption of nanoporous silicon: quasiparticle band gaps and absorption spectra[1]

GUANGSHA SHI, EMMANOUIL KIOUPAKIS, University of Michigan, Department of Materials Science and Engineering — Silicon is an earth-abundant material of great importance in semiconductors electronics, but its photovoltaic applications are limited by the low absorption coefficient in the visible due to its indirect band gap. One strategy to improve the absorbance is to perforate silicon with nanoscale pores, which introduce carrier scattering that enables optical transitions across the indirect gap. We used density functional and many-body perturbation theory in the GW approximation to investigate the electronic and optical properties of porous silicon for various pore sizes, spacings, and orientations. Our calculations include up to 400 atoms in the unit cell. We will discuss the connection of the band-gap value and absorption coefficient to the underlying nanopore geometry. The absorption coefficient in the visible range is found to be optimal for appropriately chosen nanopore size, spacing, and orientation. Our work allows us to predict porous-silicon structures that may have optimal performance in photovoltaic applications.

3:42PM W38.00005 Absorption enhancement in amorphous silicon thin films via plasmonic resonances in nickel silicide nanoparticles[1]

JORDAN HACHTEL, XIAO SHEN, SOKRATES PANTELIDES, Vanderbilt University, RITESH SACHAN, CARLOS GONZALEZ, ONDREJ DYCK, SHAOFANG FU, RAMKI KALNAYARAMAN, PHILLIP RACK, GERD DUSCHER, University of Tennessee at Knoxville — Silicon is a near ideal material for photovoltaics due to its low cost, abundance, and well documented optical properties. The sole detriment of Si in photovoltaics is poor absorption in the infrared. Nanoparticle surface plasmon resonances are predicted to increase absorption by scattering to angles greater than the critical angle for total internal reflection (16° for a Si/air interface), trapping the light in the film. Experiments confirm that nickel silicide nanoparticles embedded in amorphous silicon increases absorption significantly in the infrared. However, it remains to be seen if electron-hole pair generation is increased in the solar cell, or whether the light is absorbed by the nanoparticles themselves. The nature of the absorption is explored by a study of the surface plasmon resonances through electron energy loss spectrometry and scanning transmission electron microscopy experiments, as well as first principles density functional theory calculations. Initial experimental results do not show strong plasmon resonances on the nanoparticle surfaces. Calculations of the optical properties of the nickel silicide particles in amorphous silicon are performed to understand why this resonance is suppressed.

3:54PM W38.00006 Progress Developing Hybrid Silicon Quantum Dot/Amorphous Silicon Thin Films for Photovoltaics Application[1]

TIANYUAN GUAN, JEREMY FIELDS, GRANT KLAFEHN, CHITO KENDRICK, ROBERT LOCHNER, ZAHRA NOURBAKHSH, MARK LUSK, Colorado School of Mines, PAUL STRADINS, National Renewable Energy Laboratory, CRAIG TAYLOR, REUBEN COLLINS, Colorado School of Mines — Quantum confined (QC) nanostructures exhibit novel, size tunable, quantum mechanical phenomena and their use in solar cell architectures may yield significant efficiency gains. We demonstrate QC hybrid silicon nanocrystal(nc-Si:H) – hydrogenated amorphous silicon (a-Si:H) structures, which can potentially serve as photo-stable, thin film silicon, solar cell materials and provide higher open-circuit voltage compared to conventional materials. We deposit a/nc-Si:H films sequentially, where nc-Si:H and a-Si:H are grown layer-by-layer using separate plasma reactors in a common deposition chamber. X-ray diffraction, Raman spectroscopy, and electron microscopy results confirm the nanoparticles are the appropriate size to achieve QC (3-7nm). Photoluminescence spectroscopy reveals the QC. Co-planar electrical probe experiments investigate carrier transport in a/nc-Si:H, which could be limited by defects accompanying plasma interruption in the sequential deposition process. Defect spectroscopies, such as electron paramagnetic resonance and photothermal deflection spectroscopy are used to study this relationship. These studies reveal material quality limitations to be addressed for realizing film silicon materials that harvest QC to enhance PV device performance.

4:06PM W38.00007 Computational spectroscopy of nanocomposites[1]

MARCO GOVONI, TUAN ANH PHAM, GIULIA GALLI, Department of Chemistry, University of California Davis — Most of the first principles calculations of the opto-electronic properties of nanoparticles appeared in the literature were conducted using structural models of isolated particles. However experiments are carried out on nanocomposites, e.g. nanoparticles in solution or embedded in solid matrices. Recent ab initio studies [1,2] pointed at the importance of taking into account interactions between nanoparticles and the environment surrounding them, in order to provide sensible predictions of their electronic properties, as well as interpretation of experiments. Here we report calculations of the relative position of energy levels of Si nanoparticles embedded in amorphous matrices, as obtained using many body perturbation theory, at the GW level. Our calculations were carried out using a newly developed method to obtain quasi particle energies, based on the spectral decomposition of the dielectric matrix [3].

4:18PM W38.00008 Complementary transport channels in Si-ZnS nanocomposites: first principles simulations[1]

STFAN WIPPERMANN, Dep. of Chemistry, University of California, Davis, MARTON VOROS, ADAM GALI, Dep. of Atomic Physics, Budapest University of Technology and Economics, Budapest, GERGELY ZIMANYI, Dep. of Physics, University of California, Davis, GIULIA GALLI, Dep. of Chemistry, University of California, Davis — In solar energy conversion devices, nanoparticles (NPs) are often embedded in solid matrices, either crystalline or amorphous. At present a detailed understanding of the influence exerted by the embedding matrix on the absorption of sunlight by the nanoparticle, and the role of the nanoparticle-matrix interface remain elusive. We investigated Si NPs embedded in ZnS, a system that was used as a charge transport layer in recent experiments. A realistic model of the NP-matrix interface was created from ab-initio molecular dynamics simulations. We found that this nanocomposite exhibits complementary transport channels, where electron transport occurs by hopping between NPs and hole transport through the ZnS-matrix. In analogy to Si NPs embedded in SiO2 [1] we found a strong gap reduction and corresponding red-shifted optical absorption, caused by chemical shifts at the NP-matrix interface.

4:30PM W38.00009 ABSTRACT WITHDRAWN –

4:42PM W38.00010 Quantum Monte Carlo Characterization of Excited States and Energy-Level Alignment of Oligomer/Quantum-Dot Interfaces[1] , JONATHAN DUBOIS, DONGHWA LEE, Lawrence Livermore National Laboratory, YOSUKE KANAI, The University of North Carolina, Chapel Hill — Charge separation of excitons in materials is one of the most important physical processes to utilize the solar energy in diverse devices including solar cells and photo-catalysts. Heterogeneous interfaces with the so-called type-II character are often employed to infer the interfacial charge transfer in this context. As a simple criterion for designing such an interface, the energy alignment of the quasi-particle states together with the exciton binding energy of electron-donating materials is often discussed in the literature. However, an accurate description of the effect of exciton binding at the interface has not been investigated extensively. Although density functional theory (DFT) is a powerful method to investigate various electronic properties of materials, incomplete description of many-body interactions can lead to an incorrect interpretation of the energy level alignment. While Many-Body Perturbation Theory and Quantum Monte Carlo are promising in this context, much more work is necessary to assess how well these methods perform in practice. In this talk, we will discuss our preliminary results using diffusion Quantum Monte Carlo to calculate the excited states and energy-level alignment at an Oligomer/Quantum-Dot interface – a system that is often discussed in context of solar energy conversion.

4:54PM W38.00011 Binding mechanism of CdSe quantum dots to carbon nanotubes/graphene , JIE JIANG, SOHRAB ISMAIL-BEIGI , Applied Physics, Yale University — Decorating carbon nanotube or graphene with CdSe quantum dots (QDs) is one approach to creating next generation high efficiency photovoltaics. We have used first principles methods to calculate the binding mechanisms of oleic acid (OA) to CdSe QDs as well as how -COOH functional groups can link the QD to graphene. In both cases, the strongest binding involves the terminating double-bonded oxygen atom in the -COOH group covalently bonding to a surface Cd atom while the hydrogen (from the OH part of the -COOH) aligns to make a weak hydrogen-like bond to a neighboring surface Se. We find a strong defect enhanced binding of the QD to graphene via -COOH: when the -COOH links the QD to a defect site on the graphene, the binding energy of the complex is 0.5 eV larger than when a -COOH links the QD to a pristine graphene region. These results are consistent with available edge X-ray absorption fine structure (EXAFS) data and also rationalize the growth procedure by which ultrasonication of the OA functionalized QDs leads to the replacement of some QD-OA bonds by QD-COOH-graphene bonds, which strongly link the QDs to the graphene surface.

5:06PM W38.00012 ABSTRACT WITHDRAWN –

5:18PM W38.00013 ZnO Transistor Interfaces Sensitized with Photo Donor Molecules[1] , JOSEF SPALENKA, LUSHUAI ZHANG, PADMA GOPALAN, PAUL EVANS, University of Wisconsin-Madison — A better understanding of the physics at interfaces between semiconducting oxides and monolayers of covalently bonded organic molecules is relevant to important applications such as inexpensive chemical sensors and improved dye-sensitized solar cells. We use field-effect transistor (FET) structures in which electrical measurements are made before and after functionalizing the surface of ZnO nanocrystalline films, which form the channel of the FET, with organic dye molecules based on rhenium-bipyridine complexes that act as electron donors during illumination with monochromatic light. Measurements of the charge transfer as a function of light intensity and dye coverage give the ratio between the rates of charge transfer and recombination between the dyes and the ZnO, an important parameter to maximize to further improve the efficiency of solar cells based on donor functionalized oxides.

Session W39 DFD: Computational Fluid Dynamics 348 - Gorges L. Chahine, Dynaflo, Inc

2:30PM W39.00001 Transient Non-Newtonian Screw Flow , NARIMAN ASHRAFI, Azad University — The influence of axial flow on the transient response of the pseudoplastic rotating flow is carried out. The fluid is assumed to follow the Carreau-Bird model and mixed boundary conditions are imposed. The four-dimensional low-order dynamical system, resulted from Galerkin projection of the conservation of mass and momentum equations, includes additional nonlinear terms in the velocity components originated from the shear-dependent viscosity. In absence of axial flow the base flow loses its radial flow stability to the vortex structure at a lower critical Taylor number, as the pseudoplasticity increases. The emergence of the vortices corresponds to the onset of a supercritical bifurcation which is also seen in the flow of a linear fluid. However, unlike the Newtonian case, pseudoplastic Taylor vortices lose their stability as the Taylor number reaches a second critical number corresponding to the onset of a Hopf bifurcation. Existence of an axial flow, manifested by a pressure gradient appears to further advance each critical point on the bifurcation diagram. In addition to the simulation of spiral flow, the proposed formulation allows the axial flow to be independent of the main rotating flow. Complete transient flow field together with viscosity maps are also presented.

