1:51PM N35.00014 Density Functional Theory studies of Epitaxial Charge Transfer Salts , GEOFFREY A. ROJAS, P. GANESH, SIMON KELLY, BOBBY J. SUMPTER, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, JOHN A. SCHLUETER, Materials Science Division, Argonne National Laboratory, PETRO MAKSYMOVICH, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory — Some of the fulvalene-based charge transfer salts (CTS) become superconducting in bulk. The basic physics and ways to control it has been explored by changing the intermolecular spacing using both chemical substitution and pressure, but the fixed stoichiometry limit the occupation of the filled states to what is naturally available. Recent experiments suggest growth of 2D epitaxial layers of CTS allowing stoichiometric and geometric control of the electronic structure, thereby leading to engineered superconducting interfaces. In a combined experiment and theory study, we provide new insight to understand the interplay between structure, stoichiometry and electronic-structure of epitaxially grown (ET)2SF5CH2CF2SO3 salt on Ag(111) surface. Density functional theory studies show that the cohesive energy of the 2D salts are very high, in spite of strong bonding to the underlying Ag surface via Ag-S metallic bonds, and provide a rationale for off-stoichiometric growth with different electronic structures as seen in our experiments, such as 3:1 and a 1:1 cation:anion stoichiometry, necessary for a monolayer coverage and different from the bulk 2:1 stoichiometry. We also explore the role of van der Waals interactions for structural stability. This research was conducted at the Center for Nanophase Materials Sciences, sponsored at ORNL by the Division of User Facilities, U.S. DOE.

2:03PM N35.00015 Rational design of novel thallium halide high T_c superconductors from first-principles , ZHIPING YIN, GABRIEL KOTLIAR, Department of Physics, Rutgers University — Searching for new high-temperature superconductors remains one of the most active research areas in condensed matter physics and material physics. In this talk I will show how we designed, from first principles calculations, a novel family of thallium halide-based compounds as candidates for new high-temperature superconductors. This family together with the celebrated (Ba,K)BiO_3 and electron-doped HfNCl families are the "other high-temperature superconductors," whose superconductivity is mediated by the recently proposed mechanism of non-local correlation-enhanced strong electron-phonon coupling (arXiv:1110.5751). Two prototype compounds namely $CsTlF_3$ and $CsTlCl_3$ are studied with various hole doping levels and volumes. The critical superconducting temperature T_c are predicted to be about 30 K and 20 K with optimal hole doping and volume, respectively. Our procedure of designing this class of superconductors is quite general and can be used to search for other "other high temperature superconductors."

Session N36 DCMP: Superconductivity: Mesoscopic Techniques and Applications 344 - Timir Datta, University of South Carolina

11:15AM N36.00001 Cantilever micro-susceptometry of mesoscopic Bi2212 samples[1] , HRYHORIY POLSHYN, RAFFI BUDAKIAN, University of Illinois at Urbana-Champaign, GENDA GU, Brookhaven National Laboratory — Fluxoid quantization provides a direct means to study phase coherence. In cuprate superconductors, there have been observations which suggest that phase coherent superconducting fluctuations may persist at temperatures significantly above Tc. The focus of this work is to study the vortex states in mesoscopic cuprate superconducting samples to directly probe phase coherence over a wide range of temperatures. We present cantilever torque susceptometry measurements of micron and sub-micron size Bi2212 rings and disks. The high sensitivity of this technique allowed observation of transitions between different fluxoid states of a single ring, and the discrete vortex states of micron size disks. The dependence of magnetic susceptibility on diameter and wall thickness of the ring was investigated. Measurements were made at different values of the in-plane magnetic field, and over a wide range of temperatures.

11:27AM N36.00002 Measuring superconducting delta-doped strontium titanate bilayers using the scanning SQUID technique , HILARY NOAD, KATJA C. NOWACK, HISASHI INOUE, CHRISTOPHER BELL, YASUYUKI HIKITA, HAROLD Y. HWANG[1], KATHRYN A. MOLER[2], Stanford Institute for Materials and Energy Science, Stanford University, SLAC National Accelerator Laboratory, Menlo Park, CA 94025, USA — Delta-doped strontium titanate is a highly tunable system well-suited for studying two-dimensional superconductivity. Bilayer structures, in particular, offer the possibility of modifying interlayer coupling between sheets of superconducting electrons. We can locally probe superconductivity and magnetism as a function of temperature using scanning SQUID susceptometry. We will discuss prospects for using the scanning SQUID technique to measure unusual effects, such as multi-component superconductivity, that may arise in delta-doped strontium titanate bilayers.

11:39AM N36.00003 Fabrication of $La_{2-x}Sr_xCuO_4$ Superconductor Nanodevices[1] , NICHOLAS LITOMBE, Harvard University, ANTHONY BOLLINGER, IVAN BOZOVIC, Brookhaven National Laboratory, JENNY HOFFMAN, Harvard University — In order to investigate dimension-limited superconductivity in cuprates, we explore methods of nanopatterning $La_{2-x}Sr_xCuO_4$ (LSCO). We use high resolution e-beam and photo-lithographic fabrication techniques, coupled with appropriate chemical and physical pattern transfer techniques. In particular, we focus on quasi-1D LSCO nanowire devices where we study random telegraph noise (RTN) signals from possible nematic domain fluctuation dynamics.

11:51AM N36.00004 Development of a Nb-AlxOy-Nb trilayer process at the University of Washington[1] , ANDREW WAGNER, University of Washington, AXION DARK MATTER EXPERIMENT COLLABORATION — We present progress made at the Washington Micro-Fabrication Facility toward the production of SQUID amplifiers from a $\mathrm{Nb-Al_xO_y-Nb}$ trilayer process. Details of a simplified trilayer process are presented and the capability to fabricate 3 micrometer Josephson Junctions from the process with controllable critical current densities is demonstrated. We discuss how these results can be applied to the production of SQUID, SLUG or Josephson Parametric amplifiers operating in the microwave band for the Axion Dark Matter eXperiment (ADMX) located at the University of Washington.

12:03PM N36.00005 Superconducting spin switch with infinite magnetoresistance[1] , BIN LI, Francis Bitter Magnet Lab, MIT, NIKLAS ROSCHEWSKY, FBML, MIT and Georg-August-Universitaet, Goettingen, MARKUS MUNZENBERG, Georg-August-Universitaet, Goettingen, MARIUS EICH, FBML, MIT, MARGUERITE EPSTEIN-MARTIN, FBML, MIT and Spencer School, New York, JAGADEESH S. MOODERA, FBML and Physics Department, MIT — Nearly five decades ago de Gennes theoretically predicted that below the superconducting transition temperature T_C the resistance in a FI/S/FI (FI-ferromagnetic insulator; S-superconductor) trilayer structure depends on the magnetization direction of the two FI layers [de Gennes, *Phys. Lett.* **23**, 10 (1966)]. This prediction is experimentally demonstrated here. We present magneto-transport properties in a EuS/Al/EuS structure, showing an infinite magnetoresistance by tuning the internal exchange field at the FI/S interface. The superconducting order parameter was suppressed when the magnetic moment of the two EuS layers aligned in parallel whereas it was least affected when the two EuS layers have their magnetizations in antiparallel alignment: one could tune between the superconducting and normal states by the FI magnetization configuration. Importantly either of these two states could be maintained in zero applied fields, thus creating a nonvolatile two-level memory state. It was also shown that this is entirely an interface proximity effect and could be destroyed by introducing just a monolayer of Al_2O_3 barrier in between the interfaces. Furthermore the observed resistance switching field correlated with the surface anisotropy of the EuS layers.

12:15PM N36.00006 Thin semi-rigid coaxial cables for cryogenics applications , AKIHIRO KUSHINO, Asahikawa National College of Technology, SOICHI KASAI, COAX CO., LTD. — We have developed cryogenic coaxial cables for low temperature signal readout from sensitive devices, such as transition edge sensors, superconducting tunnel junctions, and kinetic inductance detectors. In order to reduce heat penetration into cryogenic stages, low thermal conductivity metals were chosen for both center and outer electrical conductors. Various types of coaxial cables, employing stainless-steel, cupro-nickel, brass, beryllium-copper, phosphor-bronze, niobium, and niobium-titanium, were manufactured using drawing dies. Thermal and electrical properties were investigated between 1 and 8 K. Coaxial cables made of copper alloys showed thermal conductance roughly consistent with literature, meanwhile Nb coaxial cable must be affected by the drawing process and thermal conductance was lowered. Attenuation of superconducting Nb and NbTi coaxial cables were observed to be adequately small up to above 10 GHz compared to those of normal conducting coaxial cables, which are subject to the Wiedemann-Franz law. We also measured normal conducting coaxial cables with silver-plated center conductors to improve high frequency performance.

12:27PM N36.00007 Novel structural transformation in the ultrathin films of cuprates and its influence on electronic and magnetic properties , D. SAMAL, University of Twente, TAN HAIYAN, University of Antwerp, H. MOLEGRAAF, B. KUIPER, University of Twente, W. SIEMONS, Oak Ridge National Lab, SARA BALS, JO VERBEECK, GUSTAAF VAN TENDELOO, University of Antwerp, Y. TAKAMURA, University of California, Davis, ELKE ARENHOLZ, CATHERINE JENKINS, Advanced Light Source, G. RIJNDERS, GERTJAN KOSTER, University of Twente — We report on the evidence found for structural transformation in ultrathin films of two cuprate systems viz. $SrCuO_2$(SCO) and CuO. In case of SCO ultrathin films, we show a transformation from the bulk planar to chain-like structure, below a critical thickness, due to associated electrostatic instability. Results based on X-ray diffraction, X-ray photoelectron diffraction and scanning transmission electron microscopy reveal an elongation of the unit cell by $\sim$0.5Å along the c-axis and the presence of oxygen in the Sr plane for chain like structure. Polarized X-ray absorption spectroscopy reveals a preferential occupation of Cu $3d_{3z^2-r^2}$ orbital in case of the chain like structure unlike to the planar one. For the case of ultrathin CuO films, we find strain induced structural transformation from monoclinic to tetragonal phase, akin to other 3d transition metal monoxides and reveals relatively higher Neel temperature. Our findings point to a unique structural stabilization process for ultrathin cuprate layers and provide new insight for the experimental realization of novel hybrids to look for enhanced superconducting properties. 12:39PM N36.00008 Dynamical I-V Characteristics of SNS Junctions , KEVIN SPAHR, JONATHAN GRAVELINE, CHRISTIAN LUPIEN, Université de Sherbrooke, MARCO APRILI, Université Paris-Sud, BERTRAND REULET, Université de Sherbrooke — We probe the dynamics of a Superconductor /Normal Metal/ Superconductor junction (SNS: Nb / Al above its critical temperature / Nb) by measuring its voltage / current characteristics while applying an ac current of frequency in the range 1-200 MHz. We observe a dynamical phase transition as a function of the frequency and amplitude of the ac current. At low frequency there is a continuous change in the dynamical behavior of the junction, replaced an abrupt change and hysteresis at high frequency. The crossover frequency between the two regimes has a strong temperature dependence similar to that of the electron-phonon interaction rate.

12:51PM N36.00009 Spectroscopy of Andreev Bound States: revealing the hidden side of the Josephson effect , ÇAĞLAR GIRIT, LANDRY BRETHEAU, HUGUES POTHIER, DANIEL ESTEVE, CRISTIAN URBINA, Groupe quantronique CEA Saclay — The Josephson effect describes how phase coherence is established between two weakly coupled superconductors. Microscopically, the Josephson current is carried by Cooper pairs, occupying Andreev Bound States, localized at the weak link. Andreev Bound States, which come in particle-hole symmetric pairs, consitute a spin-like degree of freedom. In our experiment, we detect the transition to the *excited* Andreev bound state in a superconducting atomic contact using a Josephson junction as a broadband (5-90 GHz) spectrometer. Not only do we clearly resolve the Andreev transition, but we also identify spectroscopic lines arising from anticrossings with a Josephson plasma mode of the environment. Our results demonstrate the accessibility of a pseudospin degree of freedom in the Josephson effect.

1:03PM N36.00010 X-ray Structural Studies of Bi2Sr2CaCu2O8+δ Exfoliated Nanocrystals , ANDREEA LUPASCU, Department of Physics, University of Toronto, RENFEI FENG, Canadian Light Source, LUKE J. SANDILANDS, ZIXIN NIE, VIKTORIYA BAYDINA, Department of Physics, University of Toronto, GENDA GU, Condensed Matter Physics & Materials Science Department, Brookhaven National Laboratory, SHIMPEI ONO, Central Research Institute of Electric Power Industry, YOICHI ANDO, Institute of Scientific and Industrial Research, Osaka University, KENNETH S. BURCH, YOUNG-JUNE KIM, Department of Physics, University of Toronto — Structural studies of nanocrystals produced via mechanical exfoliation are not only essential for examining structure quality or structural changes at reduced-dimensionality, but also for understanding the role of substrates in the exfoliation process. Highly focused, tunable synchrotron X-ray beams enable the use of non-destructive characterization tools to study exfoliated samples on a variety of substrates. We demonstrate that structural and spectroscopic information can be obtained on nanocrystals as thin as 6 nm, by using a combination of micro X-ray fluorescence (μ XRF), micro X-ray absorption near-edge spectroscopy (μ XANES), and X-ray microdiffraction (μ XRD) techniques. μ XRF is used to locate the sample of desired thickness; μ XANES and μ XRD are used to obtain electronic and structural information, respectively. We report a substantial substrate effect for Bi2Sr2CaCu2O8+δ nanocrystals exfoliated on Si/SiO2 and mica substrates. The "4.7 b" structural modulation, characteristic of bulk crystals, vanishes below a thickness of 60 nm on mica, and is drastically suppressed below 60 nm for the Si/SiO2 substrate.

1:15PM N36.00011 Mechanical detection of single-quantum-level fluxoid relaxation in an Nb micro-ring , JAE-HYUK CHOI, HEON-HWA CHOI, YUN-WON KIM, Division of Physical Metrology, Korea Research Institute of Standards and Science, Daejeon, Korea, SOON-GUL LEE, Department of Display and Semiconductor Physics, Korea University, Jochiwon, Chungnam, Korea, MAHN-SOO CHOI, Department of Physics, Korea University, Seoul, Republic of Korea — We developed a highly sensitive static force magnetometry, originally proposed for sub-pico-newton force standard, which enabled the observation of single fluxoids selectively and their dynamics in a superconducting micro-ring. For an Nb ring with inner diameter of 4.0 μm, the magnetic moment of a single fluxoid quantum was determined as 7.4 pico-emu, corresponding to the static force of 74 femto-newton, in good agreement with a theoretical estimate within 8%. The magnetic relaxation of moderate number of fluxoids, ranging from 20 to 60, was also measured at temperatures of 4 $\sim$ 6 K and at zero magnetic field. The relaxation results with single-quantum-step feature were analyzed with a theoretical model for thermally activated transition.

1:27PM N36.00012 Studying phonon and quasiparticle heating effects on SINIS Coolers , THOMAS AREF, HUNG NGUYEN, JUHA MUHONEN, JUKKA PEKOLA, O.V. Lounasmaa Laboratory, Aalto University — A Normal-Insulating-Superconductor (NIS) tunnel junction can function as an electronic cooler. This is typically done in the SINIS configuration where the normal metal island is the object being cooled. By applying proper biasing, the bandgap in the superconductor can be used as an energy filter, allowing hot electrons to escape from the normal island and cold electrons to enter the island from the superconductor. This narrows the Fermi distribution of the electrons on the island, effectively lowering their temperature. By coupling this electronic refrigeration to phonons, the phononic temperature can be reduced as well. These SINIS coolers have potential for replacing other cryogen based refrigeration techniques at low temperatures. One primary aim is to produce an efficient, solid-state, cooling platform that cools small devices from 300 to 100 mK. Our most recent research has helped illuminate various effects that adversely affect the performance of these coolers. Examples of effects probed included geometrical factors, phonon heating, quasiparticle heating, substrate modification, ground planes and direct traps.

1:39PM N36.00013 Coupling carbon nanotube mechanics to a superconducting circuit , B.H. SCHNEIDER, S. ETAKI, H.S.J. VAN DER ZANT, G.A. STEELE, Tu-Delft — The quantum behaviour of mechanical resonators is a new and emerging field driven by recent experiments reaching the quantum ground state. The high frequency, small mass, and large quality-factor of carbon nanotube resonators make them attractive for quantum nanomechanical applications. A common element in experiments achieving the resonator ground state is a second quantum system, such as coherent photons or a superconducting device, coupled to the resonators motion. For nanotubes, however, this is a challenge due to their small size. Here, we couple a carbon nanoelectromechanical (NEMS) device to a superconducting circuit. Suspended carbon nanotubes act as both superconducting junctions and moving elements in a Superconducting Quantum Interference Device (SQUID). We observe a strong modulation of the flux through the SQUID from displacements of the nanotube. Incorporating this SQUID into superconducting resonators and qubits should enable the detection and manipulation of nanotube mechanical quantum states at the single-phonon level.

1:51PM N36.00014 Spin-precession-assisted tunneling in hybrid superconducting point contacts , CECILIA HOLMQVIST, WOLFGANG BELZIG, University of Konstanz, MIKAEL FOGELSTROM, Chalmers University of Technology — The charge and spin transport properties of a quantum point contact coupled to a nanomagnet depends strongly on the dynamics of the nanomagnet's spin. We analyze the current-voltage characteristics of a junction coupled to a spin whose dynamics is modeled as Larmor precession brought about by an external magnetic field. The interaction between the spin dynamics and the Josephson effect leads to a rich subgap structure due to spin-precession-assisted multiple Andreev reflections. Additionally, the spin current displays Shapiro-like resonances due to the interplay between the ac Josephson current and the Larmor precession.

2:03PM N36.00015 Probing the Dynamics of Andreev States in Coherent Normal/Superconducting ring: Evidence for a noisy supercurrent , BASTIEN DASSONNEVILLE, Laboratoire de Physique des Solides, F-91405 Orsay, FRA, FRANCESCA CHIODI, Institut d'Electronique Fondamentale, F-91405 Orsay, FRA, SOPHIE GUERON, MEYDI FERRIER, HELENE BOUCHIAT, Laboratoire de Physique des Solides, F-91405 Orsay, FRA — Most properties of a non superconducting (N) metal connected to two superconductors (an SNS junction) can be seen as resulting from the phase dependent Andreev states (AS) in N. Density of states in N is then drastically changed with the emergence of a small energy gap, the minigap. Whereas AS equilibrium properties are well understood, AS dynamics is a more complex issue [1]. We perform experiments on a phase (ϕ) biased NS ring coupled to a superconducting resonator. The modification of the resonances (f from 200 MHz up to 14 GHz) yields the complex phase dependent susceptibility $\partial_\phi I_{ring} = \chi(f,\phi) = \chi' + i\chi''$. As expected, we find a non-dissipative χ' related to the supercurrent flowing through the ring. A more striking finding [2] is the existence of a dissipative χ'' revealing a noisy supercurrent, predicted [3] but never observed before. Moreover, as f increases we show that the main dissipation mechanism changes from population relaxation to microwave-induced transitions across the minigap.

Session N37 DMP DCOMP: Focus Session: Fe-based Superconductors: Spin Fluctuations

345/346 - Guangyong Xu, Brookhaven Natl Lab

11:15AM N37.00001 Neutron Scattering as a Probe of Fermi Surface Nesting in Iron-Based Superconductors[1] , RAYMOND OSBORN, Argonne National Laboratory — Superconductivity in the iron-based compounds is induced by suppressing a magnetically ordered phase by doping, pressure, or disorder, so it is no surprise that neutron scattering has had an important role in the field, elucidating both the origin of magnetic fluctuations and their role in the unconventional superconductivity. Our investigations of $BaFe_2As_2$ doped with potassium [1], sodium, and phosphor, can be interpreted within the framework of weakly correlated itinerant magnetism, in which Fermi surface nesting between hole pockets at the zone center and electron pockets at the zone boundary is responsible for both the magnetic (SDW) order and the superconductivity. Resonant spin excitations that occur when the superconducting energy gap changes sign on different parts of the Fermi surface were initially observed by inelastic neutron scattering in $Ba_{1-x}K_xFe_2As_2$ representing the first phase-sensitive evidence of $s_{\pm}$-symmetry [2]. We have since shown that the resonance splits into two with hole-doping because of the growing mismatch in the hole and electron Fermi surface volumes, accompanied by a decrease in the binding energy of the resonance and its spectral weight in accordance with RPA theory [3]. A detailed examination of the phase diagram close to the critical phase boundary for SDW order has identified a new phase that is further evidence of the role of Fermi surface nesting in generating magnetic order.

11:51AM N37.00002 Spin fluctuations of BaFe2(As,P)2 studied by neutron scattering , CHUL-HO LEE, AIST, Japan, P. STEFFENS, ILL, France, N. QURESHI, Universitat zu Koln, K. KIHOU, M. NAKAJIMA, A. IYO, H. EISAKI, AIST, Japan, M. BRADEN, Universitat zu Koln — Superconductivity can be induced in parent compounds of iron-based superconductors by several methods: carrier doping, external pressure and chemical pressure. To understand their superconducting mechanism, clarifying what is a common property for achieving high-Tc superconductivity is crucial. To date, studies on spin fluctuations have been mainly performed on carrier doped samples. On the other hand, there are only a few studies on chemical pressurized samples examined by powder samples. In this work, thus, we studied spin fluctuations of P doped $BaFe_2(As,P)_2$ (T_c = 29.5K) using single crystal samples. Inelastic neutron scattering measurements were conducted using triple axis spectrometer IN8 of ILL. As results, well-defined commensurate peaks have been observed at (0.5,0.5,L), which is consistent with the nesting vector of the Fermi surface. Energy spectrums at $T = T_c$ show L dependence, suggesting a three dimensional character remains even in superconducting $BaFe_2(As,P)_2$. Clear spin gap has been observed below T_c, whose gap structure depends on L. Details will be discussed at the conference.

12:03PM N37.00003 Role of the spin-orbit coupling in the spin-resonance formation in Fe-based superconductors[1] , M.M. KORSHUNOV, L.V. Kirensky Institute of Physics, Akademgorodok, 660036 Krasnoyarsk and Siberian Federal University, Svobodny Prosp. 79, 660041 Krasnoyarsk, Russia, YU.N. TOGUSHOVA, Siberian Federal University, Svobodny Prosp. 79, 660041 Krasnoyarsk, Russia, I. EREMIN, Institut fur Theoretische Physik III, Ruhr-Universitat Bochum, D-44801 Bochum, Germany and Kazan Federal University, 42008 Kazan, Russia, P.J. HIRSCHFELD, Department of Physics, University of Florida, Gainesville, Florida 32611, USA — Determination of the gap symmetry is an important step towards uncovering mechanism of superconductivity in Fe-based materials. One of the key experiments in support of the $s_{\pm}$ spin-fluctuation-mediated gap was observation of the spin-resonance peak in many pnictides and chalcogenides, see P.J. Hirschfeld et al., Rep.Prog.Phys. 74, 124508 (2011). Recently, in inelastic polarized neutron scattering measurements by Lipscombe et al., Phys.Rev. B 82, 064515 (2010), it was found that the peaks in the transverse and longitudinal components of the spin susceptibility of $BaFe_{1.9}Ni_{0.1}As_2$ exhibit rather different behavior, and argued that the true spin resonance exists in the transverse channel only. Here, on the basis of the 5-orbital model, we argue that this disparity arises from spin-orbit coupling. It also leads to the relative shift of the two component's resonance frequency with lower frequency one exhibiting larger enhancement.

[1]Partial support was provided by DOE DE-FG02-05ER46236 (PJH), and RFBR 12-02-31534, Russian FCP GK 16.740.12.0731, The Dynasty Foundation and ICFPM (MMK)

12:15PM N37.00004 Compositional dependence of low energy spin fluctuations in $Ba(Fe_{1-x}Co_x)_2As_2$[1] , GREGORY TUCKER, D.K. PRATT, A. THALER, N. NI, Ames Laboratory and Department of Physics & Astronomy, Iowa State University, Ames, IA 50011, K. MARTY, A.D. CHRISTIANSON, M.D. LUMSDEN, Quantum Condensed Matter Division, Neutron Science Directorate, Oak Ridge National Laboratory, Oak Ridge, TN 37831, S.L. BUD'KO, P.C. CANFIELD, A. KREYSSIG, A.I. GOLDMAN, R.J. MCQUEENEY, Ames Laboratory and Department of Physics & Astronomy, Iowa State University, Ames, IA 50011 — The low energy magnetic fluctuation spectrum of $Ba(Fe_{1-x}Co_x)_2As_2$ samples in the range $x = (0.014, 0.055)$ were studied in their antiferromagnetic ordered states using inelastic neutron scattering. The parent compound $BaFe_2As_2$ exhibits gapped spin-wave excitations at $\mathbf{Q}_{\rm AFM} = (1, 0, 1)$ with two gap energies [corresponding to in-Fe-plane and out-of-Fe-plane transverse excitations of the ordered moment]. Substitution of Co for Fe via doping acts to increase Landau damping without significantly modifying the parent compound spin-gap structure. For small amounts of Co the two-gap structure is resolvable in our measurements. For larger Co-doping the damping increases sufficiently to obscure the parent compound gap structure and the measured $\mathbf{Q}_{\rm AFM}$ excitation spectra is best described by a diffusive model. Interestingly, the change in excitation character corresponds in composition with the appearance of superconductivity in $Ba(Fe_{1-x}Co_x)_2As$; these two effects may very well be related.

[1]The work at the Ames Laboratory was supported by US DOE, Office of Basic Energy Sciences, DMSE, contract DE-AC02-07CH11358.

12:27PM N37.00005 Spin Excitations in Overdoped $Ba(Fe_{1-x}Co_x)_2As_2$, A.D. CHRISTIANSON, S. CALDER, J.E. MITCHELL, K. MARTY, C.H. WANG, M.B. STONE, A.S. SEFAT, B.C. SALES, M.D. LUMSDEN, Oak Ridge National Laboratory — The relationship between spin excitations and unconventional superconductivity has been and continues to be the subject of considerable experimental and theoretical scrutiny. While the underdoped and optimally doped regions of the phase diagrams of unconventional superconductors have been extensively studied there have few studies of the spin excitations in the overdoped region. Here we report an inelastic neutron scattering study of an overdoped sample of the unconventional superconductor $Ba(Fe_{1-x}Co_x)_2As_2$ with x=0.15 and T_c = 12 K. At energies below 40 meV the spin excitations are much broader and weaker when compared to samples close to optimal doping. Despite the weakness of the spin excitations a broad spin resonance is still observed at an energy of ~8 meV at the wave vector (0.5 0.5 0). This corresponds to a value of 7.7 K_BT_c which is nearly double the value of 4 K_BT_c found for many Fe-based superconductors.

12:39PM N37.00006 Magnetism in parent Fe-chalcogenides: quantum fluctuations select a plaquette order[1] , NATALIA PERKINS, SAMUEL DUCATMAN, ANDREY CHUBUKOV, Physics Department UW Madison — The analysis of magnetism in parent compounds of iron-based superconductors (FeSCs) is an integral part of the program to understand the origin of superconductivity in these materials. Here we analyze magnetic order in iron-chalcogenide $Fe_{1+y}Te$ – the parent compound of high-temperature superconductor $Fe_{1+y}Te_{1-x}Se_x$. Neutron scattering experiments show that magnetic order in this material contains components with momentum $Q_1 = (\pi/2, \pi/2)$ and $Q_2 = (\pi/2, -\pi/2)$ in Fe-only Brillouin zone. The actual spin order depends on the interplay between these two components. Previous works argued that spin order is a single-Q state (either Q_1 or Q_2). Such an order breaks rotational C_4 symmetry and order spins into a double diagonal stripe. We show that quantum fluctuations actually select another order – a double Q plaquette state with equal weight of Q_1 and Q_2 components, which preserves C_4 symmetry but breaks Z_4 translational symmetry. We argue that the plaquette state is consistent with recent neutron scattering experiments on $Fe_{1+y}Te$.

[1]supported by the grant NSF-DMR-0844115

12:51PM N37.00007 Unexpected (π, π) order in $Fe_{1.1}Te$[1] , DAVID FOBES, IGOR ZALIZNYAK, ZHIJUN XU, GENDA GU, JOHN M. TRANQUADA, CMPMSD, Brookhaven National Lab, Upton, NY 11973 USA, DEEPAK SINGH, NCNR, National Institute of Standards and Technology, Gaithersburg, MD 20899 USA — We have studied the evolution of the magnetic and crystal structure in single crystalline $Fe_{1.1}Te$, an iron-rich parent of the chalcogenide superconductor family. While a structural transition to a monoclinic symmetry occurs at ~ 60 K, magnetic peaks at $2\pi \cdot (0.48, 0)$ only arise below $T_N \approx 58$ K, and can be understood as bicollinear magnetism with discommensuration defects. [2] Unexpectedly, we have also observed resolution limited peaks at approximately (π, π), arising at the same temperature T_N, and exhibiting temperature hysteresis similar to that seen in magnetic susceptibility, perhaps indicating that these peaks are of magnetic origin. Additionally, the position of these peaks is nearly the same as in the parent compounds of the iron pnictide family of superconductors, where magnetic order is simple collinear commensurate antiferromagnetism. The origin of these new peaks near (π, π) and their relationship to the dominant bicollinear magnetic order observed in $Fe_{1.1}Te$ presents a puzzle.

1:03PM N37.00008 Inelastic neutron scattering studies on the incommensurate-to-commensurate transformation of low energy magnetic excitations in $Fe_{1+\delta-y}(Ni/Cu)_yTe_{1-x}Se_x$, ZHIJUN XU, Brookhaven National Lab, JINSHENG WEN, University of California, Berkeley, JOHN SCHNEELOCH, Brookhaven National Lab, YANG ZHAO, NIST, MASAAKI MATSUDA, Oak Ridge National Lab, WEI KU, XUERONG LIU, GENDA GU, Brookhaven National Lab, D.-H. LEE, R.J. BIRGENEAU, University of California, Berkeley, J.M. TRANQUADA, GUANGYONG XU, Brookhaven National Lab — We have performed a series of neutron scattering and magnetization measurements on $Fe_{1+\delta-y}(Ni/Cu)_yTe_{1-x}Se_x$ system to study the interplay between magnetism and superconductivity. Both non-superconducting and superconducting samples with T_c 8$\sim$15K are studied. The low energy magnetic excitations of all samples at $T >> T_c$ consist of two incommensurate vertical columns. They change to a distinctly different U-shaped dispersion at $T > T_c$ for the superconducting samples and the transition temperature depend on the composition.[1] On the other hand, for all non-superconducting samples, there is no clear temperature dependence, and the low energy magnetic excitations remain two columns for temperatures down to 1.5 K. Work is supported by the Office of Basic Energy Sciences, DOE. [1]Zhijun Xu et al., arXiv:1201.4404(accepted by PRL).

1:15PM N37.00009 Cu-induced localization in the Fe-based superconductor $FeTe_{0.5}Se_{0.5}$[1] , JINSHENG WEN, UC Berkeley, ZHIJUN XU, CHENG ZHANG, BNL, MASA MATSUDA, ORNL, OLEG SOBOLEV, JITAE PARK, FRM II, EDITH BOURRET, LBNL, DUNGHAI LEE, UC Berkeley, QIANG LI, GENDA GU, GUANGYONG XU, JOHN TRANQUADA, BNL, ROBERT BIRGENEAU, UC Berkeley — We report neutron scattering and resistivity results on the Cu-substitution effects in $FeTe_{0.5}Se_{0.5}$ with a T_c of $\sim$15 K. With a 2% Cu substitution, the T_c is reduced to 8 K, and for $Fe_{0.9}Cu_{0.1}Te_{0.5}Se_{0.5}$, it is not superconducting. In $Fe_{0.9}Cu_{0.1}Te_{0.5}Se_{0.5}$, the low-energy magnetic excitations around the in-plane wave vector (0.5, 0.5) is greatly enhanced. Upon heating, the magnetic scattering is weakened, which is different from the temperature dependences of the Cu-free and 2% Cu-doped sample. The spectral weight reduction upon warming decreases with increasing energy in the 10% Cu-doped sample. We take these as evidences that Cu drives the system towards localization, which is confirmed by our resistivity data. These observations probably explain why superconductivity is absent in the Cu-doped $BaFe_2As_2$ system and demonstrate the inadequacy of the rigid-band shift model on the substitution effects of the $3d$ transition metals.

1:27PM N37.00010 Neutron Scattering in Co Doped NaFeAs , YU SONG, CHENGLIN ZHANG, SCOTT CARR, ZACHARY COLE, NICOLAS LUTTRELL, PENGCHENG DAI, University of Tennessee — In this presentation we will discuss some of our recent neutron scattering work done on Co doped NaFeAs, focusing on the evolution of magnetism and superconductivity with doping. The phase diagram of Co doped NaFeAs is similar to Co,Ni doped BaFe2As2, but also show significant differences in the magnetic response despite the similar Tc in both systems. Thus by comparing these systems, we attempt to find common features for unconventional superconductivity in both systems.

1:39PM N37.00011 Magnetic excitation in Co-doped NaFeAs studied by neutron scattering , CHENGLIN ZHANG, YU SONG, GUOTAI TAN, SCOTT CAR, PENGCHENG DAI, Univ of Tennessee, physics, UNIV OF TENNESSEE TEAM — Even though NaFeAs "111" shares many similarities with BaFe2As2 "122" such as magnetic structure and phase diagram with doping , actually they are quite different from many aspects. For one example, the spin resonance is very sharp like delta function and well below 2detal, in sharp contrast with the broaden resonance observed in doped-122 systems. Our result provide a strong piece of evidence to support S+$_-$ and exclude S++ pairing symmetry in Fe-based superconductors.

1:51PM N37.00012 NMR Search for the Spin Nematic State in LaFeAsO Single Crystal , MINGXUAN FU, DAVID A. TORCHETTI, Department of Physics and Astronomy, McMaster University, Hamilton, ON, L8S4M1 CAN, TAKASHI IMAI, Department of Physics and Astronomy, McMaster University, Hamilton, ON, L8S4M1 CAN; Canadian Institute for Advanced Research, Toronto M5G 1Z8 CAN, FANLONG NING, Department of Physics, Zhejiang University, Hangzhou 310027, China, JIAQIAN YAN, ATHENA S. SEFAT, Materials Science and Technology Division, Oak Ridge National Laboratory, TN 37831, USA — The mechanism underlying high-T_c superconductivity in iron-pnictides remains a major puzzle in condensed matter. Earlier NMR measurements provide evidence for a correlation between T_c and the enhancement of low frequency spin fluctuations[1]. However, slowing of spin fluctuations is accompanied by lattice softening, which is a major complication in this scenario. The intermediate temperature range between the tetragonal-orthorhombic structural phase transition at T_{TO} and SDW transition at T_{SDW} may be a realization of spin nematic state[2]. We report ^{75}As single crystal NMR study of LaFeAsO [3]. We have found that the low frequency spin dynamics exhibits a strong two-fold anisotropy within each orthorhombic domain below T_{TO} This intermediate state then freezes progressively into a static SDW below T_{SDW}. Our results reveal the presence of an exotic intermediate spin state below T_{TO} with the signature of spin nematicity.

2:03PM N37.00013 Two-dimensional magnetic interactions in LaFeAsO , MEHMET RAMAZANOGLU, JAGAT LAMSAL, Ames Lab. DoE, GREGORY S. TUCKER, Iowa State Univ. and Ames Lab. DoE, STUART CALDER, Oak Ridge National Lab., JIAQIANG YAN, Univeristy of Tenessee, Knoxville, TATIANA GUIDI, TOBY PERRING, ISIS Facility, Rutherford Appleton Laboratory, Chilton, Didcot, Oxon OX11 OQX, United Kingdom, THOMAS A. LOGRASSO, ANDREAS KREYSSIG, ALAN GOLDMAN, ROBERT J. MCQUEENEY, Ames Lab. DoE — The magnetic excitations in antiferromagnetic (AFM) ordered LaFeAsO (La1111) are mapped out by inelastic neutron scattering (INS) technique using both time-of-flight and triple-axis spectroscopies. The energy dependence of the observed intensity at the AFM ordering wavevector, Q_{AFM}, yields a spin gap of $\sim$11 meV. The independence of the spin gap along the c-direction suggests nearly two-dimensional magnetic interactions. A steep magnetic excitation spectrum is observed for in-plane wavevectors for energy transfers up to 100 meV. The constant energy cuts of these steep excitations are elliptically shaped for the low energy transfers below 50 meV. As energy transfer increases, the elliptical anisotropy develops into a splitting above 50 meV. A phenomenological model based on highly damped diffuse spin dynamics is used to analyze the data. The calculated parameters of anisotropic spin wave velocities, spin gap and the damping values are similar to the previous results in $BaFe_2As_2$ and $CaFe_2As_2$ based materials but La111 has a more two-dimensional character.

Wednesday, March 20, 2013 11:15AM - 2:15PM –

Session N38 GERA DPOLY DCOMP: Novel Photophysics and Transport in NanoPV I 347 - Sean Shaheen, University of Denver

11:15AM N38.00001 Tuning charge transport in organic devices: From in silico to carbon to device , ALAN ASPURU-GUZIK, Department of Chemistry and Chemical Biology, Harvard University — I will describe our work towards first-principles design of organic semiconducting materials. In particular, I will describe our efforts towards the rational design of high hole-mobility organic crystals. I will describe a case study where the in silico prediction of a material led to the synthesis and characterization of it by the Bao and Toney groups. I will also discuss other related research directions.

11:51AM N38.00002 Conformational Disorder in Energy Transfer: Beyond Forster Theory , TAMMIE NELSON, Los Alamos National Lab, Los Alamos, New Mexico, SEBASTIAN FERNANDEZ-ALBERTI, Universidad Nacional de Quilmes, Bernal, Argentina, ADRIAN ROITBERG, University of Florida, Gainesville, SERGEI TRETIAK, Los Alamos National Lab, Los Alamos, New Mexico — Energy transfer in donor/acceptor chromophore pairs, where the absorption of each species is well separated, can be understood through a Förster resonance energy transfer model. The picture is more complex for organic conjugated polymers, where the total absorption spectrum can be described as a sum of the individual contributions from each subunit, whose absorption is not well separated. Although excitations in these systems tend to be well localized, traditional *donors* and *acceptors* cannot be defined and energy transfer can occur through various pathways. In addition, fast torsional motions between individual monomers can break conjugation and lead to reordering of excited state energy levels. Energy transfer in these systems can be induced by both electronic transitions and by fast torsional fluctuations where both mechanisms occur simultaneously. We use non-adiabatic excited state molecular dynamics (NA-ESMD) to simulate energy transfer between two poly-phenylene vinylene (PPV) segments composed of 3-rings and 4-rings separated by varying distances. The transition density decay represents the transfer rate, and can be decomposed into contributions from various transfer pathways.

12:03PM N38.00003 Phonon-assisted nonradiative energy transfer in quantum dot-silicon nanostructures , PEDRO LUDWIG HERNANDEZ MARTINEZ, School of Electrical and Electronics Engineering, Nanyang Technological University, Department of Physics, Bilkent University, AYDAN YELTIK, Department of Physics, Bilkent University, BURAK GUZELTURK, Department of Electrical and Electronics Engineering, Bilkent University, ALEXANDER O. GOVOROV, Department of Physics and Astronomy, Ohio University, HILMI VOLKAN DEMIR, School of Electrical and Electronics Engineering, Nanyang Technological University, Department of Physics, Bilkent University — Silicon is one of the most dominant materials in photovoltaics and understanding the processes of energy transfer is of great importance. In this work, we study the phonon-assisted nonradiative energy transfer (NRET) in quantum dot (QD)-silicon hybrid nanostructures. Here, the NRET dynamics is investigated as a function of temperature for distinct separation thicknesses between the donor QDs and the acceptor silicon plane. We propose a theoretical model based on the phonon-assisted energy transfer process. We estimate the energy transfer rate using the Fermi's Golden rule where the matrix elements are derived for the phonon-assisted energy transfer process. To support our findings the temperature-dependent fluorescence lifetimes in QD-silicon nanostructures are analyzed. The experimental data analyses agree with the resulting theoretical model. The results indicate that phonons play an important role in NRET to Si as an indirect bandgap semiconductor.

12:15PM N38.00004 Directed Energy Transfer through Size-Gradient Nanocrystal Layers into Si Substrates , MICHAEL NIMMO, LOUIS CAILLARD, WILL DEBENEDETTI, HUE NGUYEN, YVES CHABAL, YURI GARTSTEIN, ANTON MALKO, University of Texas at Dallas — Nanostructured materials attract great interest as candidates for next generation of photoelectronic devices. Presently, the majority of hybrid devices are based on charge transfer in which exciton break-up occurs at the interface between dissimilar materials. Poor interface quality and carrier transport are issues that result in a conversion efficiencies lower than in the inorganic crystalline devices. An alternative approach is based on hybrid structures, which combine strongly absorbing components such as nanocrystal quantum dots (NQDs) and adjacent high-mobility semiconductor layers coupled via proximal energy transfer. Building on our previous work,[1] we examine non-radiative energy transfer (NRET) between NQDs grafted on a hydrogenated Si surface via amine modified carboxy-alkyl chain linkers. A macroscopically thick, size–gradient NQD film is prepared on top of crystalline Si layer to explore directed energy tranfer into the substrate. Steady-state and time-resolved photoluminescence studies show effective energy transfer between adjacent layers and into the Si substrate with the transfer efficiency exceeding 90% among layers. This demonstrates the viability of NQD-Si hybrid structures for photovoltaic devices.

12:27PM N38.00005 Quantum coherence and noise in open quantum systems , AHSAN NAZIR, Imperial College London — Recent experiments demonstrating signatures of quantum coherence in the excitonic energy transfer dynamics of a variety of systems have sparked renewed interest in the theoretical modelling of energy transfer processes within a dissipative environment. A major challenge remains the development of techniques that allow one to probe the diverse parameter regimes relevant to such systems. Master equation methods provide useful tools with which to efficiently analyse energy transfer dynamics in open quantum systems. However, they are often valid only in rather restrictive parameter regimes, limiting their applicability in the present context. Here, I shall present a versatile variational master equation approach to the non-equilibrium dynamics of dissipative excitonic quantum systems, which allows for the exploration of a wide range of parameter regimes within a single formalism. Derived through the combination of a variationally optimised unitary transformation and the time-local projection operator technique, the master equation can be applied to a range of bath spectral densities, temperatures, and system-bath coupling strengths, and accounts for both non-Markovian and non-equilibrium environmental effects. Applying the formalism in the case of excitonic energy transfer, I shall show that while it correctly reproduces Redfield, polaron, and Foerster dynamics in the appropriate limits, it can also be used in intermediate regimes where none of these theories may be applicable. I shall also discuss the extension of the theory to many-site energy transfer systems Variational master equations thus represent a promising avenue for the exploration of (essentially non-perturbative) dissipative dynamics in a variety of physical systems.

1:03PM N38.00006 Quantum Relaxation in Singlet Fission , PAUL TEICHEN, JOEL EAVES, The University of Colorado at Boulder — Singlet fission is a multielectron process in organic chromophores, where an initially excited singlet state decays into two independent triplets. First observed in organic semiconductors almost 40 years ago, the phenomenon may be a promising route for increasing yields in next-generation photovoltaics. Early theories that ignored quantum coherence between excited states were capable of explaining the fission process on nanosecond timescales, but recent observations of fission on sub picosecond timescales call several tenants of those theories into question. We present a theory of optical dephasing and decoherence in singlet fission, drawing on ideas from quantum information theory to establish conditions for decoherence and disentanglement between the relevant quantum states on the picosecond timescale.

1:15PM N38.00007 Double Super-Exchange in Silicon Quantum Dots Connected by Short-Bridged Networks[1] , HUASHAN LI, ZHIGANG WU, MARK LUSK, Colorado School of Mines — Silicon quantum dots (QDs) with diameters in the range of 1-2 nm are attractive for photovoltaic applications. They absorb photons more readily, transport excitons with greater efficiency, and show greater promise in multiple-exciton generation and hot carrier collection paradigms. However, their high excitonic binding energy makes it difficult to dissociate excitons into separate charge carriers. One possible remedy is to create dot assemblies in which a second material creates a Type-II heterojunction with the dot so that exciton dissociation occurs locally. This talk will focus on such a Type-II heterojunction paradigm in which QDs are connected via covalently bonded, short-bridge molecules. For such interpenetrating networks of dots and molecules, our first principles computational investigation shows that it is possible to rapidly and efficiently separate electrons to QDs and holes to bridge units. The bridge network serves as an efficient mediator of electron superexchange between QDs while the dots themselves play the complimentary role of efficient hole superexchange mediators. Dissociation, photoluminescence and carrier transport rates will be presented for bridge networks of silicon QDs that exhibit such double superexchange.

[1]This material is based upon work supported by the Renewable Energy Materials Research Science and Engineering Center (REMRSEC) under Grant No. DMR-0820518 and Golden Energy Computing Organization (GECO).

1:27PM N38.00008 Highly Efficient Charge Transfer in Nanocrystalline Si:H[1] , REUBEN COLLINS, MATTHEW BERGREN, BRIAN SIMONDS, JEREMY FIELDS, CRAIG TAYLOR, THOMAS FURTAK, Colorado School of Mines, KRISTIN KIRILUK, Abengoa Solar, GUOZHEN YUE, BAOJIE YAN, JEFF YANG, TINING SU, SUBHENDU GUHA, United Solar Ovonic, MATTHEW BEARD, National Renewable Energy Laboratory — We demonstrate that in films of silicon nanocrystals imbedded in a hydrogenated amorphous silicon matrix, carriers generated in the amorphous region are efficiently transported to the nanocrystals prior to thermalization into band tail states of the amorphous phase. This transfer causes electron paramagnetic resonance and photoluminescence signals from the amorphous phase to be rapidly quenched as the volume fraction of Si nanocrystals exceeds about 30 percent. Ultrafast carrier dynamics, probed using time-resolved terahertz spectroscopy (TRTS), confirm rapid transport between phases before complete relaxation. TRTS results are consistent with a model where electrons excited in the amorphous material are first trapped at interface states at the amorphous/nanocrystal boundary prior to being thermally emitted into the crystalline phase. These results, which indicate nanocrystalline Si:H is effectively a type I bulk heterojunction material, help explain the enhanced photo stability of this material compared to amorphous silicon by itself. They also suggest routes to using similar structures to increase the efficiency of thin film silicon solar cells.

[1]Support from the NSF and DOE are gratefully acknowledged

1:39PM N38.00009 Ultrafast carrier dynamics of CdSe quantum dots prepared by pulse laser deposition for photovoltaic applications[1] , MEG MAHAT, BAICHHABI YAKAMI, Department of Electrical and Computor Engineering, University of Wyoming, QILIN QILIN DAI, JINKE TANG, Department of Physics, University of Wyoming, JON PIKAL, Department of Electrical and Computor Engineering, University of Wyoming — Quantum-dot sensitized solar cells are a promising alternative to existing photovoltaic technology. Over the last decade solution based colloidal quantum dots (QDs) have been extensively studied. Here we have carried out ultrafast transient absorption measurements on CdSe QDs fabricated using pulse laser deposition (PLD) in order to understand the carrier relaxation dynamics in these nanostructures. The differential transmission measurements show that the PLD QDs have a very fast decay process resulting in a recovery time of less than 10 picoseconds. This is in stark contrast to the colloidal QDs that show a decay process of more than 4 nanoseconds. We also find that the fast decay process observed in the PLD QDs is a function of the carriers density generated in CdSe QDs. To understand these carrier relaxation processes and improve the optical properties of the QDs we perform transient absorption measurements on PLD QDs prepared in different media (e.g. water, methanol, ethanol), under different growth conditions, and with and without ligand. We present a comparison study of the carrier relaxation dynamics in these PLD grown QDs to provide insight into the competing relaxation effects and guide their use in Quantum-dot sensitized solar cells.

[1]DOE

1:51PM N38.00010 Spin-Dependent Light-Harvesting in Colloidal Nanocrystals by Controlling Electronic Trap States with Optically Detected Magnetic Resonance , K.J. VAN SCHOOTEN, University of Utah, J. HUANG, D.V. TALAPIN, University of Chicago, C. BOEHME, University of Utah, J.M. LUPTON, Universität Regensburg — Colloidal synthesis of semiconductor nanocrystals offers high levels of control over both particle size and geometry, leading to the development of novel optoelectronic device architectures (e.g. CdSe/CdS tetrapods). Unfortunately, realization of such devices is forestalled due to the ubiquitous existence of energetic "trap" states which compete with quantum-confined band-edge excitonic states and drive down device efficiencies. Although the existence of such states is readily confirmed via observation of single particle photoluminescence blinking and delayed photoluminescence decay dynamics, little detail is actually known as to the characteristics of these trap states due to difficulties in directly accessing them experimentally. We use pulsed optically detected magnetic resonance spectroscopy in order to begin to probe the chemical and electronic nature of these long-lived states, shedding light on their relation to band-edge states. Ultimately, it is found that spin coherence extends up to $T_2 = 328 \pm 22$ ns at 3.5 K, allowing for the coherent control of light harvesting in heterostructured nano-tetrapods which permits remote readout of spin information.

2:03PM N38.00011 Charge transfer between a CdSe/CdS quantum rod and an attached ferrocene molecule: a first principle study , KARTICK TARAFDER, LIN-WANG WANG, Lawrence Berkeley National Laboratory, Berkeley, CA-94720 — Semiconductor quantum dot (QD) shows interesting opto-electrical properties, very different from bulk semiconductors. However, one major challenge for opto-electrical application is to get the charge carrier out of the QD. One approach is to use an attached molecule to extract the photon generated carrier from the QD. Ferrocene has a potential to change its electron transition level either by adjusting the Ferrocene and Ferrocene+ ratio in a solvent, or by adding other functional groups. However, proper understanding of the interactions between QD and molecule is limited, which is extremely useful for further design of such system. One of the main difficult is that there are thousands of atoms contained in the system, a first principle study of which is beyond the limit of existing computational power using direct density functional theory method. In this work we used a novel technique called charge-patching method [1], and combined that with Marcus model to study the electron and hole transfer between ferrocene and CdS/CdSe core-shell quantum dot. This study allows us to gain insights into the molecule dot interactions and underlying photoluminescence quenching process.

Wednesday, March 20, 2013 11:15AM - 1:51PM –

Session N39 DFD: Drops, Bubbles, and Interfacial Fluid Mechanics II 348 - Patricia McGuiggan, Johns Hopkins University

11:15AM N39.00001 Multimode Multidrop Serial Coalescence Effects during Condensation on Two-Tier Superhydrophobic Surfaces[1] , KONRAD RYKACZEWSKI, ADAM T. PAXTON, SUSHANT ANAND, MIT, XUEMEI CHEN, ZUANKAI WANG, City University of Hong Kong, KRIPA K. VARANASI, MIT — Mobile coalescence leading to spontaneous drop motion was initially reported to occur only during water condensation on two-tier superhydrophobic surfaces (SHS), consisting of both nanoscale and microscale topological features. However, subsequent studies have shown that mobile coalescence also occurs on solely nanostructured SHS. Thus, recent focus has been on understanding the condensation process on just nanostructured surfaces rather than on two-tier SHS. Here, we investigate the impact of microscale topography of two-tier SHS on the droplet coalescence dynamics and wetting states during the condensation process. We identify new droplet shedding modes, which consist of serial coalescence events that lead to merging of multiple droplets. The formed drops either depart or remain anchored to the surface. We explain the observed post-merging drop adhesion trends through direct correlation to formation of drops in nanoscale as well as microscale Wenzel and Cassie-Baxter wetting states. We find that optimally designed two-tier SHS, which promote the highest number of departing microdrops, consists of microscale features spaced close enough to enable transition of larger droplets into micro-Cassie state, yet at the same time provide sufficient area in-between the features for occurrence of mobile coalescence.

[1]This work was funded by NSF and the Dupont-MIT Alliance and was in part performed using facilities at NIST.

11:27AM N39.00002 Elasticity of the contact line for droplets on anisotropic superhydrophobic surfaces , MARCO RIVETTI, ANAIS GAUTHIER, JEREMIE TEISSEIRE, ETIENNE BARTHEL, CNRS - Saint Gobain — We present an experimental and numerical investigation on the receding of contact line for water droplets on glass superhydrophobic surfaces. In particular, we focus our attention on surfaces textured with anisotropic lattice posts. We measure that the receding contact angle is not affected by the anisotropy of the lattice. This surprising behavior is closely related to the elastic deformations of the contact line which can be by studied by direct observation. We interpret this phenomenon in term of propagation of kink defects along the lattice. We detail the influence of the morphology of the lattice on the propagation of kinks, as well as the importance of the shape of the posts. Three dimensional numerical simulations confirm that kinks are the key ingredient for the comprehension of the receding contact angle.

11:39AM N39.00003 Dynamics of condensation on lubricant impregnated surfaces , SUSHANT ANAND, ADAM PAXSON, KONRAD RYKACZEWSKI, Massachusetts Institute of Technology, DANIEL BEYSENS, UMR CNRS-ESPCI ParisTech, KRIPA VARANASI, Massachusetts Institute of Technology — Replacing the filmwise condensation mode with dropwise condensation promises large improvements in heat transfer that will lead to large cost savings in material, water consumption and decreased size of the systems. In this regards, use of superhydrophobic surfaces fabricated by texturing surfaces with nano/microstructures has been shown to lead decrease in contact line pinning of millimetric drops resulting in fast shedding. However, these useful properties are lost during condensation where droplets that nucleate within texture grow by virtue of condensation to large sized droplets while still adhering to the surface. Recently we have shown that liquid impregnated surfaces can overcome many limitations of conventional superhydrophobic surfaces during condensation. Here we discuss aspects related to condensation on lubricant surfaces, such as behavior of growing droplets. We compare the characteristics of droplets condensing on these surfaces with their behavior on conventional un-impregnated superhydrophobic surfaces and show how use of lubricant impregnated surfaces may lead to large enhancement in heat transfer and energy efficiencies.

11:51AM N39.00004 Contact Angle Hysteresis of Photo-Responsive Materials[1] , SAMUEL ROSENTHAL, PATRICIA MCGUIGGAN, Johns Hopkins University — An atomic force microscope (AFM) is used to measure the meniscus force on individual microspheres coated with photo-responsive materials such as anatase and rutile TiO_2, azobenzene, and other doped oxides as they contact and are retracted from an air/water interface. By exposing the coated microspheres to UV light, the contact angle change. The change can be detected by measuring the increase in the meniscus force. Exposure to visible, infrared, or far infrared light – as the specific material requires - reverses the contact angle change. The measured force-distance curves are fitted to macroscopic wetting theory. From these measurements, the contact angle, the contact angle hysteresis, and the position of the contact line pinning were simultaneously determined. This allowed for a quantification of the contact angle changes from photo-switching.

[1]NSF CMMI-0709187

12:03PM N39.00005 Thermodynamic Model for Contact Angle Hysteresis on Rough Surfaces , RISHI RAJ, Device Research Laboratory, Department of Mechanical Engineering, Massachusetts Institute of Technology, RYAN ENRIGHT[1], Stokes Institute, University of Limerick, SOLOMON ADERA, EVELYN WANG, Device Research Laboratory, Department of Mechanical Engineering, Massachusetts Institute of Technology — Wettability of solid surfaces can be tuned by introducing roughness. This effect has been explained by Wenzel, whereby texturing increases the degree of hydrophilicity (hydrophobicity) of an intrinsic hydrophilic (hydrophobic) flat surface. However, experimentally observed dynamic contact angles deviate significantly from those predicted by Wenzel equation. In this work, we demonstrate that local contact line distortion and pinning on structured surfaces is the key aspect that needs to be accounted for in the dynamic droplet models. Contact line distortions and pinning were visualized and analyzed to develop a thermodynamic model for contact angle hysteresis on rough surfaces. The developed model showed good agreement with the experimental advancing and receding contact angles, both at low and high solid fractions. The thermodynamic model was further extended to demonstrate its capability to capture droplet shape evolution during liquid addition and removal in our experiments and those in literature. The understanding developed in this study offers new insight extending the fundamental understanding of solid-liquid interactions required for the design of advanced functional coatings for microfluidics, biological, manufacturing, and heat transfer applications.

12:15PM N39.00006 Wetting Transition of Water , SERAH FRIEDMAN, MATT KHALIL, PETER TABOREK, University of California, Irvine — Pure liquid water does not wet most solid surfaces. Liquid water on these surfaces beads up and forms droplets with a finite contact angle. General thermodynamic principles suggest that as the temperature approaches the critical point, the contact angle should go to zero, marking the wetting transition. We have made an optical cell which can operate near the critical point of water (Tc=373C, Pc=217 atm) to study this phenomenon on sapphire, graphite and silicon. We have used two methods to measure the wetting temperature of water on these surfaces. Firstly, we studied a single droplet on a horizontal surface and optically measured the change in contact angle as a function of increasing temperature. Second, we studied the condensation of droplets on a vertical plate as a function of temperature. As the temperature approached the wetting temperature in both cases, the droplets spread and eventually form a smooth film along the surface of the plate. The wetting temperature on sapphire is near 240C and is considerably higher on graphite. Our observed values of Tw are significantly higher than the predictions made by the sharp-kink approximation and recent molecular dynamics simulations.

12:27PM N39.00007 Moving Water Droplets on Aluminum and Copper Surfaces Using Surface Tension Gradients , MUIDH ALHESHIBRI, NATHANIEL ROGERS, ANDREW SOMMERS, KHALID EID, Miami University — The behavior of water droplets on metal surfaces is very important for many applications, especially in heat exchangers in air conditioning and refrigeration. We use photolithography and/or shadow masks to create alternating hydrophobic/hydrophilic Cu micro-channels on an aluminum surface and to move water droplets on the surface. The contact angle that is formed between water droplets and the surface is clearly asymmetrical due to the different surface properties at the contact line between the droplets and the patterned surface. An HDFT self-assembled mono-layer allows for a large change in the water droplet contact angle on the copper, but seems to have no effect on the aluminum surface. We will show our results on the effect of the surface patterning and surface roughness on water droplet behavior. We also demonstrate that the engineered surface gradients cause water droplets to travel more than 1" on a horizontal or upward tilted surface.

12:39PM N39.00008 Atomistic simulations of surfactant adsorption kinetics[1] , EUGENIYA ISKRENOVA, Propulsion Directorate, Air Force Research Laboratory, Wright Patterson Air Force Base, OH 45433, USA and UES, Inc., Dayton, OH 45432, USA, SOUMYA PATNAIK, Propulsion Directorate, Air Force Research Laboratory, Wright Patterson Air Force Base, OH 45433, USA — Enhancing heat transfer is an important and challenging problem in a variety of industrial and technological applications including aircraft thermal management. Nucleate pool boiling is recognized as one of the most efficient methods to enhance heat transfer. Describing the plethora of multi-physics phenomena involved in nucleate pool boiling requires developing a multiscale model aimed at not only advancing our understanding but also at providing insights into the mechanisms for control and prediction of heat transfer in boiling. Adding surfactants to boiling water has been experimentally observed to enhance or inhibit the heat transfer depending on the surfactant concentration and chemistry. On a molecular level, addition of surfactants leads to the development of dynamic surface tension and changes in interfacial and transfer properties, thus contributing to the complexity of the multiscale model. We present an atomistic modeling study of the interfacial adsorption kinetics of aqueous surfactant systems at a range of concentrations at room and boiling temperature. Large scale classical molecular dynamics simulations were used to study the surfactant kinetics and estimate the adsorption and desorption rates at liquid-solid and liquid-vacuum interfaces.

12:51PM N39.00009 Small Scale Evaporation Kinetics of a Binary Fluid Mixture , CARL BASDEO, DEZHUANG YE, DEVENDRA KALONIA, TAI-HSI FAN, University of Connecticut, MECHANICAL ENGINEERING TEAM, PHARMACEUTICAL SCIENCES COLLABORATION — Evaporation induces a concentrating effect in liquid mixtures. The transient process has significant influence on the dynamic behaviors of a complex fluid. To simultaneously investigate the fluid properties and small-scale evaporation kinetics during the transient process, the quartz crystal microbalance is applied to a binary mixture droplet of light alcohols including both a single volatile component (a fast evaporation followed by a slow evaporation) and a mixture of two volatile components with comparable evaporation rates. The density and viscosity stratification are evaluated by the shear wave, and the evaporation kinetics is measured by the resonant signature of the acoustic p-wave. The evaporation flux can be precisely determined by the resonant frequency spikes and the complex impedance. To predict the concentration field, the moving interface, and the precision evaporation kinetics of the mixture, a multiphase model is developed to interpret the complex impedance signals based on the underlying mass and momentum transport phenomena. The experimental method and theoretical model are developed for better characterizing and understanding of the drying process involving liquid mixtures of protein pharmaceuticals.

1:03PM N39.00010 Red blood cell in simple shear flow , WEI CHIEN, Dept. of Physics, National Taiwan University, Taipei 106, Taiwan, YAYU HEW, Dept. of Physics,U. Texas-Arlington, TX, USA, YENG-LONG CHEN, Inst. of Physics, Academia Sinica, Taipei 11529, Taiwan — The dynamics of red blood cells (RBC) in blood flow is critical for oxygen transport, and it also influences inflammation (white blood cells), thrombosis (platelets), and circulatory tumor migration. The physical properties of a RBC can be captured by modeling RBC as lipid membrane linked to a cytoskeletal spectrin network that encapsulates cytoplasm rich in hemoglobin, with bi-concave equilibrium shape. Depending on the shear force, RBC elasticity, membrane viscosity, and cytoplasm viscosity, RBC can undergo tumbling, tank-treading, or oscillatory motion. We investigate the dynamic state diagram of RBC in shear and pressure-driven flow using a combined immersed boundary-lattice Boltzmann method with a multi-scale RBC model that accurately captures the experimentally established RBC force-deformation relation. It is found that the tumbling (TU) to tank-treading (TT) transition occurs as shear rate increases for cytoplasm/outer fluid viscosity ratio smaller than 0.67. The TU frequency is found to be half of the TT frequency, in agreement with experiment observations. Larger viscosity ratios lead to the disappearance of stable TT phase and unstable complex dynamics, including the oscillation of the symmetry axis of the bi-concave shape perpendicular to the flow direction. The dependence on RBC bending rigidity, shear modulus, the order of membrane spectrin network and fluid field in the unstable region will also be discussed.

1:15PM N39.00011 Non-laminar motion of biological suspension: an illustration for blood cell passing a 3-micrometer capillary[1] , IAT NENG CHAN, University of Macau — Discovering in video images of blood cell motion, a new concept is developed for cell passing a tight capillary that has a large difference compared to the published simulation results. In video image the deformation of moving blood cell shows abnormal pressure from cell membrane under highly contacted condition with capillary wall. Moreover, when the cell struggles through the narrow capillary the appearance of additional force to assist the cell motion is necessary. In more detail analysis, the flow motion in capillary displaying a non-laminar pattern which is obviously different to that shows in a nearby larger capillary on the same image, can be explained as a non-regular flow described by an equivalent flow companied with sink and source. Using this illustration with the calculated volumes for normal and deformed cells, the flow speed and pressure are derived to compare with the best known results and also to the calculated flow speed from the images. After compared to diffusion effect, the exchange rate of materials in the flow and the efficiency factor to the circulatory system can be estimated.

1:27PM N39.00012 Stability of a falling viscous sheet , CLAUDE PERDIGOU, University Paris 6, GILLES PFINGSTAG, Saint Gobain Recherche Aubervilliers, BASILE AUDOLY, University Paris 6 and CNRS, AREZKI BOUDAOUD, Ecole Normale Superieure de Lyon and CNRS — Falling films can be found in various processes of the food, glass and polymer industry. We study thin viscous films flowing vertically under the action of gravity, when poured from a slit. The lateral sides are unconstrained and the stretching effect of gravity induces a narrowing of the film in the horizontal direction, by Poisson's effect. This leads to compressive stress for some range of parameters, and we study the associated viscous buckling instabilities. A local stability analysis is used to characterized the flow parameters leading to potential instabilities. A global stability analysis is carried out, and an eigenvalue problem is solved numerically. This is implemented using the finite-element method with high order derivatives.

1:39PM N39.00013 A Different Cone: Bursting Drops in Solids , XUANHE ZHAO, Duke University — Drops in fluids tend to be spheres—a shape that minimizes surface energy. In thunderstorm clouds, drops can become unstable and emit thin jets when charged beyond certain limits. The instability of electrified drops in gases and liquids has been widely studied and used in applications including ink-jet printing, electrospinning nano-fibers, microfluidics and electrospray ionization. Here we report a different scenario: drops in solids become unstable and burst under sufficiently high electric fields. We find the instability of drops in solids morphologically resembles that in liquids, but the critical electric field for the instability follows a different scaling due to elasticity of solids. Our observations and theoretical models not only advance the fundamental understanding of electrified drops but also suggest a new failure mechanism of high-energy-density dielectric polymers, which have diverse applications ranging from capacitors for power grids and electric vehicles to muscle-like transducers for soft robots and energy harvesting.

Session N40 DAMOP: Dipolar Gases and Rydberg Atoms 349 - Ryan Wilson, National Institute of Standards and Technology

11:15AM N40.00001 Time-reversal-breaking and d-wave superfluidity of ultracold dipolar fermions in optical lattices[1] , CARLOS SÁ DE MELO, LI HAN, Georgia Institute of Technology — We describe possible superfluid phases of ultracold dipolar fermions in optical lattices for two-dimensional systems. Considering the many-body screening of dipolar interactions at larger filling factors, we show that several superfluid phases with distinct pairing symmetries naturally emerge in the singlet channel: local s-wave (sl), extended s-wave (se), d-wave (d) or time-reversal-symmetry breaking ($sl+se\pm id$)-wave. The temperature versus filling factor phase diagram indicates that d-wave is favored near half-filling, that ($sl+se$)-wave is favored near zero or full filling, and that time-reversal-breaking ($sl+se\pm id$)-wave is favored in between. When a harmonic trap is included a sequence of phases can exist in the cloud depending on the filling factor at the center of the trap. Most notably in the region where the ($sl+se\pm id$)-wave superfluid exists, spontaneous currents are generated, and may be detected using velocity sensitive Bragg spectroscopy.

[1]We thank NSF (Grant No. DMR-0709584) and ARO (Grant No. W911NF-09-1-0220) for support.

11:27AM N40.00002 Dipolar Fermions in Quasi-Two-Dimensional Square Lattice , CHEN-YEN LAI, SHAN-WEN TSAI, University of California Riverside — Motivated by recent experimental realization of quantum degenerate dipolar Fermi gas, we study a system of ultralcold single- and two-species polar fermions in a double layer two-dimensional square lattice. The long-range anisotropic nature of dipole-dipole interaction has shown a rich phase diagram on a two dimensional square lattice*. We investigate how the interlayer coupling affects the monolayer system. Our study focuses on the regime where the fermions are closed to half-filling, which is when lattice effects play an important role. We find several correlated phases by using a functional renormalization group technique, which also provides estimates for the critical temperature of each phase. [*] S. G. Bhongale et. al. arXiv:1209.2671 and Phys. Rev. Lett. 108 145301 (2012).

11:39AM N40.00003 Orbital coupled dipolar fermions in an asymmetric optical ladder[1] , XIAOPENG LI, W. VINCENT LIU, University of Pittsburgh — We study a quantum ladder of dipolar atoms/molecules with coupled s and p orbitals. The interaction of such a system can be controlled with dipole moments being aligned by an external field. The two orbital components have distinct hoppings. The tunneling between them is equivalent to a partial Rashba spin-orbital coupling when the orbital space (s, p) is identified as spanned by pseudo-spin 1/2 states. A rich phase diagram is established. In particular a superconducting phase is found for repulsive fermions and a plaquette phase is found for bosons at 1/4 filling.

[1]A. W. Mellon Fellowship, AFOSR, ARO, ARO-DARPA-OLE

11:51AM N40.00004 Emergence of unconventional spin density waves in dipolar Fermi gases , S. G. BHONGALE, George Mason University, LUDWIG MATHEY, University of Hamburg, SHAN-WEN TSAI, University of California, Riverside, CHARLES W. CLARK, NIST, JQI, and University of Maryland, ERHAI ZHAO, George Mason University — Motivated by experiments on Fermi gases of dipolar molecules and dysprosium, we study the competing quantum phases of two- component (pseudo-spin 1/2) dipolar fermions on a two-dimensional optical lattice. The anisotropic, long-range dipole-dipole interaction leads to the occurrence of numerous exotic many-body states, e.g. supersolid, nematic, and topological superfluid. Here, using unbiased functional renormalization group approach, we discover that another quantum phase of matter, spin density wave (SDW) with p-wave orbital symmetry, emerges in this system when the dipoles are tilted at intermediate angles with respect to the lattice plane. This phase can be viewed as the particle-hole analogue of p-wave superconductors. We present the phase diagram of the system and show that the order parameter of the unconventional SDW is a vector quantity in spin space, and, moreover, is defined on lattice bonds rather than on lattice sites.

12:03PM N40.00005 Topological phases in polar-molecule quantum magnets , ALEXEY GORSHKOV, California Institute of Technology, SALVATORE MANMANA, Georg-August-University Goettingen, E.M. STOUDENMIRE, University of California, Irvine, KADEN HAZZARD, ANA MARIA REY, University of Colorado, Boulder, NORMAN YAO, CHRIS LAUMANN, STEVEN BENNETT, Harvard University, ANDREAS LAUCHLI, PETER ZOLLER, University of Innsbruck, JUN YE, University of Colorado, Boulder, EUGENE DEMLER, MIKHAIL LUKIN, Harvard University — We show that ultracold polar molecules pinned in an optical lattice and interacting via dipolar interactions can be used to implement a huge variety of exotic quantum magnets. These can be used to realize, for example, fractional Chern insulators, symmetry protected topological phases, the bilinear-biquadratic spin-1 Hamiltonian, and the Kitaev honeycomb model. [References for some of the results: arXiv:1207.4479, arXiv:1210.5518]

12:15PM N40.00006 Symmetry Protected Topological Phases in Polar Molecule Spin Ladder Systems , S.R. MANMANA, Institute f. Theoretical Physics, University of Göttingen, D-37077 Göttingen, Germany, E.M. STOUDENMIRE, Department of Physics and Astronomy, UC Irvine, CA 92697, USA, K.R.A. HAZZARD, A.M. REY, JILA, NIST and Department of Physics, CU Boulder, CO 80309, USA, A.V. GORSHKOV, IQI, Caltech, Pasadena, CA 91125, USA — We show how to use polar molecules in an optical lattice to engineer quantum spin models with arbitrary spin $S \geq 1/2$ and with interactions featuring a direction-dependent spin anisotropy. This is achieved by encoding the effective spin degrees of freedom in microwave-dressed rotational states of the molecules and by coupling the spins through dipolar interactions. We demonstrate how one of the experimentally most accessible anisotropies stabilizes symmetry protected topological phases in spin ladders. Using the numerically exact density matrix renormalization group method, we find that these phases – previously studied only in the nearest-neighbor case – survive in the presence of long-range dipolar interactions. We also show how to use our approach to realize the bilinear-biquadratic spin-1 and the Kitaev honeycomb models. Experimental detection schemes and imperfections are discussed.

12:27PM N40.00007 Realizing Fractional Chern Insulators with Dipolar Spins , NORMAN YAO, CHRIS LAUMANN, Harvard University, ANDREAS LAUCHLI, University of Innsbruck, EUGENE DEMLER, Harvard University, JUN YE, JILA, CU Boulder, PETER ZOLLER, University of Innsbruck, MIKHAIL LUKIN, Harvard University, ALEXEY GORSHKOV, IQIM, California Institute of Technology — Strongly correlated quantum systems can exhibit exotic behavior that is determined and controlled by topology. Such topological systems are of interest because they constitute fundamentally new states of matter exhibiting fractionalized excitations and robust chiral edge modes. We theoretically predict that the nu $= 1/2$ fractional Chern insulator, a recently proposed topological state of lattice bosons, arises naturally in a two-dimensional array of driven, dipolar-interacting spins.

12:39PM N40.00008 Preparation and detection of dipolar fractional Chern insulators , CHRIS LAUMANN, NORMAN YAO, Harvard University, ALEXEY GORSHKOV, IQI, MIKHAIL LUKIN, Harvard University — We describe schemes for preparation and detection of fractional Chern insulators as arise in driven dipolar spin systems. Such topological phases generically compete with superfluid and crystalline orders. We discuss the nature of the phase transitions and describe a dynamical preparation procedure. Prospects for measuring the properties of these topological phases using cold atomic techniques are considered.

12:51PM N40.00009 Parafermion excitations in superfluid of quasi-molecular chains formed by dipolar molecules or indirect excitons[1] , ANATOLY KUKLOV, CSI, CUNY, ALEXEI TSVELIK, BNL — We study a quantum phase transition in a system of dipoles confined in a stack of N identical 1D lattices (tubes) polarized perpendicularly to the lattices. The dipoles may represent polar molecules or indirect excitons. The transition separates two phases; in one of them superfluidity takes place in each individual lattice, in the other (chain superfluid) the order parameter is the product of bosonic operators from all lattices. We argue that in the presence of finite inter-lattice tunneling the transition belongs to the universality class of the $q = N$ two-dimensional classical Potts model. For $N = 2, 3, 4$ the corresponding low energy field theory is the model of Z_N parafermions perturbed by the thermal operator. Results of Monte Carlo simulations are consistent with these predictions. The detection schemes for the chain superfluid of dipolar molecules and indirect excitons are outlined.

1:03PM N40.00010 Collective excitations of quasi-two-dimensional trapped dipolar fermions , MEHRTASH BABADI, EUGENE DEMLER, Harvard University — We study the collective excitations of quasi-two-dimensional fermions with dipole-dipole interactions in an isotropic harmonic trap by solving the collisional Boltzmann-Vlasov equation. Except for the scaling monopole mode which exhibits a negligible damping, the other collective modes undergo a transition from the collisionless regime to a highly dissipative crossover regime and finally to the hydrodynamic regime upon increasing the dipolar interaction strength. In the 2D limit, we predict the existence of a temperature window within which the characteristics of the collective modes become temperature independent.

1:15PM N40.00011 Unconventional triplet pairing state in a polarized dipolar Fermi gas[1] , YUKI ENDO, DAISUKE INOTANI, YOJI OHASHI, Keio University — We theoretically discuss the possibility of a triplet superfluid state in a polarized dipolar Fermi gas. In this system, it is usually believed that a high-energy cutoff is necessary in solving the superfluid BCS gap equation, reflecting the non-convergent behavior of a dipole-dipole interaction in the high-momentum limit. Because of this, the superfluid theory for a dipolar Fermi gas is believed to need a regularization for the angular-dependent dipole-dipole interaction as in the case of the s-wave interaction. In this talk, we show that such a renormalization is actually unnecessary, when one carefully includes the detailed structure of a dipolar molecule. We present a superfluid theory for a dipolar Fermi gas where the dipole-dipole interaction is only described by the two physical parameters, dipole size and dipole-dipole coupling constant. Using this, we discuss the possibility of a triplet pairing state, as well as superfluid properties, of this system. Since our theory only involves observable physical parameters, it would be useful in quantitatively evaluating superfluid properties of a dipolar Fermi gas, such as the superfluid phase transition temperature.

[1]This work is supported by a Grant-in-Aid for JSPS Fellows.

1:27PM N40.00012 P-wave superfluid in a quasi-two-dimensional dipolar Bose-Fermi quantum gas mixture[1] , BEN KAIN, College of the Holy Cross, HONG LING, Rowan University — The p-wave $(p_x + ip_y)$ superfluid has attracted significant attention in recent years mainly because its vortex core supports a Majorana fermion which, due to its non-Abelian statistics, can be explored for implementing topological quantum computation (TQC). Mixing in bosons may lead to p-wave pairing in a Fermi gas. In a dipolar condensate, the dipole-dipole interaction represents a control knob inaccessible to nondipolar Bosons. Thus, mixing dipolar bosons with fermions opens up new possibilities. We consider a mixture of a spin-polarized Fermi gas and a dipolar Bose-Einstein condensate in a quasi-two-dimensional trap setting. We take the Hartree-Fock-Bogoliubov mean-field approach and develop a theory for studying the stability of the mixture and estimating the critical temperature of the p-wave superfluid. We use this theory to identify the experimentally accessible parameter space in which the mixture is stable against phase separation and the p-wave superfluid pairing can be resonantly enhanced. An enhanced p-wave superfluid order parameter can make the fault tolerant TQC less susceptible to thermal fluctuations. This work aims to stimulate experimental activity in creating dipolar Bose-Fermi mixtures.

1:39PM N40.00013 Superfluidity of atomic Fermi gases with dipolar interactions[1] , YANMING CHE, QIJIN CHEN, Zhejiang University — While quantum degenerate dipolar Fermi gases have been made available in experiment, the superfluidity in such Fermi gases has been of very high interest. In this talk, we study the superfluidity and associated BCS-BEC crossover behavior of a two-component atomic Fermi gases in three dimensions in the presence of dipole-dipole interactions, such as polar molecules ^{40}K^{87}Rb and magnetic atoms ^{161}Dy, using a pairing fluctuation theory. The relative interaction strength can be tuned via the atomic number. Various geometric configurations will be explored. We show that in certain configurations, the superfluidity may disappear altogether for a narrow range of interaction strength, and the Tc curve throughout the BCS-BEC crossover exhibits a reentrant behavior. We argue that such disappearance of the superfluidity is associated with the long range nature of the dipole-dipole interaction. A pseudogap develops naturally as the relative interaction becomes strong.

1:51PM N40.00014 Superfluid Pairing and Majorana Zero Mode in an Ultracold Rydberg Fermi Gas , BO XIONG, H.H. JEN, JHIH-SHIH YOU, DAW-WEI WANG, Physics Department National Tsing-Hua University, Hsinchu, Taiwan — We systematically calculate the p-wave superfluid phase of spin polarized Fermi gases in a Rydberg state. The mutual interaction between atoms are dressed by external fields and show nonlocal attractive 1/(a+r6) interaction. Different from the p-wave pairing phase of regular atoms near p-wave Feshbach resonance, the obtained p-wave superfluid phase can be stable away from three-body collision and has intrinsic nontrivial nodes in the momentum space. The critical temperature and order parameter for various interaction parameters have been calculated analytically and numerically, both in the 2D and 3D free space. When loading into optical lattice, we also show the proximity effect of Tc near half filling. Finally, when considering the harmonic confinement potential, we obtain the gapless Majorana Fermions confined to the boundary via self-consistently solving the DBG equation. We will discuss how to experimentally prepare and measure these Majorana states in Rydberg atoms.

2:03PM N40.00015 Supersolid phases of two-species Rydberg-dressed Bose-Einstein condensates[1] , C.-H. HSUEH, Department of Physics, National Taiwan Normal University, Taiwan, Y.-C. TSAI, Department of Physics, National Changhua University of Education, Taiwan, M.-S. CHANG, Institute of Atomic and Molecular Sciences, Academia Sinica, Taiwan, W. C. WU, Department of Physics, National Taiwan Normal University, Taiwan — We investigate the supersolid ground states of a binary Rydberg-dressed BEC system. From a many-body perturbation expansion, both intra- and inter-species long-range dressed interactions are derived, which are essential for the study of the ground-state manifold of the binary Rydberg-dressed BEC system. Due to the long-range interactions, five distinct phases of the supersolid ground states are identified, which are experimentally observable.

[1]Financial support from the NSC of Taiwan is acknowledged.

Wednesday, March 20, 2013 11:15AM - 2:15PM –
Session N41 GSNP DAMOP: Hybrid Systems for Quantum Simulation 350 -

11:15AM N41.00001 Counting statistics of phase slips in superconducting interferometers , PHILLIP WEINBERG, Michigan State University, ANDREW MURPHY, University of Illinois Urbana-Champaign, ALEX LEVCHENKO, Michigan State University, VICTOR VAKARYUK, The Johns Hopkins University, ALEXEY BEZRYADIN, University of Illinois Urbana-Champaign — In the superconducting proximity circuits, stochastic switching from the super-current carrying state to dissipative normal state is triggered by the topological fluctuations of the order parameter - phase slips. We study theoretically switching current statistics in a double-nanowire quantum interferometer as a function of the applied magnetic field perpendicular to the plane of the device. This system is a prototype of the double-slit experiment in optics which allows to probe macroscopic coherence of superconducting condensates. Magnetic field induces Meissner currents in the leads that lock superconducting phases across the wires. As a results phase slips that occur in the wires are not independent. We calculate dispersion of the switching current distribution as well as higher moment and find that they oscillate as the function of the field.

11:27AM N41.00002 Inverse Landau-Zener-Stuckelberg interferometry for the measurement of a resonator's state using a qubit , SERGEY SHEVCHENKO, B. Verkin Institute for Low Temperature Physics and Engineering, Kharkov, Ukraine, SAHEL ASHHAB, FRANCO NORI, RIKEN Advanced Science Institute, Wako-shi, Saitama, Japan; Department of Physics, The University of Michigan, Ann Arbor, Michigan, USA — We consider theoretically a superconducting qubit - nanomechanical resonator system, which was realized recently by LaHaye et al. [Nature 459, 960 (2009)]. We formulate and solve the inverse Landau-Zener-Stuckelberg problem, where we assume the driven qubit's state to be known (i.e. measured by some other device) and aim to find the parameters of the qubit's Hamiltonian. In particular, for our system the qubit's bias is defined by the nanomechanical resonator's displacement. This may provide a tool for monitoring the nanomechanical resonator 's position. [S. N. Shevchenko, S. Ashhab, and F. Nori, Phys. Rev. B 85, 094502 (2012).]

11:39AM N41.00003 Towards a spin-ensemble quantum memory for superconducting qubits , PATRICE BERTET, YUIMARU KUBO, CECILE GREZES, DENIS VION, DANIEL ESTEVE, CEA Saclay, IGOR DINIZ, ALEXIA AUFFEVES, Institut Neel, JUNICHI ISOYA, Tsukuba University, ANAIS DREAU, JEAN-FRANÇOIS ROCH, VINCENT JACQUES, ENS Cachan, BRIAN JULSGAARD, KLAUS MOELMER, Aarhus University — A multi-mode quantum memory able to store coherently large numbers of qubit states is a desirable resource for quantum information. We report progress towards this direction, using an ensemble of electronic spins (NV centers in diamond) coupled to a superconducting transmon qubit via a tunable resonator. We demonstrate the reversible coherent storage and retrieval of a single microwave photon from the qubit into the spin ensemble [1]. In this experiment the storage time was however limited by inhomogeneous broadening of the ensemble of spins. We propose a realistic protocol that should extend the ensemble storage time by several orders of magnitude, based on spin-echo like pulse sequences; first experimental results will be presented.

[1] Y. Kubo et al., PRL 107, 220501 (2011).

11:51AM N41.00004 Superconducting Microstrip Resonator for Spin-Based Quantum Processor , HAMID REZA MOHEBBI, Institute for Quantum Computing, University of Waterloo, OLAF BENNINGSHOF, TROY BORNEMAN, IVAR TAMINIAU, Institute for Quantum Computing, University of Waterloo, GUO-XING MIAO, Institute for Quantum Computing, University of Waterloo, DAVID G. CORY, Institute for Quantum Computing, University of Waterloo — We report the design and results of a novel superconducting microstrip line resonator for pulsed ESR experiments of thin films. The resonator generates a homogeneous in-plane microwave magnetic field. This resonator consists of an array of superconducting half-wave microstrip transmission lines to achieve high-Q resonance. They are driven via an in-phase splitter and so maintain a resonance at one single frequency. In addition the resonator has a relatively small mode. The performance, sensitivity and small mode volume are demonstrated through our observation of strong coupling and ESR spectroscopy.

12:03PM N41.00005 Systematic studies of optically-trapped dielectric nanospheres , LEVI NEUKIRCH, Department of Physics and Astronomy, University of Rochester, Rochester, New York 14627, USA, JAN GIESELER, ROMAIN QUIDANT, ICFO-Institut de Ciencies Fotoniques, Mediterranean Technology Park, 08860 Castelldefels (Barcelona), Spain, LUKAS NOVOTNY, Institute of Optics, University of Rochester, Rochester, New York 14627, USA; Photonics Laboratory, ETH Zürich, 8093 Zürich, Switzerland, NICK VAMIVAKAS, Institute of Optics, University of Rochester, Rochester, New York 14627, USA — Mesoscopic resonators have garnered significant interest recently in a number of experiments designed to blur the line between classical and quantum systems. In particular, optically trapped mesoscopic particles offer a distinct advantage over many other systems, as they can be mechanically isolated from the environment. We present results from dynamical studies of micro- and nano-scale dielectric particles suspended in a free-space optical dipole trap. Particle position is monitored via the interference of scattered and unscattered laser light. Of interest are the effects of the trap laser and ambient pressure on the external motion and internal temperature of the particles.

12:15PM N41.00006 Atomic manipulation for a hybrid system: tapered optical fibers with high transmission and a pyramid MOT[1] , J.E. HOFFMAN, J.A. GROVER, JQI/UMD, M. HAFEZI, JQI/NIST, J.B. HERTZBERG, P. KORDELL, J. LEE, JQI/UMD, S. RAVETS, Institute d'Optique, Palaiseau, U. CHUKWU, K.D. VOIGT, J.R. ANDERSON, G. BEADIE, F.K. FATEMI, C.J. LOBB, L.A. OROZCO, JQI/UMD, J.M. TAYLOR, JQI/NIST, S.L. ROLSTON, F.C. WELLSTOOD, JQI/UMD — To create a hybrid quantum system, we plan to trap neutral atoms in the evanescent optical field from an optical nanofiber and move them to within a few microns above a SQUID in a dilution refrigerator that operates at 10 mK. A key component in this experiment is a long section (10 cm) of optical fiber with a uniform diameter of about 500 nm, sufficiently small that the light propagates on the surface of the fiber as an evanescent wave. We have produced suitably long nanofibers with carefully tapered sections that allow matching of the optical field in the tapered and untapered sections. We have achieved more than 99.95% transmission of the fundamental mode and good evanescent fields; as well as more than 85% transmission when using higher order modes. A single-beam, magneto-optical trap that uses optical gratings captures and cools atoms to load on the nanofiber to work at cryogenic temperatures. We will present our technique, key results, and progress towards trapping atoms on the fibers.

[1]Work supported by ONR, ARO Atomtronics MURI, DARPA, the Fulbright Foundation, and NSF through the PFC at JQI.

12:27PM N41.00007 Development of a hybrid quantum system employing a tunable high-Q superconducting microwave resonator and trapped laser-cooled atoms[1] , JARED HERTZBERG, K. VOIGT, Z. KIM, J. HOFFMAN, J. GROVER, J. LEE, S. RAVETS, JQI/UMD, M. HAFEZI, J. TAYLOR, JQI/NIST/UMD, A. CHOUDHARY, UMD, J. ANDERSON, JQI/UMD, C. LOBB, JQI/NIST/UMD, L. OROZCO, S. ROLSTON, F. WELLSTOOD, JQI/UMD — We present progress toward a hybrid quantum system in which microwave quanta stored in a superconducting flux qubit are coupled through a magnetic dipole interaction to laser-trapped atoms. In initial experiments, our goal will be to couple a microfabricated superconducting LC resonator to the 6.835 GHz hyperfine splitting in an ensemble of ^{87}Rb atoms. By trapping the atoms in the evanescent field of a 500-nm-wide optical fiber, we will seek to place them within 10 micrometers of the chip surface, where they will interact with the near-field of the microwave mode. In previous work we have demonstrated a frequency-tunable superconducting resonator having Q >100,000. [1] Here we will describe improvements in the resonator's design to reduce its sensitivity to absorbed photons, as well as the design of components to position the resonator relative to the optical fiber within a dilution refrigerator.

[1]Work supported by NSF through the Physics Frontier Center at the Joint Quantum Institute, Dept. of Physics, Univ. of Maryland.

12:39PM N41.00008 Quantum hybrid platform using electrons and superconducting electronics[1] , N. DANIILIDIS, D. GORMAN, Department of Physics, University of California Berkeley, L. TIAN, School of Natural Sciences, University of California, Merced, H. HAEFFNER, Department of Physics, University of California Berkeley; Materials Sciences Division, Lawrence Berkeley National Laboratory — We describe a quantum information processing (QIP) architecture based on single trapped electrons and superconducting electronics. The electron spins function as quantum memory elements, and the electron motion is used to couple the electrons to microwave circuits. To achieve this, we propose a parametric coupling mechanism which utilizes the non-linearity of the electrostatic potential of a sharp electrode placed $10\,\mu$m from a single trapped electron. This mechanism allows parametric coupling rates higher than 350 kHz for electrons with trap frequency of 300 MHz, coupled to a 7 GHz resonant circuit. We discuss state transfer and entangling operations between distant electrons, as well as between electrons and superconducting qubits, e.g. transmon qubits. The coupling to high frequency superconducting electronics enables initialization as well as state read-out of the electron motion. In addition, the electron's $\{|0\rangle, |1\rangle\}$ motional manifold can be mapped onto its spin using a non-linear oscillating magnetic field, completing all requirements for quantum computing with the electron spin. We estimate that all involved operations can be carried out with fidelities on the order of 0.999 enabling fault-tolerant quantum computing.

12:51PM N41.00009 Discrete Two-Level Systems Coupled to a Tunable High Q Superconducting Microwave Resonator[1] , KRISTEN VOIGT, J. HERTZBERG, Z. KIM, J. HOFFMAN, J. GROVER, J. LEE, S. RAVETS, JQI/UMD, M. HAFEZI, J. TAYLOR, JQI/NIST/UMD, A. CHOUDHARY, UMD, J. ANDERSON, JQI/UMD, C. LOBB, JQI/NIST/UMD, L. OROZCO, S. ROLSTON, F. WELLSTOOD, JQI/UMD — We have developed a tunable "lumped-element" thin-film superconducting Al microwave resonator [1] and used it for measuring two level systems. The device is intended for coupling to the hyperfine splitting of trapped ^{87}Rb atoms at 6.83 GHz. By moving a superconducting Al pin towards the inductor of the resonator using a piezo stage, we can tune the resonance over a range of 130 MHz. We measure the system by weakly coupling to an on-chip transmission line. At 12 mK the quality factor is typically 100,000. While holding the tuning pin at a fixed position, we can also apply a dc voltage to the transmission line. We observe small reproducible shifts of the resonance frequency as the voltage is changed. These shifts are more pronounced at lower power, which suggests the effect is attributable to discrete charged two-level systems in the sapphire substrate or surface Al oxide. We discuss our results and the characteristics of the underlying two-level systems.

1:03PM N41.00010 High cooperativity in coupled microwave resonator - ferromagnetic insulator hybrids , HANS HUEBL, CHRISTOPH ZOLLITSCH, JOHANNES LOTZE, FREDRIK HOCKE, MORITZ GREIFENSTEIN, ACHIM MARX, RUDOLF GROSS, SEBASTIAN T.B. GROSS, Walther-Meissner-Institut, Bayerische Akademie der Wissenschaften, Garching, Germany — Solid-state based quantum systems (e.g. single spin systems like NV centers in diamond or phosphor donors in silicon, superconducting qubits, nanomagnets) are building blocks for devices exploiting quantum physics phenomena. With different quantum systems available, schemes allowing to couple them move into focus. In particular, a coupling will enable the exchange of information between dressed states. Here, we report the observation of strong coupling between the exchange-coupled spins in gallium-doped yttrium iron garnet, and a superconducting coplanar microwave resonator made from Nb [1]. The measured coupling rate of 450 MHz is proportional to the square-root of the number of exchange-coupled spins and well exceeds the loss rate of 50 MHz of the spin system. This demonstrates that exchange-coupled systems are suitable for cavity quantum electrodynamics experiments, while allowing high integration densities due to their extraordinary high spin densities. Our results furthermore show that experiments with multiple exchange-coupled spin systems interacting via a single resonator are within reach. [1] H. Huebl, C. Zollitsch, J. Lotze, F. Hocke, M. Greifenstein, A. Marx, R. Gross, S.T.B. Goennenwein, arXiv: 1207.6039 (2012).

1:15PM N41.00011 Interfacing Rydberg atoms with superconducting circuits , S. FILIPP, T. THIELE, M. STAMMEIER, A. WALLRAFF, ETH Zurich, S.D. HOGAN, University College London, J.A. AGNER, F. MERKT, ETH Zurich — Hybrid quantum system are promising candidates for future quantum computing architectures because they provide the potential to combine the best properties of different physical systems. Here, we bring together Rydberg atoms and microwave photons emanating from a co-planar waveguide with the ultimate goal to interface long-lived Rydberg atoms with well-controllable superconducting qubits. In our cryogenic experiment, helium atoms pass over microwave electrodes hosted on a printed circuit board. By applying resonant microwave pulses, we induce transitions between Rydberg states with principal quantum number n=31-35 and observe coherent Rabi oscillations with typical oscillation periods of about 50ns [1]. From spectral measurements we can characterize the interaction between the atoms and surface fields leading to decoherence. The analysis of the inhomogeneously broadened lineshapes indicates that the stray electric field strength decreases with the inverse square of the atom-surface distance [2]. In experiments in preparation we plan to employ on-chip superconducting resonators to study the strong interaction of Rydberg atoms with few or individual microwave photons.

1:27PM N41.00012 Quantum-classical transition of synchronization of two coupled cavities , TONY LEE, ITAMP / Harvard, MICHAEL CROSS, Caltech — Synchronization is a phenomenon that appears throughout physics, biology, and chemistry. There has been much work on how synchronization arises in the classical regime. Motivated by current interest in quantum dissipative systems, we investigate whether synchronization can exist in the quantum regime. We consider a pair of cavities with second harmonic generation. In the classical limit, each cavity has a limit cycle solution, in which the photon number oscillates periodically in time. Coupling between the cavities leads to synchronization of the limit cycles. We follow what happens to the synchronization as the system becomes more quantum, by decreasing the photon number. We find that temporal correlations between the cavities survive deep in the quantum limit when there is much less than one photon in each cavity, because classical correlations are replaced by quantum correlations. Our results can be extended to optomechanics and Jaynes-Cummings cavities.

1:39PM N41.00013 Linear Coupling between Transverse Modes of a Nanomechanical Resonator , PATRICK TRUITT, Montclair State University, JARED HERTZBERG, University of Maryland, KEITH SCHWAB, California Institute of Technology — Recently, several groups have identified a linear coupling between different vibrational modes of nanomechanical resonators. We report observations of such a coupling between the two transverse modes of a doubly-clamped Si_3N_4 resonator with transverse resonance frequencies of 8.4 and 8.7 MHz. The resonator is voltage biased with respect to a nearby gate electrode for capactive readout. Increasing the gate bias introduces an electrostatic contribution to the spring constant of each mode, reducing the frequency gap between the two modes. At degeneracy, we observe an avoided crossing of 100 kHz. Measurements of the displacement amplitudes and quality factors through degeneracy is consistent with a linear superposition of the two modes. Magnetomotive measurements, which are sensitive to the projection of each mode's displacement onto an applied field, show that the coupled modes remain linearly polarized, with the direction of polarization rotating with increasing gate bias. In an effort to identify the source of the coupling, we constructed a finite element model of the resonator-gate capacitance and find that the observed coupling is an order of magnitude larger than what is expected from electrostatic gradients alone.

1:51PM N41.00014 Dynamic Simulation of Trapping and Controlled Rotation of a Microscale Rod Driven by Line Optical Tweezers[1] , MAHDI HAGHSHENAS-JARYANI, ALAN BOWLING, University of Texas at Arlington, Department of Mechanical and Aerospace Engineering, SAMARENDRA MOHANTY, University of Texas at Arlington, Department of Physics — Since the invention of optical tweezers, several biological and engineering applications, especially in micro-nanofluid, have been developed. For example, development of optically driven micromotors, which has an important role in microfluidic applications, has vastly been considered. Despite extensive experimental studies in this field, there is a lack of theoretical work that can verify and analyze these observations. This work develops a dynamic model to simulate trapping and controlled rotation of a microscale rod under influence of the optical trapping forces. The laser beam, used in line optical tweezers with a varying trap's length, was modeled based on a ray-optics approach. Herein, the effects of viscosity of the surrounding fluid (water), gravity, and buoyancy were included in the proposed model. The predicted results are in overall agreement with the experimental observation, which make the theoretical model be a viable tool for investigating the dynamic behavior of small size objects manipulated by optical tweezers in fluid environments.

2:03PM N41.00015 Ion photon networks for quantum computing and quantum repeaters , SUSAN CLARK, DAVID HAYES, DAVID HUCUL, I. VOLKAN INLEK, CHRISTOPHER MONROE, University of Maryland and Joint Quantum Institute — Quantum information based on ion-trap technology is well regarded for its stability, high detection fidelity, and ease of manipulation. Here we demonstrate a proof of principle experiment for scaling this technology to large numbers of ions in separate traps by linking the ions via photons. We give results for entanglement between distant ions via probabilistic photonic gates that is then swapped between ions in the same trap via deterministic Coulombic gates. We report fidelities above 65% and show encouraging preliminary results for the next stage of experimental improvement. Such a system could be used for quantum computing requiring large numbers of qubits or for quantum repeaters requiring the qubits to be separated by large distances.