2:42PM W39.00002 Indeterminism in Classical Dynamics of Particle Motion , GREGORY EYINK, The Johns Hopkins University, ETHAN VISHNIAC, University of Saskatchewan, CRISTIAN LALESCU, The Johns Hopkins University, HUSSEIN ALUIE, Los Alamos National Laboratory, KALIN KANOV, RANDAL BURNS, CHARLES MENEVEAU, ALEX SZALAY, The Johns Hopkins University — We show that "God plays dice" not only in quantum mechanics but also in the classical dynamics of particles advected by turbulent fluids. With a fixed deterministic flow velocity and an exactly known initial position, the particle motion is nevertheless completely unpredictable! In analogy with spontaneous magnetization in ferromagnets which persists as external field is taken to zero, the particle trajectories in turbulent flow remain random as external noise vanishes. The necessary ingredient is a rough advecting field with a power-law energy spectrum extending to smaller scales as noise is taken to zero. The physical mechanism of "spontaneous stochasticity" is the explosive dispersion of particle pairs proposed by L. F. Richardson in 1926, so the phenomenon should be observable in laboratory and natural turbulent flows. We present here the first empirical corroboration of these effects in high Reynolds-number numerical simulations of hydrodynamic and magnetohydrodynamic fluid turbulence. Since power-law spectra are seen in many other systems in condensed matter, geophysics and astrophysics, the phenomenon should occur rather widely. Fast reconnection in solar flares and other astrophysical systems can be explained by spontaneous stochasticity of magnetic field-line motion

2:54PM W39.00003 Higher Order Thermal Lattice Boltzmann Model[1]

, SHAHAJHAN SORATHIYA[2], SANTOSH ANSUMALI[3], JNCASR — Lattice Boltzmann method (LBM) modelling of thermal flows, compressible and micro flows requires an accurate velocity space discretization. The sub optimality of Gauss-Hermite quadrature in this regard is well known [1]. Most of the thermal LBM in the past have suffered from instability due to lack of proper H-theorem and accuracy [2]. Motivated from these issues, the present work develops along the two works [3] and [4] and imposes an eighth higher order moment to get correct thermal physics. We show that this can be done by adding just 6 more velocities to D3Q27 model and obtain a "multi-speed on lattice thermal LBM" with 33 velocities in 3D and $\mathcal{O}(u^4)$ and $\mathcal{O}(T^4)$ accurate f_i^{eq} with a consistent H-theorem and inherent numerical stability. Simulations for Rayleigh-Bernard as well as velocity and temperature slip in micro flows matches with analytical results. Lid driven cavity set up for grid convergence is studied. Finally, a novel data structure is developed for HPC.

3:06PM W39.00004 ODTLES: Simulations of wall-bounded turbulent flows with small-scale resolution[1]

, ESTEBAN GONZALEZ, Combustion Science & Engineering, Inc., ALAN KERSTEIN, Consultant, ROD SCHMIDT, Sandia National Laboratories — The numerical simulation of turbulent flows is difficult because of their broad range of scales of motion and because they include a large variety of small-scale processes, such as friction near a wall, diffusion at an interface, multiphase couplings, and chemical reactions. Traditional approaches to model these flows are limited in breadth and accuracy because they filter out information from small-scale processes. An alternative method that circumvents this problem is ODTLES. This method resolves, not models, small-scale phenomena in a computationally affordable way, in comparison with full three-dimensional resolution, through the use of a lattice-work of one-dimensional (1D) domains, where flow properties are time-advanced with 1D stochastic simulations. This talk will discuss the methodology behind ODTLES and results for incompressible wall-bounded turbulence.

3:18PM W39.00005 Shock Formation and Disintegration in Fluids with Non-Convex Equations of State[1]

, FATEMEH BAHMANI, MARK CRAMER, Virginia Polytechnic Institute and State University — We consider the steady, two-dimensional, inviscid, high-speed, flow around thin turbine blade profiles with special attention given to fluids having a non-convex equation of state; such fluids are commonly known as Bethe-Zel'dovich-Thompson (BZT) fluids. We show that the essential flow physics can be described by an inviscid Burgers equation having quartic nonlinearity rather than the quadratic nonlinearity of perfect gases. In order to illustrate the flow behavior, a fifth-order WENO (weighted essentially non-oscillatory) numerical scheme is employed. New results of interest include the formation of oblique expansion shocks, shock-splitting induced by the interaction of a single shock with Mach waves, the capture of shock-fan combinations, and the collision of oblique compression and expansion shocks.

[1]NSF grant CBET-0625015

3:30PM W39.00006 Polarized Turbulence on the 3-sphere

, OWEN DIX, RENA ZIEVE, University of California, Davis — We have simulated He II superfluid turbulence on a 3-sphere, using the Hopf vector field $(-y, x, -w, z)$ as the driving velocity. This vector field lies along parallel great circles of the 3-sphere. It has a uniform magnitude, is divergence-free, and is analogous to a uniform driving velocity in periodic boundaries (a flat 3-torus), with the important exception that it has a non-zero curl tangent to the field itself. The resultant system is an interesting modification of rotating counterflow turbulence, which produces a state of polarized turbulence for driving velocities above a critical velocity V_{DG}. The average polarization of the vortex tangent field on the 3-sphere is 0.8-0.95, significantly higher than rotating counterflow. We also found a vortex reconnection rate proportional to $L^{1.6}$, in contrast to homogeneous turbulence, which yields exponents of 5/2 or 2, depending on the importance of the local velocity term and on the turbulence state. A reduced exponent is consistent with predictions and previous simulations of polarized turbulence, but the degree of reduction is remarkable. Development of this polarized turbulence state is still under investigation.

3:42PM W39.00007 A Spectral Adaptive Mesh Refinement Method for the Burgers equation

, LEILA NASR AZADANI, Graduate Student, ANNE STAPLES, Assistant Professor — Adaptive mesh refinement (AMR) is a powerful technique in computational fluid dynamics (CFD). Many CFD problems have a wide range of scales which vary with time and space. In order to resolve all the scales numerically, high grid resolutions are required. The smaller the scales the higher the resolutions should be. However, small scales are usually formed in a small portion of the domain or in a special period of time. AMR is an efficient method to solve these types of problems, allowing high grid resolutions where and when they are needed and minimizing memory and CPU time. Here we formulate a spectral version of AMR in order to accelerate simulations of a 1D model for isotropic homogenous turbulence, the Burgers equation, as a first test of this method. Using pseudo spectral methods, we applied AMR in Fourier space. The spectral AMR (SAMR) method we present here is applied to the Burgers equation and the results are compared with the results obtained using standard solution methods performed using a fine mesh.

3:54PM W39.00008 Multiscale simulation of electroosmotic flows

, LIN GUO, MARK ROBBINS, Johns Hopkins University, SHIYI CHEN, Johns Hopkins University, Peking University, JIN LIU, Washington State University — We develop an efficient hybrid multiscale method for simulating nano-scale electroosmotic flow based on spatial "domain decomposition" [1]. Molecular dynamics (MD) is used in the near wall region where atomistic details are important. A multigrid Particle-Particle Particle-Mesh (PPPM) method [2] is used to calculate the long-range Coulombic interaction between charged ions. Continuum (incompressible Navier-Stokes) equations for the solvent are solved in the bulk region, reducing the computational cost substantially. A discrete description of ions is retained in the continuum region because of the low density of ions and the long-range of electrostatic interactions. Langevin dynamics is used to model the Brownian motion of these ions in the implicit solvent. The fully atomistic and continuum descriptions are coupled through "constrained dynamics" [1] in an overlap region. Continuity of flux of both charged and solvent particles is ensured. The scheme is implemented in channel flow simulations with and without wall roughness. Results are compared with pure MD simulations.

4:06PM W39.00009 Chaos Synchronization in Navier-Stokes Turbulence[1] , CRISTIAN LALESCU, CHARLES MENEVEAU, GREGORY EYINK, The Johns Hopkins University — Chaos synchronization (CS) has been studied for some time now (Pecora & Carroll 1990), for systems with only a few degrees of freedom as well as for systems described by partial differential equations (Boccaletti et al 2002). CS in general is said to be present in coupled dynamical systems when a specific property of each system has the same time evolution for all, even though the evolution itself is chaotic. The Navier-Stokes (NS) equations describe the velocity for a wide range of fluids, and their solutions are usually called turbulent if fluctuation amplitudes decrease as a power of their wavenumber. There have been some studies of CS for continuous systems (Kocarev et al 1997), but CS for NS turbulence seems not to have been investigated so far. We focus on the synchronization of the small scales of a turbulent flow for which the time history of large scales is prescribed. Our DNS results show that high-wavenumbers in turbulence are fully slaved to modes with wavenumbers up to a critical fraction of the Kolmogorov dissipation wavenumber. The motivation for our work is to study deeply sub-Kolmogorov scales in fully developed turbulence (Schumacher 2007), which we found to be recoverable even at very high Reynolds number from simulations with moderate resolutions.

4:18PM W39.00010 Multiscale Modeling of Cavitating Bubbly Flows[1] , J. MA, C.-T. HSIAO, G.L. CHAHINE, Dynaflow, Inc — Modeling of cavitating bubbly flows is challenging due to the wide range of characteristic lengths of the physics at play: from micrometers (e.g., bubble nuclei radius) to meters (e.g., propeller diameter or sheet cavity length). To address this, we present here a multiscale approach which integrates a Discrete Bubble Model for dispersed microbubbles and a level set N-S solver for macro cavities, along with a mesoscale transition model to bridge the two. This approach was implemented in 3DYNAFS© and used to simulate sheet-to-cloud cavitation over a hydrofoil. The hybrid model captures well the full cavitation process starting from free field nuclei and nucleation from solid surfaces. In low pressure region of the foil small nuclei are seen to grow large and eventually merge to form a large scale sheet cavity. A reentrant jet forms under the cavity, travels upstream, and breaks it, resulting in a bubble cloud of a large amount of microbubbles as the broken pockets shrink and travel downstream. This is in good agreement with experimental observations based of sheet lengths and frequency of lift force oscillation.

4:42PM W39.00012 Surface cooling mechanism of fire suppression by aqueous foam , MICHAEL CONROY, RAMAGOPAL ANANTH, U.S. Naval Research Laboratory — We investigate the ability of room-temperature foam to directly cool the surface of a liquid fuel pool at burning conditions and to reduce the fuel vapor pressure. We solve an unsteady, one-dimensional heat conduction equation using the finite element method to predict the temperature within an aqueous foam layer above a liquid fuel (heptane) layer. The sharp gradients in temperature and thermal properties at the foam-fuel interface are treated approximately inside of a thin interfacial layer above the fuel surface. We predict a rapid, significant reduction in the fuel surface temperature due to the large initial temperature gradient and the foam thermal diffusivity. The predicted surface cooling leads to a significant decrease in the fuel vapor pressure in less than a second. The mechanisms of fire suppression by aqueous foams are not well understood and the model predictions show that direct surface cooling could provide an important contribution to fire suppression. Experiments are in progress to quantify the surface cooling effect on heptane pool fire suppression.

4:54PM W39.00013 Formation of Kinneyia via shear-induced instabilities in microbial mats , KATHERINE THOMAS, STEPHAN HERMINGHAUS, MPI Dynamics and Self-Organization, HUBERTUS PORADA, Universitat Göttingen, LUCAS GOEHRING, MPI Dynamics and Self-Organization — Kinneyia are a class of microbially mediated sedimentary fossils. Characterised by clearly defined ripple structures, Kinneyia are generally found in areas that were formally littoral habitats and covered by microbial mats. To date there has been no conclusive explanation as to the processes involved in the formation of these fossils. Microbial mats behave like viscoelastic fluids. We propose that the key mechanism involved in the formation of Kinneyia is a Kelvin-Helmholtz instability induced in a viscoelastic film under flowing water. A ripple corrugation is spontaneously induced in the film and grows in amplitude over time. Theoretical predictions show that the ripple instability has a wavelength proportional to the thickness of the film. Experiments carried out using viscoelastic films confirm this prediction. The ripple pattern that forms has a wavelength roughly three times the thickness of the film. This behaviour is independent of the viscosity of the film and the flow conditions. Well-ordered patterns form, with both honeycomb-like and parallel ridges being observed, depending on the flow speed. These patterns correspond well with those found in Kinneyia fossils, with similar morphologies, wavelengths and amplitudes being observed.

5:06PM W39.00014 Optimal Concentrations in Transport Networks , KAARE JENSEN, JESSICA SAVAGE, Harvard University, WONJUNG KIM, JOHN BUSH, Massachusetts Institute of Technology, N. MICHELE HOLBROOK, Harvard University — Biological and man-made systems rely on effective transport networks for distribution of material and energy. Mass flow in these networks is determined by the flow rate and the concentration of material. While the most concentrated solution offers the greatest potential for mass flow, impedance grows with concentration and thus makes it the most difficult to transport. The concentration at which mass flow is optimal depends on specific physical and physiological properties of the system. We derive a simple model which is able to predict optimal concentrations observed in blood flows, sugar transport in plants, and nectar feeding animals. Our model predicts that the viscosity at the optimal concentration $\mu_{\rm opt} = 2^n \mu_0$ is an integer power of two times the viscosity of the pure carrier medium μ_0. We show how the observed powers $1 \leq n \leq 6$ agree well with theory and discuss how n depends on biological constraints imposed on the transport process. The model provides a universal framework for studying flows impeded by concentration and provides hints of how to optimize engineered flow systems, such as congestion in traffic flows.

5:18PM W39.00015 Resonating Vector Strength: How to Find Periodicity in a Time Sequence[1] , J. LEO VAN HEMMEN, Physik Department T35, TU Muenchen — For a given periodic stimulus with angular frequency $\omega_\circ = 2\pi/T_\circ$ we find responses as events at times $\{t_1, t_2, \ldots, t_n\}$ located on the real axis R. How periodic are they? And do they repeat in "some" sense in accordance with the stimulus period $T_\circ$? The question and the answer are at least as old as a classical paper of von Mises dating back to 1918. The key idea is simply this. We map the events t_j onto the unit circle or torus through $t_j \mapsto \exp(i\omega t_j)$ and consider their center of gravity, $\rho(\omega)$, a complex number in the unit disk. Its absolute value $|\rho(\omega_\circ)|$ with $\omega := \omega_\circ$ is what von Mises studied and is now called the vector strength. We prove that the nearer $|\rho(\omega_\circ)|$ is to 1 the more periodic the events t_j are w.r.t. $T_\circ$. Furthermore, we also show why it is useful to study $\rho(\omega)$ as a function of ω so as to obtain a 'resonating' vector strength, an idea strongly deviating from the classical characteristic function.

Session W40 DAMOP: Quantum Information in AMO Physics 349 - Kevin Wright, Dartmouth College

2:30PM W40.00001 Nonlinear Optics Quantum Computing and Quantum Simulation with Circuit-QED , PRABIN ADHIKARI, Joint Quantum Institute, University of Maryland, College Park, MOHAMMAD HAFEZI, JACOB TAYLOR, Joint Quantum Institute, University of Maryland, College Park/NIST — One approach to quantum information processing is to use photons as quantum bits and rely on linear optical elements for most operations. However, some optical nonlinearity is necessary to enable universal quantum computing. Here, we suggest a circuit-QED approach to photon-based quantum processors and quantum simulators in the microwave regime, including a deterministic two-photon interaction. Our specific example uses a hybrid quantum system comprising a LC resonator coupled to a superconducting flux qubit to implement a nonlinear coupling. Compared to the self-Kerr nonlinearity, we find that our approach has improved tolerance to noise in the qubit while maintaining fast operation. We also envision using a similar resonator and fluxonium qubit system to create higher order photon nonlinearities, which is a generalization of effective two-photon interactions and opens the range of potential Hamiltonians that can be efficiently simulated.

2:42PM W40.00002 Two Electromagnetically Induced Transparency Windows and Cross-Phase Modulation with Four-Level Superconducting Artificial Atoms[1] , HESSA ALOTAIBI, BARRY SANDERS, University of Calgary — Superconducting circuit quantum electrodynamics (SCQED) employs microwave transmission lines coupled to artificial atoms, which are typical two-level and recently three-level for electromagnetically induced transparency (EIT). We propose SCQED with a four-level tripod-configuration artificial atom to enable cross-phase modulation between two traveling-wave microwave fields. Our master-equation analysis for three driving fields ("signal," "probe" and "coupling") demonstrates the existence of two distinct EIT transparency windows in the spectral-response profile as a function of coupling and weak fields strength. We provide the first theoretical analysis of this unexpected second window and show its advantages over the known first EIT window. Specifically we show that this second EIT window provides both the signal and probe fields with identical response functions provided that their Rabi frequencies and detunings are the same. Exploiting the second window with judiciously chosen external flux and energy detuning result in low absorption, excellent group velocity matching, and high nonlinearity, thereby enabling strong cross-phase modulation for SCQED.

2:54PM W40.00003 Nonlocal Interferometry Using Macroscopic Coherent States and Weak Nonlinearities[1] , BRIAN KIRBY, JAMES FRANSON, University of Maryland, Baltimore County — Bell's inequality has been violated numerous times in microscopic systems with the use of nonlocal interferometry. Described here will be an extension of the Franson interferometer to the macroscopic case of coherent states entangled in phase. The entanglement is generated using weak nonlinearities, and the entanglement is probed using single photons and homodyne detection. Without loss the predicted nonlocal interference visibility of the interferometer is unity, and the inclusion of atomic absorption allows for a large number of photons to be absorbed with only a small reduction in the visibility. This interferometer can be extended in a straightforward manner to a quantum key distribution scheme using the Ekert protocol to insure security. A method for the extension of the entanglement distance using entanglement swapping is described. This nonlocal interferometer may therefore be of practical use in quantum communications in addition to being of fundamental interest.

3:06PM W40.00004 Efficacy of weak measurement reversal for stochastic amplitude damping , DAVID STARLING, Penn State Hazleton, NATHAN WILLIAMS, Willamette University — A recent experiment demonstrated the restoration of entanglement in a photonic system using weak measurement reversal [S. Kim et al., Nature Physics 8, 117 (2012)]. Here, we analyze the statistical properties of entanglement for pairs and triples of entangled qubits subject to stochastic amplitude damping followed by restoration. After the random disturbance, the state is restored by applying a static weak measurement reversal. We then show that the fidelity of the restored state, and therefore its entanglement, can be restored with high success, despite the statistical fluctuations of the disturbance. In particular, we show that the variance of the entanglement of the restored states is substantially reduced, independent of the strength of the disturbance. We conclude with a proposed experimental implementation.

3:18PM W40.00005 Nonlinear waveguide arrays and disorder , AMIT RAI, DIMITRIS ANGELAKIS, Centre for Quantum Technologies, National University of Singapore — Waveguide arrays with quadratic nonlinearity has been studied recently. We investigated the waveguide arrays with quadratic nonlinearity and explored the possibility of generating broadband continuous-variable entanglement in such structures. We propose an integrated approach toward continuous-variable entanglement based on integrated waveguide quantum circuits, which are compact and relatively more stable. We further continued our work on waveguide arrays by studying a hybrid system which contains a combination of linear and nonlinear waveguides. We assume that all the waveguides except the central one are assumed to be linear. The central waveguide is assumed to have $\chi^{(2)}$ nonlinearity. We assume that the central waveguide is pumped through a coherent light. The coupling between the waveguide is achieved by the evanescent overlap of the guided modes. For all the other waveguides in the array the light propagates in the linear regime. We also study the effect of disorder which can be introduced by varying the distance between the waveguides. We are particularly interested in investigating the effect of disorder and quadratic non-linearity in the waveguide array system.

3:30PM W40.00006 Squeezing of Spin Waves in a Three-Dimensional Atomic Ensemble[1] , LEIGH NORRIS, BEN BARAGIOLA, CQuIC University of New Mexico, ENRIQUE MONTANO, PASCAL MICHELSON, POUL JESSEN, CQuIC University of Arizona, IVAN DEUTSCH, CQuIC University of New Mexico — Spin squeezed states (SSS) have generated considerable interest for their potential applications in quantum metrology and quantum information processing. Many protocols for generating SSS in atomic gases rely on the Faraday interaction that creates entanglement between atoms through the coupling of the collective spin of the ensemble to polarization modes of an optical field. Most descriptions of this process rely on an idealized one-dimensional plane wave model of light-matter interactions that is not appropriate for describing a real system consisting of a cigar-shaped cold atomic cloud in dipole trap interacting with a probe laser beam. We provide a first principles three-dimensional model of squeezing via a quantum nondemolition measurement of the collective magnetization for an ensemble of atoms with hyperfine spin f. The model includes spin waves, diffraction, paraxial modes, and optical pumping, derived by a full master equation description. Including dissipative dynamics, we find the optimal ensemble geometry and input Gaussian beam parameters for generating spin squeezing. We also study the effect of enhancing the atom-light interface using internal hyperfine control of atoms with large spin f.

3:42PM W40.00007 Selection of semiconductor quantum dots for multi-qubit encoding using an optical microcavity , ANGELA GAMOURAS, MATHEW BRITTON, Dalhousie University, DAN DALACU, PHILIP POOLE, DANIEL POITRAS, ROBIN L. WILLIAMS, National Research Council of Canada, KIMBERLEY C. HALL, Dalhousie University — Controlling the quantum states of excitons or spin-polarized carriers in semiconductor quantum dots (QDs) has been the focus of a considerable research effort in recent years due to the promise of using this approach to develop a solid state quantum computing architecture. In such experiments, the need to isolate the optical response of a single QD represents a formidable challenge, one that is greatest for QDs with emission wavelengths compatible with existing telecommunications infrastructure due to the lower quantum efficiency of the associated detectors. Encoding qubits in ensembles of QDs would greatly facilitate quantum state readout due to the larger optical signals involved, however the spread of optical transition energies limits the fidelity of the control process. Here we report time-resolved differential transmission experiments on QDs in a dielectric Bragg stack optical microcavity. Our results indicate that the angle dependent transmission resonance of the cavity allows for the separate excitation and detection of distinct subsets of QDs in the ensemble differentiated by their optical transition energies. These findings demonstrate the feasibility of developing a scalable computing architecture based on multi-qubit encoding using semiconductor QDs.

3:54PM W40.00008 Quantum plasmonics of a metal nanoparticle array for on-chip nanophotonic network , CHANGHYOUP LEE, CHANGSUK NOH, DIMITRIS ANGELAKIS[1], Centre for Quantum Technologies, National University of Singapore, Singapore, MARK TAME, QOLS, The Blackett Laboratory, Imperial College London, United Kingdom, JAMES LIM, JINHYOUNG LEE, Department of Physics, Hanyang University, Korea — With the advancement of nanofabrication techniques, metallic nanoparticles have been attracting significant attention due to their novel capabilities offering the prospects of miniaturization, scalability, and strong coherent coupling to single-emitters that conventional photonics cannot achieve. In this work, we investigate an array of metal nanoparticles for on-chip quantum networking, quantum computation and communication on scales far below the diffraction limit. For this purpose, we first consider the transfer of quantum states, including single qubits as plasmonic wave packets, and explore the interference of single plasmons associated with the quantum properties of the plasmon excitation. In addition, we study dipole induced reflection effects in the plasmonic setting. The results seem promising for quantum control applications such as single-photon switching and slow light in the nanoscale. We also propose a scheme of entanglement generation between distant emitters embedded in the array of metal nanoparticles. The techniques introduced in this work may assist in the further theoretical and experimental studies of plasmonic nanostructures for quantum control applications and probing nanoscale optical phenomena.