Session N42 DCP: Focus Session: Supercooled and Nanoconfined Water I Hilton Baltimore Holiday Ballroom 3 - Valeria Molinero, University of Utah

11:15AM N42.00001 Liquid-liquid transition in the ST2 model of water , PABLO DEBENEDETTI, Princeton University — We present clear evidence of the existence of a metastable liquid-liquid phase transition in the ST2 model of water. Using four different techniques (the weighted histogram analysis method with single-particle moves, well-tempered metadynamics with single-particle moves, weighted histograms with parallel tempering and collective particle moves, and conventional molecular dynamics), we calculate the free energy surface over a range of thermodynamic conditions, we perform a finite size scaling analysis for the free energy barrier between the coexisting liquid phases, we demonstrate the attainment of diffusive behavior, and we perform stringent thermodynamic consistency checks. The results provide conclusive evidence of a first-order liquid-liquid transition. We also show that structural equilibration in the sluggish low-density phase is attained over the time scale of our simulations, and that crystallization times are significantly longer than structural equilibration, even under deeply supercooled conditions. We place our results in the context of the theory of metastability.

11:51AM N42.00002 Entropy-driven liquid-liquid transitions in supercooled water[1] , MIKHAIL ANISIMOV, University of Maryland, College Park — Twenty years ago it was suggested that the anomalous properties of supercooled water may be caused by a critical point that terminates a line of metastable liquid-liquid separation of lower-density and higher-density water. I describe a phenomenological model in which liquid water at low temperatures is viewed as an athermal solution of two hydrogen-bond network structures with different entropies and densities. Alternatively to the lattice-gas/regular solution model, in which fluid phase separation is driven by energy, the phase transition in the athermal two-state water is driven by entropy upon increasing the pressure, while the critical temperature is defined by the reaction equilibrium constant. The order parameter is associated with the entropy, while the ordering field is a combination of temperature and pressure. The model predicts the location of density maxima at the locus of a near-constant fraction of the lower-density structure. Another example of entropy-driven liquid polyamorphism is the transition between the structurally ordered "Blue Phase III" and disordered liquid in some chiral materials; this transition is experimentally accessible. I also discuss the application of the two-state model to binary solutions of supercooled water in which liquid-liquid transition may also become accessible to direct observation. Some atomistic "water-like" models such as mW, do not show liquid-liquid separation in the metastable liquid domain. However, even without actual liquid-liquid separation, the anomalies observed in MD simulations of mW can be accurately described by the entropy-driven nonideality of two molecular configurations, the same physics that presumably drives the liquid-liquid transition in real water.

12:27PM N42.00003 Interplay of the Glass Transition and the Liquid-Liquid Phase Transition in Water , NICOLAS GIOVAMBATTISTA, City University of New York (CUNY), Brooklyn College — Most liquids can form a single glass or amorphous state when cooled sufficiently fast (in order to prevent crystallization). However, there are a few substances that are relevant to scientific and technological applications which can exist in at least two different amorphous states, a property known as polyamorphism. Examples include silicon, silica, and in particular, water. In the case of water, experiments show the existence of a low-density (LDA) and high-density (HDA) amorphous ice that are separated by a dramatic, first-order like phase transition. It has been argued that the LDA-HDA transformation evolves into a first-order liquid-liquid phase transition (LLPT) at temperatures above the glass transition temperature Tg. However, obtaining direct experimental evidence of the LLPT has been challenging since the LLPT occurs at conditions where water rapidly crystallizes. In this talk, I will (i) discuss the general phenomenology of polyamorphism in water and its implications, and (ii) explore the effects of a LLPT on the pressure dependence of Tg(P) for LDA and HDA. Our study is based on computer simulations of two water models – one with a LLPT (ST2 model), and one without (SPC/E model). In the absence of a LLPT, Tg(P) for all glasses nearly coincide. Instead, when there is a LLPT, different glasses exhibit dramatically different Tg(P) loci which are directly linked with the LLPT. Available experimental data for Tg(P) are only consistent with the scenario that includes a LLPT (ST2 model) and hence, our results support the view that a LLPT may exist for the case of water.

1:27PM N42.00006 The Putative Liquid-Liquid Transition is a Liquid-Solid Transition in Atomistic Models of Water , DAVID CHANDLER, DAVID LIMMER, Department of Chemistry, University of California, Berkeley — Our detailed and controlled studies of free energy surfaces for models of water find no evidence for reversible polyamorphism, and a general theoretical analysis of the phase behavior of cold water in nano pores shows that measured behaviors of these systems reflect surface modulation and dynamics of ice, not a liquid-liquid critical point. A few workers reach different conclusions, reporting evidence of a liquid-liquid critical point in computer simulations of supercooled water. In some cases, it appears that these contrary results are based upon simulation algorithms that are inconsistent with principles of statistical mechanics, such as using barostats that do not reproduce the correct distribution of volume fluctuations. In other cases, the results appear to be associated with difficulty equilibrating the supercooled material and mistaking metastability for coarsening of the ordered ice phase. In this case, sufficient information is available for us to reproduce the contrary results and to establish that they are artifacts of finite time sampling. This finding leads us to the conclusion that two distinct, reversible liquid phases do not exist in models of supercooled water.

1:39PM N42.00007 Amorphous ices explained in terms of nonequilibrium phase transitions in supercooled water , DAVID LIMMER, DAVID CHANDLER, Department of Chemistry, University of California, Berkeley — We analyze the phase diagram of supercooled water out-of-equilibrium using concepts from space-time thermodynamics and the dynamic facilitation theory of the glass transition, together with molecular dynamics simulations. We find that when water is driven out-of-equilibrium, it can exist in multiple amorphous states. In contrast, we find that when water is at equilibrium, it can exist in only one liquid state. The amorphous non-equilibrium states are solids, distinguished from the liquid by their lack of mobility, and distinguished from each other by their different densities and local structure. This finding explains the experimentally observed polyamorphism of water as a class of nonequilibrium phenomena involving glasses of different densities. While the amorphous solids can be long lived, they are thermodynamically unstable. When allowed to relax to equilibrium, they crystallize with pathways that pass first through liquid state configurations and then to ordered ice.

Wednesday, March 20, 2013 11:15AM - 2:03PM –

Session N43 DCP DBIO: Focus Session: Protein Misfolding and Aggregation III Hilton Baltimore Holiday Ballroom 2 - Elsa Yan, Yale University

11:15AM N43.00001 Structural Transformation and Aggregation of cc-beta Peptides Into Amyloid Proto-fibrils , YUBA BHANDARI, TIMOTHY STECKMANN, PREM CHAPAGAIN, BERNARD GERSTMAN, Florida International University, Miami, Florida — The study of amyloid fibrils has important implications in understanding and treatment of various neurodegenerative diseases such as Alzheimer's and Parkinson's. During the formation of amyloid fibrils, peptide polymers manifest fascinating physical behavior by undergoing complicated structural transformations. We examine the behavior of a small engineered peptide called cc-beta, that was designed to mimic the structural changes of the much larger, naturally occurring amyloid beta proteins. Molecular dynamics (MD) simulations are performed to uncover the underlying physics that is responsible for the large scale structural transformations. By using implicit solvent replica exchange MD simulations, we examined the behavior of 12 peptides, initially arranged in four different cc-beta alpha helix trimers. We observed various intermediate stages of aggregation, as well as an organized proto-fibril beta aggregate. We discuss the time evolution and the various interactions involved in the structural transformation.

11:27AM N43.00002 Gelation, Phase Behavior and Dynamics of Beta-Lactoglobulin Amyloid Fibrils at Varying Concentrations and Ionic Strengths , RAFFAELE MEZZENGA, SREENATH BOLISETTY, ETH Zurich, LUDGER HARNAU, Max-Planck-Institut, Stuttgart, JIN-MI JUNG, University of Fribourg — We discuss the thermodynamic and dynamic behavior of Beta-lactoglobulin fibrils in a vast region of the concentration-ionic strength phase diagram, by combining static, dynamic and depolarized light scattering (SLS, DLS, DDLS), small angle neutron scattering (SANS), and cryo-TEM. We focus on the region of the phase diagram where ionic strength and concentration changes induce transitions in gelation and lyotropic liquid crystalline behavior. Increase in ionic strength, by NaCl salt, causes the phase transitions from nematic to gel phases. Increase in fibril concentration induces first a phase transition from an isotropic to a nematic phase; further increase induces the formation of a gel phase. SANS and osmotic compressibility calculated by SLS measurements, capture the main features of the IN transition of Beta-lactoglobulin protein fibrils. The form and structure factors measured by scattering experiments are analyzed by polymer reference interaction site model (PRISM). Dynamics of the protein fibrils at different concentrations, measured by polarized and depolarized dynamic light scattering, shows both individual and collective diffusion after the IN transition. cryo-TEM images further demonstrate the alignment of the protein fibrils, quantified by a 2D order parameter.

11:39AM N43.00003 Amyloid fibril networks nucleated under oscillatory shear , KIERSTEN BATZLI, BRIAN LOVE, Department of Materials Science and Engineering, University of Michigan — The process of amyloid fibril formation is of interest due to the link between these self-aggregating proteins and the progression of neurodegenerative disease. More recently, research has been directed at the exploitation of self-assembly properties of amyloid proteins for use as templates for nanowires and fibrillar networks. Insulin is an ideal protein for these purposes due to the ease of aggregation, as well as the large aspect ratio and high chemical stability of the produced fibrils. Insulin in pH 2 solution quickly forms aggregates in the presence of 65 $^{\circ}$C heat. We have investigated the effect of oscillatory shear on the nucleation and growth of amyloid fibrillar networks using rheology and TEM to characterize the mechanical properties and structure of the network respectively. We contrast networks nucleated under oscillatory shear with networks nucleated in static and agitated conditions, and discuss network properties in the context of use in templating nanostructures. We find that the structural characteristics of the formed networks, including the density of fibrils, are affected by shear during the nucleation phase of amyloid growth.

11:51AM N43.00004 Amyloid Structure In Vitro and In Vivo[1] , ROBERT TYCKO, National Institutes of Health — Solid state nuclear magnetic resonance (NMR) measurements can provide unique information about the structural properties of proteins in noncrystalline states that are of interest from both the biophysical and the biomedical perspectives. I will discuss recent results from my lab's efforts to characterize the molecular structures of amyloid fibrils, especially the Aβ peptide fibrils that are associated with Alzheimer's disease. From a combination of solid state NMR and electron microscopy measurements, we have developed full structural models for 40-residue wild-type Aβ fibrils that form in vitro and contain parallel β-sheets with 2-fold and 3-fold overall rotational symmetry. We have recently discovered that the "Iowa mutant" (D23N-Aβ) peptide can also form metastable fibrils with a surprising antiparallel β-sheet structure. And we are in the process of investigating Aβ fibril structures that develop in human brain tissue. In addition to recent results, I will briefly describe recent advances in methodology that contribute to this work.

12:27PM N43.00005 Yeast prion architecture explains how proteins can be genes , REED WICKNER[1], National Institutes of Health, Bethesda, MD — Prions (infectious proteins) transmit information without an accompanying DNA or RNA. Most yeast prions are self-propagating amyloids that inactivate a normally functional protein. A single protein can become any of several prion variants, with different manifestations due to different amyloid structures. We showed that the yeast prion amyloids of Ure2p, Sup35p and Rnq1p are folded in-register parallel beta sheets using solid state NMR dipolar recoupling experiments, mass-per-filament-length measurements, and filament diameter measurements. The extent of beta sheet structure, measured by chemical shifts in solid-state NMR and acquired protease-resistance on amyloid formation, combined with the measured filament diameters, imply that the beta sheets must be folded along the long axis of the filament. We speculate that prion variants of a single protein sequence differ in the location of these folds. Favorable interactions between identical side chains must hold these structures in-register. The same interactions must guide an unstructured monomer joining the end of a filament to assume the same conformation as molecules already in the filament, with the turns at the same locations. In this way, a protein can template its own conformation, in analogy to the ability of a DNA molecule to template its sequence by specific base-pairing.

1:39PM N43.00007 ABSTRACT HAS BEEN MOVED TO J45.00003 –

1:51PM N43.00008 Self-Assembly of Peptides at the Air/Water Interface , MEHMET SAYAR, Koc University — Peptides are commonly used as building blocks for design and development of novel materials with a variety of application areas ranging from drug design to biotechnology. The precise control of molecular architecture and specific nature of the nonbonded interactions among peptides enable aggregates with well defined structural and functional properties. The interaction of peptides with interfaces leads to dramatic changes in their conformational and aggregation behavior. In this talk, I will discuss our research on the interplay of intermolecular forces and influence of interfaces. In the first part the amphiphilic nature of short peptide oligomers and their behavior at the air/water interface will be discussed. The surface driving force and its decomposition will be analyzed. In the second part aggregation of peptides in bulk water and at an interface will be discussed. Different design features which can be tuned to control aggregation behavior will be analyzed.

[2] O. Engin, A. Villa, M.S. & H. Berk, "Driving Forces for Adsorption of Amphiphilic Peptides to Air-Water Interface," J. Phys. Chem. B 114, 11093-11101 (2010)

Wednesday, March 20, 2013 11:15AM - 2:15PM –

Session N44 DBIO: Focus Session: Translocation through Nanopores II Hilton Baltimore Holiday Ballroom 1 - Gary Slater, University of Ottawa

11:15AM N44.00001 How tension propagates for a driven semi-flexible chain while translocating through a nano-pore[1] , RAMESH ADHIKARI, ANIKET BHATTACHARYA, University of Central Florida, Orlando, FL 32816 — Driven translocation of a stiff chain through a nano-pore is studied using Langevin dynamics in two dimension (2D). We observe that for a given chain length N the mean first passage time (MFPT) $\langle\tau\rangle$ increases for a stiffer chain and the translocation exponent α ($\langle\tau\rangle \sim N^{\alpha}$) satisfies the inequality $2\nu < \alpha < 1+\nu$, where ν is the equilibrium Flory exponent for a given chain stiffness. We calculate the residence time of the individual monomers and observe that the peak position of the residence time $W(m)$ as a function of the monomer index m shifts at a *lower* m-value with *increasing chain stiffness* κ_b. Finally, we provide qualitative physical explanation for dependence of various quantities on chain stiffness κ_b by using ideas from Sakaue's tension propagation(TP) theory [Phys. Rev. E **76**, 021803 (2007)] and its recent implementation into a Brownian dynamics tension propagation (BDTP) scheme for a finite chain by Ikonen et al. [J. Chem. Phys. **137**, 085101 (2012); Phys. Rev. E **85**, 051803 (2012)]for a semi-flexible chain.

11:39AM N44.00003 Linear and ring DNA macromolecules moderately and strongly confined in nanochannels[1] , PETER CIFRA, Polymer Institute, Slovak Academy of Sciences, Dúbravská cesta 9, 842 36 Bratislava, Slovakia, ZUZANA BENKOVA, REQUIMTE, Chemistry Department, University of Porto, Rua do Campo Alegre 687, 4169-007 Porto, Portugal, TOMAS BLEHA, Polymer Institute, Slovak Academy of Sciences, Dúbravská cesta 9, 842 36 Bratislava, Slovakia — Understanding the mechanism of DNA extension in nanochannels is necessary for interpretation of experiments in nanofluidic channel devices that are conducted recently not only with linear but also with ring chains. Except reviewing the situation with linear chains we analyze here the experimental results and simulations for the channel-induced extension (linearization) of ring chains. Results of simulations for confined rings indicate that similar transition between moderate and strong confinement as in the case of linear chains exists also for rings. Due to stronger self-avoidance in confined rings the transition and relative chain extension is shifted in comparison to linear DNA. We suggest that similar relation as used in experiments for the extension of linear chains may be used also for circular DNA. For linear DNA in channel relatively stable distinctive events due to chain backfolding, which complicate chain linearization experiments, are analyzed. The abundance of DNA chains folded at the chain ends and in the chain interior was analyzed as a function of the channel width. Z. Benkova, P.Cifra, Macromolecules 45, 2597-2608 (2012) P. Cifra, T.Bleha, Soft Matter 8, 9022-9028 (2012)

11:51AM N44.00004 Polymer Translocation in a Crowded Environment: Effects due to Obstacle Density and Arrangement , HENDRICK W. DE HAAN, Department of Physics, University of Ottawa — The translocation of a polymer across a membrane through a nanopore has received much attention, primarily due to emerging nanotechnology applications such as DNA sequencing. However, translocation is also a process that is ubiquitous in the natural world with examples including the transport of DNA and proteins across cell walls. Considering this latter motivation, the environment in which translocation occurs is relatively complicated with many intracellular and extracellular inclusions such as the cell organelles, soluble proteins, and components of the cytoskeleton and extracellular matrix. In this talk, we examine translocation in such a crowded environment via computer simulations in which we place immobile, spherical "obstacles" on both sides of the membrane. We show that an effective driving force arises i) when the concentration of obstacles across the pore differs and ii) when the arrangement of obstacles across the pore differs. A simple force model is used to estimate the magnitude of these entropic driving forces. Good agreement is found between the results and the simple models. Simulations are also performed with both effects present such that a bias resulting from a lower concentration of obstacles on the cis side of the membrane is opposed by a bias arising from an increased amount of disorder on $trans$. Results from this setup indicate that in a real system where both effects are likely to play a role, it could be difficult to guess even the direction of the intrinsic resulting driving force, let alone the magnitude. We also present results from simulations in which the obstacles are mobile but restricted to different degrees.

12:27PM N44.00005 Electric field controlled small molecule transport through vertically aligned large diameter multiwalled carbon nanotube forest membrane[1] , PURUSHOTTAM TIWARI, Florida International University, PADMINI KRISHNAKUMAR, Arizona State University, YESIM DARICI, JIN HE, Florida International University, DEPARTMENT OF PHYSICS, ARIZONA STATE UNIVERSITY COLLABORATION — Vertically aligned multi-walled carbon nanotube (MWCNT) forest based porous membranes have been fabricated. The average inner diameter of the CNT is about 7 nm and the length is about 45 μm. The translocation behaviors of small charged molecules and gold nanoparticles through the CNT membrane under electric field have been investigated. Electrophoresis is found to be the main mechanism for the translocation of small molecules under the applied electric field in the range of 10000 Vm^{-1}. The interactions between the molecule and the hydrophobic CNT inner surface play an important role for the transport of small molecules. The chemical modifications at CNT ends can also effectively regulate the transport of molecules.

[1]Purushottam Tiwari highly acknowledges Florida International University School of Integrated Science and Humanity, College of Arts and Sciences, for the research assistantship.

12:39PM N44.00006 Electric-field driven translocation of colloidal wild-type and mutant fd viruses through a solid-state nanopore , WANG MIAO, Brown University, LIPING LIU, Brown University and Southeast University, China, ANNA LU, Brown University and Deerfield Academy, MA, PRERNA SHARMA, ZVONIMIR DOGIC, Brandeis University, CHUONG HUYNH, LARRY SCIPIONI, Carl Zeiss Microscopy LLC, Peabody MA, XINSHENG LING, Brown University — Colloidal suspensions of fd viruses are useful model systems for condensed matter physics. Here we explore the transport processes of fd particles in solid-state nanopores. Recently we have observed a nonlinear behavior in the electrophoretic mobility of wild-type fd particles. Here we carried out a comparative study of wild-type and mutant Y21M in their translocation dynamics through a nanopore. This work was supported by NSF-DMR and NSF-MRSEC.

12:51PM N44.00007 Polymer Translocation Dynamics in the Quasi-Static Limit[1] , JAMES POLSON, University of Prince Edward Island — Monte Carlo and Langevin dynamics simulations are used to study the dynamics of polymer translocation through a nanopore using a coarse-grained model. We examine the relationship between the translocation free energy barrier and the translocation times through a comparison of the simulation results to predictions using the Fokker-Planck formalism. We illustrate the importance of using free energy profiles obtained from precise numerical calculations rather than those obtained from simple theoretical models. In addition, we determine the parameter regime within which the Focker-Planck approach is valid and beyond which non-equilibrium effects become appreciable. The relevance of these results to recent theoretical and simulation studies of polymer translocation dynamics is discussed.

1:03PM N44.00008 Nonequilibrium Dynamics of Polymer Translocation , TAKAHIRO SAKAUE, Department of Physics, Kyushu University, Japan & JST, PREST — When a flexible chain is pulled or sucked, it can initially respond only locally, and sequential nonequilibrium processes with large conformational distortion follow in line with the propagation of tensile force along the chain backbone. This is a generic dynamical response property of polymers, the understanding of which provides us with a viewpoint to capture an essential aspect of the driven translocation process. In the meeting, I will summarize a basic framework to analyze the nonequilibrium dynamics of driven translocation process alongside of recent progresses.

1:39PM N44.00009 Active Control of Protein and Ionic Transport through Semiconducting Conical Nanopores , TEENA JAMES, YEVGENIY KALININ, CHIH-CHIEH CHAN, JATINDER RANDHAWA, Johns Hopkins University, MIKHAIL GAEVSKI, Princeton University, DAVID GRACIAS, Johns Hopkins University — Nanopores with conical geometries have been found to rectify ionic current in electrolytes. While nanopores in semiconducting membranes offer the ability to modulate ionic transport, the fabrication of conical nanopores in silicon has proven challenging. Here, we report the discovery that Au nanoparticle-assisted plasma etching results in the formation of conical etch profiles in Si [1]. We show that this process provides a versatile means to fabricate nanopores on Si substrates with variable pore-diameters and cone-angles. When in contact with aqueous electrolyte solution (pH>3), the nanopore was found to exhibit negative surface charge due to de-protonation of the Si-OH surface groups. The rectification ratio of ionic current through the pore was thus found to be variable by altering the pH, owing to the amphoteric nature of Si-OH surface groups (pKa 6.9) and was also dependent on the ionic strengths, agreeing with the theoretical predictions based on Poisson−Nernst−Planck equation. We demonstrate that these semiconducting conical nanopores can function as ionic switches with high on-off ratios, by varying Si surface charge through voltage gating. Further, we demonstrate voltage gated control over protein translocation through these pores. [1]. Voltage-gated ion transport through semiconducting conical nanopores formed by metal nanoparticle assisted plasma etching, T. James, *et al.* Nano Letters 12, 7, 3437–3442 (2012).

1:51PM N44.00010 Rapid fabrication of sub-5nm solid-state nanopore for low cost biosensing , HAROLD KWOK, KYLE BRIGGS, VINCENT TABARD-COSSA, University of Ottawa — Nanopores-based technologies are emerging as a powerful tool for single molecule analysis. They are also the leading candidates for future generation DNA sequencing platforms. Despite all of these potentials, current solid-state nanopore fabrication techniques, based on focused beams of energetic particles, remains low throughput, complex and expensive. Such drawbacks greatly limit the breadth of applications, and are major barriers to commercialization of any nanopore-based technologies. We have demonstrated a simple, highly scalable and low cost method to fabricate solid-state nanopores. It relies on stressing a thin dielectric membrane with high-electric field while submerged in aqueous salt solution. The technique allows a single sub-5nm nanopore be fabricated within a minute directly in liquids. In addition, a pore can be precisely enlarged by the similar used of high-electric field stressing. We will describe the fabrication method, present our current understanding of the physical mechanism leading to pore formation, and demonstrate its usefulness for single-molecule detection by studying DNA translocation kinetics. The discovery of this new method opens a wide range of possibilities for single-molecule biophysics and commercial sensing applications.

2:03PM N44.00011 Probing the Influence of Coil Configuration on DNA Translocation Dynamics in Solid-State Nanopores[1] , XU LIU, KARRI DIPETRILLO, JASON CHAN, LUCAS EGGERS, ANGUS MCMULLEN, DEREK STEIN, Brown University — We studied electrophoretic DNA translocations of asymmetric nanopore-cavity structures designed to control the initial configurations of molecules. The structures comprise a thin SiN membrane with a nanopore that leads into a 400 nm-high cavity, which is in turn covered by a 400-nm thick SiN membrane with a circular opening whose diameter ranged from 150 nm to 1.5 μm. These structures maintain a gap between the nanopore and a DNA coil translocating from above, but not one translocating from below. The viscous drag on the DNA segment extending from the coil to the nanopore significantly slowed translocations from above. The mean translocation times for those events were 2.5 times longer than for tranlocations from below when the upper opening of the cavity was only 200 nm wide. The translocation times converged as the opening was increased to micrometer diameters. This last result can be explained by the DNA coil, whose radius of gyration is $\sim$600 nm, squeezing into the upper opening by increasing amounts. Our experimental results compare favourably with a quantitative model of DNA translocation speeds, similar to models by Lu *et al.* and by Grosberg, which accounts for the initial configuration of the DNA coil.

Session N45 DBIO: Focus Session: Cell Mechanics I Hilton Baltimore Holiday Ballroom 4 - Jennifer Curtis, Georgia Institute of Technology

11:15AM N45.00001 Cellular Tug-of-War: Forces at Work and DNA Stretching in Mitosis , BRIAN GRIFFIN, MARIA L. KILFOIL, University of Massachuestts - Amherst — In the microscopic world of the cell dominated by thermal noise, a cell must be able to successfully segregate its DNA with high fidelity in order to pass its genetic information on to its progeny. In this process of mitosis in eukaryotes, driving forces act on the cytoskeleton-based architecture called the mitotic spindle to promote this division. Our preliminary data demonstrates that the dynamics of this process in yeast cells is universal. Moreover, the dynamics suggest an increasing load as the chromosomes are pulled apart. To investigate this, we use three-dimensional imaging to track the dynamics of the poles of this architecture and the points of attachment to chromosomes simultaneously and with high spatial resolution. We analyze the relative motions of chromosomes as they are organized before segregation and as they are pulled apart, using this data to investigate the force-response behavior of this cytoskeleton-chromosome polymer system.

11:27AM N45.00002 *in vivo* Measurements of Conformational Fluctuations of Chromosomal DNA in *Escherichia Coli* , RUDRA KAFLE, JENS-CHRISTIAN MEINERS, University of Michigan — The cell is the site of active, motor-driven processes far from thermodynamic equilibrium. Therefore, the intracellular dynamics are complex and subject to a multitude of constraints and forces. We study the conformational fluctuations of chromosomal DNA *in vivo* in live and dead *E. coli* cells by Fluorescence Correlation Spectroscopy (FCS). The fluctuations move the DNA-bound fluorophores stochastically into the diffraction-limited excitation volume of a focused laser beam in a confocal microscope. From the time correlation functions of the fluorescence intensity, we obtain the mean square displacements of the DNA on a time scale from microseconds to seconds. We see a substantial decrease in the power spectral density (PSD) of the displacement fluctuations at frequencies below 10 Hz in the dead cells, compared to the live cells. The larger fluctuations in the living cells may indicate that the fluctuations on this time scale may be driven by active processes involving molecular motors that generate forces by ATP hydrolysis. A small difference in PSD between live and dead cells on shorter time scales suggests that the processes on corresponding short length scales rely primarily on thermally-driven diffusive mechanisms.

11:39AM N45.00003 ABSTRACT WITHDRAWN –

11:51AM N45.00004 Mediation of cell adhesion by the pericellular matrix[1] , JENNIFER CURTIS, School of Physics, Georgia Institute of Technology — Cell adhesion requires a close proximity on the nanometer scale between the plasma membrane and the surrounding material (or neighboring cell). Yet, in many classic scenarios where cell adhesion is carefully regulated, including proliferation, migration, embryogenesis and cancer metastasis, the cell's surface is insulated by an invisible but microns thick polymer brush-like structure, called the pericellular matrix. Indeed the presence of the pericellular matrix has been correlated with increased migration and proliferation rates, where disruption of this bound polymer brush interferes with the efficacy of these processes. We present methods to characterize the pericellular matrix distribution, mechanics and mesh size and explore how cells orchestrate adhesion with the help of the pericellular matrix.

[1]JEC gratefully acknowledges funding provided by NSF grants PHYS 0848797 and DMR 0848797

12:27PM N45.00005 Modifications of the structure of the pericellular matrix measured via optical force probe microscopy , LOUIS MCLANE, ANTHONY KRAMER, PATRICK CHANG, JENNIFER CURTIS, Georgia Institute of Technology — The pericellular matrix is a large protein and polysaccharide rich polymer layer attached to the surface of many cells, and which often extends several microns out from the cell surface into the surrounding extracellular space. Here we study the intrinsic nature and modifications of the structure of the pericellular coat on rat chondrocytes with the use of optical force probe microscopy. Optical force probe studies allow us to make both dynamic force measurements as well as equilibrium force measurements throughout the coat. These force measurements are used to observe the structural change in the coat with the addition of exogenous aggrecan. Not only does addition of exogenous aggrecan dramatically swell our coat to well over twice in size, our analysis indicates that the addition of exogenous aggrecan decreases the mesh size throughout the coat. We speculate that the added aggrecan binds to available binding sites along the hyaluronan chain, both enlarging the coat's size as well as tightening up the opening within the coat. We further suggest that the available binding sites for the exogenous aggrecan are abundant in the outer edges of the coat, as both the dynamic and equilibrium forces in this region are changed. Here, both force measurements show that forces closest to the cell membrane remain relatively unchanged, while the forces in the outer region of the coat are increased. These results are consistent with those obtained with complementary measurements using quantitative particle exclusion assays.

12:39PM N45.00006 Quantitative particle exclusion assays of the pericellular coat reveal changing mesh size , PATRICK CHANG, LOUIS MCLANE, NOLAN KRAMER, JENNIFER E. CURTIS, Georgia Institute of Technology — We present a quantitative assay of the pericellular coat, a tethered polymer matrix that decorates the surface of numerous cell types. In these assays, we look at how passivated microspheres of varying diameter penetrate the cell coat. Distinct spatial distributions correspond to different particle sizes. These measurements confirm that the cell coat (on the chondrocyte RCJ-P cell line) has a spatially varying mesh size, in agreement with our independent assays performed with optical force probe microscopy. The data indicate that particles with diameters of 500 nm or greater do not penetrate the inner layer of the matrix, while particles smaller than 500 nm reach different regions, with the smallest reaching the cell surface. In an ongoing effort, we are developing a model for the observed statistical distribution of the beads. These experiments show that accessibility of the cell surface is strongly mediated by the presence of the cell coat, and they have important implications regarding the transport of molecules to the cell surface, protection from bacterial infection, drug delivery, as well as the way the cell interacts and adheres to the surrounding extracellular matrix.

12:51PM N45.00007 Reversible and irreversible deformations of bacterial cell walls , ARIEL AMIR, Harvard University, FARINAZ BABAEIPOUR, Harvard University, UCSD, DAVID NELSON, Harvard University, SUCKJOON JUN, Harvard University, UCSD — Bacterial cell walls determine their shape and hold their large internal pressure. In spite of their biological importance, a full understanding of their structure and mechanics is lacking. Here, we shed new light on the nature of the deformations of bacterial cell walls by showing, theoretically and experimentally, that these can be either elastically (reversibly) or plastically (irreversibly) deformed, depending on the timescales involved. Our data suggests that irreversible bending of the cell wall arises due to an asymmetric insertion of new material, responding to the mechanical stresses.

1:03PM N45.00008 Mechanical Properties of Primary Cilia , CHRISTOPHER BATTLE, CHRISTOPH F. SCHMIDT, University of Goettingen — Recent studies have shown that the primary cilium, long thought to be a vestigial cellular appendage with no function, is involved in a multitude of sensory functions. One example, interesting from both a biophysical and medical standpoint, is the primary cilium of kidney epithelial cells, which acts as a mechanosensitive flow sensor. Genetic defects in ciliary function can cause, e.g., polycystic kidney disease (PKD). The material properties of these non-motile, microtubule-based 9+0 cilia, and the way they are anchored to the cell cytoskeleton, are important to know if one wants to understand the mechano-electrochemical response of these cells, which is mediated by their cilia. We have probed the mechanical properties, boundary conditions, and dynamics of the cilia of MDCK cells using optical traps and DIC/fluorescence microscopy. We found evidence for both elastic relaxation of the cilia themselves after bending and for compliance in the intracellular anchoring structures. Angular and positional fluctuations of the cilia reflect both thermal excitations and cellular driving forces.

1:15PM N45.00009 The influence of myosin-generated force to the intracellular microrheology in living cells , MING-TZO WEI, H. DANIEL OU-YANG, Lehigh University — The mechanics of cells are governed by cytoskeletal filaments and molecular motors forming a dynamic mechanical entity. A recent experimental study by Mizuno et al. showed local shear modulus of a synthesized cytoskeletal network could increase as a result of myosin-generated internal stresses. To examine whether similar behaviors could take place in living cells we combined active and passive microrheology to measure the myosin-generated fluctuating force and intracellular shear modulus in HeLa cells. While our experiment showed an increase in the fluctuations of the shear modulus with increasing motor forces, the experiment did not find a direct correlation between the mean intracellular shear modulus and the motor-generated fluctuating force. Based on Mizuno et al's assumption shear modulus is increasing as local tensions, the difference between the results obtained by the intracellular behavior and the synthesized cytoskeletal network could be due to the existence of a steady-state intracellular tension that is stronger than the motor-generated fluctuating force.

1:27PM N45.00010 Cellular pressure and volume regulation and implications for cell mechanics , HONGYUAN JIANG, SEAN SUN, Johns Hopkins University — In eukaryotic cells, small changes in cell volume can serve as important signals for cell proliferation, death and migration. Volume and shape regulation also directly impacts the mechanics of the cell and multi-cellular tissues. Recent experiments found that during mitosis, eukaryotic cells establish a preferred steady volume and pressure, and the steady volume and pressure can robustly adapt to large osmotic shocks. Here we develop a mathematical model of cellular pressure and volume regulation, incorporating essential elements such as water permeation, mechano-sensitive channels, active ion pumps and active stresses in the actomyosin cortex. The model can fully explain the available experimental data, and predicts the cellular volume and pressure for several models of cell cortical mechanics. Furthermore, we show that when cells are subjected to an externally applied load, such as in an AFM indentation experiment, active regulation of volume and pressure leads to complex cellular response. We found the cell stiffness highly depends on the loading rate, which indicates the transport of water and ions might contribute to the observed viscoelasticity of cells.

1:39PM N45.00011 Direct mechanical measurements of cytoskeleton-mediated intercellular fluid flow , STEVEN ZEHNDER, JOLIE BREAUX, ALISON DUNN, JUAN URUEÑA, W. GREGORY SAWYER, THOMAS ANGELINI, University of Florida — Cell behavior in tissues is intimately tied to forces generated by cytoskeletal contractions. Contraction generated tensions are balanced by deformations in the cell's microenvironment, by internal cytoskeletal structures, and by the incompressible cytosolic fluid contained by the cell membrane. However, contraction generated pressures cannot be supported by the cytosol if the cell membrane is adequately permeable. Small, non-selective pores called gap junctions connect cells in a layer, allowing small molecules to pass between cells. The ability of contraction driven fluid movement to transmit forces across gap junctions and the ability of cells to respond to this movement is unexplored. To study the mechanics of intercellular fluid flow, we apply biologically relevant pressures to large regions of cells in a monolayer with a micro-indentation system. We directly measure indentation force and volume as a function of time to determine fluid flow rates and associated stresses between cells. Preliminary results will be presented.

1:51PM N45.00012 Cell stretching in extensional flows for assaying cell mechanics , DANIEL GOSSETT, HENRY TSE, OLADUNNI ADEYIGA, OTTO YANG, JIANYU RAO, DINO DI CARLO, University of California, Los Angeles — There is growing evidence that cell deformability is a useful indicator of cell state and may be a label-free biomarker of metastatic potential, degree of differentiation, and leukocyte activation. In order for deformability measurements to be clinically valuable given the heterogeneity of biological samples, there exists a need for a high-throughput assay of this biophysical property. We developed a robust method for obtaining high-throughput (>1,000 cells/sec) single-cell mechanical measurements which employs coupled hydrodynamic lift forces and curvature-induced secondary flows to uniformly position cells in flow, extensional flow stretching, high-speed imaging, and automated image analysis to extract diameter and deformability parameters. Using this method we have assayed numerous in vitro models of cellular transformations and clinical fluids where malignant cells manifest. We found transformations associated with increased motility or invasiveness increased deformability and the presence of large and deformable cells within clinical pleural fluids correlated well with cytological diagnoses of malignancy. This agrees with the hypothesis that cancerous cells are deformable by necessity–to be able to transverse tight endothelial gaps and invade tissues.

Wednesday, March 20, 2013 11:15AM - 2:03PM –

Session N46 GIMS: Detectors, Sensors, and Transducers Hilton Baltimore Holiday Ballroom 5 - Brad Ramshaw, Los Alamos National Laboratory

11:15AM N46.00001 Sub-diffraction Position Determination with Four Laser Diodes for Tracking/Trapping a Single Molecule

, JAMES A. GERMANN, BRIAN K. CANFIELD, JASON K. KING, LLOYD M. DAVIS, University of Tennessee Space Institute — Prolonged observation of single biological molecules by overcoming diffusion can reveal interesting new properties. Observation times may be increased by physically confining a particle, but this often leads to interactions that affect molecular properties. Another way of increasing observation time is to trap a single molecule in solution three-dimensionally. However, optimal trapping of single particles relies on rapid determination of particle position for feedback to counteract Brownian diffusion. In our experiment, a tetrahedral region with foci located at the vertices is created by combining four modulated 635 nm laser diodes with three beam splitters. Fluorescence is measured with a single-photon avalanche diode and separated into bins corresponding to each excitation focus. A maximum-likelihood estimation algorithm is used to determine particle position with sub-diffraction precision in real time. To test the tracking capability of the four-focus setup, fluorescently labeled latex beads were tracked in an aqueous glycerol solution. Two setups, a piezoelectric stage and a three-dimensional electrokinetic trap, are being implemented to maintain a single fluorescent latex bead in the middle of the tetrahedral region.

11:27AM N46.00002 ac-Calorimetric Measurements of Transverse Thermal Conductivity[1]

, HAO ZHANG, JOSEPH BRILL, University of Kentucky — We are developing an ac-calorimetric technique, heating one surface of a thin sample with oscillating power and measuring the temperature oscillations on the opposite surface, to measure the thermal conductivity of solids. While the temperature oscillations are inversely proportional to the heat capacity at low frequencies, at higher frequencies the response is limited by the transverse thermal diffusivity. Because of the response times of thermometers and the fact that the magnitude of the temperature oscillation varies inversely with frequency, this technique is most useful for materials with low thermal conductivities, such as the interlayer conductivity in layered materials. We will show results on "standard" materials (teflon, sapphire) as well as the layered organic semiconductors, rubrene and TIPS-pentacene.

[1]Research supported by NSF grants DMR-0800367 and EPS-0814194.

11:39AM N46.00003 Thermal expansion measurement using optical grating diffraction shifts

, TRAN VINH SON, MOHAMED TOUAIBIA, ALAIN HACHE, Universite de Moncton — We demonstrate a novel optical method for accurately measuring thermal expansion in materials. When an optical grating expands or contracts, the Bragg diffraction condition is altered, and the diffracted beams undergo angular shifts. Using a diffracted laser beam, we demonstrate that this effect can be used to measure expansion coefficients as small as 10^{-6} C^{-1}. By patterning samples of PMMA and chitosan with grating lines, we measure their thermal expansion coefficients by heating the sample by only a few degrees Celsius. The method can be generalized to opaque materials by texturing the surface and measuring diffraction in reflection. A theory is presented to determine the ideal experimental conditions and the limits of accuracy.

11:51AM N46.00004 Properties of Holmium Implanted Gold Films and a YSias Absorbers in TES Microcalorimeters for Holmium Neutrino Mass Experiment[1]

, KRISHNA PRASAI, University of Miami, Miami, Fl, USA, E. ALAVES, University and CFNUL, Lisbon, Portugal, D. BAGLIANI, University of Genoa and INFN, Genoa, Italy, N. BARRADAS, University and CFNUL, Lisbon, Portugal, M. BIASOTTI, University of Genoa and INFN, Genoa, Italy, M. GALEAZZI, University of Miami, Miami, Fl, USA, F. GATTI, University of Genoa and INFN, Genoa, Italy, P. MANFRINETTI, M.R. GOMES, University and CFNUL, Lisbon, Portugal, Y. UPRETY, S. YANARDAG, University of Miami, Miami, Fl, USA — The electron capture decay of Ho-163 can be used for the direct measurement of the electron neutrino mass with Transition Edge Sensor (TES) microcalorimeters. A major requirement for a microcalorimetric holmium experiment is to embed the source in the detector absorber. A logical choice would be to implant the isotope into a regular gold absorber, assuming that it does not change the absorber properties. As an alternate option, since most chemical processes to extract the Ho-163 isotope after fabrication involve yttrium based compounds, it could be possible to use a yttrium compound as absorber, rather than just as an intermediate step. We have studied the properties of gold films implanted with holmium and erbium (which is present due to source manufacturing) and Yttrium silicide (YSi) in the working temperature range of the TES microcalorimeters (90-300 mK).In this paper we present the results of our investigation

12:03PM N46.00005 Quasiparticle diffusion in Al film and transmission with an Al/W interface

, JEFFREY YEN, Stanford University, PAUL BRINK, SLAC, BLAS CABRERA, MATT CHERRY, Stanford University, MATT PYLE, University of California, Berkeley, PETER REDL, Stanford University, ASTRID TOMADA, SLAC, BETTY YOUNG, Santa Clara University, CDMS COLLABORATION — The Cryogenic Dark Matter Search (CDMS) experiment uses both high-purity Si and Ge crystals to directly search for Weakly Interacting Massive Particles (WIMPs). These detectors simultaneously measure the ionization and phonon energy produced by particle interactions. This talk will focus on experiments performed with a separate set of test devices fabricated to study the fundamental physics of the CDMS phonon sensors. In our test experiments, an ^{55}Fe source was used to excite a NaCl reflector, producing 2.6 keV x-rays that hit our test devices after passing through a collimator. The devices under study consisted of a 250 μ m wide x 350 μ m long Al absorber film (300 nm thick) coupled to two 250 μ m x 250 μ m (40 nm thick) W transition edge sensors (TESs), one at each end of the Al film. The impinging x-rays break Cooper pairs in the Al film, producing quasiparticles that we detect as they propagate into the W TESs. We studied the diffusion of these quasiparticles, trapping in the Al film, and their transmission probability at the Al/W interfaces. Results from our precision experiments will be presented in this talk. These results are also being used to further optimize the design of SuperCDMS detectors for a proposed 100 kg scale dark matter search.

12:15PM N46.00006 Depolarization factors in electro-optic crystals and their effects in sensing applications

, ANTHONY GARZARELLA, Naval Research Laboratory — Many applications involving electric field measurements require sensors that are compact and non-intrusive. This is especially true for tests inside small cavities, where conventional antennas and metallic probes are not only too bulky, but will also perturb the very fields they measure. Electro-optic (EO) sensors are ideal in such situations, because they are small and all-dielectric. Despite this, antennas are still predominantly used due to their higher sensitivity (2-3 orders of magnitude). Therefore to make EO sensors viable, sensitivity must be improved. The customary figure of merit (FOM) is the ratio of the EO coefficient to the dielectric constant. $LiNbO_3$ and similar crystals are preferred because of their large FOMs. In these crystals, the EO tensor is such that a transverse configuration must be used where the E-field and laser path are orthogonal. In this report, we demonstrate that sensors based on longitudinal crystals (E-field and laser collinear) can have greater sensitivities, even though their FOMs are substantially lower due to depolarization effects that enhance internal fields. Explicit examples are shown, and the practical limits in making EO sensors more competitive with conventional antennas will be discussed.

12:27PM N46.00007 Stress reconfigurable tunable magnetoelectric resonators as magnetic sensors

, JILLIAN KISER, PETER FINKEL, Naval Undersea Warfare Center, CHRISTOPHE DOLABDJIAN, GREYC — Magnetoelectric multiferroic materials are extremely attractive due to their potential in sensing, filtering and energy transduction applications. We report a magnetoelastic effect in doubly-clamped ferromagnetic magnetostrictive Metglas resonators, as well as the magnetic field dependence of the resonance frequency as a function of uniaxial stress. Magnetostrictive strain results in a resonance frequency shift when the resonator is exposed to a magnetic field. The resonance frequency can be tracked in real time as a function of magnetic field bias using a feedback loop based on the quadrature of the excited motion. This magnetically reconfigurable resonance response can be used as a simple, tunable, magnetoelectric (ME) magnetic field sensor. The effect of sample pre-tension on the field dependent magnetostrictive constant and the sensor sensitivity is examined, and the resolution of such a sensor is estimated.

12:39PM N46.00008 Disruptive Approach Towards 10nm Spatial Resolution In X-PEEM Using Diamondoids , HENDRIK OHLDAG, SLAC National Accelerator Laboratory, HITOSHI ISHIWATA, Stanford University, YVES ACREMANN, ETH Zuerich, OLAV HELLWIG, Hitachi Global Storage Technologies, PETER SCHREINER, Justus-Liebig University, NICK MELOSH, ZHI-XUN SHEN, Stanford University — Diamondoids are unique molecular nano-materials with diamond structure and fascinating new properties such as negative electron affinity (NEA) and short electron mean free paths. A thin layer of diamondoids deposited on a cathode is able to act as an electron monochromator, reducing the energy spread of photo-emitted electrons from a surface. This property can be applied effectively to improve the spatial resolution in x-ray photoemission electron microscopy (X-PEEM), which is limited by chromatic aberration of the electron optics. In this talk we will present X-PEEM measurements reaching the technological relevant spatial resolution of 10-nm without the need of expensive and complex corrective optics. Our results provide a simple approach to image surface chemical and magnetic information at nanometer scales by employing diamondoid. [1] H. Ishiwata et al. Appl. Phys. Lett. **101**, 163101 (2012)

12:51PM N46.00009 Energy Analysis in Near Field-Emission SEM , LORENZO GIUSEPPE DE PIETRO, DANILO ANDRA ZANIN, HUGO CABRERA, URS RAMSPERGER, DANILO PESCIA, MEHMET ERBUDAK, Laboratory for Solid State Physics, ETH Zurich — In Near Field-Emission Scanning Electron Microscopy (NFESEM) cold field emitted electrons from a sharp polycrystalline W-tip are the source of a primary electron beam. The applied voltage for field-emission accelerates these electrons up to some tens of eV. After having interacted with the sample, secondary and backscattered electrons are detected, while an STM controller is used to scan the tip at a constant average distance (10 to 20 nm) from the sample surface. This technique has been used for topography images on various metals and semiconductors achieving nm lateral resolution. In case of a W(110) surface covered by Fe islands a chemical contrast was observed. We recently added an energy analysis of the electrons used for imaging. The energy distribution of this electrons from the sample shows presence of both secondary and back scattered electrons. The ratio of the two groups of electrons may vary for different distances and energies. In view of including spin polarization analysis, we are currently working to optimize the secondary electron yield.

1:03PM N46.00010 Scale invariance of a diode-like tunnel junction , HUGO CABRERA, DANILO ANDREA ZANIN, LORENZO GIUSEPPE DE PIETRO, THOMAS MICHAELS, PETER THALMANN, URS RAMSPERGER, ALESSANDRO VINDIGNI, DANILO PESCIA, ETHZ — In Near Field-Emission SEM (NFESEM), electrostatic considerations favor a diode-like tunnel junction consisting of an atomic-sized source mounted at the apex of a thin wire placed at nanometric distances from a collector. The quantum mechanical tunnel process, instead, can provide a barrier toward miniaturization. In the first place, it deteriorates the generation of electrons by introducing non-linearities within the classically forbidden zone that exponentially increase with decreasing sizes. In addition, in the direct tunnelling regime, i.e. when the distance between emitter and collector d approaches the subnanometer range, a characteristic length appears, making the cross-over from the (almost) scale-invariant electric-field assisted regime to the essentially different STM-regime. We have observed that the experimental data relating the current I to the two experimental variables V (bias voltage between tip and collector) and d can be made (almost) collapse onto a "scaling curve" relating I to the single variable $V \cdot d^{-\lambda}$, λ being some exponent that depends solely on the geometry of the junction. This scaling property can be used to highlight non-linear aspects of the quantum mechanical tunnelling process.

1:15PM N46.00011 Particle acceleration on a chip: A laser-driven micro-accelerator for research and industry[1] , R.B. YODER, Goucher College, G. TRAVISH, UCLA — Particle accelerators are conventionally built from radio-frequency metal cavities, but this technology limits the maximum energy available and prevents miniaturization. In the past decade, laser-powered acceleration has been intensively studied as an alternative technology promising much higher accelerating fields in a smaller footprint and taking advantage of recent advances in photonics. Among the more promising approaches are those based on dielectric field-shaping structures. These "dielectric laser accelerators" (DLAs) scale with the laser wavelength employed and can be many orders of magnitude smaller than conventional accelerators; DLAs may enable the production of high-intensity, ultra-short relativistic electron bunches in a chip-scale device. When combined with a high-Z target or an optical-period undulator, these systems could produce high-brilliance x-rays from a breadbox-sized device having multiple applications in imaging, medicine, and homeland security. In our research program we have developed one such DLA, the Micro-Accelerator Platform (MAP). We describe the fundamental physics, our fabrication and testing program, and experimental results to date, along with future prospects for MAP-based light-sources and some remaining challenges.

1:27PM N46.00012 Webcam science – Can a useful transmission ion microscope be built for less than $1000? , ARTHUR PALLONE, PATRICK BARNES[1], Norwich University — Scientists and engineers build simple, low-cost, webcam-based instruments for use in many disciplines. Analysis of the optical signal received through the three broadband color filters – red, green and blue – form the basis of many of those instruments. The CMOS sensors in webcam pixels also produce signals in response to ionizing radiations – such as alpha particles from a radioactive source. Simple alpha radiography has been demonstrated with an alpha source and a webcam modified to expose the sensors. The performance of a direct imaging transmission ion microscope built from such a modified webcam and a commercially available polonium-210 antistatic device mounted to an optics rail is analyzed. Potential uses and limitations of the microscope are also discussed.

[1]Undergraduate student

1:39PM N46.00013 Design and implementation of a wireless passive microsensor for methanol detection[1] , DIEGO SANZ, CMUA. Universidad de los Andes, WALTER ROSAS, Department of Chemical Engineering. Universidad de los Andes, EDGAR UNIGARRO, CMUA. Universidad de los Andes, WATSON VARGAS, Department of Chemical Engineering. Universidad de los Andes, FREDY SEGURA-QUIJANO, CMUA. Universidad de los Andes — Methanol is a public health concern due to its toxicity, characterized by metabolic acidosis and blindness, among others. The third world population affected by the exposure to this compound is increasing, mainly due to the consumption of illicit distilled or adulterated alcoholic beverages. Although methanol is naturally present in some alcoholic drinks, the maximum allowed concentration cannot exceed 10 g of methanol per liter of anhydrous alcohol (0.4% (v/v) at 40% of ethanol) according to the general EU limit. A wireless passive microsensor was designed to detect small amounts of methanol at 40% of alcoholic dissolutions. The sensor consists of a planar inductor in series with an interdigital capacitor that changes its capacitance with the solution's dielectric constant. An antenna is used to readout the real part of the impedance to obtain the resonant frequencies for different amounts of methanol in the solution. The aim of this work was to develop a low cost wireless sensor with the capability to detect concentrations of at least 0.4% (v/v) of methanol in a 40% of alcoholic solution. The results obtained show variations of 403 kHz in the resonant frequency for changes of 0.2% (v/v) on the concentration of methanol in a 40% alcoholic ethanol-based solution.

[1]This project was possible thanks to the collaboration of the Department of Electrical and Electronics Engineering and the Department of Chemical Engineering of Universidad de los Andes.

1:51PM N46.00014 Phase conjugate Sagnac interferometer based on degenerate four-wave mixing using evanescent field , LIJUAN GU, ZIZHAO GAN, State Key Laboratory of Mesoscopic Physics, School of physics, Peking University, STATE KEY LABORATORY OF MESOSCOPIC PHYSICS, SCHOOL OF PHYSICS, PEKING UNIVERSITY TEAM — We propose a phase conjugate Sagnac interferometer based on degenerate four-wave mixing using evanescent field to improve the performance of fiber optic gyroscope. Degenerate four-wave mixing relies on interaction between two pump waves and evanescent fields surrounding the waveguide. By decreasing the radius of the waveguide, we can get sufficient fraction of the evanescent field. Degenerate four-wave mixing process can generate phase conjugated wave of the signal field and they are coherent intrinsically. In a rotational system, the two conjugated waves possess phase difference that is proportional to the rotational velocity of the system. So by measuring the phase difference, we can get the rotational information of the system and this method can avoids noises caused by wave propagation in fiber.

Q1.00001 POLYMERS AND SOFT MATTER PHYSICS —

Q1.00002 Phase Behavior of Miscible Block copolymer Blends , YONGHOON LEE, HYUNGJU AHN, HOYEON LEE, DU YEOL RYU, Yonsei University — We have investigated the phase behavior for the binary block copolymer (BCP) blends composed of a weakly interacting (with no specific interaction) polystyrene-*b*-poly(alkyl methacrylate) (PS-*b*-PAMA) copolymers using small-angle neutron scattering (SANS), small-angle x-ray scattering (SAXS), and depolarized light scattering (DPLS) experiments. A series of phase behaviors were reproduced from a lower disorder-to-order transition (LDOT) to closed-loop having a LDOT and an upper order-to-disorder transition (UODT), to an UODT type depending on composition in the BCP blends. On the basis of the results and previous observations, we will discuss the phase behavior type of polystyrene-*b*-poly(alkyl methacrylate) (PS-*b*-PAMA) copolymers.

Q1.00003 Investigation of Ternary Multiblock Copolymer Melts using Self-consistent Field Theory[1] , DACHUAN SUN, JUNHAN CHO, Department of Polymer Science and Engineering, Dankook University, South Korea — Recently, A-b-(B-b-A)n-b-C multiblock copolymers have drawn attention due to their hierarchical nanostructures. Several phase diagrams for these copolymers using an analytical method have been made by G. ten Brinke et al. Here, we performed numerical self-consistent field calculations on the same copolymers to reconstruct the phase diagrams. The perpendicular lamellae phase disappears and is replaced by the parallel lamellae phase in our phase diagrams. For the parallel lamellae phase, there are only two A layers rather than three. Moreover, one B layer is located between the two A layers, with another two thin B layers located near the interface between the A and C chunks. The interfacial energy between the C and A chunks is reduced dramatically due to the existence of the B layers between them. Because thus formed parallel lamellae phase has much lower free energy, the perpendicular lamellae phase is replaced by the parallel ones.

Q1.00004 Self-assembly of polymer systems in the presence of disorder , DAVID TEMPEL, Harvard University Department of Chemistry and MIT Department of Materials Science and Engineering, HSIEH CHEN, ALFREDO ALEXANDER-KATZ, MIT Department of Materials Science and Engineering — A solid mathematical understanding of how complex polymer systems behave in the presence of disorder is important for understanding a variety of recent experiments on systems that have important applications. Examples include self-assembly on patterned substrates for lithography applications, and adsorption of charged polymers and biopolymers onto patterned substrates. In all these systems, one finds competition between phases exhibiting long-range order driven by the self-assembly properties of the polymers, and phases exhibiting short-range or no order due to the presence of random external forces. In this work we will present a general mathematical description of this competition, using tools from localization theory in solid-state physics. Our results will help guide experimentalists in determining how much external disorder can be tolerated to achieve a given self-assembled phase and conversely, which phases are most robust to external disorder. Results from simple analytical models and self-consistent field theory simulations will be presented.

Q1.00005 Efficient Formation of Multicomponent Ion Gels by Stepwise Self-Assembly of Thermoresponsive ABC Triblock Terpolymers , SCOTT DANIELSEN, University of Pennsylvania, CAN ZHOU, TIMOTHY LODGE, University of Minnesota — The gelation behavior of a poly(ethylene-*alt*-propylene)-*b*-poly(ethylene oxide)-*b*-poly(N-isopropyl acrylamide) (PON) triblock terpolymer in room-temperature ionic liquids, 1-butyl-3-methylimidazolium tetrafluoroborate ([BMIM][BF_4]) and 1-ethyl-3-methylimidazolium bis(trifluoromethylsulfonyl)imide ([EMIM] [TFSI]), has been studied by rheology over the concentration range 1-10 wt.%. PON terpolymers have proven better gelation efficiency and mechanical properties (modulus) in hydrogels. Physical ion gels from PON terpolymers in [BMIM][BF_4] and [EMIM][TFSI] have been studied to determine improvements in gelation efficiency and mechanical properties (modulus) for triblock terpolymers. A two-compartment micellar network is believed to result from the stepwise gelation of PON terpolymers involving micellization at elevated temperatures and gelation at lower temperatures.

Q1.00006 Design of Optimal Surface Topographies for Low Fouling Surfaces by Computer Simulation , PHILLIP SCHOCH, JAN GENZER, North Carolina State University — Biofouling is a major problem affecting many industries ranging from shipping to medical implants. Recent work in had pointed towards the importance of surface topography in limiting the adhesion of biofouling agents. Here we report on a Monte Carlo model to simulate the adhesion of spherical particles with sticky polymeric hairs on a variety of surfaces that possess sinusoidal variation of amplitude and periodicity in an effort to design the optimal set of surface attributes. We explore adhesion of such particles with varying diameter and the number and length of hairs on a range of sinusoidal periodic surface structures. This approach allows us to establish the optimal surface parameters minimizing the adhesion of particles with varying properties. Specifically, we will report that surfaces with very large or very low periodicity are nearly indistinguishable from flat supports (in some cases they even perform worse). Optimal surfaces are those whose periodicities are comparable to the "hydrodynamic size" of the particle (i.e., particle and hair). Additionally the role of amplitude has been less significant than wavelength as long as the amplitude of the surface corrugation is larger than the size of the particle. We have also developed an order parameter that characterizes how well the particles organize over the periodic structures on the surface.

Q1.00007 Template Polymerization using a controlled reaction scheme , PREETA DATTA, JAN GENZER, North Carolina State University — We employ a Monte Carlo simulation scheme based on the bond fluctuation model to simulate template polymerization via controlled scheme ($i.e.$, termination and chain transfer reactions are neglected) involving co-polymerization of free monomers and monomers bound to a planar template with equidistant sites occupied by bound monomers. A new macromolecule is initiated in bulk by activation of an initiator; any monomer (free or bound) that is within the reaction distance (nearest neighbors) of the initiator can be incorporated into the growing chain. As the chain propagates, it adds new monomers to the macromolecule. Those monomers can either be bulk ($i.e.$ free) monomers or those that are placed on the predefined template. We analyze the effect of the number and the density of monomers bound on the substrate on the composition and monomer distribution in the resultant co-polymers. Our results reveal that a greater number of bound monomers on the planar template promotes polymerization of most/all of the bound monomers to form an array attached to the template. In addition, there exists an optimum density of spacing of bound monomers on the template, at which the likelihood of the bound monomers getting incorporated in the growing chains is maximum. This is in contrast to our earlier findings for linear templates, where a higher density of spacing favors the incorporation of bound monomers in the growing chains.

Q1.00008 The Co-axial Flow of Injectable Solid Hydrogels with Encapsulated Cells , BRANDON STEWART, DARRIN POCHAN, SAMEER SATHAYE, University of Delaware — Hydrogels are quickly becoming an important biomaterial that can be used for the safe, localized injection of cancer drugs, the injection of stem cells into areas of interest or other biological applications. Our peptides can be self-assembled in a syringe where they form a gel, sheared by injection and, once in the body, immediately reform a localized pocket of stiff gel. My project has been designed around looking at the possibility of having a co-axial strand, in which one gel can surround another. This co-axial flow can be used to change the physical properties of our gel during injection, such as stiffening our gel using hyaluronic acid or encapsulating cells in the gel and surrounding the gel with growth medium or other biological factors. Rheology on hyaluron stiffened gels and cells encapsulated in gels was performed for comparison to the results from co-axial flow. Confocal microscopy was used to examine the coaxial gels after flow and to determine how the co-axial nature of the gels is affected by the concentration of peptide.

Q1.00009 Kinetic control of block copolymer self-assembly into novel multicompartment and multigeometry nanoparticles[1] , YINGCHAO CHEN, University of Delaware, SHIYI ZHANG, ANG LI, University of Texas A&M, XIAOJUN WANG, University of Tennessee, JIAHUA ZHU, University of Delaware, KAREN WOOLEY, University of Texas A&M, JIMMY MAYS, University of Tennessee, DARRIN POCHAN, University of Delaware, UNIVERSITY OF DELAWARE TEAM, UNIVERSITY OF TEXAS A&M COLLABORATION, UNIVERSITY OF TENNESSEE COLLABORATION — Nanoparticles with the phase separation of unlike hydrophobic blocks trapped in the same core have been produced via blending of two block copolymers in THF/water dilute solution. The dissolution of two amphiphilic block copolymer sharing the same polyacrylic acid PAA block and different hydrophobic block in pure THF undergoes consequent aggregation and phase separation via different kinetic control pathways. Importantly, the polymer is complexed with diamine molecules prior to either slow titration or fast addition of selective solvent which is the key of forming controlled micelle structure. Vesicle-cylinder, nested vesicle MCM and MGM nanoparticles were assembled and characterized via cryogenic TEM and selective staining methods. Small Angle X-ray scattering is applied to track the early-stage phase separation behavior which determines the final MCM/MGM nanoparticle formation.

Q1.00010 Printing Polymer Semiconductors with Controlled Crystal Orientations

, NIKHILA MAHADEVAPURAM, DAVID SHAKARISAZ, SUCHANUN MOUNGTHAI, PAUL RUCHHOEFT, GILA STEIN, University of Houston — Solar energy is considered to be an alternate promising source of clean energy. Polymer-based solar cells have low manufacturing costs and these devices can be fabricated in light weight, flexible and durable modules. The most widely studied active layer in polymer-based solar cells is the bulk heterojunction (BHJ) design. BHJs are formed by arresting the phase separation of a polymer/fullerene blend and producing an interpenetrating network that provides a large interfacial area for charge separation. However, the non-equilibrium BHJ structure makes it difficult to understand the fundamental structure-property relations. We report a simple approach to control the active layer morphology by direct patterning of π-conjugated polymers into nanostructures or microstructures.[1] We studied polymer crystallinity in patterned poly(3-hexylthiophene) (P3HT) films as a function of developing solvent using grazing incidence wide angle X-ray scattering. It was observed that the $\pi - \pi$ stacking of patterned P3HT domains can be changed from edge-on to face-on orientation by varying the developing solvent. This change in orientation improves the power-conversion efficiency by nearly a factor 2.

Q1.00011 Investigation of phase coexistence in block copolymer/salt mixtures near order-disorder phase transitions[1]

, JACOB THELEN, NITASH BALSARA[2], University of California Berkeley — Mixtures of polystyrene-b-poly(ethylene oxide) (PS-b-PEO) copolymer and lithium bis(trifluromethanesulfonyl) imide (LiTFSI) salt can microphase separate into ion-conducting (PEO/LiTFSI) and mechanically reinforcing (PS) domains, facilitating their application as solid electrolytes in lithium batteries. PS-b-PEO/LiTFSI mixtures that exhibit thermally accessible order-disorder phase transitions (ODTs) are used to gain thermodynamic insight to the polymer/salt system. The Gibbs phase rule requires a coexistence of phases during a phase transition in binary systems. We use birefringence and SAXS measurements to confirm the presence of coexisting ordered and disordered phases near the ODT and quantify their relative volume fractions throughout the coexistence temperature window.

Q1.00012 Self-assembled nanostructures in cross-linkable block copolymer/homopolymer blends

, CHUNLIN HE, IAN CAMPBELL, MARK STOYKOVICH, CU-Boulder — The self-assembly of block copolymers in films that are 50∼100 nm thick provides an attractive approach to patterning nanoscale features. Thermal, chemical, and mechanical stability of the nanoscale morphology in thin films is critical for the generation of robust templates for subsequent fabrication processes, and can be improved by cross-linking the copolymer domains. We have used atom transfer radical polymerization to synthesize PS-b-PMMA diblock copolymers with cross-linkable units capable of reacting through a thermally-activated mechanism or by photoinitiation in response to UV exposure. The self-assembly behavior of lamellar-forming block copolymers with or without cross-linkable units will be compared in thin films. We have developed approaches, including solvent-annealing, for processing the cross-linkable materials in thin films that enable the self-assembly behavior to be decoupled from the cross-linking behavior. The cross-linked nanostructures exhibited enhanced solvent and thermal stability, and have been demonstrated for the fabrication of three-dimensional block copolymer nanostructures in thick films using a layer-by-layer approach.

Q1.00013 Adjusting microstructure and properties of polypropylene nanocomposites through *in situ* interfacial reaction[1]

, TAO TANG, YUJIE WANG, DONG WAN, XIN WEN, Changchun Institute of Applied Chemistry, CAS — In this report, polypropylene (PP) nanocomposites, in which the interfacial reaction between PP and nanoparticles was *in situ* mediated by peroxide, were prepared by melt mixing method. Carbon nanotubes (CNTs) showed a well dispersed state in the resultant nanocomposites. Interestingly, aligned morphology of CNTs appeared in PP/CNTs nanocomposites in the presence of peroxide and tetrabenzylthiuramdisulfide (TBzTD). We found that two kinds of interfacial interaction between PP chains and CNTs, including chemical linking between two components and π-π interaction between the grafted TBzTD to PP chains and CNTs, showed a synergistic effect on enhancing stress sensitivity of CNTs. As a result, the responsive ability of CNTs in PP matrix to external stress field becomes strong. In this case, CNTs can be easily oriented in PP matrix under weak stress field, such as mold-pressing and injection molding. The resultant nanocomposites have shown more than three times impact strength as pristine PP.

Q1.00014 Interfacial assembly of Graphene Oxide at oil/water and polymer/polymer interfaces

, ZHIWEI SUN, TAO FENG, THOMAS RUSSELL, University of Massachusetts Amherst — Amphiphilic structure of graphene oxide makes it a candidate "surfactant" to preferentially segregate to the interface between different fluids. The affinity of graphene oxide towards different phases was tuned by grafting with polystyrene (PS-NH_2) through hydrogen bonding, and its interfacial behavior, both in toluene/water and polystyrene/poly(methyl methacrylate), was studied. The surface tension of the toluene/water interface decreases in the presence of PS-NH_2 grafted graphene oxide, indicating that graphene oxide flakes can be forced to the toluene/water interface when grafted with PS-NH_2. Transmission electron microscopy shows that graphene oxide can even be forced into a "jammed" state at the water/toluene interface. In addition, polystyrene and poly(methyl methacrylate) were blended with graphene oxide, its morphology changes from island type to co-continuous structure, but the mechanism of this behavior is still not clear. These interfacial sheets may provide a model system to study buckling and crumpling behavior at interfaces.

Q1.00015 Designing Reconfigurable Stimuli-Responsive Gel/Nanofibers Composites

, XIN YONG, OLGA KUKSENOK, ANNA BALAZS, Chemical Engineering Dept, University of Pittsburgh — Using dissipative particle dynamics (DPD), we model the response of a composite gel, which encompasses active nanofibers, to external stimuli, such as light and temperature. The gel is constructed by crosslinking polymer chains in a coarse-grained manner. We probe the volume phase transition and swelling kinetics of the gels in explicit solvents. Our model is validated through qualitative comparisons with Flory-Huggins theory, and the effects of solvent quality, crosslink density and temperature are analyzed. By incorporating nanofibers into the gel matrix, we utilize different responses of the fibers and gel to variations in external stimuli. We focus on the fiber-gel and fiber-fiber interactions and establish routes for modeling composites with multiple types of fibers, which enable greater control of materials functionality. Utilizing the adaptability of gel/nanofiber composites, we design composites that can dynamically reconfigure shape via external stimuli to achieve actuation and locomotion. Our findings provide fundamental insights into the dynamics of gel-based composites, as well as guidelines for designing re-programmable multi-functional materials.

Q1.00016 Interfacial activity of acid functionalized single-walled carbon nanotubes (SWCNTs) at the fluid-fluid interface

, TAO FENG, THOMAS RUSSELL[1], DAVID HOAGLAND[2], University of Massachusetts at Amherst — Interfacial assembly of acid-functionalized single-walled carbon nanotubes at the oil/water interface is achieved by the addition of low molecular weight (MW) amino-terminated polystyrene in the oil phase. The surface activity of carboxylated SWCNTs is strongly influenced by the end-group chemistry and molecular weight of the polystyrene component, the concentrations of this component and the SWCNTs, along with the degree of functionalization of the SWCNTs. The prerequisites for interfacial trapping are amino termini on chains with MW less than 5K and 6 hours or longer incubation of pristine SWCNTs to achieve their carboxylation. Plummets in interfacial tension resembling those for surfactants were observed at critical bulk concentrations of both SWCNTs and PS-NH_2. In dried droplets, SWCNTs densely packed with associated PS-NH_2 form a bird nest-like interfacial structure, with the SWCNTs preferentially oriented perpendicular to the original interface.

Q1.00017 Plasmonic Coupling via Au@stimuli-responsive polymer Hybrid Core@shell Nanoparticles Monitored by Surface Plasmon Resonance Spectroscopy

, JI-EUN LEE, KYUNGWHA CHUNG, DONG HA KIM, Ewha Womans University — Noble metal nanostructures with responsive polymers can be used to probe unique plasmonic properties associated with swelling-shrinking transitions in polymer chains triggered by a specific external stimulus. The phase transition causes changes in the refractive index in the vicinity of the particle surface and induces concurrent changes in the characteristic inter-particle distance. We designed a plasmonic-coupling-based sensing device consisting of Au nanoparticles separated from the Au substrate in Kretschmann configuration SPR spectroscopy through a thermo-responsive polymer linker layer. Concretely, Au NPs having stimuli-responsive polymer chains tethered to the Au surface were first fabricated through SI-ATRP. The optical properties of these stimuli-responsive devices were investigated by both in-situ and static SPR analysis. Also, we demonstrate that bimetallic nanostructures containing another type of metal NP at the stimuli-responsive polymer periphery exhibit a controlled optical sensing property based on LSPR coupling phenomenon.

Q1.00018 Supramolecular Nanocomposites: Effects of the Aspect Ratio of Nanorods

, KARI THORKELSSON, Materials Science and Engineering, University of California, Berkeley, TING XU, Materials Science and Engineering, Chemistry, University of California, Berkeley; Materials Sciences Division, Lawrence Berkeley National Laboratory — Anisotropic particles display many unique electrical, mechanical, and optical properties useful in applications ranging from photovoltaic devices, plasmonic devices, and sensors to mechanically strengthened composites. These properties depend not only on size and shape, but also on spatial distribution and orientation. It is thus desirable to control both distribution and orientation with methods applicable to a wide range of size and shape. We have recently demonstrated control over spatial distribution and in some cases local orientation of nanorods by using a supramolecular approach to tailor the conformational entropy of block copolymer chains [1]. Alkyl-passivated nanoparticles can in this way be arranged into aligned arrays, sheets, continuous networks, and clusters. Here, we expand the application of this method to nanorods with a range of aspect ratios, showing that the spatial distribution of the nanorods can be controlled regardless of length, and orientation can also be finely controlled in the case of lengths comparable to the BCP periodicity. Findings will be accounted for by considering the interparticle interactions, the particle-supramolecule interactions and the phase behavior of supramolecules.

Q1.00019 Multi-Color Emission of Hybrid Block Copolymer-Quantum Dot Microspheres by Controlled Quantum Dot Spatial Isolation

, KANG HEE KU, MINSOO KIM, KWANYEOL PAEK, JAE MAN SHIN, SUNHAENG CHUNG, KAIST, SE GYU JANG, KEPRI, WEON-SIK CHAE, KBSI, GI-RA YI, Sungkyunkwan University, BUMJOON KIM, KAIST, SE GYU JANG COLLABORATION, WEON-SIK CHAE COLLABORATION, GI-RA YI COLLABORATION — Fluorescent quantum dots (QDs) are promising candidates for multi-color or white light-emitting systems, however, most current systems involve undesired Forster resonance energy transfer (FRET) between QDs. Herein, we developed multi-color emitting hybrid microspheres with block copolymers (BCPs) and QDs through control of the locations of different-colored QDs in BCP micelles. Hydrogen interaction assisted method was exploited to confine QDs within the BCP spheres without sacrificing any quantum yield efficiency. BCP microspheres with raspberry-like surface structures were prepared by an evaporation-induced self-assembly from an emulsion. When different-colored QDs were independently incorporated into isolated micelles, FRET was completely suppressed because the size of the protective micellar corona was greater than the Forster radius. In contrast, FRET was observed when QDs were concurrently incorporated into the same micelle cores. This spatial control of QDs in microsphere was confirmed by TEM, EDX, PL, and FLIM measurements. Through the isolated BCP micelles, ratiometric control of different colored QDs can display a wide range of colors

Q1.00020 NIR fluorescent chitosan-based nanoparticles for tracking and delivery of cancer therapeutic molecule in living systems

, GIULIA SUARATO, AMANDA CHIN, Materials Science and Engineering, Stony Brook University, New York, USA, YIZHI MENG, Materials Science and Engineering, Chemical and Molecular Engineering, Stony Brook University, New York, USA — Tumor metastasis is associated with the epithelial-to-mesenchymal transition (EMT), in which cells lose their polarized phenotype to acquire the asymmetry and motility of mesenchymal cells. Among the many molecular determinants for EMT is bone morphogenetic protein-7 (BMP-7), a critical regulator of skeletal tissue formation and kidney development. Current treatments for metastatic cancer primarily involve surgery and chemotherapy, both with considerable side effects. Therefore the goal of our research is to evaluate the ability of BMP-7 to reverse EMT using a delivery system based on glycol chitosan nanoparticles (GCNP), naturally biodegradable. The GCNP are labeled with Cy5.5, a near infrared (NIR) excitable dye that enables non-invasive imaging in living systems. The chitosan shell provides affinity for the cell surface and protection from intracellular enzymes during transport. Preliminary data show that Cy5.5-GCNP vehicles were successfully delivered to murine preosteoblast (MC3T3-E1), rat osteosarcoma (ROS) 17/2.8 and human embryonic kidney (HEK293) cells. Release kinetics using a model protein (BSA) and BMP-7, and the stability of the protein nano-cargo are currently being evaluated. Cell morphology will be examined with immunofluorescence microscopy.

Q1.00021 Do attractive interactions slow down diffusion in polymer nanocomposites?

, CHIA-CHUN LIN, SANGAH GAM, University of Pennsylvania, JEFFREY S. METH, DuPont Co. , NIGEL CLARKE, University of Sheffield, KAREN I. WINEY, RUSSELL J. COMPOSTO, University of Pennsylvania — Diffusion of deuterated poly(methyl methacrylate) (dPMMA) is slowed down in PMMA matrix filled with spherical silica nanoparticles (NPs) ranging from 13 to 50 nm in diameter. NPs are well dispersed in the matrix up to 40 vol%. The normalized diffusion coefficients (D/D_0) decrease as the volume fractions increases, and this decrease is stronger as NPs size decreases. When plotted against the confinement parameter, $ID/2R_g$, where ID is interparticle distance and $2R_g$ is probe size, D/D_0 collapse onto a master curve. In the strongly confined region where $ID < 2R_g$, D/D_0 decrease dramatically up to 80 %, whereas in the weakly confined region where $ID > 2R_g$, D/D_0 decrease moderately. Even when ID is eight times larger than $2R_g$, a 15 % reduction in the diffusion is observed. The master curve of this study, an attractive system, compared with a weakly interacting system previously studied, indicating attractive interactions do not significantly alter center of mass polymer diffusion in polymer nanocomposites.

Q1.00022 Confinement and Interfacial Effects in Polymer Nanocomposites , ADAM HOLT, University of Tennessee, JOSHUA SANGORO, YANGYANG WANG, ALEXANDER AGAPOV, Oak Ridge National Laboratory, ALEXEI SOKOLOV, Oak Ridge National Laboratory & University of Tennessee — The influence of different nanoparticles on segmental and chain dynamics of poly(2-vinyl-pyridine) nanocomposites is investigated by broadband dielectric spectroscopy (BDS), dynamic mechanical spectroscopy (DMS), and calorimetry. While remarkable changes in dynamics are observed with increasing nanoparticle loading, only weak effects in the segmental mobility are found. These results are discussed in the context of recent studies of polymer nanocomposites.

Q1.00023 Thermally Switchable Aggregation of Gold Nanoparticles in Polymer Nanocomposites , KYUYOUNG HEO, CAROLINE MIESCH, TODD EMRICK, RYAN HAYWARD, Department of Polymer Science & Engineering, University of Massachusetts Amherst — The level of dispersion or aggregation of nanoparticles is a key factor in determining the performance of polymer-based nanocomposites for a wide range of applications. However, controlling this dispersion can often be challenging due to the interplay between chemical and physical interactions between the nanoparticles and polymer matrix. In this study, we characterize a simple and effective means of controlling the aggregation state of nanoparticles based on hydrogen bonding between the nanoparticle ligands and the matrix. Strong hydrogen bonding interactions provides almost uniform dispersion of poly(styrene-r-2-vinylpyridine) functionalized gold nanoparticles for annealing temperatures well above the glass transition temperature of the poly(styrene-r-4-hydroxystyrene) matrix. However, annealing at higher temperatures diminishes the strength of hydrogen bonds, leading to the formation of aggregates. This aggregation was found to be largely reversible, with nanoparticles dispersing once again by annealing the nanocomposites at reduced temperature. We track the thermal switching behavior during a series of heating/cooling cycles through changes in optical properties and by transmission electron microscopy.

Q1.00024 Peptides (P1, P2 and its mutations) binding with a graphene sheet: an all-atom to all-residue hierarchical coarse-grained approach[1] , ZHIFENG KUANG, BARRY FARMER, Air Force Research Laboratory, RAS PANDEY, University of Southern Mississippi — Binding of peptide P2 (EPLQLKM) [1] and its mutations (P2G, P2Q) to a graphene sheet are studied by a coarse-grained computer simulation. Our hierarchical coarse-grained approach involves all-atom MD simulation to assess the binding interaction of each residue with the graphene sheet. Data from all-atom simulations are then used as input to phenomenological interaction in a coarse-grained MC simulation [2]. Binding of each peptide and its residue in corresponding sequence (P2, P2G, P2Q) are evaluated by analyzing the adsorption of each residue, its mobility, and structural profiles. Although it is difficult to identify overall morphological differences in adsorbed peptides by visual inspections, quantitative analysis of the conformational changes of adsorbed peptides shows variations in size among P2E and its mutations. Results on binding of peptide P1 (HSSYWYAFNNKT) may also be presented if data become available.

Q1.00025 Syntactomer Peptide Assembly on Deformable Silicone Elastomer Surfaces , JULIE N. L. ALBERT, JAN GENZER, North Carolina State University, Chemical and Biomolecular Engineering — Surfaces of biocompatible poly(vinylmethylsiloxane) (PVMS) networks can be functionalized readily through modification of pendent vinyl groups. In this work, we also took advantage of network elasticity to examine how the conformation of surface-grafted peptides depended on their grafting density (i.e., the areal density of peptides). PVMS networks were cross-linked via reactive end groups, leaving the pendent vinyl groups available for peptide attachment via a carboxylic acid terminated thiol linker. To control grafting density, the networks were stretched uniaxially up to ≈30% strain during the attachment of the thiol linker (via thiol-ene click chemistry) and the peptide (via sulfo-NHS/EDC coupling chemistry). After deposition, the strain was released. The resultant peptide-modified PVMS networks were imaged using scanning probe microscopy. The specific peptides of interest are called "syntactomers" because they are made up of repeating amino acid sequences much like a polymer is made up of repeating monomer units. In solution, these peptides display interesting pH-sensitive LCST and UCST phase behaviors that may impart surfaces with pH- and temperature-responsiveness in addition to biocompatibility.

Q1.00026 Peptide Length Determines Equilibrium Secondary Structure in Protein-Analogous Micelles , MATTHEW TIRRELL, University of Chicago, RACHEL MARULLO, Cooper Vision, MARK KASTANTIN, University of Colorado — This work seeks improved bottom-up design of bioinspired materials built from peptide-amphiphiles, which are a class of bioconjugates whereby a biofunctional peptide is covalently attached to a hydrophobic moiety that drives self-assembly in aqueous solution. Specifically, this work highlights the importance of peptide length (i.e. molecular weight) in determining the equilibrium secondary structure of the peptide as well as the self-assembled (i.e. micelle) geometry. Peptides used here repeat a seven-amino acid sequence between one and four times to vary peptide length while maintaining similar peptide-peptide interactions. Without a hydrophobic tail, these peptides all exhibit a combination of random coil and α-helical structure. Upon self-assembly, however, short peptides are prone to β-sheet structure and cylindrical geometry while longer peptides remain helical in spheroidal micelles. The transition to β-sheets in short peptides is kinetic, whereby amphiphiles first self-assemble with helical peptide structure, then overcome an activation barrier as they transition to their equilibrium β-sheet structure at a rate that depends on both temperature and ionic strength. These results identify peptide length as an important control over equilibrium peptide secondary structure and micelle geometry. Furthermore, the kinetic nature of the helix-to-sheet transition opens the door for shape-changing bioinspired materials with tunable conversion rates.

Q1.00027 Using Lipid Vesicles to Achieve Selective Removal or Deposition of Janus Particles on Rough Surfaces , EMILY CRABB, NICHOLAS MOELLERS, XIN YONG, ISAAC SALIB, ANNA BALAZS, Chemical Engineering Dept., University of Pittsburgh — Using dissipative particle dynamics (DPD), we explore the interaction between a nanoscopic lipid vesicle and Janus nanoparticles that are localized on rough hydrophilic substrates. We have previously shown that a fluid-driven vesicle can adsorb and transport up to four nanoparticles on a flat hydrophilic surface. Furthermore, we showed that it is possible to induce pick-up and drop-off of particles by varying parameters such as particle composition and particle-substrate attraction. We now introduce a nano-scale crack that spans the substrate's width onto the otherwise flat surface and determine under what conditions the vesicle either removes the particles from or deposits the particles into this trench. We then use these results to perform particle sorting by having the vesicle only pick up or drop off particles with certain compositions. The ability to selectively pick up and deliver nanoparticles could allow for more efficient cleaning and repair of a surface, as the particles compositions could be chosen so that the vesicle can remove the unwanted particles from the damaged areas and deposit other particles that are needed for recovery.

Q1.00028 Target Diffusion and Concentration Control of Varying Hydrophobicity Drugs in an Injectable Solid Self-Assembling Peptide Hydrogel , JESSIE E.P. SUN, University of Delaware, SIGRID LANGHANS, SEUNG JOON LEE, AI DuPont Children's Hospital, SAMEER SATHAYE, University of Delaware, JOEL P. SCHNEIDER, National Cancer Institute at Frederick, DARRIN J. POCHAN, University of Delaware — We studied diffusion profiles of varying hydrophobicity drugs in a beta-hairpin peptide hydrogel solid that is shear thinning, injectable, and immediate reheals after shear. These rheological properties result from its entangled and branched fibrillar nanostructures, formed from intrmolecular folding and consequent intermolecular assembly of the peptides. Different chemotherapeutic drugs at different concentrations with greatly differing properties were encapsulated to show direct targeting drug delivery. Using in vitro and spectroscopy techniques, we showed controlled, sustained diffusion of the drugs. We were able to protect and keep active, hydrophobic agents that otherwise would be deactivated through traditional delivery methods. We also showed that we can maintain low, targeted, and constant dosages, preserving surrounding areas from lack of target specificity of certain drugs.

Q1.00029 Expanding Cancer Detection Using Molecular Imprinting for a Novel Point-of-Care Diagnostic Device

, YINGJIE YU, MIRIAM RAFAILOVICH, YANTIAN WANG, YEONA KANG, LINGXI ZHANG, BASIL RIGAS, Department of Materials Science and Engineering, State University of New York at Stony Brook, DIVISION OF GASTROENTEROLOGY, SCHOOL OF MEDICINE TEAM — We propose the use of a potentiometric biosensor that incorporates the efficient and specific molecular imprinting (MI) method with a self-assembled monolayer (SAM). We first tested the biosensor using carcinoembryonic antigen, CEA, a biomarker associated with pancreatic cancer. No change in detection efficiency was observed, indicating that the sensor is able to discriminate for the template analyte even in concentrated solution of similar substances. In addition, we use biosensor to discriminate normal fibrinogen and damaged fibrinogen, which is critical for the detection of bleeding disorder. Computer simulations of the protein structure were performed in order to estimate the changes in morphology and determine the sensitivity of the biosensor to conformational changes in the proteins. We found that even small changes in PH can generate rotation of the surface functional groups. Yet, the results show that only when the detection and imprinting conditions are similar, robust signals occurs. Hence we concluded that both morphology and surface chemistry play a role in the recognition.

Q1.00030 Reconstruction of Bone Nanostructure using Hierarchically Ordered Polymer Nanofibers

, XI CHEN, WENDA WANG, SHAN CHENG, BIN DONG, CHRISTOPHER LI, Drexel University — Natural bone is comprised of hydroxyl apatite (HA) crystals periodically templated by collagen fibers with precisely controlled crystal orientation. No synthetic materials can mimic natural bone with controlled mineral orientation and periodicity. Herein we report that this structural challenge can be met using hierarchically ordered nanofiber shish kebabs (NFSKs), constructed via combination of electrospinning polycaprolactone (PCL) and controlled crystallization of PCL-*b*-poly acrylic acid (PCL-*b*-PAA). These NFSKs were employed as a template to control the nucleation and growth of hydroxypatite nanocrystals. HA crystals were formed on such templates with controlled orientation and periods. Such a biomimetic structure serves as a promising bone scaffold material for tissue engineering.

Q1.00031 Mechanics and geometry in the seashell-like (Turritella) surface

, QIAOHANG GUO, ZI CHEN, Washington University in St. Louis, WEI LI, KUN REN, JUNJIE LIN, Fujian University of Technology, LARRY A. TABER, Washington University in St. Louis, WENZHE CHEN, Fujian University of Technology — Helical structures are ubiquitous in nature and engineering, ranging from DNA molecules to plant tendrils, from sea snail shells to nanoribbons. While the helical shapes in natural and engineered systems often exhibit nearly uniform radius and pitch, helical shell structures with changing radius and pitch, such as seashells and some plant tendrils, adds to the variety of this family of aesthetic beauty. Here we report the first biomimetic seashell-like structure resulting from mechanics of geometric frustration. In previous studies, the total potential energy is everywhere minimized when the system achieves an equilibrium. In this study, however, the local energy minimization cannot be realized because of the geometric incompatibility, and hence the whole system deforms into a shape with a global energy minimum whereby the energy in each segment may not necessary be locally optimized. This novel approach can be applied to develop materials and systems with desirable geometries by exploiting mechanics of geometric frustration. The authors would like to thank Yushan Huang, Zhen Liu, Si Chen for their assistance in the experimental demonstration. This work has been in part supported by NSFC (Grant No.11102040 and No.11201001044), the Sigma Xi Grants-in-Aid of Research (GIAR) program, American Academy of Mechanics Founder's Award from the Robert M. and Mary Haythornthwaite Foundation, and Society in Science, The Branco Weiss Fellowship, administered by ETH Zurich. Qiaohang Guo and Zi Chen contributed equally to this work.

Q1.00032 Bulk Heterojunction Polymer Solar Cells Based on Ternary Blend System[1]

, YU GU, FENG LIU, University of Massachusetts - Amherst, CHENG WANG, Advanced Light Source, Lawrence Berkeley National Laboratory, THOMAS RUSSELL, University of Massachusetts - Amherst — To enhance the absorption of the solar light, we mixed two hole-transporting polymers that are active in complementary wavelength ranges of the solar spectrum, e.g., P3HT and PCPDTBT, with one electron transporting material, PCBM, to fabricate the single active layer for bulk heterojunction solar cells. This simple one-step method has been shown to efficiently improve the device performance compared with the corresponding binary references. Multiple scattering techniques and transmission electron microscopy were used to determine the morphology for the ternary blend. It is shown that when keeping a low ratio of PCPDTBT in the ternary blend, P3HT could still crystallize and phase-separate from other amorphous components. A continuous network of P3HT fibril bundles was formed, PCPDTBT/ PCBM/ amorphous P3HT filled the interfibrillar region and PCPDTBT wrapped the P3HT fibrils. Such morphology is compatible with the well aligned HOMO-LUMO levels of the three components and the sensitization effect of PCPDTBT. As a result, PCPDTBT benefits the charge transfer; the two polymers act not only individually but also synergistically.

[1]This work was supported by the Department of Energy supported Energy Frontier Research Center at University of Massachusetts and the NSF-supported Materials Research Science and Engineering Center at University of Massachusetts.

Q1.00033 Characterization of Nanostructure and Electrical Properties of Polymer-Fullerene Bulk Heterojunction Solar Cells

, DONG WANG, FENG LIU, XIAOBO SHEN, University of Massachusetts Amherst, KEN NAKAJIMA, Tohoku University, THOMAS RUSSELL, University of Massachusetts Amherst — The ability to control and optimize the active layer morphology is critical for achieving high power efficiency with bulk heterojunction (BHJ) organic photovoltaic (OPV) devices. Here, we fabricated three types of polymer-fullerene BHJ active layers: diketopyrrolopyrrole (DPP)/PCBM, poly[N-9''-hepta-decanyl-2,7- carbazole-alt- 5,5-(4',7'-di- 2-thienyl-2',1',3'- benzothi adiazole) (PCDTBT)/PCBM, and poly(3-hexylthiophene) (P3HT)/PCBM. A comparative study of the nanostructure and electrical properties resulting from different donors and annealing processes was done by conductive atomic force microscopy (c-AFM), grazing incidence small angle scattering (GI-SAXS), wide angle scattering (GI-WAXS), and transmission electron microscopy (TEM). To obtain a signal from the c-AFM, a percolated pathway for either electrons or hole is required, with details on the internal structure of the assemblies being provided by GI-WAXS and morphology of the assemblies being provided by GI-SAXS and TEM.

Q1.00034 Processing Solvent Dependent Morphology of Diketopyrrolopyrrole (DPP) based Low Band Gap Polymer and PCBM Blends

, SUNZIDA FERDOUS, FENG LIU, THOMAS RUSSELL, Polymer Science and Engineering, University of Massachusetts-Amherst — Solution processing of polymer semiconductors is widely used for fabrication of low cost organic solar cells. Recently, mixed solvent systems or additive based systems for fabricating polymer solar cells have proven to be beneficial for obtaining high performance devices with multi-length scale morphologies. To control the morphology during the processing step, one needs to understand the effect of solvent as it evaporates to form the final thin film structure. In this study, we used diketopyrrolopyrrole (DPP) based low band gap polymer and phenyl-C71-butyric acid methyl ester (PCBM) blend in a series of mixed solvent systems consisting of a good solvent for both of the active material components, as well as different solvents that are good solvents for PCBM, but poor solvents for the polymer. Different evaporation times of the poor solvents during the drying process, and different solubility of the polymer in these poor solvents as well as their interaction with the substrate play an important role in the final morphology. In-situ GIWAXS studies were performed to observe the evolution of the structure as the solvent evaporates. The final morphologies of the thin film devices were also characterized by AFM, TEM, and various x-ray scattering techniques to correlate the morphology with the obtained device performances.

Q1.00035 The Effect of Binding Groups on the Seebeck Coefficient of Phenyl Derivative Molecular Junctions[1]

, WILLIAM CHANG, UC Berkeley, CHENGKANG MAI, UC Santa Barbara, MICHELE KOTIUGA, JEFFREY URBAN, JEFFREY NEATON, Lawrence Berkeley National Lab, GUI BAZAN, UC Santa Barbara, RACHEL SEGALMAN, UC Berkeley — Thermoelectrics currently suffer from low efficiencies due to inverse coupling of the Seebeck coefficient and electrical conductivity, limiting the power factor. Decoupling of these two physical properties has previously been demonstrated in molecular junctions. Using an STM break junction measurement technique, we demonstrate the effect that the direct binding group Au-C has on the Seebeck coefficient. Phenyl derivative molecules with an Au-C direct binding group show a significantly lower Seebeck coefficient than molecules with an Au-S binding group. This lower Seebeck coefficient is explained by theoretical calculations as a broadening in the transmission function due to the direct bonding group. This demonstrates the importance of the metal-molecule interface and binding group selection in tuning the transmission function, and the resultant conductance and Seebeck coefficient. This result will lend further insight in rational design for molecules with higher power factors.

Q1.00036 A Facile Route to Large-Scale Hierarchically Structured Conjugated Polymer Assemblies with Enhanced Electrical Conductivity

, WEI HAN, Georgia Institute of Technology, MING HE, Fudan University, MYUNGHWAN BYUN, University of Massachusetts, BO LI, ZHIQUN LIN, Georgia Institute of Technology — By subjecting a drying droplet containing conjugated homopolymers or all-conjugated diblock copolymer to a judiciously designed geometry consisting of a cylinder situated on a flat substrate (i.e., cylinder-on-flat geometry), a set of highly ordered straight or wavy stripes at the microscopic scale over a large area were yielded, in which each microscopic stripe was composed of bundles of nanofibers or nodule-like nanodomains (i.e., forming hierarchical assemblies). These hierarchical patterns of conjugated homopolymers and all-conjugated diblock copolymer exhibited good electrical properties. Quite intriguingly, the crystallinity of the as-prepared assemblies of all-conjugated diblock copolymer was largely improved after the solvent vapor annealing, resulting in four times increase in electric conductivity. This facile, scalable deposition technique based on controlled evaporative self-assembly renders the crafting of hierarchically structured semicrystalline conjugated optoelectronic materials, and may provide a paradigm to develop high-performance electronic devices in a simple and controllable manner.

Q1.00037 Random Conjugated Copolymers with Panchromatic Absorption for High-Efficiency Polymer Solar Cells

, JAE WOONG JUNG, WON HO JO, Seoul National University — One of the most important issues for polymer solar cells (PSCs) is to develop conjugated polymers with broad light absorption, high mobility and appropriate orientation to provide effective pathways to electrode. Particularly, the broad light absorption of the polymer is important to enhance the power conversion efficiency because the limited absorption leads to low current in comparison with other inorganic-based solar cells. A fascinating approach to extend light absorption is the synthesis of copolymers composed of several chromophores. Among various building blocks, diketopyrrolo[3,4-c]pyrrole (DPP) and 6,6'-[3,3']biindolylidene-2,2'-dione (isoindigo) have attracted much interest since they are easily accessible and exhibit promising optoelectronic properties. Here, we report random conjugated copolymers consisting of DPP and isoindigo as co-electron acceptor of donor-acceptor conjugated polymer. The random copolymers exhibited not only broad light absorption but also low-lying HOMO levels. Also, the predominant face-on orientation of the copolymers is beneficial for vertical charge transport in PSCs. The combination of excellent optoelectrical properties and favorable molecular conformation makes copolymers promising candidate for active material in high performance PSCs.

Q1.00038 Synthesis of Graphene Nanoribbons with Various Widths and Its Application to Thin-Film Transistor

, KYUNG TAE KIM, WON HO JO, Seoul National University — Although graphene itself is a zero-bandgap semimetal, graphene nanoribbon (GNR) with a width smaller than 10 nm exhibits semiconducting behavior that renders them suitable for active materials of electronic devices. Several methods have been reported to produce GNRs, such as lithography, unzipping of CNTs, mechanical exfoliation and CVD. However, the uncontrollable character of these methods or in some case the harsh conditions restrict severely the quality of the resulting graphenes and consequently limit their applications. In this study, we synthesized GNRs with various widths from the corresponding polymer precursors and investigated their TFT properties. For synthesis of GNRs, we first synthesized polymers with phenylene, naphthalene and anthracene units by the Suzuki coupling reaction between dibromine monomer and diboronic ester monomer. The polymers were then converted into the corresponding GNRs through intramolecular cyclodehydrogenation reaction. The cyclodehydrogenation were identified quantitatively by NMR analysis. All GNR-based TFTs showed ambipolar transport behavior. The anthracene-based GNR exhibits the best TFT performance among three GNRs due to longer conjugated length, larger width and stronger π-stacking as compared to phenylene- and naphthalene-based GNRs.

Q1.00039 Tuning the crystal structure of contorted hexabenzocoronene thin films for transistors applications

, ANNA HISZPANSKI, Chemical and Biological Engineering Department, Princeton University, MATTHEW BRUZEK, Chemistry Department, University of Kentucky, ARTHUR WOLL, Cornell High Energy Synchrotron Source, JOHN ANTHONY, Chemistry Department, University of Kentucky, YUEH-LIN LOO, Chemical and Biological Engineering Department, Princeton University — Though the structure of organic semiconductors in the active channels of thin-film transistors is known to impact device performance, controlling such structure has been a long-standing challenge. We demonstrate the ability to fine-tune the crystal packing of semiconducting contorted hexabenzocoronene (HBC) thin films via solvent-vapor annealing. Solvent-vapor annealing with weakly hydrogen-bonding solvents having large molar volumes preferentially yields the P21/c crystal structure of HBC. Annealing with solvent vapors having smaller molar volumes and stronger tendencies to hydrogen-bond coaxes HBC films to adopt a previously-unpublished crystal structure that is similar to that of the Pbcn structure. Elucidating the structures of HBC thin films when they are exposed to a myriad of solvent vapors has allowed us to produce a processing diagram, with which we have been able to predictively access different crystal structures for thin-film transistor applications.

Q1.00040 Active layer morphologies for device simulations

, JUTTA LUETTMER-STRATHMANN, KIRAN KHANAL, Departments of Physics and Chemistry, The University of Akron — The morphology of the active layer has a strong effect on charge generation and transport in organic photovoltaics. In bulk heterojunction devices, amorphous and crystalline regions with varying compositions coexist due to microphase separation and crystallization of the blend components. Accounting for these effects in device simulations is difficult since the size of the active layer is too large to generate realistic morphologies from molecular simulations of the constituents. In this work we perform Monte Carlo simulations of a coarse-grained lattice model of polymer mixtures to generate microphase separated layers with ordered and disordered regions. We employ external fields and surface interactions to control the morphologies and investigate the effect of domain size and distribution on charge transport.