4:06PM W40.00009 Dynamic Hole Trapping Effect in an InAs/AlGaAs quantum dot molecule , WEIWEN LIU, University of Delaware, ALLAN BRACKER, DANIEL GAMMON, Naval Research Laboratory, MATTHEW DOTY, University of Delaware — It is well established that the charge and spin configurations of single electrons or holes are promising candidates for next generation computational and logic devices. Quantum Dots Molecules (QDMs) are attractive components for confining and manipulating single charges because the discrete energy levels, charge interactions and spin properties can be tailored with size and composition. The strong confinement QDMs causes overlap of wavefunctions and results in different Coulomb interactions and unique energy levels for different numbers of charges and even for distinct spatial distributions of the same total charge. Quantitative measurements of the Coulomb interactions are important in order to understand charge and spin interactions and design structures for device applications. We present a new phenomenon discovered during optical spectroscopy of a QDM with an AlGaAs barrier between two QDs. AlGaAs barrier allows an extra hole to be trapped in a metastable state of the higher energy QD due to the higher barrier potential. This ?dynamic trapped hole? occurs only under certain electric field conditions and perturbs the Coulomb interactions of the other charges present in the QDM. We propose a model of the kinetic pathways that leads to this dynamic hole trapping effect. We compare the energy of states with and without the extra hole in order to understand many body Coulomb interactions that perturb states energies. We then discuss the challenges and opportunities this effect provides for future devices.

4:18PM W40.00010 Ideal Multipole Ion Traps from Planar Ring Electrodes , ROBERT CLARK, The Citadel, Charleston, SC, 29409 — We present designs for multipole ion traps based on a set of planar, annular, concentric electrodes which require only rf potentials to confine ions. We illustrate the desirable properties of the traps by considering a few simple cases of confined ions. We predict that mm-scale surface traps may have trap depths as high as tens of electron volts, or micromotion amplitudes in a 2-D ion crystal as low as tens of nanometers, given realistic experimental parameters. We also discuss applications to quantum information science, frequency metrology, and cold ion-atom collisions.

4:30PM W40.00011 Resolved sideband spectra of calcium ions in a Penning trap , JOE GOODWIN, GRAHAM STUTTER, DANIEL SEGAL, RICHARD THOMPSON, Imperial College London — I report on recent work at Imperial College London, with laser cooled calcium-40 ion Coulomb crystals in Penning traps. Penning traps provide a number of advantages over the more common radiofrequency (RF) trap; namely the ability to trap 3-dimensional, micromotion-free ion Coulomb crystals, and the ability to produce deep traps while maintaining a large ion-electrode surface distance. While these factors should permit lower heating rates than in typical RF traps, very little research has been conducted into the behavior and control of small Coulomb crystals in Penning traps due to the experimental challenges involved. We have spent several years developing techniques to overcome these obstacles, and are now making rapid progress towards the sub-Doppler cooling and coherent control of small ion crystals. We have already observed high resolution optical spectra showing sidebands due to radial and axial motions, giving estimated temperatures close to the Doppler limit.

4:42PM W40.00012 Rapid ion cooling by controlled collision , HOI KWAN LAU, University of Toronto — I propose a method to cool trapped ions by controlled collisions. Motional excitation of a hot ion is transferred to a coolant ion due to Coulomb interaction when they are brought to proximity. The whole process can be conducted diabatically, involving only a few oscillation periods of the harmonic trap. Our proposal is useful for rapid recooling of ion qubits during quantum computation and fast cooling of an ion whose mass is significantly different from the coolant ion.

Thursday, March 21, 2013 2:30PM - 5:30PM –

Session W41 DAMOP: Bose Gauge Fields 350 - Mark Edwards

2:30PM W41.00001 3D quaternionic condensation and spin textures with Hopf invariants from synthetic spin-orbit coupling[1] , CONGJUN WU, YI LI, Department of Physics, University of California, San Diego, XIANGFA ZHOU, Key Laboratory of Quantum Information, University of Science and Technology of China, CAS, Hefei, Anhui 230026, China — We study unconventional condensations of two-component bosons in a harmonic trap subject to the 3D $\vec{\sigma} \cdot \vec{p}$-type spin-orbit (SO) coupling. The topology of condensate wavefunctions manifests in the quaternionic representation. The spatial distributions of the S^3 quaternionic phase exhibit 3D skyrmion configurations, while those of the S^2 spin orientation possess non-zero Hopf invariants. As increasing SO coupling strength, spin textures evolve from concentric distributions to lattice structures at weak interactions. Strong interactions change condensates into spin-polarized plane-wave states, or, superpositions of two plane-waves exhibiting helical spin spirals.

2:42PM W41.00002 Rashba Spin-Orbit Coupled Bose-Einstein Condensates with Magnetic Dipole-Dipole Interactions , RYAN WILSON, BRANDON ANDERSON, CHARLES CLARK, Joint Quantum Institute, National Institute of Standards and Technology and University of Maryland, Gaithersburg, MD 20899, USA — In this talk we consider the effect of Rashba spin-orbit coupling on a quasi-two dimensional Bose-Einstein Condensate with dipolar interactions. The interplay of the spin-orbit coupling, which favors textured and vortex-antivortex lattice ground states, and the dipole-dipole interaction, which introduces non-local spin-exchange processes and a strongly geometry-dependent interaction character, leads to a variety of novel ground states including combinations of spin and purely motional vortices. With the assistance of a numerical Bogoliubov-de Gennes analysis, we map the relevant phase boundaries, thereby characterizing the rich ground-state phase diagram of this system.

2:54PM W41.00003 Exotic Quantum States of Rashba Bosons , TIGRAN SEDRAKYAN, ALEX KAMENEV, Fine Theoretical Physics Institute, University of Minnesota, LEONID GLAZMAN, Department of Physics, Yale University — The recently discovered spin-orbit coupled boson systems are remarkable for their capacity to explore physics that may not be revealed in any other way. The spin-orbit couplings, which can be artificially engineered in cold-atom experiments, in many instances lead to single-particle dispersion relations exhibiting multiple minima or even degenerate manifold of minimal energy states. It is entirely the effect of collisions (i.e. boson-boson interactions) which lifts this degeneracy and leads to an amazing variety of completely new quantum many-body states. This talk describes a theoretical discovery of a novel phase of matter that realizes for Rashba spin-orbit coupled bosons, where, at low densities, bosons essentially redress themselves and behave as fermions. This state is a composite fermion state with a Chern-Simons gauge field and filling factor one.

3:06PM W41.00004 Exotic Quantum Spin Models in Spin-Orbit-Coupled Mott Insulators , JURAJ RADIC, University of Maryland, College Park, ANDREA DI CIOLO, University of Maryland, College Park and Georgetown University, KAI SUN, University of Maryland, College Park and University of Michigan, Ann Arbor, VICTOR GALITSKI, University of Maryland, College Park — We study cold atoms in an optical lattice with synthetic spin-orbit coupling in the Mott-insulator regime. We calculate the parameters of the corresponding tight-binding model using Peierls substitution and "localized Wannier states method" and derive the low-energy spin Hamiltonian for bosons and fermions. The spin Hamiltonian is a combination of Heisenberg model, quantum compass model and Dzyaloshinskii-Moriya interactions and it has a rich classical phase diagram with collinear, spiral and vortex phases. We discuss the state of the art of experiments to realize and detect magnetic orderings in strongly correlated optical lattices.

3:18PM W41.00005 The Fate of Bose-Einstein Condensate in the Presence of Spin-orbit Coupling , QI ZHOU, Department of Physics, The Chinese University of Hong Kong, XIAOLING CUI, Institute for Advanced Study, Tsinghua University, Beijing — We show that spin-orbit coupling can destroy a Bose-Einstein condensate. For non-interacting bosons, some types of spin-orbit coupling destroy a condensate at any finite temperature or even at the ground state, due to the drastic change of single-particle Density of States at low energies. Whereas interaction stabilizes the condensate at zero temperature, condensate depletion is significantly enhanced by spin-orbit coupling. Particularly, thermal depletion becomes divergent when both interaction and spin-orbit coupling become isotropic, leading to the disappearance of a three-dimensional condensate at any finite temperature.

3:30PM W41.00006 Emergence of Topological and Strongly Correlated Ground States in Rashba Spin-Orbit Coupled Bose Gases[1] , B. RAMACHANDHRAN, Rice University, Houston, TX 77005, USA, HUI HU, Swinburne University of Technology, Melbourne 3122, Australia, HAN PU, Rice University, Houston, TX 77005, USA — We theoretically study an interacting few-body system of two-component Bose gases with isotropic Rashba spin-orbit coupling in a 2D isotropic harmonic trap. We show that the Hamiltonian is gauge-equivalent to particles subject to a pure non-abelian vector potential preserving time-reversal symmetry. We use Exact Diagonalization scheme to obtain the low-energy states of the system with large Rashba spin-orbit coupling strength for a range of interatomic interaction strengths. At small particle numbers, we observe that the bosons condense to an array of topological ground states that have $n + 1/2$ -quantum angular momentum vortex configuration, with $n = 0, 1, 2, 3$. At relatively large particle numbers, we observe two distinct regimes: (a) at weak interaction strengths (mean-field regime), we observe ground states with topological and symmetry properties that are also obtained via mean-field theory computations. (b) at intermediate to strong interaction strengths (beyond mean-field regime), we report the emergence of strongly correlated ground states. We analyze ground state properties using various techniques: energy spectrum, density distribution, pair-correlation function, conditional wavefunction, entanglement spectrum, and entanglement entropy.

[1]We acknowledge support by the NSF (PHY-1205973), the Welch Foundation (Grant No. C-1669) and the DARPA OLE program.

3:42PM W41.00007 Many-body ground states for bosons with Rashba spin-orbit coupling[1] , WILLIAM COLE, Department of Physics, the Ohio State University, SHIZHONG ZHANG, Department of Physics and Center of Theoretical and Computational Physics, the University of Hong Kong, ZHENHUA YU, Institute for Advanced Study, Tsinghua University, NANDINI TRIVEDI, Department of Physics, the Ohio State University — The ground state of N non-interacting bosons with a Rashba dispersion is macroscopically degenerate. It is of fundamental interest—and also relevant to current experiments in cold atomic gases with synthetic spin-orbit coupling—to determine whether a unique ground state is stabilized by interactions and what the properties of such a state might be. Motivated by exact solutions for the two-body problem, we construct many-body bosonic wave functions that saturate the kinetic energy and minimize the interaction energy, and compare with other recently proposed trial ground states.

[1]W.S.C. and N.T. acknowledge support from NSF DMR-0907275

3:54PM W41.00008 Flat-band engineering of interactions in spin-orbit coupled optical lattices[1] , FEI LIN, VITO SCAROLA, Virginia Tech — The recent experimental realization of spin-orbit coupled ultra cold atomic gases established a new platform to investigate many-body states of matter. In this talk we show that for such a system in optical lattices we can tune the spin-orbit coupling to achieve a flat energy band. We then model this system with a tight-binding Hamiltonian and further project the Hamiltonian to the Hilbert subspace of the lowest flat band. We will also discuss the important effect of interactions in such a projected flat-band system.

[1]This work is supported by AFOSR (FA9550-11-1-0313) and DARPA-YFA (N66001-1-1-4122).

4:06PM W41.00009 Bosons on the Kagome lattice with artificial gauge fields , ALEXANDRU PETRESCU, Yale University and Center For Theoretical Physics (CPHT), Ecole Polytechnique, S.M. GIRVIN, Yale University, KARYN LE HUR, Center For Theoretical Physics (CPHT), Ecole Polytechnique and CNRS, 91128 Palaiseau France — We investigate bosons on the Kagome lattice subject to artificial gauge fields such that no net flux is applied on a unit cell [1]. This allows for example the existence of quantized and non-quantized anomalous Hall effects on the Kagome lattice [2]. If two layers or two-component bosons are introduced, the topological phase is robust to inter-species interactions of moderate strength. We study the conditions under which the total density degree of freedom undergoes a Mott transition, while the pseudo-spin, or charge difference between layers, is in a superfluid phase with topological properties. Similar results can be obtained for two-component bosons on the honeycomb lattice. Such systems could work as a template for the realization of interacting topological phases in cold atom or cavity QED systems.

4:18PM W41.00010 A spin Hall effect in a quantum gas , MATTHEW BEELER, ROSS WILLIAMS, KARINA JIMENEZ-GARCIA, LINDSAY LEBLANC, ABIGAIL PERRY, IAN SPIELMAN, Joint Quantum Institute, National Institute of Standards and Technology and University of Maryland — The spin Hall effect is a phenomenom that couples spin current to particle current via spin-orbit coupling. The effect may be used to develop useful devices for spintronics, which may have advantages over corresponding conventional electronic devices. In addition, the spin-Hall effect is intimately related to certain types of topological insulators. Spin-orbit coupling in an ultracold bosonic sample of ^{87}Rb has been demonstrated. We now use this spin-orbit coupling to produce a spin Hall effect in a bosonic sample, the first demonstration of the effect in an ultracold atom system.

4:30PM W41.00011 Experiments on BECs with Synthetic Gauge Fields and Spin Orbit Coupling , ROBERT NIFFENEGGER, ABRAHAM OLSON, YONG P. CHEN, Purdue University, QUANTUM MATTER AND DEVICES TEAM — We report experiments on ^{87}Rb BECs subject to synthetic gauge fields and spin orbit interactions created by optical Raman fields that couple different hyperfine spin and momentum states. We have reproduced several recently shown results of the effects of such synthetic gauge potentials by characterizing the quasimomentum of the dressed states. We have also observed a spin Hall-like effect on our BECs in a spatially inhomogeneous synthetic spin orbit coupling. We create BECs with equal populations of $|F = 1, m_F = -1 >$ and $|F = 1, m_F = 0 >$, representing a pseudo spin 1/2 system, and launch them into a common mode oscillation within an optical dipole trap. When an inhomogeneous spin orbit coupling Raman field is applied, they exhibit an anticorrelated transverse oscillation, manifesting in cyclotron motions of opposite chirality. Measurements of such a spin dependent transport versus the intensity and detuning of the Raman coupling and versus the position of the BEC are also presented with discussions of possible interpretations.

4:42PM W41.00012 Measuring the Berry Curvature of Optical Lattices , HANNAH PRICE, NIGEL COOPER, University of Cambridge — New schemes propose how artificial gauge fields may be imprinted on ultracold atomic gases in optical lattices, allowing experiments to access strongly correlated phenomena. In particular, fractional quantum Hall physics may be explored in systems where the lowest energy band resembles a Landau level, as in the proposed "optical flux lattices". These energy bands have a nonzero Chern number and are topologically nontrivial. The physical properties of such a band are encoded not only in its energy spectrum over the Brillouin zone (the "bandstructure" in the usual sense) but also importantly, in its Berry curvature. When the Berry curvature is nonzero, it can have many important physical consequences; for example it can modify the semiclassical dynamics of a wave packet undergoing Bloch oscillations. We will explain how experimentalists may turn such physical consequences into new tools to determine the topological properties of a band. We will discuss how Berry curvature effects may be observed in ultracold gases and give examples in systems relevant to future experiments. [H. M. Price and N. R. Cooper, Phys. Rev. A 85, 033620 (2012)]

4:54PM W41.00013 Controllable Transport of Ultra-Cold Atoms in 1D Optical Lattices with Uniform Peierls Substitution[1] , CHIH-CHUN CHIEN, Los Alamos National Laboratory, MASSIMILIANO DI VENTRA, University of California, San Diego — We show that the recently developed optical lattices with Peierls substitution (PRL 108, 225303 and 225304 (2012)) – which can be modeled as a lattice with a complex tunneling coefficient – may be used to induce quantum transport of ultra-cold atoms. In particular, we show that by ramping up the phase of the complex tunneling coefficient in a spatially uniform fashion, a finite quasi steady-state current (QSSC) ensues from the exact dynamics of non-interacting fermions. The direction and magnitude of the current can be controlled by the overall phase difference but not the details of the ramp. The entanglement entropy does not increase when the QSSC lasts. Due to different spin statistics, condensed non-interacting bosons do not support a finite QSSC under the same setup. We also find that an approximate form of the QSSC survives when perturbative effects from interactions, weak harmonic background traps, and temperature are present, which suggests that our findings should be observable with available experimental capabilities. Our study could be useful in developing novel devices in the thriving field of atomtronics.

[1]This work is partly suppored by US DOE.

5:06PM W41.00014 Phase Transitions and Collective Modes in Spin-Orbit Coupled Bose-Einstein Condensates[1] , QIN-QIN LU, DANIEL E. SHEEHY, Louisiana State University — Recent experiments on trapped bosonic atomic gases interacting with Raman lasers have realized an artificial spin-orbit coupling (SOC) among two dressed spin states of bosons. The phase diagram of this system, as a function of the interaction parameters, strength of SOC, and the densities of the two species of bosons, possesses regimes of mixed superfluid (featuring two interpenetrating dressed-state condensates), and phase separation (between regions of single dressed-state condensate). We present our results on the Bogoliubov sound velocity in the mixed phase, and propose that it can be used as a probe of the spatially-varying density (i.e. stripe order) of the mixed phase as well as of the phase transition to the phase separation regime. The effects of the trapping potential are also discussed.

5:18PM W41.00015 Phase-modulated superfluids of bosons in spin-orbit coupled optical lattice , YINYIN QIAN, MING GONG, The University of Texas at Dallas, VITO SCAROLA, Virginia Tech, CHUANWEI ZHANG, The University of Texas at Dallas — We study the phase diagram of spin-orbit coupled ultra-cold bosons in a square lattice using the Gutzwiller method. In the superfluid regime, we show that the interplay between spin independent and spin-dependent tunnelings may give rise to a few different types of phase-modulated superfluids. The transitions between different superfluids are found to be the first-order. We investigate the rich periodic structure of the phases of the superfluids, which may be directly probed using the spin structure factor. Different types of superfluids may also possess different excitation spectra.

Thursday, March 21, 2013 2:30PM - 5:06PM –

Session W42 DCP: Focus Session: Supercooled and Nanoconfined Water IV Hilton Baltimore Holiday Ballroom 3 - Valeria Molinero, University of Utah

2:30PM W42.00001 Freezing of supercooled water nanodroplets[1] , BARBARA WYSLOUZIL, The Ohio State University — All three states of water play important roles in nature, from thermostating the atmosphere to providing reactive surfaces environments. The rates at which transitions between the phases occur, the degree to which pure liquid water can be supercooled, and the solid phases that form are all fundamentally interesting questions with strong atmospheric relevance. We have followed and characterized the nucleation, growth, and subsequent freezing of pure water droplets formed in a supersonic nozzle apparatus using both Small Angle X-ray Scattering (SAXS) and Fourier Transform Infrared Spectroscopy (FTIR). Because the droplets have radii r between 3 nm and 6 nm, and the cooling rates are on the order of 5E5 K/s, liquid water only begins to freeze below approximately 215 K. These temperatures are well below the homogeneous freezing limit for bulk water. The experiments show the expected decrease in freezing temperature with decreasing droplet size, or alternatively, with increasing droplet internal pressure.

[1]This work was supported by the National Science Foundation under Grant number CHE-0911144.

3:06PM W42.00002 Probing no man's land: ice nucleation at the nanoscale , TIANSHU LI, Department of Civil and Environmental Engineering, George Washington University — Nucleation is a stochastic process. At a given thermodynamic condition, nucleation events occur at a frequency that scales with the volume of the system. Therefore at the nanoscale, *e.g.*, in nano droplets, one may expect to obtain supercooled liquids below the bulk homogeneous nucleation temperature. However it is not clear to what extent would nucleation in nano droplet be connected with bulk water. In this talk, I will discuss the insight gained from our recent molecular simulations on ice nucleation at nanoscale. In particular, the study provides direct computational evidence for size-dependent ice nucleation rate within supercooled water nano droplets. Using a thermodynamic model based on classical nucleation theory, I will show that it is the Laplace pressure induced by the curved liquid vapor interface present in droplets that is responsible for the suppression of ice crystallization. Consistent with this model, our simulations show that the nucleation rates found for droplets are similar to those of liquid water subject to a pressure of the order of the Laplace pressure within droplets. The findings thus provide a link between supercooled bulk water and nano droplet through ice nucleation rate. In addition, the findings also support the hypothesis of surface crystallization of ice in microscopic water droplets in clouds.

3:42PM W42.00003 Experimental Observation of Bulk Liquid Water Structure in "No Man's Land"[1] , JONAS SELLBERG, TREVOR MCQUEEN, CONGCONG HUANG, SSRL, SLAC, DUANE LOH, HARTAWAN LAKSMONO, RAYMOND SIERRA, CHRISTINA HAMPTON, DMITRI STARODUB, PULSE, SLAC, DANIEL DEPONTE, ANDREW MARTIN, ANTON BARTY, CFEL, DESY, THOR WIKFELDT, DANIEL SCHLESINGER, LARS PETTERSSON, Physics Department, Stockholm University, MARTIN BEYE, DENNIS NORDLUND, THOMAS WEISS, SSRL, SLAC, JAN FELDKAMP, CHIARA CARONNA, MARVIN SEIBERT, MARC MESSERSCHMIDT, GARTH WILLIAMS, SEBASTIEN BOUTET, LCLS, SLAC, MICHAEL BOGAN, PULSE, SLAC, ANDERS NILSSON, SSRL, SLAC — Experiments on pure bulk water below about 235 K have so far been difficult: water crystallization occurs very rapidly below the homogeneous nucleation temperature of 232 K and above 160 K, leading to a "no man's land" devoid of experimental results regarding the structure. Here, we demonstrate a new, general experimental approach to study the structure of liquid states at supercooled conditions below their limit of homogeneous nucleation. We use femtosecond x-ray pulses generated by the LCLS x-ray laser to probe evaporatively cooled droplets of supercooled bulk water and find experimental evidence for the existence of metastable bulk liquid water down to temperatures of 223 K in the previously largely unexplored "no man's land".

[1]We acknoweledge NSF (CHE-0809324), Office of Basic Energy Sciences, and the Swedish Research Council for financial support.