Q1.00041 Thermally-Induced Dewetting in Ultra-Thin C_{60} films on Copper Phthalocyanine

, TERRY MCAFEE, HARALD ADE, DANIEL DOUGHERTY, North Carolina State University — Organic photovoltaics have made significant advances in the past decade. These advances have occurred primarily by the synthesis of new materials that manipulate the bandgap to improve the short circuit currents and open circuit voltages. Domain size and orientation of the donor and acceptor materials has shown to also have a significant impact on device performance, and must be better understood and controlled to achieve organic solar cells that are a feasible alternative energy source. The evolution of thermally-annealed ultra-thin fullerene-C60 layers on copper phthalocyanine is examined by Atomic Force Microscopy and Near Edge X-Ray Absorption Fine Structure spectroscopy. Annealing at 105C causes 2 nm thick C60 films to de-wet the copper pthalocyanine substrate surface. Coarsening of C60 clusters is observed that creates mounds that exceed the nominal C60 thickness by more than an order of magnitude. Sequential deposition and annealing of C60 layers alternated with a donor material such as CuPc could be utilized to engineer a Bulk Heterojunction structure with C60 domain sizes catered to the exciton diffusion length.

Q1.00042 Distinguishing excitonic from vibronic oscillations in ultrafast spectroscopy , JACOB KRICH, University of Ottawa, JOEL YUEN, Harvard University, ALLAN JOHNSON, University of Ottawa, JOSEPH GOODKNIGHT, ALÁN ASPURU-GUZIK, Harvard University — Ultrafast experiments on photosynthetic and conjugated organic systems have indicated that coherent delocalization of exciton states significantly contributes to exciton transport, even up to room temperature. Oscillations in 2D spectra due to excitonic delocalization can be similar to those from vibronic oscillations, which are not important for exciton transport. We describe a straightforward experiment – broadband pump-probe – to distinguish between ultrafast oscillations from excitonic or vibronic-only sources. We consider anharmonic molecular oscillators and consider the requirements for how broadband (short in time) the experimental pulses must be to distinguish excitonic from vibronic oscillations.

Q1.00043 Structure development of bilayer PCDTBT and PCBM films , HSIN-WEI WANG, THOMAS RUSSELL, TODD EMRICK, UMass Amherst — Poly[N-9''-hepta-decanyl-2,7-carbazole-alt- 5,5-(4',7'-di- 2-thienyl-2',1',3'-benzothiadiazole)] (PCDTBT) is a promising low band gap material. with power conversion efficiency approaching 6% when blended with $PCBM_{70}$. However, unlike the benchmark P3HT:PCBM system, annealing at high temperature results in performance reduction. To gain a deeper understanding of this material, bilayer films of crystalline PCDTBT and PCBM were prepared, and the kinetics associated with the structure development were investigated. It was found that the diffusion of PCBM disturbs the ordering of PCDTBT along (100) direction. A decrease in domain size was also observed by transmission electron microscopy..

Q1.00044 Effects of supercritical carbon dioxide on immobile bound polymer chains on solid substrates[1] , MANI SEN, Stony Brook University, MITSUNORI ASADA, Kuraray Co., NAISHENG JIANG, MAYA K. ENDOH, Stony Brook University, BULENT AKGUN, SUSHIL SATIJA, Center for Neutron Research, NIST, TADANORI KOGA, Stony Brook University — Adsorbed polymer layers formed on flat solid substrates have recently been the subject of extensive studies because it is postulated to control the dynamics of technologically relevant polymer thin films, for example, in lithography. Such adsorbed layers have been reported to hinder the mobility of polymer chains in thin films even at a large length scale. Consequently, this bound layer remains immobile regardless of processing techniques (i.e. thermal annealing, solvent dissolution, etc). Here, we investigate the use of supercritical carbon dioxide ($scCO_2$) as a novel plasticizer for bound polystyrene layers formed on silicon substrates. In-situ swelling and interdiffusion experiments using neutron reflectivity were performed. As a result, we found the anomalous plasticization effects of $scCO_2$ on the bound polymer layers near the critical point where the anomalous adsorption of CO_2 molecules in polymer thin films has been reported previously.

[1]Acknowledgement: We acknowledge the financial support from NSF Grant No. CMMI-084626.

Q1.00045 A Length Scale for the Free Surface of Polymer Films , ETHAN GLOR, MARY KLING, NOLAN AVERBUCH, ZAHRA FAKHRAAI, University of Pennsylvania — Recent work in polymer physics shows that the relaxation dynamics near a free surface of a thin polymer film are significantly different from that of the bulk polymer. While experiments directly probing the surface and bulk relaxation dynamics are rare, the effect of this difference can be seen in the properties of some polymer thin films. For instance, studies have shown that polystyrene thin films exhibit a decreased glass transition temperature with decreased thickness. A common explanation for this observation is that the mobile surface occupies a greater percentage of a thin film, thus the average relaxation dynamics of the film is affected, and the glass transition temperature decreases. Despite extensive research in this area, little is known about many fundamental questions of this mobile surface layer, including the penetration depth of the layer and the mechanism by which the free surface of a polymer film is more mobile. In this study, we use ellipsometry to measure the Tg of polystyrene films of various film thicknesses, molecular weights, and at various cooling rates. From these experiments, we estimate both a length scale and molecular weight dependence for the depth of enhanced mobility near the free surface.

Q1.00046 Effect of Adjacent Rubbery Layers on the Physical Aging Rate of Polymer Glasses , PHILLIP RAUSCHER, CONNIE ROTH, Department of Physics, Emory University, Atlanta, GA 30329 — Recent advances in block copolymer synthesis have led to new routes for forming nanostructured polymer blends putting glassy and rubbery phases in intimate contact. The long-term stability of these systems is crucial for their performance and functionality. In order to investigate the effect of glassy-rubbery interfaces between neighboring polymer domains on the local stability and physical aging of the confined glassy layers, we have modified our streamlined ellipsometry method to be able to determine the physical aging rate of thin glassy layers adjacent to rubbery layers. We present results demonstrating how ellipsometry can be used to measure the physical aging rate of glassy polystyrene (PS) layers atop rubbery poly(n-butyl methacrylate) (PnBMA) layers. With decreasing PS layer thickness, down to 55 nm, we observe a slight increase in the aging rate. This is in strong contrast to single layer PS films, which show a decrease in aging rate with decreasing thickness due to the local Tg reduction at the free surface. The slight increase in aging rate of the glassy PS layers atop rubbery PnBMA cannot be explained by any shift in local Tg suggesting that this faster aging rate caused by the presence of the rubbery-glassy interface must be due to some separate mechanism.

Q1.00047 Oxidatively stable polyaniline derivatives for electrodes in energy storage[1] , JODIE LUTKENHAUS, JU-WON JEON, Texas A&M University, LUTKENHAUS LABORATORY TEAM — Conjugated polymers have been explored as electrodes in batteries and pseudocapacitors for over 30 years. Yet, their widespread implementation has been hindered for several reasons such as oxidative stability, low capacity, and rate limitations associated with ionic mobility relative to current state-of-the-art. On the other hand, conjugated polymers have much to offer because of their good electronic conductivity, high Coulombic efficiency, and theoretical capacities comparable to those of metal oxides. Our lab's current goal is to overcome the aforementioned challenges, so that conjugated polymeric electrodes can be suitable used in energy storage for applications such as mechanically flexible energy storage and structural power system. This talk will present one of several experimental approaches towards synthesis and processing of polyaniline that achieve oxidatively stable, high capacity, ionically mobile electrodes. This derivative is a water-processable colloid of intimately mingled polyaniline and polyacid, where the polyacid acts as the dopant. The origin of the oxidative stability is investigated using computation modeling.

Q1.00048 Conjugated block copolymer photovoltaics with near 3% efficiency , CHANGHE GUO, The Pennsylvania State University, YEN-HAO LIN, Rice University, MATTHEW WITMAN, The Pennsylvania State University, KENDALL SMITH, Rice University, CHENG WANG, ALEXANDER HEXEMER, Lawrence Berkeley National Lab, RAFAEL VERDUZCO, Rice University, ENRIQUE GOMEZ, The Pennsylvania State University — Conjugated polymer blend solar cells are devices where the active layers are composed of polymer donor and polymer acceptor pairs. These devices suffer from macrophase separation in the active layer, limiting efficiency. The self-assembly properties of block copolymers have the potential to overcome the thermodynamic incompatibility between different polymers and form unique nanoscale structures for efficient photovoltaic operation. Using a poly(3-hexylthiophene) - poly((9,9-dioctylfluorene)-2,7-diyl-alt-[4,7-bis(thiophen-5-yl)-2,1,3-benzothiadiazole]-2',2''-diyl) conjugated block copolymer (P3HT-PFOTBT), we demonstrate for the first time that devices composed of donor-acceptor block copolymers can work as solar cells with efficiencies around 3%. Lamellar morphologies formed in block copolymer thin films have been characterized using resonant soft X-ray scattering.

Q1.00049 Unconventional Routes for the Enhancement of the Efficiency of Dye-Sensitized Solar Cells (DSSCs) Based on Self-Assembled Block Copolymer Nanotemplates , YOONHEE JANG, DONGHA KIM, Ewha Womans University — We introduce distinctly different and creative two strategies for improving the efficiency of TiO_2-based DSSCs by incorporation of tailored hybrid nanostrcutures prepared from self-assembled block copolymer nanotemplates. Firstly, carbonized TiO_2 thin layer was incorporated into at the interface either between the transparent electrode and TiO_2 NP layers or between the electrolyte and TiO_2 NP layers. Massively-ordered arrays of TiO_2 dots embedded in carbon matrix were fabricated via direct carbonization of UV-stabilized PS-*b*-P4VP block copolymer films containing TiO_2 sol-gel precursors. DSSCs containing carbon/TiO_2 thin layers exhibited remarkably enhanced overall power conversion efficiency compared with DSSCs based on neat TiO_2 NPs. Secondly, we introduce a new class of organic/inorganic 1D photonic crystals exhibiting stop bands in the specific wavelength range, which was created by stepwise layer-by-layer deposition of UV-crosslinked BCP reverse micelle layers. The simple yet novel 1D layered BCP films have been introduced into the back-side of the counter electrodes as light reflector in DSSCs system to increase the light harvesting of dye.

Q1.00050 Microwave energy application on carbon cathode for high efficient microbial electrosynthesis , HUARONG NIE, MENGMENG CUI, Department of Polymer Science & Engineering, University of Massachusetts, Amherst, TIAN ZHANG, DEREK LOVLEY, Department of Microbiology, University of Massachusetts, Amherst, THOMAS RUSSELL, Department of Polymer Science & Engineering, University of Massachusetts, Amherst — Microbial electrosynthesis represents a promising strategy of energy storage through microbial conversion of carbon dioxide to transportation fuels or other organic commodities. One key feature for its commercialization is to enhance the cathode performance associated with microbial inoculums. A biocompatible, high surface area, multi-level porous cathode was developed from microwave pyrolysis of ferrocene on carbon felt to support the microorganism to produce acetate from carbon dioxide. The formed nanostructure flake composite on fibers increased the biofilm-cathode interfacial surface area, the interaction between the cathode surface and the microbial biofilm and the electractivity of cathode, while the macroscale porous structure of the intertwined carbon fibers provides easy microbe access. Around 743 mM cm^{-2} d^{-1} of acetate was generated by Sporomusa, which is 3.2 fold larger than the reported highest value coming from the chitosan coated carbon cloth cathode.

Q1.00051 Ordered Mesoporous Carbon/Iron Oxide Nanoparticle Composites for Supercapacitor Applications[1] , YING LIN, XINYU WANG, JAMES WATKINS, Department of Polymer Science and Engineering, University of Massachusetts Amherst — Novel mesoporous carbon/iron oxide composites were prepared through a simple carbonization procedure of blends of block copolymer precursors containing the source of carbon, i.e., polyacrylonitrile-block-poly(t-butyl acrylate) (PtBA-b-PAN) with iron oxide nanoparticles. The addition of functionalized nanoparticles that selectively hydrogen bond with PAN segments was shown to induce order in otherwise disordered system. The ordered mesostructure of the composites was confirmed by both small x-ray scattering and transmission electron microscopy. The preparation of nanocomposites with pore structure was enabled by the high ?delity preservation of the phase-separated nanostructure between two polymer blocks driven by nanoparticle additive upon carbonization at 700oC. The electrochemical performance of the composite films was compared to that of the neat carbon and the mesoporous carbon without iron oxide nanoparticles. The mesoporous structure together with the high iron contents in such materials make them particularly promising for use in supercapacitor applications.

Q1.00052 Control ion transport by tuning the crystalline morphology in polyethylene oxide-based solid electrolyte , SHAN CHENG, CHRISTOPHER LI, DERRICK SMITH, Drexel University — The crystalline structure of polyethylene oxide (PEO) strongly affects the ion transport in solid PEO-Lithium salt electrolytes. Four possible phases can exist in a PEO-LiClO4 electrolyte membrane, e.g. crystalline PEO, amorphous PEO, amorphous PEO-Li complex and crystalline PEO-Li complex. It has been widely accepted so far that ion can transport through either amorphous PEO phase or PEO-Li crystalline complex phase. The ion conduction mechanism of the former is based on ion hopping as well as PEO segment motion. In the latter case two PEO chains form cylindrical channels within which Lithium cation can transport. In this presentation, we will show that tuning the crystalline morphology can optimize ion conduction. This can be achieved by controlling the orientation of the PEO lamellae as well as PEO-Li crystalline complex to optimize the ion conducting pathways.

Q1.00053 Tunable morphology of P3HT: PCBM films by combinatorial methods for bulk heterojunction solar cells[1] , YAN SUN, GURPREET SINGH, ALAMGIR KARIM, University of Akron — P3HT: PCBM films for bulk heterojunction (BHJ) solar cells were processed by dynamic annealing method termed as cold zone annealing (CZA) with varying velocities in conjunction with a confining and conformal surface energy controlled polydimethylsiloxane (PDMS) capping layer on top. Morphologies and optical properties of P3HT: PCBM were investigated by atomic force microscopy, optical microscope and UV-Vis absorption spectroscopy. Effect of CZA annealing rate and surface energy of PDMS as well as CZA annealed films without PDMS on P3HT: PCBM morphologies were compared. It was observed that the growth of large PCBM crystals can be suppressed with the confining PDMS under CZA annealing conditions. The thermal expansion of PDMS is several times the BHJ film, so that there is significant shear effect on the BHJ under the confined annealing process. High resolution TEM was used for further investigation of the film morphology and the orientation of the P3HT in the BHJ was studied by UV-VIS absorption spectroscopy with polarized incident light and grazing incidence wide angle X-ray spectroscopy (GIWAXS) at a synchrotron source.

Q1.00054 The influence of ion content on mobility and ion aggregation in PEO-based single-ion conductors , DAVID CALDWELL, JANNA MARANAS, Pennsylvania state university — PEO-based ionomers reduce concentration polarization in solid polymer electrolytes by binding the anion to the polymer backbone. Ionomers have significant ion aggregation compared to PEO/salt systems, and the influence of these aggregates is unclear. When ion transport is coupled to the segmental dynamics of the polymer, aggregation will always reduce ion motion and conductivity. However, the conductivity of PEO ionomers is not sensitive to the degree of aggregation. We present results of molecular dynamics simulations where ion content is systematically varied. We consider the influence of ion content on ion aggregation, polymer mobility and cation motion.

Q1.00055 X-ray absorption spectroscopy of reaction intermediates of lithium-sulfur batteries dissolved in polymer electrolytes , KEVIN WUJCIK, NITASH BALSARA, University of California, Berkeley — Lithium polysulfide reaction intermediates formed during the charge and discharge reactions of a lithium-sulfur battery are known to diffuse out of the cathode during cycling, thus lowering battery capacity and lifetime. While numerous techniques have been developed to confine intermediates to the battery cathode, little is known about the complex reaction mechanism responsible for their formation. Work to understand the reaction mechanism requires an experimental technique capable of distinguishing the various lithium polysulfide intermediates formed during the charge/discharge reactions. We report on the use of x-ray absorption spectroscopy (XAS) to distinguish lithium polysulfide molecules in polymer electrolytes. Polysulfide intermediates dissolved in poly(ethylene oxide) and a block copolymer of polystyrene-poly(ethylene oxide) were probed at the oxygen, carbon, and sulfur K-edges. Simulated x-ray spectra based on ab-initio molecular dynamics were used to interpret experimental x-ray spectra. Theories regarding the physical and chemical nature of the polysulfide–polymer electrolyte interaction were developed.

Q1.00056 Investigation of PVDF/TiO_2 Composite Films for Use in the Capacitive Storage of Energy , JOEL IWAGOSHI, Northern Arizona University — Research on alternative energies has become an area of increased interest due to economic and environmental concerns. Fluctuations due to changing environmental conditions cause instability in the electrical grid. Capacitors made from composite polymer/nanoparticle thin films have been shown to be an economically viable solution. Precise compositional tuning of the two materials in the film can lead to very high energy density storage capacitors. Through thermal vapor deposition, we synthesized dielectric thin films of polyvinylidene fluoride (PVDF) containing the ceramic nanoparticle titanium dioxide (TiO_2). Film composition was analyzed XPS and EDX. Films have been produced with a TiO_2 content up to about 8%. Nanoparticle cluster size was examined using intermittent AFM. Images from this technique confirm uniform TiO_2 dispersion with cluster size less than 150 nm. Our research on the deposition process will contribute to the understanding of PVDF/TiO_2 composite thin films. These results will lead to the investigation of PVDF/TiO_2 high density energy storage capacitors. These capacitors can potentially increase the efficiency of alternative energy sources already in use.

Q1.00057 Rational Design of POSS-Based Janus Particles into Supramolecular Structures: Symmetry Breaking and Shape Commensuration , ZHAO WANG, YIWEN LI, WEN-BIN ZHANG, STEPHEN Z.D. CHENG, Department of Polymer Science, The University of Akron — The synthesis, self-assembly and applications of structured nanoparticles have significantly intensified over the past decade. In the recent year, a series of precisely-defined polyhedral oligomeric silsesquioxane (POSS)-based molecular dumbbell-like Janus particles has been prepared. It was found that those non-spherical POSS Janus nanoparticles processing equally sized blocks could self-organize into a bi-layered structure with a head-to-head, tail-to-tail type of packing in its bulk state. The driving force of this hierarchical structure formation was attributed to the symmetry breakings of both geometrical sense (molecular shape) and chemical sense (selective amphiphilic interactions) of dumbbell-like Janus particles. Based on this modal system, we further developed a family of POSS-based structured nanoparticles for supramolecular structure formation in the solid state. It was found that the snowman-like Janus particle with two POSS cages in different sizes (a Janus particle with long alkyl chains on one POSS and carboxylic groups on the other) could self-assemble into frustrated lamellar structure (1.5 layered structure). Meanwhile, the supramolecular structure of corresponding mickeymouse-like Janus particle (long alkyl chains on one POSS and carboxylic groups on the other two POSS cages) could recover into normal lamellar structure (bi-layered structure). The self-assembly behaviors of those shape-persistent nanoparticles are absolutely different from those of di-block copolymers.

Q1.00058 Self-Assembly of Giant Gemini Surfactants Based on Polystyrene- Hydrophilic Polyhedral Oligomeric Silsesquioxane Shape Amphiphiles , YIWEN LI, ZHAO WANG, STEPHEN CHENG, Department of Polymer Science, The University of Akron, Akron, OH, 44325 — A series of giant gemini surfactants consisting of two hydrophilic carboxylic acid-functionalized polyhedral oligomeric silsesquioxane (APOSS) heads and two hydrophobic polystyrene (PS) tails covalently linked via rigid spacers (PS-$(APOSS)_2$-PS) was designed and synthesized Our current study revealed a morphological transition from vesicles to wormlike cylinders and further to spheres as the degree of ionization of the carboxylic acid groups on POSS heads increases in their micelle solutionPS tails were found to be less stretched in micellar cores of PS-$(APOSS)_2$-PS than those of the corresponding single-chained giant surfactant. It was also observed that the PS tail conformations in the micelles were also affected by the length of rigid spacers where the one with longer spacer exhibits more stretched PS chain conformation. Both findings could be explained by the topological constraint imposed by the short rigid spacer in giant gemini surfactants. This constraint effectively increases the local charge density and leads to an anisotropic head shape that requires a proper re-distribution of the APOSS heads on the micellar surface to minimize the total electrostatic repulsive free energy. Moreover, their supramolecular structures in bulk were also found to be strongly affected by rigid spacer effects. Our study has general implications in the basic physical principles underlying their self-assembly behaviors in solution and bulk states

Q1.00059 Hierarchical Structure from the Self-Assembly of Giant Gemini Surfactants in Condensed State , HAO SU, ZHAO WANG, YIWEN LI, STEPHEN CHENG, Department of Polymer Science, the University of Akron — In the past a few years, a new class of amphiphiles with both asymmetrical shapes and interactions named "shape amphiphiles" has been significantly intensified. Recently, a new kind of shape amphiphiles called "Giant Gemini Surfactants" consisting of two hydrophilic carboxylic acid-functionalized polyhedral oligomeric silsesquioxane (APOSS) heads and two hydrophobic polystyrene (PS) tails covalently linked via rigid spacers (p-phenylene versus biphenylene) has been successful behavior of giant gemini surfactants. We currently continue to investigate the spacer effects on the self-assembly behaviors of giant gemini surfactants in condensed state by utilizing DCS, SAXS and TEM. Preliminary results showed that giant gemini surfactants with different spacers have diverse phase behaviors. As we use the same 3.2k PS chains, the giant gemini surfactant with p-phenylene spacer showed double gyroid morphology, while the one with biphenylene spacer revealed cylindrical morphology. This study expands the scope of giant gemini surfactants and contributes a lot to the basic physical principles in self-assembly behavior.

Q1.00060 Curvature-directed crystallization of isotactic poly(propylene) in nanopores[1] , DARIYA REID, BRIDGET EHLINGER, JODIE LUTKENHAUS, Texas A&M University — Properties of a cylindrically confined polymer may greatly differ from its properties in bulk state when the geometrical restrictions approach the size of the polymer itself. Confinement of polymer dielectrics, such as isotactic polypropylene (iPP), in nanoporous templates can potentially enhance the dielectric properties of the material via directed crystallization. iPP was melt-wetted into nanoporous templates of varying diameter (15 - 200 nm) in order to study the effect of pore dimensions on crystallization. Using differential scanning calorimetry (DSC) and X-ray diffraction (XRD), it is shown that iPP crystallizes into the α-phase and preferentially orients along the long axis pore. A transition from hetero to homogeneous crystallization was observed in relation to pore diameter. The isothermal crystallization kinetics was analyzed using Avrami analysis. As the pore diameter decreases crystallization shifts to a multi-mode process, whose origins will be discussed in this presentation.

Q1.00061 Fabrication of Micropatterns using Salt Crystals from Solvent Evaporation[1] , DONG-EUN LEE, SEUNG JAE GO, DONG HYUN LEE, Dankook University — Herein, we investigated the crystallization behaviors of sodium carbonate (Na_2CO_3) from highly diluted aqueous solutions. Aqueous Na_2CO_3 solutions which were applied on substrate surfaces by either dropping or draining exhibited a variety of well-defined crystal structures over large areas during water evaporation. It was also found that both sizes and shapes of salt crystals could be effectively controlled by the experimental conditions such as their concentration, evaporation rate, temperature and humidity. Furthermore, it was observed that the salt crystals could be oriented to specific direction as the evaporation of water occurred on the tilted substrates. The crystals of Na_2CO_3 were then employed as the master pattern to fabricate the soft mold of poly(dimethyl siloxane) (PDMS). Then silver (Ag) inks were filled into the pores of PDMS molds and transferred to various substrates by imprinting techniques to produce electrically conductive electrodes for potential electric devices.

Q1.00062 Small Molecule-Guided Thermoresponsive Supramolecular Assemblies

, BENJAMIN J. RANCATORE, CLAYTON E. MAULDIN, Department of Chemistry, UC Berkeley, JEAN M.J. FRÉCHET, College of Chemistry, UC Berkeley, TING XU, Department of Materials Science and Engineering, UC Berkeley — Small organic molecules with strong intermolecular interactions have a wide range of desirable optical and electronic properties and rich phase behavior. Incorporating them into block copolymer (BCP)-based supramolecules opens a new route to generate functional responsive materials. A quaterthiophene semiconductor containing alkyl and phenolic moieties was hydrogen-bonded to the 4-vinylpyridine groups of a block copolymer, polystyrene-b-poly(4-vinylpyridine) or a homopolymer, poly(4-vinylpyridine) (1,2). Hierarchical co-assemblies of oligothiophene and BCP with a number of potentially useful morphologies for optoelectronic materials were obtained. Crystallization of the oligothiophene from a melt not only induced chain stretching of the BCP block the oligothiophene was hydrogen bonded to, but also changed the conformation of the other BCP coil block, which led to an over 70% change in the BCP periodicity. The present studies have demonstrated the experimental feasibility of generating thermoresponsive materials that convert heat into mechanical energy and provides access to large BCP periodicities using fairly low molecular weight BCP. Q1.00063 Polymer single crystal membrane from liquid/liquid interface

, WENDA WANG, CHRISTOPHER LI, Drexel University, SOFT MATTER RESEARCH GROUP-DREXEL UNIVERSITY TEAM — Vesicles, mimicking the structure of cell membrane at the molecular scale, are small membrane-enclosed sacks that can store or transport substances. The weak mechanical properties and the nature of environment-sensitivity of the current available vesicles: liposomes, polymersomes, colloidsomes limit their applications as an excellent candidate for targeting delivery of drugs/genes in biomedical engineering and treatment. Recently, we developed an emulsion-based method to grow curved polymer single crystals. Varying the polymer concentration and/or the emulsification conditions (such as surfactant concentration, water-oil volume ratio), curved crystals with different sizes and different openness could be obtained. This growing process was attributed to polymer crystal growth along the liquid/liquid interface. In addition, the liquid/liquid interfacial crystal growth is promising for synthesis of enclosed hollow sphere.

Q1.00064 Rate of Formation of Trigonal Phase in Blends of Homogeneous Propylene 1-Hexene Copolymers

, HAMED JANANI, GABRIEL TRUJILLO, RUFINA ALAMO, Florida State University, FAMU-FSU College of Engineering — Blends of polyolefins such as polyethylenes, polypropylenes or their copolymers are often used to balance the strengths of each component towards improving processing, physical properties and performance. The final properties depend on the semicrystalline state acquired upon melt-solidification which is highly impacted by the state of melt miscibility. In this work we have assessed the critical composition difference for melt miscibility of propylene 1-hexene copolymers (PH) and selected a miscible pair with 11 and 21 mol% of 1-hexene respectively. PH21 crystallizes in a trigonal packing, while PH11 develops monoclinic crystallites (at low undercooling) or the mesomorphic form (at high undercooling). In situ DSC and WAXD analysis indicate that while the content of trigonal phase decreases with increasing PH11, the rate of formation of trigonal phase in the whole range of undercooling increases with addition of PH11, which as a pure component does not form trigonal phase. The unexpected enhanced kinetics of formation of trigonal phase with blending is attributed to the increasing composition of 1-hexene in the melt during isothermal crystallization of the blend.

Q1.00065 The Thickness And Stretch Dependence Of The Electrical Breakdown Strength Of An Acrylic Dielectric Elastomer

, JIANGSHUI HUANG, ZHIGANG SUO, DAVID CLARKE, Harvard University — The performance of dielectric elastomer actuators is limited by electrical breakdown. Attempts to measure this are confounded by the voltage-induced thinning of the elastomer. A test configuration is introduced that avoids this problem: A thin sheet of elastomer is stretched, crossed-wire electrodes attached, and then embedded in a stiff polymer. The applied electric field at breakdown E_B is found to depend on both the deformed thickness, h, and the stretch applied, λ. For the acrylic elastomer investigated, the breakdown field scales as $E_B = 51\, h^{-0.25}\, \lambda^{0.63}$. The test configuration allows multiple individual tests to be made on the same sheet of elastomer.

Q1.00066 Crystal Engineering of Tetrahedral 'Nano Molecules' Constructed by POSS Cages

, MINGJUN HUANG, SHAN MEI, STEPHEN CHENG, Department of Polymer Science, the University of Akron — Functional hybrid materials provide us a powerful approach to acquire novel hierarchical structures and exceptional properties. Designed nanoparticle building blocks with specific interactions can self-assemble into targeted ordered structures with intriguing shapes, sizes and functionalities. Classical high symmetric 'nano atoms', Polyhedral Oligomeric Silsesquioxane (POSS) can be utilized to construct 'nano molecules' with different symmetry, which can further act as novel nanoparticle building blocks. Very interesting rigid tetrahedral 'nano molecules' covalent linking four POSS cages were synthesized. Their close packing structures in crystal were determined by transmission electron microscopy (TEM) and wide angle X-ray diffraction (WAXD).

Q1.00067 Dielectric Characterization of Poly(styrene-b-methyl methacrylate) Block Copolymer Films[1]

, CHRISTOPHER GRABOWSKI, MICHAEL DURSTOCK, RICHARD VAIA, Air Force Research Laboratory, Wright Patterson Air Force Base — Polymer films that incorporate nanoscale features have been previously investigated for their suitability as dielectric insulating materials, such as mixtures of high dielectric strength polymers with high permittivity nanoparticles. Block copolymers, due to their highly customizable molecular-scale morphologies, may exhibit useful energy storage properties. Spherical, cylindrical, or lamellar morphologies can all be generated by altering block size ratio. We report the dielectric study of thin, substrate supported poly(styrene-b-methyl methacrylate) linear block copolymer films. Energy storage capabilities will be determined through dielectric strength and permittivity measurements. As both polymer blocks have similar permittivity, field enhancement effects that typically occur in inorganic nanoparticle/polymer composites are limited. Our experiments with block copolymers will more directly test how dielectric breakdown is influenced by interfacial interactions.

Q1.00068 High Temperature Dielectric Behavior of Polycarbonate/Poly(vinylidene fluoride) Multilayer Films

, CRAIG LEWIS, JUNG-KAI TSENG, MATHEW MACKEY, ERIC BAER, LEI ZHU, Case Western Reserve University, LEI ZHU GROUP TEAM — Because of significant dielectric and resistivity constants for polycarbonate (PC) and poly(vinylidene fluoride) (PVDF), the Maxwell-Wagner-Sillars interfacial polarization is observed in PC/PVDF multilayer films and is able to increase the overall electric displacement. However, based on the dielectric displacement-electric field (D-E) loop study, the PC/PVDF 50/50 32 layer film has higher dielectric constant calculated from the slope of D-E loop as compared to the 256 layer film. In other words, the maximum D decreases with decreasing the PC layer thickness. Since the electron tunneling is significant for thinner PC layers (i.e., internal conduction), the interfacial polarization is decreased. This study elucidates the relationship between the maximum D and the PC layer thickness, as well as the dielectric behavior at high temperatures.

Q1.00069 Diffusion of gaseous and supercritical CO_2 through polycarbonate[1] , MICHAEL GOODMAN, RAHMI OZISIK, Rensselaer Polytechnic Institute — The design of polymeric materials for applications such as separation membranes and nanostructured foams requires prediction of gas transport properties under a wide range of pressures. In the current study, transport of CO_2 both in gaseous and supercritical state through samples of polycarbonate at 51 °C and pressures from 15 to 2000 psi was measured using an asymptotic time lag apparatus. Through volumetric calibration, the traditional analysis was extended to yield permeability (P) and solubility (S), in addition to the usual asymptotic diffusivity (D_a). Nonlinear least squares fitting to a truncated series solution then provided an alternative measurement of the (transient) diffusivity (D_t), as well as the surface concentration (C_o) of adsorbed gas. At 1 atm, D_a and D_t were within a factor of 2 from selected handbook values; and with increasing pressure, both exhibited an overall downward trend, consistent with other studies, but an unexpected dropoff occurred between 1350 and 1500 psi. As expected, C_o showed an overall increase with pressure, but as with P and S, displayed a peculiar drop between 1350 and 1500 psi. Measurement of C_o in polycarbonate has never been done before and constitutes a novel feature of this study.

Q1.00070 Scaling of the strain hardening modulus with nanoparticle loading and the rejuvenated yield stress in polymer nanocomposites , ROBERT HOY, University of South Florida, ALAN LESSER, University of Massachusetts, JOSEF JANCAR, Brno University of Technology — We examine the nonlinear mechanics of polymer glasses by using silica nanoparticles as"probes" that alter the segmental packing and relaxation dynamics of glassy PMMA. At low $T = T_g - 80K$, the scalings of both the strain hardening modulus G_R and the rejuvenated yield stress σ_{yr} with NP loading (i.e. the silica volume fraction ν_f) are predicted by a simple volume-replacement model. At higher $T = T_g - 20K$, this scaling breaks down, indicating substantially interface-retarded dynamics and packing frustration. At high strain rates, G_R scales linearly with σ_{yr}, with a ν_f-dependent offset. This linear scaling breaks down at lower strain rates $\dot{\epsilon} < \dot{\epsilon}^{crit}(\nu_f)$. Surprisingly, $\dot{\epsilon}^{crit}$ increases with increasing ν_f, violating the intuitive expectation that NP filling would increase the controlling relaxation times. We explain this phenomena in terms of the increasing dynamical heterogeneity induced by filler particles.

Q1.00071 Physical Property Requirements of Ion-exchange Polymer Membranes for Acid-base Flow Batteries , SUPACHAREE RODDECHA, PETER THAYER, JACOB JORNE', MITCHELL ANTHAMATTEN, University of Rochester — Flow batteries offer feasible solutions to grid-scale storage of intermittent power. We are developing a new type of flow battery that reversibly controls an acid-base neutralization reaction. The battery consists of two highly reversible hydrogen gas electrodes that are exposed to low and high pH process streams. A brine solution runs between the acid and base streams and is separated by cationic and anionic exchange membranes. For both charge and discharge phases, hydrogen gas is produced at one electrode and consumed at the other. During charging, an external potential is applied across the two electrodes to electrochemically produce acid and base from the fed brine solution. Discharge involves electrochemical neutralization of acid and base streams, resulting in current flow through an external load. Several charge and discharge cycles were performed to demonstrate proof of concept. Experiments were conducted to determine the physical property requirements of the ionic exchange polymer layers. Properties including ion conductivity, permselectivity, and membrane stability will be discussed.

Q1.00072 Magnetic fields-directed self-assembly of soft nanomaterials for energy harvesting and storage[1] , PAWEL MAJEWSKI, MANESH GOPINADHAN, CANDICE PELLIGRA, CHINEDUM OSUJI, Yale University — We utilize magnetic fields to impose long range order in self-assembled soft materials including block copolymers, polymer-nanowire composites, and surfactant mesophases. Due to the space-pervasive nature of magnetic fields, this method can be utilized to produce arbitrarily large volumes of highly anisotropic materials with a quality of the alignment frequently approaching that of single crystals as assessed by X-ray scattering. The high fidelity of the alignment allows us to systematically explore and characterize the anisotropy of the charge transport in these materials. We present the results for improving charge transfer in cobalt doped ZnO nanowire-polythiophene composites for photovoltaic applications by the alignment of the nanowires. In block copolymers, we focus on enhancing Li-ion transport in membranes by the alignment of the Li-conducting PEO domains. We compare the magnitude of anisotropy and temperature dependence of ionic conductivity to the data obtained for non-polymeric surfactant-water systems.

Q1.00073 Fluctuation Effects on Phase Behavior of Gradient Copolymer Systems , GUNJA PANDAV, VENKAT GANESAN, University of Texas at Austin — We consider the effect of sequence polydispersity on fluctuation induced shift in order-disorder transition (ODT) temperature for symmetric systems of gradient copolymers. Using single chain in mean field simulations, a systematic change in scaling prediction for shift in ODT with Ginzburg parameter is reported. We demonstrate that gradient strength and overall blockiness of sequences has a significant impact on shift in ODT temperature. The weak gradient copolymers having high compositional polydispersity mimic random copolymers whereas, strong gradient copolymers possess inherent blockiness and are close to diblock copolymers. The blockiness parameter has a minimal impact on shift in ODT in strong gradient copolymers. Also, ternary blends of homopolymer/gradient copolymer are investigated to capture effect of compositional polydispersity on phase diagram and formation of microemulsion structures.

Q1.00074 Influence of substrate confinement on the phase-correlation in the capillary breakup of lithographically patterned polymer stripes[1] , ZHENG ZHANG, YIFU DING, University of Colorado at Boulder — We study the simultaneous capillary breakup of parallel polymer stripes, which were partially embedded in an immiscible polymer and confined on elastic substrates. Polystyrene (PS) and Poly(methyl methacrylate) (PMMA) were used because of their immiscibility. When annealed at a temperature above the glass transition temperatures of both polymers, capillary instabilities of the stripes were observed. We found that substrate-induced confinement influenced the phase-correlation in the breakup of neighboring stripes. With the increase of substrate confinement, the simultaneous breakup of the parallel polymer stripes transitioned from non-correlated to in-phase, irrespective of the viscosity ratio between PS and PMMA.

Q1.00075 The Structural Change Depending on the Buckling Direction and Alignment of Block Copolymer Thin Films , DOKYEONG KWON, HYO SEON SUH, KOOKHEON CHAR, Seoul National University — Buckling of thin films on elastomeric substrates such as polydimethylsiloxane (PDMS) is the well-known phenomenon in buckling instability originating from the moduli mismatch between a substrate and a thin film placed at the top. Recently, many studies on the microstructure created by the buckling have been reported but most of the work has employed either metal or semiconductor thin films and few studies utilized block copolymer (BCP) thin films as the top layer. Here, we present the buckling of oriented BCP thin films placed on top of PDMS substrates, resulting in hierarchical structures combining nanostructured BCP with microstructured buckling. Buckling instability was induced by applying a mechanical stress to the BCP-PDMS bilayer. Due to the buckling of BCP thin films, we observed the structural change of the films depending on the alignment of BCP domains with respect to the buckled direction of a substrate, which could give us insights on the buckling of mechanically heterogeneous films. This work could even be extended to a new patterning technique, utilizing both BCP thin film lithography and the microscale patterning induced by buckling.

Q1.00076 The formation of standing cylinders in block copolymer films by irreversibly adsorbed polymer layers on substrates[1] , JUN SHANG, NAISHENG JIANG, MAYA ENDOH, TADANORI KOGA, Department of Materials Science and Engineering, Stony Brook University — Block copolymers offer a simple and effective route to produce standing cylindrical nanostructures with regularity on the order of 10-100 nm, the length scale that is desirable for many advanced applications. However, these formations have been especially troublesome due to the fact that preferential interactions between one of the blocks and the surfaces will induce parallel alignment of the cylinders in order to minimize interfacial and surface energy. Here we introduce an alternative simple method utilizing an irreversibly adsorbed polymer layer (a "Guiselin" brush) as a neutral "substrate" formed on solid substrates for the arrangement of standing cylindrical nanostructures. The effect of polymer adsorbed layer on the long range ordering of asymmetric cylinder forming poly(styrene-block-ethylene/butylene-block-styrene) (SEBS) triblock copolymer thin films were investigated by using a combination of grazing incidence small angle x-ray scattering and atomic force microscopy techniques. We found that the SEBS, which forms cylinders lying parallel to the surface when prepared on silicon substrates, show standing cylindrical structures on selected Guiselin brush layers after prolong thermal annealing. The details will be discussed in the presentation.

[1]We acknowledges the financial support from NSF Grant No. CMMI-084626

Q1.00077 Sequences of Mixed Ions in Polypeptoid Surfaces , HILDA BUSS, WENDY VAN ZOELEN, NATHAN ELLEBRACHT, University of California, Berkeley, RONALD ZUCKERMANN, Lawrence Berkeley National Lab, RACHEL SEGALMAN, University of California, Berkeley — Polypeptoids, a unique, sequence specific class of polymers, are used to investigate the influence of charge spacing, grouping, and chemistry on the surface properties of polymer coatings. Short peptoid oligomers composed of cationic and anionic groups, and superhydrophobic (fluorinated) functionalities were attached to a synthetic backbone to form comb-shaped molecules. These molecules display different surface chemistry as a function of side chain composition, as indicated by near edge X-ray absorption fine structure spectroscopy (NEXAFS). A 50:50 ratio of peptoid:fluorinated functionality resulted in optimal surface segregation of the comb block while preventing surface reconstruction upon immersing the polymer films in water. Antifouling experiments with the green algae Ulva showed that polymers with non-ionic peptoid functional groups resulted in superior antifouling coatings compared to polymers with charged peptoids. The effects of decreasing the peptoid charge spacing even further (zwitterionic side chains) and exploring stronger ionic moieties, such as phosphate groups, will also be discussed.

Q1.00078 Self-Consistent Field Simulation of Block Copolymer Thin Films Located on Topographic Pattern , JUNG GUN BAE, Nano-Structuered Complex Fluids Lab, School of Chemical and Biomolecular Engineering — Motivated by recent experiments of directed self-assembly of AB diblock copolymer(BCP) thin film induced from patterned substrates, there is need to compare with simulation. We employ self-consistent field theory(SCFT) simulation which is known as well fitted. Especially, we investigated the effect of each roughness factors, such as period and depth of eroded line patterns. The higher-order accurate and stable pseudo-spectral method is adopted to numerically solve the SCFT equations and appropriate cavity function is also employed to represent the square wave patterns. There is some correspondence between the orientation of BCP micro-domain and roughness factors. We can examine the critical condition that occur inversion between parallel and perpendicular orientation of BCP on patterned substrates.

Q1.00079 Sulfonated block copolymer thin films for fast responsive dual-mode humidity sensors , EUNYEONG KIM, MOON JEONG PARK, POSTECH — Polymer electrolytes have been widely used to fabricate humidity-sensing devices by taking advantages of easy fabrication and low cast. In present study, we developed humidity sensors from sulfonated block copolymer thin films with tailored hygroscopic properties. The films exhibit hexagonal cylindrical morphology where hydrophobic cylinders are dispersed within a hydrophilic matrix. Under the level of humidity, it has been revealed that the films self-display discernible reflective color changes, which cover almost entire visible light spectrum from violet (RH = 20%) to red (RH = 95%). This is due to fact that the hydrophilic matrix absorbs water yielding anisotropic swelling of the film along the film thickness direction. In addition, the sensors exhibit a few orders of magnitude changes in impedance with exposure to humid air owing to the strong polyelectrolyte characteristics. To the best of our knowledge, our system is the first example of dual-mode humidity sensor among any existing humidity sensors. What is most interesting is that the time to complete the changes in color and/or impedance was only 5s regardless of RH gradients, as rationalized by well-connected hydrophilic matrices, offering short water diffusion pathways in nanostructured block copolymer thin films.

Q1.00080 Nanomanufacturing of Gold Nanoparticle Arrays Using Peptide-Derivatized Block Copolymer Templates[1] , TINGLING RAO, Department of Polymer Science, University of Akron, GURPREET SINGH, Department of Polymer Engineering, University of Akron, SIBAI XIE, Department of Polymer Science, University of Akron, ALAMGIR KARIM, Department of Polymer Engineering, University of Akron, MATTHEW BECKER, Department of Polymer Science, University of Akron — Collective surface plasmons (SPs) displayed by two-dimensional (2-D) Au nanostructures are important for applications such as plasmonics and plasmonic sensing. However, methods for fabricating programmable highly-ordered arrays of Au nanoparticles with nanoscale precision are limited. Here, we report a peptide—derivated block copolymer based rout towards continuous fabrication of Au nanoparticle superlatice with tunable structures. We successfully obtain discrete, hexagonally-packed Au nanoparticle hierarchical structures where Au-to-Au nanoparticle spacing is precisely controlled by the underlying PMMA cylindrical phase of the block copolymer (BCP). Dynamic thermal field processing techniques offer a facile and continuous rout to tune the BCP assembly, thus enabling versatile arrangement of Au nanostructures from Au-dots to Au-lines. Our method may open a cost-effective way towards assembly of 2-D Au nanoparticles with tunable structures by carefully tuning molecular parameters – a promising step to novel nanodevices.

[1]Akron Functional Materials Center (AFMC) and The University of Akron Research Foundation

Q1.00081 Three dimensional mesoporous silica strucutres with templated macropores , ROHIT KOTHARI, NICHOLAS R. HENDRICKS, JAMES J. WATKINS, University of Massachusetts Amherst — A novel approach to fabricate three dimensional macroporous structures comprised of mesoporous silica is demonstrated. Well-ordered mesoporous silica structures with macroporosity were obtained by using humidified supercritical carbon dioxide as a carrier medium to infuse and domain selectively condense silica alkoxide precursor in a microphase separated block copolymer/small molecule additive blend solution casted on macroporous supports such as cellulose filter paper and sponge. Subsequent calcination was used to remove both the block copolymer template and the macroporous support. Transition electron microscopy (TEM) and small angle x-ray diffraction (SAXD) confirmed the presence of well-ordered mesopores. Scanning electron microscopy confirmed faithful replication of the features of the macroporous supports. Physisorption showed BET surface areas as high as 400m^2/g and the BJH pore size distributions obtained are in close agreement with the TEM and SAXD results. This dual scale porosity within the silica template will enhance overall transport and diffusion, which is appropriate for many applications including catalysis and sensing.

Q1.00082 Thickness and Confinement Effects on the Morphology of Gyroid PS-PDMS Thin Films

, WUBIN BAI, KEVIN GOTRIK, ADAM HANNON, ALFREDO ALEXANDER-KATZ, Massachusetts Institute of Technology, APOSTOLOS AVGEROPOULOS, University of Ioannina, CAROLINE ROSS, Massachusetts Institute of Technology — The self-assembly of thin films of a block copolymer with a bulk gyroid structure was examined for a range of thicknesses and annealing conditions. The poly(styrene-b-dimethylsiloxane) (SD80, 80kg/mol, f_{PDMS} =40%, PDI =1.07) formed a gyroid structure in bulk (the microdomain period, Lo∼45 nm). Thin films were spin-cast from 1% solution of SD80 in toluene and annealed in cosolvent vapors consisting of mixed toluene and heptane vapors, which swelled the film by a factor of 2.2 - 2.4. The morphology of the microdomains was revealed by removing the PS with oxygen plasma. Thick films (>∼2Lo) showed gyroid-like morphologies, but thinner films (∼Lo) exhibited perforated lamellar structures whose period varied slowly with film thickness. Self-consistent field theory simulations reproduced the wetting layer – perforated lamella – gyroid morphological transitions with increasing thickness. Results are compared with a 45 kg/mol PS-PDMS/homo-PDMS blend with the same f_{PDMS}, and templating of the perforated lamellae by substrate topography is described. The perforated lamellae structures produced by these methods can be used as templates for fabricating highly ordered periodic arrays of nanowires or magnetic dots with tunable sizes.

Q1.00083 Additive Driven Self Assembly and Photo-induced Ordering in Poly(ethylene glycol)monomethyl ether monomethacrylate-block-Poly(ethyl methacrylate) Copolymers

, CHENG LI, JAMES WATKINS, Umass Amherst — Recent work in our labs has shown that blending of hydrogen-bond donating polymers, small molecules or nanoparticles with a block copolymer that contains poly(ethylene oxide) (PEO) can enhance microphase segregation strength and yield well ordered morphologies. While PEO crystallization in these polymers is suppressed by strong interactions between the additive and the PEO segments at high additive loadings, crystallization of the PEO block in the absence of these interactions or at low additive loadings is highly undesirable for many applications. To remedy this issue, poly[poly(ethylene glycol) monomethyl ether monomethacrylate]-block-poly(ethyl methacrylate) was prepared using reversible addition-fragmentation chain transfer polymerization(RAFT). This block copolymer is a phase mixed, non-crystallizable system at room temperature. We find that incorporation of organic additives with multiple carboxylic acid groups such as mellitic acid induces phase segregation in this system. Furthermore, the use of additives in which the hydrogen bond donating group is protected with an acid labile group in combination with a photo acid generator enables photo-induced microphase segregation of the composite to yield well ordered films.

Q1.00084 In-situ Grazing-incidence Small-angle X-ray Scattering Study of Diblock Copolymer Thin Films during Solvent Annealing

, XIAODAN GU, University of Massachusetts Amherst, ILJA GUNKEL, ALEXENDER HEXEMER, Lawrence Berkeley National lab, THOMAS RUSSELL, University of Massachusetts Amherst, UNIVERSITY OF MASSACHUSETTS AMHERST COLLABORATION, LAWRENCE BERKELEY NATIONAL LAB COLLABORATION — Solvent annealing emerged as a convenient means to obtain ordered structures in block copolymer thin films. The mechanism, however, by which this ordering occurs is ill-understood. Here, we performed in-situ grazing incidence small-angle scattering (GISAXS) experiments on diblock copolymers thin films during annealing in organic solvent vapors to study the underlying mechanism that underpins the self-assembly process. We used two different cylinder forming block copolymers, poly(styrene-block-ethylene oxide) (PS-b-PEO) and poly(styrene-block-2-vinylpyridine) (PS-b-P2VP) that were spin-coated on silicon wafers and. The films were annealed in tetrahydrofuran (THF), which is slightly selective for the PS block. We performed in-situ scattering experiments at constant swelling of the films and also investigated the effect of deswelling at different rates of solvent removal. Our results show that the films undergo a disorder-to-order transition during swelling. Also we found that the lateral ordering of the microdomains after deswelling is highly sensitive to the rate of solvent removal.

Q1.00085 Analysis of Crystallization on Polymeric Thin Films Deposited on Silicon Dioxide

, ETHAN CUMMINGS, James Madison University — Polyvinyl Alcohol (PVA) is a synthetic polymer containing carbon chains with hydroxide groups bonded to every other carbon. Poly (propylmethacrylisobutyl POSS co-methylmethacrylate) (POSS-MA) is a co-polymer that contains polyhedral oligomeric silsesquioxane (POSS) cages co-polymerized to a poly methyl methacrylate (PMMA) backbone. PVA is dissolved into water at various concentrations and coated onto a silica wafer using spin casting. Then, various concentrations of 30-40 wt% POSS-MA are dissolved in chloroform and deposited onto the same sample. After spin casting, these samples are analyzed using AFM and ellipsometry. Typical samples of POSS-MA and PVA/POSS-MA thin films exhibit varying rates of micro-phase separation in the form of dendritic structures. Once seperation is completed, the pixel areas of the dendrite structures are measured using IDL. These varying area determinations are normalized, and then fit to an Avrami plot by graphing ln(-ln(1-f)) vs. ln(time), where "f" is normalized area, and the time is the time after deposition. On the graphs, the slope is the dimensionality of the growth constant, and the y-intercept is the natural log of the rate constant (ln(k)). Samples also undergo ellipsometry to determine the thickness of the SiO_2/PVA/POSS-MA thin films. Additional experiments include a process that etches away the PVA thin film layer in water, leaving the POSS-MA thin film layer on the surface of the water. The thin film is then lifted onto a TEM grid to be analyzed using TEM.

Q1.00086 Photo-Activated Replication of Thin Film Block Copolymer Patterns

, CHRISTOPHER ELLISON, DUSTIN W. JANES, Department of Chemical Engineering, The University of Texas at Austin, CHRISTOPHER J. THODE, Department of Chemical Engineering, The University of Wisconsin-Madison, C. GRANT WILLSON, Department of Chemistry, The University of Texas at Austin, JEONG IN LEE, PAUL F. NEALEY, Institute for Molecular Engineering, University of Chicago — Strategies to replicate nanopatterns formed by the self-assembly of block co-polymer (BCP) thin films could help enable high-throughput nanopatterning technologies. Our approach involves placing liquid compositions between the top surface of a block copolymer thin film and a transparent substrate. Upon irradiation the liquid composition solidifies and covalently binds to the BCP, thus creating a mirror-image copy of the original pattern on the transparent substrate. This replicated pattern serves to direct the assembly of a new BCP thin film, while the wetting characteristics of the original substrate are recovered for use in further replication cycles. The process is scalable to large areas, photo-activated, takes less than 1 h, and occurs below the glass transition of the BCP.

Q1.00087 An Automated System for GISAXS and GIWAXS Measurements

, JESSICA JIMENEZ, Jema Technology LLC, ERIC SCHAIBLE, Lawrence Berkeley National Laboratory, MATTHEW CHURCH, Jema Technology LLC, CHRISTINA YEE, ALASTAIR MACDOWELL, DILWORTH PARKINSON, EDWARD DOMNING, BRIAN SMITH, STEVEN ALVAREZ, ALEXANDER HEXEMER, Lawrence Berkeley National Laboratory — Grazing incidence small-angle scattering (GISAXS) and grazing incidence wide-angle scattering (GIWAXS) are important techniques for characterizing thin films, and their use is rapidly expanding. The current bottleneck in conducting GISAXS measurements is the time it takes to load and align samples. In order to meet increasing demand, we are implementing a fully automated system to conduct GISAXS and GIWAXS measurements. A robot arm will load samples from a holding tray onto the measurement stage. Intelligent software will align each sample in turn, and measure each according to user-defined specifications. Users will be able to mail in trays of samples, and will be able to monitor and control their experiments remotely.

Q1.00088 Co-assembly of polymer covered cyclic peptide nanotubes and block copolymer in thin films

, CHEN ZHANG, THOMAS LAZZARA, Department of Materials Science and Engineering, University of California, Berkeley, CHANGYI LI, Department of Chemical Engineering, University of California, Berkeley, BRETT HELMES, The Molecular Foundry, Lawrence Berkeley National Laboratory, TING XU, Department of Materials Science and Engineering, University of California, Berkeley — Nanotubular structures have gained prevalent interest for their unique hollow structures and high aspect ratio and their potential applications ranging from molecular separation to nanocomposite membranes. We used nanotube forming cyclic peptide (CP) as the structural motif and studied the self-assembly of polymer conjugated CPs in block copolymer (BCP) matrix in thin films. The co-assembly process is mainly driven by thermodynamic quantities, namely Flory-Huggins polymer-polymer interactions that governs the interaction between CP and BCP, interfacial interactions that affects polymer chain orientation, and thin film commensurability. In addition, due to the dynamic nature of the nanotube formation, the co-assembly process is also pathway-dependent. Thus, processing conditions are critical in co-assembling CP nanotubes and BCP in thin films. Our result shows that the initial aggregation state of polymer covered CP nanotubes determines the pathway the system takes and hence the final morphology of the films. The co-assembly of polymer-conjugated CPs and BCPs demonstrates the feasibility of assembling 1D nanotubes in supramolecular thin films and opens up a new avenue for the generation of novel nanotubular structures.

Q1.00089 sPP gel with high mechanical properties and high transparency by supercooling in mixed solvents

, KEITA TAKAESU, ATSUSHI HOTTA, Department of Mechanical Engineering, Keio University — Polymer gels are generally classified into chemical gels and physical gels depending on the types of crosslinking points. Physical gels are known to possess significantly poorer mechanical properties than chemical gels due to relatively weak crosslinking bonds in physical gels such as hydrogen bond and an intermolecular bond. In this work, physical sPP gels with extremely high mechanical properties and high transparency were successfully created by supercooling in mixed solvents. From our previous work, it was found that supercooling of physical gels (sPP/decalin gels) could produce gels with high mechanical properties comparable to chemical gels but maintaining the advantages of physical gels such as stimulus-responsiveness and reversibility, which cannot be realized by using chemical gels. Here, we also used tetrahydronaphthalene (tetralin) as solvent. The mechanical properties of sPP/tetralin were degraded by supercooling but intriguingly enhancement in the mechanical properties of sPP gels could be observed by using mixed solvent of decalin and tetralin, which eventually showed twice as high fracture stress as sPP/decalin gels.

Q1.00090 Polymer-induced depletion attraction between nanoparticles in confined conditions

, VICTOR PRYAMITSYN, VENKAT GANESAN, University of Texas at Austin — We studied the polymer-mediated depletion pair interaction between nanoparticles and/or proteins in polymer solutions in confined conditions. The self-consistent field (SCF) theory for a polymer - nanoparticles systems in confined systems is solved numerically by using the pseudo-spectral method. We have analyzed the behavior of non-adsorbing particles in a polymer solution near a non-adsorbing wall for which the polymer mediated particle-particle and particle-wall interaction in such systems are known to be a depletion attraction. Our main results for such system are the following: polymer depletion from the wall causes the polymer density to decrease near the wall and reduces the particle-particle depletion attraction near the wall. In a similar manner, the particle-wall attraction is also screened due to presence of another particle. Our results surprisingly suggested a simple scaling to rationalize the wall-mediated interparticle potentials. Specifically, the wall-mediated depletion interactions were shown to be semi-quantitatively captured by the depletion interaction between two particles in an unconfined polymer solution at a density corresponding to the density of the polymer solution at midpoint between the two particles. These results suggest that the phase behavior of

Q1.00091 Application of near-field microwave microscopy in in-situ detection of microfluids under dielectric cover[1]

, WEIQIANG SUN, Key Laboratory for Physics and Chemistry of Nanodevices, Department of Electronics, Peking University, YONG YANG, Institute of Microelectronic, Chinese Academy of Sciences, TAO FENG, SHENGYONG XU, Key Laboratory for Physics and Chemistry of Nanodevices, Department of Electronics, Peking University — Based on the capability of penetrating through low permittivity materials and the sensitivity to impedance of microwave, we have applied the near-field scanning microwave microscopy (NSMM) to the in-situ detection of microfluids packed with dielectric covers. By means of a NSMM system, we obtained two dimensional maps showing the frequency shift and magnitude of the reflection coefficient S_{11}, which correspond well to the spatial distribution and electrical conductance of various microfluidic structures underneath 15-200 μm thick dielectric covers. The spatial resolution and sensitivity are found closely related to the thickness of the cover layer. The underlying physics is discussed in detail. The time-resolvable detection of ionic concentration in microfluids is also demonstrated in different conditions for study of transport of particles in microfluids. This technique offers a real-time, in-situ and non-invasive approach for monitoring local chemical reactions, motion of fluids, distribution and concentration of ions in lab-on-a-chip systems, and has a potential to be developed for detection of cells and tissues.

Q1.00092 Evaluating the Role of Interfacial Molecules in Cp Measurements using Differential Scanning Calorimeter[1]

, WILL LINTHICUM, SAMUEL AMANUEL, Dept. of Phys. & Astro., Union College — Differential Scanning Calorimeter (DSC) has been used to evaluate the specific heat capacity of bulk ethylene glycol and physically confined ethylene glycol in porous silica with well-defined porosity. By controlling the pore sizes, we were also able to control the surface to volume ratio of ethylene glycol that comes in contact with the silica walls. Previously, we have demonstrated that about 2.14 nm layers of interfacial cyclohexane molecules do not participate in phase transition. In this case, how the physical size and the interfacial molecules affect the overall specific heat capacity of the silica ethylene glycol system is evaluated in the temperature range 303K - 413K. These empirical results are compared with computed specific heat capacities of composite materials, where the specific heat capacities of the composite systems are evaluated from the weighed average of the individual specific heat capacities. We are seeking means of reconciling the experimental observations with the computed specific heat capacities and looking for correction terms where the role of interface can be accounted.

Q1.00093 Analysis of Fluid Dynamics and Reactant Consumption in Microchannel Based Fuel Cells

, JOSEPH DALESSANDRO, PETRU FODOR, Cleveland State University — In this work, the fluid dynamics within a membraneless microchannel fuel cell is analyzed computationally. The membraneless design is a result of the laminar nature of the fluid flow at small Reynolds numbers, restricting the fuel and oxidant to the vicinity of the corresponding electrodes, without the need of a proton exchange membrane (PEM). The performance of such cells is limited by the mass transport near the electrodes, with much of the reactants leaving the channel without coming in contact with the catalytic surfaces. We use various strategies similar with those used in grooved micromixers to overcome this limitation. While the flow is still laminar in nature, the addition of ridges to the top and bottom of the cell introduce a transverse element to the fluid flow, increasing reactant consumption and overall cell efficiency. The characteristics of the cells are investigated as a function of the Peclet number.

Q1.00094 Precise measurement of spring constant and friction coefficient of nano-confined T4 DNA , CHRISTOPHER LÜSCHER, JONAS PEDERSEN, RODOLPHE MARIE, ANDERS KRISTENSEN, HENRIK FLYVBJERG, Naotech DTU — A simple method for accurate detection of dynamic parameters for DNA confined in nano fluidic channels is presented. T4 DNA is stained with YOYO-1 fluorescent dye and studied by epifluorescense under confinement in nanofluidic capillaries with cross-section less than 250 nm. A DNA molecule confined in a nanochannel of width below the molecule's radius of gyration is stretched to fill a length, L_0 of the channel. In equilibrium, the DNA will be subject to thermal fluctuations, which are governed by the drag force of the surrounding fluid and by the entropic spring constant of the DNA conformation in the channel. The power spectrum of the end-to-end length is described by a superposition of vibrational modes. The observed power spectrum reveals a shoulder at the lower frequencies, from which both the entropic spring constant and the friction coefficient of the nano-confined DNA can be determined. With this method, the spring constant and friction coefficient of nano-confined, YOYO-1 stained T4 DNA has been measured with a relative error below 15%.

Q1.00095 Viscoelasticity of Epoxy nano-composites , SURESH AHUJA, Retired — Nanocomposites have been modeled in a multiscale covering from molecular scale (e.g., molecular dynamics, Monte Carlo), microscale (e.g., Brownian dynamics, dissipative particle dynamics, lattice Boltzmann, time-dependent Ginzburg–Landau method, dynamic density functional theory method) to mesoscale and macroscale (e.g., micromechanics, equivalent-continuum and self-similar approaches, finite element method) The presence of layered silicates in nonaqueous polymers changes the viscoelastic behavior of the unfilled matrix from liquid-like to solid-like because of the formation of a three-dimensional percolating network of exfoliated or intercalated stacks. This gel-like behavior is a direct consequence of the highly anisotropic nature of the nanoclays which prevents their free rotation and the dissipation of stress. Particle to particle interactions is the dominant mechanism in fumed silica nanocomposites whereas particle to polymer interaction is the dominant one in colloidal silica nanocomposites at identical filler concentrations. These interactions are balanced in each nanocomposite systems by the silica surface treatments (chain grafting, silane modification) and the molecular weight of the matrix. Two different types of nanocomposite structures exist namely, intercalated nanocomposites where the polymer chains are sandwiched between silicate layers and exfoliated nanocomposites where the layers can be considered individually but remain more or less dispersed in the polymer matrix. Yield stress from Carreau-Yasuda model has been correlated to exfoliation. Also, equilibrium modulus and zero shear rate viscosity has been used to analyze percolation threshold and sol-gel transition. Nano clays organically functionalized were mixed with Epoxy in a high shear mixer.

Q1.00096 Heterogeneous nanoparticles at water-oil interfaces: Structure, Order, Diffusion, and Implications for the stability of Pickering emulsions[1] , ALBERTO STRIOLO, XUAN-CUONG LUU, The University of Oklahoma, MOLECULAR SCIENCE AND ENGINEERING TEAM TEAM — Pickering emulsions find applications, e.g., in food processing, personal care products, and drug delivery. The emulsions stability is naturally related to the structural and dynamical properties of the nanoparticles adsorbed at oil-water interfaces. Such properties are investigated here by means of dissipative particle dynamics simulations, informed by atomistic molecular dynamics simulations results (*Langmuir* **2011,** 27, (9), 5264-5274). Several nanoparticles are considered, including Janus and homogeneous, and of several different shapes (spherical, elliptical, discoid, etc.) Structural and transport properties are quantified as a function of surface density and system composition. Results for radial distribution functions, hexagonal order parameters, and self-diffusion coefficients are reported. We sometimes find unexpected behavior. For example, self-diffusion coefficient maxima are observed in mixed systems. Implications of such observations on macroscopic observables (i.e., the stability of Pickering emulsions) are discussed.

Q1.00097 A Polyhedral Oligomeric Silsesquioxane-Polyoxometalate Hybrid Shape Amphiphile: Facile Synthesis, Characterization and Crystal Structure , HAO LIU, JING WANG, KAN YUE, JING JIANG, WEN-BIN ZHANG, STEPHEN CHENG, Department of Polymer Science, The University of Akron — This study contains the synthesis and characterization of a novel shape amphiphile composed of two covalently conjugated inorganic nanoparticles, i.e. an isobutyl substituted polyhedral oligomeric silsesquioxane (BPOSS) cage and a Lindqvist-type hexamolybdate ([Mo6O19]2-) cluster, and its crystal structure. The facile one-step coupling strategy was realized via the highly efficient palladium-catalyzed Sonogashira reaction between an alkyne-bearing POSS derivative (BPOSS-Alkyne) and an iodo-functionalized Lindqvist precursor (Lind-Iodide) in high yield. The precisely defined molecular structure was thoroughly characterized by combination of routine techniques, such as $_1$H and $_{13}$C NMR, FT-IR, and MALDI-TOF mass spectroscopy. The persistent shape and chemical incompatibility of the two building blocks, as well as the rigid p-phenylene ethynylene linker, drive BPOSS-Lind to pack into a monoclinic lattice, which was confirmed by bright field transmission electron microscopy (TEM), selected area electron diffraction (SAED), small angle X-ray scattering (SAXS) and wide angle X-ray scattering (WAXS). This work introduces a new dumbbell-shaped giant hybrid molecule (BPOSS-Lind) and shed light on the packing behavior of this shape amphiphile.

Q1.00098 Hierarchical Assembly of a Diblock Copolymer-based Supramolecule Containing Liquid Crystal Side Chains , PETER BAI, MYUNG IM KIM, TING XU, University of California, Berkeley — Liquid crystalline side chain block copolymers (LCSCBCPs) are a novel class of soft materials that combine the rich morphology of block copolymers with the unique structural and electrooptical properties of liquid crystals. A supramolecular LCSCBCP composed of a cholesteric small molecule, 3-hydroxylphenyl cholesteryl succinate (ChHP) hydrogen bonded to a diblock copolymer, polystyrene-block-poly-4-vinylpyridine (PS-b-P4VP) was investigated for its structural and thermoresponsive properties using DSC, POM, DSC, TEM and SAXS. The supramolecule, PS-b-P4VP(ChHP), retained both block copolymer and liquid crystalline phase behavior in the form of hierarchical assembly on multiple length scales to form lamellar-within-lamellar and lamellar-within-cylinder morphologies. Upon thermal annealing, the supramolecule demonstrated thermoresponsive behavior in the form of a series of morphological transitions from a P4VP(ChHP) majority morphology to a P4VP(ChHP) minority morphology. The observed hierarchical assembly and thermoresponsiveness could potentially be applied towards templated assembly of nanomaterials with unique nanostructures for optical and photonic applications.

Q1.00099 Simulations of liquid crystalline phases of semiflexible polymer melts and blends , KIRAN KHANAL, JUTTA LUETTMER-STRATHMANN, Departments of Chemistry and Physics, The University of Akron — We perform Monte Carlo simulations of a bond-fluctuation model for polymers and introduce a bending energy so that polymer chains are flexible at high temperatures and rod like at low temperature. The phase diagram of polymer melts is determined in the temperature-density plane and the isotropic to nematic transition temperature is found to increase with increasing density. Single chain properties show that coupling between density and stiffness effects lead to nematic order. Blending with flexible chains leads to microphase separation and the formation of ordered domains of rods embedded in disordered regions.

Q1.00100 Morphological Control and Characterization of Liquid Crystalline Materials for Organic Electronics Applications , NABIL KLEINHENZ, KARTHIK NAYANI, JUNG OK PARK, MOHAN SRINIVASARAO, ELSA REICHMANIS, Georgia Institute of Technology — Pi-conjugated polymers have been widely explored for use in organic electronics applications. However, their performance is largely limited by the material morphology. We present research on the control and characterization of morphology for conjugated polymers that exhibit a liquid crystalline phase, while making use of their unique properties in organic field effect transistors and organic photovoltaics. Synthesis of novel materials as well as studies on processing conditions have been utilized to elucidate the relationships between structure, properties and device performance.

Q1.00101 Length and sequence dependence in the association of Huntingtin protein with lipid membranes , SUDI JAWAHERY, ANU NAGARAJAN, SILVINA MATYSIAK, University of Maryland, College Park — There is a fundamental gap in our understanding of how aggregates of mutant Huntingtin protein (htt) with overextended polyglutamine (polyQ) sequences gain the toxic properties that cause Huntington's disease (HD). Experimental studies have shown that the most important step associated with toxicity is the binding of mutant htt aggregates to lipid membranes. Studies have also shown that flanking amino acid sequences around the polyQ sequence directly affect interactions with the lipid bilayer, and that polyQ sequences of greater than 35 glutamine repeats in htt are a characteristic of HD. The key steps that determine how flanking sequences and polyQ length affect the structure of lipid bilayers remain unknown. In this study, we use atomistic molecular dynamics simulations to study the interactions between lipid membranes of varying compositions and polyQ peptides of varying lengths and flanking sequences. We find that overextended polyQ interactions do cause deformation in model membranes, and that the flanking sequences do play a role in intensifying this deformation by altering the shape of the affected regions.

Q1.00102 Interaction of Complex Liquids with Lipid Biomembranes , BENXIN JING, Y. ELAINE ZHU, Department of Chemical and Biomolecular Engineering, University of Notre Dame, Notre Dame, Indiana 46556, United States — With the emerging of smart molecular probes and functional nanocolloids for various biomedical applications, it becomes critical to understand the interaction of complex liquids with cell biomembranes in order to effectively use them with minimal cytotoxicity. Deciphered mainly by fluorescence imaging and fluorescence correlation spectroscopy, this poster will emphasize some recent studies in our group of how ionic liquids, macroionic nanoclusters, and nanocolloids interact with cell biomembrane. Using lipid bilayers as model biomembranes, I will show that adsorbed molecules and nanocolloids can not only disrupt the morphology of lipid bilayers, but also induce their phase transition due to sufficiently strong electrostatic attraction. With ionic liquids and macroionic nanoclusters whose dimensions are comparable to lipids, intriguing supramolecular assembly is also observed at lipid bilayer interface, showing a strong dependence on the chemical makeup of adsorbed ionic species.

Q1.00103 Ion Induced Changes in Phosphoinositide Monolayers at Phisiological Concentrations[1] , ADOLPHE KAZADI BADIAMBILE, Syracuse University, MARTIN B. FORSTNER, Physic Department, Syracuse University, Syracuse, NY, 13244. Syracuse Biomaterials Institute, Syracuse University, Syracuse, NY 13244 — Phosphoinositides (PIPs) play a crucial role in many cellular process that occur at the plasma membrane such as calcium release, exocytosis or endocytosis. In order to specifically regulate these functions PIPs must segregate in pools at the plasma membrane. A possible mechanism that could induce and regulate such organization of phosphoinositides is their interaction with bivalent cations. Understanding the physicochemical mechanism that can regulate membrane structure is a crucial step in the development of adaptive biomimetic membrane systems. Using Langmuir monolayers, we investigated the effect of calcium and magnesium on the surface pressure-area/lipid isotherm of monolayer of phosphatidylinositol (PI), phosphatidylinositol bisphosphate (PIP2), dioleoylphosphatidylglycerol (DOPG) and palmitoyl-2-oleoyl-sn-glycero-3-phosphocholine (POPC). It is found that the decrease of area per lipid, i.e. the increase in aggregation, is mostly dependent on the lipid's head group charge but ion specific. In addition, we discuss changes in free energy and compressibility of these monolayer-ion systems.

Q1.00104 Low Temperature Energy Phase Diagrams of Dimer Adsorption on Square Nanotubes With Attractive First Neighbor Interactions , ALAIN PHARES, Villanova University, DAVID GRUMBINE, JR., St. Vincent College — We consider dimer adsorption on a nanotube with square lattice geometry that is an arbitrary number M of atomic sites in normal cross-section. First-neighbor adsorbate-adsorbate interactions, V, are assumed to be attractive while second-neighbor interactions, W, are allowed to be repulsive, attractive or negligible. The effective potential energy per dimer, μ, is the sum of the adsorbate-substrate interaction energy and the chemical potential of dimer molecules in the medium surrounding the nanotube. At low temperature, the energy phase diagrams are two-dimensional with parameters $u = W/V$ and $v = \mu/V$. These diagrams have been generated numerically for increasing values of M. They fall into two categories which depend on whether M is even or odd. The occupational characteristics of the phases have analytic expressions in M. The occupational configurations of, and line boundaries between phases are determined.

Q1.00105 Polymer adsorption from the melts - In-situ x-ray/neutron reflectivity studies on the chain conformations at the polymer/solid interfaces[1] , NAISHENG JIANG, JUN SHANG, MAYA ENDOH, Department of Materials Science and Engineering, Stony Brook University, BULENT AKGUN, SUSHIL SATIJA, Center for Neutron Research, NIST, Gaithersburg, TADANORI KOGA, Department of Materials Science and Engineering, Stony Brook University — Adsorbed polymer layers formed on flat solid substrates have recently been the subject of extensive studies due to their strong influence on the physical properties of polymeric materials confined at the nanometer scale. Such adsorbed layers are stable against temperature and solvents and can be formed even onto weakly attractive substrate surfaces. In this study, we aim to clarify the detailed structures and thermal properties by the combined use of in-situ x-ray/neutron reflectivity and atomic force microscopy techniques. Various polymers including polystyrene, polybutadiene, poly (2-vinylpyridine), polycarbonate, and poly(methyl methacrylate) were used to prepare equilibrium adsorbed polymer layers on silicon substrates. We report the effects of the intramolecular architectures, molecular weight, and polymer/substrate interactions on the structures, leading to a better understanding of the thermodynamics at the polymer melt/solid interfaces.

[1]We acknowledges the financial support from NSF Grant No. CMMI-084626.

Q1.00106 Ionic Interactions for Aqueous Templating of Biofunctional Molecules in Block Copolymer Nanostructures , BRADLEY OLSEN, BOKYUNG KIM, CHRISTOPHER LAM, CHARLOTTE STEWART-SLOAN, EMMANOUIL GKIKAS, Massachusetts Institute of Technology — The use of ionic interactions to direct both biomolecular templating and block copolymer self-assembly into nanopatterned films with only aqueous processing conditions is demonstrated using block copolymers containing both thermally responsive and pH responsive blocks. Reversible addition-fragmentation chain transfer (RAFT) polymerization is employed to synthesize diblock copolymers with one neutral thermoresponsive and one polycationic block and the pH-dependnent complexation between model proteins or biomimetic J-aggregating chromophores and the polycationic block is demonstrated. Spin casting is used to prepare nanostructured films from the protein-block copolymer and chromophore-block copolymer coacervates. After film formation, the lower critical solution temperature (LCST) of the thermoresponsive block allows the nanomaterial to be effectively immobilized in aqueous environments at physiological temperatures, enabling use of the materials for biomolecule immobilization and controlled release. In the case of protein nanotemplating, the ionic environment in which the protein is confined enables the majority of the protein (80%) to retain its activity, even after having been dehydrated in vacuum and confined in the thin film.

Q1.00107 Computational Exploration of the Surface Properties of Cs2Te5 Photoemissive Material , ANTHONY RUTH, Student, KAROLY NEMETH, Adjunct Professor of Physics, KATHERINE HARKAY, Physicist at Argonne, LINDA SPENTZOURIS, JEFF TERRY, Associate Professor of Physics — Cs2Te is a broadly used photoemissive material due to its exceptionally high quantum efficiency ($\sim$ 20%). Our group has recently predicted that the acetylation of this material (Cs2TeC2) would lower its workfunction down to about 2.4 eV from $\sim$ 3 eV, and preserve its high quantum efficiency. Such a modification is advantageous because visible light can be used in the operation of such a photoemissive device instead of ultraviolet light. To explore other variants of Cs2Te, we conducted DFT-based computational analysis of the photoemissive properties of Cs2Te5 which is a known phase of Cs and Te. Cs2Te5 attracted our attention for its rod-like 1D Te substructures embedded in a Cs matrix. This structure is similar to Cs2TeC2 as Cs2TeC2 contains TeC2 polymeric rods in a Cs matrix. In addition to that, exploration of various Cesium Telluride phases is necessary to better understand the working of Cs2Te photocathodes. We have calculated surface energies, workfunctions, and optical absorption spectra of several different surfaces of Cs2Te5. A comparison of the properties of various Cs2Te5 surfaces and their utilization in photoemissive devices will be presented.

Q1.00108 Measuring graft stability in a tethered polyelectrolyte film by X-ray and neutron reflectivity , MICHAEL D. DIMITRIOU, NIST Center for Neutron Research, CASEY J. GALVIN, NC State Chemical and Biomolecular Engineering Department, SUSHIL K. SATIJA, NIST Center for Neutron Research, JAN GENZER, NC State Chemical and Biomolecular Engineering Department — The instability of tethered polymer films in mild conditions has recently brought into question the limits of use of such layers in certain technologies, such as anti-fouling coatings. In order to better understand the process of chain degrafting in a polymer brush, we have used X-ray reflectivity (XR) and neutron reflectivity (NR) to examine tethered layers of poly(2-dimethylaminoethyl methacrylate) (PDMAEMA). Exposing an $\approx$ 30 nm thick film of PDMAEMA brushes grafted on flat silica-coated substrates to a range of relative humidities (RH) resulted in reproducible thickness changes as measured by XR, illustrating the need of ambient solvent to induce degrafting. The thickness change showed non-linear behavior, increasing rapidly above $\approx$ 70% RH and swelling to $\approx$ 230% of its original thickness at $\approx$ 99% RH. In order to better understand the apparent diffusive process of vapor into the brush, we have exposed brushes to isotopically labeled vapors. Using XR and NR, we examined the extent of modification in scattering length density within the brush using box and gradient models, and discuss the apparent entropic and enthalpic forces at play. We also conducted *in situ* aqueous measurements of similar samples to comprehend the degrafting process of a polymer brush. Through an appropriate choice of model, we detect variations in grafting density as a function of incubation time.

Q1.00109 Self-folding of Polymer Sheets Responding to Light: Applications and Mechanistic Study , YING LIU, MICHAEL DICKEY, JAN GENZER, North Carolina State University — We describe a simple approach to self-folding that uses localized light absorption on a pre-stressed polymer sheet. Self-folding takes advantage of 2D patterning techniques (e.g., lithography, inkjet printing) and converts predefined 2D templates into 3D structures. Self-folding is useful for packaging, actuation, and sensing. Most approaches to self-folding use hinges (regions that fold) that have unique chemical composition from the rest of the sheet, which requires photolithography or other multiple fabrication steps. Our approach employs homogeneous polymer sheets and inkjet printing. The black ink (i.e., the hinge) is patterned using a desktop printer on the sheet. Hinges absorb selectively the light to locally heat the underlying polymer and cause the shrinkage. We study experimentally the key physical parameters (hinge geometry, line width and support temperature) which affect the folding. We also explore various light and ink sources for folding complex 3D structures. Moreover, we model thermal profiles inside the polymer film, and investigate folding dynamics based on thermal shrinkage and rheological properties of polymer networks.

Q1.00110 Formation of Lenses by Liquid Interfacial Surfaces , CHARLOTTE ZIMMERMAN, BENJAMIN CERJAN, MARTHA-ELIZABETH BAYLOR, Carleton College — In this study, we examined the geometry of polymer lenses formed by liquid interfacial surfaces. We formed lenses by dropping hydrophobic photo-curable monomer on the surface of various hydrophilic liquid substrates. Due to intermolecular forces between the monomer and the substrate liquid, the interface is pulled into a curved shape. Upon exposure to UV light, the monomer solidifies while maintaining the boundary interface. The result is a plano-convex, optically-smooth polymer lens. The interfacial surface tension is manipulated by altering the amount of thin film present on the surface of the hydrophilic liquid, producing lenses of different curvatures. The lens curvature is further modified by using various salts that change the polarity of the substrate solution. We will present data demonstrating modification of the lens shape due to specific changes made to the physical and chemical properties of the hydrophilic liquid. We believe this liquid interfacial fabrication technique offers an alternative to current molding techniques for forming polymer lenses.

Q1.00111 Improving the Adhesion of Au Thin Films Onto PMMA Substrates Using Chloroform , COURTNEY WARDWELL, ALAN MO, BRIAN AUGUSTINE, CHRIS HUGHES, THOMAS DEVORE, None, JAMES MADISON UNIVERSITY TEAM — Conventional techniques such as O_2 plasma treatment to improve Au thin film adhesion have resulted in limited success. In this study, the adhesion of 6 nm and 100 nm Au thin films onto 0.8 mm poly(methyl methacrylate) (PMMA) sheets was significantly improved when Au thin film samples were exposed to a saturated chloroform environment after metallization. The shear force required to remove the Au films was calculated by placing samples onto a polisher spinning at 150 rpm and using a spring loaded device to apply the force. Au thin samples were characterized through optical microscopy, atomic force microscopy (AFM) and attenuated total reflectance Fourier transform infrared spectroscopy (ATR-FTIR). AFM and optical images show a roughening of the Au thin films after chloroform exposure. ATR-FTIR spectra indicate that residual chloroform solvent remains on the PMMA. Our research indicates chloroform may improve adhesion by relieving the stresses at the PMMA-Au interface. X-ray photoelectron spectroscopy (XPS) studies on chloroform pre-treated PMMA samples show residual solvent at the surface one-week after exposure. We have attributed this to a Lewis acid-base interaction between chloroform and the PMMA surface. We will report on the XPS data of post treated samples.

Q1.00112 Thermodynamics and Preliminary Size Parameters of a Polymer Confined to a Lattice of Finite Size: Matrix Method , CHAD SNYDER, CHARLES GUTTMAN, Materials Science and Engineering Division, NIST, Gaithersburg, Maryland, EDMUND DIMARZIO, Bio-Poly-Phase, 14205 Parkvale Road, Rockville, Maryland — We write exact equations for the thermodynamic properties and end-to-end distance of a linear polymer molecule confined to walk on a lattice of finite size. A theory is presented wherein the dimension of the space in which the lattice resides can be arbitrary. In this theory, the boundary can be of arbitrary shape and the attraction of the monomers for the sites can be an arbitrary function of each site. The formalism is even more general in that each monomer can have its own energy of attraction for each lattice site. In particular, we look at the effect of energy variation along the lattice walls with the idea of studying the effect of heterogeneities in the energies of a surface on polymer attachment.

Q1.00113 Influence of Slip on the Rayleigh-Plateau Rim Instability in Dewetting Polymer Films , OLIVER BAEUMCHEN, Department of Physics & Astronomy and the Brockhouse Institute for Materials Research, McMaster University, Hamilton, ON, Canada, L8S 4M1, KARIN JACOBS, LUDOVIC MARQUANT, SABRINA HAEFNER, MISCHA KLOS, Saarland University, Department of Experimental Physics, 66123 Saarbruecken, Germany, RALF BLOSSEY, Interdisciplinary Research Institute (IRI), CNRS USR 3078, Villeneuve d'Ascq, France, ANDREAS MUENCH, Mathematical Institute, University of Oxford, Oxford OX1 3LB, UK, BARBARA WAGNER, Technical University of Berlin, Institute for Mathematics, 10623 Berlin, Germany — A dewetting polymer film develops a characteristic fluid rim at its receding edge due to mass conservation. In the course of the dewetting process the rim becomes unstable via an instability of Rayleigh-Plateau type. An important difference exists between this classic instability of a liquid column and the rim instability in the thin film as the growth of the rim is continuously fueled by the receding film. We explain how the development and macroscopic morphology of the rim instability are controlled by the slip of the film on the substrate. A single thin-film model, valid for all slip lengths, captures quantitatively the characteristics of the evolution of the rim observed in our experiments.

Q1.00114 What information can frictional properties of polymer brushes tell us? , ZHENYU ZHANG, Department of Physics and Astronomy, University of Sheffield, Sheffield, S3 7RH, UK, MARK MOXEY, ANDREW MORSE, STEVEN ARMES, Department of Chemistry, University of Sheffield, Sheffield, S3 7HF, UK, ANDREW LEWIS, Biocompatibles UK Ltd., Chapman House, Farnham Business Park, Weydon Lane, Farnham, Surrey, GU9 8QL, UK, MARK GEOGHEGAN, Department of Physics and Astronomy, University of Sheffield, Sheffield, S3 7RH, UK, GRAHAM LEGGETT, Department of Chemistry, University of Sheffield, Sheffield, S3 7HF, UK — We have used friction force microscopy (FFM) to quantitatively examine surface grown zwitterionic polymer brushes: poly(2-(methacryloyloxy)ethyl phosphorylcholine) (PMPC), and to establish the correlation between its frictional behaviour to other intrinsic properties. In a good solvent, it was found that the coefficient of friction (μ) decreased with increasing film thickness. We conclude that the amount of bound solvent increases as the brush length increases, causing the osmotic pressure to increase and yielding a reduced tendency for the brush layer to deform under applied load. When measured in a series of alcohol/water mixtures, a significant increase in μ was observed for ethanol/water mixtures at a volume fraction of 90%. This is attributed to brush collapse due to co-nonsolvency, leading to loss of hydration of the brush chains and hence substantially reduced lubrication. We show that single asperity contact mechanics is strongly dependent on solvent quality. Friction-load relationship was found linear in methanol (good solvent), but sub-linear in water and ethanol (moderate solvent).

Q1.00115 Dynamics of Nanoparticle Adhesion[1] , J.-M.Y. CARRILLO, A.V. DOBRYNIN, University of Connecticut — We performed molecular dynamics simulations and theoretical analysis of nanoparticle pulling off from adhesive substrates. Our theoretical model of nanoparticle detachment is based on the Kramers solution of the stochastic barrier crossing in effective one dimensional potential well. The activation energy, ΔE, for nanoparticle detachment first decreases linearly with increasing the magnitude of the applied force, f, then it follows a power law $\Delta E \propto (f* - f)^{3/2}$as magnitude of the pulling force f approaches a critical detachment force value, f*. These two different regimes in activation energy dependence on magnitude of the applied force are confirmed by analyzing nanoparticle detachment in effective one dimensional potential obtained by Weighted Histogram Analysis Method. Simulations show that detachment of nanoparticle proceeds through neck formation such that magnitude of the activation energy is determined by balancing surface energy of the neck connecting particle to a substrate with elastic energy of nanoparticle deformation. In this regime the activation energy at zero applied force, ΔE_0, for nanoparticle with radius, R_p, shear modulus, G, surface energy, γ_p, and work of adhesion, W, is a universal function of the dimensionless parameter $\delta \propto \gamma_p W^{-2/3} (G R_p)^{-1/3}$. Simulation data are described by a scaling function $\Delta E_0 \propto \gamma_p^{5/2} R_p^{1/2} G^{-3/2} \delta^{-3.75}$. Molecular dynamics simulations of nanoparticle detachment show that the Kramers approach fails in the vicinity of the critical detachment force f* where activation energy barrier becomes smaller than $k_B T$.

[1]NSF DMR-1004576

Q1.00116 Swelling-Induced Hierarchical Structures , WEI HAN, BO LI, ZHIQUN LIN, Georgia Institute of Technology — When the two layer structures comprised of the polyvinylpyrrolidone (PVP) thin film as substrate and the upper gradient poly (methyl methacrylate) (PMMA) stripes prepared via controlled self-assembly (CESA) were subjected to ethanol vapor, which is selective solvent for PVP, hierarchical wrinkles were observed due to the osmotically driven swelling associated with solvent-vapor sorption. Due to the confinement imposed by the PMMA stripes, the wrinkles aligned perfectly perpendicular to stripes. Quite intriguingly, three-levelhierarchical arrangement of winkles containing nanoscale micelles were also produced by CESA of PS-b-P4VP on the PVP film, followed by the exposure to the ethanol vapor. The patterns were stable in both swollen and dry states, thus creating a versatile approach that is useful for diverse polymers to produce complex patterns with long-range orders.

Q1.00117 Listening in on Friction: Stick-Slip Acoustical Signatures in Velcro , SEBASTIAN HURTADO PARRA, LESLIE MORROW, MILES RADZIWANOWSKI, PAUL ANGIOLILLO, Saint Joseph's University — The onset of kinetic friction and the possible resulting stick-slip motion remain mysterious phenomena. Moreover, stick-slip dynamics are typically accompanied by acoustic bursts that occur temporally with the slip event. The dry sliding dynamics of the hook-and-loop system, as exemplified by Velcro, manifest stick-slip behavior along with audible bursts that are easily micrphonically collected. Synchronized measurements of the friction force and acoustic emissions were collected as hooked Velcro was driven at constant velocity over a bed of looped Velcro in an anechoic chamber. Not surprising, the envelope of the acoustic bursts maps well onto the slip events of the friction force time series and the intensity of the bursts trends with the magnitude of the difference of the friction force during a stick-slip event. However, the analysis of the acoustic emission can serve as a sensitive tool for revealing some of the hidden details of the evolution of the transition from static to kinetic friction. For instance, small acoustic bursts are seen prior to the Amontons-Coulomb threshold, signaling precursor events prior to the onset of macroscopically observed motion. Preliminary spectral analysis of the acoustic emissions including intensity-frequency data will be presented.

Q1.00118 Investigating Molecular Level Stress-Strain Relationships in Entangled F-Actin Networks by Combined Force-Measuring Optical Tweezers and Fluorescence Microscopy , KENT LEE, DEAN HENZE, RAE M. ROBERTSON-ANDERSON, University of San Diego — Actin is an important cytoskeletal protein involved in cell structure and motility, cancer invasion and metastasis, and muscle contraction. The intricate viscoelastic properties of filamentous actin (F-actin) networks allow for the many dynamic roles of actin, thus warranting investigation. Exploration of this unique stress-strain/strain-rate relationship in complex F-actin networks can also improve biomimetic materials engineering. Here, we use optical tweezers with fluorescence microscopy to study the viscoelastic properties of F-actin networks on the microscopic level. Optically trapped microspheres embedded in various F-actin networks are moved through the network using a nanoprecision piezoelectric stage. The force exerted on the microspheres by the F-actin network and subsequent force relaxation are measured, while a fraction of the filaments in the network are fluorescent-labeled to observe filament deformation in real-time. The dependence of the viscoelastic properties of the network on strain rates and amplitudes as well as F-actin concentration is quantified. This approach provides the much-needed link between induced force and deformation over localized regimes (tens of microns) and down to the single molecule level.

Q1.00119 Structure and Dynamics of Polymer nanocomposite hydrogels , DI XU, MIRIAM RAFAILOVICH, DILIP GERSAPPE, Department of Materials Science and Engineering, Stony Brook University. NY-11794 — Polymer hydrogels are widely used in fields like food science, tissue engineering and drug delivery. A lot of research has focused on developing hydrogels with novel properties. However, a lack of understanding of the dynamics and structure of the hydrogel has become a big obstacle. We use molecular dynamic simulations, which provide a direct observation of gel formation and gel structures, to study the local structural and dynamic properties of hydrogels. Our work focuses on using coarse-graining molecule dynamic simulations to study physically linked polymer nano-composite hydrogels. Our goal is to study how the aspect ratio and shape of the nanofiller introduced to the hydrogel can lead to different mechanical behavior. Our simulation looks at the effects of polymer species, chain length, and water content and the effect on the mechanical properties of the hydrogel.

Q1.00120 Creating Controlled Thickness Gradients in Polymer Thin Films via Flowcoating , RALEIGH DAVIS, SAHANA JAYARAMAN, RICHARD REGISTER, Princeton University, PAUL CHAIKIN, New York University — Flow coating is a technique which has a unique capacity to create polymer thin (10-1000 nm) films which possess a thickness gradient. This has greatly enhanced the throughput of many experiments which seek to investigate the effect of film thickness on polymer structure or properties by enabling one to study a wide range of film thicknesses using only a single flowcoated sample. Until recently, there was limited understanding of how to predict or control the film thickness profiles generated with this device. A recently published first-principles approach uses Landau-Levich theory to derive an equation which identifies the experimental variables which are thought to govern film thickness. These parameters are the capillary number (a function of the solution viscosity, surface tension, and coating blade velocity) as well as the gap height between the blade and the substrate. In this work, many of these experimental variables, as well as some others, were varied and the resulting film thickness values showed excellent quantitative agreement with the model. These results, coupled with the first principles model, provide a design method which allows a user to produce polymer thin films of virtually any desired thickness profile.

Q1.00121 Measuring the Dynamic Parameters of MCF7 Cell Microtubules , CARLY WINTON, MITRA SHOJANIA FEIZABADI, Seton Hall University — Microtubules are the key component of the cytoskeleton. They are intrinsically dynamic displaying dynamic instability in which they randomly switch between a phase of growing and shrinking, both in vitro and in vivo. This dynamic is specified by the following parameters: growing rate, shrinking rate, frequency of catastrophe, and frequency of rescue. In this work, we will present our primary results in which we measured the dynamic parameters of a single microtubule polymerized from MCF7 tubulin in vitro. The results are significant since the MCF7 microtubules are non-neural mammalian consisting of different beta tubulin isotypes in their structures as compared to neural mammalian microtubules, such as bovine brain. The unique dynamic parameters of individual MCF7 microtubules in vitro, which are reported for the first time, indicate that non-neural microtubules can be fundamentally different from neural microtubules.

Q1.00122 Feedback-enhanced Microrheology , HEEV AYADE, MARCEL BREMERICH, HIROSHI ARIMATSU, DAISUKE MIZUNO, Kyushu University — An essential feature of the cytoskeleton is their ability to perform variety of mechanical functions in cells. The active force generation by molecular motors keeps the living cytoskeletons far from equilibrium that makes the understanding of cell mechanics and behaviors particularly challenging. Here, we have investigated the non-equilibrium mechanical properties of cells using optical trapping based microrheology, which tracks the motion of phagocytosed probe particles with high spatial and temporal resolution than video tracking microrheology. In order to perform high resolution measurement in cells or active soft materials, the active fluctuations of the beads have to be compensated for in order to keep the bead stably in a highly focused beam spot. We achieve this by implementing a PID-controlled feedback mechanism to reposition the sample chamber with a 3D-piezo stage, for large-scale but slow motions of the probes. The stage motion is recorded as piezo-control, and the motion of the probe from the laser focus is provided as the quadrant photodiode output. Sum of those signals reconstitutes the complete bead trajectory. The method reported here is robust in accessing thermal and athermal fluctuations in active systems.

Q1.00123 Viscoelastic chiral liquid crystals: Response to heat and light. , DANIEL BATEMAN, None, PETR SHIBAEV, Fordham University — Highly viscous cholesteric liquid crystals with distinctive viscoelastic properties were studied [1,2] as heat and light driven materials able to contract under light irradiation and heating. Materials are comprised of glass-forming oligomers (Wacker oligomers), low molar mass liquid crystals, and azo dyes. The latter provide sensitivity of the whole material to light irradiation. Mixtures with different azo dyes were studied and their effectiveness in terms of mechanical response (sample contraction) was determined. The optimal concentration of oligomers in terms of maximizing the elastic response and retaining high processability was found for different compositions of material. The mechanism of mechanical response is discussed in terms of the contraction of helical pitch and entropic changes in the overall structure of oligomer-liquid crystal mixture. [1] Petr V. Shibaev[1], Benjamin Crooker[1], Michael Manevich[2], and Eckhard Hanelt[3] Appl. Phys. Lett. **99**, 233302 (2011), [2] Peter V. Shibaev, Pierre Rivera, Dashiell Teter, Salvatore Marsico, Martin Sanzari, Veena Ramakrishnan, Eckhard Hanelt, Optics Express **16**, 2965 (2008)

Q1.00124 Influence of curvature on the morphology of brain microvascular endothelial cells , MAO YE, ZHEN YANG, ANDREW WONG, PETER SEARSON, Johns Hopkins University, SEARSON GROUP TEAM — There are hundreds or thousands of endothelial cells around the perimeter of a single artery or vein, and hence an individual cell experiences little curvature. In contrast, a single endothelial cell may wrap around itself to form the lumen of a brain capillary. Curvature plays a key role in many biological, chemical and physical processes, however, its role in dictating the morphology and polarization of brain capillary endothelial cells has not been investigated. We hypothesize that curvature and shear flow play a key role in determining the structure and function of the blood-brain barrier (BBB). We have developed the "rod" assay to study the influence of curvature on the morphology of confluent monolayers of endothelial cells. In this assay cells are plated onto glass rods pulled down to the desired diameter in the range from 5 – 500 μm and coated with collagen. We show that curvature has a significant influence on the morphology of endothelial cells and may have an important role in blood-brain barrier function.

Q1.00125 Thermal response of a protein (H3.1) by a coarse-grained model with knowledge-based interactions[1] , BARRY FARMER, Air Force Research Laboratory, RAS PANDEY, University of Southern Mississippi — The effect of temperature on the conformation of a histone (H3.1) is studied by a coarse-grained Monte Carlo simulation based on three knowledge-based contact potentials (MJ[1], BT[2], BFKV[3]). We find that the histone H3.1 undergoes a systematic (possibly continuous) structural transition from a random coil to a globular conformation on reducing the temperature, a general feature from each potential. The range over which such a systematic response in variation of the radius of gyration (R_g) with the temperature (T) occurs, however, depends on the potential. Multi-scale structures of the protein are examined by analyzing the scaling of the structure functions with the wave vector. Quantitative comparison of the structure emerging from three potentials will be presented.