3:54PM W42.00004 Glass softening, crystallization, and vaporization of nano-aggregates of Amorphous Solid Water: Fast Scanning Calorimetry studies[1] , DEEPANJAN BHATTACHARYA, LIAM O'REILLY, VLAD SADTCHENKO, The George Washington University — Despite intense efforts, complete understanding of relationships between various condensed phases of water remains an elusive goal. In particular, the molecular kinetics and phase transitions of water in confining geometries (e.g., nano-scale films) are of special interest due to the relevance to environmental and biological processes. With the objective of gaining insights into fundamental distinctions in physical and chemical properties of confined water, we have developed an experimental approach which relies on rapid (10^5 K/s) heating of nanoscale films of Amorphous Solid Water (ASW) prepared by vapor deposition in vacuum at cryogenic temperatures. With recent advances, the approach, Fast Scanning Calorimetry (FSC), facilitates studies of glass softening, crystallization, and vaporization of ASW films with thicknesses down to two nanometers. Unlike bulk samples, the thermograms of ultrathin ASW films show two endotherms at 40 and 10 K below the onset temperatures of crystallization. We will report the conclusion of our analysis of the FSC thermograms of nanoscale ASW aggregates, and discuss the implications of these studies for developing better models of molecular kinetics of water in confining geometries.

4:06PM W42.00005 Temperature dependence of the Oxygen-Oxygen separations in water from high energy x-ray diffraction , LAWRIE SKINNER, Stony Brook Univ. & Argonne Nat. Lab., CHRIS BENMORE, Argonne National Laboratory, JOHN PARISE, Stony Brook University — We have used state of the art, high energy x-ray diffraction to obtain detailed measurements of the Oxygen-Oxygen (O-O) pair distribution function (g(r)) of liquid water between -20 and 92 degrees Celsius. These measurements show ordinary linear behavior of the first O-O distance, over the full temperature range, even through the density maximum. Conversely we do see interesting, non-linear behavior in the O-O distribution at higher separations distances, particularly around the 4.5Å peak. Another interesting feature of these measurements is the presence of a temperature-independent crossover point in the running O-O coordination number at the location of the first minimum in r^2[g(r)-1], which defines the end of the first shell. At this 3.4(1)Å distance the O-O coordination number is 4.5(2) at all the temperatures studied. We believe this work offers important insight into some of the unusual physical properties of water, and provides a valuable validation point for the many Molecular dynamics models of liquid water.

4:18PM W42.00006 The structure of ice crystallized from supercooled water[1] , BENJAMIN MURRAY, University of Leeds — The freezing of water to ice is fundamentally important to fields as diverse as cloud formation to cryopreservation. Traditionally ice was thought to exist in two well-crystalline forms: stable hexagonal ice and metastable cubic ice. It has recently been shown, using X-ray diffraction data, that ice which crystallizes homogeneously and heterogeneously from supercooled water is neither of these phases. The resulting ice is disordered in one dimension and therefore possesses neither cubic nor hexagonal symmetry and is instead composed of randomly stacked layers of cubic and hexagonal sequences. We refer to this ice as stacking-disordered ice I (ice I_{sd}). This result is consistent with a number of computational studies of the crystallization of water. Review of the literature reveals that almost all ice that has been identified as cubic ice in previous diffraction studies and generated in a variety of ways was most likely stacking-disordered ice I with varying degrees of stacking disorder, which raises the question of whether cubic ice exists. New data will be presented which shows significant stacking disorder (or stacking faults on the order of 1 in every 100 layers of ice I_h) in droplets which froze heterogeneously as warm as 257 K. The identification of stacking-disordered ice from heterogeneous ice nucleation supports the hypothesis that the structure of ice that initially crystallises from supercooled water is stacking-disordered ice I, independent of nucleation mechanism, but this ice can relax to the stable hexagonal phase subject to the kinetics of recrystallization. The formation and persistence of stacking disordered ice in the Earth's atmosphere will also be discussed.

4:54PM W42.00007 Investigation of water-graphite interaction using molecular beam technique. , NOBUYA MIYOSHI, SHOHEI HODOTA, KENICHI OSUKA, IKUYA KINEFUCHI, SHU TAKAGI, YOICHIRO MATSUMOTO, The University of Tokyo, Department of mechanical engineering — We have investigated water scattering from a graphite surface using the molecular beam technique. The time-of-flight and angular distributions of the scattered molecules were measured at the incident energy lower than 100 meV with the surface temperature of 300 K. As the incident energy decreases from 35 to 130 meV, adsorption-desorption component increases in the time-of-flight distributions. At the incident energy of 35 meV, the angular flux distribution deviates from lobular pattern and approaches to cosine distribution. The final energy of the scattered molecules at the incident energy of 35 meV becomes less dependent on the scattering angle than at the incident energy of 130 meV. These results confirm that the reduction of the incident energy from 130 to 35 meV enhances the accommodation of water molecule to graphite surface.

Session W43 DCP: Chemical Physics of Graphene and Other Crystals Hilton Baltimore Holiday Ballroom 2 - Jeff Cina, University of Oregon

2:30PM W43.00001 Mullite Ceramics at Extreme Conditions[1] , PATRICIA KALITA, ANDREW CORNELIUS, Dept. of Physics and Astronomy, University of Nevada Las Vegas, Las Vegas, NV, USA, KRIS LIPINSKA, OLIVER HEMMERS, Harry Reid Center for Environmental Studies, University of Nevada Las Vegas, NV, USA, STANISLAV SINOGEIKIN, Geophysical Lab., Carnegie Institution of Washington, Washington, DC, USA, REINHARD FISHER, Department of Geosciences, University of Bremen, Bremen, Germany, HARTMUT SCHNEIDER, Institute of Crystallography, University of Koeln, Koeln, Germany — Mullite is perhaps one of the most important phases in both traditional and advanced ceramics and thus one of the most widely studied ceramic phases. Even though the thermo-elastic behavior of mullites have been studied extensively (spectroscopy, diffraction, dilatometry, theoretical simulations), there are only few studies into the effects of pressure on mullites. This work aims at filling this gap by examining the role of oxygen vacancies on the mechanical stability and on the bulk modulus of mullite-type structures.

2:42PM W43.00002 Chemical structure of multilayer oxidized epitaxial graphene , SI ZHOU, ANGELO BONGIORNO, Georgia Institute of Technology — In this work, density functional theory (DFT) calculations are used to interpret new X-ray photoelectron spectroscopy (XPS), X-ray diffraction (XRD), and atomic force microscope (AFM) measurements of the oxide of epitaxial graphene. This layered carbon material is obtained by Hummers oxidation of 6- to 17-layer graphene films grown epitaxially at high temperature on a silicon carbide substrate. The extensive DFT calculations carried out to solve the inverse problem posed by the aforementioned measurements show that a most plausible molecular structure for the oxide of epitaxial graphene consists of mildly oxidized graphene layers covalently bridged by short polyoxymethylene chains. Possible chemical reactions leading to this form of graphene derivative are discussed.

2:54PM W43.00003 ABSTRACT WITHDRAWN –

3:06PM W43.00004 Study on Hydrogen Interaction with Graphene, Graphene Hydroxide, and Lithiated Graphene , S. ADAK, University of Tennessee, A.I. ACATRINEI, L.L. DAEMEN, Los Alamos National Laboratory, B. ESTES, University of Tennessee, M.H. HARTL, Los Alamos National Laboratory, J.Z. LARESE, University of Tennessee — Neutron vibrational spectroscopy, together with adsorption isotherm measurements, has been employed to investigate interaction of hydrogen with graphene, hydroxylated graphene, and lithium incorporated graphene. The adsorption studies of hydrogen on these materials indicate varying degrees of hydrogen storage capacity. Graphene is found to have significantly higher hydrogen uptake than graphite and graphite oxide. Neutron vibrational spectroscopy provides direct information concerning hydrogen dynamics including the occurrence of the rotational mode at 119 cm-1; slightly below the free rotor position observed for H2 rotation on graphite. We have also explored how the interaction of hydrogen changes when hydroxyl groups are attached onto the graphene surface and when lithium is incorporated into graphene. The outcome of these studies will also be discussed.

3:18PM W43.00005 Superpermeability of water through graphene based membranes , RAHUL RAVEENDRAN NAIR, RAKESH JOSHI, School of Physics and Astronomy, University of Manchester, HENGAN WU, CAS Key Laboratory of Mechanical Behavior and Design of Materials, University of Science and Technology of China, JAYARAM NARAYANAN, IRINA V. GRIGORIEVA, ANDRE K. GEIM, School of Physics and Astronomy, University of Manchester — Permeation through nanometre-pore materials has been attracting unwavering interest due to fundamental differences in governing mechanisms at macroscopic and molecular scales, the importance of water permeation in living systems, and relevance for filtration and separation techniques. One of the most spectacular findings in this field was the observation that carbon nanotubes and other hydrophobic nanocapillaries allow anomalously fast permeation of gases and liquids and, in particular, of water. In this contribution we show that membranes made from graphene oxide which are impermeable to liquids, vapours and gases, including helium, but allow unimpeded permeation of water (H_2O permeates through the membranes at least 10^{10} times faster than He). We attribute these seemingly incompatible observations to a nearly frictionless flow of a monolayer of water through two dimensional capillaries formed by closely spaced graphene sheets. The flow is driven by a large capillary-like pressure and normally limited only by evaporation from the wetted surface of the membranes. The permeation can be stopped by either reducing graphene oxide or inducing a reversible drying transition in low humidity, which narrow nanocapillaries in both cases. I will also give an overview of our latest results on ion permeation through these membranes.

3:30PM W43.00006 Quantification of crumpling in sheet-like nanostructures , PETER BEAUCAGE, DURGESH RAI, GREGORY BEAUCAGE, University of Cincinnati, SIDDHARTH PRADHAN, University of Tennessee — Two-dimensional sheet-like nanostructures have garnered significant scientific interest in recent decade, particularly due to their inherent high specific surface areas (SSAs). Such large SSAs also result in an intrinsic tendency to crumple or fold based on surface interactions under ambient conditions. An understanding of the topological details of such structures has revealed various qualitative features driven by thermodynamics and interfacial chemistry. A scaling model based methodology will be presented which can be utilized to do quantitative analysis using small angle scattering data. A wide range of materials like graphene oxide, membrane layers as well exfoliated sheets of molybdenum oxide and tungsten oxide have been investigated to understand how such quantification may yield a general classification of such materials based on crumpling behavior.

3:42PM W43.00007 Concavity effects on the optical properties of aromatic hydrocarbons[1] , MARILIA J. CALDAS, Institute of Physics, University of Sao Paulo, CATERINA COCCHI, DEBORAH PREZZI, Centro S3, CNR-Istituto Nanoscienze, Italy, ALICE RUINI, Centro S3, CNR-Istituto Nanoscienze, and Dept. of Physics, University of Modena and Reggio Emilia, Italy, ANNALISA FASOLINO, Institute for Molecules and Materials, Radboud University Nijmegen, The Netherlands, ELISA MOLINARI, Centro S3, CNR-Istituto Nanoscienze, and Dept. of Physics, University of Modena and Reggio Emilia, Italy — We address the modifications on the ground and excited state properties of polycyclic aromatic hydrocarbons (PAHs) induced by variations of concavity and π-connectivity. We study three series of PAHs, inspired by experimentally feasible systems, from hydrogen-saturated graphene flakes to concave "buckybowls" related to the formation of fullerene C_{60} and carbon nanotube caps. We work within the framework of Hartree-Fock-based semiempirical methods (AM1 and ZINDO/S), and our results are supported by a generally good agreement with the available data. We see clearly that the interplay between concavity and π-connectivity shifts the bright optical lines to higher energies, and introduces symmetry-forbidden dark excitations at low energy [1]. These features can be the basis for designing optical properties of novel curved aromatic molecules.

4:06PM W43.00009 Giant Fullerenes for Target Specific Drug Delivery[1] , ROBERT COURTNEY, BORIS KIEFER, New Mexico State University — Carbon nano-structures, such as giant fullerenes, have a great potential for biological and medical applications. Most of the previous research is dedicated to investigate the use of fullerenes as vehicles for carrying medication which is chemisorbed on the outside surface of the fullerenes. In contrast, using fullerenes as an enclosure was largely abandoned due to the high strength of the carbon-carbon bonds which has been perceived to prevent the rupturing of the fullerene to release their cargo. We performed atomistic computations based on classical force fields that will address this perception. Specifically we explore the physics and chemistry of OH functionalized carbon based giant fullerenes with diameters from 0.72 nm (60 atoms) to 5.7 nm (3840 atoms). The preliminary results show that OH functionalization on these fullerenes is not only viable but also provides a pH sensitive release mechanism. Furthermore our current results show that carbon-carbon bonds can be broken in low energy biological environments in the presence of a flow induced strain field. These insights may have implications for target specific drug delivery in general and cancer treatment in particular.

4:18PM W43.00010 Photo-Electron Injection into TiO2: Quantum Dot vs. Graphene[1] , RUN LONG, University College Dublin — We presented a detailed comparison on the similalaries and differences of the ultrafast photoinduced electron transfer (ET) from two kinds of donor species, namely PbSe quantum dot (QD) and graphene, into the acceptor TiO_2 surface via *ab initio* time domain density functional theory simulations. The main diffrences stem from the size and dimensionality of the donor species and donor-acceptor bonding characteristics. For exmaple, the QD is localized species and composed by heavy atoms that connected to TiO_2 surface via chemical bonds. In contrast, the graphene layer is delocalized two-dimensional object that attached to TiO_2 substrate by van der Waals interaction and partial chemical bonds. The ET mechanism depends on the dimensionality of the donor and donor-acceptor chemical bonding. The injection from the localized donor states of the QD is dominatly adiabatic. In contrast, the injection from the two-dimensional graphene into TiO_2 exhibits prominently nonadiabatic (NA) component. The NA mechanism is efficient for the graphene/TiO_2 composites because it is delocalized over two dimensions and is able to couple with a dense manifold of delocalized TiO_2 conduction band states and weak coupling as well. The high density of acceptor states in this case favors the NA mechanism.

4:30PM W43.00011 Lattice dynamics of cubic $CaSiO_3$ perovskite at high temperatures and pressures[1] , TAO SUN, DONG-BO ZHANG, RENATA M. WENTZCOVITCH, Department of Chemical Engineering and Materials Science, University of Minnesota — Cubic $CaSiO_3$-perovskite is a minor but important phase of the Earth's lower mantle. It is a mechanically unstable phase at low temperatures but it is stabilized at lower mantle temperatures. We have investigated its vibrational properties at high pressures and temperatures of the lower mantle. We have projected ionic velocities from ab initio molecular dynamics trajectories onto vibrational normal modes and computed the mode-mode correlation function from which we extract phonon frequencies and life times at finite temperatures. These correlations clearly indicate that normal modes with imaginary frequencies at 0 K are stabilized with increasing temperature. To overcome the finite size effect inherent in molecular dynamics simulations, a renormalized second-order force constant matrix in real space is constructed from the phonon frequencies at finite temperature and the phonon polarization vectors. Phonon dispersions and vibrational density of states are then determined by Fourier interpolation using the renormalized force matrix. These temperature dependent dispersions allow us to investigate thermodynamics and thermal elastic properties at lower mantle conditions.

4:42PM W43.00012 *In situ* neutron diffraction study of SII CO deuterohydrate clathrate , JINLONG ZHU, LANSCE-LC, Los Alamos National Laboratory, SHIYU DU, T-Division, Los Alamos National Laboratory, XIAOHUI YU, LANSCE-LC, Los Alamos National Laboratory, HONGWU XU, EES, Los Alamos National Laboratory, SVEN VOGEL, LANSCE-LC, Los Alamos National Laboratory, CHANGQING JIN, Institute of Physics, Chinese Academy of Sciences, YUSHENG ZHAO, HiPSEC, University of Nevada — SII CO clathrate has been successfully synthesized at $\sim$ 100 bar and 252 K. During the synthesis process, SI CO clathrate was formed first as an intermediate phase and then transformed to SII clathrate. Structural parameters of SII CO clathrate at temperatures from 25 K to 260 K have been determined from Rietveld analysis of neutron diffraction data. With decreasing temperature, the decrease of lattice parameter can be described by a two-order polynomial thermal expansion equation. The molecular lengths of CO in the small and large cages decrease linearly with decreasing temperature. There is one CO molecule in each small cage, whereas two CO molecules occupy in each large cage. CO molecules are not localized at the cage centers. Rather, they exhibit disordered distributions in both small and large cages, while the CO in small cage shows a donut shape nuclear distributions around the cage center, the CO in large cage delocalized from the cage center and more disordered with increasing temperature.

4:54PM W43.00013 Study of growth mechanism and atomic structure of Au-Pd core-shell nanocube by Cs-corrected scanning transmission electron microscopy[1] , NABRAJ BHATTARAI, GILBERTO CASILLAS, J. JESUS VELAZQUEZ SALAZAR, ARTURO PONCE, MIGUEL JOSE-YACAMAN, The University of Texas at san Antonio — Au-Pd core-shell nanocubes of controlled sizes from 14 nm to 30 nm were synthesized using seed mediated growth process. The Pd shell layers were controlled from some monolayers to 10 nm. The stepwise growth mechanism from nucleation and growth of Au nanoparticles to final core-shell nanocube was studied by using conventional transmission electron microscopy (TEM) and Cs-corrected scanning transmission electron microscopy (STEM). It was found that the nanocubes grew from octahedral Au seeds due to fast growth along <111> directions and concavity occurred because of high reduction rate of ascorbic acid (AA). The concave nanocube showed a change in strain-release mechanism as the Pd shell grew from a few layers to a 30 nm nanocube. Shockley partial dislocations (SPD), stacking faults (SF) and edge dislocations were found to be the mechanism to release the mismatch strain. The smallest size nanocube with HIFs will be suitable in order to maximize the catalytic activity per unit weight and mass specific activity.

5:06PM W43.00014 Study of B1 (NaCl-type) to B2 (CsCl-type) pressure-induced structural phase transition in BaS, BaSe and BaTe using first-principles computations[1] , SANJAY KHARE, Dept. of Physics, University of Toledo, XIUQUAN ZHOU, Dept. of Chemistry, University of Toledo, JASON L. ROEHL, Dept. of Physics, University of Toledo, CORA LIND, Dept. of Chemistry, University of Toledo — We have studied the pressure-induced phase transitions from NaCl-type (B1) to CsCl-type (B2) structure in BaS, BaSe and BaTe by using *ab initio* density functional theory computations in the local density approximation. The Buerger and WTM[2] mechanisms were explored by mapping the enthalpy contours in two and four dimensional configuration space for the two mechanisms, respectively. Transition pressures for BaS, BaSe and BaTe were determined to be 5.5 GPa, 4.9 GPa and 3.4 GPa, respectively. From these configuration space landscapes, a low enthalpy barrier path was constructed for the transitions to proceed at three different pressures. We obtained barriers of 0.18, 0.16 and 0.15 eV/pair (17.4, 15.4 and 14.5 kJ/mol) for the Buerger mechanism and 0.13, 0.13 and 0.12 eV/pair (12.5, 12.5 and 11.6 kJ/mol) for the WTM mechanism at the transition pressures for BaS, BaSe and BaTe, respectively, indicating that the WTM mechanism is slightly more favorable in these compounds. We describe the difference of the two mechanisms by differences in their symmetry and atomic coordination.

5:18PM W43.00015 The quasi-Bragg law, transforming the icoshedral diffraction pattern onto a hierarchic structure , ANTONY BOURDILLON, UHRL — Previously, we have demonstrated [1]: 1) The golden section τ is as fundamental to the icosahedral structure (length /edge) as π is to the sphere (circumference /diameter). 2) The diffraction series are in restricted Fibonacci order because the ratio of adjacent terms f_n/f_{n-1} does not vary, but is the constant τ. The series is therefore geometric. 3) The matrix fcc Al is an approximant for i-Al_6Mn. 4) A three dimensional stereographic projection and a quasi-Bragg law are derived, correctly representing the diffraction series in powers of τ [2], without redundancy. 5) By the normal conventions of electron microscopy, the diffraction patterns are completely indexed in three dimensions. Now we describe significant consequences: 1) The diffraction pattern intensities near all main axes are correctly simulated, and all atoms are located on a specimen image. 2) The quasi-Bragg law has a special metric that we have measured. Atomic locations are consistently calculated for the first time. 3) Whereas the Bragg law transforms a crystal lattice into a reciprocal lattice in diffraction space, the quasi-Bragg law transforms a geometric diffraction pattern into a hierarchic structure. 4) Hyperspatial indexation [3] is superceded.

2:30PM W44.00001 Computational and physiological mechanisms of sensory-motor processing , LESLIE OSBORNE, Neurobiology, U of Chicago — No abstract available.

3:06PM W44.00002 Dimentionality and behavior of swimming Zebrafish: "The EigenFish" , KIRAN GIRDHAR, MARTIN GRUEBELE, YANN CHEMLA, University of Illinois at Urbana Champaign — How simple is the underlying control mechanism for the complex locomotion of vertebrates? To answer this question, we study the swimming behavior of zebrafish larvae. A dimensionality reduction method (singular value decomposition), in analogy to previous studies of worms, is used to analyze swimming movies of fish. That way, the animals can directly provide us with a minimal set of shapes to describe their motion, rather than us imposing arbitrary coordinates. We show that two low imensional attractors (an ellipse and a distorted ellipse) embedded in a threedimensional space of motion coordinates are sufficient to describe $>$ 95% of the locomotion. We also show that scoots and R-turns, previously thought to be independent behaviors based on qualitative studies, are in fact just extremes of a continuous family of motions bounded by the two attractors.

3:18PM W44.00003 Controlling neural activity in *Caenorhabditis elegans* to evoke chemotactic behavior , ASKIN KOCABAS, CHING-HAN SHEN, Harvard University, ZENGCAI V. GUO, Janelia Farm Research Campus, Howard Hughes Medical Institute, SHARAD RAMANATHAN, Harvard University — Animals locate and track chemoattractive gradients in the environment to find food. With its simple nervous system, *Caenorhabditis elegans* is a good model system in which to understand how the dynamics of neural activity control this search behavior. To understand how the activity in its interneurons coordinate different motor programs to lead the animal to food, here we used optogenetics and new optical tools to manipulate neural activity directly in freely moving animals to evoke chemotactic behavior. By deducing the classes of activity patterns triggered during chemotaxis and exciting individual neurons with these patterns, we identified interneurons that control the essential locomotory programs for this behavior. Notably, we discovered that controlling the dynamics of activity in just one interneuron pair was sufficient to force the animal to locate, turn towards and track virtual light gradients.

3:30PM W44.00004 Quantification of Nociceptive Escape Response in *C.elegans*[1] , KAWAI LEUNG, Department of Physics, Emory University, Atlanta, Georgia, USA, AYLIA MOHAMMADI, Department of Physics, University of Toronto, Toronto, Ontario, Canada, WILLIAM RYU, Department of Physics and The Donnelly Centre, University of Toronto, Toronto, Ontario, Canada, ILYA NEMENMAN, Department of Physics and Department of Biology, Emory University, Atlanta, Georgia, USA — Animals cannot rank and communicate their pain consciously. Thus in pain studies on animal models, one must infer the pain level from high precision experimental characterization of behavior. This is not trivial since behaviors are very complex and multidimensional. Here we explore the feasibility of *C.elegans* as a model for pain transduction. The nematode has a robust neurally mediated noxious escape response, which we show to be partially decoupled from other sensory behaviors. We develop a nociceptive behavioral response assay that allows us to apply controlled levels of pain by locally heating worms with an IR laser. The worms' motions are captured by machine vision programming with high spatiotemporal resolution. The resulting behavioral quantification allows us to build a statistical model for inference of the experienced pain level from the behavioral response. Based on the measured nociceptive escape of over 400 worms, we conclude that none of the simple characteristics of the response are reliable indicators of the laser pulse strength. Nonetheless, a more reliable statistical inference of the pain stimulus level from the measured behavior is possible based on a complexity-controlled regression model that takes into account the entire worm behavioral output.