Q1.00126 Computational model for Halorhodopsin photocurrent kinetics[1] , JAIME BRAVO, Department of Biomedical Engineering, The Ohio State University, ROXANA STEFANESCU, Department of Pediatric Neurology, University of Florida, SACHIN TALATHI, Department of Biomedical Engineering, University of Florida — Optogenetics is a rapidly developing novel optical stimulation technique that employs light activated ion channels to excite (using channelrhodopsin (ChR)) or suppress (using halorhodopsin (HR)) impulse activity in neurons with high temporal and spatial resolution. This technique holds enormous potential to externally control activity states in neuronal networks. The channel kinetics of ChR and HR are well understood and amenable for mathematical modeling. Significant progress has been made in recent years to develop models for ChR channel kinetics. To date however, there is no model to mimic photocurrents produced by HR. Here, we report the first model developed for HR photocurrents based on a four-state model of the HR photocurrent kinetics. The model provides an excellent fit (root-mean-square error of 3.1862×10^{-4}, to an empirical profile of experimentally measured HR photocurrents. In combination, mathematical models for ChR and HR photocurrents can provide effective means to design test light based control systems to regulate neural activity, which in turn may have implications for the development of novel light based stimulation paradigms for brain disease control.

Q1.00127 Kinetics of inter-segmental contact in semiflexible polymers , REZA AFRA, BRIAN TODD, Dept of Physics, Purdue University — Diffusion-limited contact between polypeptide segments is an elementary step in protein folding and this process sets an upper limit on protein folding kinetics. A common theoretical approach to calculating this "speed limit" is to reduce the high-dimensional conformational search to a one-dimensional diffusion along an effective reaction coordinate. We employed Brownian dynamic simulations to test the validity of this approximation for inter-segmental contact kinetics in the semiflexible polymer model. This model is often used to describe the unfolded protein state. We find that one-dimensional diffusion models cannot capture the correct scaling between contact dynamics and either capture radius or chain length. Our findings highlights the difficulty of describing high-dimensional protein molecules with simple kinetic theories.

Q1.00128 Effect of Mutations on HP Lattice Proteins[1]

, GUANGJIE SHI, THOMAS VOGEL, DAVID P. LANDAU, The University of Georgia, YING WAI LI, Oak Ridge National Laboratory, THOMAS WÜST, Swiss Federal Research Institute WSL — Using Wang-Landau sampling with approriate trial moves[2], we investigate the effect of different types of mutations on lattice proteins in the HP model. While exact studies have been carried out for short HP proteins[3], the systems we investigate are of much larger size and hence not accessible for exact enumerations. Based on the estimated density of states, we systematically analyse the changes in structure and degeneracy of ground states of particular proteins and measure thermodynamic quantities like the stability of ground states and the specific heat, for example. Both, neutral mutations, which do not change the structure and stability of ground states, as well as critical mutations, which do change the thermodynamic behavior qualitatively, have been observed.

Q1.00129 Nearest Neighbor Interactions Affect the Conformational Distribution in the Unfolded State of Peptides

, SIOBHAN TOAL, REINHARD SCHWEITZER-STENNER, Drexel University, KARIN RYBKA, HARDOL SCHWALBE, Johann Wolfgang Goethe University — In order to enable structural predictions of intrinsically disordered proteins (IDPs) the intrinsic conformational propensities of amino acids must be complimented by information on nearest-neighbor interactions. To explore the influence of nearest-neighbors on conformational distributions, we preformed a joint vibrational (Infrared, Vibrational Circular Dichroism (VCD), polarized Raman) and 2D-NMR study of selected GxyG host-guest peptides: GDyG, GSyG, GxLG, GxVG, where x/y={A,K,LV}. D and S (L and V) were chosen at the x (y) position due to their observance to drastically change the distribution of alanine in xAy tripeptide sequences in truncated coil libraries. The conformationally sensitive amide' profiles of the respective spectra were analyzed in terms of a statistical ensemble described as a superposition of 2D-Gaussian functions in Ramachandran space representing sub-ensembles of pPII-,β-strand-, helical-, and turn-like conformations. Our analysis and simulation of the amide I′ band profiles exploits excitonic coupling between the local amide I′ vibrational modes in the tetra-peptides. The resulting distributions reveal that D and S, which themselves have high propensities for turn-structures, strongly affect the conformational distribution of their downstream neighbor. Taken together, our results indicate that Dx and Sx motifs might act as conformational randomizers in proteins, attenuating intrinsic propensities of neighboring residues. Overall, our results show that nearest neighbor interactions contribute significantly to the Gibbs energy landscape of disordered peptides and proteins.

Q1.00130 A large scale membrane-binding protein conformational change that initiates at small length scales

, TREVOR GRANDPRE, MATTHEW ANDORF, DePaul University, SRINIVAS CHAKRAVARTHY, Illinois Institute of Technology, ROBERT LAMB, TAYLOR POOR, Northwestern University, ERIC LANDAHL[1], DePaul University — The fusion (F) protein of parainfluenza virus 5 (PIV5) is a membrane-bound, homotrimeric glycoprotein located on the surface of PIV5 viral envelopes. Upon being triggered by the receptor-binding protein (HN), F undergoes a greater than 100Å ATP-independent refolding event. This refolding event results in the insertion of a hydrophobic fusion peptide into the membrane of the target cell, followed by the desolvation and subsequent fusion event as the two membranes are brought together. Isothermal calorimetry and hydrophobic dye incorporation experiments indicate that the soluble construct of the F protein undergoes a conformational rearrangement event at around 55 deg C. We present the results of an initial Time-Resolved Small-Angle X-Ray Scattering (TR-SAXS) study of this large scale, entropically driven conformational change using a temperature jump. Although we the measured radius of gyration of this protein changes on a 110 second timescale, we find that the x-ray scattering intensity at higher angles (corresponding to smaller length scales in the protein) changes nearly an order of magnitude faster. We believe this may be a signature of entropically-driven conformational change.

Q1.00131 Shear History Independence in Colloidal Aggregation

, WILLIAM HEINSON, AMITABHA CHAKRABARTI, CHRISTOPHER SORENSEN, Department of Physics, Kansas State University — Stimulated by experiments, we have carried out detailed simulations of aggregation in the presence of shear in a model colloidal system with a short-range attractive potential. For weak shear rates we find that the shear enhanced the aggregation and that the long time state of the system is independent of the shear history. For strong shear rates, precipitous fragmentation occurred after the shear was turned on and after an induction period, the aggregation quickly rebounded in a stochastic manner similar to classical nucleation phenomena. However, the long -time state of the system is, once again, independent of the shear history. Thus, for both weak and strong shear cases, shear rate acts as a state variable of the aggregating system. Shear rates employed in the simulations can be attained in laboratory experiments as confirmed by computing the dimensionless Péclet numbers

Q1.00132 Crystal-like Complex Formation with Binary Charged Block Copolymer Micelles in Dilute Aqueous Media

, MISOOK LEE, KYUNG JEE MIN, Seoul National University, JINKEE HONG, Kyunghee University, KOOKHEON CHAR, Seoul National University — The morphology of charged block copolymer micelle (BCM) complexes, consisting of polystyrene-*block*-poly(acrylic acid) (PS-*b*-PAA) and polystyrene-*block*-poly(4-vinyl pyridine) (PS-*b*-P4VP) micelles, was controlled by pH of aqueous solvent as well as solvent quality. To determine the effective pH range for the inter-corona combination of PAA and P4VP blocks in aqueous media, we studied the dissociation behavior of both coronas using Fourier Transform Infrared Spectroscopy. Lower pH region (pH$<$5.0) in aqueous media offers stronger interactions between oppositely charged corona blocks, resulting in polymeric hexagonal prism complexes. In the higher pH region (pH$>$5.5), they first self-assembled into hierarchical spheres induced by the simple adsorption of small PS-*b*-PAA BCMs on the surfaces of PS-*b*-P4VP large compound micelles since the degree of ionization of P4VP blocks is relatively low. However, the crew-cut BCM complex morphology with high aggregation number does not allow the hexagonal prism structure to be formed without rearranging strongly aggregated core blocks. We note that the crew-cut BCM complexation in higher DMF content of a mixed solvent induces inter-corona association leading to the hexagonal prism structure due to the decrease in selectivity of water for PS blocks.

Q1.00133 Free energy change for aggregation of charged monolayer-protected gold nanoparticles

, REID VAN LEHN, ALFREDO ALEXANDER-KATZ, Massachusetts Institute of Technology — Monolayer-protected gold nanoparticles (AuNPs) are an important class of nanomaterials with applications in drug delivery and biosensing. However, the utility of AuNPs is limited by the spontaneous aggregation of particles in solution, which is observed even for highly charged, water-soluble AuNPs. Such aggregation cannot be well-described by continuum theories that would predict the dominance of repulsive electrostatic interactions over weaker van der Waals interactions. In this work, we show that small AuNPs (diameter $<$10 nm) protected by charged alkanethiol monolayers may aggregate due to a ligand-mediated short-range attraction that compensates for electrostatic repulsion. The short-range attraction is driven by the hydrophobic effect as the flexible ligands deform to shield hydrophobic surface area from water. We use novel simulations to calculate the free energy change for bringing two AuNPs together from infinite separation and show that the free energy change depends on particle size, monolayer composition, and the surrounding environment. This work provides insight into the key role that ligand interactions play in AuNP aggregation and suggests guidelines for the design of protecting monolayers.

Q1.00134 Direct Measurement of Diffusion of Terbium Ions Through a Silica Gel Matrix[1]

, M. BLADES, T. IGNATOVA, Lehigh University, J.G. DUQUE, S.K. DOORN, Los Alamos National Laboratory , S.V. ROTKIN, Lehigh University — The use of rare earth ions as optical bio-markers and for the study of complex nanoscale systems via resonant energy transfer has been suggested and successfully demonstrated. Our capability to extract reliable information from such an experiment critically depends on understanding the underlying physics of interactions in the studied material. Here we investigate the diffusion of Terbium into a silica hydrogel matrix. Diffusion rates and optical properties can be related to differences in gel morphology and rare earth ion behavior in gels prepared with and without nanotubes. Absorption mechanisms, micelle formation, and Terbium/nanotube interaction are discussed.

[1]NSF Grant ECCS-1202398

Q1.00135 Mechanical characterization of diblock copolymer "armored" emulsion droplets

, DAMITH P. ROZAIRO, ANDREW B. CROLL, North Dakota State University — There has been an increased interest in block copolymer vesicles due to a plethora of possible application ranging from targeted drug delivery to cosmetically active agents. In this regard, understanding the physics of the block copolymer vesicle and its morphology is critical to the rational development of these technologies. As a step towards more complex vesicle structures, we describe experiments in which we carefully examine the interface and morphology of polystyrene-b-polyethyleneoxide (PS-PEO) emulsion drops. In our study, PS-PEO acts as a surfactant and at the toluene-water interface creates a monolayer, inhibiting drop recombination and minimizing interfacial energies. Our experiments are conducted in a water cell where the buoyant force is exploited to push drops against a thin sheet of mica. The shape of the drops is measured using an upright confocal microscope and compared with a Bashforth-Adams model in order to examine the mechanical response to the buoyant force. We observe unique dynamics as the drops buckle at short timescales trapping a small pocket of fluid which slowly drains away. Furthermore, the influence of polymer concentration, changes in pH and block copolymer architecture on the morphology and dynamics of the droplets is examined.

Q1.00136 The order-to-disorder transition behavior of PS-b-P2VP thin film system

, HYUNGJU AHN, DU YEOL RYU, Yonsei University — We investigated the transition behavior such as the order-to-disorder transition (ODT) for symmetric poly(styrene)-block-poly(2-vinly pridine) (PS-b-P2VP) using SAXS and GISAXS for block copolymer bulks and films. The bulk transition temperature of PS-b-P2VP was significantly influenced by the interfacial interactions in thin films, leading to the different transition temperature. From these results, we will discuss about the interfacial interaction effects on the phase behaviors in bulks and thin films system of PS-b-P2VP.

Q1.00137 Reactivity of End-functionalized Polymers Containing Diels-Alder Functional Groups

, YUAN MENG, YUAN ZHANG, MITCHELL ANTHAMATTEN, University of Rochester — Incorporation of reversible covalent bond into macromolecular systems has proven useful in engineering novel responsive architectures, and Diels-Alder bonding in this context is now well established. However, efficient synthesis of end-functionalized polymers is a major obstacle hindering further development of responsive and modular polymer architectures. In this current research, two immiscible polymers, poly(methyl methacrylate) (PMMA) and poly(benzyl methacrylate) (PBzMA) with controlled molecular weight, bearing terminal furan-maleimide groups, are prepared via Reversible Addition-Fragmentation chain transfer (RAFT) polymerization. The reactivity of such end-functionalized polymers is explored to expose the relationship between chain composition and their ability to undergo modular cross-coupling to form monodisperse block copolymers. To elucidate how reaction conditions affect the efficiency of the Diels-Alder reaction, Hydrogen Nuclear Magnetic Resonance (H-NMR) and Size Exclusion Chromatography (SEC) techniques are actively applied. Experimental results will be interpreted on the basis of dissimilarity between interaction energies of polymer segments and the concentration of reactive groups.

Q1.00138 Can coarse-grained force field parameters be transferable?

, MALGORZATA KOWALIK, Department of Chemical Engineering, 121 Fenske Laboratory, University Park, Pennsylvania 16802, USA, JANNA K. MARANAS, Department of Chemical Engineering, 107 Fenske Laboratory, University Park, Pennsylvania 16802, USA — We present results from molecular dynamics simulations of self-assembled copolymers in explicit coarse-grained water. Our goal is to provide intermolecular potentials for coarse-grained beads that are mixture independent. With such transferable potentials, forming new combinations of copolymers and adding new polymers is relatively straightforward. In this approach, each coarse-grained bead (polymer as well as water) is assigned mixture independent Lennard-Jones parameters. We use generic combining rules, with a pair-independent scaling parameter for interactions between hydrophilic and hydrophobic beads. We succeed in describing six coarse-grained beads system using only six intermolecular parameters, to describe 15 individual interactions. We conclude that a transferable set of intermolecular parameters is possible.

Q1.00139 Diffusion of liquid polystyrene into glassy poly(phenylene oxide) characterized by DSC[1]

, LINLING LI, XIAOLIANG WANG, DONGSHAN ZHOU, GI XUE, Department of Polymer Science and Engineering, Nanjing Univeristy — We report a diffusion study on the polystyrene/poly(phenylene oxide) (PS/PPO) mixture consisted by the PS and PPO nanoparticles. Diffusion of liquid PS into glassy PPO (l-PS/g-PPO) is promoted by annealing the PS/PPO mixture at several temperatures below Tg of the PPO. By tracing the Tgs of the PS-rich domain behind the diffusion front using DSC, we get the relationships of PS weight fractions and diffusion front advances with the elapsed diffusion times at different diffusion temperatures using the Gordon-Taylor equation and core-shell model. We find that the plots of weight fraction of PS vs. elapsed diffusion times at different temperatures can be converted to a master curve by Time-Temperature superposition, and the shift factors obey the Arrhenius equation. Besides, the diffusion front advances of l-PS into g-PPO show an excellent agreement with the t1/2 scaling law at the beginning of the diffusion process, and the diffusion coefficients of different diffusion temperatures also obey the Arrhenius equation. We believe the diffusion mechanism for l-PS/g-PPO should be the Fickean law rather than the Case II, though there are departures of original linearity at longer diffusion times due to the limited liquid supply system.

[1]Diffusion of liquid polystyrene into glassy poly(phenylene oxide) characterized by DSC

Q1.00140 Polymer Brush Grafted Nanoparticles and Their Impact on the Morphology Evolution of Polymer Blend Films

, HYUN-JOONG CHUNG, University of Alberta, KOHJI OHNO, Kyoto University, RUSSELL J. COMPOSTO, University of Pennsylvania — We present an novel pathway to control the location of nanoparticles (NPs) in phase-separating polymer blend films containing poly(methyl methacrylate) (PMMA) and poly(styrene-ran-acrylonitrile) (SAN). Because hydrophobic polymer phases have a small interfacial energy, $\sim$1 mJ/m^2, subtle changes in the NP surface functionality can be used to guide NPs to either the interface between immiscible polymers or into one of the phases. Based on this idea, we designed a class of NPs grafted with PMMA brushes. These PMMA brushes were grown from the NP surface by atom transfer radical polymerization (ATRP), which results in chains terminated with chlorine atoms. The chain end can be substituted with protons (H) by dehalogenation. As a result, the NPs are strongly segregated at the interface when grafted PMMA chains are short (Mn=1.8K) and the end group is Cl, whereas NPs partition into PMMA-rich phase when chains are long (Mn=160K) and/or when chains are terminated with hydrogen. The Cl end groups and shorter chain length cause an increase in surface energy for the NPs. The increase in surface energy of short-chained NPs can be attributed to (i) an extended brush conformation (entropic) and/or (ii) a high density of "unfavorable" end groups (enthalpic). Finally, the impact of NPs on the morphological evolution of the polymer blend films will be discussed. Ref: H.-J.Chung et al., ACS Macro Lett. 1(1), 252-256 (2012).

Q1.00141 Polymer Blend Emulsions Stabilized by Janus Particles , KYLE BRYSON, THOMAS RUSSELL, RYAN HAYWARD, University of Massachusetts - Amherst — Kinetic trapping of bicontinuous polymer morphologies through the interfacial segregation of nanoparticles is of interest due to the unique combination of the properties of each component provided by such structures, and their potential for use as membranes and composite materials. However, this strategy is challenging to realize in polymeric systems, due to the difficulties in preparing particles that are neutrally wetted by the two polymer phases. Janus particles afford a route to circumvent the necessity of neutral wettability. In addition, both theory and experiment have shown enhanced interfacial adsorption energies for Janus particles, as well as greater flexibility in controlling particle orientation at the interface, in comparison to homogeneous particles. Dumbbell-shaped gold-silica Janus particles were synthesized using several sizes of gold seeds. These particles were made amphiphilic by functionalization with both polymeric and small molecule silanes and thiols. Their interfacial activity was measured using pendant drop tensiometry, and their ability to stabilize bicontinuous emulsions of polymers was examined by TEM. The results elucidate the role of particle wettability on interfacial behavior and the structure of stabilized emulsions.

Q1.00142 A new method for homogeneous and uniformly dispersed nanofiber composites using electrospinning , KENTARO WATANABE, ATSUSHI HOTTA, Department of Mechanical Engineering, Keio University — A method for the fabrication of a new type of homogeneous and well-dispersed nanofiber composite was introduced. Electrospinning can fabricate unwoven polymer nanofibers (NF) by electrostatic repulsion, which can be used for nano-filters and cell scaffolds. Polymer solution was put in a syringe and a high voltage was applied to the needle tip, while the polymer solution was ejected from the syringe toward a grounded metal plate (collector) to form unwoven NF. In order to make a nanofiber composite, the NF were then sandwiched by base polymers and molded. The traditional sandwich method would produce biased and relatively inhomogeneous composites. We therefore modified the metal plate to an optimized metal container that could contain polymer solution for the base composite material. This new method resulted in homogeneous mixing of NF that were ejected from the syringe to be directly included in the polymer solution. Polyvinylalchohol (PVA) was used for NF and polydimethylsiloxane (PDMS) was used for the polymer matrix. Field emission scanning electron microscopy (FE-SEM) revealed homogeneous and well-dispersed PVA NF in PDMS. The new method for the fabrication of homogeneous composites could be used for other combinations of polymeric NF and polymer matrix.

Q1.00143 Effect of Carbon Nanotubes on Thermal Behavior of Poly(L-lactide) and Poly(D-lactide) Electrospun Fibers[1] , YAZHE ZHU, MAO BIN, PEGGY CEBE, Tufts University — Thermal properties and crystallization behavior of electrospun polymer composites fibers of poly (L-lactide) (PLLA) and poly (D-lactide) (PDLA) blended with a small amount of carbon nanotubes (0.1-4 wt%) were systemically studied by differential scanning calorimetry, wide- and small- angle X-ray scattering , and time-resolved Fourier transform infrared spectroscopy. The disordered α'-form crystal and the more stable α-form crystal in polymer composites are produced respectively at low and high crystallization temperatures (Tc). It was found that the α'- to α-crystalline phase transition occurs prior to the dominant melting in both polymer composites PLLA and PDLA crystallized at low Tc. We compare the effect of carbon nanotubes on this transition for neat and filled samples. Moreover on increasing the content of CNTs from 0.1 to 4 wt%, the induction period for crystallzation was shortened and the polymer composites' crystallization rate was enhanced. The α'- to α-crystalline phase transition of PLLA and PDLA was better accelarated at low Tc from 80° to 120°. With increasing Tc, CNTs have smaller influence on the transition.

Q1.00144 The investigation of the viscoelastic properties of silica/PMMA nanocomposites as a function of silica surface chemistry[1] , HEATHER CONWAY, DENIZ RENDE, RAHMI OZISIK, Rensselaer Polytechnic Institute — Poly(methyl methacrylate), PMMA, has been used as an economic alternative to glass and polycarbonate in differing situations because of its lightweight, shatter resistance, and ease of processability. The uses of PMMA can be expanded if its weakness to impact force and its scratch resistance are improved. In the current study, viscoelastic properties of silica nanoparticle filled PMMA were investigated via nanoindentation experiments. Silica nanoparticles are known to increase the toughness of PMMA. In the current study, silica nanoparticles were chemically modified with fluorinated alkanes to alter nanofiller-polymer interactions. Results show that viscoelastic properties are strongly affected by silica surface chemistry and silica concentration.

Q1.00145 Responsive metal/polymer nanocomposites via photothermal effect[1] , MERVE SEYHAN, Rensselaer Polytechnic Institute and Yeditepe University, DENIZ RENDE, LIPING HUANG, Rensselaer Polytechnic Institute, SEYDA MALTA, Yeditepe University, RAHMI OZISIK, NIHAT BAYSAL, Rensselaer Polytechnic Institute — Metal nanoparticles can efficiently generate heat when exposed to electromagnetic radiation. The amount of heat generated and the temperature increase depends on the number of nanoparticles and their shape. In the current work, gold nanoparticles (AuNPs) were used as heat sources within polyethylene oxide (600,000 g/mol) via the photothermal effect. AuNPs were synthesized through Frens method, and were characterized using TEM. A laser source with a wavelength of 532 nm was used to heat AuNPs. Raman spectroscopy data showed that irradiation of AuNPs led to increasing temperature profiles in the vicinity of AuNPs, which is a result of the surface plasmon resonance. This property of AuNPs would enable the control of viscoelastic response of the polymer by altering crystallinity and temperature of the polymer matrix, thereby, providing responsive materials.

Q1.00146 Simulation of heat transport in polymer nanocomposites , NING SUN, MIRIAM RAFAILOVICH, DILIP GERSAPPE, Department of Materials Science and Engineering, Stony Brook University, NY, 11794 — The design of fire-safe materials by using flame retardants within polymers requires a fundamental understanding of the physics and dynamics of the heat transport process with in the multiphase systems. We have developed a Lattice-Boltzmann model to simulate the 3-D heat transfer in a two-component system comprised of a polymer matrix and flame retardant nanocomposite fillers. By varying the volume fraction of the fillers, we compared the heat propagation phenomena before and after the percolation of the nano-fillers in the system. We also vary the size, shape, thermal conductivity and heat capacity of the nanofiller to study their effects on the heat dissipation and the time to ignition.

Q1.00147 Modified thiol-ene networks: Tuning the glass transition temperature and energy damping capabilities , DANIEL SAVIN, OLIVIA MCNAIR, DAVIS BRENT, The University of Southern Mississippi — Utilizing thiol-ene 'click' reactions, it is possible to produce thermoset networks that are highly homogeneous and thus exhibit enhanced energy damping capabilities. This talk will present recent results in the characterization and impact testing of modified thiol-ene networks with tunable physical properties. In particular, we synthesize ternary networks containing (1) bulky side-chain substituents, (2) isocyanate functionality, or (3) dual thiol components to improve control over the glass transition temperature and strain at break. In addition, we present results in the high-impact compression testing to demonstrate the energy damping capabilities of these materials.

Q1.00152 Solid State Charge Transport in Radical Polymers , LIZBETH ROSTRO, BRYAN BOUDOURIS, School of Chemical Engineering, Purdue University — Organic electronic devices based on π-conjugated polymers have attracted increasing attention over the past decades; however, many important synthetic and structural issues ($e.g.$, uncontrolled polymerization schemes, the presence of residual metal catalysts) currently stymie the ability of these materials to replace traditional inorganic electronic materials. Here, we present the controlled and impurity-free synthesis of a fundamentally new type of charge-conducting polymer in which a pendant stable radical group on each repeat unit allows for charge transport ($i.e.$, radical polymers). Specifically, these molecules were synthesized using controlled radical polymerization techniques such that well-defined and easily tunable molecular weights and narrow molecular weight distributions could be had without the use of metal-based catalysts. Additionally, for the first time, we systematically characterize the charge transport ability of radical polymers and the effect of molecular weight on the transport properties of a model radical polymer, poly(2,2,6,6-tetramethylpiperidinyloxymethacrylate). Furthermore, we have utilized temperature-dependent transport measurements in order to suggest a mechanism for carrier transport in this emerging class of optoelectronically-active polymers.

Q1.00153 Microstructure and conductivity of in-situ polymerized poly(3,4-ethylenedioxythiophene) (PEDOT) crystals[1] , JINGLIN LIU, LIANGQI OUYANG, Materials Science and Engineering, The University of Delaware, JINGHANG WU, Materials Science and Engineering, The University of Delaware; Macromolecular Science and Engineering Center, The University of Michigan, CHIN-CHEN KUO, BIN WEI, DAVID MARTIN, Materials Science and Engineering, The University of Delaware — Conjugated polymers are widely used in organic solar cells, biomedical devices, and chemical sensors. Both chemical and electrochemical methods have been developed for preparing conducting polymers, but the extent of crystalline order is usually modest. Here we synthesized highly-ordered brominated (3,4-ethylenedioxythiophene) (EDOT-Br) monomer crystals via electrochemical methods. The kinetics of the synthesis was studied with a Quartz Crystal Microbalance (QCM) and Cyclic Voltammetry (CV). The chemical structure of the EDOT-Br monomer has been confirmed by Nuclear Magnetic Resonance (NMR), Ultraviolet-Visible Spectroscopy (UV-Vis), Fourier Transform Infrared Spectroscopy (FTIR), and Mass Spectrometry (MS). The EDOT-Br monomer crystals can be in-situ polymerized into highly ordered PEDOT conjugated polymer crystals by annealing at temperatures below the EDOT-Br melting point. The crystalline structure was studied by optical microscopy, electron microscopy and X-Ray analysis. The conductivity and electrochemical properties of both the EDOT-Br monomer and corresponding PEDOT polymer crystals were examined with electrochemical impedance spectroscopy (EIS) and CV.

Q1.00154 Adaptive lenses using transparent dielectric elastomer actuators , SAMUEL SHIAN, ROGER DIEBOLD, DAVID CLARKE, School of Engineering and Applied Sciences, Harvard University — Variable focal lenses, used in a vast number of applications such as endoscope, digital camera, binoculars, information storage, communication, and machine vision, are traditionally constructed as a lens system consisting of solid lenses and actuating mechanisms. However, such lens system is complex, bulky, inefficient, and costly. Each of these shortcomings can be addressed using an adaptive lens that performs as a lens system. In this presentation, we will show how we push the boundary of adaptive lens technology through the use of a transparent electroactive polymer actuator that is integral to the optics. Detail of our concepts and lens construction will be described as well as electromechanical and optical performances. Preliminary data indicate that our adaptive lens prototype is capable of varying its focus by more than 100%, which is higher than that of human eyes. Furthermore, we will show how our approach can be used to achieve certain controls over the lens characteristics such as adaptive aberration and optical axis, which are difficult or impossible to achieve in other adaptive lens configurations.

Q1.00155 Nanostructure and Dynamics of Ionic and Non-Ionic PEO-Containing Polyureas , SUNANTA CHUAYPRAKONG, JAMES RUNT, Penn State University — A series of polyethylene oxide (PEO) - based diamines with molecular weights ranging from 250 – 6000 g/mol were polymerized in solution with 4,4'-methylene diphenyl diisocyanate (MDI). In addition, PEO soft segment diamines where modified to incorporate ionomeric species and also polymerized with MDI. The role of PEO soft segment molecular weight and the presence of ionic species on nanoscale segregation and cation conductivity were explored. The former was investigated using small-angle X-ray scattering and atomic force microscopy. Dielectric relaxation spectroscopy was used to investigate polymer and ion dynamics. Local environment and hydrogen bonding were identified by using FTIR spectroscopy.

Q1.00156 Phase Behavior and Conductivity of Block Copolymers Containing Heterocyclic Diazole-Based Ionic Liquids , ONNURI KIM, MOON JEONG PARK, POSTECH — Recently, Ionic liquids(ILs) integrated polymer electrolyte membranes(PEMs) is becoming important ingredients of diverse applications such as high temperature PEM fuel cells. In present study, we explored morphology and conductivity of sulfonated PEMs upon incorporating ILs. Instead of the use of quaternary alkyl-imidazole based ILs, we employed a set of Brönstead heterocyclic diazole-based ILs possessing protic sites in cation of ILs. A wide variety of self-assembled morphologies, i.e, lamellar, hexagonal cylinder, and gyroid, have been uncovered for the IL embedded PEMs depending on kinds of heterocyclic diazoles. It is worthwhile to note that the ring structures and alkyl substituents in diazoles are found out to play important role in determining the morphology upon manipulating the Flory-Huggins interaction parameters of block copolymers. Heating of ILs-containing PEMs results in thermo-reversible phase transitions. This leads us to investigate the morphology effects of ILs incorporated PEMs on conductivities where the data demonstrate that gyroid morphology is certainly beneficial in obtaining enhanced conductivity values. Our results showed that both molecular design of ILs and structural optimization are crucial for the achievement of the utmost ionic transport properties

Q1.00157 Explicit Solvent Simulations of Friction between Brush Layers of Charged and Neutral Bottle-Brush Macromolecules[1]

, J.-M.Y. CARRILLO, University of Connecticut, W.M. BROWN, Oak Ridge National Laboratories, A.V. DOBRYNIN, University of Connecticut — We study friction between charged and neutral brush layers of bottle-brush macromolecules using molecular dynamics simulations. The deformation of the bottle-brush macromolecules under the shear were studied as a function of the substrate separation and shear stress. For charged bottle-brush layers we study effect of the added salt on the brush lubricating properties to elucidate factors responsible for energy dissipation in charged and neutral brush systems. Our simulations have shown that for both charged and neutral brush systems the main deformation mode of the bottle-brush macromolecule is associated with the backbone deformation. This deformation mode manifests itself in the backbone deformation ratio, α, and shear viscosity, η, to be universal functions of the Weissenberg number W. The value of the friction coefficient, μ, and viscosity, η, are larger for the charged bottle-brush coatings in comparison with those for neutral brushes at the same separation distance, D, between substrates. The additional energy dissipation generated by brush sliding in charged bottle-brush systems is due to electrostatic coupling between bottle-brush and counterion motion. This coupling weakens as salt concentration, c_s, increases resulting in values of the viscosity, η, and friction coefficient, μ, approaching corresponding values obtained for neutral brush systems.

Q1.00158 Influence of Ion Content, Cation Size and Polymerization Method on Ion Association States of Poly(ethylene oxide)-based Ionomers

, HANQING MASSER, JING-HAN HELEN WANG, RALPH COLBY, PAUL PAINTER, JAMES RUNT, Penn State University — The effects of ion content, cation size and polymerization method on ion association states are systemically studied using FTIR spectroscopy in a series of ionomers with short ethylene oxide and ionic sulfonated styrene side chains. Ion content is controlled by the ratio of these side chains. When comparing similar ionomers with different ion content, there are more free ions at higher ion content. Free radical and RAFT polymerizations yield ionomers with different molecular weights, polydispersity and ionic side chain distributions. FTIR spectroscopy demonstrates that the ionomers synthesized via free radical polymerization have more free ions compared to their RAFT analogs. The ionomers with larger cations, such as tetrammonium, have higher free ion contents. Information on ion association states is then related to ion conductivity and crystallinity characterized by dielectric relaxation spectroscopy and wide angle X-ray scattering, respectively.

Q1.00159 Melt State Morphology Evolution in Precise Acid Copolymers as a Function of Strain[1]

, LURI MIDDLETON, University of Pennsylvania, JOSEPH CORDARO, Sanida National Labratories, KAREN WINEY, University of Pennsylvania — Acid- and ion-containing polymers have specific interactions that produce complex and hierarchical morphologies that provide a remarkable combination of mechanical properties. Historically, correlating the hierarchical structure and the mechanical properties of these polymers has been challenging because (1) the polymers have random arrangements of the acid or ionic groups along the backbone and (2) structural characterization is typically performed ex situ relative to mechanical testing. We addresses both of these challenges through in situ deformation of PRECISE acid copolymers. PRECISE acid copolymers were synthesized by from well-defined macromonomers via acylic diene metathesis (ADMET). The precision of the molecular structure imposes uniformity in the polymer morphologies through precise separation between acid groups leading to better defined lamellae thickness and well-defined interaggregate spacings. Here, we report the first results from simultaneous synchrotron X-ray scattering and melt state uniaxial extensional flow of precise acid copolymers. These in situ studies will be discussed alongside ex situ studies of the mechanical properties.

Q1.00160 Polysiloxane-graft-PEG/Phosphonium Ionomer Morphology and Ion Transport

, MICHAEL O'REILLY, University of Pennsylvania, SIWEI LIANG, JOSHUA BARTELS, JAMES RUNT, RALPH COLBY, Pennsylvania State University, KAREN WINEY, University of Pennsylvania — A series of random polysiloxane-based copolymer single ion conductors with phosphonium and polyethylene glycol side chains have been synthesized at various compositions and counterions. Morphology is investigated via X-ray scattering, and reveals microphase separation on extremely small length scales. Despite the low molecular weight of the PEG side chain, polysiloxane and PEG assemble into microdomains with covalently bound phosphonium cations at the interface. Exceptionally low glass transition temperatures in these microphase separated ionomers allow for high ionic mobility for both bulky, charge delocalized counterions as well as small, electronegative counterions. Morphology interpretation is complemented by measurement of ion transport properties via dielectric relaxation spectroscopy.

Q1.00161 Li+ transport in poly(ethylene oxide) based electrolyte: A combined study of neutron scattering, dielectric spectroscopy, and MD simulation

, CHANGWOO DO, Oak Ridge National Laboratory, PETER LUNKENHEIMER, Experimental Physics V, Center for Electronic Correlations and Magnetism, University of Augsburg, 86159 Augsburg, Germany, DIDDO DIDDENS, Institut für Physikalische Chemie, Westfälische Wilhelms-Universität Münster, 48149 Münster, Germany, MARION GÖTZ, MATTHIAS WEIß, ALOIS LOIDL, Experimental Physics V, Center for Electronic Correlations and Magnetism, University of Augsburg, 86159 Augsburg, Germany, XIAO-GUANG SUN, Oak Ridge National Laboratory, JÜRGEN ALLGAIER, MICHAEL OHL, Jülich Centre for Neutron Science, Forschungszentrum Jülich, 52425 Jülich, Germany — Dynamics of Li+ transport in polyethylene oxide (PEO) and lithium bis(trifluoromethanesulfonyl)imde (LiTFSI) mixtures are investigated by combining various experimental techniques (neutron spin-echo and dielectric spectroscopy) with molecular dynamics (MD) simulations. Our results suggest that the characteristic live times within the cages formed by oxygens are mainly determined by the alpha-relaxation which corresponds to local segmental motions of polymers, to a much lesser extent by the main chain relaxation, and not at all by the beta-relaxation or any other faster processes. The significant contribution of Li+ hopping process to the ion conductivity is also identified. Subsequently, detailed characteristic length and time scales of various Li+ transport processes in solid polymer electrolytes are presented and interpreted.

Q1.00162 Nonlinear Elasticity of Biological and Polymeric Networks and Gels[1]

, A.J. OYER, J.-M.Y. CARRILLO, A.V. DOBRYNIN, University of Connecticut, F.C. MACKINTOSH, Vrije Universiteit — Biological and polymeric networks show remarkably high deformability at relatively small stresses and can sustain reversible deformations up to ten times of their initial size. Using theoretical analysis and molecular dynamics simulations we propose and test a theory that describes nonlinear mechanical properties of a broad variety of biological and polymeric networks and gels by relating their macroscopic strain-hardening behavior with molecular parameters of the network strands. This theory provides a universal relationship between the strain-dependent network modulus and the network deformation as a function of the first invariant, I_1, of the network deformation matrix. Our analysis shows that depending on the rigidity of the polymeric strands between cross-links there are two different nonlinear network deformation regimes. Networks made of polymer chains with bending constant $K>1$ behave as polymeric network made of a worm-like chains in the interval of network deformations $\frac{\beta I_1}{3} < 1 - \left(K^2+2\right)^{-1/2}$ and as networks made of freely-jointed chains for $\frac{\beta I_1}{3} > 1 - \left(K^2+2\right)^{-1/2}$ ($\beta \approx \left\langle R_{in}^2 \right\rangle / R_{\max}^2$ is a strand extensibility ratio of the mean-square value of the undeformed strand size, $\left\langle R_{in}^2 \right\rangle$, to the square of the fully extended strand size, $R_{\max}^2$. However, networks made of flexible chains with $K<<1$ have only one nonlinear deformation regime.

[1]NSF DMR-1004576

Q1.00163 Mechanical similarities observed between polypropylene gels and molten polypropylenes , TETSU OUCHI, MISUZU YAMAZAKI, ATSUSHI HOTTA, Department of Mechanical Engineering, Keio University — The gelation of syndiotactic and isotactic polypropylenes (sPP and iPP) was found when PPs were dissolved in 1,2,3,4-tetrahydronaphthalene (tetralin). Interestingly, it was found that the storage modulus of sPP-gel became higher than that of iPP-gel when PPs were dissolved in tetralin at low PP concentration (<40 wt%). The result was distinctly different from the result of the neat PPs without solvent, as it is widely known that the modulus of sPP is significantly lower than that of iPP. Moreover, by measuring the storage moduli of solid sPP and iPP as a function of temperature, it was found that, above the melting points of PP, the storage modulus of sPP became higher than that of iPP, which was similar to the behavior of the storage modulus observed in the dilute PP-gels. Such mechanical similarity between PP-gels and PP-melts was also observed within iPP samples with different molecular weights. From these experimental results, it was considered that the amorphous phase of PP had profound influence on the mechanical properties of PP-gels at low PP concentration (<40 wt%), while the crystalline phase of PP had a major impact on the mechanical properties of PP-gels at relatively higher PP concentration (>40 wt%).

Q1.00164 Dynamics of Surface Reorganization of Poly(methyl methacrylate) in Contact with Water , AYANOBU HORINOUCHI, Department of Applied Chemistry and International Institute for Carbon-Neutral Energy Research (WPI-I2CNER), Kyushu University, HIRONORI ATARASHI, YOSHIHISA FUJII, KEIJI TANAKA, Department of Applied Chemistry, Kyushu University — New tools for tailor-made diagnostics, such as DNA arrays and tips for micro-total-analysis systems, are generally made from polymers. In these applications, the polymer surface is in contact with a water phase. However, despite the importance of detailed knowledge of the fundamental interactions of polymer interfaces with liquids, such studies are very limited. As an initial benchmark for designing and constructing specialized biomedical surfaces containing polymer, aggregation states and dynamics of chains at the water interface should be systematically examined. We here apply time-resolved contact angle measurement to study the dynamics of the surface reorganization of poly(methyl methacrylate) (PMMA) in contact with water. By doing the measurements at various temperatures, it is possible to discuss the surface dynamics of PMMA based on the apparent activation energy. Also, sum-frequency generation spectroscopy revealed that the surface reorganization involves the conformational changes in the main chain part as well as the side chains. Hence, the dynamics observed here may reflect the segmental motion at the outermost region of the PMMA film, in which water plays as a plasticizer.

Q1.00165 Observation of Birefringence of an Electrospinning Jet in Flight , KAIYI LIU, DARRELL RENEKER, The University of Akron — Solutions of polystyrene in N,N-dimethylformamide, polyacrylonitrile in N,N-dimethylformamide, and polyethylene oxide in water were electrospun. The charged liquid jets in flight were illuminated with polarized light converged on the jets by a Fresnel lens with a black background at the center, and were observed using a high speed camera, coaxial with the Fresnel lens, behind an analyzer which was crossed with a polarizer in front of the light source. The first several turns of coiled jet after the onset of electrical bending instability showed birefringence for all solutions, while no obvious birefringence was observed in the straight segments of the jets. This indicated that molecular chains in the coiled jet were aligned under elongation to a higher extent than those in the thicker straight jet.

Q1.00166 Explicit Proof of the Tube Concept in Polymer Dynamics , MAX KOLB, Laboratoire de Chimie, Ecole Normale Supérieure de Lyon, F-69364 Lyon, France, MONIQUE A.V. AXELOS, Biopolymères, Interactions, Assemblages, INRA, F-44300 Nantes, France — The key to the understanding of the dynamics of strongly entangled polymers is the tube concept and the reptation theory. For the lack of a mathematically unambiguous definition these concepts have been supported mostly by indirect evidence, such as crossover phenomena in various time correlation functions. Here we formulate the tube in a mathematically precise way and use this definition to explicitely calculate the predicted properties of reptation tube. Dynamic Monte Carlo simulations show that for strongly entangled polymers the tube does exist with the expected properties, most notably with a finite tube width. At the same time, slower than predicted early time Rouse dynamics and unexpectedly fast disentanglement effects due to finite chain lengths are responsible that the reptation limit can only be seen clearly for polymers whose contour length well exceeds one hundred tube widths. This is an explanation for the generally observed deviations from the asymptotic scaling predictions, both in experiments and in simulations. Effects such as dynamic tube shortening and tube dilation can be explicitely monitored in the present approach.

Q1.00167 Anisotropy Analysis of Polymer Chains upon Uniaxial Extension , HOWARD WANG, Institute for Material Research, State University of New York, Binghamton, HAO SUN, SHI-QING WANG, Department of Polymer Science, University of Akron, YANGYANG WANG, Department of Chemistry, University of Tennessee, Knoxville — Small angle neutron scattering has been used to measure entangled chains in polymer melts upon uniaxial stretching. The scattering anisotropy strongly depends on neutron moment transfer vector, revealing chain relaxation at different length scales. Such analysis allows for the comparison of various model predictions.

Q1.00168 Structure and Dynamics of Polymer/Ionic Liquid Systems Studied by In-Situ Electron Microscopy , PAUL KIM, THOMAS RUSSELL, DAVID HOAGLAND, Polymer Science and Engineering Department, University of Massachusetts — Ionic liquids (ILs) have extremely low vapor pressures and high conductivities, which taken together, make many IL-soft matter systems suitable for investigation by electron microscopy. Polymer crystallization in ultrathin film has attracted increasing attention as it provides (i) new clues on the nature of polymer crystallization and (ii) opportunity for enhancing the performance of polymer thin film devices. Exploiting ILs as crystallizing solvents, the evolving morphologies of several semi-crystalline polymers were investigated in-situ by optical microscopy, scanning electron microscopy (SEM), and transmission electron microscopy (TEM). To understand polymer dynamics in ILs, nanoparticles dispersed in ILs were investigated as model dynamical systems. Spatial and temporal imaging information affords insight into polymer-IL interactions.

Q1.00169 Crystallization Control in Crystalline-Crystalline PEO-*b*-PCL Diblock Copolymers , RYAN M. VAN HORN, ELLIOTT HASENKOPF, CHRISTINA MUCCI, Allegheny College — Understanding the crystallization behavior of crystalline-crystalline (CC) diblock copolymers is crucial in tailoring their macroscopic properties. The order of crystallization and structure of the phase-separated CC material is dependent on many factors including, but not limited to, T_{ODT}, T_{m}^{0}, M_{n}, and domain size. PEO-*b*-PCL copolymers are unique in that their T_{m}^{0} values are similar. As such, manipulation of the crystallization sequence or overall crystallinity of each block is more difficult. Using DSC and FTIR analysis, work has been done to observe the effects of thermal history and solvent interactions on the crystallization of PEO-*b*-PCL copolymers with differing M_{n} ratios. Preliminary results indicate that the mechanism, crystallinity, and eventually macroscopic properties may be tuned using different crystallization conditions.

Q1.00170 SAXS/WAXS studies of flow-induced crystallization of poly(1-butene) in uniaxial extensional flow , ERICA MCCREADY, WESLEY BURGHARDT, Northwestern University — We report studies of flow-induced crystallization of poly(1-butene) in uniaxial extensional flow. Flow was produced using an SER extensional flow fixture housed in a custom built convection oven designed to provide x-ray access for in situ studies of polymer structure using synchrotron x-ray scattering techniques. Samples were loaded into the SER fixture, heated well into the melt, and then cooled to a temperature at which quiescent crystallization would be prohibitively slow. A short interval of uniaxial extensional flow was then applied, after which simultaneous wide- and small-angle x-ray scattering (SAXS and WAXS) patterns were collected to study the phase transformation kinetics and morphology of the subsequent accelerated crystallization. The impact of both deformation rate and total applied strain on the crystallization process were examined.

Q1.00171 SAXS/WAXS studies of flow-induced crystallization of poly(1-butene) in shear flow

, BINBIN LUO, WESLEY BURGHARDT, Northwestern University — Flow-induced crystallization of poly(1-butene) was studied in shear flow. Flow was produced using a Linkam shear cell that has been modified to allow x-ray access for in situ studies of polymer structure using synchrotron x-ray scattering techniques. After loading in the the shear cell, samples were first heated well into the melt, and then cooled to a crystallization temperature selected such that negligible quiescent crystallization would occur on reasonable time scales. A short burst of shear flow was then applied at various rates, after which simultaneous wide- and small-angle x-ray scattering (SAXS and WAXS) data were collected to study the resulting accelerated crystallization kinetics, as well as the morphology of the resulting crystallites (e.g. degree of crystallite orientation). The impact of both deformation rate and total applied strain on the crystallization process were examined.

Q1.00172 Statistics of single molecule rotation driven by electrons

, CHARLES SYKES, Tufts University — In stark contrast to nature, current manmade devices, with the exception of liquid crystals, make no use of nanoscale molecular motion. In order for molecules to be used as components in molecular machines, methods are required to couple individual molecules to external energy sources and to selectively excite motion in a given direction. Recently a new, stable and robust system of molecular rotors consisting of thioether molecules bound to metal surfaces has offered a method with which to study the rotation of individual molecules as a function of temperature, molecular chemistry, proximity of neighboring molecules, and surface structure [1,2]. Arrhenius plots for the rotation of dibutyl sulfide yielded a rotational barrier of 1.2 kJ per mol. While these results reveal that small amounts of thermal energy are capable of inducing rotation, thermodynamics dictates that thermal energy alone cannot be used to perform useful work in the absence of a temperature gradient. Electrical excitation of individual thioether molecular rotors is performed using with electrons from a scanning tunneling microscope tip. Experimental data for the electrically excited motion of asymmetric thioether molecules is presented and the statistics of and mechanism for directed motion is discussed [1,2].

Q1.00173 Active contractility and motor-driven effective interactions in a model cytoskeleton[1]

, SHENSHEN WANG, Massachusetts Institute of Technology, PETER WOLYNES, Rice University — Contractile forces are essential for many developmental processes involving cell shape change and tissue deformation. Recent experiments on reconstituted actomyosin network, the major component of the contractile machinery, have shown that active contractility occurs above a threshold motor concentration and within a window of cross-link concentration. We present a microscopic dynamic model that incorporates two essential aspects of actomyosin self-organization: the asymmetric load response of individual actin filaments and the correlated motor-driven events mimicking myosin-induced filament sliding. Using computer simulations, we examine how the concentration and susceptibility of motors contribute to their collective behavior and interplay with the network connectivity to regulate macroscopic contractility. Our model is shown to capture the formation and dynamics of contractile structures and agree with the observed dependence of active contractility on microscopic parameters. We further provide a theoretical framework to investigate the intricate interplay between local force generation, network connectivity and collective action of molecular motors. This framework is capable of accommodating both regular and heterogeneous pattern formation, arrested coarsening and macroscopic contraction in a unified manner.

Q1.00174 Generalized formulation of Brownian Vortexes

, HENRIQUE W. MOYSES, ROSS BAUER, DAVID G. GRIER, Department of Physics and Center for Soft Matter Research, New York University — Brownian vortexes are stochastic noise driven machines that arise from the motion of particles subjected to static non conservative force fields. This motion is characterized by a toroidal circulation in the probability flux whose direction can be tuned by changing the temperature of the system. A discrete minimal model for Brownian Vortexes were described by previous work done by B.Sun, D.G.Grier and A.Y.Grosberg. Here we theoretically look for a continuous model in the form of a generalization of the equilibrium Boltzmann relation for the probability density in the case where the driven forces have a non conservative solenoidal component. This generalized relation features the temperature induced probability flux reversal. We further extend our theory to time dependent force fields and study the possibility of stochastic resonance in the characteristic frequency of circulation of the driven particle. This model is experimentally applied to investigate the motion of colloidal spheres in an optical trap whose intensity is oscillatory in time.

Q1.00175 Electric control interfacial jamming and dynamics

, MENGMENG CUI, CAROLINE MIESCH, IREM KOSIF, HUARONG NIE, TODD EMRICK, THOMAS RUSSELL, University of Massachusetts Amherst — Particles, partially wetted by two immiscible fluids, can adsorb at the interface and interfacially jammed when the interfacial area is decreased. Here, electric fields were used to change the interfacial area by distorting or merging fluid droplets suspended in an immiscible liquid. To get the desired interfacial jamming, ligand exchange was used to enhance the binding energy of the particles at the interface. Jamming nanoparticles at the interface arrests the dynamics so as to kinetically trap morphologies in highly non-equilibrium states. Morphologies hitherto inaccessible using conventional routes were obtained by the interfacial jamming. The hyper-diffusive dynamics of interfacial jamming and its dependence on nanoparticle concentration, size and shape were observed by X-ray photo correlation spectroscopy (XPCS). Kinetics were studied by tensiometer and optical microscopy.

Q1.00176 SOFT CONDENSED MATTER –

Q1.00177 Modeling the tuning of lasing in liquid crystal based one-dimensional Photonic Crystal using the Finite Difference Time-Domain Method

, PAOLA CASTRO-GARAY, Departamento de Fisica, Universidad de Sonora, Blvd. Luis Enci- nas y Rosales, Hermosillo, Sonora 83180, Mexico., JESUS MANZANARES-MARTINEZ, Departamento de Investigacion en Fisica, Universidad de Sonora, Apartado Postal 5-088, Hermosillo, Sonora 83180, Mexico, YOHAN JASDID RODRIGUEZ-VIVEROS, DAMIAN MOCTEZUMA-ENRIQUEZ, Departamento de Fisica, Universidad de Sonora, Blvd. Luis Enci- nas y Rosales, Hermosillo, Sonora 83180, Mexico. — In this work, a numerical study based on the Finite Difference Time-Domain Method to determine the lasing from a finite one-dimensional Photonic Crystal composed by Porous Silicon and Liquid Crystal is proposed. As a consequence of the zero density of states in the Band Gap and the high Density of States at its edges, the emission is inhibited in the Gap and stimulated in its edges. We investigate the conditions where light emitted by a Gaussian source embedded in the Photonic Crystal can be switched into a monochromatic emission. We present the tuning of the lasing by changing the Density of States due to the tunability of the liquid crystal dielectric function.

Q1.00178 On the variation of Differential Polarizability in polarized Raman Scattering measurements

, KARTHIK NAYANI, JUNG OK PARK, MOHAN SRINIVASARAO, Georgia Institute of Technology — Jones et al recently developed a framework to measure P_2 and P_4 using PRS.[1] The method requires the measurement of the angular dependence of the depolarization ratio. While the agreement of the results of P_2 and P_4 with theory is satisfactory there are some aspects to the methodology that need further scrutiny. The differential polarizability ratio (r) is used as a fitting parameter to the depolarization profile. The value of r so calculated from the method of Jones et al. has a sharp discontinuity at the phase transition from the nematic to the istropic phase (T_{NI}) and also the variation of r in the nematic phase is not well understood. Further we show that when values of the r as obtained by data fitting are used in the expression of the original method of Jen et al, the values of P_2 and P_4 are in excellent agreement with theoretical predictions, rising the premise that a better understanding of the variation of r needs to be developed more accurate experiments using PRS.

Q1.00179 Effect of protein (Myoglobin) on the isotropic to nematic phase transitions

, GERMANO IANNACCHIONE, PARVATHALU KALAKONDA, JOHN ARNOLD, SHAUN MARSHALL, IZABELA STROE, Worcester Polytechnic Institute — High-resolution calorimetry and broad-band dielectric spectroscopy have been performed on colloidal dispersions of myoglobin protein in a nematic liquid crystal as a function of protein content. The myoglobin protein was uniformly dispersed in the dry state in pentylcyanobyphenyl (5CB) liquid crystal with weight fraction from 0 to 100 wt%, and cover the temperature range of 180 to 420 K under near equilibrium conditions. Such colloidal systems may be attractive to isolate the behavior of the protein as it interacts with the desired liquid crystal property as well as probing the effect of functional/active nano-particles on LC behavior.

Q1.00180 Effect of applied *ac* electric field on surface plasmon excitations at metal/liquid-crystal interface

, KUNAL TIWARI, SURESH SHARMA, University of Texas at Arlington — It is well known that surface plasmon polaritons (SPPs) can be excited by $p-$polarized laser beam incident upon high-index prism/metal/dielectric medium used in Kretschmann configuration. The SPPs' onset, evidenced by a loss in the intensity of totally reflected light at a certain angle greater than the critical angle for total reflection, is sensitive to the dielectric properties of the medium. In the case when the dielectric medium is liquid crystal (LC), its dielectric properties can be modified by applied electric fields. We have carried out a set of experiments on high-index prism/Au/LC used in the Kretschmann configuration. Specifically, we have measured a set of attenuated total reflection (ATR) data as functions of incident angle for $p-$polarized 632 nm laser beam and *ac* electric fields for liquid crystals. We present data on the effects of the applied *ac* electric fields on the nature of the reflectivity *vs* angle curves and discuss the relevance of our observations to the electric-field-induced changes in the dielectric properties of the liquid crystal.

Q1.00181 Entanglement and Relaxation of Liquid Crystal Shaped Granular Media[1]

, THERESA ALBON, The College of Wooster, Wooster OH 44691, WILDER IGLESIAS, ANTAL JAKLI, Kent State University, Kent OH 44240, SHILA GARG, The College of Wooster, Wooster OH 44691 — We studied the entanglement and relaxation of V-shaped, U-shaped, and rod-shaped granular media. Our experiment was modeled after Gravish et al.'s work [1]. A clear understanding on how these particles interact with each other on a macroscopic scale can help us model how microscopic liquid crystal molecules with similar shapes behave. In order to entangle the granular media, the particles were subjected to a sinusoidal acceleration within a confined cylinder. Once entangled the cylinder was removed to leave a freestanding column, which was then accelerated at various 'g forces' to untangle and cause a collapse. Video recordings of the experiment were used to analyze the dynamics of packing and collapse. The U-shaped granular media took a longer time to relax in comparison with the rod-shaped and V-shaped granular media. We conclude that this is because the U-shaped granular media had 90° angles, which allowed the particles to latch on to each other better than the rod-shaped and the V-shaped particles. [1] N. Gravish, S. Franklin, D. Hu, D. Goldman, Phys. Rev. Lett., 108, 208001 (2012).

Q1.00182 Elastic constants and material properties of novel shaped liquid crystals[1]

, M. SCHMITTHENNER, The College of Wooster, Wooster OH 44691, P.K. CHALLA, J.T. GLEESON, Kent State University, Kent OH 44240, S. GARG, The College of Wooster, Wooster OH 44691 — We report the Frank elastic constants along with other material properties of the newly synthesized liquid crystals RB01115 and RB01189. These materials are being investigated due to their Y and H-shaped structures respectively and possible biaxial nature of the latter. At $T^* = (T / T_{NI}) = 0.94$, we found the extraordinary refractive index of RB01189 to be 1.548 while the ordinary index was 1.469. We applied magnetic fields to induce Freedericksz transitions in order to find the elastic constants and determined their values to be: $K_{11} = 0.12 \times 10^{-12}$ N, $K_{22} = 5.6 \times 10^{-12}$ N, and $K_{33} = 4.6 \times 10^{-12}$ N. For the Y-shaped RB0115 at T^*=0.98, we found $K_{11} = 2.8 \times 10^{-12}$ N, $K_{22} = 2.5 \times 10^{-12}$ N, and $K_{33} = 4.5 \times 10^{-12}$ N. These constants are similar to values found for other materials with non-rod shaped or bent-core structure.

[1]This work was supported by NSF DMR 0964765.

Q1.00183 Optical Investigation of Novel Liquid Crystals

, JOSEPH VIRGILIO, ARIELLE ADAMS, LOGAN TATE, CHRISTOPHER WECKERLY, CHANDRA PRAYAGA, AARON WADE, University of West Florida, Physics Department — We present our research on the optical investigation of the phase transitions of novel, optically active liquid crystals (LC's) fabricated at the UWF Chemistry Department. As liquid crystals transition from the isotropic to the nematic to the smectic phases, they have different levels of alignment. This results in a change in the fluorescence spectra and transmitted optical properties as a function of temperature. Sample preparation consists of spin coating the LC, forming an optical cell. The sample is then placed in a temperature-controlled environment. Fluorescence is induced by pumping the sample at 355 nm from a frequency-tripled, pulsed ND:YAG laser. The fluorescence is measured with a spectrograph. Simultaneously, the transmission is measured with a photodiode. The results show significant changes in spectra and transmitted light near the phase transitions, allowing for precise measurements of the phase transitions.

Q1.00184 Novel chiral dopants: Light and environmental sensitivity

, SETH BOURG, SHANNON ROSARIO, PETR SHIBAEV, Fordham University, Department of Physics — The effectiveness of novel chiral dopants based on compounds able to form hydrogen bonds is studied for the compounds themselves, their hydrogen-bonded associates with non-chiral light sensitive molecules and with other chiral dopants. The effect of association is discussed in terms of the chemical structure and the shape of the substitute. Light irradiation of chiral hydrogen-bonded associates based on light sensitive azo-derivatives leads to changes of twisting power of the latter. This change is compared to that produced by chemical bonding between chiral dopants and associates. The behavior of chiral dopants in different liquid crystalline matrices is studied, and the response of liquid crystals to environmental changes, manifested not only in changes of helical pitch [1] but also in structural changes, is discussed.

Q1.00185 Vesicles sensing using resistive-pulse method[1] , YAUHENI RUDZEVICH, YUQING LIN, LEE CHOW, University of Central Florida — Here we present a "resistive-pulse" method that allows translocations, counting and measuring size distribution liposomes with radii from 25 nm to 125 nm. This technique is based on using two chambers filled with electrolyte solution and separated by a partition with a nanopore between electrodes. It was found that ionic current drops when nanoparticle entering sensing nanopore of a pulled glass micropipette, producing a clear translocation signal. Pulled borosilicate micropipette with opening 50 $\sim$ 150 nm was used as a sensing instrument. This method provides a direct, fast and inexpensive way to characterize inorganic and organic nanoparticles in a solution.

Q1.00186 Different Transition Mechanisms and Tunable Wall Thicknesses of Block Copolymer Vesicles , MENGYING XIAO, RONG WANG, DAIQIAN XIE, School of Chemistry and Chemical Engineering, Nanjing University — By using dissipative particle dynamics, we studied how to control the two pathways for vesicle-formation mechanism considering the hydrophobic/hydrophilic block ratio, polymer-solvent interaction, and polymer concentration. A crucial balance between the segregation of inner-hydrophobic beads and the attraction of outer-hydrophilic beads drastically affects the self-assembly pathways of amphiphilic block copolymer into vesicles from one mechanism over the other. And during the transition period between these two pathways, vesicles are formed through an in-between pathway. In addition, we have evaluated the thickness of the hydrophobic layer and observed two types of dependence on the vesicle size. Our results indicate that as the degree of hydrophobicity of the blocks increases, from the whole strong behavior to the whole weak behavior relationship, the transformation is observed in large sized vesicles first and then in small sized vesicles. Two characteristics, the chain compaction of the vesicles and the area densities of inner corona, are thought to be important in controlling the membrane thickness. **Acknowledgments.** This work has been supported by NNSFC (Nos. 20874046, 21074053 and 21133006) and NBRPC (No. 2010CB923303).

Q1.00187 Hyper-branched Structures via Flow Coating , YUJIE LIU, DONG YUN LEE, University of Massachusetts-Amherst, CÉCILE MONTEUX, CNRS-ESPCI-Université Pierre et Marie Curie, ESPCI, ALFRED J. CROSBY, University of Massachusetts-Amherst — Evaporative self-assembly has been shown to be a scalable method for organizing non-volatile solutes, e.g. nanoparticles; however, the influence of substrate surface energy in this technique has not been studied extensively. In this work, we utilize an evaporative self-assembly process based upon flexible blade flow coating to fabricate organized structures on substrates that have been modified to systematically vary surface energy. We focus on the patterning of polystyrene. We observe a variety of polystyrene structures including dots, hyper-branched patterns, stripes and lines that can be deposited on substrates with a range of wetting properties. We explain the mechanism for these structural formations based on the competition between Marangoni flow, adsorption, friction and viscosity. The development of this fundamental knowledge is important for controlling hierarchical manufacturing of nanoscale objects with different surface chemistries and compositions.

Q1.00188 Synthesis of highly tunable Janus particles in chemical and physical anisotropy and their assembly , JONGMIN KIM, CHANG-HYUNG CHOI, SUNG-MIN KANG, CHANG-SOO LEE[1], Chungnam National University — Self-assembly has been explored as a novel strategy for making new functional materials with unique physical, chemical, and mechanical properties in various fields. To date, many assembly building blocks and techniques has been introduced from molecular to meso-scale, which rely on chemical and physical driving forces. Janus particles are considered as a favorable building block to make various structures. However, to achieve complex 3D structure in self-assembly, it still requires further complexity in particle shapes. Several techniques have been reported in literatures providing variety in shapes but, it is still difficult to make 3D shapes such convex or concave particles. Herein, we present a simple micromolding method for synthesis of complex Janus particles and its self-assembly via 2D orbital shaking. The synthetic method allows for both chemical and physical anisotropy such as the length of hydrophobic block and 3D shapes with high controllability. We also demonstrate self-assembly induced by shape complexity, aspect ratio and solvent polarity which results in various assembled structures including simple dimer, linear polymer like structure, and ring like structure.

Q1.00189 Using Light to Create Nanogrids in Polymer/Nanoparticles Composites[1] , YA LIU, OLGA KUKSENOK, ANNA BALAZS, University of Pittsburgh — One of the challenges in creating high-performance polymeric nanocomposites is establishing effective routes for controlling the morphology of both the polymeric components and the nanoparticles, which impart the desirable optical, electrical and mechanical properties to the material. Using computational modeling, we design an effective method to control assembly of polymeric nanocomposites comprising nanorods and a photosensitive binary blend. We focus on scenarios where the composites can be organized into variety of nanogrids with well defined structural features. We harness non-uniform light illumination with the background illumination of the entire composite and secondary, higher intensity light sources that are rastered over the sample. We show that our system displays an essentially defect-free morphology, with the nanoparticles localized in the energetically favorable domains. Furthermore, we demonstrate that by controlling the length and a chemical nature of nanorods (such as their wetting properties), one can order both polymeric components and nanoparticles into variety of complex nanogrid structures. The ability to control morphology provides a means of tailoring the properties and ultimate performance of these hybrid materials.

Q1.00190 Supramolecular Assembly of Organic-Inorganic Hybrid Polyoxometalate Nanoclusters at Solid-liquid Interface , NA QI, BENXIN JING, YINGXI ZHU, Department of Chemical and Biomolecular Engineering, University of Notre Dame, Notre Dame, IN 46556 — Polyoxometalate (POM) inorganic nanoclusters have recently emerged as building blocks for the design and synthesis of novel functional materials for broad applications ranging from catalysis to nanomedicines. Rather than taking the slow self-assembly of POMs in aqueous solutions, we have investigated the assembly of hybrid Anderson-type Mo-based POMs with organic ligands at a solid surface by Langmuir-Blodgett (LB) deposition and characterized the films by AFM, TEM, and X-ray diffraction. We have observed the formation of well-ordered monolayer or bilayer consisting of periodic arrangement of hybrid POM nanoclusters, showing a strong dependence on substrate chemistry and LB compression pressure. The controlled assembly of hybrid POM nanocluster films by LB deposition could be used as a template with stoichiometric crystalline nanostructure to the programmed assembly of novel multi-functional supramolecular complexes.

Q1.00191 Mechanical Behavior of Randomly Packed Nanoellipsoid Films , DAEYEON LEE, University of Pennsylvnia, LEI ZHANG, University of Pennsylvania, GANG FENG, Villanova University — We investigate the mechanical behavior of films composed of randomly packed nanoellipsoids with varying aspect ratio using nanoindentation. The packing fraction of nanoellispoids, determined using gravimetric analysis, is found to have excellent agreement with previously reported results based on simulations. Our study shows that the volume fraction of the films rather than the aspect ratio of the particles is the primary factor that determines the modulus and hardness of nanoellipsoid films. We show, however, that the aspect ratio of the nanoellipsoids has a significant impact on the toughness and the failure mechanism of nanoellipsoid films. While short aspect ratio nanoellipsoid films develop shear bands under nanoindentation, films with high aspect ratio nanoellipsoids do not exhibit shear band formation. We will discuss the potential relevance of our results to other types of random packings such as granular materials and bulk metallic glasses.

Q1.00192 Evaporation induced ordering in polymer-colloid suspensions , ERKAN SENSES, Stevens Institute of Technology, MATTHEW BLACK, University of Maryland at College Park, THOMAS CUNNINGHAM, PINAR AKCORA, Stevens Institute of Technology — When evaporated from aqueous solutions, colloidal particles tend to deposit non-uniformly on hydrophilic substrates due to capillary flow from the center of droplet to the pinned contact line. The so called "coffee-ring" deposition has been extensively studied in polymer solutions and colloidal suspensions; however, the behavior of the mixtures of polymer-colloid suspensions under evaporation remains unexplored. The competition between the homogenous fluid phase and the depletion induced phase separation offers rich phase behavior to these three component systems over a wide range of size ratios and concentrations. In this work, we present the formation of long-range, ordered colloid-rich and polymer-rich phases with a well-defined periodicity from homogenous mixture of colloids and polymer via solvent evaporation. The kinetics of the phase separation, studied by video microscopy and Fourier transform analysis of the images obtained at different times, suggests that the early growth of the phases can be quantitatively described by spinodal decomposition kinetics. The effect of particle and polymer concentrations, polymer and particle size ratios, interparticle bridging and substrate on microscopic phase separation will be discussed.

Q1.00193 Controlling the scattering properties of thin, particle-doped coatings , WILLIAM ROGERS, MADELEINE CORBETT, Harvard SEAS, VINOTHAN MANOHARAN, Harvard SEAS and Physics — Coatings and thin films of small particles suspended in a matrix possess optical properties that are important in several industries from cosmetics and paints to polymer composites. Many of the most interesting applications require coatings that produce several bulk effects simultaneously, but it is often difficult to rationally formulate materials with these desired optical properties. Here, we focus on the specific challenge of designing a thin colloidal film that maximizes both diffuse and total hemispherical transmission. We demonstrate that these bulk optical properties follow a simple scaling with two microscopic length scales: the scattering and transport mean free paths. Using these length scales and Mie scattering calculations, we generate basic design rules that relate scattering at the single particle level to the film's bulk optical properties. These ideas will be useful in the rational design of future optically active coatings.

Q1.00194 Local strain fields in two-dimensional colloidal crystals with bond strength disorder[1] , MATTHEW GRATALE, YE XU, TIM STILL, ARJUN YODH, Department of Physics and Astronomy, University of Pennsylvania — We study the local strain fields of two-dimensional colloidal crystals consisting of random distributions of hard polystyrene particles and soft microgel particles. Using standard video microscopy and particle tracking techniques, we analyze the variations of local configurations around each particle due to thermal motion. With this information we derive the best-fit affine strain tensor and the non-affinity for each particle in the sample, which allow us to study the mechanical properties of our colloidal crystals. We than observe the changes in these properties as we transition from a predominately hard-sphere crystal to predominately soft-sphere crystal, that is we explore how the mechanical properties are affected by replacing hard inter-particle bonds with soft inter-particle bonds.

Q1.00195 Structural and Dynamical Studies of Concentrated Micrometer-Sized Colloidal Suspensions , FAN ZHANG, ANDREW ALLEN, LYLE LEVINE, National Institute of Standards and Technology, JAN ILAVSKY, GABRIELLE LONG, Argonne National Laboratory — It is a well-documented challenge to quantify the dynamic behaviors of concentrated, optically opaque micrometer-sized colloidal suspensions with laser scattering techniques due to the complications introduced by multiple scattering events. In order to overcome this limit, we have developed an ultra-small angle X-ray scattering (USAXS) based X-ray photon correlation spectroscopy (XPCS) technique to probe the equilibrium dynamics of such materials. With this technique as well as USAXS, we have tracked the structural and dynamical properties of concentrated monodisperse suspensions of different sized polystyrene (PS) microspheres in glycerol. For these PS suspensions, we found their static structures display a hard-sphere like behavior. Furthermore, by analyzing the intensity autocorrelation functions, we found the inverse of the effective diffusion coefficients display a peak with respect to the scattering vector that resembles the peaks in the static structure factors, a signature of de-Gennes narrowing. We also identified evidence supporting a collective motion of the microspheres.

Q1.00196 Transient Memories in Experiments on Sheared Non-Brownian Suspensions , JOSEPH PAULSEN, SIDNEY NAGEL, University of Chicago — A novel kind of memory has been observed in simulations of cyclically sheared non-Brownian suspensions [1]. Here we report on experiments designed to see these effects in the lab. In this type of memory, a system remembers a set of shear amplitudes but forgets most of them later on, even as they are continually applied. If noise is added, the system can store all memories indefinitely. While exceedingly counterintuitive, these properties can be understood from simple considerations, and the phenomenon is expected to be generic—the same effect is seen in simulations and experiments on traveling charge-density waves [2]. We perform experiments on a non-Brownian suspension at low Reynolds number, motivated by previous work with this system [3]. In our experiments, we form multiple memories that appear to forget in the same fashion. The final and crucial point is whether the forgetting is sufficiently gradual, so that one memory erodes away as another takes over. This key point distinguishes multiple transient memories from other classes of memory, where forgetting is immediate and unforgiving.

Q1.00197 Extensional rheology of a two dimensional foam , NICHOLAS HAGANS, KLEBERT FEITOSA, James Madison University Department of Physics and Astronomy — We report on changes in the packing structure and flow properties of a two dimensional bubble raft of slightly polydisperse bubbles. High resolution image video is used to track the collective motion of the bubbles as the foam is subjected to an oscillatory extensional driving. The foam displays both elastic and plastic behavior under varying stress, with sudden collective rearrangements occurring along slip lines separating semi-crystalline domains. Measurements of local bubble rearrangements show that the events are temporally correlated, but not spatially correlated.

Q1.00198 Formation of a quasi-two dimensional bubble pile , DANIEL SHORTS, James Madison University Student, KLEBERT FEITOSA, James Madison University Professor — We investigate the formative stages of a bubble pile at a liquid interface before the foam reaches steady-state. The pile is produced by a continuous bubbling of air into a soapy solution in a container of rectangular cross section. We find that above a critical flow rate, the bubbling produces a crater at the interface whose diameter is proportional to the flow rate. Extending from the borders of the crater, we observe a gentle slope at the water-foam interface whose angle with the horizontal is weakly dependent on the flow rate. As the pile is formed, the foam above the interface develops a dome-like profile that grows in diameter until it reaches the boundaries of the container. We show that the slope and the foam profile are a result of an isotropic pressure exerted by the arriving bubbles at the interface.

Q1.00199 Creating Reconfigurable Materials Using "Colonies" of Oscillating Polymer Gels , DEBABRATA DEB, University of Pittsburgh, PRATYUSH DAYAL, Indian Institute of Technology Gandhinagar, OLGA KUKSENOK, ANNA C. BALAZS, University of Pittsburgh — Species ranging from single-cell organisms to social insects can undergo auto-chemotaxis, where the entities move towards a chemo-attractant that they themselves emit. This mode of signaling allows the organisms to form large-scale structures. Using computational modeling, we show that millimeter-sized polymer gels can display similar auto-chemotaxis. In particular, we demonstrate that gels undergoing the self-oscillating Belousov-Zhabotinsky (BZ) reaction not only respond to a chemical signal from the surrounding solution, but also emit this signal and thus, multiple gel pieces can spontaneously self-aggregate. We focus on the collective behavior of "colonies" of BZ gels and show that communication between the individual pieces critically depends on all the neighboring gels. We isolate the conditions at which the BZ gels can undergo a type of self-recombining: if a larger gel is cut into distinct pieces that are moved relatively far apart, then their auto-chemotactic behavior drives them to move and autonomously recombine into a structure resembling the original, uncut sample. These findings reveal that the BZ gels can be used as autonomously moving building blocks to construct multiple structures and thus, provide a new route for creating dynamically reconfigurable materials.

Q1.00200 The conformations of cyclic polymers in bidisperse blends of cyclic polymers , MICHAEL LANG, Leibniz Institut für Polymerforschung Dresden, Hohe Straße 6, 01069 Dresden, Germany — The size of cyclic polymers in bidisperse blends of chemically identical molecules is analyzed by computer simulations. The compression of entangled rings can be explained by the changes in the penetrable fraction of the surface bounded by the ring. Corrections for small rings can be approximated by a concatenation probability $1 - P_{OO}$ that a cyclic polymer entraps at least one other cyclic polymer. Both results are in line with a previous work [1] on the compression of entangled cyclic polymers in monodisperse melts. For entangled cyclic polymers, bond-bond correlations show a constant anti-correlation peak at a curvilinear distance of about ten segments that coincides with a horizontal tangent in the normalized mean square internal distances along the ring for sufficiently large degrees of polymerization. In consequence, the length scale of topological interactions must be considered as constant in contrast to a recent proposal by Sakaue [2]. Our data is not in accord with an extension of the model of Cates and Deutsch [3] to bidiperse blends of ring polymers.

Q1.00201 Disorder-assisted melting and the glass transition in amorphous solids , ALESSIO ZACCONE, EUGENE TERENTJEV, Cavendish Laboratory, University of Cambridge — The mechanical response of solids depends on temperature because the way atoms and molecules respond collectively to deformation is affected at various levels by thermal motion. This is a fundamental problem of solid state science and plays a crucial role in metallurgy, aerospace engineering, energy. In disordered solids (glass, amorphous semiconductors, ceramics, metallic glass, polymers) the vanishing of rigidity as a function of temperature is not well understood because continuum elasticity is inapplicable due to the disorder leading to nontrivial (nonaffine) components in the atomic displacements. Our theory explains the basic mechanism of the melting transition of amorphous solids in terms of the lattice energy lost to nonaffine motion, compared to which thermal vibrations turn out to play a negligible role. The theory is in good agreement with data on melting of amorphous polymers (where no alternative theory can be found in the literature) and offers new opportunities in materials science.

Q1.00202 Effect of particle stiffness on glassy dynamics of dense colloidal liquids in the Bulk and Confined Regimes , RAYMOND SEEKELL, University of Notre Dame, PRASAD SARANGAPANI, MedImmune, LLC, One Medimmune Way, Gaithersburg, MD 20878, YINGXI ZHU, University of Notre Dame — "Fragile" glassy materials show a non-Arrhenius dependence of relaxation time with temperature close to the glass transition and have been extensively studied for molecular glass formers as model "hard-sphere" colloidal suspensions, but we lack a complete understanding of "strong" glass formers which show an Arrhenius dependence on temperature approaching the glass transition. In this work, we investigate the glassy dynamics of microgels of varied particle stiffness in dense aqueous suspensions using confocal microscopy. Poly(N-isopropylacrylamide) (PNIPAM) microgel particles of variable stiffness in aqueous media are synthesized by free radical polymerization with varied cross-linking density. We investigate five separate crosslinking densities to fully encompass the transition from "soft" to "stiff" glasses. We have observed that the dynamic heterogeneity is more pronounced as stiffness increases, indicating the effect of fragility on glassy dynamics of dense colloidal liquids. Furthermore, when the "soft" glasses are confined between two solid surfaces at a gap spacing of several particle diameters, particle motions become arrested with notably increasing dynamic length scales at smaller volume fractions, suggesting the enhanced fragility by special confinement.

Q1.00203 The propagation of magneto elastic waves in double-layer system in conditions of sliding contacts , ARTYOM DAVTYAN, Mr., MELS BELUBEKYAN, Professor, THE NATIONAL ACADEMY OF SCIENCES OF ARMENIA TEAM — This article takes an insight into the problem of the propagation of waves in the double layer system. The physical-mechanical properties and thicknesses of layers are different. The conditions of sliding contact take place on the outer surfaces and on the contact surfaces of layers that means they can slide over each other freely. As a result, the dispersion equation is obtained. The case when the physical-mechanical properties and thicknesses of layers are the same, the dispersion equation is obtained, which in it's turn is divided into three independent dispersion equations. The two of them state the independent distribution of waves in the layers, and the third dispersion equation states the simultaneous distribution of the waves by double layers. In case of short waves interfacial Stoneley type waves are received (waves that are localized near the layers separating surface). The results of the numerical calculations are given for the waves mentioned last, which describe the dependence between phase velocity and relative thickness of layer and Poisson coefficient.

Q1.00204 Development of a multi-resolution simulation approach , ANU NAGARAJAN, SILVINA MATYSIAK, University of Maryland, College Park, MD — The accurate representation of the aqueous environment in molecular dynamics simulations of medium to large systems poses a challenge in terms of simulation time scale and computational power. Multi-resolution simulation technique can be used to represent the solvent environment for simulating very large systems by splitting the system into nested regions.The different resolutions are combined to represent the solvent environment based on its physical relevance so that important regions of the solvent environment are in full atomistic representation and rest are in coarse-grained representation. Our method aims to represent the correct electrostatic properties in different representations and enable smooth transitions across the various resolutions. The ultimate goal of this work is to develop a multi-scale simulation method, for simulating bio-molecules in a multi-resolution solvent environment. This will allow us to gain the speed up necessary to simulate big macromolecular systems.

Q1.00205 Elastic Constants of Indium Arsenide at Room Temperature by Resonant Ultrasound Spectroscopy , FOUZI ARAMMASH, MING YIN, Benedict College — The three independent elastic constants, C_{11}, C_{12}, and C_{44} of indium arsenide (InAs) single crystal were determined at room temperature using resonant ultrasound spectroscopy (RUS) technique. We will present and compare our results with those obtained from more conventional measurement techniques. We also compare our results to those of other III-V compound semiconductors such as gallium arsenide (GaAs).

Q1.00206 The role of substrate pre-compression on post-wrinkling bifurcations , ANESIA AUGUSTE, University of Massachusetts - Amherst, LIHUA JIN, ZHIGANG SUO, Harvard University, RYAN HAYWARD, University of Massachusetts - Amherst — Surface instabilities play key roles in a variety of contexts including flexible electronics, surfaces with switchable properties, tissue engineering and biosensors. Wrinkles for elastic bilayers are well known to result from a balance between the bending energy of the stiffer skin layer and the stretching/compression of the softer substrate. Previous work has also shown that due to non-linearity in the substrate elasticity, post-wrinkling bifurcations can also occur, corresponding to emergence of sub-harmonic modes and eventual formation of self-contacting folds. To further elucidate the role of substrate elasticity in this process, we developed an experimental system that allows independent variation of the degree of compression in the substrate and in the thin film. We found that adding pre-compression to the substrate not only substantially reduces the critical strain for emergence of sub-harmonic modes, but also qualitatively changes the evolution of post-wrinkled structures. Our findings highlight the critical importance of substrate elasticity in determining the nature of post-wrinkling bifurcation modes.

Q1.00207 CHEMICAL PHYSICS –

Q1.00208 Non-linear responses of glass formers under temperature modulation , TAKASHI ODAGAKI, TAKAHIRO UENO, Tokyo Denki University, YASUO SARUYAMA, Kyoto Institute of Technology — The free energy landscape (FEL) approach to non-equilibrium systems has been shown to explain, in a unified manner, dynamic and thermodynamic characteristics observed in the vitrification process of super cooled liquids, and it is important to devise experiments which give information on the structure of the FEL. Here, we present a theoretical analysis of a new experimental technique which measures nonlinear responses under temperature modulation. Exploiting a simple model for glass formers, we first investigate dielectric relaxation when the temperature is subjected to a sudden change. We also report that three characteristic temperatures related to the glass transition can be determined from the analysis of the non-linear dielectric responses under oscillating temperature. Finally we discuss characteristic behavior of the frequency dependent diffusion constant, the intermediate scattering function and the generalized susceptibility under oscillating temperature.

Q1.00209 Thermal Conductivity in Supercooled Water[1] , JOHN BIDDLE, VINCENT HOLTEN, JAN SENGERS, MIKHAIL ANISIMOV, University of Maryland, College Park — The heat capacity of supercooled water, measured down to -37 C, shows an anomalous increase as temperature decreases. The thermal diffusivity, the ratio of thermal conductivity and the heat capacity per unit volume, shows a decrease. These anomalies may be associated with a hypothetical liquid-liquid critical point in metastable water below the line of homogeneous nucleation. The data suggest that the thermal conductivity does not show a significant critical enhancement, in contrast to what is observed near the vapor-liquid critical point. We have used mode-coupling theory to investigate the possible effect of critical fluctuations on the thermal conductivity of supercooled water, and shown that indeed this effect would be too small to be measurable at experimentally accessible temperatures. We discuss physical reasons for the striking difference between the vapor-liquid and liquid-liquid critical enhancements of thermal conductivity in water. We also discuss the discrepancy between the thermal conductivity calculated from experimental data and that obtained by computer simulations of the TIP5P water-like model.

Q1.00210 Mechanical output of myosin II motors is regulated by myosin filament size and actin network mechanics , SAMANTHA STAM, Biophysics Graduate Program, University of Chicago, Chicago, IL, JONATHAN ALBERTS, Center for Cell Dynamics, University of Washington, Friday Harbor, Washington, MARGARET GARDEL, Department of Physics, University of Chicago, Chicago, IL, EDWIN MUNRO, Department of Molecular Genetics and Cell Biology, University of Chicago, Chicago, IL — The interactions of bipolar myosin II filaments with actin arrays are a predominate means of generating forces in numerous physiological processes including muscle contraction and cell migration. However, how the spatiotemporal regulation of these forces depends on motor mechanochemistry, bipolar filament size, and local actin mechanics is unknown. Here, we simulate myosin II motors with an agent-based model in which the motors have been benchmarked against experimental measurements. Force generation occurs in two distinct regimes characterized either by stable tension maintenance or by stochastic buildup and release; transitions between these regimes occur by changes to duty ratio and myosin filament size. The time required for building force to stall scales inversely with the stiffness of a network and the actin gliding speed of a motor. Finally, myosin motors are predicted to contract a network toward stiffer regions, which is consistent with experimental observations. Our representation of myosin motors can be used to understand how their mechanical and biochemical properties influence their observed behavior in a variety of in vitro and in vivo contexts.

Q1.00211 Development of a Polarizable Protein-like Coarse Grained Model , SAI JANANI GANESAN, SUDI JAWAHERY, SILVINA MATYSIAK, University of Maryland, College Park — The use of coarse grained simulations to explore larger biological systems and longer timescales has become increasingly popular. One of the major drawbacks of most coarse grained protein models is the absence of polarization effects and hence the inability to reproduce accurate electrostatic screening. The inclusion of polarization effects to amino acids will allow us to characterize the role of dipole-charge interactions in driving secondary structural preferences. We have formulated a polarizable coarse-grained protein-like model using the Drude oscillator approach. The root of the model is based on the coarse-grained MARTINI force field. We apply the new model to polyalanine peptides and observe secondary structure changes in different solvent environments, caused due to changes in dipole interactions. We also explore the effects of adding charged amino acids like Lysines, on conformational preferences of the polyalanine system. Extensions of the current model to more complex systems will also be presented.

Q1.00212 Highly scalable many-GPU simulations of soft matter systems using HOOMD-blue , JENS GLASER, Dept. of Chemical Engineering and Materials Science, University of Minnesota, Minneapolis, JOSHUA ANDERSON, SHARON GLOTZER, Department of Chemical Engineering, University of Michigan, Ann Arbor, DAVID MORSE, Dept. of Chemical Engineering and Materials Science, University of Minnesota, Minneapolis — We present a new version of the highly optimized, versatile and easy to use molecular dynamics software HOOMD-blue [1] running on tens to hundreds of GPUs. By taking advantage of a refined version of Plimpton's communication scheme [2] fully implemented on the GPU and of standard MPI software, we demonstrate excellent strong scaling in simulations that have as few as 20,000 particles per GPU. This opens up the possibility of carrying out extremely performant multi-million particle simulations on GPU-based clusters and supercomputers, which are becoming increasingly available to the scientific community.

[1] Anderson, J., Lorenz, C., & Travesset, A. (2008), J. Comp. Phys., 227, 5342-5359.
[2] Plimpton, S. (1995), J. Comp. Phys., 117, 1-19.

Q1.00213 Application of Zwanzig-Mori projection in model coarse-graining , JIANHUA XING, ABHISHEK MUKHOPADHYAY, Virginia Tech — Reconstruction of equations of motion from incomplete or noisy data and dimension reduction are two fundamental problems in the study of dynamical systems with many degrees of freedom. We generalize the Zwanzig–Mori projection formalism, originally developed for Hamiltonian systems close to thermodynamic equilibrium, to general non-Hamiltonian systems lacking detailed balance. Then we develop a numerical algorithm to extract dynamic information for constructing the generalized Langevin equation. Numerical tests show that the formalism works remarkably.

Q1.00214 Molecular Simulations of The Formation of Gold-Molecule-Gold Junctions

, HUACHUAN WANG, The George Washington University — We perform classical molecular simulations by combining grand canonical Monte Carlo (GCMC) sampling with molecular dynamics (MD) simulation to explore the dynamic gold nanojunctions in a Alkenedithiol (ADT) solvent. With the aid of a simple driving-spring model, which can reasonably represent the long-range elasticity of the gold electrode, the spring forces are obtained during the dynamic stretching procedure. A specific multi-time-scale double reversible reference system propagator (double-RESPA) algorithm has been designed for the metal-organic complex in MD simulations to identify the detailed metal-molecule bonding geometry at metal-molecule-metal interface. We investigate the variations of bonding sites of ADT molecules on gold nanojunctions at Au (111) surface at a constant chemical potential. Simulation results show that an Au-ADT-Au interface is formed on Au nanojunctions, bond-breaking intersection is at 1-1 bond of the monatomic chain of the cross-section, instead of at the Au-S bond. Breaking force is around 1.5 nN. These are consistent with the experimental measurements.

Q1.00215 Computational NMR, IR/RAMAN calculations in sodium pravastatin: Investigation of the Self-Assembled Nanostructure of Pravastatin-LDH (Layered Double Hydroxides) Systems[1]

, PHILIPPE PETERSEN, VANESSA CUNHA, MARCOS GONÇALVES, HELENA PETRILLI, VERA CONSTANTINO, Universidade de Sao Paulo, INSTITUTO DE FíSICA, DEPARTAMENTO DE FíSICA DE MATERIAIS E MECÂNICA TEAM, INSTITUTO DE QUíMICA, DEPARTAMENTO DE QUíMICA FUNDAMENTAL TEAM — Layered double hydroxides (LDH) can be used as nanocontainers for immobilization of Pravastatin, in order to obtain suitable drug carriers. The material's structure and spectroscopic properties were analyzed by NMR, IR/RAMAN and supported by theoretical calculations. Density Functional Theory (DFT) calculations were performed using the Gaussian03 package [1]. The geometry optimizations were performed considering the single crystal X-ray diffraction data of tert-octylamonium salt of Pravastatin [2]. Tetramethylsilane (TMS), obtained with the same basis set, was used as reference for calculating the chemical shift of 13C. A scaling factor was used to compare theoretical and experimental harmonic vibrational frequencies. Through the NMR and IR/RAMAN spectra, we were able to make precise assignments of the NMR and IR/RAMAN of Sodium Pravastatin.

Q1.00216 Electric-Field Induced Structural Evolution of Water Clusters $(H_2O)_n$ [n = 9 - 20]: *Ab initio* Density Functional Approach[1]

, RAJEEV PATHAK[2], Department of Physics, University of Pune, Pune, Maharashtra, India — Response of neutral water clusters $(H_2O)_n$, n = 9 through 20; to external electrostatic fields (0 to 1V/Å), is studied for the lowest-energy conformers within in the energy band ∼2 kcal/mol, for each "n," employing the versatile B3LYP hybrid prescription of density functional theory in conjunction with the polarized basis 6-311++G(2d, 2p). Increase in the field elongates and weakens hydrogen-bond networks; "opening up" three-dimensional cluster morphologies to complex net-like structures culminating into their disintegration at specific threshold values. All conformations are stable: they manifest as local minima on their potential energy surfaces. Field-induced structural transitions are invariably accompanied by an abrupt increase in the electric dipole moment, which is marked at breakdown, where the highest-occupied and lowest-unoccupied molecular orbital energy gap diminishes to zero. Remarkably, as a consequence of their zero or very small electric dipole moments, certain conformers endowed with molecular symmetry exceptionally exhibit a peculiar behavior: they either remain completely robust to increase in the field, or break up into smaller, identical, robust building units with tetramer, pentamer and hexamer ring- or cubic-geometries.

Q1.00217 Promote Water Photosplitting via Tuning Quantum Well States in Supported Metal Clusters

, ZIJING DING, Beijing National Laboratory for Condensed Matter Physics, and Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China, ZI LI, GANG LU, Department of Physics and Astronomy, California State University, Northridge, California 91330-8268, USA, SHENG MENG, Beijing National Laboratory for Condensed Matter Physics, and Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China — In an effort to facilitate water photosplitting at surfaces, we identify quantum well states of magic gold clusters supported on ultrathin MgO/Ag(001) as the key to favor sunlight absorption and photocatalytic reactions. Based on density functional theory (DFT) and time-dependent DFT calculati ons, the adsorption geometry, electronic structures, and excited state properties of supported metal nanoparticles can be precisely controlled. By decreasing the thickness of MgO film, charge transfer to supported gold clusters, and therefore the occupation and energy spacings of quantum well states, can be gradually tuned, leading to redshifted and enhanced plasmonic excitations and optimized energy levels for water splitting. Using nudged elastic band (NEB) and constrain DFT, we further calculate the barriers for water splitting in the ground state as well as in excited states. The barriers are found correlated with adsorption sites of water on the gold cluster. Surface hopping calculations indicate the lifetime of excited states is long enough to induce water photo-dissociation.

Q1.00218 Helical inversion reaction pathway for π/π stacking in aromatic compounds

, AZUSA MURAOKA, Meiji University, CREST, HIROSHI USHIYAMA, KOICHI YAMASHITA, University of Tokyo, CREST — Polyaromatics have the π/π stacking interaction, which shows that two aromatic units preferentially interact in a parallel-displaced orientation, such as the crystal packing of organic molecules. Recently, π/π stacking compounds have become of interest in the photocatalysis solor energy transformational materials. In particular, the stable configurations of neutral and cationic o-phenylenes have helical tightly packed n-phenylenes with π/π stacking interactions. To investigate helical inversion pathways, we have studied theoretically the stable and transition-state geometries of neutral and cationic o-phenylenes using the density functional theory method. We have found that o-phenylenes follow an inversion reaction pathway with three transition-states in which the configuration of each phenylene is inverted. This means that o-phenylenes cannot convert from right- to left-handed geometry at once; however, we suggest a step-by-step reaction pathway through the three transition-state structures.

Q1.00219 Cathode Luminescence Spectroscopy of Gold Nanoparticle Catalyst in CO and O_2 Environments

, TAKAYUKI TANAKA, NAOKI YAMAMOTO, KUNIO TAKAYANAGI, Tokyo Institute of Technology; CREST, JST — Gold nanoparticle catalysts for low-temperature CO oxidation ($2CO+O_2 \rightarrow 2CO_2$) [1] are especially attractive for applications in air purification. It is proposed that the resonance state of O_2 (O_2^-) activates oxidation of CO and hydrocarbon in and gold nanoparticle on TiO_2 (Au/TiO_2) [1, 2] and TiO_2 photocatalyst [3]. The TiO_2 is prepared by cleavage and annealing of rutile single crystal. Gold nanoparticles were deposited at vacuum. The Au/TiO_2 catalyst was observed by scanning transmission electron microscopy (STEM). Cathode luminescence spectra were acquired, when the electron probe were scanned in Au/TiO_2. A CL peak is detected in spectra of vacuum. The peak energy depended on specimen and its location, e.g. 3.10 and 3.15 eV. The energies were close to band gap energy (3.0 eV). The CL peak of vacuum is attributed to electron-hole recombination of TiO_2. The peak energy shifts because of interference effects. Cathode luminescence spectra change by O_2 exposure of $3x10^{-4}$ Pa. The differential spectra from vacuum to O_2 show new peaks, which have larger energies than band gap energy, 3.1 to 3.6 eV. The new peaks by O_2 exposure are the resonance state of O_2 adsorption. We will report the results of CL experiments of O_2, CO exposure and co-exposure of CO and O_2 and propose mechanism of CO oxidation in Au/TiO_2. [1] M. Haruta, et al., J. Catal. 144 (1999) 175. [2] T. Tanaka, et al., Surf. Sci. 604 (2010) L75. [3] H. Irie et al, J. Phys. Chem. C 113, 10761 (2009).

Q1.00220 Investigation of oxygen adsorption on Pt nanoparticles with large-scale DFT calculations , ALVARO RUIZ-SERRANO, PETER CHERRY, CHRIS-KRITON SKYLARIS, University of Southampton — The oxygen reduction reaction (ORR) is of central importance to the operation of fuel cells. An understanding of the chemistry of the adsorption of oxygen on the metallic surface of the cathode electrode, which is one of the stages involved in this reaction, can be acquired through ab initio calculations based on Density Functional Theory (DFT). The use of metallic nanoparticles can improve the performance of fuel cells, so it is important to understand how their material, shape, surface and size affect their chemical properties. However, traditional DFT approaches for metallic systems have constrained the investigations to a small number of atoms. Our recent developments within the ONETEP program for large-scale DFT calculations enable us to study much larger metallic systems consisting of hundreds or even thousands of atoms. In this work we use such calculations to perform a study of oxygen adsorption on platinum nanoparticles of a range of sizes, and examine properties such as the optimized structures, electronic effects and adsorption energies.

Q1.00221 Molecule-based kinetic Monte Carlo modeling of hydrotreating processes applied to Light Cycle Oil gas oils , MAX KOLB, Laboratoire de Chimie, Ecole Normale Supérieure de Lyon, F-69364 Lyon, France, LUIS PEREIRA DE OLIVEIRA, Luis.Pereiradeoliveira@gmail.com, JAN J. VERSTRAETE, IFP Energies nouvelles, BP 3, 69360 Solaize, France — A novel kinetic modeling strategy for refining processes for heavy petroleum fractions is proposed. The approach allows to overcome the notorious lack of molecular details in describing the petroleum fractions. The simulation of the reactions process consists of a two-step procedure. In the first step, a mixture of molecules representing the feedstock of the process is generated via two sucessive molecular reconstruction algorithms. The first algorithm, termed stochastic reconstruction, generates an equimolar set of molecules with the appropriate analytical properties via a Monte Carlo method. The second algorithm, called reconstruction by entropy maximization, adjusts the molar fractions of the generated molecules in order to further improve the properties of the mixture. In the second step, a kinetic Monte Carlo method is used to simulate the effect of the refining reactions on the previously generated set of molecules. The full two-step methodology has been applied to the hydrotreating of LCO gas oils and to the hydrocracking of vacuum residues from different origins (e.g. Athabasca).

Q1.00222 Characterization of Self-Assembly Processes in Ionic Liquids , MICHAEL MCCUTCHEN, SILVINA MATYSIAK, University of Maryland, College Park — Surfactants are commonly used in a large number of industrial applications because of their remarkable ability to influence the properties of surfaces and interfaces. The spontaneous self-assembly of surfactants into micelles in an aqueous environment has been very well characterized. With the emergence of room-temperature ionic liquids (ILs), there is a clear need to revisit the driving forces behind the aggregation of surfactants in IL. This project aims to obtain a mechanistic description of the self-assembly of anionic surfactants ($SO_4C_6H_{13}$ $SO_4C_8H_{17}$ and $SO_4C_{12}H_{25}$) in an ionic liquid ([EMIM][EtSO4]). We are exploring the evolution of aggregates with time and the stability of micelle-like aggregates using atomistic simulations. The structural phase behavior is also characterized to explore morphological modifications. In addition, structural properties of the ionic liquid close to the aggregates are evaluated to characterize the link between aggregated structure and changes in the solvent structure.