3:42PM W44.00005 Discovery of stereotypy through behavioral space embedding , GORDON BERMAN, DANIEL CHOI, WILLIAM BIALEK, JOSHUA SHAEVITZ, Princeton University — Most experiments in the neurobiology of behavior rely upon the concept that animals frequently engage in stereotyped movements – behaviors that an animal performs often and with great similarly. While these actions are often the basis for mapping neural circuits and understanding the effects of genetic manipulations, stereotypy is usually defined in an ad hoc manner, thereby limiting the sensitivity and repeatability of subsequent analyses. Moreover, the underlying assumption that an animal's behavior can be described in terms of discrete states typically remains unverified. In this talk, I will describe our novel method for the identification and characterization of stereotyped behaviors. Using the fruit fly *Drosophila melanogaster* as a model organism, we show that it is possible to start from raw videos of a freely-behaving animal and statistically isolate stereotyped movements. Our method achieves this through leveraging ideas from statistical physics, non-linear dynamics, and information theory. The rigorous behavioral metrics resulting from this technique allow us to explore questions in animal behavior ranging from speciation, to aging, to the control of locomotion, thus providing further insight in the interplay between genes, neurons, and behavior.

3:54PM W44.00006 Swarming in disordered environments , AJAY GOPINATHAN, DAVID A. QUINT, University of California Merced — The emergence of collective motion over a wide range of length scales in biology has inspired research in a multitude of disciplines. Possessing only local information, a group of moving individuals can form crowds, swarms or flocks which can traverse the entire system forming a self organized co-moving collective. An important question that arises is: how do these groups deal with environmental disorder? It is rare that perfectly connected homogeneous environments exist in nature and more often biological environments are intrinsically spatially disordered. We investigate the effects of intrinsic disorder or *topological noise* on the formation of collective motion by studying interacting agents on a $2d$ percolated lattice with bond occupation probability p. We find that the existence of collective motion depends critically on p and disappears completely for rather small amounts of disorder. Furthermore, we show that repulsive forces between agents within the swarm can rescue collective motion even for large amounts of topological disorder, suggesting that nearest neighbor alignment alone is not enough for swarms to navigate a disordered environment.

4:06PM W44.00007 Physical limits to gradient sensing by swimming cells , NICHOLAS LICATA, University of Michigan-Dearborn — The chemotactic motion of cells relies on their ability to infer the location of a chemical source from the random arrival of molecules at chemical receptors on the cell surface. Small organisms like bacterial cells generally employ a temporal sensing mechanism to measure spatial gradients in concentration. For example, the bacterium Escherichia coli compares concentrations in time as it swims, and modulates its swimming behavior accordingly to swim up the concentration gradient. Slightly larger eukaryotic cells are able to directly sense spatial gradients of chemicals across their surface. Previous studies have demonstrated that the physical process of diffusion sets a fundamental limit to the accuracy with which cells can sense spatial gradients. However, most of these studies neglect the intrinsic coupling between the sensory task and the behavioral response of swimming. The swimming cell stirs the surrounding fluid, which in turn affects the arrival location of molecules at the cell surface, and hence the inferred spatial gradient. By considering the appropriate advection-diffusion equation for the arrival of molecules at the cell surface, we determine the fundamental physical limit to the accuracy of direct gradient sensing by swimming cells.

4:18PM W44.00008 Measurement of Behavioral Evolution in Bacterial Populations[1] , ROBERT AUSTIN, Princeton University — A curious aspect of bacterial behavior under stress is the induction of filamentation: the anomalous growth of certain bacteria in which cells continue to elongate but do not divide into progeny. We show that *E.coli* under the influence of the genotoxic antibiotic ciprofloxacin have robust filamentous growth, which provides individual bacteria a mesoscopic niche for evolution until resistant progeny can bud off and propagate. Hence, filamentation is a form of genomic amplification where even a single, isolated bacteria can have access to multiple genomes. We propose a model that predicts that the first arrival time of the normal sized progeny should follow a Gompertz distribution with the mean first arrival time proportional to the elongation rate of filament. These predictions agree with our experimental measurements. Finally, we suggest bacterial filament growth and budding has many similarities to tumor growth and metastasis and can serve as a simpler model to study those complicated processes.

4:54PM W44.00009 Environmental engineering simplifies subterranean locomotion control , NICK GRAVISH, DARYA MONAENKOVA, MICHAEL A.D. GOODISMAN, DANIEL I. GOLDMAN, Georgia Institute of Technology — We hypothesize that ants engineer habitats which reduce locomotion control requirements. We studied tunnel construction, and locomotion, in fire ants (*Solenopsis invicta*, body length $L = 0.35 \pm 0.05$). In their daily life, ants forage for food above ground and return resources to the nest. This steady-state tunnel traffic enables high-throughput biomechanics studies of tunnel climbing. In a laboratory experiment we challenged fire ants to climb through 8 cm long glass tunnels (D = 0.1 - 0.9 cm) that separated a nest from an open arena with food and water. During ascending and descending climbs we induced falls by a motion-activated rapid, short, downward translation of the tunnels. Normalized tunnel diameter (D/L) determined the ability of ants to rapidly recover from perturbations. Fall arrest probability was unity for small D/L, and zero for large D/L. The transition from successful to unsuccessful arrest occurred at $D/L = 1.4 \pm 0.3$. Through X-Ray computed tomography study we show that the diameter of ant-excavated tunnels is independent of soil-moisture content (studied from 1-20%) and particle size (50-595 μm diameter), and has a mean value of $D/L = 1.06 \pm 0.23$. Thus fire ants construct tunnels of diameter near the onset of fall instability.

5:06PM W44.00010 Mosh pits and Circle pits: Collective motion at heavy metal concerts , MATTHEW BIERBAUM, JESSE L. SILVERBERG, JAMES P. SETHNA, ITAI COHEN, Cornell University — Heavy metal concerts present an extreme environment in which large crowds ($\sim 10^2 - 10^5$) of humans experience very loud music (~ 130dB) in sync with bright, flashing lights, often while intoxicated. In this setting, we find two types of collective motion: mosh pits, in which participants collide with each other randomly in a manner resembling an ideal gas, and circle pits, in which participants run collectively in a circle forming a vortex of people. We model these two collective behaviors using a flocking model and find qualitative and quantitative agreement with the behaviors found in videos of metal concerts. Futhermore, we find a phase diagram showing the transition from a mosh pit to a circle pit as well as a predicted third phase, lane formation.

5:18PM W44.00011 Lift-off dynamics in a simple jumping robot[1] , JEFFREY AGUILAR, ALEX LESOV, KURT WIESENFELD, DANIEL I. GOLDMAN, Georgia Tech — Jumping is an important behavior utilized by animals to escape predation, hunt, reach higher ground, and as a primary mode of locomotion. Many mathematical and physical robot models use numerous parameters and multi-link legs to accurately model jumping dynamics. However, a simple robot model can reveal important principles of high performance jumping. We study vertical jumping in a simple robot comprising an actuated mass-spring arrangement. The actuator frequency and phase are systematically varied to find optimal performance. Optimal jumps occur above and below (but not at) the robot's resonant frequency f_0. Two distinct jumping modes emerge: a simple jump which is optimal above f_0 is achievable with a squat maneuver, and a peculiar stutter jump which is optimal below f_0 is generated with a counter-movement. A simple dynamical model reveals how optimal lift-off results from non-resonant transient dynamics. An expanded explanation of this work is provided at http://crablab.gatech.edu/pages/jumpingrobot/index.html

2:30PM W45.00001 Gene Location and DNA Density Determine Transcription Factor Distributions in *E. coli*[1]

THOMAS KUHLMAN, University of Illinois at Urbana Champaign, EDWARD COX, Princeton University — The diffusion coefficient of the prototypical transcription factor LacI within living *Escherichia coli* has been measured directly by in vivo tracking to be D = 0.4 μm^2/s. At this rate, simple models of diffusion lead to the expectation that LacI and other proteins will rapidly homogenize throughout the cell. We have tested this expectation of spatial homogeneity by single molecule visualization of LacI molecules non-specifically bound to DNA in fixed cells. Contrary to expectation, we find that the distribution depends on the spatial location of its encoding gene. We demonstrate that the spatial distribution of LacI is also determined by the local state of DNA compaction, and that *E. coli* can dynamically redistribute proteins by modifying the state of its nucleoid. Finally, we show that LacI inhomogeneity increases the strength with which targets located proximally to the LacI gene are regulated. We propose a model for intranucleoid diffusion which can reconcile these results with previous measurements of LacI diffusion.

2:42PM W45.00002 A model for the condensation of the bacterial chromosome by the partitioning protein ParB

CHASE BROEDERSZ, NED WINGREEN, Princeton University — The molecular machinery responsible for faithful segregation of the chromosome in bacteria such as *Caulobacter crescentus* and *Bacillus subtilis* includes the ParABS a.k.a. Spo0J/Soj partitioning system. In *Caulobacter*, prior to division, hundreds of ParB proteins bind to the DNA near the origin of replication, and localize to one pole of the cell. Subsequently, the ParB-DNA complex is translocated to the far pole by the binding and retraction of the ParA spindle-like apparatus. Remarkably, the localization of ParB proteins to specific regions of the chromosome appears to be controlled by only a few centromeric *parS* binding sites. Although lateral interactions between DNA-bound ParB are likely to be important for their localization, the long-range order of ParB domains on the chromosome appears to be inconsistent with a picture in which protein-protein interactions are limited to neighboring DNA-bound proteins. We developed a coarse-grained Brownian dynamics model that allows for lateral and 3D protein-protein interactions among bound ParB proteins. Our model shows how such interactions can condense and organize the DNA spatially, and can control the localization and the long-range order of the DNA-bound proteins.

2:54PM W45.00003 Effect of an Antimicrobial Compound on Different Processes within the Oscillation of Min Proteins in E. coli Bacterial Cells

MAXIMILIANO GIULIANI, JOHN DUTCHER, Department of Physics, University of Guelph — A key step in the life of a bacterium is its division into two daughter cells of equal size. This process is carefully controlled and regulated so that equal partitioning of the cellular machinery is obtained. In E. coli, this regulation is accomplished, in part, by the Min protein system. The Min proteins undergo an oscillation between the poles of rod-shaped E. coli bacteria. We use high magnification, time-resolved total internal reflection fluorescence microscopy to characterize the temporal distributions of different processes within the oscillation: the MinD-MinE interaction time, the residence time for membrane bound MinD, and the recruitment time for MinD to be observed at the opposite pole. We also characterize the change in each of these processes in the presence of the antimicrobial compound polymyxin B (PMB). We show that the times corresponding to the removal of MinD from one pole and the recruitment of MinD at the opposite pole are correlated. We explain this correlation through the existence of a concentration threshold. The effect of PMB on the concentration threshold is used to identify which process within the oscillation is most affected.