Q1.00223 Probing the interface of Charged Surfactants in Ionic Liquids by XPS[1] , LANG CHEN, HARRY BERMUDEZ, Department of Polymer Science and Engineering, University of Massachusetts Amherst — Room-temperature ionic liquids (ILs) are playing increasingly vital roles in many processes of both fundamental and applied natures such as separations and catalysis. It is therefore critical to obtain a better understanding of their interfacial properties such as surface charge and composition. Here we examine the influence of positively-charged surfactants on IL interfaces by X-ray photoelectron spectroscopy (XPS). The roles of surfactant alkyl chain length, concentration, and information depth on interfacial properties are investigated. Depending on the chain length and concentration, the surfactants can alter the IL interface to varying extents, highlighting a simple route to manipulate interfacial properties. XPS also reveals that surfactant counterions predominantly dissociate into the bulk. As a consequence, ion exchange occurs between surfactant and like-charged IL ion. Our results are a further demonstration of the ability of XPS to give insights into the surface activity and aggregation behavior in multi-component ionic liquid systems.

Q1.00224 Physisorption, Diffusion, Adsorption/Desorption of Molecular Hydrogen on Graphene , MAJID KARIMI, Indiana University of PA, JUSTIN PETUCCI, Indiana Univesity of PA, GIANFRANCO VIDALI, Syracuse University — The interaction of a H2 molecule with a graphene surface is studied using AIREBO bond -order potential. Adsorption potential, desorption potential, and diffusion barriers of H2 on graphene are obtained and compared with the corresponding results from the first-principles. The massively parallel molecular dynamics codes (lammps) and nudged elastic band (NEB) method are employed to do these calculations.

Q1.00225 Experimental study of Ar-CH4 gas mixture adsorption over exfoliated graphite: kinetic reversal of adsorption selectivity[1] , MATIAS RAFTI, Instituto de Investigaciones Fisicoquímicas Teoricas y Aplicadas, (INIFTA-CONICET), Universidad Nacional de La Plata, VAIVA KRUNGLEVICIUTE[2], ALDO MIGONE, Southern Illinois University Carbondale — Adsorption is one of the processes used for achieving the separation of gas mixtures. In this poster we present the results of a combined gas composition and adsorption isotherm study performed to investigate how a mixture of two gases with different binding energies adsorbs on exfoliated graphite at temperatures between 70 and 90 K. In our experiments we observed a very interesting phenomenon: adsorption overshoot. This is a phenomenon that occurs in the initial stages of adsorption when the lower binding energy species adsorbs onto the substrate in a greater proportion than the stronger binding species. As time elapses and adsorption equilibrium is approached, the stronger species starts replacing the weaker species in the adsorbed phase. In principle, this phenomenon would allow the possibility of achieving gas mixture separation by controlling the adsorption time. Our results will be compared with those from recent numerical simulations that predicted similar behavior on a one dimensional uniform substrate.

[1]The authors thanks CONICET-UNLP and the Fullbright Commission for the scholarship granted. One of us (A.D.M) gratefully acknowledges support for this research from the NSF, through Grant NSF-DMR-#1006428.

[2]Present address: UPenn/NIST, 100 Bureau Drive, Gaithersburg, MD.

Q1.00226 Observation of CO_2 photodesorption from ZnO Nanowires under Ultraviolet illumination , ZHIHUA SU, Department of Electrical and Computer Engineering, University of Houston, Houston, Texas 77204, USA, CARSTEN RONNING, SEBASTIAN GEBURT, Institute of Solid State Physics, University of Jena, Jena, Germany, ABDELHAK BENSAOULA, Department of Electrical and Computer Engineering and Department of Physics, University of Houston, Houston, Texas 77204, USA, JIMING BAO, Department of Electrical and Computer Engineering, University of Houston, Houston, Texas 77204, USA — Electrical and optical properties of ZnO nanowires were greatly affected by surface-related gas adsorption and photo-desorption process. Oxygen was widely accepted as photo-desorption species from ZnO surface for years, but the conclusion came from indirect evidence. In this report, residual gas analyzer was used to directly monitor gas signal inside the chamber in which ZnO nanowires grown by CVD method was placed, while 362nm UV laser pulse with 2 second duration time was used as light source. The results showed CO_2 not O_2, was photo-desorption species. The desorption rate decreased with increase of illumination time. 532nm laser was also used as comparison light resource, and results showed that only under above band-gap illumination could CO_2 photo-desorption happen. Photocurrent measurement was also employed in situ with photo-desorption experiments, and coordinate results were obtained. Above observation suggested an impurity carbon involved process under above bang-gap radiation that results in CO_2 desorption. This report provided experimental support for study on ZnO surface-related electrical and optical properties.

Q1.00227 Phases transitions and interfaces in temperature-sensitive colloidal systems , DUC NGUYEN, PhD, PETER SCHALL, Dr. — Colloids are widely used because of their exceptional properties. Beside their own applications in food, petrol, cosmetics and drug industries, photonic, optical filters and chemical sensor, they are also known as powerful model systems to study molecular phase behavior. Here, we examine both aspects of colloids using temperature-sensitive colloidal systems to fully investigate colloidal phase behavior and colloidal assembly.

Q1.00228 Dynamics of concentration fluctuations in nanocolloidal suspensions. , ALEXIS PAYNE, ANA OPRISAN, College of Charleston — We studied the dynamics of concentration fluctuations in nanocolloidal suspensions using the shadowgraph visualization technique. The set up involved a CCD camera capturing the fluctuations occurring in a sample cell undergoing a free diffusion process. We performed three experiments with different gold, silver, and silica colloidal suspensions. For each trial, the colloid's power spectrum, structure factor, and correlation time were found using a dynamic structure method. Each experiment's fluctuations varied significantly from the others. This was due to variations in particle size, concentration and possible plasmonic interactions. All the nanocolloidal suspensions' structure factors and correlation times followed the expected power laws. From the correlation time, the diffusion coefficient for all three colloidal suspensions was calculated which coincided with expected results.

Q1.00229 Active Microrheology Using Optical Tweezers to Characterize Viscoelastic Properties of Entangled DNA , COLE D. CHAPMAN, UCSD, KENT LEE, DEAN HENZE, University of San Diego, DOUGLAS E. SMITH, UCSD, RAE M. ANDERSON, University of San Diego — We use active microrheology techniques to investigate the frequency-dependent linear elastic and viscous moduli (G', G") of entangled DNA. Utilizing optical tweezers, single microspheres, embedded within solutions of entangled DNA of varying molecular lengths and solution concentrations, are driven sinusoidally over a frequency range of 0.6 - 95 Hz, while fluorescence microscopy is used to simultaneously visualize the deformation of a sparse number of DNA molecules entangled in the solution. DNA lengths of 11 kbp – 115 kbp and solution concentrations of 1.0 – 2.5 mg/ml are probed to determine the dependence of the viscoelasticity of entangled DNA on solution concentration and, for the first time, molecular length. Results are compared to theoretical predictions for entangled polymers, as well as previously reported macrorheology results.

Q1.00230 Structure of high-PT water and mineral interface with high-resolution x-ray reflectivity[1] , HONGPING YAN, CHANGYONG PARK, Carnegie Institution of Washington — Hydration and chemistry at mineral-water interface are fundamental to control mineral dissolution and growth at microscopic level. The structure is crucial to describe the interfacial processes such as electrical double layer and ion exchange. Density profiles across various mineral-water interfaces revealed characteristic water orderings in accordance with the termination and morphology of mineral surfaces [1]. The previous observations, however, have been limited to ambient pressure conditions due to the lack of proper instrument to handle extreme conditions (e.g., high-pressures). Here, we developed a high-pressure and high-temperature (high-PT) aqueous interface cell specifically designed for high-resolution x-ray reflectivity measurement from mineral-water interface under pressure up to 40 MPa and a temperature up to 770K. The first demonstration is presented with a few examples including olivine (010)-water interface. Observation of structure and reactivity of hydrothermal fluids on mafic and/or ultramafic mineral surfaces can provide a fundamental basis of our understanding of the hydration process of mineral surface in deep-sea environment. [1] Fenter, P. and Sturchio, N.C., 2004, Mineral-water interfacial structures revealed by synchrotron X-ray scattering, Progress in Surface Science 77, 171-258

Q1.00231 The role of rare earth oxide nanoparticles in suppressing the photobleaching of fluorescent organic dyes , ANUBHAV GUHA, Horace Greeley High School, ANINDITA BASU[1], University of Pennsylvania — Organic dyes are widely used for both industrial as well as in scientific applications such as the fluorescent tagging of materials. However the process of photobleaching can rapidly degrade dye fluorescence rendering the material non-functional. Thus exploring novel methods for preventing photobleaching can have widespread benefits. In this work we show that the addition of minute quantities of rare earth (RE) oxide nanoparticles can significantly suppress the photobleaching of dyes. The fluorescence of Rhodamine and AlexaFluor dyes was measured as a function of time with and without the addition of CeO_2 and La_2O_3 nanoparticle additives (two RE oxides that contain an oxygen vacancy based defect structure), as well as with FeO nanoparticles (which has an oxygen excess stoichiometry). We find that the rare earth oxides significantly prolonged the lifetimes of the dyes. The results allow us to develop a model based upon the presence of oxygen vacancies defects that allow the RE oxides to act as oxygen scavengers. This enables the RE oxide particles to effectively remove reactive oxygen free radicals generated in the dye solutions during the photoabsorption process.

Q1.00232 Quantum Chemistry based Coupled Electron Nuclei Dynamics Simulation , TOMOTAKA KUNISADA, HIROSHI USHIYAMA, KOICHI YAMASHITA, The University of Tokyo — Electron dynamics with classical nuclei motion was performed to study electron-nuclei coupled (non-adiabatic) process of molecular system. Non-adiabatic transition from one adiabatic state from another adiabatic state occurred during the simulation, which was confirmed by monitoring adiabatic state populations. The change of charge distribution and dipole moment in the molecule was analyzed in order to study electron dynamics. To see electron dynamics more clearly, the change of the electronic character of the electron wave function was examined in terms of configuration functions. These results show that, not only the population of each adiabatic state but also the coherence between adiabatic states plays important roles in such ultrafast electron dynamics induced by non-adiabatic transition.

Q1.00233 Strain effects on electron transport through ds-DNA molecules , SADEQ MALAKOOTI, ERIC HEDIN, YONG JOE, Ball State University — Molecular electronics of a double stranded poly(G)-poly(C) DNA molecule under axial mechanical strain is examined with a tight binding scheme. Slater-Koster theory is implemented to describe electronic coupling constants in terms of inter-orbital distances. Electronic structure of an infinite-length DNA model, including band structure and total density of states, is studied for both stretching and compressional cases. In addition, electronic transmission spectra as well as current-voltage characteristics under application of mechanical strain for a 30 base-pair DNA molecule coupled between two semi-infinite electrodes are investigated. Results demonstrate a very sensitive strain dependency for DNA electronics.

Q1.00234 Quantification of crumpling in graphene oxide and other sheet-like nanostructures , PETER BEAUCAGE, DURGESH RAI, GREGORY BEAUCAGE, University of Cincinnati, SIDDHARTH PRADHAN, University of Tennessee Knoxville — Two-dimensional sheet-like nanostructures have garnered significant scientific interest in recent decade, particularly due to their inherent high specific surface areas (SSAs). Such large SSAs also result in an intrinsic tendency to crumple or fold based on surface interactions under ambient conditions. An understanding of the topological details of such structures has revealed various qualitative features driven by thermodynamics and interfacial chemistry. A scaling model based methodology will be presented which can be utilized to do quantitative analysis using small angle scattering data. A wide range of materials like graphene oxide, membrane layers as well exfoliated sheets of molybdenum oxide and tungsten oxide have been investigated to understand how such quantification may yield a general classification of such materials based on crumpling behavior.

Q1.00235 Electrical properties of the α-pyrochlore $Bi_{2-y}Sr_yIr_2O_7$ solid solution

, PABLO DE LA MORA, Facultad de Ciencias, CARLOS COSIO CASTAÑEDA, Facultad de Quimica, FRANCISCO MORALES LEAL, Instituto de Investigacion en Materiales, GUSTAVO TAVIZON, Facultad de Quimica, Universidad Nacional Autonoma de Mexico — To study the electrical properties of the $Bi_{2-y}Sr_yIr_2O_7$ ($\{Ir_2O1_6\}\{Bi_{2-y}Sr_yO2\}$) solid solution *ab-initio DFT* (*WIEN2k*) calculations were done. In this compound, when *Sr* is introduced the resistivity increases and the ρ/T slope also increases. In this system the $Bi_{2-y}Sr_yO2$ substructure has little contribution to the conductivity, even so, it is indirectly responsible to the conductivity modifications, since it affects the other substructure; Ir_2O1_6, which is conducting. When *Bi* is substituted by *Sr*, it pushes *O1*, shortening the *Ir-O1* bond and the resistivity is supposed to decrease; instead a small increment is found. What is found is that this increment is due to the relaxation time, τ. There are two contributions to τ; a) static; the random replacement of *Bi* by *Sr* introduces 'impurities', shortening τ, therefore increasing the resistivity, b) dynamic; due to the thermal oscillations of the atoms. What is found is that the effect of the oscillations in the compound with *Sr* has a larger impact on the electronic structure, thus increasing the ρ/T slope.

Q1.00236 Micellization behavior of Poly[2,7-(9,9-dihexylfluorene)]-b-Poly(2-vinylpyridine) in MeOH/THF Mixed Solvents via a Combination of Coarse-Grained and All-Atom Molecular Dynamics Methods[1]

, CHIN-WEN CHEN, JING-SAIN LIN, WEN-CHANG CHEN, CHING-I HUANG, National Taiwan University, CHEN WEN-CHANG COLLABORATION — Coarse-grained (CG) and all-atom (AA) molecular dynamics (MD) methods are proposed to investigate the micellar behavior of a semiconducting conjugated diblock polymer, poly[2,7-(9,9-dihexylfluorene)]-b-poly(2-vinylpyridine) (PF-b-P2VP) in MeOH/THF. We adopt the iterative Boltzmann inversion method to obtain CG force filed through mapping route with AA MD data. In order to compare experimental result [1], we first choose PF_8-b-$P2VP_{11}$ with Φ =0.1 and varying ratio of MeOH/THF. When MeOH/THF = 0/100, due to the fact the THF is a common solvent. We observe no micellar formation with increasing ratio of P2VP selective solvent in MeOH/THF from 0/100 to 30/70. The PF block tends to aggregate to form micelles, and size of micelle keeps increasing. The spherical micelles transform into the worm-like formation in 90/10. Our simulation results are in agreement with the experimental study, indicating the constructive CGMD parameters are successful to describe the PF-b-P2VP in MeOH/THF.

Q1.00237 SEMICONDUCTORS —

Q1.00238 Characterization of free-standing GaN with thermal treatment[1]

, CHEN-CHI YANG, IKAI LO, CHENG-HUNG SHIH, CHIA-HSUAN HU, YING-CHIEH WANG, YU-CHIAO LIN, CHENG-DA TASI, SHUO-TING YOU, Department of physics, National Sun Yat-Sen University, Kaohsiung 80424, Taiwan, R. O. C., WEI-I LEE, CHUO-HAN LEE, Electrophysics, National Chiao Tung University, 1001 University Road, Hsinchu 30010, Taiwan, R. O.C. — We have grown free-standing GaN by hydride vapor phase epitaxy. The free-standing GaN samples were annealed by rapid thermal annealing for 3 minutes at 600, 650, 700, 750, and 800°C in vacuum. The crystal structure and quality of GaN samples were characterized by X-ray diffraction. We found that the full width half maximum of the (0002) and (10-12) of GaN samples are decreased significantly after thermal annealing. The (0002) rocking curve of GaN sample was 218.8 arc-sec without thermal annealing, and it became 49.5 arc-sec after annealing at 800°C. The FWHM of the (10-12) rocking curve was 113.5 arc-sec without thermal annealing, and it reduced to 58.3 arc-sec after annealing at 800°C. According to the observation of atomic force microscopy, we found that the dislocation density of annealed GaN samples ($7.04\text{x}10^6/\text{cm}^2$) is smaller than that of pre-annealed GaN samples ($1.02\text{x}10^7/\text{cm}^2$). The optical properties of the samples by photoluminescence measurement which showed that the sample annealed at 650°C had the best quality due to its narrowest FWHM at 3.4eV. According to these analytic results, we found that thermal annealing treatment could improve the quality of free-standing GaN.

Q1.00239 GaN Grown on Sputtering AlN Buffer Layer with Sapphire Substrate by Plasma-Assisted Molecular-Beam Epitaxy[1]

, YU-CHIAO LIN, IKAI LO, WEN-YUAN PANG, CHENG-HUNG SHIH, CHEN-CHI YANG, CHENG-DA TSAI, SHUO-TING YOU, Department of Physics, National Sun Yat-Sen University, Kaohsiung, Taiwan, SEAN WU, Department of Electronics Engineering and Computer Sciences, Tung-Fang Institute of Technology, Kaohsiung, Taiwan — The non-polar gallium nitride (GaN) film is a potential candidate for high-efficient optoelectronic devices. This study reports the characterization of GaN grown on aluminum nitride (AlN) buffer layer by plasma-assisted molecular-beam epitaxy (PA-MBE). The AlN buffer layer containing both c-plane and M-plane AlN was grown by RF magnetron sputter on a sapphire substrate before growing GaN. The growth direction of GaN is [1$\underline{1}$00] oriented (M-plane) instead of [0001] oriented (c-plane). It was found that the c-plane GaN disappeared for higher growth temperature and the zinc-blende GaN appeared. The band gap was changed when we tuned III/V ratio. The crystal characteristics of GaN films for different growth parameters were studied by scanning electron microscopy (SEM), transmission electron microscopy (TEM),photoluminescence (PL), X-ray diffraction (XRD),and reflection high-energy electron diffraction (RHEED).

[1]This project is supported by National science council of Taiwan (NSC101-2112-M-110-006-MY3).

Q1.00240 Characterization of c-plane GaN epi-flim Grown on $LiGaO_2$ substrate by Plasma-assisted Molecular Beam Epitaxy[1]

, SHUO-TING YOU, CHEN-HUNG SHIH, IKAI LO, YING-CHIEH WANG, CHEN-CHI YANG, Department of Physics, National Sun Yat-Sen University, Kaohsiung 80424, Taiwan, R. O. C, MITCH CHOU, Department of Materials and Optoelectronic Science, National Sun Yat-Sen University, Kaohsiung 80424, Taiwan, R. O. C — $LiGaO_2$ (001) is a nearly lattice-matched substrate for growth of **c**-plane GaN film. However, $LiGaO_2$ single crystal has multi-domains defect on $LiGaO_2$ (001), ie. metal domain and oxygen domain. In this work, we have studied the growth mechanism of **c**-plane GaN on two domain areas by plasma-assisted molecular beam epitaxy. We found that the growth mechanism of **c**-plane GaN on $LiGaO_2$ (001) was in the form from 3D to 2D evaluated by the observation of in-situ reflection high energy electron diffraction (RHEED). According to RHEED and TEM analyses, we found that zinc-blend GaN islands were formed at early growth stage. The surface morphology of GaN grown on two domains was observed by AFM image which showed that the GaN grown on the metal domain was flat. The luminescence properties of the GaN grown on two-domain $LiGaO_2$ were also analyzed by phtonluminescence and cathodoluminecence, which also showed that the **c**-plane GaN grown on metal domain has better luminescence property than that grown on oxygen domain. Our study indicates that metal domain $LiGaO_2$ (001) is suitable to grow high quality **c**-plane GaN.

Q1.00241 Characterization of textitM-plane GaN thin film grown on pre-annealing β-$LiGaO_2$ (100) substrate[1]

, CHENG-DA TSAI, CHENG-HUNG SHIH, IKAI LO, YING-CHIEH WANG, CHEN-CHI YANG, YU-CHIAO LIN, Department of Physics, National Sun Yat-Sen University, Kaohsiung, Taiwan, R.O.C, MITCH M.C. CHOU, Department of Materials and Optoelectronic Science, National Sun Yat-Sen University, Kaohsiung, Taiwan, R.O.C — We used the plasma-assisted molecular-beam epitaxy to grow the M-plane GaN thin films on β-lithium gallate, β-$LiGaO_2$, which had been annealed in vacuum and in air ambient. With the X-ray diffraction analysis, different azimuth angles (0° and 90°) were applied in $\omega-2\theta$ scanning measurement. The signal of M-plane GaN was deviated from the normal value to be -0.147 in vacuum and -0.048 in air ambient, which showed that LGO substrate pre-annealed in air can reduce the compressive strains in the growing sample effectively. The same result was confirmed by the Raman scattering analysis. It showed that the sample pre-annealed in vacuum had E_2 phonon frequency which was shifted to 574.35 cm^{-1} due to the stress and the sample pre-annealed in air had E_2 phonon frequency which was shifted only to 568.73 cm^{-1}. In conclusion, thermal annealing of β-$LiGaO_2$ substrate in air can improve the quality of growing M-plane GaN and effectively suppresses the formation of lithium-rich surface for the growth M-plane GaN thin films on β-$LiGaO_2$ substrate.

Q1.00242 Hubbard U Calculations for Dilute Magnetic Semiconductors[1]

, TETSUYA FUKUSHIMA, Graduate School of Engineering Science, Osaka University, KAZUNORI SATO COLLABORATION, GUSTAV BIHLMAYER COLLABORATION, PETER DEDERICHS COLLABORATION, PHIVOS. MAVROPOULOS COLLABORATION, RUDOLF ZELLER COLLABORATION — Based on constrained density functional theory, we present ab initio calculations for the Hubbard U parameter of transition metal impurities in dilute magnetic semiconductors, by choosing Mn in GaN as an example. The calculations are performed by two methods: (i) the Korringa-Kohn-Rostoker (KKR) Green function method for a single Mn impurity in GaN and (ii) the Full-potentian Linear Augmented Plane-Wave (FLAPW) method for large supercell of GaN with a single Mn impurity in each cell. By changing the occupancy of the majority t_2 gap state of Mn, we determine the U parameter either from the total energy differences $E(N+1)$ and $E(N-1)$ of the $N+1$ and $N-1$ excited states with respect to the ground state $E(n)$, or by using the single particle energies for $N+1/2$ and $N-1/2$ occupancies (Janak's transition state model). Both methods give nearly identical results. Moreover the values calculated by the Green function technique and the supercell method agree quite well.

Q1.00243 Spin-polarized transmission through multiple, series-coupled Aharonov-Bohm rings

, ERIC HEDIN, YONG JOE, JAMES CUTRIGHT, Ball State University, Dept. of Physics & Astronomy — Multiple, series-coupled nanoscale Aharonov-Bohm rings with a quantum dot (QD) embedded in each arm are analyzed for their transmission and current-voltage (I-V) characteristics. A tight-binding model is used to obtain the electron transmission as a function of energy. Application of an external magnetic field is shown to produce spin-polarized transmission bands as a result of Zeeman-splitting of the QD energy levels. The band structure of the multiple-ring device is studied as a function of Zeeman splitting energy, QD energy levels, and inter-dot coupling. I-V calculations correlating to the band structure demonstrate that this device can produce highly spin-polarized current with either ohmic or semiconductor behavior, depending on the Fermi energy and the Zeeman splitting energy of the system.

Q1.00244 Enhancement of the Spin Conductance of a Magnetic Superlattice[1]

, NAMMEE KIM, HEESANG KIM KIM, Department of Physics, Soongsil University, JINWOO KIM, Research Center for Integrative Basic Science, Soongsil University — For a spin device application of a magnetic superlattice, we investigate the optimal condition to get a fully spin-polarized current with sizable ballistic conductance. We consider a quasi-one dimensional magnetic superlattice, formed by a periodic magnetic field and a split gate technique on a two dimensional electron gas system. We obtain such a condition by analyzing an energy miniband dispersion and a spin dependent transmission probability for each channel. The transfer matrix theory and Bloch's theorem are used in the detailed calculation. From the results, we propose an optimized aspect ratio of size parameters of a quasi-one dimensional magnetic superlattice as a spin filter to generate currents having simultaneous full spin-polarization and sizable ballistic conductance.

Q1.00245 The optical, electronic and magnetic properties of Fe based binaries and diluted alloys

, AHMAD ALSAAD, Department of Physics, Jordan University of Science & Technology, ISSAM ALQATTAN. DEPARTMENT OF APPLIED MATHEMATICS AND SCIENCES TEAM — The optical, electronic, and magnetic properties of binaries and alloys containing small amount of iron (Fe) have been presented. In particular, diluted Fe alloys have been examined by several experimental techniques such as magnetization measurements, nuclear magnetic resonance or neutron scattering. Theoretically, the understanding of diluted Fe alloys has not been yet satisfactorily studied. We present *ab initio* calculations based on Local Density Approximation of Density Functional Theory for Fe based binaries and Fe lightly doped alloys (not to exceed 10%) with *3d* and *4d* transition elements. Results on the densities of states, the local magnetic moments, and the electronic specific heat around the *3d* and *4d* impurities have been reported. Contrary to the case of Co, Mn, and Ni alloys. Our density of states results indicate that most of the optical, electronic and magnetic properties of Fe alloys is attributed to the majority-spin states rather than the minority-spin states. This arises from the fact that the Fermi energy falls into the minimum of the minority-spin density of states rather than the minimum of the majority-spin states. The mechanism behind this very complicated magnetic behavior of Fe based binaries and alloys have been addressed and explained. The comparison between our theoretical results and the available experimental results will be presented.

Q1.00246 Electronic Structures of the Doped Cesium Niobate $Cs_2Nb_4O_{11}$

, JIANJUN LIU, ROBERT SMITH, Department of Chemistry, University of Nebraska Omaha, Lincoln, NE 68182, LU WANG, WAI-NING MEI, RENAT SABIRIANOV, Department of Physics, University of Nebraska at Omaha, Omaha, NE 68182, HSIN-YI HSU, HSIANG-LIN LIU, Department of Physics, National Taiwan Normal University, Taipei 11677, Taiwan — Samples of the photocatalyst cesium niobate ($Cs_2Nb_4O_{11}$) have been prepared with various amounts tantalum and sulfur doped onto the niobium and oxygen sites, respectively. Tantalum doping was effected by solid-state reactions at very high temperatures. Sulfur substitution was effected by passing gaseous carbon disulfide over pure or tantalum-doped samples at elevated temperatures. The amount of sulfur substitution was controlled by varying the time and temperature of the reaction, with higher temperatures and longer reaction times affording greater substitution. Band-gap values varied in accordance with composition are compared with the density functional theory calculations and experimental techniques such as the optical reflectance spectroscopy and spectroscopic ellipsometry, and the agreement is impressive.

Q1.00247 Dielectric Polarization 1/f Noise: a signature of defect-free oxides at nanotransistors interface

, NICOLAS CLEMENT, IEMN-CNRS (France), KATSUHIKO NISHIGUCHI, NTT Basic Research Labs (Japan), DOMINIQUE VUILLAUME, IEMN-CNRS (France), AKIRA FUJIWARA, NTT Basic Research Labs (Japan) — Low frequency 1/f noise has been a well-studied method for evaluation of materials quality for devices operation. The two main sources of 1/f noise have been identified as the mobility noise (Hooge's equation) related to defects in the channel and the trapping-detrapping noise (Mc Whorter equation) related to defects in oxide at semiconductor interface. Here we show that for a 0D nanotransistor (typically 15 nm diameter and 40 nm length), dielectric polarization 1/f noise is observed at room temperature when there is no defect at interface. Such noise, derived from the fluctuation-dissipation theorem and related to the imaginary part of the capacitance (fluctuation of dipoles in oxide), has been measured in capacitors but never reported in field-effect transistors due to its lower amplitude compared to trapping-detrapping noise inducing almost 1/f curve with only 2 active traps. Since in 0D transistors the Debye screening length is larger than devices dimensions at room temperature, trapping-detrapping noise amplitude is easily determined and distinguished from DP noise. Therefore, we believe that such noise is a non-invasive and direct method for claiming the absence of defects at semiconductor-oxide interface in nanodevices and probe the dynamics of dipoles in materials at nanoscale.

Q1.00248 Physical Insight into III-Nitride Material Quality for RF Transistors Based on Delay Time Analysis

, PANKAJ SHAH, TONY IVANOV, FRANK CROWNE, TERRANCE O'REGAN, ANTHONY BIRDWELL, EDWARD VIVEIROS, US Army Research Laboratory — A delay time analysis provides valuable guidance on optimizing III-nitride high electron mobility transistors (HEMTs). The procedure involves extracting an RF lumped element compact model with parasitics. We will present trends observed for different III-nitride HEMTs. One case indicated an AlGaN/GaN structure with a thin GaN channel layer on a thicker low aluminum AlGaN buffer exhibited lower total carrier delays (2.48 ps) in the saturation region of operation (Vds between 4V and 9V) compared to a structure with a single thick GaN buffer (3.14 ps). This is related to the former structure's lower total transit time (1.88 ps vs. 2.21 ps). This result may be due to fewer defects in the thin GaN channel region grown on a thicker AlGaN buffer compare to using a single somewhat thicker GaN buffer on a thin AlGaN buffer, and a different electrostatic potential distribution due to the AlGaN acting as a back barrier. The former had a maximum intrinsic current cutoff frequency of 67 GHz vs 56 GHz for the latter. The influence of temperature which can affect carrier transport (intrinsic delay) and series resistances (charging delay) will be discussed. In-house pulsed current-voltage analysis and impedance analyzer based conductance measurements provide related information to confirm our results.

Q1.00249 Density functional calculations of point defects in InAs[1]

, JONATHAN MOUSSA, PETER SCHULTZ, Sandia National Laboratories — Standard semilocal density functionals do not generate a gap in the Kohn-Sham eigenvalues for InAs, a semiconductor with an experimental gap of 0.4 eV. Without a theoretical band gap, it becomes difficult to identify, specify, and characterize pure localized states of point defects with energy levels within the experimental band gap. The bulk band gap problem can be alleviated with screened hybrid density functionals, such as the Heyd-Scuseria-Ernzerhof (HSE) functional, that open the generalized Kohn-Sham eigenvalue gap of InAs to near the experimental value. However, even without a Kohn-Sham gap, the local moment countercharge (LMCC) method [Phys. Rev. Lett. 96, 246401 (2006)] is able to predict charge transition energy levels of localized defect states, using standard semi-local functionals. We present an LMCC-based study of standard point defects in InAs using semilocal density functionals and compare the results to HSE-based calculations to assess the validity of LMCC calculations in this situation.

[1]Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. DOE's National Nuclear Security Administration under contract DE-AC04-94AL85000.

Q1.00250 Electron relaxation via interaction with optical phonons in disordered metals and semiconductors

, ANDREI SERGEEV, MICHAEL REIZER, VLADIMIR MITIN, University at Buffalo — Using the Green function formalism we study the energy transfer from hot electrons to phonons due to interference between inelastic electron scattering on optical phonons and elastic scattering from impurities and defects. We calculated the electron-phonon relaxation time and the electron-phonon thermal conductance as a function of the electron mean free path with respect to elastic electron scattering. We also investigate concentration dependencies of the relaxation processes. The results show that while in semiconductors and in semiconductor structures the relaxation is enhanced by disorder, in metals and metallic structures the interference effect is strongly depends on vibrations of impurities and defects.

Q1.00251 Large Area Synthesis of WS_2 Crystalline Sheets Directly on SiO_2 and Their Transfer to Other Substrates

, ANA LAURA ELIAS, NESTOR PEREA-LOPEZ, The Pennsylvania State University, ANDRES CASTRO-BELTRAN, Universidad Autonoma de Nuevo Leon, AYSE BERKDEMIR, SIMIN FENG, RUITAO LV, AARON LONG, The Pennsylvania State University, TAKUYA HAYASHI, YOONG AHM KIM, MORINOBU ENDO, Shinshu University, HUMBERTO R. GUTIERREZ, University of Louisville, SUJOY GHOSH, SAIKAT TALAPATRA, Southern Illinois University Carbondale, NIHAR R. PRADHAN, LUIS BALICAS, Florida State University, FLORENTINO LOPEZ-URIAS[1], HUMBERTO TERRONES, MAURICIO TERRONES[2], The Pennsylvania State University — Metal dichalcogenides (e.g. MoS_2, WS_2, NbS_2) have attracted attention because they are layered materials that could exhibit either semiconducting or metallic properties. These properties could be significantly modified when these materials become monolayers. Here we report for the first time the synthesis of large area few-layer WS_2 by a two step method. WO_x thin films were first grown on a Si/SiO_2 substrate and these films were sulfurized in a second step. Furthermore, we have developed an efficient route to transfer these WS_2 films onto different substrates. WS_2 films of different thicknesses have been analyzed by Raman spectroscopy, HRTEM and AFM. Characterization techniques demonstrate the presence of mono-, bi- and few-layered WS_2 in the as-grown samples. The novel photoluminescence properties of the films will also be discussed.

[2]Shinshu University

Q1.00252 RuO_2/Graphene composites for super-capacitor electrodes[1]

, FATIMA AMIR, TARIQ RAMLALL, St John's University, REBECCA FOREST, University Of Houston — Metal oxides/graphene composites show significant improvement in their electrochemical proprieties compared to their individual constituents, such as high capacity, high rate capability and excellent cycling stability. Ruthenium dioxide (RuO_2) has been recognized as an important electrode material for water electrolysis, oxygen reduction, and super-capacitors. A crucial aspect of all these applications is their structural, morphological and electrical properties. We have synthesized RuO_2 from hydrolysis and oxidation of ruthenium tri-chloride $RuCl_3$, which we physically mixed to graphene and used to coat tungsten substrates. For comparison, we also have deposited commercial RuO_2 hydrate mixed with graphene on tungsten. The samples were then annealed at different temperatures. The effect of temperature has been studied in detail. Surface morphology analysis using a scanning electron microscope (SEM) shows smaller grain size at temperatures higher than 180 C. Structural properties obtained by using x-ray diffraction revealed an amorphous structure at temperatures lower than 180 C. The supercapacitance of the RuO_2/graphene electrode is found to be dependent on the surface morphology.

[1]This project was supported by the Clare Booth Luce Foundation

Q1.00253 Diameter Control of HP-Ge Crystal Growth , HAO MEI, Univ of South Dakota — Large single crystals of germanium are being grown using the Czochralski technique, in which a precisely cut seed crystal is dipped into the molten germanium and then withdrawn slowly, while maintaining the temperature of the melt just above the freezing point. Typically the seed is rotated while the crystal is being formed. The resulting crystal is typically oriented with a (100) crystal axis parallel to the growth direction. The crystal growth process is conducted in a hydrogen (H_2) atmosphere, with the H_2 flowing inside a quartz envelope. High purity germanium (HP-Ge) crystals with diameter 3 $\sim$ 9 cm are grown on weekly basis at university of South Dakota. As Czochralski growth is a dynamic process, the thermal geometry in the furnace undergoes a considerable change during the crystal growth process. A load cell was introduced to control the crystal growth process. Growing crystals with automation system is studied. In order to grow crystal automatically, the relationship between input power and crystal weight or crystal diameter is investigated. We show that HP-Ge crystal growth could be controlled automatically using software with feedback system.

Q1.00254 Surface passivation effects on the performance of p-planar HPGe radiation detector[1] , MUHAMMAD KHIZAR, GUOJIAN WANG, DONGMING MEI, University of South Dakota, South Dakota, USA — Surface passivation of HPGe detectors are always critical to reduce or eliminate the surface effects responsible for limiting both the leakage current and breakdown voltages of these devices. Among the critical part of any HPGe detector is the intrinsic surface, where the full bias voltage is applied at 77K. Typically, in order to make these surfaces electrically passive, and to avoid surface leakage currents, a thick layer of SiO2 is deposited by using different high temperature dry/wet deposition techniques. However, surface passivation using such techniques can result modifying the electric field, by compromising the charge collection in the volume near the contact surfaces. Another option is the amorphous germanium (a-Ge), which acts as a passivant as well as bi-polar blocking contacts. In this study, we have designed a controlled experiment to use Ge oxidation contact as a passivation layer by testing the electrical behavior of the crystal after each oxidation treatment. For this, a high quality a-Ge layer ($\sim$ 100 nm to 150 nm) is deposited at 1.5x10^6 torr using low temperature RF plasma sputtering deposition technique. Among the key characteristics of the deposited passivation layer includes the depositions rates, the precursors (pre-mixed (H2 $\sim$ 15% and Ar) flow rates, plasma power, chamber pressure, and target to-substrate distance. We show the results from our study using home grown HPGe crystals at USD.

Q1.00255 Performance optimization of c-Si1-xGex/Si heterostructure thin film solar cells with step-graded bandgap profile , MUHAMMAD KHIZAR, MD. AMIMUAL EHSAN, JAYESH GOVANI, DONGMING MEI, University of South Dakota, South Dakota, USA — In this paper, the performance optimization of c-Si1-xGex/Si heterostructure thin film solar cells along with the effect of step-graded absorber layer is discussed by modeling and simulation. Different cells with 1, 3, 5 and 7μm thick step-graded layers of p-type c-Si1-xGex on top of 20μm p-Si buffer layer are simulated. A comparative study of the thin film solar cell structures with and without a step-graded absorption layer is also performed. Some of the key characteristics such as short-circuit current density (Jsc), open circuit voltage (V_{OC}), and fill factor (FF) are calculated for varying concentration of Germanium (Ge) in c-Si1-xGex graded layer. With the optimized Ge concentration in the step-graded layer, significant enhancement in the overall efficiency of the solar cells has been calculated. The effect of thickness variation of alloyed layer for varying Ge composition $\sim$ 0.1—10% has also been carried out. Finally, the cell performance is calculated on the bases of current density–voltage characteristics curves and external quantum efficiency. We found that the optimized graded cell structure with larger Ge fractions was responsible for a higher magnitude and smaller thickness dependence of the short circuit current density. This is attributed due to the larger absorption coefficient that increases optical carrier generation in the near surface region for larger Ge contents. Further studies for the band-gap engineering of this step-graded absorber layer is still being performed.

Q1.00256 Magneto-transport measurement in BiTeI single crystal[1] , CHANG-RAN WANG, Institute of Physics, Academia Sinica, CHIA-TSO HSIEH, Institute of Physics, Academia Sinica, Department of Physics, National Taiwan University, RAMAN SANKAR, Center for Condensed Matter Sciences, National Taiwan University, WEI-LI LEE, Institute of Physics, Academia Sinica, GUANG-YU GUO, Graduate Institute of Applied Physics, National Chengchi University, Department of Physics , National Taiwan University, FANG-CHENG CHOU, Center for Condensed Matter Sciences, National Taiwan University, INSTITUTE OF PHYSICS, ACADEMIA SINICA TEAM, DEPARTMENT OF PHYSICS, NATIONAL TAIWAN UNIVERSITY COLLABORATION, CENTER FOR CONDENSED MATTER SCIENCES, NATIONAL TAIWAN UNIVERSITY COLLABORATION, GRADUATE INSTITUTE OF APPLIED PHYSICS, NATIONAL CHENGCHI UNIVERSITY COLLABORATION — Noncentrosymmetric BiTeI has attracted many attentions in recent years. It exhibits unusual giant bulk Rashba-type spin splitting that may have great potential in spin electronics application. Here, we show the magneto-transport measurement results in high quality BiTeI single crystals with magnetic field up to 15 Tesla. Two distinct frequencies in Shubnikov-de Hass (SdH) oscillation were observed giving extremal Fermi surface areas of A_{e1} = 9.1x10^{12} cm^{-2} and A_{e2} = 3.47x10^{14} cm^{-2}. From temperature dependence of the SdH oscillation amplitude, we determined the corresponding cyclotron masses to be m_1 = 0.036 m_e and m_2 = 0.17 m_e. Those results are in good agreement with relativistic band structure calculations showing large bulk Rashba-type spin splitting effect.

Q1.00257 Surface Reconstruction and Molecular Adsorption on Anatase TiO_2(001)-(1$\times$4) , HUIJUAN SUN, YANG WANG, JIN ZHAO, BING WANG, JINLONG YANG, JIANGUO HOU, University of Science and Technology of China, UNIVERSITY OF SCIENCE AND TECHNOLOGY OF CHINA TEAM — TiO_2 is a large band gap semiconductor with a wide range of applications including in photocatalysis, decontamination, and solar-energy conversion. Comparing to the well studied rutile phase, the anatase phase appears more common in nanocrystals and shows higher activity in photocatalysis. However, only a few literatures investigated the surface structure of anatase(001), which is assumed to be the origin of anatase's high reactivity, due to its thermodynamic instability and the difficulty in obtaining high quality samples. In the present work, reconstructed anatase TiO_2(001)(1$\times$4)surface has been investigated by atomic resolved STM together with the first-principles calculations. Two types of defects were found on the surface, which appear as dark spots and bright spots. The adsorption behavior of H_2O, O_2 and CO_2 molecules were studied. Surprisingly, it was found that all the molecules only adsorbed on the defect sites, which is against to the current understanding of the high activity of anatase (001) surface. Based on first-principles calculations we provide a new structure model of O saturated TiO_2 (001) (1$\times$4) surface, which behaves inactive in photocatalysis.

Q1.00258 Characterization of Terminal Hydroxyl on TiO2(110) Surface , QIJING ZHENG, HAO FENG, SHIJING TAN, JIN ZHAO, BING WANG, JINLONG YANG, JIANGUO HOU, University of Science & Technology of China, UNIVERSITY OF SCIENCE & TECHNOLOGY OF CHINA TEAM — TiO_2 is important in a wide variety of applications, among which is the water splitting and hydrogen production. However, as an important intermediate product of H_2O splitting, terminal hydroxyl has not been well studied. In the present work, we have used STM together with first-principles calculations to investigate the terminal hydroxyl, ie., the hydroxyl adsorbed on 5 coordinated Ti atom. At 77K the STM image shows a fuzziness feature, which is associated with a high conductance and a low conductance state in the I-V spectral. Based on the first-principles calculations, we assign this feature to proton hopping between bridge oxygen and terminal oxygen with a hopping barrier of 0.29 eV. The hopping rate under various applied biases and the current follow a power-law: R $\sim$ I^N, which implies an inelastic electron tunneling process. Moreover, the hopping rate increased exponentially with increasing biases, reminiscent of thermal excited Arrhenius relation, while in our case it is hot electron excitation.

Q1.00259 Ultrafast coherent acoustic and optical phonon dynamics of amorphous $Ge_2Sb_2Te_5$ thin films

, MIN JU SHIN, DONG HAK KIM, DAEYOUNG LIM, Kyung Hee University — The coherent acoustic and optical phonon dynamics of $Ge_2Sb_2Te_5$ (GST) thin films are investigated by pump-probe spectroscopy. The transient reflectivity changes with oscillation period on the order of sub-picosecond and tens of picoseconds were observed. The longer oscillation with oscillation period and dephasing time on a time-scale of tens of picoseconds hasn't been reported previously and can be consistently explained by coherent acoustic phonon generation in the form of a stain pulse propagating into substrate. The shorter period oscillations correspond to coherent optical phonon A_1 mode by displacive excitation of coherent phonon mechanism. Its temperature dependent frequency shift was due to a three-phonon anharmonic decay, while its dephasing was dominated by temperature independent phonon-defect scattering. Laser fluence-dependent coherent optical phonon A_1 mode softening and a dephasing rate increase were observed and attributed to the high density electrons and accompanying lattice distortion as well as to the lattice heating.

Q1.00260 Obsavation of amorphous InGaZnO by aberration corrected transmission electron microscope

, TAKAHIRO SUZUKI, KUNIO TAKAYANAGI, Tokyo Institute of Technology; Crest, JST — Transparent amorphous oxide semiconductors (TAOSs) such as amorphous InGaZnO (a-IGZO) have been receiving a good deal of attention [1,2]. High conductivity of TAOSs is understood by the overlap between metal s- orbitals, where metals locate at oxygen octahedral sites. We investigated local order of metals by transmission electron microscopy in which electron phases are well adjusted using aberration correctors up to the wave vector of $2\pi/50$ pm. Auto correlation of high resolution electron micrographs of a-IGZO thin films showed the first nearest neighbor metal-metal distance. Metal-metal distance depends on the overlapping between the s-orbitals, so that such structural information helps characterization of electron mobility of TAOSs.

Q1.00261 Zero-point motion and temperature effects on the band gap of semiconductor nanoclusters

, GABRIEL BESTER, P. HAN, Max-Planck-Institut für Festkörperforschung, Heisenbergstraße 1, 70569 Stuttgart, Germany — We calculate the band gap renormalization of semiconductor nanoclusters, avoiding the large computational costs associated with the calculations of the self-energy (Fan) and the Debye-Waller terms. This approach allows us to address clusters with a few hundred atoms. For Silicon nanoclusters, we obtain a band gap reduction of hundreds of of meV associated with the quantum zero point motion. This reduction rapidly increases with decreasing cluster size. Based on the Bose-Einstein distribution, we further study the temperature dependence of the band gap in semiconductor nanoclusters and find a band gap shift of -580 meV and -270 meV when going from T=0 to room temperature for silicon clusters with radius of 9.6 and 11.9 Å, respectively. Furthermore, we find that the band gap renormalization of semiconductor nanoclusters is dominated by the optic-like vibrational modes with Γ_4 point group symmetry.

Q1.00262 Calculation of Energy States for Multi-Layer GaAs-AlGaAs Semiconductor Laser

, CHIN-SHENG WU, Yuan Ze University — .Semiconductor laser operation requires high frequency performance. Multi-layer Quantum wells are effective prameters in semiconductor lasers because they allow some extra degree of freedom in the design of the desired emitted wavelength through adjustment of the wells numbers in addition to width w around 15 nm and barrier height V around 300 meV. Those wells are to provide the potential term of the Schrödinger equation Dispersion relation between the energy and wave number increases the first term of the Schrödinger equation, which is the kinetic energy. Hence dispersion relations in conduction band and valence band are applied for the effective mass approximation. We also add the exchange-correlation energy into the Schrödinger equation. Alternating GaAs-AlGaAs layers produce a variety of energy states. Transitions among states are related to laser frequencies. Because of the presence of multi-layer quantum wells the electrons have discrete energies and these appear as peak in the absorption measurements.

Q1.00263 Tunable Band Gap of Boron Nitride Interfaces under Uniaxial Pressure[1]

, ELIZANE MORAES, TAISE MANHABOSCO, ALAN DE OLIVEIRA, RONALDO BATISTA, Federal University of Ouro Preto — In this work we show, by means of a density functional theory formalism, that the interaction between hydrogen terminated boron nitride surfaces gives rise to a metallic interface with free carries of opposite sign at each surface. A band gap can be induced by decreasing the surface separation. The size of the band gap changes continuously from zero up to 4.4 eV with decreasing separation, which is understood in terms of the interaction between surface states.Due to the high thermal conductivity of cubic boron nitride and the coupling between band gap and applied pressure, such tunable band gap interfaces may be used in high stable electronic and electromechanical devices. In addition, the spacial separation of charge carries at the interface may lead to photovoltaic applications.

Q1.00264 Bending strain induced exciton fine-structure splitting and shift in bent ZnO microwires

, XUEWEN FU, QIANG FU, ZHIMIN LIAO, XINLI ZHU, JUN XU, School of physics, Peking University, Beijing, China, HANCHUN WU, CRANN and School of Physics,Trinity College Dublin, Dublin, Ireland, ZHUHUA ZHANG, WANLIN GUO, Institute of Nano Science, Nanjing University of Aeronautics and Astronautics, Nanjing 210016, P. R. China, Nanjing, China, DAPENG YU, School of physics, Peking University, Beijing, China — Bending Strain causes rich physical phenomena, such turning the mechanical energy into electricity in nanowire nano-generators by Z. L. Wang, significant modification of the emission energy of semiconductor micro/nanowire materials up to 100 meV, and enhancement of the light emission intensity up to 17 times of the LEDs etc.. Here, we investigate for the first time the exciton spectra evolution in bent ZnO microwires along the radial direction via high spatial/energy resolution cathodeluminescence spectroscopy at 5.5 K. Our experiments show that the exciton peak splits into multi fine peaks towards the compressive part while retains one peak in the tensile part and the emission peak displays a continuous blue-shift from tensile to compressive edges. In combination with first-principles calculations, we show that the observed near-band-edge emission splitting in compressive side is due to the valence band splitting by compressive strain and the absence of peak splitting in the tensile part maybe due to the highly localized holes in the A band and the carrier density distribution across the microwire by piezoelectric effect induced electric field. Our studies may pave the way to design nanophotonic and electronic devices using bent ZnO nanowires.

Q1.00265 Applications of the Reduced-Density-Matrix Description to Electronic Relaxations in Solids and Nanostructures Due to Scattering by Phonons[1]

, ALEX KUTANA, Rice University, VERNE JACOBS, Naval Research Laboratory — We show some examples of the application of our reduced-density-matrix description to electronic relaxations in solids and nanostructures. We carry out first-principles calculations for the relaxations of excited electrons due to scattering by phonons, using density functional theory (DFT), ab initio electronic structure methods, and reduced-density-matrix theory (RDMT) in the isolated-line and short-memory-time (Markov) approximations. Our description allows calculating properties related to the dynamical behavior of electrons in these systems without using any of the customary approximations. The main ingredients in these calculations – electronic energy levels, dipole-transition matrix elements, and analytical electron-phonon coupling matrix elements – are obtained entirely from first principles. In this work, we apply the theory to study the behavior of electrons and holes in the bulk phase as well as at the interface between two nanoscale materials. We evaluate carrier lifetimes and quantify charge and energy transfer in these systems. We also calculate line widths and shifts that are then used to construct theoretical linear absorption spectra, which are compared with experimental results.

Q1.00266 Reduced-Density-Matrix Approach for the Spectral Description of Multi-Photon Processes in Quantized Many-Electron Systems[1]

, VERNE JACOBS, Naval Research Laboratory, ALEX KUTANA, Rice University
— A reduced-density-matrix description is developed for the evaluation of the frequency-dependent transition rates for multi-photon processes in quantized many-electron systems. Our objective is to provide a fundamental foundation for systematic spectral simulations for atomic, molecular, and solid-state systems. A perturbation expansion of the frequency-domain Liouville-space self-energy operator is employed to evaluate the spectral-line widths and shifts in the isolated-line and short-memory-time (Markov) approximations. The lowest-order contributions from environmental electron-photon and electron-phonon interactions are systematically taken into account. The proposed description is directly applicable to dynamical processes in a variety of systems, including semiconductor, photochemical, and biological, without further approximations. In particular, our description can be applied to investigate the dynamical behavior of electrons in bulk and nanoscale semiconductor materials entirely from first principles, using the density functional formalism and existing electronic structure codes.

Q1.00267 Microscopic charge fluctuations in hexagonal boron nitride[1]

, ADELA NICOLAEV, University of Bucharest, Faculty of Physics, Materials and Devices for Electronics and Optoelectronics Research Center, CLAUDIA RODL, GIULIA PEGOLOTTI, RALF HAMBACH, LUCIA REINING, Laboratoire des Solides Irradies, UMR 7642, CNRS-CEA, Ecole Polytechnique, F-91128 Palaiseau, France and European Theoretical Spectroscopy Facility, STEFAN ANTOHE, University of Bucharest, Faculty of Physics, Materials and Devices for Electronics and Optoelectronics Research Center
— We present an ab initio approach to the electron dynamics through the calculation of the total polarizability matrix, including the off-diagonal elements. The charge density induced in a system by an external perturbation is computed in real space and time, following the idea of Abbamonte et al. The difference between our approach and the one from Ref. [1] is that we can calculate not only the diagonal response χ(q,q,ω), but also the off-diagonal elements of the matrix χ(q,q',ω). Hence, we have access to the microscopic charge oscillations which are induced by the local-field effects. We have studied these charge oscillations at various frequencies comprising interband-transition and plasmon-excitation energies. The real-space approach allows us to see which electrons (or orbitals) contribute to which kind of excitation. The final goal is to offer theoretical support and benchmark to future inelastic x-ray scattering experiments that may measure also the off-diagonal elements of the polarizability. The method is applied to hexagonal boron nitride (h-BN) which is the most stable of the three existing structures (hexagonal, cubic, and wurtzite) at room temperature and ambient pressure.

Q1.00268 Infrared optical properties of Mn1.56Co0.96Ni0.48O4 thin films prepared by chemical solution deposition[1]

, YANQING GAO, ZHIMING HUANG, YUN HOU, JING WU, WEI ZHOU, LEIBO ZHANG, JUNHAO CHU, Shanghai Institute of Technical Physics
— Mn1.56Co0.96Ni0.48O4 (MCN) films have been prepared on Al2O3 substrate by chemical solution deposition method. X-ray diffraction and microstructure analyses show a cubic spinel structure and the thickness of the films is 2.12 μm. Mid-infrared optical properties of MCN films have been investigated using transmission spectra and infrared spectroscopic ellipsometry. The transmission spectra can roughly be divided in two regions: a transparent oscillating one at longer wavelength and a strongly absorbing one for wavelength less than 2.2 μm. The optical band gap of the MCN film has been derived to be 0.64 eV by assuming a direct transition between valence and conduction bands. The optical constants and thickness of the thin films have been obtained by fitting the measured ellipsometric parameter data with classical infrared model. The refractive index n of the MCN films decreases as the wavelength increases, but the extinction coefficient k monotonously increases in the wavelength range of 2-7 μm. The maximal n value is 2.63, and the maximal k value is only 0.024. The above results are instructive for the applications of MCN films in infrared detecting.

Q1.00269 Carrier recombination in m-plane GaN thin films

, ZHI-XUAN TZENG, Department of Physics, National Kaohsiung Normal University, YAN-ZHI TZENG, Department of Physics, National Sun Yat-sen University, MENG-EN LEE, Department of Physics, National Kaohsiung Normal University, IKAI LO, DER-JUN JANG, Department of Physics, National Sun Yat-sen University
— We report the ultrafast time-resolved photoluminescence (TRPL) study of m-plane GaN thin films grown on γ-LiAlO$_2$ substrates by molecular beam epitaxy. The TRPL was measured by a time-correlated single-photon counting instrument with temporal resolution of 150 ps using laser pulses of energy 4.5 eV from a Ti:sapphire laser. Two major PL peaks were found in all the three GaN samples with different N/Ga ratios. The PL contributed by the bandgap recombination was found first blue-shift below 100 K and then red-shift as temperature increases. We found that the internal quantum efficiency as well as the nonradiative recombination rate decreased with N/Ga ratio may be due to the large defect concentration in high N/Ga ratio. The radiative recombination rate was constant below 100 K in all samples and was dependent on temperature with T.$^{-3/2}$ The temperature dependence of radiative recombination time is consistent with theoretical prediction. The carrier localization, for both holes and electrons, is responsible for the blue-shift in PL spectra and constant of radiative rates below 100 K.

Q1.00270 The carrier recombination of InGaN/GaN MQW LED

, CHING-LIANG LIN, SHAN-FU WANG, ZHI-XUAN CHEN, DER-JUN JANG, Department of Physics, National Sun Yat-sen University, MENG-EN LEE, Department of Physics, National Kaohsiung Normal University
— The radiative and nonradiative recombination of InGaN/GaN multi-quantum well light emitting diode was studied by a time-correlated single-photon counting apparatus with temporal resolution of 150 ps using laser pulses of energy 4.5 eV from a Ti:sapphire laser. The energy of the PL peak intensity was found to be blue-shift below 100 K and become red-shift with increasing temperature. Activation energies of 11 and 109 meV were found by fitting the temperature dependent PL intensity with the Arrhenius equation. These two activation energies are associated the hole and electron delocalization. The recombination lifetime was found to decrease with photon energy. The radiative recombination lifetime was found to be constant below 100 K and this observation is related to the S-shape behavior in temperature dependent PL spectrum, which is attributed to the formation of triangular potentials at the valence and conduction bands. The radiative lifetime, after 100 K, increases with temperature by T.$^{3/2}$ The nonradiative recombination is insignificant at low temperature and is dominated at temperature above 200 K.

Q1.00271 Electronic and optical properties of hexagonal boron nitride thin films

, Y. CHEN, B. CAI, M.L. NAKARMI, Department of Physics, Graduate Center and Brooklyn College - CUNY, R.C. RAI, Department of Physics, SUNY College at Buffalo
— We report the surface, structural, electronic, and optical properties of hexagonal boron nitride (h-BN) thin films grown on (0001) sapphire substrate by an electron-beam deposition technique. The h-BN thin films have been deposited in nitrogen environment and post-deposition annealed to improve the stoichiometry and the crystalline quality. Atomic force microscopy, x-ray diffraction, optical spectroscopy, and Hall-effect measurement were employed to characterize the h-BN thin films. We carried out temperature dependent transmittance measurements (78 – 450 K and 190 – 3000 nm) on the h-BN thin films in order to investigate the optical properties and the temperature dependence of the energy band gap. The optical data below the energy band gap have been modeled with the Urbach effect and a free exciton. We present the temperature dependence of a free exciton and the energy gap of undoped h-BN thin films. The results will be compared with photoluminescence measurements. We will also present the results of Mg-doped h-BN thin films in an effort to make p-type h-BN.

Q1.00272 Calculation of the gap in $Ce_{1/3}NbO_3$, PABLO DE LA MORA, Facultad de Ciencias, JOSE FRANCISCO GOMEZ GARCIA, Facultad de Quimica, GUSTAVO TAVIZON, Facultad de Quimica, Universidad Nacional Autonoma de Mexico — With experimental measurements, *$Ce_{1/3}$ NbO_3* was found to have a small gap of *0.25-0.78eV*. In order to find whether this gap is due to electronic origin *ab-initio DFT* (*WIEN2k*) calculations were done. To find the correct gap, the calculations were done using a modified Becke-Johnson (*mBJ*) potential. A 'conducting' *Nb-O* gap with a *Ce:4f* peak in the middle was found. In the convergence process, due to the nature of the *mBJ* potential, this *Ce:4f* interfered with the Fermi energy E_F. To avoid this problem a Hubbard U_H was added to the *Ce* atom, then it was possible to extrapolate back and obtain the correct 'conducting' *Nb-O* gap of *2eV* with the *Ce:4f* peak at *1.3eV* from the lower end of the gap. With this it can be confirmed that the conduction is not of electronic nature.

Q1.00273 Ab-Initio Study of Excitonic Absorption for Layered LaCuChO and BaCuChF (Ch={S,Se,Te}) Structures , JASON VIELMA, GUENTER SCHNEIDER, Oregon State University — Layered oxychalcogenides LnCuChO (Ln = {La,Pr,Nd}, Ch = {S,Se,Te}) and isostructural layered fluorochalcogenides BaCuChF have drawn much interest in recent years as p-type wide bandgap semiconductors with applications in transparent electronics and photovoltaics. Members of both materials show strong excitonic absorption, which is observable at room temperature. However, recent studies disagree on the origin and nature of the room temperature excitons in the respective families of materials, with Ueda et al. [1] attributing the room temperature excitonic absorption in LaCuSeF to 2 dimensional quantum confinement of hole carriers in the layered structure, while Zakuatyev et al. [2] argue that the room temperature excitonic absorption in BaCuChF is well described by a 3 dimensional Wannier-Mott excitonic model. We report an ab-initio computational study of the optical properties including the excitonic effects for both families of materials. The optical properties are calculated using the Bethe-Salpeter equation in the GW approximation.

[1] K. Ueda, et al. *Phys. Rev. B*, **69** 155305 (2004).

Q1.00274 Monovacancy in hcp-Zirconium , Q. PENG, W. JI, Rensselaer Polytechnic Institute, HANCHEN HUANG, University of Connecticut, XIAO-JIA CHEN, Carnegie Institution of Washington, SUVRANU DE, Rensselaer Polytechnic Institute — We investigate the stability of the monovacancy of hcp-Zirconium under various strains by examining the vacancy formation energy through density functional theory calculations. There is a maximum formation energy of monovacancy under uniaxial strain with the value of 0.094 along the c direction, corresponding to a c/a ratio of 1.75. Under volumetric strain, the formation energy decreases with respect to the increment of volumetric strain. The formation energy as a function of pressure was also examined, with a minimum value of 2.00 eV at zero pressure. The formation volume decreases with respect to the pressure, with a value of 0.6 unit-atom-volume at zero pressure particularly. The formation enthalpy increases monotonically as the pressure increases. At a pressure of -15 GPa, the formation enthalpy becomes negative and thus the system fails.

Q1.00275 The rare earth $4f$ hybridization with the GaN valence band , LU WANG, WAI-NING MEI, Department of Physics, University of Nebraska at Omaha, Omaha, NE 68182, STEVE MCHALE, JOHN MCCLORY, JAMES PETROSKY, Department of Engineering Physics, Air Force Institute of Technology, OH 45433, J. WU, RATNAKAR PALAI, Department of Physics and Institute for Functional Nanomaterials, University of Puerto Rico, San Juan, Puerto Rico 00931, YAROSLAV LOSOVYJ, The J. Bennett Johnston Sr. Center for Advanced Microstructures and Devices, Louisiana State University, Baton Rouge, LA 70806, PETER DOWBEN, Department of Physics and Astronomy, University of Nebraska-Lincoln, Lincoln, NE 68588 — The placement of the Gd, Er, and Yb 4f states within the GaN valence band has been explored by both experiment and theory. The $4d - 4f$ photoemission resonances for various rare earth doped GaN thin films (RE = Gd, Er, Yb) provide an accurate depiction of the occupied $4f$ state placement within the GaN. The resonant photoemission show that the major Er and Gd rare earth $4f$ weight is at about 5-6 eV below the valence band maximum, similar to the $4f$ weights in the valence band of many other rare earth doped semiconductors. For Yb, there is very little resonant enhancement of the valence band of Yb doped GaN, consistent with a largely $4f^{14-\delta}$ occupancy. The placement of the rare earth $4f$ levels is in qualitative agreement with theoretical expectations.

Q1.00276 MAGNETISM –

Q1.00277 Competition between the screening effect and exchange interactions in the system $CeCu_{1-x}Al_xGe$[1] , W.H. LEE, J.R. LEE, H.H. SUNG, K.J. SYU, S.C. CHEN, Department of Physics, National Chung Cheng University, W. H. LEE TEAM — As revealed in the powder x-ray diffraction and crystallographic data, the single phase sample in the series $CeCu_{1-x}Al_xGe$ ($0.1<x<0.5$) crystallizes in the $PuGa_2$-type structure with space group P6/mmm. The substitution of Cu by Al in $CeCu_{1-x}Al_xGe$, which increases the average conduction electron density, was found to be able to attenuate the localized Ce-4f moments. As determined from the electrical-resistivity and magnetic susceptibility measurements, both the ferromagnetic transition temperature T_c value and the magnitude of the saturation moment in the series $CeCu_{1-x}Al_xGe$ reflect the decreasing strength of exchange interactions with the Al concentration. These results suggest that the screening effect surpasses the RKKY interactions in this system.

Q1.00278 Measuring nontrivial fusion rule of Majorana fermions in inhomogeneous transverse Ising chain , YAN CHEN, YINCHEN HE, Fudan University, China — We describe various dynamical processes aimed to create and fuse Majorana fermions in an inhomogeneous Kitaev's wire. We show that, with the undesired excitations suppressed by inhomogeneity, fusion of Majorana fermions will result in universal measurable excitations, which can serve as a direct verification of Majorana fermions fusion rule. Moreover, we design a protocol to detect the oscillatory tunneling between two unpaired Majorana fermions. Most remarkably, our proposal is valid for transverse Ising chain, which provides a promising way to test nontrivial properties of Majorana fermions experimentally.

Q1.00279 Magnetic structure of $BiFeO_3$, V. KIRYUKHIN, M. RAMAZANOGLU, S. LEE, S-W. CHEONG, Rutgers University, W. RATCLIFF, M. LAVER, NIST, J.G. PARK, Seoul Natl. Univ. — Neutron scattering studies of the magnetic structure of single-crystalline $BiFeO_3$ are presented. Temperature dependence of the magnetic order parameter, the anharmonicity of the magnetic cycloid, and the small tilt of the spins out of the cycloid plane (local weak ferromagnetism) are discussed. Inelastic neutron scattering measurements of the microscopic magnetic coupling constants are also presented.

Q1.00280 Dynamic decay of single vortex into vortex-antivortex tuples , SHIKHA JAIN, VALENTYN NOVOSAD, Materials Science Division, Argonne National Laboratory — A variety of metastable states, including vortices, antivortices, and their combinations is typical for magnetically-soft thin films and patterned structures. Physics of individual spin vortices in patterned structures has been rather extensively explored. In contrast, there are only few studies of vortex – antivortex – vortex (v-av-v) system, in a part because v-av-v is rather difficult to obtain in experimental samples. In this work we will demonstrate how a recently proposed resonant-spin-ordering technique can be used to induce the dynamic decay of a single vortex into vortex-antivortex states in elongated elements. The approach is based on driving the system from the linear regime of constant vortex gyrations to the non-linear regime of vortex-core reversals at a fixed excitation frequency. Subsequently reducing the excitation field to the linear regime stabilizes the system into v-av-v state that is completely decoupled from the initialization excitation frequency. Newly acquired v-av-v state is a stable state in remanence, is characterized by a number of collective excitation modes, depending on the combination of the vortex core polarities, and/or the excitation field direction.

Q1.00281 Percolation transition in quantum Ising and rotor models with sub-Ohmic dissipation[1]

, MANAL AL-ALI, Missouri University of Science and Technology, JOSÉ HOYOS, Instituto de Física de São Carlos, Universidade de São Paulo, THOMAS VOJTA, Missouri University of Science and Technology — We investigate the influence of sub-Ohmic dissipation on randomly diluted quantum Ising and rotor models. The dissipation causes the quantum dynamics of sufficiently large percolation clusters to freeze completely. As a result, the zero-temperature quantum phase transition across the lattice percolation threshold separates an unusual super-paramagnetic cluster phase from an inhomogeneous ferromagnetic phase. We determine the low-temperature thermodynamic behavior in both phases which is dominated by large frozen and slowly fluctuating percolation clusters. We relate our results to the smeared transition scenario for disordered quantum phase transitions, and we compare the cases of sub-Ohmic, Ohmic, and super-Ohmic dissipation.

[1]This work has been supported in part by the NSF under grant no. DMR-0906566, by FAPESP under Grant No. 2010/ 03749-4, and by CNPq under grants No. 590093/2011-8 and No. 302301/2009-7.

Q1.00282 Effect of Crystal Fields in $Ho_{1-x}Dy_xNi_2B_2C$

, W.C. LEE, Dept. of Physics, Sookmyung Women's Univ. Seoul 140-742, Korea — From the anisotropy and the temperature dependence of magnetic susceptibilities of $Ho_{1-x}Dy_xNi_2B_2C$ system with magnetic field H perpendicular or parallel to c-axis, the crystalline electric field (CEF) effect has been studied and the magnetic exchange interaction constant J_{ex} of rare-earth ions perpendicular to the c-axis estimated for 0 $\leq$x$\leq$1. The crystalline electric field parameter, B_{02}, the first Steven parameter and the most dominant term in this system, are determined from the high-temperature-limit anisotropic Weiss temperatures of the magnetic susceptibilities and there is a broad minimum around x $\sim$ 0.3, where superconducting transition temperature, T_C, and Néel temperature, T_N, are almost same.

Q1.00283 A mean-field study of the Hubbard model on the anisotropic kagomé lattice

, MATTHEW ENJALRAN, Southern Connecticut State University — The study of material and model systems with the kagomé lattice structure has been an active area in the field of frustrated magnetism for decades. Formed from a 2D network of corner sharing triangles, the kagomé lattice can be realized as well separated planes in materials with large moments (jarosites, S=5/2) and quantum spins (herbertsmithite, S=1/2) or as a derived lattice structure, for example in pyrochlore spin ice materials in the presence of a external field along the [111] crystallographic direction. Numerous magnetic model Hamiltonians have been applied to the kagomé lattice and studied via a range of theoretical and numerical techniques. Much has been learned about new phases of matter from these works, and interest in these systems continues to grow. However, comparatively less is known about the possible low temperature phases of correlated electrons on the kagomé lattice. Hence, we study the single band Hubbard model on the kagomé lattice using mean-field theory. We allow for anisotropic hopping in order to study the effects of variable frustration on the low temperature phases of the model and for comparison to materials with distorted kagomé structures. We present preliminary results from our work.

Q1.00284 Entanglement Entropy of zig-zag spin chains with Ring Exchange

, JON SPALDING, California State University, Northridge — In the study of interacting quantum spin chains, the ground state wavefunction carries information about the phases of matter that occur for different interaction parameters. In this case, a spin-1/2 chain with 3 interaction terms in the Hamiltonian–nearest neighbor, next nearest neighbor, and ring exchange, is investigated using entanglement entropy to map out a ground state phase diagram. In addition, further information can be obtained from the entanglement spectrum. Finally, preliminary investigations of the effects of an impurity on this triangular Heisenberg ladder are reported.

Q1.00285 Theoretical Study of Anisotropic Magnetoresistance Effect: Magnetization Direction Dependence in Ferromagnet with Crystal Field of Cubic Symmetry

, SATOSHI KOKADO, Faculty of Engineering, Shizuoka University, MASAKIYO TSUNODA, Graduate School of Engineering, Tohoku University, FUJUN YANG, Faculty of Physics and Electronic Technology, Hubei University, YUYA SAKURABA, KOKI TAKANASHI, Institute for Materials Research, Tohoku University, KIKUO HARIGAYA, Nanosystem Research Institute, AIST, AKIMASA SAKUMA, Graduate School of Engineering, Tohoku University — We theoretically study the magnetization direction dependence of anisotropic magnetoresistance (AMR) effect of a ferromagnet with a crystal field of cubic symmetry. We first extend our theoretical model [1] to a model including the crystal field effect. Using the model, we next obtain an analytical expression of the AMR ratio; that is, $\mathrm{AMR}(\theta)=C_0+C_2\cos(2\theta)+C_4\cos(4\theta)$, where θ is the relative angle between the magnetization direction and the electric current direction. The coefficients C_0, C_2, and C_4 are expressed by a spin-orbit coupling constant, an exchange field, a crystal field, and s-s and s-d scattering resistivities. Using this expression, we analyze the following experimental results for Fe_4N [2] and Co_2MnSi Heusler alloy [3]: As for Fe_4N [2], $|C_2|$ and $|C_4|$ increase with decreasing temperature. In contrast, Co_2MnSi Heusler alloy [3] has a small temperature dependence of C_2 and $C_4 \sim 0$.

Q1.00286 ABSTRACT WITHDRAWN –

Q1.00287 High-field magnetization studies of spin-dimer behaviors on low-dimensional spin systems, $LiCu_{2-x}Zn_xO_2$ and $FeTe_3O_7X$ (X = Cl, Br)

, J.L. HER, Division of Natural Science, Chang Gung University, Taiwan, H.C. HSU, Institute of Physics, Academia Sinica, Taiwan, Y.H. MATSUDA, K. KINDO, Institute for Solid State Physics, The University of Tokyo, Japan, C.C. CHOU, H.D. YANG, Department of Physics, National Sun Yat-Sen University, Taiwan, H. BERGER, Institutes of Physics of Complex Matter, EPFL, Lausanne, Switzerland, F.C. CHOU, Center for Condensed Matter Sciences, National Taiwan University, Taiwan — High-field magnetization of two kinds of low-dimensional spin system was studied in pulsed magnets. Several anomalies were clearly observed in dm/dH curves of doped $LiCu_{2-x}Zn_xO_2$ (x = 0.07) at low temperatures (1.3 K $< T <$ 20 K). When temperature decreases, the anomalies sharper / splits at certain critical temperatures which are related to the formation of isolated spin-dimer and spin freezing state. A field-induced spin density wave state was suggested to exist at high magnetic fields. The doping of Zn^{2+} ions breaks the spin-chain of Cu^{2+} ions, leading to the formation of isolated spin-dimers and lowering the critical field of formation of spin density state. The magnetization process measurements were preformed on another series of samples, $FeTe_3O_7X$ (X = Cl, Br), which has spin-dimer, formed by Fe^{3+} ions, at low temperatures and magnetic fields up to 100 T. At low temperatures, the magnetization processes show four step-like structures, which have nearly equal spaces of 25 T. Both samples show similar behavior. These steps are considered to be the magnetic excitation of the antiferromagnetic spin-dimers.

Q1.00288 Giant magnetic moment in Mn11Si19 microparticles at room temperature

, KIYOTAKA HAMMURA, Hitachi Cambridge Laboratory, University of Cambridge, HARUHIKO UDONO, TOMOSUKE AONO, Ibaraki University — Following our previous paper reporting enhancement of magnetic moment in powder Mn11Si19 ($\sim$30 microns in diameter), we report here on magnetic moment for smaller particles ($\sim$5 microns in diameter) at 5 K to 300 K. Apart from the larger particles case, magnetisation curves against field exhibit distinctive features of soft magnetic materials over the whole range of temperatures. We observed a sort of superparamagnetism in non-nanoparticles.

Q1.00289 Thermal-magnetic-electric oscillator based on spin-valve effect , HEE CHUL PARK, Korea Institute for Advanced Study, Seoul, Korea, ANATOLY M. KADIGROBOV, Theoretische Physik III, Ruhr-Universitat Bochum, Germany, S. ANDERSSON, Nanostructure Physics, Royal Institute of Technology, Stockholm, Sweden, DANKO RADIC, Department of Physics, Faculty of Science, University of Zagreb, Zagreb, Croatia, ROBERT I. SHEKHTER, MAT JONSON, Department of Physics, University of Gothenburg, Goteborg, Sweden, V. KORENIVSKI, Nanostructure Physics, Royal Institute of Technology, Stockholm, Sweden — A thermal-magnetic-electric valve with the free layer of exchange-spring type and inverse magnetoresistance is investigated. The structure has S-shaped current-voltage characteristics and can exhibit spontaneous oscillations when integrated with a conventional capacitor within a resonator circuit. The frequency of the oscillations can be controlled from essentially dc to the GHz range by the circuit capacitance.

Q1.00290 Resonant-spin-ordering: a new approach to dynamic control of excitation bands in interacting mesomagnets , VALENTYN NOVOSAD, SHIKHA JAIN, FRANK FRADIN, JOHN PEARSON, Materials Science Division, Argonne National Laboratory, VASIL TIBERKEVICH, ANDREI SLAVIN, Department of Physics, Oakland University, SAMUEL BADER, Materials Science Division and Center for Nanoscale Materials, Argonne National Laboratory — Two interacting vortices were used as a model system to demonstrate the resonant-spin-ordering technique for effectively controlling its magnetic states and excitation bands. This is achieved by driving the system from the linear regime of constant vortex gyrations to the non-linear regime of vortex-core reversals at a fixed excitation frequency of one of the coupled modes. Subsequently reducing the excitation field to the linear regime, stabilizes the system to a polarity combination whose resonant frequency is decoupled from the initialization frequency. The transition of the state from one polarity combination to the other is clearly evident from the contrast in the microwave absorption amplitude obtained by gradually increasing the rf-field to higher magnitudes at the resonant frequency of one of the modes and subsequently decreasing it. Hysteresis is observed in the forward and backward trace of the rf-field sweep which gives a clear signature of the mode transition. Finally, a phase diagram is built to identify the conditions necessary to choose a particular ground state configuration with respect to the amplitude and the frequency of the in-plane oscillating field.

Q1.00291 Singular behavior of plasmon and magnetostatic resonances in samples with corners[1] , RODRIGO ARIAS, Universidad de Chile — The plasmon resonances of dielectric-metallic nano-particles is a subject of interest, given their potential optical applications. Localized electrostatic fields can attain large magnitudes at specific locations and frequencies.The possibility to engineer the geometry of the particles as well as their positions in eventual arrays, may lead to meta-materials with desired optical properties. Also, we explore magnetostatic modes in the same geometry (in this geometry plasmon modes are formally special cases of magnetostatic modes). This work explores the nature of long wavelength plasmon and magnetostatic modes of nano wires with rectangular cross sections: their frequencies and shapes in this effectively 2D geometry are obtained. We use a method based on singular integral equations for the potentials in order to determine the eigenmodes and their frequencies. The modes can be classified into corner modes, and modes that oscillate inside the sample. The fields associated with the corner modes have power law singularities at the corner regions, while the modes with spatial oscillations have logarithmic singularities there. We find that numerically the eigenfrequencies are very sensitive to the right determination of the singular behavior of the fields at the corners.

Q1.00292 Study of statistics of magnetization reversal in permalloy($Ni_{80}Fe_{20}$) microwires using planar Hall effect , ARNAB ROY, P. S. ANIL KUMAR, Department of Physics, Indian Institute of Science, Bangalore 560012, India — Planar Hall effect was used to study the switching behaviour of 1mm*100micron*15nm permalloy Hall bars grown in (111) orientation on Si(100). Reversal model was Arrhenius type activation over energy barriers, $p(H) = e^{\frac{-\Delta E(H)}{k_B T}}$. The model proposed by M.P.Sharrock : $\Delta E(H) = KV\left(1 - \frac{H}{H_0}\right)^m$ with H_O =2xK/M was used to find the shape of the energy landscape for the bar undergoing reversal in an applied field. Multiple reversal paths were observed for a given wire under the same conditions, each distribution in very good agreement with the above model, allowing the calculation of : 1. Temperature dependence of the effective anisotropy constant for the bar; K(T)= (1/2)*H_oM(T) (x=1 for applied field at 0^O) 2. Energy barrier landscape: An exponent m= 1.5 to 2 is expected to leading order in the expansion of the energy barrier according to the Stoner Wolfarth model, however, our results give an exponent of 2.8 to 3 for all angles (out of plane) of the applied field for the principal reversal path, pointing to mechanisms other than coherent rotation at work. If domain wall propagation and pinning is the mechanism of reversal, this study determines the energy landscape around the pinning field.

Q1.00293 Magnetic and structural anisotropies in laser ablated epitaxial thin films of full-Heusler alloy Co_2MnSi on $SrTiO_3$[1] , HIMANSHU PANDEY, P.K. ROUT, R.C. BUDHANI[2], Indian Institute of Technology Kanpur, India — We present the thickness dependent magnetic properties of laser ablated epitaxial Co_2MnSi (CMS)Heusler alloy thin films grown on (001) oriented $SrTiO_3$ substrate. In order to study the intrinsic magnetic anisotropy, a highly ordered single crystal thin film of Heusler alloys is necessary. This provides a unique opportunity to determine the behavior of magnetization reversal, and affect important properties such as the coercive field and remanence. The two important sources of the magnetic anisotropy are the magnetic dipolar interaction and the spin-orbit interaction. The strain in films due to the lattice mismatch with the substrate affects the shape anisotropy while spin-orbit coupling changes magneto-crystalline anisotropy. We have observed an in-plane biaxial compressive strain in the films which relaxes with increasing film thickness. Although the hysteresis loops show an in-plane easy axis for all films, the single-domain phase diagram reveals a gradual transition from in-plane to out-of-plane transition of magnetization as the film thickness is decreased. The magnetization starts to cant as film thickness start to decrease and we found a canting angle of $\approx 31.8^\circ$ with respect to the film plane for our thinnest 5 nm CMS films.

Q1.00294 Fabrication of fully dense nanostructured MnBi magnet by hot compaction of cryo-milled powders[1] , GEORGE HADJIPANAYIS, VENKATA RAMARAO NEELAM, ALEX GABAY, WANG LI, University of Delaware — Recently, rare-earth-free permanent magnets (REFPMs) have attracted much attention globally owing to rare-earth metal crisis and high cost. Among the REFPMs, MnBi is a potential candidate due to its unusual large magnetocrystalline anisotropy ($K \approx 10^7$ erg/cc) and positive temperature of coefficient of coercivity. In this work, we report for the first time a novel processing method that combines the cryo-milling with hot compaction to produce fully dense bulk nanostructured MnBi magnet. The effect of cryo-milling on particle size, phase formation, and magnetic properties of MnBi has been studied in detail. Also, the microstructural and magnetic properties of bulk nanostructured MnBi magnet were investigated. Adoption of cryo-milling results in nanocrystalline powders with particle size of 400-500 nm. Large coercivity (H_c) values of 18.5 kOe, and 12.9 kOe were obtained in cryo-milled powders and hot compacted magnet respectively. The MnBi magnet shows a large positive temperature coefficient of H_c and the H_c reaches a value of more than 30 kOe above 450 K.

Q1.00295 Interfacial magnetic anisotropy in $Ta/Co_xFe_{100-x}/MgO$ films for Co compositions[1] , SUNG-MIN AHN, GEOFFREY BEACH, Massachusetts Institute of Technology — To realize promising devices for high tunnel magnetoresistance and high-efficiency current-driven domain wall (DW) motion, it is crucial to optimize perpendicular magnetic anisotropy (PMA) for Ta/Co(Fe)/MOx trilayers where M is a metal such as Al, Mg, Ta, etc. Here, the PMA in Ta/Co_xFe_{100-x} (CoFe)/MgO films for alloy compositions spanning pure Co to pure Fe has been studied in order to investigate the role of chemical composition in the onset of perpendicular magnetic anisotropy at the CoFe/MgO interface. Out-of-plane magnetization is not observed in Ta/Fe/MgO (x=0) and Ta/Co/MgO (x=100), for all ranges of CoFe thickness (t), but a t-dependent crossover between in-plane and out-of-plane anisotropy is found for x=20, 50, and 80. Interestingly, effective magnetic anisotropy K_u as well as interfacial anisotropy K_i are maximized for $Co_{50}Fe_{50}$ at a fixed t=0.8 nm. The results suggest that the degree of filling of valence bands in the CoFe adjacent to the interface, which determines the relative population of the anisotropic d-bands, plays an important role in the interfacial anisotropy brought on by CoFe-O hybridization at the metal/oxide interface.

Q1.00296 Langmuir Monolayers of Superparamagnetic Nanoparticles , GORAN DOJCINOSKI, PATRICK TRUITT, Montclair State University — The surfactant coating of the superparamagnetic nanoparticles found in ferrofluids enable them to form monolayers at the air/water interface. These monolayers can be considered quasi-two-dimensional systems where the particles are confined to a surface while their magnetizations are free to rotate in all directions. Confining the nanoparticles to a surface allows observation of structure formation that is difficult to see in a bulk, opaque ferrofluid. We investigate how different surfactants affect monolayer formation. We measure pressure-area isotherms of such systems under lateral compression in a Langmuir trough and find monolayers of oleic acid coated iron nanoparticles collapse at a surface pressure between 65-70 mN/m, while dodecanoic acid coated iron nanoparticles collapse around 50 mN/m. Other surfactants with varying lengths and structure are also investigated. Studies of monolayer stability and formation in the presence of an applied magnetic will also be presented. Finally, we transfer monolayers to solid substrates and examined their morphology via atomic force microscopy.

Q1.00297 Monodisperse Magneto-Fluorescent Bifunctional Nanoprobes for Bioapplications[1] , HONGWANG ZHANG, HENG HUANG, ARND PRALLE, HAO ZENG, SUNY at Buffalo — We present the work on the synthesis of dye-doped monodisperse Fe/SiO_2 core/shell nanoparticles as bifunctional probes for bioapplications. Magnetic nanoparticles (NP) have been widely studied as nano-probes for bio-imaging, sensing as well as for cancer therapy. Among all the NPs, Fe NPs have been the focus because they have very high magnetization. However, Fe NPs are usually not stable in ambient due to the fast surface oxidation of the NPs. On the other hand, dye molecules have long been used as probes for bio-imaging. But they are sensitive to environmental conditions. It requires passivation for both so that they can be stable for applications. In this work, monodisperse Fe NPs with sizes ranging from 13-20 nm have been synthesized through the chemical thermal-decomposition in a solution. Silica shells were then coated on the Fe NPs by a two-phase oil-in-water method. Dye molecules were first bonded to a silica precursor and then encapsulated into the silica shell during the coating process. The silica shells protect both the Fe NPs and dye molecules, which makes them as robust probes. The dye doped Fe/SiO_2 core/shell NPs remain both highly magnetic and highly fluorescent. The stable dye doped Fe/SiO2NPs have been used as a dual functional probe for both magnetic heating and local nanoscale temperature sending, and their performance will be reported.

Q1.00298 Magnetic Relaxation Mechanisms in Lanthanide Single Molecule Magnets , LIVIU CHIBOTARU, LIVIU UNGUR, University of Leuven, ERIC MCINNES, RICHARD WINPENNY, University of Manchester, UNIVERSITY OF MANCHESTER COLLABORATION — *Ab initio* investigation of multiplet spectrum of lanthanides in archetypal coordination geometries shows an unexpected regular structure consisting of (i) mirror symmetry of anisotropic magnetic properties of doublet states, (*ii*) high magnetic axiality of low-lying and high-lying doublets, comparable to complexes with ideal axial symmetry, and (*iii*) the strong rotation of the anisotropy axes of individual doublets [1]. The obtained high axiality of the ground doublet states explains the SMM behaviour of low-symmetry lanthanide complexes. *Ab initio* calculations predict that depending on the relative orientation of anisotropy axes in different doublet states, the relaxation can proceed via the first or the second excited state. Here we report new lanthanide cage complexes where two competing relaxation pathways through the first and second excited states are observed, leading to very high energy barriers for loss of magnetisation [2]. [1] L. Ungur, L.F. Chibotaru, *P.C.C.P.*, **2011**, *13*, 20086–20090. [2] R.J. Blagg, L. Ungur, F. Tuna, D. Collison, E.J.L. McInnes L.F. Chibotaru, R.E.P. Winpenny,. *Nat. Chem.*, submitted.

Q1.00299 Study on novel rare-earth nitride chlorides GdNCl and Gd_2N_2Cl , NING CHEN, XIUXIA LIU, YANG LIU, School of Material Science and Engineering, University of Science and Technology Beijing, Beijing 100083, China, YANG LI, Department of Engineering Science and Materials, University of Puerto Rico at Mayaguez, Mayagues 00681-9044, USA — We report a joint experimental and theoretical investigation of magnetic and structural properties for novel rare-earth nitride chlorides GdNCl and Gd_2N_2Cl. By using the method of gas-solid phase reaction at high temperature, a new layered rare-earth nitride chloride GdNCl was synthesized recently. The structure and morphology were characterized by X-ray diffraction and transmission electron microscope. The analysis results show that GdNCl compound has the same crystalline structure as the known phase CeNCl, which crystallized in a tetragonal structure with space group P4/nmm (No.129). The lattice constants are a = b = 4.42 nm, c = 6.46 nm. The layered structure of GdNCl is comprised of the double Gd-N layers and Cl layers. In addition, another new stable phase Gd_2N_2Cl was also synthesized. The Gd_2N_2Cl structure belongs to a tetragonal system with P4mm space group (No.99) and lattice constants are a = b = 4.25 nm and c = 5.92 nm. The temperature-dependent magnetic susceptibility measurements (ZFC and FC) were performed, which showed a ferromagnetic transition occurs at 70 K. The first-principle simulation based on the density functional theory was used to investigate the physical properties and structural stability of rare-earth nitride chlorides, which is consistent with the experiments.

Q1.00300 Magnetically Controlled Capacitor Membrane System , NATHAN FORTENBURY, JOHN HYDE, REGAN BECKHAM, RANDY BACK, The University of Texas at Tyler — The effects of electric fields on elastic membranes have been studied in detail in recent years. It is the purpose of this research to explore the effects of the interaction between magnetic fields and electric fields on these membranes with the addition of magnetic ferrofluid. Variables under consideration include strength and shape of magnetic field, concentration of magnetic ferrofluid, and voltage supplied to the membrane. Of particular interest are the stable state conditions for various parameters as well as maximum stable voltages for the same.

Q1.00301 The Effect of Variation in Permittivity of Different Tissues on Induced Electric Field in the Brain during Transcranial Magnetic Stimulation , RAVI L. HADIMANI, Iowa State University, KONSTANTIN PORZIG, Ilmenau University of Technology, LAWRENCE J. CROWTHER, Iowa State University, HARTMUT BRAUER, HANNES TOEPFER, Ilmenau University of Technology, DAVID C. JILES, Iowa State University, DEPARTMENT OF ELECTRICAL AND COMPUTER ENGINEERING, IOWA STATE UNIVERSITY TEAM, DEPARTMENT OF ADVANCED ELECTROMAGNETICS, ILMENAU UNIVERSITY OF TECHNOLOGY TEAM — Estimation of electric field in the brain during Transcranial Magnetic Stimulation (TMS) requires knowledge of the electric property of brain tissue. Grey and white matters have unusually high relative permittivities of $\sim 10^6$ at low frequencies. However, relative permittivity of cerebrospinal fluid is $\sim 10^2$. With such a variation it is necessary to consider the effect of boundaries. A model consisting of 2 hemispheres was used in the model with the properties of one hemisphere kept constant at σ_1 =0.1Sm^{-1} and ε_{r1} =10 while the properties of the second hemisphere were changed kept at σ_2 =0.1Sm^{-1} to 2Sm^{-1} and $\varepsilon_{r2} = 10^2$ to 10^5. A 70 mm diameter double coil was used as the source of the magnetic field. The amplitude of the current in the coil was 5488 A at a frequency of 2.9 kHz. The results show that the electric field, **E** induced during magnetic stimulation is independent of the relative permittivity, ε_r and varies with the conductivity. Thus the variation in **E**, calculated with homogeneous and heterogeneous head models was due to variation in conductivity of the tissues and not due to variation in permittivities.

Q1.00302 Growth and Characterization of Magnetoelectric Fe_2TeO_6 Thin Films[1] , JUNLEI WANG, JUAN COLON SANTANA, NING WU, PETER DOWBEN, CHRISTIAN BINEK, University of Nebraska — Voltage-controlled spintronics is of vital importance in information technology where power consumption and Joule heating restrict progress through scaling. Motivated by spintronic concepts and specifically by device applications utilizing electrically controlled interface or boundary magnetization (BM) in magnetic thin film heterostructures, we report on growth, structural, magnetic and magnetoelectric (ME) characterization of the antiferromagnet Fe_2TeO_6. Magnetometry of synthesized Fe_2TeO_6 powder, in combination with ME susceptibility data reveals 3D Heisenberg criticality in striking similarity to the archetypical ME chromia. X-ray diffraction shows (110) texture of the PLD grown films. Measurements of the magnetic susceptibility of the latter confirm in-plane magnetic anisotropy. X-ray photoemission spectroscopy indicates a Te-O terminated (110) surface. We interpret it in terms of surface reconstruction. Measurements of X-ray magnetic circular dichroism combined with photoemission electron microscopy support the presence of electrically controllable BM in the PLD-grown Fe_2TeO_6 thin film.

[1]We acknowledge financial support by NSF-MRSEC & Nanoelectronics Research Initiative.

Q1.00303 Anomalous electron spin decoherence in an optically pumped quantum dot , XIAOFENG SHI, University of California San Diego —

Q1.00304 Computation of the modified magnetostriction coefficient b' corresponding to different depth ranges in ferromagnetic specimens by using a frequency dependent model for magnetic Barkhausen emissions , ORFEAS KYPRIS, Department of Electrical and Computer Engineering, Iowa State University, IKENNA NLEBEDIM, DAVID JILES, 1. Department of Electrical and Computer Engineering, Iowa State University 2. Ames Laboratory, US Department of Energy, Iowa State University — We have recently shown that a linear relationship exists between the reciprocal peak voltage envelope amplitude $1/V_{peak}$ of the magnetic Barkhausen signal and elastic stress σ. By applying a frequency-dependent model [1] to determine the depth of origin of the Barkhausen emissions in a uniformly stressed steel specimen, this relationship was found to be valid for different depth ranges. The linear relationship depends on a coefficient of proportionality b'. This was found to decrease with depth, indicating that the higher part of the frequency spectrum is less sensitive to changes in stress. In this study, the model equations have been applied at various depth ranges. It was found that the variation of b' with depth can be utilized in an inversion procedure to assess the stress state in ferromagnetic specimens to give stress-depth profiles. This study is useful for non-destructive characterization of stress with depth.

[1] Kypris O, Nlebedim IC and Jiles DC. Mapping Stress as a Function of Depth at the Surface of Steel Structures Using a Frequency Dependent Magnetic Barkhausen Noise Technique. *IEEE Transactions on Magnetics* 48: 4428-4431, 2012.

Q1.00305 ENERGY RESEARCH AND APPLICATIONS –

Q1.00306 Fabrication of a Scalable Free Standing Single Layer Silver Nanomesh , TIANYI SUN, CHUANFEI GUO, KRZYSZTOF KEMPA, ZHIFENG REN, Boston College — We present a method of fabricating scalable free standing single layer silver nanomeshes with uniform linewidth. The method consists of In_2O_3/SiO_x bilayer lift-off metallization, HF-H_2O_2 based catalytic etching and a chemical lift-off process. Since the linewidth and the mesh size can be well tuned by the isotropic etching of In_2O_3 islands within a broad range, this method is capable of generating nanomeshes meeting different electrical, optical, and mechanical requirements. Using this method, a 45 nm thick silver nanomesh with 20 % metallic coverage (line width 120 nm) has an average transmittance of 65 % over the whole visible range and a sheet resistance of about 10 Ω/sq. To the best of our knowledge, this is the first time that a cost-effective scalable free standing silver nanomesh with uniform linewidth was obtained. Such nanomeshes may find applications in a lot of fields where good flexibility, high transparency, and good electrical conductivity are required simultaneously, such as flexible transparent electrodes.

Q1.00307 Theoretical Evaluation of Cu-Sn-S and Cu-Sb-S Based Solar Absorbers for Earth-Abundant Thin-Film Solar Cells[1] , PAWEL ZAWADZKI, HAOWEI PENG, ANDRIY ZAKUTAYEV, STEPHAN LANY, National Renewable Energy Laboratory — Current thin-film solar absorbers such as Cu(In/Ga)Se_2 or CdTe, although remarkably efficient, incorporate limited-supply elements like indium or tellurium. Meeting the cost competiveness criterion necessary for a large-scale deployment of thin-film PV technologies requires development of new earth-abundant solar absorbers. In an effort to accelerate such development we combine first principles theory and high throughput experiments to explore In-free ternary copper chalcogenides. As part of the theoretical evaluation, we study the Cu_2SnS_3, Cu_4SnS_4, $CuSbS_2$ and Cu_3SbS_3 based compounds formed by isovalent alloying on Sn, Sb, and S sites. For this set of materials we predict band-structures and optical absorption coefficients and demonstrate the feasibility of achieving the optimal band gap of 1.3 eV for a single junction cell and a high optical absorption of $\sim 10^4$ cm^{-1} at E_g+0.2 eV. We additionally perform defect studies to elucidate the doping trends within this class of materials.

[1]The project "Rapid Development of Earth-abundant Thin Film Solar Cells" is supported as a part of the SunShot initiative by the U. S. Department of Energy, Office of Energy Efficiency and Renewable Energy under Contract No. DE-AC36-08GO28308 to NREL.

Q1.00308 Particle scattering approach for solar concentration , JEHAN SENEVIRATNE, MATTHEW BERG, Department of Physics and Astronomy, Mississippi State University — The focus of this work is on increasing the solar concentration ratio for Photovoltaic (PV) applications. In this work, the scattering patterns of particles with various shapes are computationally studied in the near field. The results are analyzed to develop models with high concentration ratios. Based on the results, our question: "Which particle arrangement gives the optimum solar power yield for a given physical condition?" is investigated. Our work may have an impact on solar harvesting methodologies in solar energy applications.

Q1.00309 Optical characterization of n-type conductive cuprous oxide photoanodes , JACKSON HALPIN, ROHANA GARUTHARA, Physics Department, 102 Berliner Hall, Hofstra University, Hempstead, NY 11549 — Electrodeposition technique was used to deposit chlorine doped Cu_2O thin films on indium tin oxide (ITO) coated glass substrates. The deposited Cu2O photoanodes were characterized by absorption, reflectance and photoluminescence spectroscopy. The effects of chlorine doped photoanodes grown in different solution pH and bath temperature on the magnitude of their photocurrent are studied. The low temperature photoluminescence spectra of chlorine doped Cu_2O films are found to depend on the solution pH in the range 10.0-7.5. We observed two photoluminescence peak positions at 1.45 eV and 1.65 eV for photoanodes made in pH 7.5 solution. At pH 9.6, we observed an additional photoluminescence peak around 1.8 eV. The results will be discussed with emphasis on the reflectance, absorption and photoluminescence observation.

Q1.00310 First Principal Optimization of Exciton Separation via Functional Modification of the Atomic Structure , LEVI LENTZ, ALEXIE KOLPAK, MIT — Low hole mobility and high recombination rates limit the incident photon-to-current collection efficiency (IPCE) of organic photovoltaics. In this study, we use a combination of rational design and first-principles density functional theory computations to tailor the properties of new hybrid organic-inorganic photovoltaic materials in order to ameliorate these issues. Starting with hybrid organic-inorganic molecules shown to self-assemble into crystalline structures, we design a nanostructured material in which inorganic charge carrier channels are separated by domains of organic absorber on the order of several nanometers thick perpendicular to the light absorption direction. By functionalizing the organic component and substituting the cations in the inorganic layer, we engineer a dipole moment to drive electrons and holes into the inorganic charge carrier channels. Furthermore, we tune the density of states of these regions via a combination of cation substitution and interactions with functional groups in the organic region in order to optimize charge carrier mobility. The combination of rational design and first-principles optimization could significantly reduce exciton recombination and increase charge carrier mobility with respect to purely organic photovoltaics.

Q1.00311 Computational Design of Photovoltaic Materials with Self Organized Nano Structures , KAZUNORI SATO, Graduate School of Engineering Science, Osaka University and PRESTO-JST, HIROSHI KATAYAMA-YOSHIDA, Graduate School of Engineering Science, Osaka University — Chalcopyrite and II-VI semiconductors, such as Cu(In, Ga)Se_2, $Cu_2ZnSn(S, Se)_4$ and Cd(S, Te), are one of the most promising materials for low cost photovoltaic solar-cells. In this paper, based on first-principles calculations, we propose that self-organized nano-structures in these compounds will enhance the conversion efficiency. Our calculations are based on the KKR-CPA-LDA [1] with the self-interaction correction [2]. We also use VASP package [3] for calculating mixing energy and effective interactions of the systems by using the cluster expansion method [4]. For phase separating systems, we simulate nano-structure formation by using the Monte Carlo method. It is expected that the photo-generated electron-hole pairs are efficiently separated by the type-II interface and then effectively transferred along the quasi-one-dimensional structures. Moreover, we can expect multiplication of generated carriers due to the multi-exciton effects in nano-structures [5].

Q1.00312 Enhancing the Efficiency of Bulk Heterojunction Solar Cells via Templated Self Assembly , CHENG PAN, HONGFEI LI, Materials Science and Engineering, Stony Brook University, BULENT AKGUN, SUSHIL SATIJIA, Center for Neutron Research, National Institute of Standards and Technology, DILIP GERSAPPE, Materials Science and Engineering, Stony Brook University, YIMEI ZHU, Center for Functional Nanomaterials, Brookhaven National Laboratory, MIRIAM RAFAILOVICH, Materials Science and Engineering, Stony Brook University — Bulk Heterojunction (BHJ) polymer solar cells are an area of intense interest due to their flexibility and relatively low cost. The mixture of polythiophene derivatives (donor) and fullerenes (acceptor) is spin coated on substrate as the active layer, and are phase-separated into interconnected domains. However, due to the disordered inner structures in the active layer, donor or acceptor domains isolated from electrodes and long path conduction, the power conversion efficiency (PCE) of BHJ solar cell is low. Therefore, morphology control in bulk heterojunction (BHJ) solar cell is considered to be critical for the power conversion efficiency (PCE). Here, we present a novel approach that introduces non-photoactive polymer that organizes the poly(3-hexylthiophene) (P3HT) into columnar phases decorated by [6,6]-phenyl C61-butyric acid methyl ester (PCBM) at the interface. This structure represents a realization of an idealized morphology of an organic solar cell, in which, both exiciton dissociation and the carrier transport are optimized leading to increased power conversion efficiency.

Q1.00313 Synthesis and Characterization of ZnO/polyaniline planar heterojunction solar cells , LEANDRO GUTIERREZ, CHRISTOPHER REEHIL, ANNE ISAH, WILLIAM MANNERS, JIMMY BARRIENTOS, ARYA NABIZADEH, PATRICK ALBERS, MEHMET SAHINER, WEINING WANG, Seton Hall University, SAHINER COLLABORATION, WANG COLLABORATION — ZnO/polymer heterojunction has attracted much research attention because of its potential application in solar cell, LED, UV photodetection and other applications. However, there are few studies on ZnO/polymer heterojunction attempting to synthesize ZnO materials using pulsed laser deposition. Comparing with other methods, PLD has the advantage of congruent evaporation, and being able to grow high quality thin films at relatively low temperature. In our previous work in CdTe/Cds based thin films we have seen correlations between the pulsed laser deposition parameters and the electrical performance of the thin film solar cells. In this work, we report our studies on pulsed-laser-deposited (PLD) ZnO/Polyaniline (PANI) heterojunction and its potential application as solar cells. We studied how the performance of ZnO/PANI solar cells depends on the deposition condition of ZnO, such as deposition temperature, background pressure of oxygen, and ZnO film thickness. X-ray diffraction (XRD) and scanning electron microscopy were used to characterize the pulsed-laser-deposited (PLD) ZnO film. The correlation between the solar cell electrical performance and the pulsed laser deposition conditions will be discussed.

Q1.00314 Mondo Grass Berry Pigment for Visible to Near Infrared Absorption in Dye Sensitized Solar Cell[1] , L.A.A. DESILVA, Department of Physics, University of West Georgia, Carrollton, GA, P.K.D.D.P. PITIGALA, A.G.U. PERERA, Department of Physics and Astronomy, Georgia State University, Atlanta, GA — The development of dye sensitized solar cells (DSSC) is an exciting field in the low cost renewable energy production. Two major draw backs in the DSSCs are the narrow spectral response and the short term stability. Synthesis of artificial dyes with broad response is important in developing an efficient DSSC. Artificial dyes can add up to the cost of the device; therefore, it is important to identify natural dyes with broad abortion and required energy levels. Work presented here shows a broad spectral response with a natural dye extracted from a Mondo Grass berry (Ophiopogonjaponicus).The dye is extracted by crushing the berries and filtering to remove the pulp. A DSSC sensitized with Mondo Grass dye, and with TiO_2 film screen printed on a Florien doped Tin Oxide (FTO) glass and baked for 30 minutes at 450 degree C as the working electrode and Iodine/triiodide red-ox electrolyte as the hole collector was tested for its performance. An open circuit photovoltage of 495 mV and a short circuit photocurrent of 0.6 mA/cm^2 were observed under a simulated lamp equivalent to 1 sun illumination and have a broad spectral response extending from 400 nm to 750 nm.

Q1.00315 Pressure and PL study of dilute-N GaInNAs films for applications in photovoltaics[1]

, GEORGE P. LINDBERG, University at Buffalo, Department of Physics, Buffalo, NY 14260, MIWA FUKUDA, University of Oklahoma, Department of Physics and Astronomy, Norman, OK 73019, M. AL KHALFIOUI, CRHEA-CNRS, Valbonne, France, KHALID HOSSAIN, Amethyst Research Inc. Ardmore OK., IAN R. SELLERS, University of Oklahoma, Department of Physics and Astronomy, Norman, OK 73019, BERNARD A. WEINSTEIN, University at Buffalo, Department of Physics, Buffalo, NY 14260 — Multi-junction photovoltaic devices employing dilute-N GaInNAs alloys are currently of high interest for efficient solar energy conversion. The negative band-bowing produced by introducing a few percent N into GaInAs provides a convenient way to match the 1eV component of the solar spectrum, providing recombination losses in localized states can be reduced while maintaining favorable carrier extraction. High pressure photoluminescence (PL) experiments exploring the localization of band-edge excitons in dilute-N GaInNAs films grown by plasma assisted MBE will be discussed. The effects of post-growth annealing and hydrogen incorporation on the PL spectra of the films are considered.

Q1.00316 Mulitlayered Nanostructured Broad Band Absorber

, TIMOTHY CORRIGAN, BENJAMIN IDE, Concord University — Wasted energy in the form of heat is perhaps the largest source of lost energy making many power systems inefficient. Systems designed to convert heat into useful energy need a method of collecting the heat. We previously described a multilayer design with successive thin metallic and dielectric (non-metal and transparent) layers, where each successive metallic layer absorbs a small fraction of the radiation. However, the regular thickness of the dielectric layer causes reflection peaks, or regions where no absorption occurs. In this work we describe a similar design where we eliminated the undesirable reflection peaks using varying thicknesses of the dielectric layer.

Q1.00317 High Frequency Supercapacitors for Piezo-based Energy Harvesting

, MATTHEW ERVIN, US Army Research Laboratory, CARLOS PEREIRA, Armament Research Development Engineering Center, JOHN MILLER, JME Inc., RONALD OUTLAW, The College of William and Mary, JAY RASTEGAR, RICHARD MURRAY, Omnitech Partners LLC — Energy harvesting is being investigated as an alternative to batteries for powering munition guidance and fuzing functions during flight. A piezoelectric system that generates energy from the oscillation of a mass on a spring (set in motion by the launch acceleration) is being developed. Original designs stored this energy in an electrolytic capacitor for use during flight. Here we replace the electrolytic capacitor with a smaller, lighter, and potentially more reliable electrochemical double layer capacitor (aka, supercapacitor). The potential problems with using supercapacitors in this application are that the piezoelectric output greatly exceeds the supercapacitor electrolyte breakdown voltage, and the frequency greatly exceeds the operating frequency of commercial supercapacitors. Here we have investigated the use of ultrafast vertically oriented graphene array-based supercapacitors for storing the energy in this application. We find that the electrolyte breakdown is not a serious limitation as it is either kinetically limited by the relatively high frequency of the piezoelectric output, or it is overcome by the self-healing nature of supercapacitors. We also find that these supercapacitors have sufficient dynamic response to efficiently store the generated energy.

Q1.00318 In Situ Investigations of Ion Transport at Oxide Surfaces[1]

, DAVID SIEGEL, KEVIN MCCARTY, FARID EL GABALY, Sandia National Laboratories — Ion transport through materials driven by electric potential is essential to many processes, including electrical energy storage. Here we study in situ the behavior of oxide surfaces in the presence of applied electric fields with low-energy electron microscopy (LEEM), angle-resolved photoemission spectroscopy (ARPES), and related structural and spectroscopic measurement techniques. We measure with high spatial resolution the electric potential on the surface of yttria-stabilized zirconia (YSZ), a prototypical oxygen ion conductor, as a function of distance from a metallic electrode. The dependence of the potential distribution on temperature and oxygen gas pressure is determined. Finally we explore which types of surface sites facilitate the gas-surface reactions that create and annihilate the oxygen ions.

Q1.00319 First-principles determination of LaMnxM1-xO3 surface structures under catalytic conditions

, XI RONG, ALEXIE KOLPAK, Department of Mechanical Engineering, Massachusetts Institute of Technology, KOLPAK GROUP TEAM — The design of efficient and cost-effective catalysts for the oxygen evolution reaction (OER) is crucial for the development of electrochemical conversion technologies. One of the most important factors determining the activity is the surface/interface structures of catalysts. However, little is known about the atomic and electronic structures and thermodynamic properties of realistic interface reconstructions, which are caused by different environments during fabrication, measurement, and eventual device operation. In this work, we apply first-principles density functional theory computations in combination with kinetic modeling to investigate the environment-dependent chemical and physical properties of perovskite oxide heterostrucutre catalysts, particularly LaMnxM1-xO3. We develop a methodology for accurate identification of constraints on the interface structure phase space and rapid computation of this identification as a function of temperature, pressure, and other chemical environments. Our work could lead to accurate and rapid prediction of surface/interface structures and properties under different environmental conditions, and contribute to the design of new high-activity OER catalysts.

Q1.00320 Self-standing paper based anodes prepared from siliconcarbonitride-MoS_2 composite for Li-ion battery applications

, LAMUEL DAVID, GURPREET SINGH, Kansas State University — We study synthesis of free-standing polymer derived SiCN/ MoS_2 composite paper anode for Li-ion battery application. This was achieved following a two-step approach: First, polysilazane was interfaced with exfoliated MoS_2 nanosheets which upon pyrolysis resulted in SiCN/MoS_2 composite. Second, dispersion of SiCN/MoS_2 in isopropanol was vacuum filtered resulting in formation of a self-standing composite paper. Physical and chemical characterization of the composite was carried out by use of electron microscopy, Fourier transform infrared spectroscopy (FT-IR) and Thermo-gravimetric analysis (TGA). FT-IR data indicated complete conversion of polysilazane precursor to SiCN ceramic, while electron microscopy confirmed layered structure of the paper. Thermo-gravimetric analysis showed enhanced thermodynamic stability of the composite paper up to 800 °C. Electrochemical analysis of SiCN/MoS_2 composite paper anodes showed that Li-ion can reversible intercalate in the voltage range of 0-2.5 V with a first cycle discharge capacity of 770 mAh/g at a current density of 100 mA/g.

Q1.00321 Transducing Energy Loss in Water Electrolysis with a 0D Ion-Sensitive Field-Effect Transistor

, NICOLAS CLEMENT, IEMN-CNRS (France), KATSUHIKO NISHIGUCHI, NTT Basic Research Labs (Japan), JEAN-FRANÇOIS DUFRÊCHE, CEA-Marcoules (France), DAVID GUÉRIN, IEMN-CNRS (France), GILLES PATRIARCHE, LPN-CNRS (France), DAVID TROADEC, IEMN-CNRS (France), AKIRA FUJIWARA, NTT Basic Research Labs (Japan), DOMINIQUE VUILLAUME, IEMN-CNRS (France) — In order to produce hydrogen as a fuel source of the future, water electrolysis is one of the most "promising" green approaches. Although electrolysis efficiency can be as high as 80%, it still means that at least 20% of the energy is lost. The use of transducers to collect the energy loss in water electrolysis is attractive. Among the various transducers, several ideas have been proposed such as an air bubble powered rotary driving apparatus or a microcantilever vibrating after impact of each bubble. However, the main source of energy lost appears at electrode interfaces with the presence of a double layer of ions acting as a resistor and capacitor. In this study, we show that using a 0D – ultra low noise - ISFET, allows getting the energy coming from the double layer fluctuation at each H2 bubble emission. Interestingly, the output signal that can be tuned with salt concentration and electrolysis current exactly corresponds to that of action potential which could be useful for bio-applications . In addition, electrical detection of bubbles emission at single bubble level also opens the door to optimization of hydrolysis efficiency and further save energy for hydrogen production.

Q1.00322 Hydrogen Adsorption onto Magnesium Palladium and Magnesium Palladium Niobium Multilayer Thin Films , CHRISTIAN STEINMETZ, JEFFREY HETTINGER, TABBETHA DOBBINS, Rowan University — We report on the synthesis and characterization of magnesium palladium and magnesium niobium multilayer thin films as a possible reversible hydrogen storage material. The multilayer thin films are characterized by x-ray diffraction (XRD) and x-ray reflectivity (XRR) before and after hydrogen uptake. This study examines the optimal thickness of the magnesium film which would allow the diffusion of hydrogen to form magnesium hydride (MgH2). Thin barriers of palladium and niobium permit hydrogen to permeate while acting as a diffusion barrier to oxygen. Multilayer thin films are grown with various magnesium thicknesses via magnetron sputtering on a sapphire substrate. Thicknesses of Mg, MgH2, Pd, and Nb are reported. Likewise, interfacial roughness attributable to hydrogenation and dehydrogenation cycling measured using XRR are reported.

Q1.00323 Cryo-Milling and the Hydrogen Storage Properties of NaAlH4 , KEVIN FELLER, TABBETHA DOBBINS, Rowan University — High energy ball milling of metal hydrides is a common way to both introduce catalysts (e.g. TiCl3) and to simultaneously increase the surface area. Both catalysis and increased surface area improve hydrogen storage capacity of the material. Nanostructuring of hydrides by depositing them into mesoporous templates (such as anodized alumina, MOFs, and SBA-15) has become a common way to increase surface area. However, the mesoporous template does not add hydrogen storage capacity—and thus, tends to decreased overall storage weight percent for the nanostructured hydride material. As with most materials, hydrides become brittle at low temperatures and will tend to fracture more readily. We will process Sodium Aluminum Hydride (NaAlH4) using cryogenic high energy ball milling using an in-house modified chamber SPEX Certiprep M8000 mixer/mill in order to gain a nanostructured hydride without mesoporous template material. Details of the modified mixer mill design will be presented. Ultimately, our planned future work is to study the resultant material using x-ray diffraction (Scherrer method for crystallite size), absorption/desorption temperature programmed desorption (TPD), and ultrasmall-angle x-ray scattering (USAXS) microstructural quantification to understand the role of cryomilling on enhancing the material's ability to store (and release) hydrogen.

Q1.00324 Study of Titanium Hydride Destabilized Lithium Aluminum Hydride as a Promising Hydrogen Storage System , TROY SMITH, TABBETHA DOBBINS, Rowan University, Dept. of Physics & Astronomy — Destabilized hydrides are a class of hydrogen storage systems whereby the theoretical hydrogen desorption temperature is reduced owing to the formation of a stable product phase which is typically comprised of cations from the destabilizer and the hydride phase. This work examines the hydrogen desorption temperatures for a mixture of titanium hydride (TiH2) (as a destabilizer) and lithium aluminum hydride (LiAlH4). X-ray diffraction (XRD) and temperature programmed desorption (TPD) were used to confirm the onset of desorption at temperatures as low as 75 deg C. The thermodynamic phase diagram corresponding to the mixed system will be presented and a reaction mechanism is suggested.

Q1.00325 Monte Carlo(MC) simulation study on ammonia anchored TON zeolite for carbon dioxide capture , SOOHO LEE, Sogang university, Nano-structured computer fluids lab — If zeolites are modified by ammonia, the electronic effect in ammonia resulted in different surface basicity of the zeolite materials. So, ammonia anchored materials show better adsorption rate of CO2 than pure materials at low pressure. MC simulations for CO2 adsorption were performed at 298K. The results show that, at pressure 1000 kpa CO2 loading is 1.404 mol/kg at ammonia anchored TON, and 0.529 mol/kg at pure TON. However, at high pressure, the ammonia effect becomes marginal. Ammonia anchored TON structures may be used to adsorb CO2 more effective than normal TON structure.

Q1.00327 INSTRUMENTATION AND MEASUREMENTS –

Q1.00328 Development of Micro-Raman Spectroscopic Instrumentation for Measurement of Novel 2D Materials , MICHAEL WATSON, ZACH THOMPSON, Student, JEFF SIMPSON, Professor, TOWSON UNIVERSITY TEAM — Recent research activity in mono-atomic layer graphene stimulates interest in other novel 2D materials, including molybdenum disulfide (MoS_2). Raman spectroscopy, based on the inelastic scattering of light, provides a powerful and high-throughput spectroscopic technique to probe low energy excitations, e.g., phonons, in graphene and related novel 2D materials. The accurate measurement of phonon frequency, especially its sensitive dependence on physical parameters such as temperature, carrier doping, and defects, requires an appropriately calibrated spectrometer. We report on the implementation and calibration of a homebuilt Raman system. Specifically we correlated peak wavelength from known atomic spectral lines with the pixel number detected on a thermoelectrically-cooled CCD camera attached to a grating monochromator. Additionally we developed software to control the grating position and maintain calibration while acquiring spectra. Once calibrated, we interfaced the spectrometer to a microscope to acquire spatial maps of small samples. Single-layer MoS_2 flakes were prepared using the mechanical exfoliation of bulk MoS_2 and transferred to substrates using techniques pioneered in graphene research. Using HeNe and Ar ion lasers for excitation, we measured the Raman spectra of single-layer MoS2 flakes. The temperature-dependence of the observed Raman-active phonons will be discussed.

Q1.00329 High sensitivity and label-free detection of Enterovirus 71 by nanogold modified electrochemical impedance spectroscopy , FANG-YU WANG, Department of Molecular Medicine and Bioengineering, National Chiao Tung University, Hsinchu, Taiwan, R.O.C., HSING-YUAN LI, SHING-HUA TSENG, TSAI-MU CHENG, HSUEH-LIANG CHU, Department of Biological Science and Technology, National Chiao Tung University, Hsinchu, Taiwan, R.O.C., JYH-YUAN YANG, Development, Centers for Disease Control, Department of Health, Taipei, Taiwan, R,O.C., CHIA-CHING CHANG, Department of Biological Science and Technology, National Chiao Tung University, Hsinchu, Taiwan, R.O.C. — Enterovirus 71 (EV71), which is the most fulminant and invasive species of enterovirus, can cause children neurologic complications and death within 2-3 days after fever and rash developed. Besides, EV71 has high sequence similarity with Coxsackie A 16 (CA16) that makes differential diagnosis difficult in clinic and laboratory. Since conventional viral diagnostic method cannot diagnose EV71 quickly and EV71 can transmit at low viral titer, the patients might delay in treatment. A quick, high sensitive, and high specific test for EV71 detection is pivotal. Electrochemical impedance spectroscopy (EIS) has been applied for detecting bio-molecules as biosensors recently. In this study, we try to build a detection platform for EV71 detection by nanogold modified EIS probe. The result shows that our probe can detect 3.6 VP1/50 μl (one EV71 particle has 60 VP1) in 3 minutes. The test can also distinguish EV71 from CA16 and lysozyme. Diagnosis of enterovirus 71 by electrochemical impedance spectroscopy has the potential to apply in clinic.

Q1.00330 Rapid detection and quantification of free hemoglobin and haptoglobin by nanogold modified electrochemical impedance spectroscopy , YU-NING LU, HSING-YUAN LI, HSUEH-LIANG CHU, TSIA-MU CHENG, SHIN-HUA TSENG, CHIA-CHING CHANG, Department of Biological Science and Technology, National Chiao-Tung University, Taiwan, R.O.C. — Free Hemoglobin (Hb) is a metabolic substance that damage tissue and vessel. It is released from destructed red blood cell and causes infection or inflammatory of human body. In blood plasma, haptoglobin (Hp) binds free Hb with high affinity and prevents the damage which is caused by cell free Hb. Hp has three phenotypes, that are Hp1-1, Hp 2-1, and Hp 2-2. Different phenotypes of Hp has been different affinities to Hb. It is known that electrochemical impedance spectroscopy (EIS) provide more information for detecting the small amount bio-molecules, include protein and DNA. In this study, we have developed a simple, fast, reliable and sensitive platform to quantify concentration of free Hb and Hp. In this platform, detection probe has been modified with nano gold and the surface charge transfer resistance of Hb and Hp binding could be detected and quantified within 18 min. This is a whole new platform to quantify free Hb in the serum of human to our knowledge.

Q1.00331 Improved transcranial magnetic stimulation coil design with realistic head modeling , LAWRENCE CROWTHER, RAVI HADIMANI, DAVID JILES, Department of Electrical and Computer Engineering, Iowa State University — We are investigating Transcranial magnetic stimulation (TMS) as a noninvasive technique based on electromagnetic induction which causes stimulation of the neurons in the brain. TMS can be used as a pain-free alternative to conventional electroconvulsive therapy (ECT) which is still widely implemented for treatment of major depression. Development of improved TMS coils capable of stimulating subcortical regions could also allow TMS to replace invasive deep brain stimulation (DBS) which requires surgical implantation of electrodes in the brain. Our new designs allow new applications of the technique to be established for a variety of diagnostic and therapeutic applications of psychiatric disorders and neurological diseases. Calculation of the fields generated inside the head is vital for the use of this method for treatment. In prior work we have implemented a realistic head model, incorporating inhomogeneous tissue structures and electrical conductivities, allowing the site of neuronal activation to be accurately calculated. We will show how we utilize this model in the development of novel TMS coil designs to improve the depth of penetration and localization of stimulation produced by stimulator coils.

Q1.00332 Near Field-Emission Scanning Electron Microscopy with Energy Analysis , DANILO ANDREA ZANIN, LORENZO GIUSEPPE DE PIETRO, HUGO CABRERA, PETER THALMANN, ANNA-LENA REDMANN, URS RAMSPERGER, DANILO PESCIA, MEHMET ERBUDAK, Laboratory for Solid State Physics ETH Zurich — We report on new results about near field-emission scanning electron microscopy (NFESEM) which emphasize the potential of generating secondary electrons using a primary electron beam of low energy electrons. Based on scanning tunneling microscopy technology NFESEM uses a sharp W-tip as a cold field emitter, which scans the surface at constant distance, usually in the range of 5 to 40 nm. An applied voltage between tip and sample induces field emission at the tip. These primary electrons are then accelerated towards the target and successively scattered by its surface generating secondary electrons. The last ones, which carry information of the sample, are emitted and energy analyzed. Spatially resolved analysis of energy and polarization of secondary electrons may provide new insight into surface microscopy.

Q1.00333 Controlled manipulation of adatoms on the oxidized $p(2 \times 1)$ Cu(110) surface using NC-AFM , JOSEPH BAMIDELE, Dept. of Physics, King's College London, U.K., ROBERT TURANSKY, Inst. of Physics, Slovak Acad. of Sciences, 84511 Bratislava, Slovakia, YASUHIRO SUGAWARA, Dept. of Applied Physics, Osaka University, Japan, IVAN STICH, Inst. of Physics, Slovak Acad. of Sciences, 84511 Bratislava, Slovakia, LEV KANTOROVITCH, Dept. of Physics, King's College London, U.K. — Experimentally, large finite regions (islands) of the $c(6 \times 2)$ reconstruction bordering (also rather substantial) regions of the $p(2 \times 1)$ reconstruction with single super-Cu atoms between some neighboring -Cu-O-Cu- rows can be created on the oxidized Cu(110) surface. We report on our combined theoretical and experimental study of the manipulation of these isolated super-Cu atoms with NC-AFM. Experiments indicate that the manipulation proceeds mostly by vertical manipulation with a small number of lateral manipulation events. Theoretical calculations were performed using the density functional theory (with particular attention paid towards including non-local correlation effects). Two Cu tip models were used terminated either with Cu or O atoms. Placing either of the two tips at various positions around the super-Cu atom on the surface, we calculated maps of the corresponding energy barriers for the transition of the super-Cu atom to the neighboring site and/or for tip adsorption and desorption. Using these comprehensive data and the virtual AFM, mimicking the actual NC AFM apparatus, we modeled the manipulation mechanism and obtained the corresponding tip response during the individual manipulation events.

Q1.00334 A 2nd Generation Interfacial X-ray Microscope , NOUAMANE LAANAIT, ZHAN ZHANG, PAUL FENTER, Argonne National Laboratory — Understanding and controlling the physical and chemical processes occurring at the interface of materials is a central theme in many of today's scientific inquiries and technological advancements. Experimental investigations of interfaces has benefited from a large set of imaging techniques such as Probe microscopy, and Electron microscopy. Yet, numerous systems comprised of buried interfaces that are of immense significance, remain out of the reach of these methods because of their lack of depth penetration capabilities or inoperability in extreme conditions of pressure and/or temperature. Such systems can benefit from the development of complementary x-ray based imaging techniques that can operate in the above cited conditions. Combining the surface sensitivity of x-ray scattering and well-established methodology and instrumentation of transmission x-ray microscopy, a second generation interfacial x-ray microscope (IXM) is currently under development at Argonne's advanced photon source with the aim of achieving a lateral resolution of 50 nm and collection times on the order of seconds. The IXM has been used to image surface topography of solid/gas, solid/liquid with sub-nanometer height sensitivity. These scientific results as well as the instrumentation will be presented.

Q1.00335 Development of Uncooled Micro-bolometer Arrays Based on Hole-doped Rare-Earth Manganites

, E. KEVIN TANYI, GRACE YONG, CAMRON KESHAVARZ, PRAKASH SHARMA, CHRISTOPHER RUBIN, RAJESWARI KOLAGANI, Towson Unviersity, STEVEN GROSS[1], Triton Services Inc. — Material properties indicate that rare earth manganites have a competitive advantage over VO_x which is a material commonly employed as bolometric sensors in state of the art uncooled imaging arrays. We will present the results of our work on developing manganite thin films for uncooled micro-bolometer arrays. By fine tuning the cation composition and stoichiometry, we have identified material compositions suitable for uncooled bolometer operation and developed thin films of these materials by Pulsed Laser Deposition (PLD) on Si. For hetero-epitaxy on Si, we employ lattice engineering schemes to circumvent problems such as chemical incompatibility and amorphization of the substrate surface due to the native oxide. We are in the process of fabricating single test bolometers and micro-bolometer arrays. We will discuss the results of materials development and device fabrication efforts and will present performance parameters and estimated figures of merit for test bolometers. We will also discuss efforts towards understanding and alleviating material problems such as the residual stresses in the thin film heterostructures which are of critical importance for the fabrication of suspended microstructures.

[1]We acknowledge support from the NSF grant ECCS 1128586 at Towson University.

Q1.00336 Auto-tuning system for NMR probe with LabView[1]

, CARMEN QUEN, OLIVIA V. MATEO, OSCAR BERNAL, Deparment of Physics and Astronomy, California State University, Los Angeles, CA 90032 — Typical manual NMR-tuning method is not suitable for broadband spectra spanning several megahertz linewidths. Among the main problems encountered during manual tuning are pulse-power reproducibility, baselines, and transmission line reflections, to name a few. We present a design of an auto-tuning system using graphic programming language, LabVIEW, to minimize these problems. The program is designed to analyze the detected power signal of an antenna near the NMR probe and use this analysis to automatically tune the sample coil to match the impedance of the spectrometer (50 Ω). The tuning capacitors of the probe are controlled by a stepper motor through a LabVIEW/computer interface. Our program calculates the area of the power signal as an indicator to control the motor so disconnecting the coil to tune it through a network analyzer is unnecessary.

Q1.00337 ABSTRACT WITHDRAWN –

Q1.00338 Characterization of Surface Topography by Line-Laser Light Scattering

, LAWRENCE HONAKER, Liquid Crystal Institute, Kent State University, Kent, OH, HYEUNSEOK CHOI, Smart Systems Research Group, Korean Institute of Industrial Technology, Cheonan, South Korea, CHANJOONG KIM, Liquid Crystal Institute, Kent State University, Kent, OH — To charaterize the topography of rough surfaces, various methods based on point-by-point analyses, such as scanning microscopy, atomic force microscopy, and profilometry, have been developed over the span of many years. However, the practical application of such methods is hampered by shortcomings such as the slow speed at which the analyses can be performed and the possibility of damaging or destroying the sample. We harness the optical properties of the reflection of plane-polarized line laser light as a non-destructive high-speed imaging method to inspect the surface. Profiles of reflected light patterns, both theoretical and experimental, have also been obtained to characterize the defects and roughness of the surface.

Q1.00339 Development and Characterization of Dynamic Light Scattering Instrumentation to Determine the Size of ZnO Nanoparticles[1]

, CHRISTOPHER DI FATTA, JEFFERY R. SIMPSON, Department of Physics, Towson University, Z. THOMPSON, M. SCHULZE , Towson University, S. M. LEV, Urban Enviromental Biogeochemistry Laboratory (UEBL) — Dynamic Light Scattering (DLS) serves as a useful tool for characterizing nanoparticles (NP) and molecules. DLS provides a high-throughput and accurate measurement of particle sizes for monodisperse (MD) spherical NPs. We are presenting the development and characterization of DLS instrumentation to measure the size of MD NPs, including ZnO. A HeNe and Argon ion laser comprise the excitation sources for the scattering experiment. We have evaluated avalanche photodiode and thermoelectrically-cooled photomultiplier tube detectors for the acquisition of the scattered light. We will determine the translational diffusion coefficient using time averaging and time-autocorrelation electronics. Considering the NPs to be MD spheres, we can determine the radius from the diffusion coefficient. ZnO NPs will be synthesized using several techniques and compared to those produced commercially. The synthesized particles are expected to range in diameter from 200 nm down to 20 nm, however, in the presence of agglomerates once suspended may extend the upper size limit for particles in suspension to 1000 nm. We will compare the DLS results on ZnO NPs with additional techniques including AFM. After size characterization, the ZnO NPs will be employed in ongoing toxicity studies in the UEBL.

Q1.00340 Inexpensive Ultrasonic Interferometer[1]

, JOHN GROSSMANN, OLEKSIY SVITELSKIY, Colgate University, Hamilton, NY 13346, ALEXEY SUSLOV, National High Magnetic Field Laboratory, Tallahassee, FL 32310 — Growing interest of small universities and colleges in research determines an increasing need in affordable laboratory equipment that would be capable of producing scientifically valuable experimental results. In this report we present the current status of our efforts to develop a simple and low-cost version of a classical experimental setup for ultrasonic pulse-echo measurements that would be easily reproducible in the electronics shop of any small educational institution. In particular, usage of a dual timer microchip LM556 allowed us to simplify the design of a probing pulse generator. Also, we propose that using modern broadband RF components in phase detection circuits will allow us to substitute the complicated and expensive superheterodyne design of receiver with the technique of direct transformation and analysis of the echo signal right at the probe frequency. Our analysis shows that these simplifications can be achieved without compromising for sensitivity of the experiment or precision of measurements.

Q1.00341 FPGA for single-molecule recycling in a nanochannel

, SULTAN BEHERY, BO WANG, BRIAN K. CANFIELD, LLOYD M. DAVIS, University of Tennessee Space Institute — Single-molecule (SM) trapping and detection experiments are important in studying biophysical processes on the molecular level. As an SM is too small for optical trapping, prolonged observation requires measurement of the position and active feedback to counteract diffusion. In previous work, a custom-built Field Programmable Gate Array (FPGA) circuit board was developed for SM detection and real-time electrokinetic trapping in a fused silica nanochannel. The FPGA was used as part of a feedback system to control the voltage for electrokinetic movement of solution along the nanochannel in response to the time stamps of individual photons from the excited SM. Other researchers have since shown that alternating the flow in a nanochannel can be used to recycle an SM through a stationary laser focus for repeated observations and that the times between each passage yield a measurement of the molecule's diffusion. Improved measurements could be obtained by use of an FPGA for more precisely timed flow control. Therefore, we are now adapting the FPGA for SM trapping to use algorithms tested in a Monte Carlo simulation of SM recycling in an attempt to extend existing capabilities. This presentation discusses the custom-built FPGA board, algorithms, and ongoing nanochannel experiments.

Q1.00342 Mechanical Loss Measurements of Coated Substrates for Gravitational Wave Interferometry[1] , JONATHAN NEWPORT, DAVID BELYEA, RAYMOND ROBIE, GREGG HARRY, American University — Gravitational waves from sources such as binary star systems, supernovae explosions and stochastic background radiation have yet to be directly detected by experimental observations. Alongside international collaborators, the Laser Interferometer Gravitational-Wave Observatory (LIGO) is designed to realize direct detection of gravitational waves using interferometric techniques. The second generation of gravitational wave observatories, known as Advanced LIGO, are currently undergoing installation and commissioning at sites in Hanford, Washington and Livingston, Louisiana. The ultimate sensitivity of Advanced LIGO within select spectral bands is limited by thermal noise in the high-reflective coatings of the interferometer optics. The LIGO lab at American University is measuring the mechanical loss of coated substrates to predict thermal noise within these spectral bands. These predictions are used to ensure the ultimate design sensitivity of Advanced LIGO and to study coating and substrate materials for future gravitational wave detectors.

Q1.00343 Development of a Slow Positron Facility at Hebrew University of Jerusalem , AIDAN KELLEHER, Hebrew University of Jerusalem — Positron annihilation spectroscopy provides both depth of penetration to study bulk defects in materials as well as nano-scale resolution. This measurement range is achieved by slowing positrons from a radioactive source, typically ^{22}Na, by sending them through a moderator, typically W or solid Ne. The nearly thermal positrons are then accelerated to the desired energy by means of an electrostatic potential. The SPOT project at The Hebrew University of Jerusalem proposes to increase the luminosity of the beam by applying the best practices currently in us, as well as using a short-lived source of positrons, ^{18}F. Simulations based on our current designs indicate this project will be able to deliver positrons in the energy range of 50-50000eV with an energy resolution of 1eV is possible. We will present the unique technical challenges of using this source of positrons, how we plan to overcome them, the results of simulations, and facility construction progress.

Q1.00344 Put forward the basic particle problems , HAN YONGQUAN, 13241375685 — The two kind of fundamental particles who constitute the material world is: superluminal particles and tachyon. First, the elementary particle velocity is a measure of quality Second, due to the quality of superluminal particles is big, strong convergence for atomic, molecular attraction, such as "entity" material composed of neutron Third, the light particles due to the quality of small, weak gravity launched into outer space, namely the Tachyon energy into light particles Fourth, The Tachyon convergence in atomic, molecular, so we can hardly observed superluminal Fifth, atom, molecule are internal Tachyon Sixth, the gravitational force between microscopic particles is greater than the static electricity Then we can draw a conclusion: now, the quality determination is based on the superluminal mechanism determination, this conclusion is quality is relative essential reason. Author: hanyongquan TEL: 13241375685

Q1.00345 Pump-probe experiments of single-pulse femtosecond laser plasma-channel formation in fused silica , TREVOR S. BOWMAN, LLOYD M. DAVIS, University of Tennessee Space Institute — Femtosecond laser pulses provide a means to machine structures with small heat-affected areas with a highly non-linear mechanism that enables direct writing of nanoscale features. Fabrication at this scale can be applied to a large range of applications, including micro-optical and micro-fluidic devices. During single-shot ablation, the formation of opaque plasma in the focal region of a tightly focused beam typically limits the depth of the feature and creates a shallow crater. However, recent reports have shown the ablation of deep nanoholes with aspect ratios greater than 20. Proposed mechanisms for creating such high aspect ratio structures include nonlinear Kerr self-focusing and the reshaping of the Gaussian pulse into a Bessel profile. These mechanisms would create an elongated plasma channel beyond the focal region. We are developing a single-shot, pump-probe experiment to study the time-resolved formation and relaxation of plasma in femtosecond laser machining of fused silica. During the fabrication of high aspect ratio holes, the transmission characteristics of a frequency-doubled probe pulse with a controlled delay provide information about the plasma dynamics. We also briefly discuss time-resolved imaging of the material ejected during the ablation process.

3:06PM R0.00002 Earth's Climate History from Glaciers and Ice Cores[1] , LONNIE THOMPSON, The Ohio State University — Glaciers serve both as recorders and early indicators of climate change. Over the past 35 years our research team has recovered climatic and environmental histories from ice cores drilled in both Polar Regions and from low to mid-latitude, high-elevation ice fields. Those ice core –derived proxy records extending back 25,000 years have made it possible to compare glacial stage conditions in the Tropics with those in the Polar Regions. High-resolution records of δ^{18}O (in part a temperature proxy) demonstrate that the current warming at high elevations in the mid- to lower latitudes is unprecedented for the last two millennia, although at many sites the early Holocene was warmer than today. Remarkable similarities between changes in the highland and coastal cultures of Peru and regional climate variability, especially precipitation, imply a strong connection between prehistoric human activities and regional climate. Ice cores retrieved from shrinking glaciers around the world confirm their continuous existence for periods ranging from hundreds to thousands of years, suggesting that current climatological conditions in those regions today are different from those under which these ice fields originated and have been sustained. The ongoing widespread melting of high-elevation glaciers and ice caps, particularly in low to middle latitudes, provides strong evidence that a large-scale, pervasive and, in some cases, rapid change in Earth's climate system is underway. Observations of glacier shrinkage during the 20th and 21st century girdle the globe from the South American Andes, the Himalayas, Kilimanjaro (Tanzania, Africa) and glaciers near Puncak Jaya, Indonesia (New Guinea). The history and fate of these ice caps, told through the adventure, beauty and the scientific evidence from some of world's most remote mountain tops, provide a global perspective for contemporary climate.

[1]NSF Paleoclimate Program

3:42PM R0.00003 Physical Controls of the Earth's Climate and Climate change , GRAEME STEPHENS, JPL, California Institute of Technology — The Earth's climate system and changes to it are determined by the physical processes that govern the flows of energy to and from the atmosphere and Earth's surface. Although the energy exchanges at the top of the atmosphere are well determined from available satellite measurements, the global character of the energy flows *within* the climate system, and to and from the Earth's surface in particular, are not directly measured and thus are much more uncertain. The surface energy balance is particularly important since geographical variations of its distribution drives ocean circulations, dictates the amount of water evaporated from the Earth's surface, fuels the planetary hydrological cycle and ultimately controls how this hydrological cycle responds to forced climate change. This talk reviews our state of understanding of the physical processes that determine the energy balance, couple to the Earth's water cycle and are responsible for the most important climate feedbacks that dictate the pace of climate change. Challenges in understanding the mechanisms responsible for feedbacks associated with clouds and precipitation, water vapor, snow cover and carbon will be highlighted. The further complexity and uncertainty that aerosols add to the cloud and precipitation feedbacks will also be reviewed. The effects of uncertainties in our understanding of the physical climate system, and feedbacks within it, will be reviewed in the context of climate change projections.

4:18PM R0.00004 Environmental Forensics: Molecular Insight into Oil Spill Weathering Helps Advance High Magnetic Field FT-ICR Mass Spectrometry[1] , AMY MCKENNA, National High Magnetic Field Laboratory — The depletion of terrestrial global oil reserves has shifted oil exploration into offshore and ultra-deep water ($>$ 5000 ft) oil reserves to meet global energy demands. Deep water reservoirs are currently in production in many parts of the world, including the Gulf of Mexico, but production is complicated by the water depth and thick salt caps that challenge reservoir characterization / production. The explosion aboard the *Deepwater Horizon* in April 2010 resulted in an estimated total release of $\sim$5 million barrels (BP claims that they collected $\sim$1M barrels, for a net release of 4 M) of light, sweet crude oil into the Gulf of Mexico and shifted attention toward the environmental risks associated with offshore oil production. The growing emphasis on deep water and ultra-deep water oil production poses a significant environmental threat, and increased regulations require that oil companies minimize environmental impact to prevent oil spills, and mitigate environmental damage when spills occur. Every oil spill is unique. The molecular transformations that occur to petroleum after contact with seawater depend on the physical and chemical properties of the spilled oil, environmental conditions, and deposition environment. Molecular-level knowledge of the composition, distribution, and total mass of released hydrocarbons is essential to disentangle photo- and bio-degradation, source identification, and long-term environmental impact of hydrocarbons released into the environment. Fourier transform ion cyclotron resonance mass spectrometry (FT-ICR MS) is unsurpassed in its ability to characterize complex mixtures at the level of elemental composition assignment. Only FT-ICR mass spectrometry can routinely achieve the required minimum resolving power necessary to elucidate molecular-level characterization of crude oil. Conversely, the spectral complexity of petroleum facilitates identification of systematic errors in the accumulation, transfer, excitation, and detection events in the FT-ICR experiment. For example, the high density of peaks at each nominal mass unit provides unprecedented insight into how excitation conditions affect ion motion during detection. Aggregated oil (i.e., tar balls, tar mats) that reached the surface exhibits a more than two-fold increase in the total number of detected species, with an increased number of oxygenated species. Principal component analysis (PCA) applied to two possible source oils (contained within the same ship) and weathered samples provide the first application of FT-ICR MS for source identification. Molecular formulae from parent and weathered oil indicate that the lightest petroleum fractions (saturated hydrocarbons) are the most readily oxidized components, and can serve as a template to determine chemical transformations that occur throughout the water column. The ability to differentiate and catalogue compositional changes that occur to oil after its release into the environment relies heavily on gains achieved in nearly all steps in the FT-ICR mass spectral experiment required to accommodate larger ion populations inherent to heavily weathered crude oil. Here, we present the requirement for FT-ICR MS for comprehensive oil spill characterization, and highlight advances made to FT-ICR MS experimental conditions developed from petroleum characterization.

2:30PM R1.00001 Electric Field Control of Magnetization Using Multiferroic BFO , SAYEEF SALAHUDDIN, University of California, Berkeley — No abstract available.

3:06PM R1.00002 Controlling Magnetism by light[1] , THEO RASING, Radboud University Nijmegen — From the discovery of sub-picosecond demagnetization over a decade ago to the recent demonstration of magnetization reversal by a single 40 femtosecond laser pulse, the manipulation of spins by ultra short laser pulses has become a fundamentally challenging topic with a potentially high impact for future spintronics, data storage and manipulation and quantum computation. In addition, when the time-scale of the perturbation approaches the characteristic time of the exchange interaction ($\sim$ 10-100 fs), the magnetization dynamics enters a novel, highly non-equilibrium, regime, which was recently demonstrated by both fs optical and X-ray experiments. Theoretically, this field is still in its infancy, using phenomenological descriptions of the none-equilibrium dynamics between electrons, spins and phonons via 2- or 3-temperature models and atomistic spin simulations. A proper description should include the time dependence of the exchange interaction and nucleation phenomena on the nanometer length scale. Such developments need to be supported by experimental investigations of magnetism at its fundamental time and length scales, i.e. with fs time and nanometer spatial resolution. Such studies require the excitation and probing of the spin and angular momentum contributions to the magnetic order at timescales of 10fs and below, a challenge that could be met by the future fs X-ray FEL's but in some cases also with purely optical techniques.

3:42PM R1.00003 Spin Mechanics in Ferromagnet/Ferroelectric Hybrid Structures , SEBASTIAN GOENNENWEIN, Walther-Meissner-Institut, Bayerische Akademie der Wissenschaften, Garching, Germany — In most ferromagnets, magnetic and elastic degrees of freedom are coupled – as evident, e.g., from the hum of a transformer. In the "spin mechanics" scheme, one intentionally exploits magneto-elastic coupling (inverse magneto-striction) to control the magnetization of ferromagnetic films. On the one hand, I will briefly review spin mechanics in the static limit, taking ferromagnetic nickel thin film/piezoelectric actuator hybrid structures as prototype examples [1]. In these hybrids, the application of an electric field to the actuator results in a uniaxial strain, which is transferred into the Ni film. Due to magneto-elastic coupling, the voltage-controlled strain modifies the magnetic anisotropy and thus induces a magnetization reorientation. This allows for a voltage-controlled, fully reversible magnetization orientation manipulation within a range of approximately 90 degrees at room temperature in these hybrids. On the other hand, I will show that the spin mechanics scheme also is operational at GHz frequencies. In the corresponding experiments, we use surface acoustic waves (SAWs) propagating in Ni/$LiNbO_3$ hybrid devices for the all-elastic excitation and detection of ferromagnetic resonance (FMR). Our SAW magneto-transmission data are consistently described by a modified Landau-Lifshitz-Gilbert approach [2], in which the magnetization precession is not driven by a conventional, external microwave magnetic field, but rather by a purely virtual, internal tickle field stemming from radio-frequency magneto-elastic interactions. This causes a distinct magnetic field orientation dependence of elastically driven FMR, observed in both simulations and experiment. Last but not least, I will address perspectives for spin mechanics experiments, e.g., the study of magnon-phonon coupling, or acoustic spin pumping [3] in normal metal/ferromagnet hybrid structures.

4:18PM R1.00004 Control of Magnetic Properties Across Metal to Insulator Transitions[1] , JOSE DE LA VENTA, University of California San Diego — Controlling the magnetic properties of ferromagnetic (FM) thin films without magnetic fields is an on-going challenge in condensed matter physics with multiple technological implications. External stimuli and proximity effects are the most used methods to control the magnetic properties. An interesting possibility arises when ferromagnets are in proximity to materials that undergo a metal-insulator (MIT) and structural phase transition (SPT). The stress associated with the structural changes produces a magnetoelastic anisotropy in proximity coupled ferromagnetic films that allows controlling the magnetic properties without magnetic fields. Canonical examples of materials that undergo MIT and SPT are the vanadium oxides (VO_2 and V_2O_3). VO_2 undergoes a metal/rutile to an insulator/monoclinic phase transition at 340 K. In V_2O_3 the transition at 160 K is from a metallic/rhombohedral to an insulating/ monoclinic phase. We have investigated the magnetic properties of different combinations of ferromagnetic (Ni, Co and Fe) and vanadium oxide thin films. The (0.32%) volume expansion in VO_2 or the (1.4%) volume decrease in V_2O_3 across the MIT produces an interfacial stress in the FM overlayer. We show that the coercivities and magnetizations of the ferromagnetic films grown on vanadium oxides are strongly affected by the phase transition. The changes in coercivity can be as large as 168% and occur in a very narrow temperature interval. These effects can be controlled by the thickness and deposition conditions of the different ferromagnetic films. For VO_2/Ni bilayers the large change in the coercivity occurring above room temperature opens the possibilities for technological applications.

Session R2 DCMP: Invited Session: New Developments in Organic Spintronics Ballroom II - Markus Wohlgenannt, University of Iowa

2:30PM R2.00001 Electrically detected magnetic resonance in organic light emitting diodes[1] , CHRISTOPH BOEHME, Department of Physics and Astronomy, University of Utah, Salt Lake City, 84112 UT, USA — Due to the built-in weak spin-orbit coupling of carbon based materials, electronic transitions in organic semiconductors are subjected to strong spin-selection rules that are responsible for a number of interesting electron spin- and even nuclear spin-dependent electrical and optical properties of these materials, including device efficiencies of organic light emitting diodes and solar cells or magnetoresistive and magneto-optic effects. In recent years, we have studied how these effects work and how they can be utilized for organic semiconductor device improvement and new device applications. Our focus has been in particular on the effects of spin on π-conjugated polymer based bipolar injection devices (more commonly known as organic light emitting diodes, OLEDs). In OLEDs, spin-interactions between recombining charge carriers do not only control electroluminescence rates but also the magnetoresistance. We have shown that spin-coherence can be observed through current measurements [1] and that these effects can be utilized for a coherent, pulsed electrically detected magnetic resonance spectroscopy (pEDMR) which enables us to encode the qualitative nature of spin-dependent mechanisms (the polaron pair mechanism [2,3] and the triplet polaron recombination [4]) and the their dynamical nature (spin-relaxation, electronic relaxation, hopping times [5]). The insights gained from these studies have led to the invention of a robust absolute magnetic field sensor based on organic thin film materials with absolute sensitivities of $<50 nT/Hz^{1/2}$ [6].

3:06PM R2.00002 Direct measurements of spin propagation in organic spin valves by low-energy muon spin rotation[1] , ALAN DREW, Queen Mary University of London — Organic semiconductors fall into a class of materials that shows significant potential for future applications, but many of the fundamental mechanisms of spin relaxation and transport are not understood. As a result, the field is becoming extremely topical, but there is a need for suitable techniques that can yield information on intrinsic spin dynamics and transport in organic materials. I will present Low Energy Muon Spin Rotation measurements and demonstrate that this technique can directly measure the depth resolved spin polarisation of charge carriers in organic spin injection devices [1]. I will then go on to show that it is possible to separate out the various contributions to spin decoherence, differentiating between interface and bulk effects. By correlating macroscopic measurements with these separated interfacial and bulk effects, I will present evidence that it is possible to engineer interfaces in organic spintronic devices [2]. Finally, I will present some of the latest results on how spin injection and transport depend on bias voltage [3].

3:42PM R2.00003 Percolative Theory of Organic Magnetoresistance and Fringe-Field Magnetoresistance

, MICHAEL E. FLATTÉ, Department of Physics and Astronomy, University of Iowa, Iowa City, Iowa, 52242 USA — A recently-introduced percolation theory [1,2] for spin transport and magnetoresistance in organic semiconductors describes the effects of spin dynamics on hopping transport by considering changes in the effective density of hopping sites, a key quantity determining the properties of percolative transport. Increases in the spin-flip rate open up "spin-blocked" pathways to become viable conduction channels and hence, as the spin-flip rate changes with magnetic field, produce magnetoresistance. Features of this percolative magnetoresistance can be found analytically in several regimes, and agree with measurements of the shape and saturation of measured magnetoresistance curves [3-5]. We find that the threshold hopping distance is analogous to the branching parameter of a phenomenological two-site model [6], and that the distinction between slow and fast hopping is contingent on the threshold hopping distance. Regimes of slow and fast hopping magnetoresistance are uniquely characterized by their line shapes. Studies of magnetoresistance in known systems with controllable positional disorder would provide an additional stringent test of this theory. Extensions to this theory also describe fringe-field magnetoresistance, which is the influence of fringe magnetic fields from a nearby unsaturated magnetic electrode on the conductance of an organic film [7]. This theory agrees with several key features of the experimental fringe-field magnetoresistance, including the applied fields where the magnetoresistance reaches extrema, the applied field range of large magnetoresistance effects from the fringe fields, and the sign of the effect.

All work done in collaboration with N. J. Harmon, and fringe-field magnetoresistance work in collaboration also with F. Macià, F. Wang, M. Wohlgenannt and A. D. Kent. This work was supported by an ARO MURI.

4:18PM R2.00004 Spin-polarized organic light emitting diode based on a novel bipolar spin-valve[1]

, THO NGUYEN, The University of Georgia — The spin-polarized organic light emitting diode (spin-OLED) has been long sought device within the field of organic spintronics. We designed, fabricated and studied a spin-OLED with ferromagnetic (FM) electrodes that acts as a bipolar organic spin valve (OSV), based on deuterated derivative of poly(phenylene-vinylene) with small hyperfine interaction [1]. In the double-injection limit the device shows $\sim 1\%$ spin-valve magneto-electroluminescence (MEL) response that follows the FM electrode coercive fields, which originates from the bipolar spin-polarized space charge limited current [2]. In stark contrast to the response properties of homopolar OSV devices, the MEL response in the double-injection device is practically bias voltage independent, and its temperature dependence follows that of the FM electrode magnetization. Our findings provide a pathway for organic displays controlled by external magnetic fields.

4:54PM R2.00005 Spin-orbit coupling in organic spintronics[1]

, ZHI-GANG YU, SRI International — I will talk about spin-orbit coupling (SOC) in π-conjugated organicmaterials and its effects on spin characteristics including the spin-relaxation time, spin-diffusion length, and g factor [1]. While π electrons are responsible for low-energy electrical and optical processes in π-conjugated organic solids, σ electrons must be explicitly included to properly describe the SOC. The SOC mixes up- and down-spin states and, in the context of spintronics, can be quantified by an admixture parameter in the electron and hole polaron states in π-conjugated organics. Molecular geometry fluctuations such as ring torsion, which are common in soft organic materials and may depend on sample preparation, are found to have a strong effect on the spin mixing. The SOC-induced spin mixing leads to spin flips as polarons hop from one molecule to another, giving rise to spin relaxation and diffusion. The spin-relaxation rate is found to be proportional to the carrier hopping rate. The spin-diffusion length depends on the spin mixing and hopping distance but is insensitive to the carrier mobility. The SOC influences the g factor of the polaron state and makes it deviate from the free-electron value. The SOC strengths in common organics are quantified based on first-principles calculations and their values in tris-(8-hydroxyquinoline) aluminum (Alq_3) and in copper phthalocyanine (CuPc) are particularly strong, due to the orthogonal arrangement of the three ligands in the former and Cu $3d$ orbitals in the latter. The theory quantitatively explains the recent measured spin-diffusion lengths in Alq_3 from muon spin rotation and in CuPc from spin-polarized two-photon photoemission.

Wednesday, March 20, 2013 2:30PM - 5:30PM –

Session R3 GSNP DCMP: Invited Session: Nonequilibrium Relaxation and Aging in Materials

Ballroom III - Uew Tauber, Virginia Polytechnical Institute and State University

2:30PM R3.00001 Nonequilibrium behavior in strongly correlated electron systems[1]

, DRAGANA POPOVIĆ, National High Magnetic Field Laboratory, Florida State University — There is growing evidence that nonequilibrium behavior may underlie many complex phenomena exhibited by strongly correlated electronic materials with disorder. A two-dimensional electron system (2DES) in Si metal-oxide-semiconductor field-effect transistors has emerged as an excellent model system for studying glassy or nonequilibrium charge dynamics near the metal-insulator transition (MIT). In particular, studies of both conductance relaxations and noise on disordered samples, using several different experimental protocols, have established that the 2DES in Si exhibits all the main manifestations of glassiness: slow, correlated dynamics, nonexponential relaxations, diverging equilibration time (as temperature $T \to 0$), aging and memory. The results provide strong evidence that many such universal features are robust manifestations of glassiness, regardless of the dimensionality of the system. In addition, the experiments show that the 2D MIT is closely related to the melting of this Coulomb glass. The observations are consistent with predictions of the theoretical models that describe the MIT as a Mott transition with disorder. Some effects that are unique to Coulomb glasses have also been revealed, which should have important implications for theoretical modeling of the glassy dynamics in a 2DES and other strongly correlated materials.

3:06PM R3.00002 Universally slow , ARIEL AMIR, Harvard University — Glassy systems are very common in nature, from disordered electronic and magnetic systems to window glasses and crumpled paper. Among their key properties are slow relaxations to equilibrium without a typical timescale, and dependence of relaxation on the system's age. After reviewing some of these physical systems, I will describe our approach to the problem, and show how it leads to a novel class of aging. The slow relaxations result from a broad distribution of "relaxation eigenmodes," which relates to a particular class of random matrices. I will discuss recent results on the structure and localization properties of these modes, and their implications.

3:42PM R3.00003 Dynamical symmetries in ageing phenomena , MALTE HENKEL, Institut Jean Lamour, Universite de Lorraine Nancy — Systems undergoing physical ageing can be characterised by (i) undergoing slow relaxation (ii) absence of time-translation-invariance and (iii) dynamical scaling. Specific examples are obtained by quenching many-body systems from a high-temperature initial state to below their critical temperature. Here, we shall consider consequences of an assumed extension of dynamical scaling to a larger group of *local scale-transformations*. Explicit scaling forms of two-time responses and correlators are obtained. These will be compared with simulational data in simple magnets, as well as in many-body systems without an equilibrium stationary state, such as critical directed percolation or domain-growth in the Kardar-Parisi-Zhang universality class.

4:18PM R3.00004 Probing equilibrium by nonequilibrium dynamics: Aging in Co/Cr superlattices[1] , CHRISTIAN BINEK, University of Nebraska-Lincoln — Magnetic aging phenomena are investigated in a structurally ordered Co/Cr superlattice through measurements of magnetization relaxation, magnetic susceptibility, and hysteresis at various temperatures above and below the onset of collective magnetic order. We take advantage of the fact that controlled growth of magnetic multilayer thin films via molecular beam epitaxy allows tailoring the intra and inter-layer exchange interaction and thus enables tuning of magnetic properties including the spin-fluctuation spectra. Tailored nanoscale periodicity in Co/Cr multilayers creates mesoscopic spatial magnetic correlations with slow relaxation dynamics when quenching the system into a nonequilibrium state. Magnetization relaxation in weakly correlated spin systems depends on the microscopic spin-flip time of about 10 ns and is therefore a fast process. The spin correlations in our Co/Cr superlattice bring the magnetization dynamics to experimentally better accessible time scales of seconds or hours. In contrast to spin-glasses, where slow dynamics due to disorder and frustration is a well-known phenomenon, we tune and increase relaxation times in ordered structures. This is achieved by increasing spin-spin correlation between mesoscopically correlated regions rather than individual atomic spins, a concept with some similarity to block spin renormalization. Magnetization transients are measured after exposing the Co/Cr heterostructure to a magnetic set field for various waiting times. Scaling analysis reveals an asymptotic power-law behavior in accordance with a full aging scenario. The temperature dependence of the relaxation exponent shows pronounced anomalies at the equilibrium phase transitions of the antiferromagnetic superstructure and the ferromagnetic to paramagnetic transition of the Co layers. The latter leaves only weak fingerprints in the equilibrium magnetic behavior but gives rise to a prominent change in nonequilibrium properties. Our findings suggest that scaling analysis of nonequilibrium data can serve as a probe for weak equilibrium phase transitions.

4:54PM R3.00005 Aging processes in disordered materials: High-T_c superconductors and ferromagnets[1] , MICHEL PLEIMLING, Virginia Tech — Physical aging is generically encountered in systems far from equilibrium that evolve with slow dynamics. Well known examples can be found in structural glasses, spin glasses, magnetic systems, and colloids. Recent years have seen major breakthroughs in our understanding of aging processes in non-disordered systems. Progress in understanding aging in disordered systems has been much slower though. In this talk I discuss non-equilibrium relaxation in two different types of disordered systems: coarsening ferromagnets with disorder, characterized by a crossover from an initial power-law like growth of domains to a slower logarithmic growth regime, and interacting vortex lines in disordered type-II superconductors, where the interplay of vortex-vortex interaction and pinning results in a very rich non-equilibrium behavior.

Wednesday, March 20, 2013 2:30PM - 5:30PM –

Session R4 DCMP: Topologocal insulators: Nanostructures and Possible Applications: Transport phenomena Ballroom IV - Vidya Madhaven, Boston College

2:30PM R4.00001 ABSTRACT WITHDRAWN –

2:42PM R4.00002 Thermoelectric power factor of topological insulator $Bi_{2-x}Sb_xTe_{3-y}Se_y$, TE CHIH HSIUNG, TING YUAN CHEN, LI ZHAO, YI HSIN LIN, YANG YUAN CHEN, Institute of Physics, Academia Sinica, Taipei, Taiwan — Topological insulator (TI) is a new quantum material. The surface states of TIs are protected by time-reversal symmetry which allows charge carrier to propagate on the edge of surface conducting channel without scattering. $Bi_{1.5}Sb_{0.5}Te_{1.7}Se_{1.3}$ is a well-known TI [1] and thermoelectric material because of its promising thermoelectric performances at room temperature. The conversion efficiency of thermoelectric material is characterized by the dimensionless figure of merit ZT. Decades of effort were devoted to ZT optimization either through composition alteration or nanostructure fabrication. In this study, the temperature dependence of resistance of bulk (exfoliated specimen with 140 μm thickness) shows semiconductor behavior (0.04 Ω cm at 300 K) without saturating regime in lower temperatures. In contrast, its nanoflake counterpart (100-500 nm) [2] shows a transition from semiconductor to metallic behavior near 100 – 150 K with decreasing temperature and saturation at 10 K. Surface contribution to the total conductance of exfoliated specimens was acquired through Hall effect measurements in the magnetic field ranging from -9 to 9 Tesla. Surface contribution of BSTS samples increases from 3% to 70% as thickness decreases from 140 to 7 μm. In this work, we report a systematic study of thermoelectric power factor for various thicknesses of BSTS specimens to examine the thermoelectric power factor of their surfaces.

2:54PM R4.00003 Spin-dependent Peltier effect in 3D topological insulators , PARIJAT SENGUPTA, TILLMANN KUBIS, MICHAEL POVOLOTSKYI, GERHARD KLIMECK, Purdue University — The Peltier effect represents the heat carrying capacity of a certain material when current passes through it. When two materials with different Peltier coefficients are placed together, the Peltier effect causes heat to flow either towards or away from the interface between them. This work utilizes the spin-polarized property of 3D topological insulator (TI) surface states to describe the transport of heat through the spin-up and spin-down channels. It has been observed that the spin channels are able to carry heat independently of each other. Spin currents can therefore be employed to supply or extract heat from an interface between materials with spin-dependent Peltier coefficients. The device is composed of a thin film of Bi2Se3 sandwiched between two layers of Bi2Te3. The thin film of Bi2Se3 serves both as a normal and topological insulator. It is a normal insulator when its surfaces overlap to produce a finite band-gap. Using an external gate, Bi2Se3 film can be again tuned in to a TI. Sufficiently thick Bi2Te3 always retain TI behavior. Spin-dependent Peltier coefficients are obtained and the spin Nernst effect in TIs is shown by controlling the temperature gradient to convert charge current to spin current.

3:06PM R4.00004 Surface-to-surface scattering in three-dimensional (3D) topological insulator (TI) thin films , GEN YIN, DARSHANA WICKRAMARATNE, ROGER LAKE, Department of Electrical Engineering, University of California, Riverside — When the thickness of a 3D TI material is reduced below approximately 6nm, hybridization of the opposite surfaces states can result in inter-surface tunneling. Due to the rotational symmetry of the thin film, the k-s locking relation on opposite surfaces also has opposite chirality. Thus, in this inter-surface scattering mechanism, back-scattering is allowed without the flip of the spin. This effect breaks the protection of TI surface states against back-scattering. To investigate the influence of the inter-surface scattering mechanism, we study different near-elastic scattering mechanisms in the surface state transport using Boltzmann transport equations within the relaxation time approximation. The effect of screened Coulomb impurities, low-energy acoustic phonons and surface magnetic impurities on the TI surface states will be discussed. The response of the inter-surface scattering of TI states to various external stimuli such as a Rashba-like splitting and the orientation of the impurity magnetic moments will also be presented. Using our simulation results, we propose possible experimental methods to modulate the back-scatter protection of TI surface states in thin film TI materials.

3:18PM R4.00005 Realization of Negative Capacitance with Topological Insulator Based MOS Capacitor[1] , HUI YUAN, GMU, KAI ZHANG, ODU, HAO ZHU, HAITAO LI, DIMITRIS IOANNOU, GMU, HELMUT BAUMGART, ODU, CURT RICHTER, NIST, QILIANG LI, GMU, ECE, GEORGE MASON UNIVERSITY TEAM, SEMICONDUCTOR AND DIMENSIONAL METROLOGY DIVISION OF NIST TEAM, ECE, OLD DOMINION UNIVERSITY TEAM — Negative capacitance is one of way to achieve steep subthreshold slope exceeding its thermal limit in metal-oxide-semiconductor field effect transistor (MOSFET). The common materials under study for negative capacitance are ferroelectric thin films. However, the integration of regular ferroelectric materials (e.g., PZT) into semiconductor based devices is usually difficult due to the high temperature required for crystallization and precise control of oxygen percentage in ferroelectric materials. In this work, we found that negative capacitance can be achieved by introducing a topological insulator interlayer into a conventional MOS capacitor. Three-dimensional topological insulators inherently contain a insulator/semiconductor bulk and a gapless conducting surface. When an electric field is added to topological insulator interlayer, imbalanced charge carriers (electrons and holes) would be generated and then accumulate on either surface of the film, resulting in a temporary residual polarization. As a result, a ferroelectric-like hysteresis and negative capacitance are achieved. We believe this approach will be very attractive to achieve steep subthreshold using negative capacitance.

3:30PM R4.00006 Transport measurements of the topological surface states in Bi_2Te_3 nanoribbon field effect devices , LUIS A. JAUREGUI, Purdue University, MICHAEL T. PETTES, LI SHI, University of Texas at Austin, LEONID P. ROKHINSON, YONG P. CHEN, Purdue University — We have grown nanoribbons (NRs) of Bi_2Te_3, a prototype topological insulator, by CVD and characterized them by TEM, Raman Spectroscopy and EDS. We fabricate backgated field effect devices where the chemical potential can be tuned and ambipolar field effect has been observed. The as-grown NRs are n-type and the 4-terminal resistance (R4p) versus temperature (T) shows a metallic behavior. Applying a sufficiently negative Vg, the R4p vs T displays an insulating behavior that saturates in a plateau at $T < 100K$, suggesting a metallic surface conduction dominant at low temperatures. Aharonov-Bohm (AB) oscillations of surface conducting carriers are observed in the magneto-resistance (MR) with a magnetic (B) field parallel to the NR axis. We have also measured the Shubnikov de Haas (SdH) oscillations with the B-field perpendicular to the NR axis at different carrier densities (n). The extrapolated Landau level crossing at $1/B = 0$ is $\sim$0.5 and the extracted cyclotron mass from the T-dependence of the SdH oscillations is proportional to $\sqrt{n}$, providing direct evidence of the Dirac fermion nature of the topological surface state. Gate-tunable weak anti-localization is observed and the extracted number of decoupled coherent conduction channels is 2 at the charge neutrality point.

3:42PM R4.00007 Majorana qubit rotations in microwave cavities , CHRISTOPH BRUDER, ANDREAS NUNNENKAMP, THOMAS L. SCHMIDT, Department of Physics, University of Basel, Klingelbergstrasse 82, CH-4056 Basel, Switzerland — Majorana bound states have been proposed as building blocks for qubits on which certain operations can be performed in a topologically protected way using braiding. However, the set of these protected operations is not sufficient to realize universal quantum computing. We show that the electric field in a microwave cavity can induce Rabi oscillations between adjacent Majorana bound states. These oscillations can be used to implement an additional single-qubit gate. Supplemented with one braiding operation, this gate allows to perform arbitrary single-qubit operations.

3:54PM R4.00008 Electrical transport studies of Topological Insulator Bi_2Te_3 Nanotubes , RENZHONG DU, WEIWEI ZHAO, Department of Physics, Penn State Univ., JIAN WANG, ICQM, PKU, YUEWEI YIN, SINING DONG, XIAOGUANG LI, Department of Physics, USTC, CHAOXING LIU, MOSES CHAN, QI LI, Department of Physics, Penn State Univ. — We have studied electrical transport properties of candidate topological insulator Bismuth Telluride (Bi_2Te_3) nanotubes. Bi_2Te_3 nanotube samples were synthesized by solution phase method, with the outer diameters in the range of 70$\pm$5 nm and inner diameter 50$\pm$5 nm and the length of 3 to 10 um. Platinum contact leads were fabricated on the nanotubes by focusing ion beam assisted deposition. Electrical transport measurements were conducted at low temperatures and high magnetic fields (up to 9T). The nanotubes showed good insulating behavior in comparison with the thin films which are often metallic. Resistance oscillation as a function of magnetic field was observed when the magnetic field is applied parallel to the nanotubes. The periods range from 6000 Oe to 8350 Oe, which correspond to the diameter of 80 to 100 nm according to Aharonov-Bohm oscillation formula. This is close but slightly larger than the outer diameter of the nanotubes. The amplitude of the oscillations decays rapidly as field increases, possibly due to scattering. When the magnetic field was applied perpendicular to the nanotube, no resistance oscillation was observed. The possible origins of the oscillation effect will be discussed.

4:06PM R4.00009 Surface state transport in MBE-grown topological insulator $(Bi_{1-x}Sb_x)_2Te_3$ thin films and field effect transistors , JIFA TIAN, Department of Physics, Purdue University, CUIZU CHANG, Department of Physics, Tsinghua University, HELIN CAO, Department of Physics, Purdue University, JIUNING HU, Electrical Engineering, Purdue University, TAI-LUNG WU, Department of Physics, Purdue University, KE HE, XUCUN MA, IOP, CAS, QIKUN XUE, Department of Physics, Tsinghua University, YONG CHEN, Department of Physics, Purdue University — Topological insulators feature spin-helical, Dirac fermion surface states, promising potential applications in both nanoelectronics and spintronics. However, experimental identification of a clear transport signal of the surface state conduction is still challenging. Here, we report a systematical study of the gate tunable magneto-transport in MBE grown $(Bi_{1-x}Sb_x)_2Te_3$ (x=0.96) thin film on $SrTiO_3$ substrate. We observed an ambipolar field effect and a sign change in the Hall resistance as the gate voltage (V_g) crosses the Dirac point (V_D). Temperature (T) dependence of the resistance at different V_g shows a transition from a metallic to an insulating bulk with 100% surface conduction at low T. Weak antilocalization measurements indicate a π Berry phase near V_D. We also performed spin valve measurements and observed a resistance asymmetry (which reverses with reversing current direction) between the positive and negative in-plane magnetic fields, demonstrating the predicted locking between spin and momentum for the surface state. We also studied the thermal-electric transport, demonstrating a sign change of the thermoelectric power across the V_D as the carrier type switches from electron to hole.

4:18PM R4.00010 ABSTRACT WITHDRAWN —

4:30PM R4.00011 Detection of Majorana Fermions in circuit QED , JEROME BOURASSA, CLEMENS MUELLER, ALEXANDRE BLAIS, Universite de Sherbrooke — Superconducting quantum circuits, such as the flux and the transmon qubits, have been proposed to measure and control the quantum state of topological qubits based on pairs of Majorana fermions [1-4]. This is possible by making the superconducting qubit transition frequencies sensitive to the fermionic parity representing the topological qubit state. In this talk, we propose to measure the fermionic parity using a flux qubit integrated in a microwave resonator. In this proposal, the flux qubit always remains in its ground state and is used as a passive circuit element which modifies the resonance frequency of the resonator depending on the charge state of a nearby pair of Majorana fermions. Since it is always in its ground state, the requirements on the qubit coherence properties and fabrication parameters are less stringent than in other proposals.

4:42PM R4.00012 Antimony arsenide: Chemical ordering and order-disorder transition in SbAs , DANIEL SHOEMAKER, Argonne National Laboratory, THOMAS CHASAPIS, Northwestern University, DAT DO, Michigan State University, MELANIE FRANCISCO, DUCK YOUNG CHUNG, Argonne National Laboratory, S. D. MAHANTI, Michigan State University, ANNA LLOBET, Lujan Neutron Scattering Center, Los Alamos National Laboratory, MERCOURI KANATZIDIS, Argonne National Laboratory — The A7 structure of the Group V elements can display chemical ordering of Sb and As, which were previously thought to mix randomly. Our structural characterization of the compound SbAs is performed by single-crystal and high-resolution synchrotron x-ray diffraction, and neutron and x-ray pair distribution function analysis. All least-squares refinements indicate ordering of Sb and As, resulting in a GeTe-type structure without inversion symmetry. This lowering of symmetry does not result in any new Bragg reflections, so high-quality scattering data are required. High-temperature diffraction studies reveal an ordering transition around 550 K. Transport and infrared reflectivity measurements, along with first-principles calculations, find that SbAs has a direct band separation larger than that of Sb or As. Because even subtle substitutions in the semimetals, notably $Bi_{1-x}Sb_x$, can open semiconducting energy gaps, a further investigation of the interplay between chemical ordering and electronic structure on the A7 lattice is warranted.

4:54PM R4.00013 Probing Topological Superconductors with Elastic Strain Fields , DAVID SCHMELTZER, City College of the City University of New York, AVADH SAXENA, Los Alamos National Lab — We introduce a model for superconductivity in a topological insulator. The response of this system is probed by applying an external stress. We find that the stain field introduces connections in the superconductor and the response of the superconductor is given by the chiral anomaly which is proportional to the disclination density (for s-wave) or dislocations density (for the p-wave) superconductor. This result modifies the sound wave equations. In particular, we find that the core of the disclinations contains the normal matter in a superconductor. The presence of the long-range field induced by the topological response modifies the elastic properties of the solid which can be probed experimentally. The effect of rotating magnetic fields is also considered. Due to the Larmor theorem it is shown that the rotations replace the magnetic field by an effective magnetic field.

5:06PM R4.00014 High resolution spin- and angle-resolved photoelectron spectroscopy for 3D spin vectorial analysis[1] , TAICHI OKUDA, KOJI MIYAMOTO, Hiroshima Synchrotron Radiation Center, Hiroshima University, AKIO KIMURA, Graduate School of Science, Hiroshima University, HIROFUMI NAMATAME, Hiroshima Synchrotron Radiation Center, Hiroshima University, MASAKI TANIGUCHI, Graduate School of Science, Hiroshima University and Hiroshima Synchrotron Radiation Center, Hiroshima University — Spin- and angle-resolved photoelectron spectroscopy (SARPES) is the excellent tool which can directly observe the band structure of crystals with separating spin-up and -down states. Recent findings of new class of materials possessing strong spin orbit interaction such as Rashba spin splitting systems or topological insulators stimulate to develop new SARPES apparatuses and many sophisticated techniques have been reported recently[1-3]. Here we report our newly developed a SARPES apparatus for spin vectorial analysis with high precision at Hiroshima Synchrotron Radiation Center. Highly efficient spin polarimeter utilizing very low energy electron diffraction (VLEED) makes high resolution ($\Delta E < 10$ meV, $\Delta\theta \sim \pm\ 0.2\ ^\circ$) compatible with the SARPES measurement[4]. By placing two VLEED spin detectors orthogonally we have realized the polarization measurement of all spin components (x, y and z) with the high resolution. Some examples of the three-dimensional spin observation will be presented. [1] M. Hoesch et al., J. Electron Spectrosc. Relat. Phenom. 124, 263 (2002). [2] T. Okuda, et al., Rev. Sci. Instrum. 79, 123117 (2008). [3] S. Souma, et al., Rev. Sci. Instrum. 81, 095101 (2010). [4] T. Okuda, et al., Rev. Sci. Instrum. 82, 103302 (2011).

5:18PM R4.00015 Transport Measurements on Topological Insulators with Superconductor Electrodes[1] , YANG XU, TAI-LUNG WU, Department of Physics, Purdue University, West Lafayette, IN 47907, LUIS A. JAUREGUI, School of Electrical and Computer Engineering, Purdue University, West Lafayette, IN 47907, IREK MITKOWSKI, Department of Physics, Purdue University, West Lafayette, IN 47907, YONG P. CHEN, Department of Physics, Purdue University, West Lafayette, IN 47907; — Interplay between topological insulators (TIs) and superconductors (SCs) is interesting to study novel physics such as Majorana fermions. Here we report transport measurements on bulk TI interfaced with superconducting electrodes, including indium (In) and niobium (Nb). The TI crystals are high quality $Bi_2Te_3, Bi_2Se_3, Bi_2Te_2Se$ grown by the Bridgman method. Multiple superconducting transitions have been observed in Bi_2Te_3/In systems, possibly due to the superconducting alloys formed by In and Bi. Below the superconducting temperature of In (or Nb), the resistance of TI/Sc structure shows a pronounced upturn which may be a probe of spin-polarized surface states in TI and the interplay with SC.

Wednesday, March 20, 2013 2:30PM - 5:06PM –

Session R5 DCMP: Graphene: Transport and Optical Properties: THz and Plasmons 301 - Elbert Chia, Nanyang Technological University

2:30PM R5.00001 Terahertz conductivity of twisted bilayer graphene[1] , ELBERT E.M. CHIA, XINGQUAN ZOU, JINGZHI SHANG, JIANING LEAW, ZHIQIANG LUO, LIYAN LUO, SIEW ANN CHEONG, HAIBIN SU, Nanyang Technological University, JIAN-XIN ZHU, Los Alamos National Laboratory, A.H. CASTRO NETO, National University of Singapore, TING YU, Nanyang Technological University — Using terahertz time-domain spectroscopy, the real part of optical conductivity [$\sigma_1(\omega)$] of twisted bilayer graphene was obtained at different temperatures (10 – 300 K) in the frequency range 0.3 – 3 THz. On top of a Drude-like response, we see a strong and narrow peak in $\sigma_1(\omega)$ at ∼2.7 THz. We analyze the overall Drude-like response using a disorder-dependent (unitary scattering) model, then attribute the peak at 2.7 THz to an enhanced density of states at that energy, that is caused by the presence of van Hove singularities arising from a commensurate twisting of the two graphene layers.

[1]Singapore MOE AcRF Tier 2 (ARC 23/08), NRF-CRP (NRF-CRP4-2008-04), NNSA of the U.S. DOE at LANL (DE-AC52-06NA25396), LANL LDRD Program, NRF-CRP (R-144-000-295-281), DOE DE-FG02-08ER46512, ONR MURI N00014-09-1-1063.

2:42PM R5.00002 Theory of optical responses in the bilayer and trilayer graphene in the quantum Hall regime , TAKAHIRO MORIMOTO, Riken, MIKITO KOSHINO, Tohoku University, HIDEO AOKI, University of Tokyo — In the graphene physics, there are growing interests toward bilayer and trilayer graphene, whose electronic structures are distinct from that of monolayer graphene. It is then interesting to ask how the variety of low-lying electronic structures will affect optical responses, i.e., optical longitudinal and optical Hall conductivities, where the former describes the absorption while the latter the Faraday and Kerr rotations. Thus we study the optical conductivities in bilayer and trilayer graphene systems. We shall show for bilayer graphene that the Lifshitz transition associated with the trigonal warping greatly affects the resonance structures in Faraday rotation not only on low-energy scale where Dirac cones emerges but also in the higher-energy range with parabolic bands as a sequence of satellite resonances. For trilayer graphene, on the other hand, we shall show that the optical conductivities are dominated by the difference in the stacking order. In ABA trilayer, the resonance spectrum is a superposition of effective monolayer and bilayer contributions with band gaps, while ABC trilayer exhibits a distinct spectrum peculiar to the cubic-dispersed bands. In the latter, the trigonal warping effect becomes strong with a larger Lifshitz transition energy (∼10 meV).

2:54PM R5.00003 Dynamical Conductivity of AA-Stacked Bilayer Graphene , CALVIN TABERT, ELISABETH NICOL, University of Guelph — Motivated by the potential availability of AA-stacked bilayer graphene samples[1,2], we investigate the optical conductivity of this stacking variation[3]. We find the band structure to be made of bonding and antibonding orbitals which are linear at low energy and decoupled for the longitudinal response; this causes the conductivity to behave as the sum of an electron-doped and hole-doped monolayer graphene system. We find a low energy Drude response at charge neutrality and two step features which can be tuned by varying the chemical potential. We find that the interlayer hopping energy plays an important role in determining the onset of these steps. We compute the partial optical sum and find that the Drude weight also depends on the value of chemical potential relative to the interlayer hopping parameter.

[1] J. K. Lee et al. J. Chem. Phys. 129 234709 (2008) [2] W. Norimatsu et al. Phys. Rev. B 81 161410 (2010) [3] C. J. Tabert et al. Phys. Rev. B 86 075439 (2012).

3:06PM R5.00004 Graphene's Dynamic Conductivity in THz Regime , SUFEI SHI, UC Berkeley and Lawrence Berkeley National Laboratory, TSUNG-TA TANG, BO ZENG, LONG JU, UC Berkeley, FENG WANG, UC Berkeley and Lawrence Berkeley National Laboratory — Graphene, a single layer of carbon atoms arranged in honeycomb structure, has linear dispersion relation. The conductivity of graphene in the THz regime is highly tunable due to its gapless dispersion relation, which makes graphene a promising candidate for THz application. Using optical excitation as the pump, we probe graphene with a THz beam and study the THz conductivity in the time domain. This study sheds light on the carrier relaxation in graphene after intense optical excitation and provides information for designing future graphene-based opto-electronic device.

3:18PM R5.00005 Mid-Infrared Graphene Photoresponse[1] , ALLEN HSU, Massachusetts Institute of Technology, PATRICK HERRING, Harvard University, YONG CHEOL SHIN, Massachusetts Institute of Technology, KI KANG KIM, Dongguk University, JING KONG, Massachusetts Institute of Technology, CHARLIE MARCUS, Harvard University, NATHANIEL GABOR, TOMAS PALACIOS, PABLO JARILLO-HERRERO, Massachusetts Institute of Technology — Graphene is a two-dimensional (2D) material that has attracted great interest for electronic devices since its discovery in 2004. Due to its zero band gap band structure, it has a broad-band optical absorption ranging from the far-infrared all the way to the visible making it potentially useful for infrared photodetectors. Electrostatically gated p-n junctions have demonstrated photocurrents in the near-IR ($\lambda = 850$nm), primarily due to hot carrier mechanisms. In order to study these mechanisms at longer wavelengths ($\lambda = 10$ μm), high quality chemically vapor grown (CVD) graphene is necessary to fabricate electrostatically controlled p-n junctions due to the longer optical length scales. Moreover, at these low energies (∼ 125 meV), optical phonon scattering is suppressed and is predicted to lead to increased carrier lifetimes and enhanced photo-response. Using electrostatic gating, we are able to study the absorption mechanisms in graphene by selecting between conventional photovoltaic effects and photo-thermoelectric effects. Experiments suggest that the photocurrent signal is enhanced by electrostatic gating near the Dirac peak and reduced disorder in the graphene sample.

3:30PM R5.00006 Ga Nanoparticle/Graphene Platforms: Plasmonic and Charge Transfer Interactions , CONGWEN YI, TONG-HO KIM, ECE, Duke University, YANG YANG, Physics, Duke University, MARIA LOSURDO, Institute of Inorganic Methodologies and of Plasmas, IMIP-CNR, Italy, APRIL S. BROWN, ECE, Duke University — Metal nanoparticle (NP) – graphene multifunctional platforms are of great interest for numerous applications, such as sensing and catalysis, and for fundamental studies on charge transfer and light-matter interactions. To understand platform-photon interactions, it is important to articulate the coupling of photon-based excitations, such as the interaction between plasmons in each of the material components, as well as their charge-based interactions dependent upon the energy alignment at the metal/graphene interface. Herein, we use liquid metal Ga nanoparticles, which can be deposited at 300K on graphene, to explore the surface-enhanced Raman spectroscopy modulation induced by the NPs,. The localized charge transfer between Ga NPs and graphene are investigated, and enhancement of the graphene Raman modes is correlated with metal coverage the transfer of electrons from Ga to graphene creating local regions of enhanced electron concentration which modify the electron-phonon interaction in graphene.

3:42PM R5.00007 Terahertz and mid-infrared reflectance of epitaxial graphene , CRISTIANE N. SANTOS, BENOIT HACKENS, IMCN/NAPS, Université catholique de Louvain, Belgium, FRÉDÉRIC JOUCKEN, ROBERT SPORKEN, LPME, Université de Namur (FUNDP), 5000 Namur, Belgium, JESSICA CAMPOS DELGADO, JEAN-PIERRE RASKIN, ICTM/ELEN, Université catholique de Louvain (UCL), 1348 Louvain-la-Neuve, Belgium, DOMINGOS DE SOUSA MENESES, PATRICK ECHEGUT, CEMHTI-CNRS, 45071 Orléans cedex 2, France — Epitaxial graphene grown by thermal decomposition on SiC substrate has been widely investigated as a promising material for electronics and optics. Here, we investigate the infrared (IR) optical properties of few-layer (FL) and multilayer (ML) graphene on the C-terminated face of 6H-SiC substrates [1]. Contrary to IR transmission spectroscopy, which is hampered over a large part of the IR range by the SiC reststrahlen band and multiphonon absorption, IR reflectance gives access to invaluable information from terahertz (THz) to mid-infrared (MIR). Experimental data are well fitted with an explicit model over the entire spectral range using the SiC dielectric function and the graphene optical conductivity, taking into account both intraband and interband transitions. The number of layers extracted from our data in the FL and ML graphene corroborates with the X-ray photoelectron spectroscopy (XPS) measurements. We demonstrate that this consistent and simultaneous analysis leads to precise information on the carrier properties, doping level and the number of layers, even in the case of thick ML (30 layers or more). MIR microscopy was also used to check the sample homogeneity. [1] F. Joucken et al., Phys. Rev. B 85, 161408(R) (2012).

3:54PM R5.00008 Self-Energy and Excitonic Contributions to the Drude Conductivity of Doped Graphene , FELIPE JORNADA, STEVEN LOUIE, UC Berkeley — There has been a growing interest in the far infrared AC conductivity of doped graphene because of possible applications in optoelectronics, but there is still disagreement between recent experiments [1,2] and theories [3] with respect to the Drude weight. In this work we study from an ab-inito GW-BSE perspective the effects of the electron-electron interactions and excitons in the renormalization of the Drude weight. We discuss the role of quasiparticle lifetimes due to electron-electron and electron-phonon interactions, and we determine the AC conductivity in the forbidden region (i.e., for $\omega < 2E_F$). This work was supported by NSF grant No. DMR10-1006184, U.S. DOE under Contract No. DE-AC02-05CH11231 and the U.S. DOD - Office of Naval Research under RTC Grant No. N00014-09-1-1066. Computational resources have been provided by NERSC. [1] J. Horng et al., PRB 83, 165113 (2011). [2] H. Yan et al., ACS Nano 5, 9854 (2011). [3] S. H. Abedinpour et al., PRB 84, 045429 (2011).

4:06PM R5.00009 Tuning optical conductivity of large-scale CVD graphene by strain engineering , GUANGXIN NI, JING WU, ORHAN KAHYA, CHEE TAT TOH, Department of Physics, National University of Singapore, JONG HYUN AHN, School of Mechanical Engineering, Sungkyunkwan University, VITOR M. PEREIRA, BARBAROS ÖZYILMAZ, Department of Physics, National University of Singapore — Strain engineering has been widely recognized as an effective way to tailor the electrical properties of graphene. In the optical domain, the strain effect is also predicted to alter the optical conductivity of graphene, making graphene possible for the atomically thin optical elements. However, a direct experimental observation is still missing. Using the nanopillar structure, here we show that optical conductivity of CVD graphene under nonuniform strain exhibits periodic modulation as a function of polarization. The optical absorption can be further modulated via the application of an external uniaxial strain, which is confirmed by Raman spectroscopy as well as AFM images. Our experimental observations are quantitatively interpreted within the Kubo-Greenwood formalism. The manipulation of the optical properties of graphene demonstrated in this study can be effectively utilized in the novel type of optical devices and strain sensor applications.

4:18PM R5.00010 Tunable magneto-plasmons in graphene: an infrared study , ZHIGUO CHEN, National High Magnetic Field Laboratory, HUGEN YAN, XUESONG LI, WENJUAN ZHU, PHAEDON AVOURIS, FENGNIAN XIA, IBM T. J. Watson Research Center, ZHIQIANG LI, National High Magnetic Field Laboratory — Plasmons, collective oscillations of electrons, in graphene have attracted much attention due to their important roles in understanding the intriguing physics of graphene and potential applications in optoelectronic devices. Using infrared spectroscopy, we investigated the optical response of the plasmons in micrometer-sized graphene disks in high magnetic fields up to 18 T. Our study shows that the plasmon resonance splits into edge and bulk modes in magnetic fields. Due to the linear band structure of graphene, the splitting exhibits a sensitive doping dependence, which is not observed in conventional two-dimensional electron gas systems. Moreover, the lifetime of the two modes can be dramatically modified by magnetic fields, with the edge plasmons developing increasingly longer lifetimes in high fields. The latter behavior can be understood from the suppression of backscattering at the edges. Our work not only opens an avenue to explore the magneto-plasmons and edge physics in graphene but also supports the great potential of graphene for tunable magneto-optical devices.

4:30PM R5.00011 Long-range plasmon-assisted energy transfer over doped graphene[1] , KIRILL VELIZHANIN, Theoretical Division, Los Alamos National Laboratory, Los Alamos, NM 87545, USA, TIGRAN SHAHBAZYAN, Department of Physics, Jackson State University, Jackson, MS 39217, USA — Förster resonance energy transfer (FRET) between spatially separated donor and acceptor fluorophores, such as dye molecules or semiconductors quantum dots, underpins diverse phenomena in physics, chemistry and biology. However, the range of present and potential applications of FRET is limited by its intrinsically short-range nature ($\sim 1/R^6$). We demonstrate that longitudinal plasmons in doped monolayer graphene can mediate highly efficient long-range ($\sim 1/R$) energy transfer between nearby fluorophores, e.g., semiconductor quantum dots. We derive a simple analytical expression for the energy transfer efficiency that incorporates all the essential processes involved. We perform numerical calculations of the transfer efficiency for a pair of PbSe quantum dots near graphene for inter-fluorophore distances of up to 1 μm and find that the plasmon-assisted long-range energy transfer can be enhanced by up to a factor of $\sim 10^4$ relative to FRET in vacuum.

[1]Work at LANL was performed under the NNSA of the U.S. DOE at LANL under Contract No. DE-AC52- 06NA25396. Work at JSU was supported by the NSF under Grants No. DMR-1206975 and No. HRD-0833178 and under EPSCOR program.

4:42PM R5.00012 Graphene multilayers as hyperbolic metamaterials , ASHLEY DASILVA, ALLAN MACDONALD, University of Texas Austin — Graphene and multilayer graphene systems show promise for numerous electronic and optical applications in part due to the extraordinary tunability of graphene via gate voltage. We discuss the optical properties of electrically decoupled multilayer graphene systems. These can be described by the reflection and transmission coefficients, which we calculate using a transfer matrix approach. This point of view allows an explicit comparison between graphene multilayers and metal/dielectric multilayer metamaterials. In particular, we will compare multilayer graphene systems to hyperbolic metamaterials which have extreme anisotropy in the effective dielectric constant: $\epsilon_x = \epsilon_y < 0$ and $\epsilon_z > 0$.

4:54PM R5.00013 Magnetoplasmons in quasi-neutral epitaxial graphene nanoribbons , JEAN-MARIE POUMIROL, National High Magnetic Field Laboratory, WENLONG YU, CLAIRE BERGER, WALTER DE HEER, School of Physics, Georgia Institute of Technology, MICHAEL SMITH, TAISUKE OHTA, WEI PAN, Sandia National Laboratories, DMITRY SMIRNOV, National High Magnetic Field Laboratory, ZHIGANG JIANG, School of Physics, Georgia Institute of Technology — We report on infrared transmission spectroscopy study of magnetoplasmons in quasi-neutral epitaxial graphene nanoribbon arrays. The energy of the $L_{0(-1)} \rightarrow L_{1(0)}$ inter-Landau level transitions deviates from the characteristic $\sqrt{B}$ dependence observed in two-dimensional graphene. This behavior is explained as a signature of the upper hybrid mode formed between the Landau level transition and the plasmon resonance. Studying the hybrid mode allows us to probe the zero magnetic field plasmon resonance in the interacting regime, when coupling to electron-holes excitations results in strong decay of plasmons. We observe a deviation of the plasmon frequency from the standard $\omega_{pl} \propto q^{1/2}$ dispersion relation, and attribute it to the finite length of the graphene ribbons.

Wednesday, March 20, 2013 2:30PM - 5:30PM –

Session R6 DMP: Focus Session: Graphene - Defects, Edges, Theory 302 - Michael Weinert, University of Wisconsin

2:30PM R6.00001 Imaging defects on epitaxial graphene/SiC(0001) using non-contact AFM[1] , L. LI, Y. LIU, M. WEINERT, University of Wisconsin, Milwaukee — Graphene exhibits linear dispersion at the Dirac point, which leads to novel properties that can be further tailored by the introduction of defects into the honeycomb lattice. In this work, we created defects on epitaxial graphene/SiC(0001) using N and Ar plasma, and studied the atomic structure of the defects using an integrated approach with non-contact atomic force microscopy (AFM) with Q-plus sensor and density functional theory (DFT) calculations. With atomic resolution AFM imaging, straightforward identifications of single- and di-vacancy defects, as well as other more convoluted vacancy complexes can be made. In addition, local contact potentials of these defects are also obtained by frequency shift-bias spectroscopy. These results and comparisons with DFT calculations will be discussed at the meeting.

2:42PM R6.00002 Graphene nanoflakes with defective edge terminations[1] , IGOR ROMANOVSKY, CONSTANTINE YANNOULEAS, UZI LANDMAN, School of Physics, Georgia Institute of Technology — Systematic tight-binding investigations of the electronic spectra (as a function of the magnetic field) are presented[2] for trigonal graphene nanoflakes with reconstructed zigzag edges, where a succession of pentagons and heptagons, that is 5-7 defects, replaces the hexagons at the zigzag edge. For nanoflakes with such reczag defective edges, emphasis is placed on topological aspects and connections underlying the patterns dominating these spectra. In addition to features that are well known to appear for graphene dots with zigzag edge termination, the electronic spectra of trigonal graphene nanoflakes with reczag edge terminations exhibit unique features. These unique features appear within a stripe of negative energies $E_b < E < 0$ and along a separate regime forming a constant-energy line outside this stripe. The lower bound (E_b) specifying the energy stripe is independent of size. A main finding concerns the limited applicability of the continuous Dirac-Weyl equation, since the latter does not reproduce the special reczag features.

2:54PM R6.00003 Magnetic-field effects in graphene nanorings: armchair versus zigzag edge terminations[1] , CONSTANTINE YANNOULEAS, IGOR ROMANOVSKY, UZI LANDMAN, School of Physics, Georgia Institute of Technology — Dirac quasiparticles in narrow graphene nanorings exhibit characteristic differences in their behavior depending on the shape (e.g., trigonal vs. hexagonal) and the type of edge terminations (armchair vs. zigzag). The differences are manifested in the tight-binding single-particle spectra as a function of the magnetic field B and in the patterns of the Aharonov-Bohm oscillations. The symmetry of shape leads to the appearance of three-member (triangles) or six-member (hexagons) braid bands.[2] With the exception of the formation of the braid bands, the characteristic differences maintain in the energy spectra of the continuous Dirac-Weyl equation for a circular ring of finite width. These differences will be further analyzed with the help of a relativistic superlattice model.

3:06PM R6.00004 Electron transport in graphene monolayers[1] , JUN-QIANG LIU, DANIEL VALENCIA, University of Puerto Rico at Mayaguez — We demonstrate electronic transmission of a monolayer can be reduced when covered by a nanoribbon. The transmission reduction occurs at different energies determined by the width of the nanoribbon. We explain the transmission reduction by using of interference between the wavefunctions in the monolayer and the nanoribbon. Furthermore, we show the transmission reduction of a monolayer is combinable and propose a concept of "combination of control" for nano-application design.

[1]This work is supported by NSF-EPSCOR program (Grants 1002410 and 1010094).

3:18PM R6.00005 Unraveling the interlayer-related phonon self-energy renormalization in bilayer graphene , PAULO ARAUJO, DANIELA MAFRA, MIT, KENTARO SATO, RICHIIRO SAITO, Tohoku University, JING KONG, MILDRED DRESSELHAUS, MIT — In this work, we present a step towards further understanding of the bilayer graphene (2LG) interlayer (IL)-related phonon combination modes and overtones as well as their phonon self-energy renormalizations by using both gate-modulated and laser-energy dependent inelastic scattering spectroscopy. We show that although the IL interactions are weak, their respective phonon renormalization response is significant. Particularly special, the IL interactions are mediated by Van der Waals forces and are fundamental for understanding low-energy phenomena such as transport and infrared optics. Our approach opens up a new route to understanding fundamental properties of IL interactions which can be extended to any graphene-like material, such as MoS_2, WSe_2, oxides and hydroxides. Furthermore, we report a previously elusive crossing between IL-related phonon combination modes in 2LG, which might have important technological applications.

3:30PM R6.00006 Space dependent Fermi velocity in strained graphene , FERNANDO DE JUAN, Materials Sciences Division, Lawrence Berkeley National Laboratory, USA, MAURICIO STURLA, MARIA A. H. VOZMEDIANO, Instituto de Ciencia de Materiales de Madrid, CSIC, Spain — We investigate some apparent discrepancies between two different models for curved graphene: the one based on tight binding and elasticity theory, and the covariant approach based on quantum field theory in curved space. We demonstrate that strained or corrugated samples will have a space dependent Fermi velocity in either approach that can affect the interpretation of local probes experiments in graphene. We also generalize the tight binding approach to general inhomogeneous strain and find a vector field proportional to the derivative of the strain tensor that has the same form as the spin connection obtained in the covariant approach.

3:42PM R6.00007 Moiré minibands in graphene heterojunctions with hexagonal 2D crystals , VLADIMIR FALKO, Lancaster University — The transformation of the linear Dirac spectrum of electrons in monolayer graphene and parabolic spectrum in bilayer graphene due to the influence of a tightly bound insulating or semiconducting layer is studied. We present a symmetry-based classification and quantitative analysis of generic miniband structures for electrons in graphene heterojunction with a 2D crystal with the hexagonal Bravais symmetry, such as boron nitride. In particular, we identify conditions at which the first moire miniband is separated from the rest of the spectrum by either one or a group of three isolated mini Dirac points and is not obscured by dispersion surfaces coming from other minibands. In such cases the Hall coefficient exhibits two distinct alternations of its sign as a function of charge carrier density. Then, we study the Hofstadter spectrum of electrons in a magnetic field.

4:18PM R6.00008 Electric-Field Dependence of the Effective Dieletric Constant in Graphene Materials[1] , ELTON SANTOS, School of Engineering and Applied Sciences, Harvard University, EFTHIMIOS KAXIRAS, Department of Physics and School of Engineering and Applied Sciences, Harvard University — The dielectric constant of a material is one of the fundamental features used to characterize its electrostatic properties such as capacitance, charge screening, and energy storage capability. Here we address the issue of the effective dielectric constant (ε_G) in a few-layer graphene materials (e.g. graphene, MoS_2, WS_2, etc.) subjected to an external electric field. In particular for graphene, the value of ε_G has attracted interest due to contradictory reports from theoretical and experimental studies. Through extensive first-principles electronic structure calculations, including van der Waals interactions, we show that the graphene dielectric constant depends on the value of the external field ($E_{\rm ext}$): it is nearly constant at $\varepsilon_G \sim 3$ for low fields ($E_{\rm ext} < 0.1$ V/Å) but increases at higher fields, reaching ε_G=4.5 at $E_{\rm ext} = 1.7$ V/Å. Further increase of $E_{\rm ext}$ drives the system to an unstable state where the layers are decoupled and can be easily separated. Calculations performed for other layered materials follow the same trend. Our results point to a promising way of understanding and controlling the screening properties of few-layer graphene materials via electrical means.

4:30PM R6.00009 RKKY interaction in monolayer and bilayer graphene: Exact results in terms of the Meijer-G functions , FARIBORZ PARHIZGAR, School of Physics, Institute for Research in Fundamental Sciences (IPM), Tehran, Iran, MOHAMMAD SHERAFATI, Department of Physics and Astronomy, University of Missouri, Columbia, Missouri, USA, REZA ASGARI, School of Physics, Institute for Research in Fundamental Sciences (IPM), Tehran, Iran, SASHI SATPATHY, Department of Physics and Astronomy, University of Missouri, Columbia, Missouri, USA — We present the results for the RKKY interaction in monolayer and bilayer graphene in terms of Meijer-G functions for the undoped, doped and biased cases. The results are obtained from the linear-response expression for susceptibility written in terms of the integral over Green's functions and using Dirac bands. The salient features of the large-distance behavior in each case will be discussed. For instance, for doped monolayer graphene, the interaction falls off as R^{-2} and oscillates as the product of two terms, one being a $\{1+\cos[(K-K').R]\}$-like interference term from both Dirac cones and the second term scaled by Fermi momentum k_F. For doped and unbiased bilayer graphene, the interaction decays as $R^{-2}\cos(k_F R)[e^{-k_F R}+\sin(k_F R)]\Phi_{K,K'}$ where $\Phi_{K,K'}$ is a similar Dirac-cone factor. For the gated bilayer graphene, k_F must be replaced by another scaled momentum k_U, which depends on Fermi energy, gate voltage and the interlayer hopping energy, allowing the possibility of tuning of the interaction by gate voltage. References: M. Sherafati and S. Satpathy, PRB, 83, 165425 (2011); PRB, 84, 125416 (2011); AIP Conf. Proc. 1461, 24 (2012)

4:42PM R6.00010 Graphene multilayers in the crossed in-plane magnetic and out-of-plane electric fields , SERGEY PERSHOGUBA, VICTOR YAKOVENKO, Condensed Matter Theory Center, Department of Physics, University of Maryland, College Park, Maryland 20742-4111, USA, YU. LATYSHEV, A. ORLOV, Kotelnikov Institute of Radio-Engineering and Electronics, 125009, Moscow, Russia, P. MONCEAU, Neel Institute, 38042, Grenoble, France, D. VIGNOLLES, National Laboratory of High Magnetic Fields, 31400, Toulouse, France — We report an experimental study of the out-of-plane differential conductivity dI/dV in graphite mesas as a function of applied out-of-plane voltage V in the in-plane magnetic fields B_y up to 55 T. The spectrum dI/dV vs V has a pronounced peak at the critical voltage V_0, which grows linearly with the magnetic field $V_0 \propto B_y$. The experimental results are consistent with a theoretical model. The electronic energy spectrum on each graphene layer is given by the two-dimensional (2D) Dirac cone $\varepsilon = v|p|$, where v and $p = (p_x, p_y)$ are the velocity and 2D momentum. As a result of magnetic field B_y, the Dirac cones of the consecutive layers are shifted in the momentum space by $\Delta p_x = eB_y d$, where d is a distance between the layers. Whereas electric field E_z shifts the energy by $\Delta\varepsilon = E_z d$. For generic E_z and B_y, the wave functions are localized on a finite number of layers in the z direction. However, when the resonant condition $\Delta\varepsilon = v\Delta p_x$ is achieved, i.e. when $E_z = vB_y$, the Dirac cones align, and wave functions become delocalized in the z direction. We believe that the resonant delocalization of the wave functions corresponds to the peak in differential conductance.

4:54PM R6.00011 Interactions between adsorbates on graphene , DMITRY SOLENOV, CHAD JUNKERMEIER, THOMAS L. REINECKE, Naval Research Laboratory, Washington, District of Columbia 20375, USA, KIRILL A. VELIZHANIN, Theoretical Division, Los Alamos National Laboratory, Los Alamos, NM 87545, USA — Interactions between adsorbates on a surface of graphene play an important role in many applications. We offer a detailed analysis of interactions between two adsorbed atoms and molecules. We compare the first principles DFT, numerical tight-binding, and analytical functional integral calculations to identify the microscopic nature of the adsorbate-adsorbate interaction and the role of different contributions. The interaction has two distinct regimes: a weak coupling regime, which is akin to RKKY (Ruderman-Kittel-Kasuya-Yosida) magnetic interaction, and a strong coupling regime which is dominated by interaction via a many-body electronic dressing "cloud" around each adsorbate. We show that the interplay between these two regimes provides an opportunity to manipulate the magnitude and the structure of the adsorbate-adsorbate interaction (up to complete reversal of sign) via a variety of easily accessible properties, such chemical potential via back-gating, type of an adsorbed atom, electronic configuration of an adsorbed molecule, and strain.

5:06PM R6.00012 *Ab Initio* Many-body Study of Cobalt Adatoms Adsorbed on Graphene[1] , YUDISTIRA VIRGUS, WIRAWAN PURWANTO, HENRY KRAKAUER, SHIWEI ZHANG, College of William and Mary — Research interest in the adsorption of transition metal adatoms on graphene has grown rapidly because of their promising use in spintronics. Single Co atoms on graphene have been extensively studied recently, and possible Kondo effects have been considered. However, these calculations show significantly varying results on the bonding nature of Co/graphene system. We use auxiliary-field quantum Monte Carlo (AFQMC) and a size-correction embedding scheme to accurately calculate the binding energy of Co/graphene.[2] We find that as a function of the distance h between the Co atom and the six-fold hollow site, there are two states that provide binding and exhibit a double-well feature with nearly equal binding energy of 0.4 eV at $h = 1.51$ and $h = 1.65$ Å, corresponding to low-spin ^{2}Co ($3d^9 4s^0$) and high-spin ^{4}Co ($3d^8 4s^1$), respectively. Binding of Co on bilayer graphene is also investigated.

5:18PM R6.00013 Polarization Waves around Coulomb Impurities in Strained Graphene , VALERI KOTOV, ANAND SHARMA, University of Vermont, A.H. CASTRO NETO, National University of Singapore — We study the distribution of polarization charge around external Coulomb centers in graphene. We consider uniaxially strained Graphene so that the Dirac cones are anisotropic and there is a preferred direction on the lattice. Under these conditions we find that the polarization charge exhibits oscillations around the impurity with predominant d-wave symmetry for small anisotropy (strain) and also admixture of g-wave as well as higher waves with increasing anisotropy. The total polarization in the ground state is zero. This rich variety of behavior is in stark contrast to the situation in undeformed graphene, where the polarization charge away from the impurity is identically zero. Thus our results could be used for detection of Coulomb impurity physics even in the case of relatively small charge ions as long as there is sufficient Dirac cone anisotropy.

Wednesday, March 20, 2013 2:30PM - 5:42PM –

Session R7 FIAP: Si and Other Semiconductors 303 - Alex Demkov, University of Texas at Austin

2:30PM R7.00001 Crystalline phase-stability of tantalum pentoxide[1] , SANTIAGO WALTON, Instituto Técnico Metropolitano, ITM, Medellin, Colombia, ANTONIO CLAUDIO PADILHA, GUSTAVO DALPIAN, Universidade Federal do ABC, UFABC, Santo André, Brazil, JORGE GUILLÉN, Universidad de Antioquia, Medellin, Colombia, DALPIAN'S RESEARCH GROUP COLLABORATION, GRUPO DE ESTADO SOLIDO COLLABORATION, GRITAD COLLABORATION — Memristive devices are attractive candidates to provide a paradigm change in memory devices fabrication. These new devices would be faster, denser and less power consuming than those available today. However, the mechanism of memristance is not yet well understood. It is believed that a voltage/current-driven phase transition occurs in the material, which leads to significant changes in the device's conductivity. In the particular case of tantalum-oxide-based devices the relevant crystalline phases are still a matter of debate. Some of these phases are not even completely known and there is no agreement about which model best explains the crystallographic results. In this work we have performed ab-initio DFT based calculations to study the structural properties of different phases (and models) of Ta_2O_5 - the structure which is believed to exist inside Tantalum Oxide based devices. The equations of state for this material were constructed through first principles total energy calculations and we have also calculated the phonon frequencies at Γ. These results show that the most stable phase of this oxide (B-Ta_2O_5) is in fact composed of octahedral, instead of pentagonal (as L-Ta_2O_5) or hexagonal (as δ-Ta_2O_5) bipyramids.

2:42PM R7.00002 Dynamical processes in semiconductor nanoclusters , PENG HAN, GABRIEL BESTER, Max-Planck-Institut für Festkörperforschung, Heisenbergstraße 1, 70569 Stuttgart, Germany — We study the electronic relaxation processes via electron-phonon interaction in colloidal semiconductor nanoclusters (NCs) using the Liouville-von Neumann equation including a phenomenological Lindblad decay term. The electron-phonon coupling matrix elements used in our study are obtained from frozen-phonon calculations based on *ab initio* density functional theory (DFT). To estimate the phonon lifetime of NCs, which is used in the Lindblad decay term, we perform *ab initio* molecular dynamics simulations of a $Si_{10}H_{16}$ cluster and extract the time evolution of the energy of selected vibrational modes from the energy auto-correlation functions. We find vibrational cooling times of around 0.1 ps for high frequency Si-H vibrations, and cooling time of around 1 ps for pure Si modes, which are close to the phonon lifetimes in bulk Si. Analyzing the electronic relaxation processes with the parameters from DFT calculations, we observe a decaying Rabi oscillation with a period of tens of femtoseconds corresponding to the emission/absorption of a phonon. We notice that the Rabi oscillation frequency is proportional to the electron-phonon coupling strength while the decay process is dominated by the phonon lifetime and the energy detuning.

2:54PM R7.00003 Characterization of Silicon CMOS Quantum Well Field Effect Transistors , CLINT NAQUIN, MARK LEE, University of Texas at Dallas, HAL EDWARDS, TATHAGATA CHATTERJEE, Texas Instruments — Silicon CMOS field effect transistors (FETs) incorporating quantum wells (QWs) are of potential interest as advanced oscillators and sensors. We report on the design and electrical characterization of a set of Si CMOS QW FETs fabricated using industrial 45 nm processing. By using low doped drain and pocket implants, lateral QW potentials between 30 nm to 100 nm in length and approximately 0.1 to 0.5 eV in potential depth have been incorporated into the channel between source and drain. The potential depth can be modulated by the gate voltage. Measurements of drain current as a function of gate voltage for devices from 1.7 K up to room temperature will be reported, with the expectation of observing resonant conductance oscillations from transport through QW levels at temperatures where the QW energy levels are well formed.

3:06PM R7.00004 Infrared spectroscopy of high purity Si for application in astronomy , BERIK UZAKBAIULY, JIAN GE, DAVID TANNER, University of Florida — High resolution infrared (IR) spectroscopy is an essential tool in astronomical studies and Silicon Immersion Gratings (SIGs) offer 3.4 times gain in spectral resolution over conventional echelle gratings of the same length and blaze angle. SIGs have Si as the host material, relying on its high transparency in much of the infrared region. Si is transparent below the multiphonon absorption for far-infrared ($\sim$20-300 microns) use as well as in the near infrared ($\sim$1-6 microns). We have measured high-purity silicon transmittance from far to near infrared. Narrow lines, due to residual impurities and with interesting temperature dependences, appear in the far IR region. We present the transmittance of high purity bulk Si from the band edge (9000 cm^{-1}) to far infrared (20 cm^{-1}) using FT-IR spectrometer and modified Perkin Elmer grating spectrometer. Impurities have been identified and their temperature dependence will be discussed.

3:18PM R7.00005 Dynamic Formation of $NiSi_2$ in Porous Amorphous Si Nanorods Observed by In Situ TEM , JIANGUO FAN, University of Georgia — We investigated the dynamic formation of $NiSi_2$ nanocrystals in a porous amorphous silicon nanorod with in situ heating TEM. The nanorod was prepared by sequential electron beam depositions of Si, Ni, and Si at an oblique angle. Due to the nature of atomic shadowing and limited diffusion at low deposition temeperature, the structure was porous and amorphous. Ni diffusion started at 300 °C and oxides in the porous structure greatly surpressed the formation of early silicide phases such as NiSi, Ni_3Si_2, and $Ni_{31}Si_{12}$. At 400-500 °C, $NiSi_2$ crystallites formed along the nanorod and were defined by the porous template. These structural evolutions were identified and confirmed by electron diffraction, X-ray analysis, and high-resolution TEM. The formation mechanism and possible applications will be discussed.

3:30PM R7.00006 Enrichment and growth of enriched ^{28}Si films , JOSHUA POMEROY, KEVIN DWYER, National Institute of Standards and Technology — In support of quantum information and spintronics efforts, we are producing enriched ^{28}Si films that are 99.9% ^{28}Si according to secondary ion mass spectrometry assessment. We use an ionization source to crack and ionize natural abundance silane gas, then extract the ions through a magnetic sector analyzer to isolate the major isotope ^{28}Si. We have presently demonstrated $>$ 100 nm thick films of silicon and carbon, which was enriched to 99.996% ^{12}C. With ongoing improvements, we expect to produce ^{28}Si enriched to better than 99.99% at thicknesses $>$ 1 μm grown epitaxially on Si(100) substrates.

3:42PM R7.00007 Atomic and Electronic Processes During the Formation of an Ionic NaCl Monolayer on Si(100)[1] , DENG-SUNG LIN, CHAN-YUEN CHANG, HONG-DAO LI, Department of Physics, National Tsing Hua University, Hsinchu, Taiwan, SHIOW-FON TSAY, Department of Physics, National Sun Yat Sen University, Kaohsiung, Taiwan, CHAN-YUEN CHANG, HONG-DAO LI, DENG-SUNG LIN TEAM, SHIOW-FON TSAY COLLABORATION — An atomic layer of stoichiometric NaCl was formed on a covalent Si(100) surface after two successive half-reactions at room temperature. The first half-reaction due to Cl_2 exposure generates a square array of Cl adatoms with a distance close to that in a NaCl(100) surface plane. By utilizing scanning tunneling microscopy, core-level photoemission spectroscopy and ab initio density functional theory calculations, it was found that progressive deposition of Na in the second-half reaction results in surface-supported Na_3Cl clusters, one dimensional cluster chains and (2×2) patches, and eventually turns the Cl-adlayer into a single-terrace, wavy NaCl layer at one monolayer Na coverage. The grown NaCl monolayer rolls over atomic steps like a carpet and covers the entire surface. The atomic and electronic structure of the topmost Si layer underneath the NaCl layer resembles that of the initial silicon surface layer with buckled dimers. Results of the comprehensive investigation together suggest that an ionic NaCl monolayer is very weakly bonded to the covalent substrate and appears nearly free standing.

3:54PM R7.00008 Electronic structure of the Sr/Si(001) Zintl template from density functional theory and photoemission , HOSUNG SEO, MIRI CHOI, RICHARD HATCH, AGHAM POSADAS, ALEXANDER DEMKOV, The University of Texas at Austin — Since the first demonstration of epitaxial growth of crystalline SrTiO3 on Si(001) by Mckee and co-workers, sub-monolayer Sr on Si(001) has been extensively investigated. Charge transfer induced by half-monolayer of Sr has been shown to be a key element enabling wetting of Si by SrTiO3. However, a detailed understanding of the electronic structure reconstruction is not complete. Such knowledge could be extended and applied to the other epitaxial crystalline oxides on semiconductors. Recently, using in-situ x-ray core-level spectroscopy, we have studied the change in electronic structure of Si(001) induced by sub-monolayer Sr deposition in terms of surface core level shift. One of the interesting features is shift of the Si 2p level toward the higher binding energy by 0.49eV after Sr deposition. In this talk, we present a detailed theoretical investigation of the surface core level shifts in sub-monolayer Sr/Si(001). Using the final state theory, we calculate the bulk 2p binding energy to be increased by 0.42eV when half-monolayer of Sr is deposited in excellent agreement with experiment. We are able to compare the calculated evolution of the surface band structure in sub-monolayer Sr/Si(001) to angle-resolved photoemission spectroscopy (ARPES) data.

4:06PM R7.00009 Purification of germanium crystal by zone-refining technique[1] , GANG YANG, JAYESH GOVANI, HAO MEI, GUOJIAN WANG, YUTONG GUAN, Department of Physics, University of South Dakota, Vermillion, SD 57069, USA, CHAOYANG JIANG, Department of Chemistry, University of South Dakota, Vermillion, SD 57069, USA, DONGMING MEI, Department of Physics, University of South Dakota, Vermillion, SD 57069, USA — Zone refining is a purification technique of metal materials, which was developed at Bell Telephone Laboratories in the early of 1950s. In zone-refining of high-purity germanium crystals, the influential factors include vacuum level, container of germanium ingot, ambient gases, speed of zone travel, the ratio of ingot length to molten zone length, etc. In the present work, we have investigated the influences of the following factors on the purification of germanium crystals: graphite/quartz boats, hydrogen/argon gas, speed of zone travel and the ratio of ingot length to molten zone length. Additionally, we have also analyzed the influences of segregation of three main impurities, such as boron, aluminum and phosphor on the electrical properties of the zone-refined crystals. In this paper, we report the results from the zone-refined germanium ingots produced at the University of South Dakota.

4:18PM R7.00010 Optical Microscopic and Spectroscopic Study of the High-Purity Germanium (HPGe) Single Crystals[1] , JAYESH GOVANI, GANG YANG, GUOJIAN WANG, MUHAMMAD KHIZAR, Physics Department, The University of South Dakota, CHAOYANG JIANG, Chemistry Department, The University of South Dakota, DONGMING MEI, Physics Department, The University of South Dakota — High-purity germanium (HPGe) single crystals are required for the fabrication of radiation detectors. Before grown HPGe crystals can be effectively utilized, they need to be characterized for their purity, identification of impurities and dislocation density. These characterizations help to determine if the grown crystal is qualified for making detector and provide the feedback for crystal growth, so the crystals with the required qualities can be grown consistently. In the present study, we have performed optical microscopic analysis of the grown HPGe crystals. Our experimental results indicated that the crystals exhibit dislocation density in a range of 3000/cm^2 to 8000/cm^2 demonstrating that the dislocation density is within the required range ($\sim 10^2$ -10^4 dislocations/cm^2) to avoid the formation of undesired di-vacancy hydrogen (V_2H) complexes. Photo-thermal ionization spectroscopic (PTIS) analysis indicated that aluminum; boron and phosphorus are the dominant impurities in the grown crystals. We also performed the Van-der Pauw hall measurement for the determination of carrier concentration, resistivity and mobility of the charge carrier. In this paper, we show some characterization results from the grown crystals at USD.

[1]This work is supported by DOE grant DE-FG02-10ER46709 and the state of South Dakota.

4:30PM R7.00011 Tracing the phosphorus contamination sources and reducing the phosphorus contamination in HPGe crystal growth[1] , GUOJIAN WANG, YUTONG GUAN, GANG YANG, JAYESH GOVANI, MUHAMMAD KHIZAR, HAO MEI, DONGMING MEI, university of South Dakota — The net impurity concentration and the dislocation density for the grown crystals must be controlled within a narrow range of values to produce crystals acceptable for large-volume coaxial germanium detector fabrication. Phosphorus is the main shallow level donor in high purity germanium crystal. The phosphorus contamination is a disaster for growing p-type high-purity germanium crystal. The phosphorus contamination mainly comes from crucible, insulation, ambient gas or crystal growth chamber. Regrowth method was used to trace the phosphorus contamination sources. The contamination level from sources was discussed in detail in this paper. For different contamination source, targeted approaches were used to reduce the contamination.

4:42PM R7.00012 Variation of electron-phonon coupling in group IV elemental semiconductors[1] , NANDAN TANDON, LISA PUGSLEY, L. R. RAM-MOHAN, Physics Department, Worcester Polytechnic Institute, Worcester, MA — Electron-phonon (e-ph) coupling determines the transfer of energy from hot electrons to the lattice, resulting in the heating of devices. In the current treatments, the e-ph coupling is determined within the long-wavelength phonon approximation. In this work, we consider the e-ph coupling and its variation over the entire Brillouin zone (BZ). The electronic structure and the full phonon dispersion are evaluated with the phonon dispersion calculated using the density functional perturbation theory (DFPT). The e-ph coupling is evaluated using maximally localized Wannier functions and generalized Fourier interpolation to generate e-ph matrix elements on arbitrary grids. Examples of specific initial electron momentum both in the valence and in the conduction bands are presented, together with the variation of the e-ph coupling over the entire BZ associated with the specific initial carrier momenta. We observe variations of up to about 400meV in Diamond and $50-100$meV in Silicon and Germanium for the evaluated e-ph matrix element. We comment on the consequence of this variation on the carrier lifetimes in these materials.

4:54PM R7.00013 Morphology control of WS2 monolayer islands: triangles, stars, and snowflakes , YUANXI WANG, Penn State University, CHENG-ING CHIA, Duke University, ANA ELIAS, NESTOR PEREA-LOPEZ, A. C. BELTRAN, A. BERKDEMIR, Penn State University, HUMBERTO GUTIERREZ, University of Louisville, FLORENTINO LOPEZ-URIAS, HUMBERTO TERRONES, MAURICIO TERRONES, VINCENT CRESPI, Penn State University — Interfaces play an important role in determining the electronic structure and equilibrium morphologies of monolayer nanoclusters. An additional difficulty for polar materials is that a conventional edge energy calculation using a nanoribbon exposes two different types of edge terminations, making the energy of each edge inextricable. Based on density functional theory, we report the energies of different types of edge terminations of monolayer WS_2 at different experimental environments in terms of varying chemical potentials of the W and S species. The Wulff construction is then applied to show that triangular shapes are most favorable at higher S chemical potential, where bulk sulfur start to become present in the system. Our results are in agreement with recent experiments that triangular islands of WS_2 are synthesized by CVD method using vaporized sulfur. Stacking energetics and kinetic growth factors will also be discussed to explain the formation of six-pointed star shapes and edge irregularities.

5:06PM R7.00014 Chemical sensing with ultra-thin MoS2 , ADAM FRIEDMAN, Mater. Sci. and Tech. Div., US Naval Research Laboratory, KEITH PERKINS, Elec. Sci. and Tech. Div., US Naval Research Laboratory, ENRIQUE COBAS, Mater. Sci. and Tech. Div., US Naval Research Laboratory, PAUL CAMPBELL, GLENN JERNIGAN, Elec. Sci. and Tech. Div., US Naval Research Laboratory, BEREND JONKER, Mater. Sci. and Tech. Div., US Naval Research Laboratory — Although the majority of focus and excitement in recent years has been on studying the remarkable properties of single atomic-layer graphene, there exists a whole class of materials called dichalcogenides that are relatively easily fabricated in single-crystal mono- or few-layer format. Graphene, being chemically inert, does not lend itself to chemical sensing applications. However, MoS2, a dichalcogenide of recent interest because of its potential for transistor applications, possesses many advantageous properties for chemical sensing. Two primary examples include a sizable bandgap, which is necessary for fabricating transistors with large on/off current ratios, and a chemically reactive surface, which is necessary for easy surface functionalization. In this talk, we discuss our current research effort on MoS2 chemical sensors. We discuss aspects of transistor device fabrication and chemical sensing experiments. We expose MoS2 chemical sensors to a variety of analytes, finding the best response to triethylamine, a nerve gas by product, and explain our results based on a donor-acceptor model. MoS2 sensors are compared to other similar low-dimensional sensors and found to be of comparable quality.

5:18PM R7.00015 ABSTRACT WITHDRAWN –

5:30PM R7.00016 Design, fabrication and performance optimization of bi-polar blocking planar HPGe radiation detector[1] , MUHAMMAD KHIZAR, GUOJIAN WANG, DONGMING MEI, University of South Dakota, South Dakota, USA — A prototype planar radiation detector is designed, fabricated and characterized using bi-polar contact deposited on high purity single crystal germanium (HPGe). Performances of planar and semi-planar detectors are carried out for their low background counting and high absolute efficiency for high-energy photons applications. For this study, 40mm ? 15mm (diameter to vertical height) p-type HPGe samples with dislocation density EPD <3000 cm-2 are taken from HPGe ingots grown by Czochralski method. After a successful mechanical preparation, and standard cleaning and polishing procedure, samples are chemically etched by using a mixture of highly concentrated acids HF:HNO3 (1:4) in order to remove the surface oxides. A bi-polar blocking layer of amorphous germanium (a-Ge) is deposited on both the samples using low temperature RF sputtering plasma in a pre-mix precursor of H2 (15%) and Ar. For this, an optimized dose of the plasma power and chamber pressure is used for a controlled low temperature. The process was completed with the evaporation of Ohmic contacts using electron beam evaporator. This is worth noticing that special care is introduced during the handling of these samples, especially for the bi-polar blocking and metal contact layers deposition. Finally, the fabricated detectors are characterized at 77K temperature. In this paper, we show the results from the first prototype detector made of home grown crystals at USD.

Session R8 GMAG: Correlated Electron Magnetism 307 - Andre-Marie Tremblay, Universite de Sherbrooke

2:30PM R8.00001 Origins of ferromagnetism and antiferromagnetism in Gd_5Ge_4[1] , DURGA PAUDYAL, V.K. PECHARSKY, K.A. GSCHNEIDNER, JR., The Ames Laboratory, U. S. Department of Energy, Iowa State University, Ames, IA 50011 — The origin of ferromagnetism appearing as a result of a magnetic-field-induced first-order phase transition in Gd_5Ge_4 is explored by calculating the total energy, local exchange splitting, density of states, and magnetic moments. The calculations were performed using density functional approaches including the on-site Coulomb interaction parameter. The total energy as a function of shear distortion along the a axis for two different orthorhombic structures is in agreement with experiment, indicating a first-order magnetostructural transition in Gd_5Ge_4. The rearrangement of Gd $5d$ and Ge $4p$ densities of states, the substantial differences in atom-projected band energies, the exchange splitting, and the magnetic moments calculated with ferromagnetic spin arrangements in the orthorhombic Sm_5Ge_4-type and Gd_5Si_4-type structures of Gd_5Ge_4 help to clarify the differences in the magnetic states of these two structures. Our calculations indicate that the Sm_5Ge_4-type structure of Gd_5Ge_4 is the structural ground state and that it is antiferromagnetic.

2:42PM R8.00002 Unconventional metallic magnetism in $LaCr_{1-x}V_xSb_3$ system[1] , XIAO LIN, VALENTIN TAUFOUR, Iowa State University, SERGEY BUD'KO, PAUL CANFIELD, Ames Laboratory, US DOE, Iowa State University — Unconventional, low temperature ground states can often be found in the vicinity of a magnetic phase transition that has been continuously tuned to 0 K. As part of our search for exotic superconductivity, we have studied the $LaCrSb_3$ system. Whereas magnetization measurements of $LaCrSb_3$ under pressure reveal no change of T_C up to ≈ 5 GPa, the ferromagnetic transition is gradually suppressed with increasing V substitution. Single crystals of the $LaCr_{1-x}V_xSb_3$ series have been characterized by measurements of, temperature dependent magnetic susceptibility, magnetization, electrical resistivity, and specific heat. Determinations of magnetic anisotropies as well as ferromagnetic ordering temperatures have been made. Below T_C, spin reorientation has been observed within *bc* plane. A $T - x$ phase diagram has been assembled to shed light on the magnetism in this system.

[1]This work was supported by AFOSR-MURI grant FA9550-09-1-0603 (X. Lin, V. Taufour and P. C. Ccanfield) and by US DOE under the Contract No. DE-AC02-07CH11358 (S.L.Bud'ko).

2:54PM R8.00003 Optical investigations on spin density wave instability in $SrMnBi_2$, HYUN-JU PARK, DA WOON JOENG, CHANG HEE SOHN, CFI-CES, Institute for Basic Science, and Department of Physics & Astronomy, Seoul National University, Seoul 151-747, Korea, JOONBUM PARK, J.S. KIM, Department of Physics, Pohang University of Science and Technology, Pohang 790-784, Korea, K.W. KIM, Department of Physics, Chungbuk National University, Cheongju 361-763, Korea, S.J. MOON, Department of Physics, Hanyang University, Seoul 133-791, Korea, T.W. NOH, CFI-CES, Institute for Basic Science, and Department of Physics & Astronomy, Seoul National University, Seoul 151-747, Korea — We investigated the electronic response of layered transition metal pnictide SrMnBi2 using infrared spectroscopy. SrMnBi2 has a crystal structure similar with that of Fe-based superconductors and shows antiferromagnetic order at high temperature 290 K. We observe that the onset of antiferromagnetic order induces a partial gap formation. Upon entering the antiferromagnetic state, the Drude response is drastically suppressed and the spectral weight is transferred to higher energies. Our results suggest that the antiferromagnetism in SrMnBi2 may be associated with spin-density-wave instability of itinerant carriers. We will discuss possible origins of the density-wave-instability based on the first-principles-calculation results.

3:06PM R8.00004 Resonant Ultrasound studies of double perovskites A_2FeReO_6 (A=Ba, Ca)[1]

LING LI, Dept. Materials Science and Engineering, The University of Tennessee, JIAQIANG YAN, DAVID MANDRUS, Dept. Materials Science and Engineering, The University of Tennessee and Materials Science and Technology Division, Oak Ridge National Laboratory, VEERLE KEPPENS, Dept. Materials Science and Engineering, The University of Tennessee — The elastic response as a function of temperature (50-380) K and magnetic field (0-2) T has been studied using Resonant Ultrasound Spectroscopy (RUS) for the polycrystalline double perovskites A_2FeReO_6 (A= Ba, Ca). An elastic softening over a wide temperature range is observed below the Curie temperature ($T_c \sim 305$K) of Ba_2FeReO_6, which is suppressed upon the application of a magnetic field. For Ca_2FeReO_6, both the longitudinal and shear modulus show a step-like softening starting around 140K, indicative of a structural transition. A large change in the magnetoelastic coupling constant is observed at this temperature, suggesting that this transition is strongly coupled to the magnetic properties of this material.

3:18PM R8.00005 Chemical Doping Induced Ferro- and Antiferro-magnetic States in non-Magnetic Insulating $FeGa_3$

N. HALDOLAARACHCHIGE, J. PRESTIGIACOMO, Y. XIONG, A. PHELAN, J. CHAN, D. SHEEHY, P. ADAMS, J. DITUSA, S. STADLER, D. YOUNG, Louisiana State University — A ferromagnetic quantum critical point (FM-QCP) in Ge-doped $FeGa_3$ was reported very recently (Umeo *et al.* PRB **86** (14), 144421, 2012). We have simultaneously observed the FM-QCP in this system. Furthermore, we analyzed the magnetic properties of $FeGa_3$ in the context of a unique structural feature, where the four Fe atoms in the unit cell exist as two Fe-Fe dimers (Yin and Picket, PRB **82** (15), 155202, 2010). We propose a phenomenological model where the extrinsic electrons from the Ge doping creates a mixed valence Fe-dimer with a net effective spin. Such a model provides a novel mechanism for the (FM-QCP) and is consistent with the system's magnetic and thermal properties. In addition to Ge doping, we have investigated effects of Ru/Mn substitution on the Fe site. Ru substitution produces an unexpected ferromagnetic (FM) insulating phase that develops immediately, and it disappears above an intermediate doping level. This behavior agrees well with our model of spin creation on the transition-metal dimers via conduction electrons, and the enhanced insulating behavior in the electrical resistivity suggests the Ru acquires a 2+ state. Interestingly, Mn-doped $FeGa_3$ shows an apparent antiferromagnetic (AFM) insulating phase, where the magnetic data is consistent with the effective moment coming from Mn(3+). These results provide further evidence of the important role of the Fe-Fe dimer structure in $FeGa_3$ in determining its unique magnetic properties.

3:30PM R8.00006 Ferromagnetic Fluctuations Enhanced by Mn Doping in Sr_2RuO_4

JOHN ORTMANN, JIN PENG, Tulane University, X. WU, Nanjing University, ZHIQIANG MAO, Tulane University — Sr_2RuO_4 is the first experimentally established example of a spin-triplet superconductor [1]; it has attracted a great deal of interest since its discovery in 1994. Like other unconventional superconductors, the superconductivity of Sr_2RuO_4 also occurs in close proximity to magnetic instability. Its normal state is characterized by incommensurate antiferromagnetic (AFM) fluctuations associated with Fermi surface nesting. Moreover, the other ruthenate compounds related to Sr_2RuO_4 in the Ruddlesden-Popper series are all magnetic. The Sr-based members $Sr_3Ru_2O_7$, $Sr_4Ru_3O_{10}$ and $SrRuO_3$ are either metamagnetic or ferromagnetic (FM), whereas the Ca-based members Ca_2RuO_4 and $Ca_3Ru_2O_7$ are AFM. We have investigated the Mn doping effect in Sr_2RuO_4 using floating-zone grown single crystal samples and observed significantly enhanced FM fluctuations in the Mn-doped Sr_2RuO_4 samples. The system becomes nearly FM with only a few percent Mn doping. This finding suggests that Sr_2RuO_4 involves competing, orbital dependent magnetic fluctuations.

3:42PM R8.00007 Spin-state controlled electronic and magnetic structures of $Sr_{2-x}La_xCoO_4$

, HUA WU, Fudan University, Shanghai, China — $Sr_{2-x}La_xCoO_4$ is an interesting group of materials, and they display abundant electronic and magnetic properties. In this work, we studied those properties, using electron-correlation corrected density functional calculations. We find that besides a charge-state variation induced by La doping, a multiple spin-state transition takes place and determines (1) a metal-insulator transition and a ferromagnetic insulating phase for x=0.5 [1], (2) a paramagnetic Mott insulating phase with a mixed high-spin and low-spin state for x=1, instead of a ferromagnetic half-metallic solution with a homogeneous intermediate-spin state [2], and (3) a charge-ordered highly insulating phase with an active spin-blockade mechanism for x=1.5 [3]. [1] H. Wu, Phys. Rev. B 86, 075120 (2012). [2] H. Wu, Phys. Rev. B 81, 115127 (2010). [3] H. Wu and T. Burnus, Phys. Rev. B 80, 081105(R) (2009).

3:54PM R8.00008 Doping Induced Itinerant Ferromagnetism in CoAs

, CHIH-WEI CHEN, EMILIA MOROSAN, Rice University — The magnetism in α-CoAs is dominated by strong spin fluctuations. In this study, we explore the effects of Phosphorus doping in α-CoAs. Phosphorus is isovalent with Arsenic, and the resulting doping introduces disorder and chemical pressure. In $CoAs_{1-x}P_x$, a cross-over from the spin fluctuation-dominated regime to an itinerant ferromagnetic (IFM) state take places around x = 0.04. The IFM state persists up to x $\leq$ 0.27. For compositions between x = 0.28 and 0.40, the magnetization data suggests a possible Stoner enhanced state. We acknowledge the support from DOD PECASE.

4:06PM R8.00009 Magnetic and Orbital Ordering of $KCuF_3$ Studied by Soft X-ray Scattering

, C. H. LAI, Department of Physics, National Tsing Hua University, Hsinchu, Taiwan, W. B. WU, M. H. CHEN, National Synchrotron Radiation Research Center, Hsinchu, Taiwan, T. C. HUNG, Department of Electrophysics, National Chao Tung University, Hsinchu, Taiwan, C. W. YUAN, Department of Physics, National Tsing Hua University, Hsinchu, Taiwan, D. J. HUANG, National Synchrotron Radiation Research Center, Hsinchu, Taiwan, Y. MURAKAMI, Condensed Matter Research Center and Photon Factory, Institute of Materials Structure Science, KEK, Tsukuba, Japan — The interplay between charge, orbital, and spin degrees of freedom plays an important role in the underlying physics of transition-metal compounds. The charge-transfer insulator $KCuF_3$ is an archetype of orbitally ordered materials with large exchange interaction energy. $KCuF_3$ has long been known to display quantum one-dimensional antiferromagnetic properties along the c-axis originating from the superexchange interaction between the e_g orbitals of Cu^{2+}. Due to the large Jahn-Teller distortion in the tetragonal structure, the degeneracy of the two e_g orbitals is lifted and the e_g orbitals form a pattern of orbital ordering . In this talk, we will present our recent measurements of spin and orbital ordering of $KCuF_3$ by soft X-ray scattering to address its magnetic transition and the coupling between spin and orbital degrees of freedom.

4:18PM R8.00010 Controllable chirality-induced geometrical Hall effect in the frustrated strongly-correlated metal UCu_5[1]

, B.G. UELAND, Los Alamos National Laboratory, C.F. MICLEA, National Institute of Materials Physics, Romania, YASUYUKI KATO, O. AYALA-VALENZUELA, R.D. MCDONALD, Los Alamos National Laboratory, R. OKAZAKI, Kyoto University, P.H. TOBASH, M.A. TORREZ, F. RONNING, R. MOVSHOVICH, Los Alamos National Laboratory, Z. FISK, University of California, Irvine, E.D. BAUER, IVAR MARTIN, J.D. THOMPSON, Los Alamos National Laboratory — A current of electrons traversing a landscape of localized spins possessing non-coplanar magnetic order gains a geometrical (Berry) phase which can lead to a Hall voltage independent of the spin-orbit coupling within the material–a geometrical Hall effect. In this talk, I will present experimental data and Monte-Carlo simulation results showing that the strongly-correlated metal UCu_5 possesses an unusually large controllable geometrical Hall effect at $T < 1.2$K due to its frustration-induced magnetic order. The magnitude of the Hall response exceeds 20% of the ν =1 quantum Hall effect per atomic layer, which translates into an effective magnetic field of several hundred Tesla acting on the electrons. The existence of such a large geometric Hall response in UCu_5 opens a new field of inquiry into the importance of the role of frustration in highly-correlated electron materials. *B.G. Ueland et al., Nat. Commun.* **3***, 1067 (2012).*

[1]Supported by the U.S. Department of Energy, LANL Laboratory Directed Research and Development Program, NSF-DMR-0801253, G.T. Seaborg Institute for Transactinium Science

4:30PM R8.00011 Dynamical spin correlation function in a frustrated two-leg spin-ladder system , TAKANORI SUGIMOTO, MICHIYASU MORI, ASRC, Japan Atomic Energy Agency; CREST, Japan Science and Technology Agency, TAKAMI TOHYAMA, YITP, Kyoto University, SADAMICHI MAEKAWA, ASRC, Japan Atomic Energy Agency; CREST, Japan Science and Technology Agency — We numerically study the magnetic excitations in a frustrated two-leg spin-ladder system, in which all magnetic exchange interactions, i.e., the nearest-, next-nearest-neighbor sites in the leg direction, and the nearest-neighbor sites in the rung direction, are antiferromagnetic. This is a minimal model describing a low-dimensional quantum spin compound, $BiCu_2PO_6$. We calculate a dynamical spin correlation function at zero temperature by using the dynamical density-matrix renormalization-group method in possible magnetic phases, columnar dimer and rung singlet. The columnar dimer phase is characterized by multi-spinon excitations, while the rung singlet phase is dominated by a triplon excitation, which is the triplet excitation in the rung direction. Difference between these two types of excitations appears in the spectral weight, in particular, of the bonding and anti-bonding modes in the rung direction. Therefore, we can distinguish one phase from the other by distribution of the spectral weight. In addition, we examine frustration effect on the bonding mode, so-called bound triplon, with a perturbation theory from the strong coupling limit in the rung direction. Our study is expected to be useful to analyze inelastic neutron scattering data for $BiCu_2PO_6$.

4:42PM R8.00012 Critical magnetic scattering in geometric frastrated multiferroic $LuMnO_3$, SHINICHIRO YANO, BING LI, DESPINA LOUCA, Univ. of Virginia, YIMING QIU, JOHN COPLEY, NIST Center for Neutron Research — The coexistence of competing order parameters in the class of materials referred to as the multiferroics is of great interest. The hexagonal manganites $AMnO_3$ (A = Y, Lu, Ho and Yb) with the $P6_3cm$ space group exhibit a ferroelectric transition, at very high temperatures, typically $\sim$ 1000 K, while the antiferromagnetic transition, T_N, occurs at $\sim$ 100K. Earlier studies on $YMnO_3$ and $LuMnO_3$ using neutron scattering on single crystals showed that diffuse scattering is present around the forbidden nuclear (100) Bragg peak which corresponds to Q=1.20 $Å^{-1}$.Its intensity rises very sharply and drops just around T_N. We performed inelastic neutron scattering measurement on a powder sample of $LuMnO_3$ form 4 to 250 K using the DCS at NIST. Strong inelastic intensity, not due to magnon excitations, is observed at Q=1.32 and 2.50 $Å^{-1}$. With cooling, the intensity gradually rises and reaches a peak around 100 K. Below, it drops drastically once the system orders. This kind of scattering is due to critical scattering arising from magnetic fluctuations above T_N. The S(Q, ω) is asymmetric suggesting that the Mn spin correlations are mosmost likely 2-dimensional in nature.

4:54PM R8.00013 Electron mediated magnetism in two-dimensional spin-ice , JORN W. F. VENDERBOS, MARIA DAGHOFER, IFW Dresden, SANJEEV KUMAR, IISER Mohali, ZOHAR NUSSINOV, Washington University, St. Louis, JEROEN VAN DEN BRINK, IFW Dresden — In this work we study the magnetic phase diagram of classical spins which interact with itinerant electrons on a checkerboard lattice, a lattice that constitutes a two-dimensional equivalent of the three-dimensional spin-ice pyrochlore lattice. We explore both the strong coupling and weak coupling limit and find a rich ground state phase diagram as function of interaction strength and electron doping. The strong coupling limit allows for unbiased Monte Carlo simulations of the classical spins combined with exact diagonalization of the fermionic Hamiltonian. For half filling we find a very robust coplanar orthogonal spin state, the robustness of which originates from the strong geometrical frustration of the checkerboard lattice. In the weak coupling approach this double-Q spin state is a consequence of fermi-surface nesting. The electronic spectrum is this state consists of two Dirac points in full analogy with graphene. For other special electron filling fractions such as $n = p/q = 1/4, 3/4, 3/8, 5/8$, we find collinear "loop" states, where the spins order in disconnected loops of fixed length q. Interestingly, for intermediate fillings the ground state is a mixture of loops of different size, which can be captured by an emergent electromagnetic theory with fractional charge.

5:06PM R8.00014 Phase diagram and chirality of the spin-1/2 J1-J2 Heisenberg model on the kagome lattice , SHOUSHU GONG, DONGNING SHENG, Department of Physics and Astronomy, California State University Northridge, Northridge, California, 91325, USA — We studied the spin-1/2 Heisenberg model on the kagome lattice with nearest (J1) and next-nearest neighbor (J2) interactions by means of the density matrix renormalization group. We set J1 as antiferromagnetic coupling (J1 $>$ 0), and J2 can be either ferromagnetic (J2 $<$ 0) or antiferromagnetic (J2 $>$ 0). By analyzing the spin-spin correlation function and the bond energy, we find a valence-bond crystal phase for J2 $<$ -0.1 and a magnetically ordered phase for J2 $>$ 0.2. In the intermediate paramagnetic phase, we investigate the evolution of spin and singlet gaps, topological entanglement entropy, dimer and chirality correlations as a function of the parameter J2. In particular, we investigate the local p6 chiral order parameter proposed recently by measuring the dimer-dimer correlation functions to study the possible reflection symmetry breaking in this spin liquid candidate.

5:18PM R8.00015 Collinear Magnetic Order in an Isotropic Triangular Antiferromagnet: The Sn/Si(111) Surface System , GANG LI, Institut für Theoretische Physik und Astrophysik, Universität Würzburg, 97074 Würzburg, Germany, PHILIPP HÖPFNER, JÖRG SCHÄFER, RALPH CLAESSEN, Physikalisches Institut, Universität Würzburg, 97074 Würzburg, Germany, WERNER HANKE, Institut für Theoretische Physik und Astrophysik, Universität Würzburg, 97074 Würzburg, Germany — The one-electron spectral function is the key quantity to extract detailed information on the complex spin pattern in a frustrated magnetic system. This is demonstrated here by a detailed comparison of theory, which combines a priori density-functional (LDA) with cluster many-body (LDA + DCA) calculations, with high-precision angle-resolved photoelectron spectroscopy (ARPES). The role model in this work is the isotropic triangular antiferromagnetic Sn/Si(111). Its geometric frustration and strong electronic correlations are shown at low temperatures to combine to an unexpected magnetic, i.e. collinear order, and not the possible spiral (120°) antiferromagnetic order or a disordered spin-liquid phase.

Session R9 FIP: Invited Session: Advances in Condensed Matter Physics in Latin America 308

- Eugenio Vogel, Universidad de La Frontera

2:30PM R9.00001 CLAF: 50 Years of Promotion and Coordination of Physics in Latin America , ELISA MARIA BAGGIO SAITOVITCH, CBPF - Brazilian Center for Physics Research — No abstract available.

3:06PM R9.00002 Marshak Lectureship: Women in Physics: Increasing in Number, and What Else? , LILIA MEZA-MONTES[1], Instituto de Física BUAP, Mexico — Latin America is a region with high contrasts. With abundant natural resources and home of several celebrities among the wealthiest in the world, the zone has elevated indexes of poverty. In spite of this, and mostly thanks to the continuing intense efforts of the scientific community, it has been possible to create many excellence research centers. In contrast, illiteracy and lack of access to information and communication technologies are widely spread across our countries. Attitudes toward women have even coined a term, *machismo*. The situation of female physicists in this scenario is analyzed. We present a statistical overview of the participation of women as students or researchers in physics and related areas, for countries where data are available. Initiatives and ongoing programs to support and promote participation of women in science are discussed. Beyond statistics, some comments are given, as expressed by colleagues about work environment and gender issues in general, which have been collected through several years of exchanging concerns on the topic. Mexico and Brazil are discussed in more detail. Finally, we propose some joint actions to increase and improve the participation of women in our scientific field, which will give rise to better conditions for us but will also contribute to building a more equitable and developed region.

[1]Member of IUPAP Working Group on Women in Physics.

3:42PM R9.00003 Brazilian Synchrotron Light Source: current results and future perspectives , ANTONIO JOSE ROQUE DA SILVA, Laboratorio Nacional de Luz Sincrotron and Instituto de Fisica da Universidade de Sao Paulo — The application of synchrotron radiation in a great variety of fields in general, and condensed matter in particular, has increased steadily worldwide. This, to a large extent, is a result of the availability of the much brighter third-generation light sources, which opened up new experimental techniques. Brazil gave an important contribution to science in Latin America through the development of the necessary technology and the construction of the first synchrotron in the southern hemisphere, still the only one in Latin America. The Laboratório Nacional de Luz Síncrotron – LNLS, operates this installation as an open facility since 1997, having today more than 1300 users yearly. Despite all this success, the current Brazilian light source is a second-generation machine, with relatively low electron energy, high emittance and few straight sections for insertion devices. LNLS is currently engaged in the design and construction of a new, third-generation synchrotron light source. It is being planned to be a state of the art machine, providing tools for cutting edge research that are non existent today in Brazil. In this talk an overview of the status of the current Brazilian light source will be provided, illustrated with some experimental results from users, as well as the future perspectives of the new synchrotron source.

4:18PM R9.00004 Physics in Argentina: The Case of Nanoscience and Nanotecnology , CARLOS A. BALSEIRO, Centro Atómico Bariloche, Comisión Nacional de Energía Atómica, Argentina — Since the creation of the Ministry of Science and Technology in 2008 the science budget has increased and new programs have been launch. After a brief introduction describing general aspects, including the structure of the Ministry and the role of the National Research Council, I will focus on the case of nanoscience and nanotechnology in our country: The main actors and their activities, new programs and facilities, international cooperation and technology oriented projects.

4:54PM R9.00005 Condensed Matter Physics in Mexico , ROMEO DE COSS, CINVESTAV-Merida, Mexico — No abstract available.

Wednesday, March 20, 2013 2:30PM - 5:30PM –

Session R10 GQI DCMP: Invited Session: New Platforms for Non-Abelian Statistics Majoranas and Beyond 309 - Kirill Shtengel, University of California, Riverside

2:30PM R10.00001 Coulomb-assisted braiding of Majorana fermions in a Josephson junction array , CARLO BEENAKKER, Leiden University, Instituut-Lorentz — We show how to exchange (braid) Majorana fermions in a network of superconducting nanowires by control over Coulomb interactions rather than tunneling. Even though Majorana fermions are charge-neutral quasiparticles (equal to their own antiparticle), they have an effective long-range interaction through the even-odd electron number dependence of the superconducting ground state. The flux through a split Josephson junction controls this interaction via the ratio of Josephson and charging energies, with exponential sensitivity. By switching the interaction on and off in neighboring segments of a Josephson junction array, the non-Abelian braiding statistics can be realized without the need to control tunnel couplings by gate electrodes. This is a solution to the problem how to operate on topological qubits when gate voltages are screened by the superconductor.

3:06PM R10.00002 Zero-bias peaks and splitting in an Al–InAs nanowire topological superconductor as signature of Majorana fermions[1] , MOTY HEIBLUM, Weizmann Institute of Science — Majorana fermions are the only fermionic particles that are expected to be their own antiparticles. While elementary particles of the Majorana type were not identified yet, quasi-particles with Majorana like properties, born from interacting electrons in the solid, were predicted to exist. Here, we present thorough experimental studies, backed by numerical simulations, of a system composed of an aluminum superconductor in proximity to an indium arsenide nanowire, with the latter possessing strong spin-orbit coupling and Zeeman splitting. Induced one-dimensional topological superconductor, supporting Majorana fermions at both ends, is expected to form. We concentrate on the characteristics of a distinct zero bias conductance peak (ZBP) and its splitting in energy - both appearing only with a small magnetic field applied along the wire. The ZBP was found to be robustly tied to the Fermi energy over a wide range of system parameters. While not providing a definite proof of a Majorana state, the presented data and the simulations support its existence.

3:42PM R10.00003 Exotic non-Abelian anyons from conventional fractional quantum Hall states[1] , DAVID CLARKE, Caltech — Non-Abelian anyons are widely sought after for the exotic fundamental physics they harbor as well as for quantum computing applications. There now exist numerous blueprints for stabilizing the simplest type of non-Abelian anyon, defects binding Majorana fermion zero modes, by judiciously interfacing widely available materials. Following this line of attack, we introduce a device fabricated from conventional fractional quantum Hall states and s-wave superconductors. We show that a new type of zero mode is bound at the interface between the quantum Hall state and the superconductor. These zero mode operators have parafermionic rather than fermionic commutation relations, implying a topologically protected ground state degeneracy larger than that of Majorana fermions. We discuss how these modes might be experimentally identified (and distinguished from Majoranas) using Josephson measurements.

[1]Supported by NSF Grant DMR-1055522

4:18PM R10.00004 Fractionalizing Majorana Fermions: Non-Abelian Statistics on the Edges of Abelian Quantum Hall States , NETANEL LINDNER, California Institute of Technology — We study the non-Abelian statistics characterizing systems in which the edges of fractional quantum Hall states are gapped by proximity coupling to superconductors and ferromagnets. We show that as more superconductor-ferromagnet interfaces are introduced, the ground state degeneracy grows with a quantum dimension of a square root of an even integer, corresponding to a new family of non-Abelian anyons. Topologically protected braiding of two anyons can be achieved by a sequence of adiabatic manipulations of the system. We show that the unitary transformations resulting from these braiding operations realize a richer set of representations of the braid group than those realized by non-Abelian anyons based on Majorana fermions. We discuss implications of these braiding operations to topological quantum computation, and consider possible realizations of these ideas in experimentally accessible solid state systems.

4:54PM R10.00005 Genons, twist defects, and projective non-Abelian statistics , MAISSAM BARKESHLI, Stanford University — An intense focus in the condensed matter community currently is the search for Majorana fermions in solid state systems. Defects which localize Majorana zero modes obey the simplest kind of non-Abelian statistics, and are of interest partially for the goal of achieving topological quantum computing. In this talk, I will present recent advances in our understanding of how to synthesize a much more general class of non-abelian defects using conventional topological states. After discussing the new theoretical foundations, I will present an experimental proposal using only conventional bilayer fractional quantum Hall states and a simple geometry of top and bottom gates. I will also discuss how these ideas can be used to perform universal topological quantum computing (TQC) using non-abelian states that by themselves are not universal for TQC.

Wednesday, March 20, 2013 2:30PM - 5:30PM –

Session R12 DMP GERA FIAP: Focus Session: Thermoelectrics Phonons and Heat Conduction

314 - David Cahill, University of Illinois at Urbana-Champaign

2:30PM R12.00001 Phonon Thermal Transport in Thermoelectric Materials from First Principles[1] , DAVID BROIDO, Department of Physics, Boston College — Breakthroughs in nanoscience and materials fabrication technology have led to the creation of materials with very low lattice thermal conductivity [1, 2], a requirement for high thermoelectric efficiency. There is now an unprecedented need for quantitative, predictive theoretical approaches to provide fundamental understanding of lattice thermal transport in thermoelectric materials and insight into the design and development of new materials for enhanced thermoelectric applications. In this talk, I will describe our atomistic first principles approach for calculating lattice thermal conductivity of materials [3-6], which combines a complete solution of the Boltzmann transport equation for phonons with harmonic and anharmonic interatomic forces determined from density functional theory. I will present an overview of this theoretical approach along with some of our recent calculated results for a range of test materials such as Si, Ge and III-V compounds. I will also discuss results for thermoelectric alloys such as Si_xGe_{1-x} and $Mg_2Si_xSn_{1-x}$ and nanoparticle embedded in alloy thermoelectric (NEAT) materials. Finally, I will discuss insights gained from this effort such as the importance of anharmonic coupling of acoustic and optic phonon modes.

3:06PM R12.00002 Beyond the constant Lorenz number for separating thermal conductivities of electrons and phonons: A DFT study[1] , MINGXING CHEN, Department of Physics, University of Wisconsin-Milwaukee, RAIMUND PODLOUCKY, Department of Physical Chemistry, University of Vienna, Austria — Lorenz number is an important quantity for separating thermal conductivities of electrons and phonons in the field of thermoelectrics, which is material- and temperature-dependent. Combing DFT calculations with Boltzmann transport equations, we have derived the Lorenz number for realistic compound $BaAu_6Ge_{40}$, a good thermoelectric material. It is demonstrated that using the constant Lorenz number of the Wiedemann-Franz law for simple metals leads to strong discrepancies, in particular at higher temperatures. The results suggest that one has to rethink the way of extracting both κ_{el} and κ_{ph} as usually done based on the measured electrical conductivity. We propose a strategy of correcting the Wiedemann-Franz Lorenz number that subtracts the metallic limiting value by S^2 as obtained from Seebeck measurements.

3:18PM R12.00003 Calculating Lattice Thermal Conductivity via Compressive Sensing Lattice Dynamics , WESTON NIELSON, University of California Los Angeles, FEI ZHOU COLLABORATION, VIDVUDS OZOLINS COLLABORATION — Calculating the lattice contribution to thermal conductivity (TC) is of great importance in a range of materials applications, including thermoelectrics. Common simulation-based methods for calculating the TC typically require either very long simulation times, large system size, or both. These constraints make it difficult or impractical to use DFT-based methods for calculating the TC. Classical molecular dynamics (MD), however, is typically unburdened by these constraints but is instead limited by the accuracy of the interatomic potentials. We have developed a method that uses DTF, combined with compressive sensing, to calculate the higher-order force constants from the theory of lattice dynamics. These force constants are then used to calculate interatomic potentials in a classical MD program. We present our findings from applying this method to a variety of materials.

3:30PM R12.00004 Phonon Surface Scattering in Monte Carlo Simulations , LEON MAURER, ZLATAN AKSAMIJA, University of Wisconsin-Madison, EDWIN RAMAYYA, Intel Corporation, AMIRHOSSEIN DAVOODY, IRENA KNEZEVIC, University of Wisconsin-Madison — Surface roughness has a significant impact on the thermal conductivity and thermoelectric properties of nanowires. We investigate the effect of surface roughness on thermal transport using a phonon Monte Carlo simulation. In addition to allowing us to simulate a wide range of wire dimensions and surface topographies, Monte Carlo enables us to investigate different models for surface scattering: constant specularity parameters, momentum-dependent specularity parameters, and specular scattering from randomly generated rough surfaces. We investigate the relative merits of different surface scattering models and the limitations on their validity.

3:42PM R12.00005 First principles and force field calculations of thermal transport in bulk semiconductors and oxides: a comparative study[1] , EAMONN MURRAY, UC Davis, IVANA SAVIC, Tyndall National Institute, Cork, Ireland, GIULIA GALLI, UC Davis — At present, large scale calculations of thermal transport properties of materials are carried using empirical potentials[2], due to difficulties in scaling ab initio methods to directly compute the thermal conductivity of complex, nanostructured systems. It is therefore important to asses the predictive ability of empirical potentials for representative bulk systems, for which ab initio simulations are possible, and to establish their accuracy in yielding absolute values of computed thermal conductivities (κ) and trends within given classes of systems. We report on comparisons between thermal conductivities of elemental semiconductors and insulators (Si, C, Ge) and simple oxides (MgO and SiO2) as obtained using the Boltzman Transport equation with first principles, DFT Hamiltonians and Tersoff type empirical potentials. The second and third derivatives of the energy with respect to atomic displacements are obtained by finite difference calculations in supercells in all cases. A detailed discussion of the reasons why these empirical potentials appear to systematically overestimate κ will be presented.

3:54PM R12.00006 A Comparative Study of Ab-Initio Thermal Conductivity Approaches: The Case of Cubic Boron Nitride , SAIKAT MUKHOPADHYAY, Cornell University, LUCAS LINDSAY, Naval Research Laboratory, DAVID BROIDO, Boston College, DEREK STEWART, Cornell University — Given its high strength and large thermal conductivity, cubic boron nitride (cBN) provides an important complement to diamond films for heat spreading applications. However, cBN, in contrast to diamond, is a polar material with significant LO-TO splitting in the phonon dispersion. In this talk, we examine the lattice thermal conductivity of cBN using several approaches based on first principles calculations. These approaches include: (1) an analytic modified Callaway-Debye model that relies on parameters from ab-initio harmonic force constants, (2) a fully self-consistent calculation of the thermal conductivity that links an iterative solution of the phonon Boltzmann transport equation (BTE) with harmonic and anharmonic interatomic force constants. The force constants for the BTE are calculated using two approaches: density functional perturbation theory and a real-space supercell approach. We will compare the results from these approaches, highlight the role of normal phonon-phonon scattering, and also examine the impact of optical modes and LO-TO splitting. In addition, we will discuss how isotope scattering affects thermal conductivity and compare this to other boron nitride structures (hexagonal BN, BN sheets and BN nanotubes).

4:06PM R12.00007 Improved Calculation of Vibrational Mode Lifetimes in Anharmonic Solids[1] , MURRAY DAW, YANG GAO, Clemson U, DOYL DICKEL, Fraunhofer Institute for Mechanics of Materials, Freiburg, Germany, DAVID HARRISON, Clemson U — We propose and evaluate a formal foundation for practical calculations of vibrational mode lifetimes in solids. The approach is based on a recursion method analysis of the Liouvillian. From this we derive the lifetime of a vibrational mode in terms of moments of the power spectrum of the Liouvillian as projected onto the relevant subspace of phase space. In practical terms, the moments are evaluated as ensemble averages of well-defined operators, meaning that the entire calculation is to be done with Monte Carlo. These insights should lead to significantly shorter calculations and improved understanding of mode lifetimes and lattice thermal conductivity. Evaluation performed on model systems have been encouraging. [See Dickel & Daw, Comp Mat Sci, v47 p698 and v49 p445 (2010)].

4:18PM R12.00008 Local Distortions in PbTe:Tl[1] , TREVOR KEIBER, FRANK BRIDGES, UC Santa Cruz, BRIAN SALES, Oak Ridge National Laboratory — Lead Telluride (PbTe) is a well characterized thermoelectric material. Tl doping increases the figure of merit with a maximum at 2% Tl. Recent X-ray diffraction and total neutron scattering experiments suggest Pb moves off-center along the 100 axis as T increases. To investigate the local structure we present an Extended X-ray Absorption Fine Structure (EXAFS) analysis for 0-3% Tl concentrations at the Tl and Pb L3 edges and at the Te K edge. At 10K the local structure about Pb is well ordered, the Pb-Te (Te-Pb) pair distribution function (PDF) broadens rapidly with T. Attempts to model the increase in σ^2(T) for the Pb-Te pair (σ is the width of the PDF) with a 100 Pb off-center displacement, were not successful. However σ^2(T) for the Pb-Te pair is well described by a correlated Debye model with a low correlated Debye temperature. The Te edge shows increased disorder for the the Te-Te pair and later peaks which may be caused by a structural change around the Te atom. For Tl, the environment is distorted even at 10K within the host material. This indicates a large variation of the Tl-Te bond lengths, presumably as a result of the presence of Tl(+1). We discuss possible models for the disorder about Tl, Pb, and Te in PbTe:Tl.

4:30PM R12.00009 Anomalous Coherent Oscillations in PbTe from Ultrafast Optical Pump-Probe Measurements , MASON JIANG, PULSE Institute, Stanford University, PAULA GIRALDO, IAN FISHER, Geballe Laboratory for Advanced Materials and Department of Physics, Stanford University, DAVID REIS, PULSE Institute, Stanford University — We report on the observation of anomalous coherent oscillations in single crystals of PbTe from ultrafast optical pump-probe measurements. PbTe is a leading thermoelectric material with an unusually low thermal conductivity, which has recently been attributed to strongly anharmonic phonon interactions. In an attempt to understand in greater detail the nature of these interactions, we perform time-resolved, optical pump-probe measurements on PbTe with femtosecond resolution in a range of temperatures from 77K to room temperature. We see previously unreported, low-frequency reflectivity oscillations that decay on the timescale of a few picoseconds and remain robust through a wide range of temperature variation. This talk will discuss possible origins and explanations for the appearance of these oscillations.

4:42PM R12.00010 Phonon Dispersions and Relaxation Times in $AgSbTe_2$ and PbTe[1] , OLIVIER DELAIRE, JIE MA, ANDREW MAY, Oak Ridge National Laboratory, CHRIS CARLTON, MIT, MICHAEL MCGUIRE, Oak Ridge National Laboratory, LINDSAY VANBEBBER, University of Tennessee, DOUGLAS ABERNATHY, GEORG EHLERS, TAO HONG, ASHFIA HUQ, WEI TIAN, VEERLE KEPPENS, Oak Ridge National Laboratory, YANG SHAO-HORN, MIT, BRIAN SALES, Oak Ridge National Laboratory — The thermoelectric material $AgSbTe_2$ had attracted much interest due to its high thermoelectric figure-of-merit, and its anomalously low thermal conductivity for a nominally simple rock-salt structure, which is glass-like even in bulk single-crystals. We present results of systematic neutron scattering investigations of the phonon density-of-states, dispersions, and relaxation times in $AgSbTe_2$, and contrast these with PbTe. A detailed account of the thermal conductivity is obtained in terms of microscopic phonon mean-free-paths, providing good agreement with bulk transport measurements.

[1]Funding from the US DOE, Office of Basic Energy Sciences, Materials Science and Engineering Division, and from the S3TEC Energy Frontier Research Center, DOE DE-SC0001299.

4:54PM R12.00011 Phonon dynamics in SnTe[1] , CHEN LI, OLIVIER DELAIRE, XIN CHEN, DAVID SINGH, ANDREW MAY, JIE MA, MICHAEL MCGUIRE, GEORG EHLERS, ANDREW CHRISTIANSON, ASHFIA HUQ, Oak Ridge National Laboratory — Thermoelectric materials can convert waste heat into electrical energy, and have attracted much attention in recent years for power generation. IV-VI compounds in rock salt structure include some of the most efficient thermoelectric materials and giant phonon anharmonicity is believed to contribute to the low thermal conductivity. In this work, phonon dispersions and linewidths in single-crystalline SnTe were measured at a series of temperatures using time-of-flight and triple-axis neutron spectrometers to study the temperature dependence of the phonon dynamics and phonon anharmonicity. Phonon calculations and molecular dynamics simulations with first-principles methods were used to identify the anomalies in phonon modes and the results were compared to the measurements. Because the phonons involved have an important contribution to the lattice thermal conductivity in this system, the anharmonic coupling is likely to provide a key insight in understanding the surprisingly low thermal conductivity of the rocksalt tellurides in general.

[1]Funding from the US DOE, Office of Basic Energy Sciences, Materials Science and Engineering Division, and from the S3TEC Energy Frontier Research Center, DOE DE-SC0001299.

5:06PM R12.00012 Simulation of Nanostructure and Thermal Conductivity in Binary Alloys , YUSUKE KONISHI, NRI-AIST, TETSUYA FUKUSHIMA, KAZUNORI SATO, HIROSHI KATAYAMA-YOSHIDA, Graduate School of Engineering Science, Osaka University, YOSHIHIRO ASAI, NRI-AIST — Thermoelectric materials attract much attention because of concerns about energy conservation. Recently, Sugihara et al. made nanostructures using phase separation of Ni-Cu binary alloy [1]. This structure is about 10nm and has the large Seebeck coefficient. However, the way to make better thermoelectric material is under discussion. For this purpose, we need a large Seebeck coefficient, large electric conductivity, and small phonon thermal conductivity. The goal of this study is finding the condition of making good thermoelectric materials. In our simulation, we made structures in various conditions and evaluated phonon thermal conductivity. First, we simulated quenching binary alloy at high temperature by using Monte Carlo method. The potential between atoms are determined by KKR-CPA method [2]. In this simulation, nanostructures have the size distribution between 1 nm and 50 nm. Next, we simulated phonon conduction by molecular dynamics. Heat baths were placed at both ends and the thermal gradient was made. By calculating energy flux, we determined the value of phonon thermal conductivity. [1] A Sugihara et al., Appl. Phys. Exp. 3, 065204 (2010). [2] H. Akai, J. Phys.: Condens. Matter 1, 211 (1989).

5:18PM R12.00013 Landauer approach to thermoelectric transport across grain boundaries in Si , MICHAEL SHAUGHNESSY, DOUG MEDLIN, FRANCOIS LEONARD, CATALIN SPATARU, Sandia National Laboratories — Thermoelectric transport is strongly influenced by electron and phonon scattering from defects, grain boundaries, and nano structuring. While scattering from point defects is relatively well understood, the impact of the detailed structure of grain boundaries is still poorly understood. We use a Landauer approach based on ab initio Density Functional Theory and classical Molecular Dynamics simulations to compute electron and phonon transport coefficients in the presence of grain boundaries. The approach allows the calculation of all the thermoelectric quantities, including thermal conductivity, electrical conductivity, Seebeck coefficient, and the overall figure of merit, ZT. The method is applied to grain boundaries in Si, focusing on the {111}twin in the high and low density regimes. For ordered arrays of {111}twins in Si a small change in ZT is predicted because of compensating differences between thermal conductivity on the one hand and electrical conductivity and Seebeck coefficient on the other.

Wednesday, March 20, 2013 2:30PM - 5:18PM –

Session R13 DMP: Focus Session: Topological Materials - Surface Microscopy and Spectroscopy 315 - Alexander Brinkman, University of Twente

2:30PM R13.00001 Imaging the Impact of Impurities on Topological Surface States , JENNIFER HOFFMAN, Harvard University — Harnessing the technological potential of the spin-polarized surface states on topological insulators requires a detailed understanding of the impact of nanoscale disorder on those surface states. We employ spectroscopic scanning tunneling microscopy (STM) in the presence of a magnetic field to visualize the impact of intrinsic impurities on topological surface states in Sb and Bi_2Se_3. We find a variety of impurities with different energy profiles that elastically scatter surface states through dispersive quasiparticle interference (QPI), that inelastically scatter surface states into the bulk, that locally destroy the extended surface state Landau level wavefunctions, or that form local resonant states interacting with the Dirac quasiparticles. By identifying impurities that strongly interact with and limit the mobility of the topological surface states, our impurity studies can directly advise the growth and development of future topological materials.

Measurements carried out by Anjan Soumyanarayanan, Michael Yee, Yang He. Samples grown by Dillon Gardner & Young Lee; Zahir Salman & Amit Kanigel; Zhi Ren & Kouji Segawa & Yoichi Ando.

3:06PM R13.00002 Scanning tunneling microscopy studies of topological crystalline insulators , ANDRAS GYENIS, JUNGPIL SEO, OLIVER JEONG, ILYA DROZDOV, STEVAN NADJ-PERGE, QUINN GIBSON, Princeton University, GENDA GU, Brookhaven National Laboratory, ROBERT CAVA, ALI YAZDANI, Princeton University — Recent theoretical studies and experimental findings suggest the existence of a new topological phase: topological crystalline insulators (TCI). In contrast to the Z_2 topological insulators, where the time-reversal symmetry warrants the topological protection of the gapless surface states, in the TCI phase the protection is based on the crystal symmetry. $Pb_{1-x}Sn_xSe$ and $Pb_{1-x}Sn_xTe$ alloys are promising candidates for the TCI state: both of them have the rock-salt crystal structure (at certain doping values) with spatial mirror symmetry, and as a function of doping level the band structure can be changed from normal to inverted bandgap state. We present scanning tunneling microscopy/spectroscopy measurements on these alloys as a function of doping. Similar to previous experiments on spin-orbit coupled topological insulators [1], spectroscopic mapping with the STM can be used to establish the presence of topological properties through examining allowed and disallowed scattering transitions.

3:18PM R13.00003 LT-STM study of Nb islands on Bi2Se3 with W and Nb Tips , RAMI DANA, ANITA ROYCHOWDHURY, University of Maryland, IRENEUSZ MIOTKOWSKI, YONG P. CHEN, Purdue University, MICHAEL DREYER, University of Maryland — Proximity effect between an s-wave superconductor (SC) and a topological insulator (TI) are expected to induce px + ipy superconductor like state at the SC-TI interface. The vortex cores of that state are predicted to host Majorana fermions. In this work we study the TI Bi_2Se_3 using W and Nb tips at 4.2 K with and without Nb islands. The W tip shows no SC gap on top and around the islands. The Nb tip shows variable SC gaps and a verity of zero bias conductance peaks. The possible sources for these observations and the part of the TI, Nb islands and/or Nb tip will be discussed.

3:30PM R13.00004 Scanning Tunneling Microscopy of the Topological Crystalline Insulator SnTe

, DUMING ZHANG, TONG ZHANG, JEONGHOON HA, Center for Nanoscale Science and Technology, NIST, Gaithersburg, MD 20899/Maryland NanoCenter, University of Maryland, College Park, MD 20742, HONGWOO BAEK, Center for Nanoscale Science and Technology, NIST, Gaithersburg, MD 20899/Department of Physics and Astronomy, Seoul National University, Seoul, Korea, YOUNG KUK, Department of Physics and Astronomy, Seoul National University, Seoul, Korea, FRED SHARIFI, JOSEPH STROSCIO, Center for Nanoscale Science and Technology, NIST, Gaithersburg, MD 20899 — Topological insulators are a new state of matter characterized by a bulk insulating gap and gapless surface states protected by time reversal symmetry. This is realized by spin orbit coupling induced band inversion with an odd number of Dirac cones. Recently, the topological classification of states has been extended to a new class of matter called topological crystalline insulators. In contrast to topological insulators, topological crystalline insulators arise from crystal symmetry and are characterized by surface states with an even number of Dirac cones. Here, we report molecular beam epitaxy growth of SnTe thin films, a material recently predicted and experimentally confirmed as a topological crystalline insulator. The film morphology and SnTe (001) surface states were characterized *in-situ* by low temperature scanning tunneling microscopy and spectroscopy will be discussed in relation to the predicated topological properties of this material.

3:42PM R13.00005 Scanning tunneling microscopy of gate tunable topological insulator Sb2Te3

, TONG ZHANG, NIV LEVY, JEONGHOON HA, Center for Nanoscale Science and Technology, NIST/Maryland NanoCenter, UMD, YOUNG KUK, Dept. of Physics and Astronomy, Seoul National University, JOSEPH STROSCIO, Center for Nanoscale Science and Technology, NIST — We achieved gate tunable topological insulator (TI) Sb2Te3 thin films which are suitable for low temperature scanning tunneling microscopy (STM) studies. The film is epitaxially grown on pre-patterned SrTiO3 substrates which are mounted on specially designed sample holders. This allows us to do in-situ gating on epitaxial films without any ex-situ processing of the sample. The tunneling conductance as well as film resistance is investigated as a function of gate voltage (Vg). In a 3 nm thick Sb2Te3 film, a gap opening at the Dirac point due to the coupling of the top and bottom surfaces is observed. More importantly, the gap size is found to be tunable by Vg, a result of the combination of coupling of the surface state bands and electric field effect. We show that our observation can be well described by an effective model of TI thin films and first principle calculations. The reduced surface states gap versus Vg indicates it is possible to create a topological phase transition by apply a strong enough electric field through the film.

3:54PM R13.00006 Landau quantization and quasiparticle interference of Dirac fermions on a topologically protected Fermi surface[1]

, ANJAN SOUMYANARAYANAN, MICHAEL YEE, YANG HE, Harvard University, DILLON GARDNER, YOUNG LEE, Massachusetts Institute of Technology, JENNIFER HOFFMAN, Harvard University — The discovery of topological materials hosting spin-polarized Dirac fermion surface states has been driven by the use of surface-sensitive spectroscopic tools. Scanning tunneling microscopy and spectroscopy (STM/STS) can, in principle, access the surface state band structure across a range of energies on the nanometer length scale through a combination of one particle (Landau quantization) and two-particle (quasiparticle scattering) techniques. However, the equivalence of these two STS techniques has yet to be established. Here we report the surprising simultaneous observation of Landau quantization and quasiparticle interference on the Fermi surface of the topological metal Sb(111). We establish the equivalence of the two momentum-resolved STS techniques, and use them to quantitatively reconstruct the multi-component surface state band structure, which would be inaccessible via either of these techniques alone. We further use these techniques to probe the local effects of single atom impurities on the surface states.

4:06PM R13.00007 First principles transport calculations on topological surface states scattering

, IVAN RUNGGER, AWADHESH NARAYAN, STEFANO SANVITO, Trinity College Dublin — We study the scattering properties of topologically protected states on the Sb(111) and Bi_2Se_3(111) surfaces by using the ab initio transport code SMEAGOL [1]. We consider different types of defects, such as adatoms and extended barriers. In the presence of a strong surface perturbation in the form of a step separating surface terraces we obtain standing-wave states resulting from the superposition of spin-polarized surface states. By Fourier analysis, we identify the underlying two dimensional scattering processes and the spin texture [2]. We find evidence of resonant transmission across the surface barrier at quantum well state energies and evaluate their lifetimes. Our results for the Sb surface are in agreement with experimental findings [3]. We also show that despite the presence of a step edge along a different direction, the surface states exhibit unperturbed transmission around the Fermi energy for states with near to normal incidence

4:18PM R13.00008 Electronic structure studies on p-type $Pb_{1-x}Sn_xTe$ system above and below the band inversion topological transition[1]

, NASSER ALIDOUST, SU-YANG XU, M. NEUPANE, C. LIU, I. BELOPOLSKI, Department of Physics, Princeton University, D. QIAN, Department of Physics, Shanghai Jiao Tong University and Princeton University, J.D. DENLINGER, ALS, LBNL, Y.J. WANG, H. LIN, Department of Physics, Northeastern University, L.A. WRAY, ALS, LBNL and Princeton University, Q. GIBSON, Department of Chemistry, Princeton University, R. SANKAR, F.C. CHOU, Center for Condensed Matter Sciences, National Taiwan University, R.J. CAVA, Department of Chemistry, Princeton University, A. BANSIL, Department of Physics, Northeastern University, M.Z. HASAN, Department of Physics, Princeton University — We present systematic ARPES studies on p-type $Pb_{1-x}Sn_xTe$ samples at three different compositions with x = 0.26, 0.5, and 1.0. This material has been predicted as a topological crystalline insulator (TCI) upon band inversion at $x \simeq 0.3$. We show that the observed bulk valence band is a single hole-like band in the vicinity of the $\overline{X}$ points of the surface Brillouin zone, and reveal the 3D dispersive nature of the valence band with a clear k_z dispersion. We further show that despite the predicted band inversion and topological phase transition, the observed valence band electronic structure does not exhibit dramatic difference between these samples, demonstrating the critical importance of preparing in-gap or n-type samples for the realization of the TCI phase.

4:30PM R13.00009 Observing electronic structures on *ex-situ* topological insulator thin films

, BO ZHOU, SIMES/Stanford/Oxford/LBNL, S.H. YAO, M.H. LU, Nanjing University, Z.K. LIU, SIMES/Stanford, Y.B. CHEN, Nanjing University, J.G. ANALYTIS, SIMES, C. BRUNE, Universitat Wurzburg, W.H. DANG, Peking University, S.-K. MO, LBNL, Z.-X. SHEN, I.R. FISHER, SIMES/Stanford, L.W. MOLENKAMP, Universitat Wurzburg, H.L. PENG, Peking University, Z. HUSSAIN, LBNL, Y.L. CHEN, Oxford — Topological insulators represent a new state of quantum matter with insulating bulk but conducting surface states formed by an odd number of Dirac fermions. We present our progress on the study of electronic structures of *ex-situ* grown topological insulator thin films by angle resolved photoemission spectroscopy (ARPES). We successfully obtained the topological band structures, after proper surface cleaning procedures, from HgTe films grown by molecular beam epitaxy and Bi_2Te_3 nanoplates synthesized by vapor-solid method. This new development will not only enable us to study more topological insulators that cannot be measured by conventional *in-situ* ARPES technique, but also open the door to directly characterize the electronic properties of topological insulators used in functional devices.

4:42PM R13.00010 Spatial fluctuations of helical Dirac fermions on the surface of topological insulators[1] , HAIM BEIDENKOPF, Department of Condensed Matter Physics, Weizmann Institute of Science, Rehovot 76100, Israel — Strong topological insulators are materials that host exotic states on their surfaces due to a topological band inversion in their bulk band structure. These surface states have Dirac dispersion as if they were massless relativistic particles, and are assured to remain metallic by time reversal symmetry. The helical spin texture associated with the Dirac dispersion prohibits backscattering, which we have imaged using scanning tunneling microscopy (STM) and spectroscopic mappings [1,2]. This topological protection can be lifted by time-reversal breaking perturbations that induce a gap at the Dirac point and cant the helical spin texture. Massive Dirac electrons had been visualized by angular resolved photo emission spectroscopy in magnetically doped topological insulators. While we do not identify a gapped spectrum in our STM measurements of similar compounds, we do find a dominating electrostatic response to the charged content of those dopants [3]. In their presence the Dirac spectrum exhibits strong spatial fluctuations. As a result translational invariance is broken over a characteristic length scale and the Dirac-point energy is only locally defined. Possible global manifestations of these local fluctuations will be discussed, as well as alternative avenues for breaking time reversal symmetry while maintaining the integrity of the Dirac spectrum.

Session R14 DMP FIAP GMAG: Focus Session: Magneto-thermal Transport and Spin Current in Insulators 316 - Helmut Schulthei, Argonne National Laboratory

2:30PM R14.00001 Local spin currents in magnetothermal landscapes[1] , M. WEILER[2], M. SCHREIER, H. HUEBL, M. ALTHAMMER, M. OPEL, R. GROSS, S.T.B. GOENNENWEIN, Walther-Meißner-Institut, Bayerische Akademie der Wissenschaften, 85748 Garching, Germany — Spin caloritronic effects - such as the spin Seebeck effect - are concerned with the interplay of heat and spin currents and have been experimentally studied using homogeneous thermal gradients to date. However, in order to understand the underlying magnon-phonon interactions that take place on short length scales, a spatially resolved study of spin currents in magnetothermal landscapes [1] is mandatory. We here use a focussed, scannable laser beam to generate local thermal perturbations in thin film multilayers incorporating the ferromagnetic insulator $Y_3Fe_5O_{12}$ (YIG). In both, YIG/Pt thin film bilayers and YIG/Au/Pt trilayers, the laser heating results in a difference of the magnon and electron temperatures in the YIG and Pt, respectively, as quantitatively modeled in numerical simulations. In the presence of this temperature difference, we experimentally observe a local in-plane electric field in the YIG/Pt and YIG/Au/Pt samples. This electric field is ascribed to the detection of the local longitudinal spin Seebeck effect via the inverse spin Hall effect in Pt. Our experiments allow to, e.g., electrically image magnetic texture in a magnetic insulator and provide a local, bipolar, magnetically controllable spin current source. [1] M. Weiler et al. PRL 108, 106602

2:42PM R14.00002 Induced Magneto-transport Effects in Non-magnetic Metals on Yttrium Iron Garnet[1] , TAO LIN, CHI TANG, JING SHI, Department of Physics and Astronomy, University of California, Riverside, CA, 92521 — Yttrium iron garnet (YIG) was called "spin Seebeck insulator," for it supports heat-generated pure spin currents. Pt thin film, with strong spin-orbit interaction, is used as a spin current generator or detector based on the spin Hall effect or the inverse spin Hall effect. The combination of these two materials plays a very important role in spintronics. A recent magnetotransport study shows strong evidence of a magnetic proximity effect in thin Pt films deposited on YIG. Here, we present a magneto-transport study of several non-magnetic (NM) metal films (e.g. Pt, Pd) on YIG films grown on gadolinium gallium garnet substrates with laser molecular beam epitaxy. The anisotropic magnetoresistance (AMR) and anomalous Hall effect (AHE) reveal clear ferromagnetic characteristics in NM films. The magnitude of the AHE angle Θ in Pd/YIG structure increases with decreasing temperature, while Θ in Pt/YIG structure has a sign reversal at an intermediate temperature. Both AMR and AHE have been investigated as the NM film thickness is varied and an optimal effective thickness is identified. The effect of annealing has also been studied and the results are consistent with the observed thickness dependence. In thin NM films, a ln(T) temperature dependence with a resistivity minimum is observed at low temperatures, suggesting that the Kondo effect may be relevant. Detailed discussions about the origin of these effects will be presented.

2:54PM R14.00003 Nonlocal optical generation of spin and charge currents on the surface of magnetic insulators using total absorption and surface plasmons , SIU TAT CHUI, University of Delaware, Z.F. LIN, Fudan University, C.R. ZHANG, National Taiwan University, JOHN XIAO, Univeristy of Delaware — We study the nonlocal spin and charge current generation in a finite metallic element on the surface of magnetic insulators such as yttrium iron garnet due to the absorption of the magnetic surface plasmon (MSP). Whereas a surface plasmon is completely reflected by a metal, an MSP can be absorbed due to the absence of backward states. The injection of MSP generates a voltage in the longitudinal direction parallel to the wave vector, with the voltage proportional to input power. If the metal is a ferromagnet, a spin current can also be induced in the longitudinal direction. Our results provide a way to improve upon integrated circuits of spintronics and spin wave logic devices.

3:06PM R14.00004 Spin information propagation through metal/magnetic insulator interface[1]

, SHULEI ZHANG, Department of Physics, University of Arizona — In metal-based spintronics, electron spin current plays pivotal roles in propagating spin information. Here we investigate the propagation of magnon current carried by non-equilibrium magnons, which can also serve as spin carriers in ferromagnet. By exploiting of the semiclassical Boltzmann approach, we explicitly derive the non-equilibrium magnon distribution and magnon current in ferromagnetic insulators [1]. In some limiting cases, we find that magnon density satisfies a diffusion equation, similar to the electron spin diffusion equation. At the interface between a metal layer (ML) and a magnetic insulator layer (MIL), we show that the spin current of the ML and the magnon current of the MIL are mutually transferable. We introduce a concept of spin convertance [1] that quantitatively measures magnon current induced by electron spin accumulation and spin current generated by magnon accumulation at the interface. With the above formalism, we predict some interesting spin transport phenomena for several layered structures with a MIL. In particular, we anticipate a novel electric drag mediated by magnons: an applied electric current in one ML induces an electric field in the other ML separated by a thick MIL. Our theory also provides a new perspective on the longitudinal spin Seebect effect [2] from the point of view of magnon current driven by the thermal gradient across a MIL. We discuss the dependence of these phenomena on temperature, materials properties, and geometric parameters.

3:42PM R14.00005 Magnon drag thermopile[1]

, SERGIO O. VALENZUELA, Institució Catalana de Recerca i Estudis Avançats and Institut Catala de Nanotecnologia — Thermoelectric effects in spintronics are gathering increasing attention as a means of controlling spin information by using heat flow. Thermal magnons (spin-wave quanta) are expected to play a major role, however, the coupling between electrons and magnons in ferromagnetic metals remains poorly understood. We demonstrate a conceptually new device that enables us to gather information on magnon-electron scattering and magnon-drag effects [1]. The device resembles a thermopile formed by a large number of pairs of ferromagnetic wires placed between a hot and a cold source and connected thermally in parallel and electrically in series. By controlling the relative orientation of the magnetization in pairs of wires, the magnon drag can be studied independently of the electron and phonon drag thermoelectric effects. Measurements as a function of temperature reveal the effect on magnon drag following a variation of magnon and phonon populations. These results demonstrate the feasibility of directly converting magnon dynamics of nanomagnets into an electrical signal and could pave the way to novel thermoelectric devices for energy harvesting.

4:18PM R14.00006 Theory of Magnon Drag in Ferromagnetic Bilayers[1]

, TIANYU LIU, GIOVANNI VIGNALE, Department of Physics and Astronomy, University of Missouri, Columbia, MICHAEL E. FLATTÉ, Optical Science and Technology Center and Department of Physics and Astronomy, University of Iowa — We introduce and study theoretically a novel drag effect that we expect to occur in ferromagnetic bilayer systems. A steady spin-wave (magnon) spin current propagating in one layer (the active layer) induces an inhomogeneous distribution of magnons in the other layer (the passive layer) through the magnetic dipole-dipole interaction. There are significant differences between this effect and the ordinary and well-studied Coulomb drag in electronic bilayers. First, the particles in questions are bosons, and their number is not conserved (this is at variance with systems of bosonic atoms, where number is conserved). Second, it becomes essential to take into account, besides magnon-magnon scattering, processes in which two magnons in one layer merge to produce a magnon in the other, or a magnon in one layer decays producing two magnons in the other. In analogy to the theory of Coulomb drag we calculate the interlayer transport coefficients (relating, for example, the temperature gradient in one layer to the spin current in the other) for different experimental configurations.

4:30PM R14.00007 Thermoelectric detection of spin waves[1]

, HELMUT SCHULTHEISS, JOHN E. PEARSON, SAMUEL D. BADER, AXEL HOFFMANN, Materials Science Division, Argonne National Laboratory — We report on the thermoelectric detection of spin waves in permalloy stripes via the anomalous Nernst effect[2]. Spin waves are locally excited by a microwave current flowing in a coplanar waveguide placed on top of a permalloy stripe, which acts as a waveguide for spin waves. Electric contacts at the ends of the permalloy stripe measure a dc voltage generated along the stripe. Magnetic field sweeps for different applied microwave frequencies reveal, with remarkable signal-to-noise, an electric voltage signature characteristic of spin-wave excitations. The symmetry of the signal with respect to the applied magnetic field direction indicates that the anomalous Nernst effect is responsible; Seebeck effects, anisotropic magnetoresistance, and voltages due to spin-motive forces are excluded. The dissipation of spin waves causes local heating, that drains into the substrate giving rise to a temperature gradient perpendicular to the sample plane, resulting in the anomalous Nernst voltage. Since this method is solely based on the heat generation inside the magnetic film due to the relaxation of the magnetization it has practically no lower limit for the wavelength of the detected spin waves.

4:42PM R14.00008 Spin Currents coupling with magnon excitation in Ferromagnetic Insulator[1]

, TAO LIU, JIAXI LI, JIANWEI ZHANG, School of Physics, Tongji University, THEORETICAL PHYSICS GROUP TEAM — We studied spin currents coupling in two Ferromagnetic/normal metal multilayers which are connected by a Ferromagnetic Insulator(FI) layer(such as YIG). In our modeling, we adopted self-consistent spin dependent Boltzmann equations and magnon Boltzmann equation. When applying an in-plane current in first FM layer, a transverse spin current was generated due to Anomalous Hall effect(AHE), after crossing normal metal layer, this transverse spin current will produce magnon excitation at N/FI interface. With carrying spin information, magnon excitations in FI can eventually excite a new spin current at second F/N interface. Although the FI cannot support any spin current propagation across it, but spin polarization information was passed through FI with propagation of magnon. Finally, the transverse spin current in second FM layer can also generate another in-plane spin current by AHE. Our results showed the spin current in second FM layer can be large as the same order of one in first FM layer at limit case. Through the magnon propagation in FI layer, two spin current circuits were coupled indirectly, i.e.without any charge current exchange. we also showed, when applying a magnetic field on FI layer, spin current in final FM layer can be manipulated by varying magnon excitation.

4:54PM R14.00009 Effect of magnetism on the vibrational properties of the Ni-Cu alloy: a first-principles study[1] , OMAR DE LA PENA-SEAMAN, IVAN BUSTAMANTE-ROMERO, Institute of Physics (IFUAP), Benemerita Universidad Autonoma de Puebla (BUAP), ROLF HEID, KLAUS-PETER BOHNEN, Institute of Solid State Physics (IFP), Karlsruher Institute of Technology (KIT) — We have studied the lattice dynamical properties of the $Ni_{1-x}Cu_x$ magnetic alloy within the framework of density functional perturbation theory, using a mixed-basis pseudopotential method and the virtual crystal approximation for modeling the alloy. The system has been investigated for both non-magnetic (NM) and ferromagnetic (FM) phases. The performance of LDA and GGA exchange-correlation functionals on the properties under study was analyzed. The structural optimization for each magnetic phase, NM and FM, in the full range of concentrations ($0 \leq x \leq 1$) was performed. By studying the electronic structure and its evolution as a function of x, we determined the FM-NM phase transition at $x \approx 0.45$. The calculated full phonon dispersion for NM and FM phases are compared between each other and with experimental data available in the literature at different concentrations. In addition, a detailed analysis of the force constants average coupling was performed, finding a clear signature of the magnetism effects on the vibrational properties for the Ni-Cu alloy.

5:06PM R14.00010 Thermal Hall effect and Berry curvature of spin waves in magnets , SHUICHI MURAKAMI, Department of Physics and TIES, Tokyo Institute of Technology, RYO MATSUMOTO, RYUICHI SHINDOU, Department of Physics, Tokyo Institute of Technology — Spin waves (magnons) form band structure similar to electrons, and therefore their geometrical structure in k space can be characterized by Berry curvature. This Berry curvature of spin waves causes various interesting phenomena such as thermal Hall effect [1,2] and topological magnonic crystals [3]. In my presentation, we derive the thermal Hall conductivity for spin waves in generic magnets represented as a bosonic Bogoliubov-de Gennes Hamiltonian. We apply this theory to magnetostatic modes in YIG and evaluate the thermal Hall conductivity for the forward volume-wave mode in YIG. We also discuss the relationship with other previous theories on Hall effect of magnons and other bosons. We also apply our theory to magnets with topological chiral edge modes, and discuss thermal transport for the topological edge modes.

5:18PM R14.00011 Molecular dynamics, spin dynamics study of phonon-magnon interactions in BCC iron[1] , DILINA PERERA, DAVID P. LANDAU, Center for Simulational Physics, The University of Georgia, G. MALCOLM STOCKS, DON NICHOLSON, MARKUS EISENBACH, JUNQI YIN, Oak Ridge National Laboratory — By combining an atomistic many-body potential (Finnis-Sinclair) with a classical Heisenberg-like spin Hamiltonian, we perform combined molecular and spin dynamics simulations to investigate phonon-magnon interactions in BCC iron. The coupling between atomic and spin degrees of freedom is established via a distance dependent exchange interaction derived from first principles electronic structure calculations. Coupled equations of motion are integrated using a second order Suzuki-Trotter decomposition of the exponential time evolution operator. To investigate the effect of lattice vibrations on spin wave spectrum, we calculate spin-spin and density-density dynamic structure factors S(q, ω), and compare that to the results obtained from pure spin dynamics simulations performed on a rigid lattice. In the presence of lattice vibrations, we observe an additional peak in the longitudinal spin-spin dynamic structure factor which coincides with the peak position in density-density dynanmic structure factor.

Session R15 GMAG DMP: Focus Session: Spin/charge in Frustrated Lattices 317 - Daniel Arovas, University of California at San Diego

2:30PM R15.00001 Spin-charge interplay on frustrated lattices , YUKITOSHI MOTOME, Department of Applied Physics, University of Tokyo — Frustration has gained increasing interest in the study of itinerant electron systems. There, not only spin but also charge degree of freedom of electrons plays a crucial role in the structure of the energetically degenerate manifold, providing a new frontier of the frustration physics. A particular interest is in Kondo-type spin-charge coupled systems, in which itinerant electrons couple with localized moments on a frustrated lattice. In these systems, localized moments act as internal local magnetic fields for itinerant electrons, which significantly affect the electronic and transport properties. On the other hand, the kinetic motion of electrons induces effective magnetic interactions between localized moments, resulting in exotic magnetic correlations and orders. It is highly nontrivial what kind of electronic and magnetic state is realized as a consequence of the spin-charge interplay. In this contribution, we review our recent theoretical and numerical studies of the Kondo-type models on frustrated lattices. We have investigated several types of models, with Heisenberg and Ising spins for localized moments defined on 2D triangular and kagome lattices and 3D pyrochlore lattice. Complementary theoretical techniques have been adopted, such as perturbation, mean-field approximation, variational calculation, exact diagonalization, and Monte Carlo simulation. We found that these models exhibit emergent electronic and magnetic properties, such as a spontaneous spin scalar chiral order and topological Hall effect, non-Kondo resistivity upturn in spin-ice liquid, partial disorder accompanied by charge disproportionation, emergence of Dirac electrons under particular magnetic ordering, quantum anomalous Hall effect in spin scalar chiral liquid, and spin-Hall effect by spontaneous inversion symmetry breaking. These works have been done in collaboration with Y. Akagi, S. Hayami, H. Ishizuka, and M. Udagawa. For references, visit http://www.motome-lab.t.u-tokyo.ac.jp/index-e.html.

3:06PM R15.00002 Mott Physics at Integer Filling Enforced by Crystalline Symmetries[1] , D.P. AROVAS, Physics Department, UC San Diego, S.A. PARAMESWARAN, Physics Department, UC Berkeley, ARI M. TURNER, Institute for Theoretical Physics, University of Amsterdam, ASHVIN VISHWANATH, Physics Department, UC Berkeley — Insulating states of matter in a crystalline system can be either band insulators or Mott insulators. It is well known that band insulators appear only when the filling (the number of electrons per unit cell and spin projection) is an integer. An insulating phase at fractional filling is a Mott insulator, for which interactions are manifestly required. Here we pose and answer the converse question - at an integer filling is a band insulator always possible? Surprisingly, we find that crystalline symmetries may forbid a band insulator even at certain integer fillings. In these cases, the ground state is either conducting or is a Mott insulator, despite being at integer filling. The lattices on which this occurs have a simple property, they have non-symmorphic space groups. These include lattices with essential glide or screw symmetries, which comprise the majority of three dimensional crystal structures. This is shown to be a consequence of gauge invariance using a flux threading argument, which applies to free and interacting systems alike. For several non-symmorphic lattices we determine the minimum integer filling at which band insulators are possible. This result has several immediate implications for band structures as well as the phases of quantum magnets and bosonic insulat

3:18PM R15.00003 Many-Variable Variational Monte Carlo Study of Triangular Hubbard Model , RYUI KANEKO, SATOSHI MORITA, MASATOSHI IMADA, Department of Applied Physics, University of Tokyo — Motivated by the previous numerical studies on the triangular Hubbard model, we study low-energy states of the model at half filling up to 144 sites by using the many-variable variational Monte Carlo method. We consider the variational wave functions with the fermionic singlet-pairing wave functions, with the Gutzwiller-Jastrow factor, and the quantum-number projection to the total spin singlet. We reproduce the metallic state for the small Coulomb interaction, and the antiferromagnetic insulating state with 120° spin structure for the large Coulomb interaction. We discuss the energetic and magnetic properties of the intermediate Coulomb interaction region.

3:30PM R15.00004 Magnetic frustration in itinerant systems: the Kondo polaron problem , LEONID ISAEV, Louisiana State University, CRISTIAN BATISTA, T4, Los Alamos Natl Lab, ILYA VEKHTER, Louisiana State University — We study the interplay between magnetic frustration and Kondo screening in Kondo lattices by analyzing the J_1-J_2 antiferromagnetic chain coupled to a conduction band. The system is tuned to the Majumdar-Ghosh point $J_2 = J_1/2$ which stabilizes a dimer valence-bond solid at weak Kondo coupling J_K. We use an effective low-energy theory to demonstrate that sufficiently large J_K results in a proliferation of "Kondo polarons", i.e. Kondo-screened domain-wall excitations of the dimer state, and collapse of the dimer order via a 2nd order quantum phase transition. At the quantum critical point, $J_K = J_K^c$, these polarons become gapless, and we argue that the transition itself belongs to a 2D Ising universality class. For $J_K > J_K^c$ increasing concentration of the polarons leads to a continuous growth of the electron Fermi momentum until all spins are absorbed by the Fermi sea.

3:42PM R15.00005 Itinerant Kagome Ice: an Anomalous Quantum Hall Liquid[1] , ARMIN RAHMANI, GIA-WEI CHERN, IVAR MARTIN, CRISTIAN BATISTA, LANL — We show that all magnetic-charge-ordered kagome ice configurations, i.e., a highly disordered energetically stable manifold of Ising spins on the kagome lattice, support a quantized anomalous quantum Hall effect when coupled to itinerant electrons. Despite the strong disorder experienced by the electrons, the Hall effect is robust for almost all canting angles of the Ising spins. Due to the absence of magnetic long-range order, this phase of matter is characterized by the coexistence of a (classical) chiral spin liquid and an anomalous integer quantum Hall one. We further demonstrate that the magnetic monopole defects in this ice-like manifold bind a fluctuating electric dipole.

3:54PM R15.00006 Exotic correlated electron phases in the Kagome Hubbard model[1] , RONNY THOMALE, Ecole Polytechnique Federale de Lausanne — We employ different renormalization group (RG) schemes to investigate the Kagome Hubbard model at low, intermediate, and strong coupling. At weak coupling where our RG calculation is asymptotically exact, we develop a new notion of sublattice interference mechanism to describe the Fermi surface instabilities at van Hove filling. For intermediate coupling, we observe an intricate interplay of the Fermi surface topology, sublattice interference, and range of interactions. In particular, we find a charge and spin bond order phase as well as a d+id Pomeranchuk instability. At strong coupling, we employ our recently developed slave particle RG schemes to investigate the J1-J2 Kagome Heisenberg model. We discuss its quantum phase diagram in the light of experiments and evidence from other approaches.

4:06PM R15.00007 Quantum Fluctuation Effect on a Spin Scalar Chiral Ordering in Frustrated Kondo Lattice System , YUTAKA AKAGI, MASAFUMI UDAGAWA, YUKITOSHI MOTOME, Dept. of Appl. Phys., Univ. of Tokyo — Recently, noncoplanar spin configurations with spin scalar chirality have drawn considerable attention as an origin of the anomalous Hall effect. As a typical example, a scalar chiral state with noncoplanar four-sublattice magnetic ordering was stabilized through the spin-charge coupling in a Kondo lattice model on a triangular lattice at 1/4 and 3/4 fillings [1,2]. In previous studies however, localized moments are approximated as classical spins. It is interesting to ask how quantum spin fluctuations affect the nontrivial chiral order and electronic state of the system. Here, we examine the effect of quantum fluctuations by the spin-wave approximation with introducing the Holstein-Primakoff transformation to the localized spins. As a result, we find that the four-sublattice order is fragile against quantum fluctuations at 3/4 filling, whereas it remains robust at 1/4 filling. We discuss the magnon excitations in the spin-charge coupled system in details. We also discuss the quantum correction on the thermal Hall effect. [1] Y. Akagi and Y. Motome, J. Phys. Soc. Jpn. **79**, 083711 (2010). [2] Y. Akagi, M. Udagawa, and Y. Motome, Phys. Rev. Lett. **108**, 096401 (2012).

4:18PM R15.00008 Featureless and Non-Fractionalized Bose Insulator on the Honeycomb Lattice at 1/2 site-filling[1] , ITAMAR KIMCHI, S. A. PARAMESWARAN, University of California, Berkeley, ARI TURNER, University of Amsterdam, FA WANG, Peking University, ASHVIN VISHWANATH, University of California, Berkeley — We consider bosons on the Honeycomb lattice at filling one half per site. It is known that free fermions at this filling of the tight binding model cannot form an insulating state while preserving all symmetries, even though there is an integer number of particles per unit cell. We argue, however, that interacting bosons can form an insulating state that preserves all symmetries. We propose a wave function for this state and by a mapping to a classical partition function we compute its properties and demonstrate that the state is insulating, fully symmetric and has no topological order. Our construction suggests that featureless insulators are generically allowed for at a filling of one boson per unit cell on any symmorphic lattice in any dimension. We also discuss related wavefunctions of hard core bosons that model spin 1/2 magnets on this lattice.

4:30PM R15.00009 Demonstration of a D-metal from a chiral spin liquid[1] , VICTOR CHUA, GREGORY FIETE, University of Texas at Austin — We report recent results on a study of a 2D disordered but exactly solvable gapless chiral spin-liquid ground state whose fractionalised quasiparticle excitations are Majorana fermions and are classified as being in the D-class of the Altland-Zirnbauer 10-fold classification scheme [Phys. Rev. B 55, 1142 (1997)]. Transport and quasiparticle localisation properties of this Majorana metal in nanowire configurations are studied and contrasted with the previously predicted D-metal phase of Senthil and Fisher [Phys. Rev. B 61, 9690 (2000)]. The role of Z2 vortices play towards transport properties are also discussed.

4:42PM R15.00010 Fluctuation Driven Spirals Near Ferromagnetic Quantum Critical Points in Disordered Electron Systems , STEVEN THOMSON, FRANK KRUGER, University of St Andrews, ANDREW G. GREEN, London Centre for Nanotechnology — The magnetic properties of itinerant electron systems represent an area of growing experimental and theoretical interest, particularly the peculiar ordered magnetic phases that can occur at low temperatures. It has previously been shown that the quantum order-by-disorder mechanism predicts a spiral magnetic phase in the vicinity of an itinerant ferromagnetic quantum critical point in three spatial dimensions. Here, we present an analytical model of how both charge and spin disorder affect the formation of this spiral magnetic phase at low temperatures, supplemented by numerical evaluation of the fluctuation corrections to the free energy. We show the effect of disorder on the position of the tricritical point and on the stability of the ordered phases. We further discuss the possibility of a helical spin-glass phase and discuss our findings in the context of recent experiments.

4:54PM R15.00011 The effect of non-magnetic impurities on the motion of a hole in a 2D Ising antiferromagnet[1] , HADI EBRAHIMNEJAD, MONA BERCIU, University of British Columbia, MONA BERCIU'S TEAM — A hole in a 2D Ising antiferromagnet was initially believed to be infinitely heavy due to the string of wrongly-oriented spins it creates as it propagates, which trap it near its original location. Trugman showed that, in fact, the hole acquires a finite effective mass due to contributions from so-called *Trugman loops* processes, where the hole goes one and a half times around a closed loop and removes the defects it created during the first round, but ends up at a different site. This results in an effective next-nearest-neighbour hoping of the hole which keeps it on the sublattice it was created on. Here we investigate the trapping of such a hole near a single non-magnetic impurity, using a variational calculation of the hole's real-space Green's function. We consider the two cases with the hole and impurity being on the same versus on different sublattices, and contrast the differences between them.

5:06PM R15.00012 Magnetization and Hall effect measurements on the pyrochlore iridate Nd2Ir2O7[1] , STEVEN DISSELER, Boston College, SEAN GIBLIN, None, CHETAN DHITAL, KEVIN LUKAS, STEPHEN WILSON, MICHAEL GRAF, Boston College — We present magnetization and Hall effect measurements on the pyrochlore iridate $Nd_2Ir_2O_7$. Previous muon spin rotation measurements have shown that the system undergoes an unusual transition at $T_M \sim 110$ K into a magnetic phase lacking long-range order, followed by a transition at $T_{LRO} \sim 6$ K into a state with long-range magnetic order. We observe a small remnant magnetization when cycling through zero magnetic field at temperatures below T_M. Below T_{LRO} an additional hysteresis effect appears at a higher field $B_c = 2.8$ T, together with the appearance of non-monotonic and hysteretic Hall resistance with a maximum at B_c. The dependence on field sweep direction suggests a non-trivial transition in the magnetically ordered state similar to that of spin-ice systems. This work was supported in part by National Science Foundation Materials World Network grant DMR-0710525 and by NSF CAREER award DMR-1056625.

5:18PM R15.00013 Non-Kramers spin liquids on the pyrochlore lattice , JEFFREY G. RAU, HAE YOUNG KEE, University of Toronto — At low temperatures the pyrochlore iridates $Pr_2Ir_2O_7$ shows the puzzling combination of an anomalous Hall effect in the absence of experimentally observed magnetic order. The breaking of time-reversal symmetry indicated by the anomalous Hall effect, but without the usual accompanying magnetic order, points to an exotic state, possibly a chiral spin liquid. Considering the most general symmetry allowed model for the Pr non-Kramers doublets, we use the slave-fermion approach to analyze possible spin liquids at the mean field level. A variety of spin liquids can be generated using the projective symmetry group, with novel properties due to the nature of the non-Kramers doublet states. Applications to $Pr_2Ir_2O_7$ will be discussed.

2:30PM R16.00001 Ferroelectric control of magnetocrystalline anisotropy at Co/poly(vinylidene fluoride) interfaces , J.P. VELEV, Department of Physics, University of Puerto Rico, P.V. LUKASHEV, T.R. PAUDEL, Department of Physics, University of Nebraska-Lincoln, J.M. LOPEZ-ENCARNACION, Chemical Sciences and Engineering Division, Argonne National Laboratory, S. ADENWALLA, E.Y. TSYMBAL, Department of Physics, University of Nebraska-Lincoln — Electric field control of magnetization is one of the promising avenues for achieving high-density energy-efficient magnetic data storage. Ferroelectric materials can be especially useful for that purpose as a source of very large switchable electric fields when interfaced with a ferromagnet. Organic ferroelectrics, such as poly(vinylidene fluoride) (PVDF), have an additional advantage of being weakly bonded to the ferromagnet, thus minimizing undesirable effects such as interface chemical modification and strain coupling. In this work we use density functional calculations of Co/PVDF heterostructures to demonstrate the effect of ferroelectric polarization of PVDF on the interface magnetocrystalline anisotropy which controls the magnetization orientation. We show that switching of the polarization direction alters the magnetocrystalline anisotropy energy of the adjacent Co layer by about 50%, driven by the modification of the screening charge induced by ferroelectric polarization. The effect is reduced with Co oxidation at the interface due to quenching the interface magnetization. Our results provide a new insight into the mechanism of the magnetoelectric coupling at organic ferroelectric/ferromagnet interfaces and suggest ways to achieve the desired functionality in practice.

2:42PM R16.00002 The study of perpendicular magnetic anisotropy and Boron diffusion in Ta–CoFeB–MgO–CoFeB–Ta magnetic tunnel junction using polarized neutron reflectometry[1] , VALERIA LAUTER, H. AMBAYE, Oak Ridge National Laboratory, Oak Ridge, TN, USA, T. ZHU, Y. YANG, R.C. YU, Beijing National Laboratory, Beijing, China, J.Q. XIAO, University of Delaware, Newark, USA — The current-induced spin transfer torque (STT) plays an important role in spintronic devices. However, the level of current density needed to reorient the magnetization is presently too high for most commercial applications, and reducing the current density is the challenging basis for recent research in spintronics. The magnetic tunnel junction (MTJ) with a perpendicular magnetic anisotropy (PMA) enables a small critical current density for current-induced magnetization switching and provides a pathway for such STT devices. We investigated the origin of PMA in CoFeB sandwiched by MgO and Ti layers using the anomalous Hall effect (AHE) and polarized neutron reflectometry (PNR). It is found that the PMA properties of CoFeB layers deposited above and under MgO layer are different and PNR measurements confirmed that a large PMA in the CoFeB above MgO layer is related to its low magnetization. From PNR experiments, we obtained the details of the magnetic and structural depth profiles inside the film. Using the sensitivity of neutrons to the absorption cross-section of boron, we unambiguously determined the depth profile of the boron distribution and showed that after annealing, most of the boron diffused to form a 2-nm-thick interface layer between the CoFeB and tantalum layers.

2:54PM R16.00003 Spin-polarized ion scattering spectroscopy study on Si/Fe(100) surfaces[1] , TAKU SUZUKI, SHUNICHI HISHITA, National Institute for Materials Science — We investigated surface magnetic structure in the initial stage of Si deposition on an Fe(100) surface by spin-polarized ion scattering spectroscopy (SP-ISS). [1] We found silicidation at the Si/Fe interface after Si deposition followed by annealing at 823 K. The silicidation occurs by the incorporation of silicon into the Fe substrate via the substitutional site of bcc Fe. After annealing, the incorporated Si atoms are distributed in surface layers several nanometers thick. The SP-ISS analysis revealed that the average magnetic moment of Fe in the silicide surface layer is about 70% of that of Fe in the Fe(100) surface layer, whereas that of Si is almost zero. These surface magnetic moments are discussed in terms of the local magnetic environment. It is likely that the outermost surface of the silicide layer has an atomic arrangement similar to that of $Fe_3Si(100)$ with surface termination by the Fe-Si plane.

3:06PM R16.00004 Microscopic Structure of Mn Atom Chains on the Si(001) Surface Investigated by Scanning Tunneling Microscopy , A. FUHRER, F. J. RUEß, N. MOLL, A. CURIONI, D. WIDMER, IBM Research, Zürich Research Laboratory, Säumerstrasse 4, 8803 Rüschlikon — The Si(001) 2x1 reconstructed surface has the interesting property that many metal atom species form nearly perfect 1D atomic wires oriented perpendicular to the Si dimer rows during deposition at room temperature. These wires are thought to consist of metal dimers located between the dimer rows linking up to form atomic chains. More recent experiments indicated that similar wire formation occurs for Mn which, with its half filled d-shell, has interesting magnetic properties e.g. when used as a dopant in dilute magnetic semiconductors. In our experiments we use scanning tunneling microscopy to study the atomic structure of these Mn-wires in detail and find that it is different from that of the other known metal wires. We show that two distinct types of Mn wires occur, with an asymmetric appearance relative to the underlying Si lattice. While one type of asymmetry can be linked to the buckling of the Si dimers near the Mn-wires the other is found to be intrinsic to the microscopic structure of the Mn-wires. We further compare high-resolution bias-dependent constant current images with images simulated for a Mn trimer wire structure using density functional calculations employing the CPMD code.

3:18PM R16.00005 The failure of DFT computations for a stepped-substrate-supported monatomic highly-correlated wire system[1] , NADER ZAKI, RICHARD M. OSGOOD, ANDREW J. MILLIS, CHRIS A. MARIANETTI, Columbia University — The ab-initio method, density functional theory (DFT), has been immensely successful in its ability to predict physical properties of condensed matter systems. In particular, DFT calculations have proven to be quantitatively accurate in predicting structural properties in a wide range of materials and qualitative failures are rare. Here, however, we show that DFT can fail qualitatively to correctly predict the dimerized structural phase for a recently reported experimentally realized monatomic Co wire system that is self-assembled on a vicinal, i.e. stepped, Cu(111) substrate [1]. We attribute this failure to DFT's over-prediction of hybridization of the Co wire with the underlying Cu substrate. We demonstrate that this over-hybridization leads to weakening of the magnetic coupling along the wire, which is responsible for dimerization, while increasing the stiffness of the wire due to strengthening of the non-magnetic elastic term. Additionally, we show that accounting for local interactions via DFT+U also fails at predicting the correct structural phase. [1] N. Zaki et al, arXiv:1208.0612 (2012)

3:30PM R16.00006 ABSTRACT WITHDRAWN –

3:42PM R16.00007 Temperature-dependent proximity magnetism in Pt[1] , WENG L. LIM, JOHN C. OWENS, NEEMA EBRAHIM-ZADEH, HILARY G. E. HENTSCHEL, SERGEI URAZHDIN, Department of Physics, Emory University, Atlanta, GA 30322 — We report the observation of a significant magnetic coupling between two ferromagnets (FM) separated by a thin Pt layer. The coupling remains ferromagnetic regardless of the Pt thickness, and exhibits a strong dependence on temperature T. These features of the coupling cannot be explained by the well-known RKKY mechanism of coupling between FM separated by a nonmagnetic spacer. We use a phenomenological model to demonstrate that the observed effects are consistent with the existence of temperature-dependent magnetic ordering induced in Pt in proximity to the interfaces with FM, consistent with a recent report on the ferromagnetic characteristics in Pt films grown on ferromagnetic insulators [1]. The magnetization in Pt decays away from the interfaces with a characteristic length scale that increases with decreasing temperature, and reaches 0.8 nm at $T < 25$ K. Our results suggest that, in Pt/FM heterostructures, the magnetic and spin-dependent transport properties of Pt and FM are mutually affected, opening possibilities for engineering of new magnetoelectronic metamaterials. 3:54PM R16.00008 Tailoring magnetic properties of thin films with quantum well states and external electric field , TAMENE R. DASA, VALERIY S. STEPANYUK, Max Planck Institute of Microstructure Physics — Dependence of magnetic anisotropy energy (MAE) and spin-polarization of magnetic multilayers on the layer thickness is studied with *ab initio* techniques. For thin Fe films adsorbed on a Pt surface a reversal of the MAE (rotation of the easy axis) is observed with changing film thickness. Moreover, our calculation show that capping of magnetic films with Pt in most cases leads to a strong increase of MAE. Both of the later phenomena are traced back to spin-dependent quantum-well states (QWS) in the magnetic thin films. Combining the newly gained understanding with the well-known fact, that quantum well states can be tuned by external electric fields acting on the system, we show that, similar to the case of the quasi 1-D systems [1], the MAE in thin magnetic metallic films can be tailored with external electric field. For example, applying an electric field of -1 $V/$Å to a multilayer of Pt/Co/Pt(001), its MAE can be changed by more than 50%. To finalize the paper, changes in spin-polarization and the Stark-like shift accompanying exposure of the system to external electric fields are outlined and discussed.

4:06PM R16.00009 Giant proximity effect in ferromagnetic bilayers[1] , SILVIA RAMOS, Diamond Light Source, Harwell Science and Innovation Campus, U.K., TIM CHARLTON, ISIS, STFC RAL, U.K., JORGE QUINTANILLA, U. of Kent and ISIS, STFC RAL, U.K., ANDREAS SUTER, PSI, Switzerland, JAGADEESH MOODERA, Francis Bitter Magnet Lab and Physics Department, MIT, Cambridge, MA, THOMAS PROKSCHA, ZAHER SALMAN, PSI, Switzerland, TED FORGAN, U. of Birmingham, U.K. — The proximity effect is a phenomenon where an ordered state leaks from a material into an adjacent one over some finite distance, ξ. For superconductors, this distance is $\sim$ the coherence length. Nevertheless much longer-range, "giant" proximity effects have been observed in cuprate junctions. This surprising effect can be understood as a consequence of critical opalescence. Since this occurs near all second order phase transitions, giant proximity effects should be very general and, in particular, they should be present in magnetic systems. The ferromagnetic proximity effect has the advantage that its order parameter (magnetization) can be observed directly. We investigate the above phenomenon in Co/EuS bilayer films, where both materials undergo ferromagnetic transitions but at rather different temperatures (bulk T_C of 1400K for Co and 16.6K for EuS). A dramatic increase in the range of the proximity effect is expected near the T_C of EuS. We present the results of our measurements of the magnetization profiles as a function of temperature, carried out using the complementary techniques of low energy muon rotation and polarized neutron reflectivity.

4:18PM R16.00010 Asymmetric magnetic switching behavior of Py/SmFe/Py exchange spring magnet , JIYEONG GU, HANMING YUAN, Department of Physics and Astronomy, California State University Long Beach, Long Beach, CA 90840 — Magnetic switching behavior of the symmetric exchange spring magnet, Py(Permalloy)/SmFe (or SmCo)/Py thin films, was investigated. Exchange spring magnet shows a unique magnetic hysteresis curve due to the non-collinear magnetization developed by magnetic coupling of the soft and hard magnetic layers. Using Magneto Optical Kerr Effect (MOKE) we could separately measure the magnetic hysteresis loops of the top and the bottom Py layers. We found the magnetic hysteresis loops for the bottom and the top Py layers are different indicating the switching behavior is not symmetric. The coercivity of the bottom Py layer is much smaller than that of the top Py layer. From the comparison of MOKE data to the one measured by Alternating Gradient Magnetometer, we observed that the top Py layer and hard layer switch together representing the top Py layer is strongly coupled to the hard layer and shows a single switching instead of spiral magnetization distribution; while the bottom Py layer shows a non-collinear magnetization behavior as we expect from a typical exchange spring magnet. Thickness of the soft and hard layers was systematically varied to further investigate the asymmetric switching behavior of double exchange spring magnet thin films.

4:30PM R16.00011 Epitaxial Growth of Heusler Co_2MnSi Heterostructures: Electronic and Structural Properties[1] , THOMAS NEULINGER, Department of Physics; University of California, Santa Barbara, SAHIL PATEL, Department of Materials Science; University of California, Santa Barbara, ALEXANDER KOZHANOV, California NanoSystems Institute; University of California, Santa Barbara, BRIAN SCHULTZ, Department of Electrical and Computer Engineering; University of California, Santa Barbara, CHRIS PALMSTRØM, Department of Electrical and Computer Engineering and Materials Science; University of California, Santa Barbara — The Heusler alloy Co_2MnSi is predicted to be a half-metal, a material that is spin-polarized at the Fermi energy. We have demonstrated growth by molecular beam epitaxy of Co_2MnSi, Cr/Co_2MnSi, and a complete $Co_2MnSi/MgO/Co_2MnSi(001)$ magnetic tunnel junction on epitaxial GaAs(001) surfaces without air exposure. Epitaxial Cr layers have been used to exchange bias Co_2MnSi. In-situ electron diffraction and scanning tunneling microscopy, and ex-situ X-ray diffraction techniques are used to characterize the crystal quality. The magnetic properties are investigated using vibrating sample and superconducting quantum interference device magnetometry. We present these results and will compare them with temperature dependent magnetotransport and tunneling spectroscopy measurements, with emphasis on the influence of Co_2MnSi surface termination.

4:42PM R16.00012 Magnetostatics and magnetodynamics in Co_2MnSi on GaAs (001)[1] , MICHAEL PECHAN, DANIEL STANLEY, MICHAEL SINKO, Department of Physics, Miami University, SAHIL PATEL, Department of Electrical and Computer Engineering, University of California, Santa Barbara, ALEXANDER KOZHANOV, Department of Physics and Astronomy, Georgia State University, BRIAN SCHULTZ, CHRIS PALMSTROM, Department of Electrical and Computer Engineering, University of California, Santa Barbara — We present an investigation of the magnetic properties of Co_2MnSi films grown by molecular beam epitaxy on lattice matched $Sc_{0.3}Er_{0.7}As$ films grown on GaAs (001) substrates with various capping layers (Cr, Al, Au). Co_2MnSi thickness varied from 3 to 21.4 nm. X-ray diffraction analysis confirmed the single crystal nature and crystallographic orientations of the films. Magnetization measurements reveal square loops with low in-plane saturation fields and very narrow (few Oe) coercive fields. An interesting feature of the loops in several of the samples is the presence of a small ($<$10 Oe) exchange-bias field observed at room temperature. Room temperature ferromagnetic resonance (FMR) measurements were carried out at 35 GHz as a function of in-plane angle to quantify the anisotropy in these structures. Resonances follow the typical derivative lineshape with relatively narrow line widths ranging from 30 to 140 Oe, consistent with high quality Heusler alloy film formation. Four-fold anisotropy is clearly observed in all samples confirming the high quality single-crystal nature of the films. A small unidirectional anisotropy associated with the exchange bias mentioned above is also observed. We will also present results on preliminary MJT structures.

4:54PM R16.00013 topological chiral spin-wave modes in dipolar ferromagnetic thin films , RYUICHI SHINDOU, RYO MATSUMOTO, Physics Department, Tokyo Institute of Technology, JUN-ICHIRO OHE, Physics Department, Toho University, SHUICHI MURAKAMI, Physics Department, Tokyo Institute of Technology — Magnetic dipole-dipole interaction in ferromagnet plays role of locking a relative angle between the spin space and the orbital space, just in the same way as the relativistic spin-orbit interaction does in ferromagnetic metals, leading to their quantum anomalous Hall effect. Focusing on this similarity, we theoretically design a couple of periodically-structured ferromagnetic thin film models which support unidirectional (chiral) propagations of spin-waves along its sample boundaries in their dipolar regime. Contrary to the Daemon-Eshbach surface mode, the chiral direction and the number of such spin-wave edge modes are determined by so-called topological Chern integer associated with 'Bloch wavefunctions' for the volume-type spin wave modes. Namely, even if the direction of the magnetic field is fixed, the chiral direction can be still either left-handed or right-handed, depending on the periodic structuring and the frequency range, which is not the case with the Daemon-Eshbach mode. By introducing proper 'atomic orbitals' for the proposed thin film models, we present a simple tight-binding description for the proposed topological chiral edge modes.

5:06PM R16.00014 Equilibrium properties of Ising metamagnetic films[1] , JAMES MAYBERRY, MICHEL PLEIMLING, Virginia Tech — Artificial antiferromagnets have attracted attention lately due to the potential for technological applications. We model these systems as thin Ising metamagnetic films and study their equilibrium properties using Monte Carlo simulations. In variance with previous work but in agreement with the experimental systems, we consider films comprised of "sets" of planes, with an antiferromagnetic coupling between sets and a ferromagnetic coupling within sets. This allows us to consider different situations by varying the number of planes in each set. Studying the magnetization density and response functions as a function of temperature and magnetic field, we determine the corresponding phase diagrams. We discuss how a change of the number of planes in each set changes the equilibrium phase diagram.

5:18PM R16.00015 Characteriziation of Ni_2MnGa Ferromagnetic Shape Memory Alloy nanowires[1] , P. GYAWALI, KESHAB R. SAPKOTA, B. DAHAL, R. DULAL, I. L. PEGG, J. PHILIP, The Catholic University of America — Heusler type Ni_2MnGa ferromagnetic shape memory alloy has been extensively studied in thin films and in bulk. The structural transition to martinsitic phase occurs thermodynamically reversibly within the ferromagnetic region.. For the technological application, magnetic field is used to induce the motion of twin boundaries in martinsite phase. Ni_2MnGa nanowires were grown for the first time using electrospinning method. Structrual characterization were done using XRD and EDX. Nanowires exhibit tetragonal structure with a = b = 5.85 Åand c/a = 0.96. Magnetic measurements show the pre- martinsite transformation. Curie temperature of nanowires is about 360 K.

2:30PM R17.00001 Interface effects in oxide heterostructures combining superconductors, ferromagnets and ferroelectrics[1] , JAVIER E. VILLEGAS, Unite Mixte de Physique CNRS/Thales and Universite Paris Sud — In oxide heterostructures, the interactions at the interfaces often yield novel physical properties, which radically differ from the individual constituents' and provide with new functionalities. Oxide perovskites offer much potential for this, because a variety of isostructural materials exist with very different ground states (superconductors, ferromagnets, ferroelectrics, etc). One interesting possibility is to locally couple one of the heterostructure constituents' sensitivity to an external stimulus (e.g. the electric field for ferroelectrics) to a physical property of the second constituent (e.g. the magnetization in a ferromagnet, or the critical temperature in a superconductor). Such local coupling can be achieved via nanoscale field-effect doping. Through this mechanism, a form of magneto-electric coupling between the local electric polarization in the ferroelectric and the local magnetic induction in the superconductor can be obtained, which allows the electrostatic manipulation of magnetic flux quanta [1]. Another interesting possibility is to intertwine the most distinctive properties from each of the heterostructure constituents. As an example of this, we show how to unite the phase-coherent dissipationless charge transport characteristic of superconductivity and the spin-polarized charge transport characteristic of ferromagnetism [2], which may open the door to novel spintronic devices [3].

3:06PM R17.00002 Influence of Interface Engineering on the Magnetization in $La_{0.67}Sr_{0.33}MnO_3/SrTiO_3$ Heterostructures[1] , S.G.E. TE VELTHUIS, YAOHUA LIU, Materials Science Division, Argonne National Laboratory, Argonne IL, USA, V. LAUTER, Spallation Neutron Source, Oak Ridge National Laboratory, Oak Ridge TN, USA, H. BOSCHKER, G. KOSTER, G. RIJNDERS, Faculty of Science and Technology and MESA+ Institute for Nanotechnology, University of Twente, The Netherlands — Rich new phenomena have been observed at the interfaces between of complex oxides with different electronic and magnetic properties. In particular electronic reconstruction may occur at epitaxial oxide interfaces because of the broken transitional symmetry, leading to new properties, some of which are in fact less desirable. At the $La_{0.67}Sr_{0.33}MnO_3$(LSMO) - $SrTiO_3$(STO) interface, it is thought electronic reconstruction, driven by the potential build-up at the interface, results in a degradation of the magnetization of LSMO. To explore this, we have studied LSMO/STO heterostructures with interfaces engineered to avoid this interfacial magnetization suppression [1]. In our case, this engineered interface refers to a $La_{0.33}Sr_{0.67}O$ monolayer replacing a $La_{0.67}Sr_{0.33}O$ monolayer at each interface. Depth-dependent magnetization profiles in the heterostructures, determined using polarized neutron reflectometry, show that indeed the interfacial magnetization of LSMO improves with interface engineering. 3:18PM R17.00003 Strain control of electronic structure in $La_{2/3}Sr_{1/3}MnO_3$, ERIC MONKMAN, CAROLINA ADAMO, DANIEL SHAI, Cornell University, DAWEI SHEN, Shanghai Institute of Microsystem and Information Technology, JOHN HARTER, Cornell University, CHARLES BROOKS, Pennsylvania State University, ILYA ELFIMOV, University of British Columbia, RICHARD HENNIG, DARRELL SCHLOM, KYLE SHEN, Cornell University — Introducing biaxial strain into complex oxide thin films by epitaxial growth on lattice mismatched substrates is a powerful approach to engineering electronic and magnetic properties not attainable in bulk materials. Due to the strong many-body interactions characteristic of transition metal oxides, a microscopic understanding of the mechanisms underlying strain-driven phase transitions remains unclear. Here we utilize an integrated oxide molecular-beam epitaxy and angle-resolved photoelectron spectroscopy system to directly measure the electronic structure of colossal magnetoresistive $La_{2/3}Sr_{1/3}MnO_3$ on four substrates, spanning -2.3% to +1.6% biaxial strain and two strain driven metal-insulator transitions. Contrary to conventional expectations of a bandwidth driven metal-insulator transition in strongly correlated systems, we find widely dispersive states in both insulating phases with finite weight at the Fermi level under compressive strain and a narrow gap under tensile strain. Our results point to two distinct mechanisms behind the metal-insulator transitions, and highlight the importance of phase coexistence and charge or orbital ordering in oxide thin films.

3:30PM R17.00004 Tuning out-of-plane strain in epitaxial La[1-x]Sr[x]MnO[3] thin films with noble ion implantation , THOMAS ZAC WARD, Oak Ridge National Laboratory, HANGWEN GUO, University of Tennesssee, CHRISTIANNE BEEKMAN, WOLTER SIEMONS, HANS CHRISTEN, Oak Ridge National Laboratory, PHILIP RACK, University of Tennesssee, JOHN BUDAI, ZHENG GAI, Oak Ridge National Laboratory — Strongly correlated materials, such as cuprates, manganites, and heavy-fermions, have a wealth of exotic properties and are often associated with the coexistence of competing nearly degenerate states which couple simultaneously active degrees of freedom—charge, lattice, orbital, and spin states. To understand correlated electronic materials, we must begin to disentangle the underlying correlations and find novel methods to tune individual order parameters to recognize how mesoscopic interactions drive emergent behaviors. In this work, we will discuss recent progress on controlling the strain along the out-of-plane direction in epitaxial [LaSr]MnO3 films through implantation of noble ions. This technique allows for very fine manipulation of the lattice parameter in a manner that effectively gives us a novel means of controlling orbital overlaps without hole/carrier doping the sample. We observe that films can remain epitaxially lattice locked to the substrate while accommodating more than 1% lattice expansion out-of-plane. We will present phase diagrams based on this new type of "strain doping" and discuss the implications. Supported by the US DOE Office of Basic Energy Sciences, Materials Sciences and Engineering Division.

3:42PM R17.00005 Characteristics of a Mott field-effect transistor (MottFET) based on $La_{1-x}Sr_xMnO_3$[1]

SUYOUN LEE, Korea Institute of Science and Technology, KEUNDONG LEE, Korea Institute of Science and Technology, Konkuk University, HYOJIN GWON, SEUNG-HYUB BAEK, Korea Institute of Science and Technology, BAEHO PARK, Konkuk University, JIN-SANG KIM, Korea Institute of Science and Technology — Recently, the metal-insulator transition (MIT) phenomenon shown in transition metal oxides has attracted much interest due to its superior characteristics such as fast switching speed ($\sim$ femtoseconds), high on/off ratio, and low power consumption. One example is the MottFET, which utilizes the MIT modulated by electric field through the band-filling in a Mott insulator. In this work, we examined MottFET devices based on $La_{1-x}Sr_xMnO_3$(LSMO), which is one of the mostly studied Mott insulators and attractive for the potential application in spintronic devices due to its intriguing properties such as colossal magnetoresistance (CMR) and half-metallicity. For the devices with the composition near the boundary of the metal-insulator transition, we confirmed that the conductivity of the channel could be modulated by a gate electric field of moderate strength. In addition, for the future application in spintronic devices, we investigated the dependence of device characteristics on the magnetic field. As the applied magnetic field increased, we found that the current-voltage characteristic showed anomalous behavior, which might be attributed to the electron-electron interaction, spin ordering, and the magnetic impurities in the channel.

3:54PM R17.00006 Structure/property relationship for ultrathin films of $La_{2/3}Sr_{1/3}MnO_3$ on $SrTiO_3$ (001)[1]

ZHAOLIANG LIAO, Louisiana State University, DIOGO DUARTE DOS REIS, Louisiana State University & Universidade Federal de Minas Gerais, PENG GAO, XIAOQING PAN, University of Michigan, RONGYING JIN, E. WARD PLUMMER, JIANDI ZHANG, Louisiana State University — Dead layer, the insulating behavior in ultrathin films of metallic oxides, is an intriguing property of TMO films. Is this intrinsic effect caused by dimensionality effect, or by interface, segregation, or stoichiometry? We have studied thickness-dependence of structure/property relationship for thin films of $La_{2/3}Sr_{1/3}MnO_3$ (LSMO) grown with PLD on $SrTiO_3$ (001) (STO) by using in-situ characterization such as LEED and STM, and ex-situ transport measurements. By minimizing oxygen deficiency, the thickness of dead layer is found to be as small as 6 u.c., which can be characterized as the intrinsic critical thickness. Our LEED-I(V) structural refinement shows non-monotonic lattice relaxation with thickness. The distortion of the c-axis bond length at surface reaches its maximum value for 6 u.c. film being 19% smaller than the bulk value. Mn is no longer at oxygen octahedron center with Mn-O-Mn bond angles between 167° and 176° varying with film thickness. Regardless of the thickness, the surface La/Sr-O layer is almost all Sr due to surface segregation. Capping with STO overlayer reduces the critical thickness of dead layer, thus suggesting that LSMO/STO interface enhances the conductivity of LSMO.

4:06PM R17.00007 Ultrafast conductivity dynamics in epitaxially strained $La_{1-x}Ca_xMnO_3$ thin films[1]

JINGDI ZHANG, RICHARD AVERITT, Department of Physics, Boston University, XUELIAN TAN, WENBIN WU, HFNL, University of Science and Technology of China — $La_{1-x}Ca_xMnO_3$ is a prototype colossal magnetoresistance (CMR) material where the conductivity displays a marked sensitivity to an external magnetic field for reasons that are not fully understood. The underlying rich physics is a result of strong coupling of the spin, lattice, orbital, and charge degrees of freedom. Optical spectroscopy provides experimental access to the underlying interactions in the manganites including spin and orbital ordering and the metal-insulator transition. Ultrafast spectroscopy can dynamically probe photo-induced changes that drive phase transitions. In this work we report on time-resolved terahertz spectroscopic studies of epitaxially strained $La_{1-x}Ca_xMnO_3$ thin films. In these films, the strain results in a robust antiferromagnetic insulating phase below 260K. Following 1.5 eV short pulse excitation the THz conductivity reveals a transition to a persistent metallic phase. This response is a result of competition in a dynamic phase fluctuation regime. We will describe, in detail, the observed differences in the conductivity dynamics as a function of lattice strain.

4:18PM R17.00008 Magnetic behavior of $La_{2/3}Ca_{1/3}MnO_3$ / $BaTiO_3$ bilayers[1]

JOHN E. ORDONEZ, MARIA E. GOMEZ, WILSON LOPERA, Universidad del Valle, Cali, Colombia, LORENA MARIN, JOSE A. PARDO, LUIS MORELLON, PEDRO ALGARABEL, Universidad de Zaragoza, Spain, PEDRO PRIETO, CENM, Colombia — We have grown ferroelectric $BaTiO_3$(BTO) and ferromagnetic $La_{2/3}Ca_{1/3}MnO_3$ (LCMO) onto (001) $SrTiO_3$ and Nb:$SrTiO_3$ by pulsed laser deposition (PLD) at pure oxygen atmosphere, and a substrate temperature of 820° C, seeking for a multiferroic behavior in this structure. From x-ray diffraction (XRD) we found lattice parameter a_{BTO}=4.068 Å, and a_{LCMO}=3.804 Å, for each individual layer. In the BTO/LCMO bilayer, (002)-Bragg peak for BTO maintain its position whereas (002) LCMO peak shift to lower Bragg angle indicating a strained LCMO film. Magnetization measurements reveal an increase in the Curie temperature from 170 K to 220 K for the bilayer when LCMO (t = 47 nm) is deposited on BTO (t=52 nm) film, while depositing the BTO (50 nm) above LCMO (48 nm) the Curie temperature remains at values close to that obtained for a LCMO single layer ($\sim$175 K), deposited under identical growth parameters

4:30PM R17.00009 Canted Antiferromagnetism in Electron-Doped $CaMnO_3$ under Epitaxial Strain

HIROMASA OHNISHI, SHOJI ISHIBASHI, National Institute of Advanced Industrial and Science Technology (AIST), KIYOYUKI TERAKURA, Japan Advanced Institute of Science and Technology (JAIST) — $CaMnO_3$ (CMO) is a G-type antiferromagnetic (G-AFM) insulator at low temperature. A small amount of electron doping to CMO induces electronic and magnetic state change to a weak ferromagnetic (FM) metal. The recent experiment in thin-film [1] has revealed that the metallic character by electron-doping is sensitive to the strain exerted by the substrate. In this study, we clarify the electron-doping effect for CMO with the existence of epitaxial strain from substrates, by first-principles electronic structure calculation with noncollinear version of local spin density approximation. We show that a metallic character with a weak FM component is brought by the spin-canting from the G-AFM spin alignment (cG-AFM) by the double exchange effect. The canting angle becomes larger with increase of doping-amount and c/a, where c and a represent in-plane and out-of-plane lattice constants, respectively. We also show that a magnetic state change from cG-AFM state to C-AFM one takes place by further enhancement of compressive strain. We analyze our results by comparing with the experimental results.

4:42PM R17.00010 Analysis of Stoichiometry Variations in La $_{1-x}$Ba$_x$MnO $_y$ Thin Films using Laser-Ablation Inductively Plasma Mass Spectrometry and X-ray diffraction , E. KEVIN TANYI, RAJESWARI KOLAGANI, MARK STEPHEN MONK, DAVID SCHAEFER, STEVEN LEV[1], Towson University — Structural, electrical and magnetic properties of thin films of the doped rare earth manganese oxide material s are known to change dramatically by varying the oxygen partial pressure employed during Pulsed Laser Deposition. In contrast to the commonly accepted idea that such variation is solely due to the variation of the oxygen stoichiometry of the films, we find that varying the deposition oxygen partial pressure also results in the variation of the cation stoichiometry at the rare earth site. We also find that in addition to oxygen partial pressure, laser fluence is a determining factor for the stoichiometry. We have analyzed the composition, structure and properties of La $_{1-x}$ Ba$_x$ MnO$_y$ thin films grown under a range of oxygen pressures. Cation composition is analyzed using the Laser-ablation Inductively Coupled Plasma Mass Spectroscopy technique (LA-ICPMS). LA-ICPMS results, coupled with structural information from 4-circle X-ray diffraction, allows us to delineate oxygen content variations from cation stoichiometry variations. We will correlate the changes in stoichiometry with surface morphology, and electrical and magneto-resistive properties.

[1]We acknowledge support from the NSF grant ECCS 1128586 at Towson University.

4:54PM R17.00011 Structural, AFM, MFM and magnetic studies of $LaMnO_3$ thin films prepared by atomic layer deposition method , MUKESH CHANDRA DIMRI, HIMANI KHANDURI, National Institute of Chemical Physics and Biophysics, Tallinn, Estonia, SAMI VASALA, Department of Chemistry, Aalto University School of Chemical Technology, Finland, SILVER LEINBERG, RÜNNO LÕHMUS, Institute of Physics, Faculty of Science and Technology, University of Tartu, Tartu, Estonia, JÜRI KRUSTOK, Tallinn University of Technology, Tallinn, Estonia, MAARIT KARPPINEN, Department of Chemistry, Aalto University School of Chemical Technology, Finland, RAIVO STERN, National Institute of Chemical Physics and Biophysics, Tallinn, Estonia — Structural, microstructural and magnetic properties of the thin films of $LaMnO_3$ (LMO) have been investigated and will be presented. Thin films were deposited by atomic layer deposition (ALD) method on silicon substrates. Effects of various process parameters have been studied on LMO thin films. Single phase perovskite crystal structure was confirmed from the X-ray diffraction and Raman spectra. SEM/AFM studies confirm the uniform and high quality films grown with grains in a range of 20-100 nm, depending on preparation conditions. MFM images measured at low temperature (65K), show different magnetic domains in films annealed in N_2 and O_2 environments. Stoichiometry, microstructure and magnetic properties of films strongly depend on annealing environments; however there was no change in their crystal structure. Curie temperature in those LMO thin films annealed in N_2 and O_2 atmospheres were 200 and 250K, respectively. Enhanced Curie temperature from the ideal value ($\sim$140 K) can be related to non-stoichiometry in our LMO films.

5:06PM R17.00012 The effects of annealing on the infrared and optical properties of $La_{0.67}Sr_{0.33}MnO_3$ films[1] , PENG XU, T.J. HUFFMAN, D.R. BRANAGAN, A.J. HOLLINGSHAD, N.E. PENTHORN, D.J. BROOKER, M.M. QAZILBASH, Department of Physics, College of William and Mary, P. SRIVASTAVA, T. GOEHRINGER, GRACE YONG, V. SMOLYANINOVA, R. KOLAGANI, Department of Physics, Astronomy and Geosciences, Towson University — $La_{0.67}Sr_{0.33}MnO_3$ (LSMO) films grown by pulsed laser deposition on lanthanum aluminate substrates undergo a phase transition from ferromagnetic metallic state to paramagnetic insulating state at T_c of about 350 K. This second-order phase transition proceeds via a phase coexistence regime over an extended temperature range. Annealing affects the strain and oxygen content in films thereby causing significant changes to the magnetic properties, electronic structure, lattice distortion, and possibly the nanoscale properties of coexisting phases. We use ellipsometry and Fourier-transform infrared spectroscopy to investigate the effects of annealing on LSMO films over a broad spectral range from ultraviolet to far infrared. We deduce the Jahn-Teller energy splitting and the Hund's coupling energy from our data on annealed and unannealed films.

Session R18 GMAG DMP FIAP: Focus Session: Spin-Dependent Phenomena in Semiconductors - GaMnAs 320 - John Peters, Northwestern University

2:30PM R18.00001 Experimental observations of optical spin-transfer and spin-orbit torques in magnetic semiconductors[1] , PETR NEMEC, Charles University in Prague, Faculty of Mathematics and Physics — The spin transfer torque (STT) is a non-relativistic phenomenon where angular momentum of spin polarized carriers electrically injected into a ferromagnet from an external polarizer is transferred to the magnetization [1]. In the absence of an external polarizer a distinct phenomenon can occur in which carriers in a magnet under applied electric field develop a non-equilibrium spin polarization due to the relativistic spin-orbit coupling, resulting in a current induced spin-orbit torque (SOT) [1]. We show, using the experimental data observed in the ferromagnetic semiconductor (Ga,Mn)As, that there exists optical counterparts of STT (OSTT) [2] and SOT (OSOT) [3]. In OSTT a circularly polarized femtosecond pump laser pulse acts as the external polarizer and it induces a coherent magnetization precession due to the angular momentum transfer, in a direct analogy to the current induced STT [2]. The absence of an external polarizer in OSOT corresponds to photo-carrier excitations which are independent of the polarization of the pump laser pulses and the phenomenon relies on spin-orbit coupling of non-equilibrium carriers, as in the case of the current induced SOT [3]. Our work demonstrates the possibility to study the spin-transfer and spin-orbit torques on the sub-picosecond time-scales using the optical pump-and-probe experimental technique.

3:06PM R18.00002 Spin-orbit current-induced torques in (Ga,Mn)As , ERIN K. VEHSTEDT, Texas A&M University, USA; Institute of Physics, ASCR, CZ, LIVIU P. ZARBO, Institute of Physics, ASCR, CZ, KAREL VYBORNY, SUNY Buffalo, USA; Institute of Physics, ASCR, CZ, HIDEKAZU KUREBAYASHI, University of Cambridge, UK, PIERRE ROY, Hitachi Cambridge Laboratory, UK, JOERG WUNDERLICH, Hitachi Cambridge Laboratory, UK; Institute of Physics, ASCR, CZ, ANDREW J. FERGUSON, University of Cambridge, UK, TOMAS JUNGWIRTH, Institue of Physics, ASCR, CZ; University of Nottingham, UK, JAIRO SINOVA, Texas A&M University, USA; Institute of Physics, ASCR, CZ — Electrical control of magnetic domains has the potential to overcome key challenges to the development of new non-volatile and down-scalable logic and memory devices. We study the spin-orbit torque induced by an unpolarized electric current in the dilute ferromagnetic semiconductor, (Ga,Mn)As. The current-induced torque (CIT) is modeled as the interaction between the uniform magnetization and an effective magnetic field representing the non-equilibrium carrier spin-polarization. We calculate the current-induced field (CIF) using the Kubo linear-response formalism for a broad range of material parameters. We find that the CIF is composed of a dominant term due to the inverse spin galvanic effect and a small component which is dependent on the relative orientation of the current, magnetization, and crystal axes. In conjunction with experimental studies, we investigate the magnetization dynamics using the phenomenological Landau-Lifschitz-Gilbert equation. The study of (Ga,Mn)As opens the door to a comprehensive theory of CITs in uniform magnetic semiconductors.

3:18PM R18.00003 Observation of a Photon Echo and Measurement of Interband Dephasing in GaMnAs

, KIMBERLEY HALL, MURAT YILDIRIM, SAM MARCH, REUBLE MATHEW, ANGELA GAMOURAS, Dalhousie University, XINYU LIU, MARGARET DOBROWOLSKA, JACEK FURDYNA, University of Notre Dame — The carrier-mediated ferromagnetism exhibited by III-V diluted magnetic semiconductors (DMS), together with their large magneto-optical response, makes these materials promising for applications in optoelectronics, including integrated optical isolators and ultrafast optically-addressable memory elements. The time scale for decay of coherence in the carrier system (T_2) is a key parameter in models of coherent magnetization rotation [1], yet very little is known about the coherent response in DMS. We present results of four-wave mixing measurements of T_2 in GaMnAs. We observe a dramatic reduction in the dephasing time with the incorporation of Mn, consistent with earlier experiments in CdMnTe [2]. This fast dephasing process, which leads to an upper bound on T_2 of 40 fs for $x \geq 0.014\%$, is attributed to spin-flip scattering between the optically excited holes and Mn ions, providing new insight into exchange coupling and nonequilibrium magnetization dynamics in these materials. Direct measurement of the envelope of the four-wave mixing emission reveals a photon echo in GaMnAs, despite the complexity of exchange coupling and defect-induced band tailing.

3:30PM R18.00004 ABSTRACT WITHDRAWN –

3:42PM R18.00005 Ferromagnetism and infrared electrodynamics of GaMnAs

, B.C. CHAPLER, University of California San Diego, S. MACK, University of California Santa Barbara, R.C. MYERS, The Ohio State University, K.S. BURCH, University of Toronto, N. SAMARTH, The Pennsylvania State University, D.D. AWSCHALOM, University of California Santa Barbara, D.N. BASOV, University of California San Diego — In this work we experimentally address both the magnetic and the electronic properties of the prototype dilute magnetic semiconductor $Ga_{1-x}Mn_xAs$ using infrared (IR) spectroscopy. We first examine the relationship between the carrier density, determined through a sum-rule analysis of our data and additional IR data available in the literature, and the ferromagnetic transition temperature T_C. Our analysis supports the conclusion that the Fermi level resides within a Mn-induced IB, and that the location of the Fermi level within the band plays a key role in controlling T_C. Additionally, we perform a detailed examination of the spectral features observed in the IR data of our $Ga_{1-x}Mn_xAs$ films, and show that these features are also consistent only with a Mn-induced IB scenario. In this latter vein, we will discuss and resolve controversies in the literature related to the peak in a broad mid-IR resonance observed in $Ga_{1-x}Mn_xAs$ IR spectra.

3:54PM R18.00006 Infrared magnetic linear dichroism spectroscopy of (Ga,Mn)As

, N. TESAROVA, J. SUBRT, P. MALY, P. NEMEC, Faculty of Mathematics and Physics, Charles University in Prague, K. VYBORNY, Institute of Physics, Academy of Sciences of the Czech Republic, C.T. ELLIS, ALOK MUKHERJEE, J. CERNE, Department of Physics, University at Buffalo, SUNY — The sensitivity of magnetic linear dichroism (MLD) to in-plane magnetization makes it well suited to study diluted magnetic semiconductors such as (Ga,Mn)As, where MLD can be used to probe electronic excitations in the material. The band structure supporting these excitations yields rich in-plane magnetization effects, which include anisotropic magnetoresistance and four non-perpendicular, in-plane easy axis orientations. Observation of these effects provides insights into the electronic structure of (Ga,Mn)As. In this work we introduce a new, low-temperature, infrared MLD measurement technique that reduces instrumentation artifacts and enables broadband (0.1 eV $< E_{ph} <$ 2.7 eV) capabilities. Through these MLD measurements we sensitively and systematically probe electronic structure in (Ga,Mn)As samples with Mn concentrations varying from 3%-14%. In general, the data show an MLD enhancement in the visible and infrared regimes, which are indicative of interband transitions between the valence and conduction bands and optical transitions within the valence band, respectively. We find that the behavior of these MLD features with increasing Mn concentration is in reasonable agreement with theoretical predictions. We acknowledge financial support provided by NSF-DMR1006078 and the Faculty of Mathematics and Physics, Charles University in Prague.

4:06PM R18.00007 Numerical studies of non-Drude ac-conductivity and infrared magneto-optics in (Ga,Mn)As

, HUAWEI GAO, JAIRO SINOVA, Department of Physics, Texas A&M University — Optical absorption experiments on (III,Mn)V diluted magnetic semiconductors (DMS's) show that the ac-conductivity has non-Drude behavior at low frequency. STM study show many states deep in the band gap. The numerical simulation of the first problem has been done previously using the effective Hamiltonian model with various treatments of the disorder effects. We re-examine the previous works with a similar numerical method to establish the nature of the transitions in the low to the high-doped regime and also the properties of states in the gap. We use the effective Hamiltonian k.p model to describe the holes introduced by Mn impurities and treat the Mn impurities exactly using the envelope function approximation. We use participation ratios to characterize the localization properties of quasi particle states. This allows us to study the ac-conductivity contributions due to delocalized states to deep in-gap localized states transitions and how the spectral weight is distributed. We will also report on numerical results of the magneto-optical response with this treatment of the effect of disorder.

4:18PM R18.00008 AC-transport measurements of ion beam irradiated GaMnAs semiconductors

, ELIS SINNECKER, MARCELO SANT'ANNA, TATIANA RAPPOPORT, JOAQUIM MENDES, MAURICIO PIRES, GERMANO PENELLO[1], DEIVID SOUZA, SERGIO MELLO, Instituto de Física, Universidade Federal do Rio de Janeiro, Rio de Janeiro 21941-909, RJ, Brazil, JACEK FURDYNA, XINYU LIU, Department of Physics, University of Notre Dame, Notre Dame, Indiana 46556, USA — GaMnAs is a diluted magnetic semiconductors in which lattice atoms have been partially substituted by magnetic atoms, thus inserting a local magnetic moment into the lattice. Recently it was shown that ion beam irradiation can be an effective tool to modify the magnetic and electronic properties of $Ga_{1-x}Mn_xAs$ thin films [1, 2]. We observed that an increase of the structural disorder by irradiation leads to a systematic decrease on the saturation magnetization. Here, we provide further information on the electronic properties of irradiated samples. Measurements of ac-resistivity, magnetoresistance and Hall resistance were performed from 5K to 300K applying a DC magnetic field up to 7T. The results show an interesting frequency dependence of the ac-transport of measured irradiated samples. For the sake of comparison, data on irradiated non-magnetic semiconductor, grown on the same conditions as Ga1-xMnxAs thin films, are provided.

4:30PM R18.00009 Andreev Reflection Measurement of Spin Polarization in GaMnAs

, KHALID EID, DIANA DAHLIAH, ROBERT TOLLEY, TAYLOR REID, Miami University, XINYU LIU, JACEK FURDYNA, University of Notre Dame — Current measurement geometries in high-resistivity materials suffer from a large extra resistance that comes from the bulk of the ferromagnet. We use the Circular Transfer Line Method (CTLM) [1-2] to measure the Andreev reflection effect at GaMnAs/superconductor interface and to extract GaMnAs spin polarization. This technique works especially well for high-resistivity films. It has multiple advantages over the point contact and planar geometries, like eliminating the extra resistance contribution from the bulk, producing actual conductance values and not normalized conductance, and eliminating the broadening of the superconducting gap. The effect of the Schottky barrier at the GaMnAs/superconductor interface plays a crucial role and will also be discussed.

[1] K.F. Eid et al, Appl. Phys. Lett 100, 212403 (2012)

4:42PM R18.00010 Electron diffusivity above and below the Curie temperature of GaMnAs , CHRIS WEBER, KASSIE MATTIA, ERIC KITTLAUS, Santa Clara University, XINYU LIU, JACEK FURDYNA, University of Notre Dame — Using a transient-grating pump-probe experiment, we measure the diffusion of photoexcited electrons in samples of (Ga,Mn)As with doping levels of 5%, 6%, and 7% Mn. At both 15 K and 80 K the diffusivity increases with density of photoexcited carriers, indicating the degeneracy of both majority holes and minority electrons. We measure electron diffusion in (Ga,Mn)As as rapid as ~ 100 cm^2/s. Converting diffusivity to mobility using the Einstein relation yields $\mu_e \sim 8000$ cm^2/Vs, similar to that of GaAs. This high mobility demonstrates that neither the density of states nor the scattering rate of the (Ga,Mn)As conduction band is significantly influenced by Mn doping or by ferromagnetism.

4:54PM R18.00011 The contribution of critical spin fluctuations to scattering and spin lifetimes in GaMnAs near the ferromagnetic transition[1] , MATTHEW MOWER, G. VIGNALE, University of Missouri — As GaMnAs transitions between the paramagnetic and ferromagnetic phases, the resistivity exhibits a peak due to enhanced scattering from critical spin fluctuations. Existing work typically focuses on the ferromagnetic side, or to a lesser extent the paramagnetic side, far away from the transition; the effect of strong spin fluctuations near the transition has received little attention. We present a simple model of spin exchange mediated by dynamic spin fluctuations, calculated in the GW approximation. This produces a finite peak in the resistivity that is qualitatively accurate. We then use this model to calculate hole spin lifetimes from the relevant spin relaxation mechanisms.

5:06PM R18.00012 Anomalous Fermi level behavior in GaMnAs at the onset of ferromagnetism , IRIYA MUNETA, HIROSHI TERADA, SHINOBU OHYA, MASAAKI TANAKA, Department of Electrical Engineering and Information Systems, The University of Tokyo — The origin of the ferromagnetism and the metal-insulator transition (MIT) has been a long-debated issue in the prototype ferromagnetic semiconductor GaMnAs. Previously, the valence band (VB) conduction picture has been widely accepted in this material, where the MIT of GaMnAs was understood by the Fermi level crossing over the VB similarly to p-type GaAs doped with non-magnetic acceptors. Here, we carefully analyze the VB structure and the Fermi level position in a series of $Ga_{1-x}Mn_xAs$ from the unexplored insulating region ($x \simeq 0.01\%$) to the metallic region ($x = 3.2\%$) by using resonant tunneling spectroscopy. We find that the Fermi level never crosses over the VB near the MIT: The Fermi level becomes closest to the VB top at $x = 1.0\%$ at the onset of the ferromagnetism, but it moves away from the VB with increasing or decreasing x from 1.0%. This anomalous behavior of the Fermi level is completely different from that of GaAs doped with other non-magnetic shallow acceptors [1]. This work was partly supported by Grant-in-Aids for Scientific Research including Specially Promoted Research, Project for Developing Innovation Systems of MEXT, and FIRST Program of JSPS.

5:18PM R18.00013 Does the physics of (Ga,Mn)N differ from (GaMn)As qualitatively or quantitatively? Is valance of Mn impurity 2+ or 3+? , RYKY NELSON, Louisiana State University, TOM BERLIJN, University of Florida, WEI KU, Brookhaven National Laboratory, JUANA MORENO, MARK JARRELL, Louisiana State University — (Ga,Mn)N is a promising material for spintronics due to its potential high currie temperature (Tc) [1]. However, unlike for (Ga,Mn)As, some of the experiments on (Ga,Mn)N are still controversial [2,3] on the intrinsic nature of the magnetism. Furthermore, under debate are the spin and charge state of the disordered Mn impurities in (Ga,Mn)N [4,5] and whether its local moments interact via the same exchange mechanism as in (Ga,Mn)As [6,7]. To address these issues we will present ab-initio-based analyses of disorder and correlation via the recently developed Wannier function based methods [8,9]. [1] T. 2:30PM R19.00001 ABSTRACT WITHDRAWN –

2:42PM R19.00002 Berezinskii-Kosterlitz-Thouless Transition in Heavy Fermion Superlattices , JIAN-HUANG SHE, Los Alamos National Laboratory, ALEXANDER BALATSKY, Los Alamos National Laboratory and Nordita — We propose an explanation of the superconducting transitions discovered in the heavy fermion superlattices by Mizukami et al. (Nature Physics 7, 849 (2011)) in terms of Berezinskii-Kosterlitz-Thouless transition. We observe that the effective mass mismatch between the heavy fermion superconductor and the normal metal regions provides an effective barrier that enables quasi 2D superconductivity in such systems. We show that the resistivity data, both with and without magnetic field, are consistent with BKT transition. Furthermore, we study the influence of a nearby magnetic quantum critical point on the vortex system, and find that the vortex core energy can be significantly reduced due to magnetic fluctuations. Further reduction of the gap with decreasing number of layers is understood as a result of pair breaking effect of Yb ions at the interface. Reference: Jian-Huang She, Alexander V. Balatsky, Phys. Rev. Lett. 109, 077002 (2012)

2:54PM R19.00003 Theory for ESR in the heavy fermion system $\beta-YbAlB_4$[1] , ALINE RAMIRES, PIERS COLEMAN, Rutgers University — We propose a theory to explain the unusual temperature dependence of the Electron Spin Resonance (ESR) lines of the critical heavy fermion superconductor β-$YbAlB_4$. This system shows a conduction electron ESR signal at high temperatures, but at low temperatures its g-factor shifts to the f-electron g-factor and it develops strong anisotropy. With our theory we are able to explain this dichotomy based on the fact that the lower crystal field configuration of the local moments in this system is a pure $|\pm 5/2\rangle$. Because of its Ising nature these spins can not be directly probed by ESR, and the f-electron features that appear at low temperatures can be explained by an emergent hybridization model. We can account for the origin of this signal and its main characteristics qualitatively, including g-factor shift and the hyperfine structure with the assumption that the scattering rate is unusually small.

3:06PM R19.00004 Effects of correlated hybridization in the single-impurity Anderson model[1]

, VALTER LÍBERO, RODRIGO VEIGA, Sociedade Brasileira de Física — The development of new materials often dependents on the theoretical foundations which study the microscopic matter, i.e., the way atoms interact and create distinct configurations. Among the interesting materials, those with partially filled d or f orbitals immersed in nonmagnetic metals have been described by the Anderson model, which takes into account Coulomb correlation (U) when a local level (energy E_d) is doubled occupied, and an electronic hybridization between local levels and conduction band states. In addition, here we include a correlated hybridization term, which depends on the local-level occupation number involved. This term breaks particle-hole symmetry (even when $U + 2E_d = 0$), enhances charge fluctuations on local levels and as a consequence strongly modifies the crossover between the Hamiltonian fixed-points, even suppressing one or other. We exemplify these behaviors showing data obtained from the Numerical Renormalization Group (NRG) computation for the impurity temperature-dependent specific heat, entropy and magnetic susceptibility. The interleaving procedure is used to recover the continuum spectrum after the NRG-logarithmic discretization of the conduction band.

3:18PM R19.00005 Fridel sum rules for one- and two-channel Kondo models and unitarity paradox via bosonization-refermionization approach[1]

, MAXIM KHARITONOV, NATAN ANDREI, PIERS COLEMAN, Center for Materials Theory, Rutgers University, Piscataway, NJ 08854, USA — We calculate the single-particle Green's functions and scattering amplitudes of the one-channel and channel-anisotropic two-channel Kondo models at the Toulouse and Emery-Kivelson lines, respectively, where exact solutions via the bosonization-refermionization approach are admitted. We demonstrate that in this approach the Friedel sum rules – the relations between the trapped spin and "flavor" moments and the scattering phase shifts in the Fermi-liquid regime – arise naturally and elucidate on their subtleties. We also recover the "unitarity paradox" [1,2] – the vanishing of the single-particle scattering amplitude at the channel-symmetric point of the two-channel Kondo model – stemming from non-Fermi-liquid behavior. We discuss the implications of these results for the development of composite pairing in heavy fermion systems.

3:30PM R19.00006 Kondo destruction and superconducting correlations in the two-impurity Bose-Fermi Anderson model

, LILI DENG, KEVIN INGERSENT, U. of Florida, JEDEDIAH PIXLEY, QIMIAO SI, Rice U. — The Bose-Fermi Kondo and Anderson models are among the simplest models for Kondo destruction, the phenomenon believed to underly the anomalous physics of certain heavy-fermion materials near the border of magnetism. With the goal of probing superconductivity near the Kondo-destruction local quantum critical point of the Kondo lattice, here we study the two-impurity Anderson model supplemented both by an inter-impurity exchange of either SU(2) or Ising symmetry and by a linear coupling between the impurity spins and a sub-Ohmic bosonic bath. Using the continuous-time quantum Monte Carlo method and the numerical renormalization group, we elucidate the phase diagram arising from the interplay of Kondo physics, inter-impurity exchange (ferromagnetic or antiferromagnetic), and bosonic decoherence, and demonstrate the existence of a Kondo-destruction quantum critical point in the model. We investigate the properties near this quantum critical point, as well as the effect of a critical suppression of the Kondo effect on superconducting pairing correlations.

3:42PM R19.00007 Quasiparticle scattering spectroscopy (QPS) of Kondo lattice heavy fermions[1]

, L.H. GREENE, S.M. NARASIWODEYAR, P. BANERJEE, W.K. PARK, University of Illinois at Urbana-Champaign, E.D. BAUER, P.H. TOBASH, R.E. BAUMBACH, F. RONNING, J.L. SARRAO, J.D. THOMPSON, Los Alamos National Laboratory — Point-contact spectroscopy (PCS) is a powerful technique to study electronic properties via measurements of non-linear current-voltage characteristic across a ballistic junction. It has been frequently adopted to investigate novel and/or unconventional superconductors by detecting the energy-dependent Andreev scattering. PCS of non-superconducting materials has been much rarely reported. From our recent studies on heavy fermions [1], we have frequently observed strongly bias-dependent and asymmetric conductance behaviors. Based on a Fano resonance model in a Kondo lattice [2], we attribute them to energy-dependent quasiparticle scattering off hybridized renormalized electronic states, dubbing it QPS. We will present our QPS results on several heavy-fermion systems and discuss QPS as a novel technique to probe the bulk spectroscopic properties of the electronic structure. For instance, it reveals that the hybridization gap in URu_2Si_2 opens well above the hidden order transition [1].

3:54PM R19.00008 Quantum Phases of the Shastry-Sutherland Kondo Lattice

, JEDEDIAH PIXLEY, RONG YU, QIMIAO SI, Rice University — Motivated by the discovery of the geometrically frustrated heavy fermion metal Yb2Pt2Pb[1], which has a quasi two dimensional Shastry-Sutherland lattice structure, we consider the Heisenberg-Kondo lattice model on a two dimensional Shastry-Sutherland geometry. Using a large-N method, we obtain the phase diagram and, in particular, the quantum transitions between a valence bond solid phase and a heavy Fermi liquid phase. Interestingly, we find intermediate states that break the C4 symmetry. We discuss the implications of our results for the experiments on Yb2Pt2Pb and related 221 materials [1], as well as the possible placement of these systems in a proposed global phase diagram for heavy fermion metals [2]. [1] M. S. Kim and M. C. Aronson, arXiv:1202.0220 (2012). [2] Q. Si, Phys. Status Solidi B 247, 476-484 (2010).

4:06PM R19.00009 Kondo hole route to incoherence in the periodic Anderson model[1]

, PRAMOD KUMAR, N.S. VIDHYADHIRAJA, Theoretical Sciences Unit, Jawaharlal Nehru Centre for Advanced Scientific Research, Bangalore, India 560064 — The interplay of disorder and interactions in strongly correlated electronic systems is a subject of perennial interest. In this work, we have investigated the effect of Kondo-hole type disorder on the dynamics and transport properties of heavy fermion systems. We employ the periodic Anderson model within the framework of coherent potential approximation and dynamical mean field theory. The crossover from lattice coherent behaviour to an incoherent single-impurity behaviour is reflected in all aspects: a highly frequency (ω)-dependent hybridization becomes almost flat, the coherence peak in resistivity (per impurity) gives way to a Hammann form that saturates at low temperature (T); the Drude peak and the mid-infrared peak in the optical conductivity vanish almost completely. The zero temperature resistivity can be captured in a closed form expression, and we show how the Nordheim's rule gets strongly modified in these systems. The thermopower exhibits a characteristic peak, which changes sign with increasing disorder, and its location is shown to correspond to the low energy scale of the system (ω_L). In fact, the thermopower appears to be much more sensitive to disorder variations than the resistivity. A comparison to experiments yields quantitative agreement.

4:18PM R19.00010 Bose-Fermi Kondo model with a local transverse field and its implications for the global phase diagram of heavy fermions , EMILIAN NICA, QIMIAO SI, Rice University, KEVIN INGERSENT, University of Florida — Recent studies of the global phase diagram of quantum critical heavy fermion metals [1] have motivated us to consider the interplay between the quantum fluctuations within the local-moment system and those associated with the Kondo interaction. Towards this goal, we studied a Bose-Fermi Kondo model with Ising anisotropy in the presence of a local transverse field. Using the numerical renormalization group method for co-existing fermionic and bosonic baths [2], we found that tuning the transverse field gives rise to a continuous phase transition between a local moment phase and a Kondo screened phase. We determine the critical fixed point structure by studying the transitions accessed by varying the transverse field for different initial values of the coupling to the dissipative boson bath. Finally, we discuss the implications of these results for the global phase diagram of the Kondo lattice.

4:30PM R19.00011 Kondo Metal and Ferrimagnetic Insulator on the Triangular Kagome Lattice , YAO-HUA CHEN, Texas Center for Superconductivity and Department of Physics, University of Houston, Houston, Texas 77204, USA, HONG-SHUAI TAO, Beijing National Laboratory for Condensed Matter Physics, Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China, DAO-XIN YAO, State Key Laboratory of Optoelectronic Materials and Technologies, Sun Yat-sen University, Guangzhou 510275, China, WU-MING LIU, Beijing National Laboratory for Condensed Matter Physics, Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China — We obtain the rich phase diagrams in the Hubbard model on the triangular kagome lattice as a function of interaction, temperature and asymmetry, by combining the cellular dynamical mean-field theory with the continuous time quantum Monte Carlo method. The phase diagrams show the asymmetry separates the critical points in Mott transition of two sublattices on the triangular kagome lattice and produces two novel phases called plaquette insulator with a clearly visible gap and a gapless Kondo metal. When the Coulomb interaction is stronger than the critical value U_c, a short range paramagnetic insulating state emerges before the ferrimagnetic order is formed independent of asymmetry. Furthermore, we discuss how to measure these phases in future experiments.

4:42PM R19.00012 Doniach Diagram in Disordered Electrons System[1] , HYUNYONG LEE, Division of Advanced Materials Science, Pohang University of Science and Technology (POSTECH), Pohang 790-784, South Korea, STEFAN KETTEMANN, School of Engineering and Science, Jacobs University Bremen, Bremen 28759, Germany — We have derived the quantum phase diagram of disordered electron systems with magnetic impurities. The competition between RKKY interaction, J_{RKKY}, and Kondo effect gives rise to a rich quantum phase diagram, or Doniach diagram. We present numerical results for disordered 2D electron systems which show that both Kondo temperature, T_K and J_{RKKY} are widely distributed and quantum critical point is extended to a critical region. We find a sharp cutoff in the distribution of their ratio, J_{RKKY}/T_K, and from that critical density of magnetic impurity below which Kondo always wins. We find that the spin coupled phase grows at the expense of Kondo phase as increasing disorder.The spin coupled phase shows a succession of 3 phases: 1. a Griffiths phase with anomalous power laws determined by distribution of J_{RKKY}, 2. spin glass phase, 3. long range magnetic ordered phase. We report the results on graphene where we find that spin coupled phase is more stable against Kondo screening, but is more easily destroyed by disorder into a paramagnetic phase [1].

4:54PM R19.00013 Transport properties of a two impurity system: a theoretical approach. , IGNACIO J. HAMAD, Departamento de Fisica, PUC Rio de Janeiro, 22453-900, Brazil, LAERCIO COSTA RIBEIRO, Centro Federal de Educacao Tecnologica Celso Suckow da Fonseca (CEFET-RJ/UnED-NI), RJ, Brazil, GEORGE MARTINS, Department of Physics, Oakland University, Rochester, MI 48309, USA, ENRIQUE V. ANDA, Departamento de Fisica, PUC Rio de Janeiro, 22453-900, Brazil — Double magnetic-impurity systems have attracted great attention due to their rich physics and possible technological applications. A system of two interacting Co atoms has been studied in a recent STM experiments (Nature Physics **7**, 901 (2011)). The precise control of the inter-impurity distance made it possible to explore in detail the transport properties of the system as a function of the impurities' interaction with each other. We explain, for all the parameter range studied, the physics observed in the experiments using a microscopic model, based on the two impurity Anderson model, including a two-path geometry for charge transport. The many-body system is treated in the finite-U Slave Boson Mean Field Approximation. Other results obtained using the Logarithmic Discretization Embedded Cluster Approximation are also discussed. We physically characterize the system and show that, as in the experiments, the features observed in the transport properties depend on the presence of two impurities but also on the existence of two conducting channels for electron transport. In particular, we obtain a splitting in the differential conductance, compatible with the one observed in the experiments, as a result of the superposition of the many-body Kondo states of each impurity.

Session R20 DMP: Focus Session: Electron, Ion, and Exciton Transport in Nanostructures - Modeling and Electrical Characterization 322 - Blanka Magyari-Kope, Stanford University

2:30PM R20.00001 Pseudopotential-based study of electron transport in low-dimensionality nanostructures , MASSIMO FISCHETTI, Department of Materials Science and Engineering, University of Texas at Dallas — Pseudopotentials– empirical and *ab initio* – are now being more commonly used to study not only the atomic and electronic structure of nanometer-scale systems, but also their electronic transport properties. Here we shall give a bird-eye view of the use of density functional theory (DFT) to calibrate empirical pseudopotentials (EPs), of EPs to calculate efficiently the electronic structure of low-dimensionality systems, the most significant electronic scattering processes, and to study semiclassical and quantum electronic transport. Low-dimensionality systems considered here include thin semiconductor layers, graphene, graphene- and silicane-nanoribbons, and silicon nanowires. Regarding graphene, the high electron mobility measured in suspended graphene sheets ($\sim$ 200,000 cm^2/Vs) is the result of a relatively weak carrier-phonon and the strong dielectric-screening property. However, in practical applications graphene is likely to be supported by an insulating substrate, top-gated, and possibly used in the form of narrow armchair-edge nanoribbons (aGNRs) in order to open a gap. We will discuss several scattering processes which may affect the electron transport properties in these situations. First, we shall present results of the calculation of the intrinsic electron-phonon scattering rates in suspended graphene using empirical pseudopotentials and the rigid-ion approximation, resulting in an electron mobility consistent with the experimental results. We shall then discuss the role of interfacial coupled substrate optical-phonon/graphene-plasmons in depressing the electron mobility in graphene supported by several insulators (SiO_2, HfO_2, Al_2O_3, and h-BN). We shall also discuss the role of Coulomb scattering with charged defects/impurities in gated graphene sheets and the role of the metal gate in screening this interaction. Finally, we shall review the strong effect of line edge roughness (LER) on electron transport and localization in narrow aGNRs resulting from the "aromatic" width dependence of the band-gap of the sp^2-coordinated aGNRs. This will lead us to consider sp^3-coordinate ribbons (silicane) and Si nanowires as possible alternative structures – less affected by LER scattering – of interest in nanoelectronics application.

3:06PM R20.00002 Electron Transport Variability in Armchair Graphene Nanorribbons , SHELA ABOUD, Stanford University, MASSIMO FISCHETTI, University Texas Dallas — Armchair graphene nanoribbons (AGNR) hold great promise in nano-electronics because of the capability of opening a semiconducting gap in narrow ribbons. However the effective use of AGNR in devices may be limited by structural and chemical modifications from a variety of sources including the support material, edge effects, width variability, and defects which all change the trends in the bandgap scaling. In this work we use density functional theory (DFT) simulations and Empirical Pseudopotentials (EPs) to investigate how structural and chemical variability in the AGNRs influence electron transport through changes in the bandstructure, phonon modes and electron-phonon coupling. Comparisons of the DFT and EPs give the same trend for ribbons with widths of 3N, 3N+1 and 3N+2 atoms with small differences stemming from the atomic structural relaxation accounted for in the DFT simulations. The dependence of the gap on the ribbon width is attributed to the aromaticity of the graphene that can be understood through the spatial distribution of the Clar resonance structures (Clar sextets) and become more localized because of the formation of the edge states. Chemical functionalization of the edges, defects at the edges and in the bulk of the ribbon, doping, and the type of support material (e.g. h-BN, SiO2, HfO and Al2O3) will all modify the aromaticity of the ribbons.

3:18PM R20.00003 Photo-induced energy transfer between carbon nanotubes , OLENA POSTUPNA, HEATHER JAEGER, OLEG PREZHDO, University of Rochester — The unique structural, mechanical, and electronic properties of carbon nanotubes (CNTs) have recently been attracting significant attention in academic research and industrial applications. Experimental investigation of the physical properties of CNTs is often hindered by questions that can be answered only with rigorous theoretical approaches, such as ab initio molecular dynamics. Results of time-domain simulations of energy transfer between photo-excited CNTs are reported. Using a system comprised of a pair of CNTs with different chiralities, (6,4) and (8,4), we elucidate the experimental results obtained by Luer at al [1]. Quantification of adiabatic and nonadiabatic contributions to the transfer process clarifies the mechanism of energy transfer. And, the delocalization of the initial exciton is representative of strong donor-acceptor coupling at high energies. Our work contributes to the ever-growing compendium of energy transfer within nanoscale systems and offers valuable insight toward tailoring CNTs for solar energy conversion.

3:30PM R20.00004 Realization of High-speed Transport in Low Dimensional Disordered Carbon Films , SOMNATH BHATTACHARYYA, MIKHAIL KATKOV, DMITRY CHUROCHKIN, GEORGE CHIMOWA, ROSS MCINTOSH, University of the Witwatersrand — Developing hybrid super-structures including carbon nanostructures for quantum information science is widely sought after and we show a possible route in carbon superlattice structures based on experimental results as well as theoretical analysis which also incorporates high-speed switching capabilities. We propose a theoretical model of disordered carbon superlattice structures where the local density of electronic states is controlled by changing the $sp^3 - C$ bond alternation as well as the hopping disorder parameter of the $sp^2 - C$ regions. In addition the incorporation of nitrogen atoms in carbon networks was modeled as a combination of disorders which vary both in correlated and uncorrelated manners. Resonant peaks associated with C and N sites in these structures show a conductance cross-over under variation of the nitrogen concentration in these structures which can explain the observed negative differential resistance in diamond-like carbon superlattices as well as the conductivity cross-over in nano-crystalline diamond films. Detailed analysis of transport measurements over a wide range of temperatures, magnetic fields and also frequency shows an enhanced characteristic length in these systems that supports switching of complex impedance in the range of 50 GHz.

3:42PM R20.00005 Preparation and electrical transport property study of MoS_2 single-layer devices on different substrates[1] , ZHIYONG WANG, ZHISHENG LIN, RAY SACHS, Department of Physics and Astronomy, University of California, Riverside, JI FENG, International Center for Quantum Materials, Peking University, China, JING SHI, Department of Physics and Astronomy, University of California, Riverside — Micro-exfoliated MoS2 flakes on SiO2/Si substrate are identified with optical microscope first and then atomic force microscopy and Raman spectroscopy. Nanodevices are subsequently prepared by E-beam lithography. The as-prepared MoS2 devices are n-type with a high sheet resistance (typically several MOhms). As a gate voltage is applied, a large gate modulation in sheet resistance is observed. At the highest negative gate voltage, the devices remain n-type but the resistance increases by at least 4 orders of magnitude. In the meantime, the current-voltage characteristics turn from linear to non-linear. The field-effect mobility extracted from the gate voltage dependence is about 10 cm^2/Vs. To study the effect of the dielectric constant, we have developed a transfer technique that transfers entire working devices from SiO2/Si to any substrates. We have successfully applied the technique to graphene and obtained a relatively high yield. We are currently transferring MoS2 devices from SiO2/Si to strontium titanate (STO) substrate which has a much higher dielectric constant (300 at room temperature). Detailed experimental results and discussions will be presented.

[1]Research was supported in part by DOE and NSF/EECS.

3:54PM R20.00006 Electrical characterization of few-layer MoS2 on HfO2 substrate , JATINDER KUMAR, HUI-CHUN CHIEN, HSIN-YING CHIU, University of Kansas — Due to the realization of graphene transistors but without applicable bandgap, the similar layered structure molybdenum disulfide (MoS2) field effect transistors with nonzero bandgap have been demonstrated and reveal promising potential. Previous experiments showed that carrier mobility could be enhanced by depositing hafnium dioxide (HfO2) on top of MoS2 devices, which was possibly attribute to the suppression of Coulomb scattering by high-κ environment and surface polar phonon scattering. In our talk, we will present the electrical transport experiments in few layers of MoS2 on HfO2 dielectrics, including the carrier mobility improvement and electrical transport phenomena in high bias region.

4:06PM R20.00007 Investigation of E^1_{2g} and A_{1g} Raman Modes of Few-Layer MoS_2 on HfO_2 Substrate , HUI-CHUN CHIEN, JATINDER KUMAR, HSIN-YING CHIU, University of Kansas — The recent research work by Radisavljevic *et al.*[1] shows that the mobilities of monolayer MoS_2 transistors can be improved by employing a thin layer of hafnium oxide as top-gate dielectric. Dielectric screening has been successfully demonstrated to suppress the Coulomb interactions of charged impurities on the substrate. Therefore, we develop an alternative method of building monolayer MoS_2 transistors on HfO_2 substrate. Owing to the low contrast of few-layer MoS_2 flakes on thin HfO_2 layer, which makes the realization of such device configuration difficult. By utilizing the thickness dependence of in-plane and out-of-plane Raman peaks of MoS_2 flakes, E^1_{2g}andA_{1g}, respectively, we establish an efficient approach to improve the identification of MoS_2 layers by Raman spectrum instead of AFM. Our investigation of Raman spectrum of few-layer MoS_2 on HfO_2 shows the significant difference from those on SiO_2. The substrate dependence of Raman spectrum as well as its further application will be discussed in this talk.

4:18PM R20.00008 Liquid-gated ambipolar transistor with ransition-metal dichalcogenides , YIJIN ZHANG, JIANTING YE, YOSHIHIRO IWASA, Quantum-Phase Electronics Center and Department of Applied Physics, the Univ. of Tokyo — Transition-metal dichalcogenides (TMDs) are graphene-like layered materials. In particular, semiconducting group of TMDs are attracting great interests as a post-graphene material since they have a finite band gap which is an important feature for FET applications. We fabricated semiconducting TMD-based FETs using a new type of gate dielectric called electric double layer (EDL). EDL is formed by solid and ions inside liquid at the solid-liquid interface. This nano-scale capacitor provides extremely large charge accumulation capability and realizes high performance FETs and field-effect phase control. We observed ambipolar FET operation of molybdenum disulfide (MoS_2) for the first time in addition to its well-known n-type operation [1] and field-effect superconducting transition [2]. High performance is not only observed in MoS_2 but also in other semiconducting TMDs like tungsten diselenide (WSe_2). The ambipolar operation is also important for applications, for example, light-emitting devices like organic materials. We investigated possibilities of EDL-based optical coupling devices. [1] Y. J. Zhang et al. Nano. Lett. 12, 1136 (2012) [2] J. T. Ye, Y. J. Zhang et al. Science in press

4:30PM R20.00009 High on/off ratio field effect transistor based on exfoliated crystalline SnS_2 nano-membrane , DEBTANU DE, Department of Physics, Texas Center for Superconductivity, University of Houston, JOHN MANONGDO, SEAN SEE, Department of Chemistry, Texas Center for Superconductivity, University of Houston, VINCENT ZHANG, Department of Physics, Texas Center for Superconductivity, University of Houston, ARNOLD GULOY, Department of Chemistry, Texas Center for Superconductivity, University of Houston, HAIBING PENG, Department of Physics, Texas Center for Superconductivity, University of Houston — We report the implementation of field effect transistors based on exfoliated nano-membranes of a layered two-dimensional semiconductor SnS_2, which exhibit an On/Off ratio exceeding $2x10^6$ and a carrier mobility of ~ 1 $cm^2V^{-1}s^{-1}$. The results demonstrate the great potential of SnS_2, a layered semiconductor with finite band gap, as the building block for future nanoelectronic applications complementary to graphene-based materials with zero or small band gap.

4:42PM R20.00010 Topological phase transition in hexagonal boron-nitride bilayers modulated by gate voltage[1] , GUOJUN JIN, XUECHAO ZHAI, Nanjing University — We study the gate-voltage modulated electronic properties of hexagonal boron-nitride bilayers with two different stacking structures in the presence of intrinsic and Rashba spin-orbit interactions. Our analytical results show that there are striking cooperation effects arising from the spin-orbit interactions and the interlayer bias voltage. For realizing topological phase transition, in contrast to a gated graphene bilayer for increasing its energy gap, the energy gap of a boron-nitride bilayer is significantly reduced by an applied gate voltage. For the AA stacking-bilayer which has the inversion symmetry, a strong topological phase is found, and there is an interesting reentrant behavior from a normal phase to a topological phase and then to a normal phase again, characterized by the topological index. Therefore, the gate voltage modulated AA-boron nitride bilayer can be taken as a newcomer of the topological insulator family. For the AB stacking-bilayer which is lack of the inversion symmetry, it is always topologically trivial, but exhibits an unusual quantum Hall phase with four degenerate low-energy states localized at a single edge. It is suggested that these theoretical findings could be verified experimentally in the transport properties of boron-nitride bylayers.

4:54PM R20.00011 Surface-Plasmon Assisted Exciton Transport in 1D Nanostructures , CHARLES CHERQUI, Theoretical Division, Los Alamos National Laboratory, and Department of Physics, University of New Mexico, DAVID DUNLAP, Department of Physics, University of New Mexico, ANDREI PIRYATINSKI, Theoretical Division, Los Alamos National Laboratory — We consider effect of coupling between exciton propagating in a 1D-nanostructure (e.g., carbon nanotube) and localized surface plasmon modes induced by a metal nanoparticle located in close proximity to the nanostructure. Both regimes of weak and strong exciton-plasmon couplings are taken into account leading to the dressed exciton and plasmon states. In this representation, the dynamics of the dressed excitons is mapped on the impurity scattering problem. The analysis of the scattering matrix indicates that the surface-plasmon modes lead to the exciton intraband scattering and possibility to form localized states within the exciton band gap. Surface plasmon induced exciton radiation pattern and the radiative and non-radiative decay rates are calculated and their dependence on the exciton-plasmon coupling is analyzed.

5:06PM R20.00012 A novel turbulent state of a dipolar exciton Bose-Einstein condensate[1] , GERMAN V. KOLMAKOV, OLEG L. BERMAN, ROMAN YA. KEZERASHVILI, the New York City College of Technology, the City University of New York — We report the formation of a new state in a non-equilibrium Bose-Einstein condensate (BEC) of dipolar excitons: steady turbulence. Two different systems where the BEC is formed are considered: coupled semiconductor quantum wells and two-layer graphene separated by a semiconducting or dielectric barrier. The non-linear dynamics of the systems are studied by using the generalized Gross-Pitaevskii equation. It is demonstrated that in the BEC a steady turbulent state is formed at high enough pumping rates. This state is characterized by oscillations of the spatial distribution of the excitons and fast redistribution of the energy between the oscillatory modes. The dynamics of the system can be explained in terms of the propagation of the fluxes of two quantities – the energy and the number of particles. The analysis of these excitonic systems as well as the comparison with an atomic condensed state show that the formation of turbulence is a general effect in the BEC.

5:18PM R20.00013 Theoretical study of electron transport in DNA , BIKAN TAN, MIROSLAV HODAK, WENCHANG LU, JERRY BERNHOLC, NC State University — Many experiments have observed high conductivity of DNA, but its origin has not yet been satisfactorily explained. In this work, we explore the dynamics of solvated B-DNA sandwiched between metallic nanotubes and connected via alkane linkers. The geometries are relaxed using the CHARMM force field. Conductivities of different snapshots of the system are calculated using the non-equilibrium Green's function method within density-functional theory. Our results show that in certain geometries, the DNA conducts significantly better than in others. For the highest conductivity configuration, a HOMO state extends across DNA's guanine sites to the alkane linkers. In general, we find that the conformational changes strongly affect the energy alignment of HOMO states of the DNA and the linker, and thus have a major effect on the conductivity of the entire system.

Session R21 DMP: Focus Session: Coupling Phenomena in Oxides and Optical and Electronic Properties 323 - Pavlo Zubko, Universite de Geneve

2:30PM R21.00001 A Transport Perspective on Local Manipulation of Ferroelectric and Correlated Electron Surfaces , PETRO MAKSYMOVYCH, Center for Nanophase Materials Sciences — The majority of transport studies aim to identify intrinsic electronic properties of materials, thus avoiding large electric fields, hysteresis, chemical reactions and hot electrons. In this talk, I will discuss the electron transport signatures of the opposite regime, where a complex oxide surface is subjected to strong local field and/or force gradients. Most notably, we have established an insulator-metal transition within an insulating perovskite oxide controlled solely by ferroelectric switching at the nanoscale [1]. This was the first time metallic conductivity has been found in a ferroelectric, despite a variety of theoretical scenarios dating back to the 70's that hypothesized such a behavior. Equally intriguing is the ability to tune the type and magnitude of metallic conductivity of ferroelectric nanodomains by orders of magnitude using applied electric field. Landau-Ginzburg-Devonshire (LGD) formalism captures the essence of these effects, by describing carrier accumulation or depletion at inclined and charged domain walls. On the other hand, local transport measurements on the surfaces of nominally conducting surfaces (such as manganites and nickel oxide) have induced an insulating state, the effect we refer to as 'piezochemistry' and assign to strain-induced redistribution of oxygen vacancies [2]. These coupled transport phenomena in oxides have practical implications, while transport itself appears to be a highly sensitivie probe of ferroic transitions and ionic effects. Experiments were conducted at the Center for Nanophase Materials Sciences, sponsored at Oak Ridge National Laboratory by the Division of Scientific User Facilities, U.S. Department of Energy. Work was also supported by the U.S. Department of Energy, Basic Energy Sciences, Materials Sciences and Engineering Division.

3:06PM R21.00002 Interplay of strain and oxygen vacancies in $CaMnO_3$, ULRICH ASCHAUER, RETO PFENNINGER, Materials Theory, ETH Zürich, SVERRE M. SELBACH, TOR GRANDE, Department of Materials Science and Engineering, Norwegian University of Science and Technology, Trondheim, NICOLA A. SPALDIN, Materials Theory, ETH Zürich — Application of strain through heteroepitaxy has become an established route to engineering novel material properties such as multiferroism in perovskites. First principles calculations have been shown to accurately describe material properties as the in-plane lattice constants are changed by strain, and often indicate that large strain magnitudes (>4%) are required to induce new functionalities. At such large values, however, it is unclear whether strain will be accommodated primarily by changes in intrinsic lattice constants as usually assumed, or by the formation of point defects. Conversely, the use of strain to engineer point-defect concentrations and stoichiometry is largely unexplored. Here we use first-principles calculations to investigate the stability of the $Pnma$ perovskite $CaMnO_3$ under bi-axial strain towards the formation of oxygen vacancies. We discuss the underlying mechanism for strain-vacancy coupling as well as the implications of our results for the growth of highly strained epitaxial films.

3:18PM R21.00003 Effect of Surface Engineering on Tunneling Across Ferroelectric Thin Films[1] , LE ZHANG, SHIJIE LI, HAIDONG LU, ALEXEI GRUVERMAN, ANDREI SOKOLOV, Department of Physics and Astronomy, University of Nebraska - Lincoln — For a practical implementation of ferroelectric based devices, it is indispensable to obtain reliable switching characteristic of ME/FE/ME heterostructures. Electrostatic force microscopy shows that polar surfaces are achievable without top ME electrode and ionic adsorbates delivers enough screening ions, it is intriguing enough that top metal electrode appears to be less effective than such screening by adsorbates. This observation emphasizes the importance of surface engineering [1] heterojunctions in order to retain or enhance ferroelectric response. We report on our study of the role of top electrodes in ferroelectric stability and tunneling properties of heterojunctions containing $BaTiO_3$ thin film, grown epitaxially on Ti-terminated $SrTiO_3$ substrate with $LaSrMnO_3$ and $SrRuO_3$ as bottom electrodes by pulsed laser deposition. Epitaxial top electrodes are formed by the same method. Alternatively, Pt and Ni-based metallic films are deposited by electron beam evaporation. PFM response and HRTEM analysis of obtained interface are presented. Transport and magneto-transport measurement are discussed in the frame of ferroelectric polarization induced effects.

3:30PM R21.00004 Graphene Field Effect Sensors for the Study of Nanoscale Ferroelectric Thin Films , ANIL RAJAPITAMAHUNI, VIJAY RAJ SINGH, ZHIYONG XIAO, XIA HONG, Department of Physics and Astronomy,University of Nebraska-Lincoln — We have constructed graphene field effect devices as sensors to study the dielectric and pyroelectric properties of nanoscale ferroelectric thin films. Using off−axis radio frequency magnetron sputtering, we have grown epitaxial single crystalline $Pb(Zr,Ti)O_3$(PZT) and $(Ba,Sr)TiO_3$ (BSTO) films of 30−100 nm thick on (001) $Nb:SrTiO_3$ substrates. X−Ray and AFM characterizations show the films have high crystallinity and smooth surface. Piezo-response force microscopy studies show that the as-grown PZT films have uniform polarization pointing towards the substrate. Graphene flakes are mechanically exfoliated on PZT and BSTO thin films and single to few layers are fabricated into field effect devices. We extract the carrier density in graphene from Hall Effect measurements, and use it to probe the polarization change of the ferroelectric gate layer. From the gating efficiency we found the dielectric constant of 100 nm PZT film to be 50. Its pyroelectric coefficient is $\sim$15 nC/cm^2K at 300 K and the polarization saturates below 100 K. We have also studied the effect of film thickness on the dielectric and pyroelectric properties of the ferroelectric thin films.

3:42PM R21.00005 Investigation of laser induced space charge fields in lithium niobate at low temperature with Raman spectroscopy[1] , GREG STONE, VOLKMAR DIEROLF, Lehigh University — We report the measurement of space charges fields generated by a laser beam at low temperatures using Raman spectroscopy. Raman spectra obtained with a focused laser exhibits frequency shifts of certain Raman peaks that appear as a function of time. Analysis of these shifts reveals that they originate from changes in the local electric field that are predominately parallel to the z-axis of the crystal. The magnitude of the frequency shifts and the corresponding maximum space charge field established inside the crystal are dependent on the defect concentration. Above a certain threshold field, the built-up space charge field is drastically reduced by discharges and builds up again afterwards. The changes in the Raman spectrum remain after the laser is turned off but disappear upon heating the sample above 200K.

3:54PM R21.00006 First-principles Investigations of Fe Impurities in $KNbO_3$, MOHUA BHATTACHARYA, STEVEN LEWIS, WILLIAM DENNIS, Department of Physics and Astronomy, The University of Georgia — The perovskite based material $KNbO_3$ has been studied extensively for its photorefractive properties, where the electro-optic effect combined with photoconductivity changes the local refractive index of the material in response to the incident intensities. The presence of a transition metal impurity like Fe is required for efficient photorefractive performance of this material. To shed light on the physical mechanism of this behavior, we perform first-principles calculations within the density functional theory framework. In this talk, we present the geometric and electronic structures of $KNbO_3$:Fe super cells and compare two cases: one in which the Fe^{3+} impurity on the Nb^{5+} site is compensated by an O vacancy in the first coordination shell and one in which the O vacancy is in the second coordination shell. Connections of this work to recent experimental measurements are discussed.

4:06PM R21.00007 Far infrared studies of $PrFe_3(BO_3)_4$[1] , KIRILL BOLDYREV, MARINA POPOVA, Institute for spectroscopy Russian Academy of Sciences, TARAS STANISLAVCHUK, ANDREI SIRENKO, Department of Physics, New Jersey Institute of Technology, LEONARD BEZMATERNYKH, Kirenskiy Institute of Physics, Siberian Branch of RAS — We present results on polarized far infrared reflectance, transmittance and ellipsometry measurements of $PrFe_3(BO_3)_4$ single crystals in a wide temperature range (5 - 300K). Rare-earth iron borates $RFe_3(BO_3)_4$ undergo an antiferromagnetic phase transition at temperatures below 40 K and all of them demonstrate magnetoelectric and magnetoelastic effects. $PrFe_3(BO_3)_4$ orders antiferromagnetically at $T_N = 32$ K. Pronounced changes in the low-frequency phonon spectra of $PrFe_3(BO_3)_4$ are observed at T_N which points to a significant spin-lattice interaction. Below 90 K, a new feature at 48 cm^{-1} appears in the pi-polarized reflectance spectra. We attribute this feature to a Pr^{3+} crystal-field transition that becomes observable in reflectance due to interaction with a nearby phonon 60cm^{-1}.

4:18PM R21.00008 Band gap hierarchy of single crystal $CoFe_2O_4$ thin films from optical absorption spectroscopy , BRIAN HOLINSWORTH, University of Tennessee - Knoxville, HUNTER SIMS, DIPANJAN MAZUMDAR, University of Alabama, QI SUN, University of Tennessee - Knoxville, MEHMET YURTISIGI, SANJOY SARKER, ARUN GUPTA, BILL BUTLER, University of Alabama, JANICE MUSFELDT, University of Tennessee - Knoxville — Thin film materials have a wide variety of applications and also serve as an useful bridge between bulk single crystals and the nanoscale. In this work, we report temperature-dependent optical absorption spectroscopy of single crystal $CoFe_2O_4$ thin-films along with complimentary electronic structure analysis. This magnetic insulator has one of the highest Curie temperature among complex oxides and potentially useful in areas such as spintronics. Similar to its Nickel analogue,[1] our work reveals $CoFe_2O_4$ to be an indirect band gap material (1.2 eV) with a direct gap much higher (2.8eV) at 300K. These gap values are robust down to 4.2K. Electronically, both chemical tuning and inversion fraction are found to be important factors in lowering of the band gap compared to $NiFe_2O_4$.

[1]Q.C. Sun, H. Sims, D.Mazumdar, J.X.Ma, B. Holinswoth, K.O'Neal, G.Kim, W.H.Butler, A.Gupta, and J.Musfeldt (accepted to Phys. Rev. B).

4:30PM R21.00009 Electrocaloric Properties of Epitaxial Strontium Titanate Films , JIALAN ZHANG, University of Connecticut, BURC MISIRLIOGLU, Sabanci University, PAMIR ALPAY, GEORGE ROSSETTI, University of Connecticut — The pyroelectric and electrocaloric effects in polar dielectric solids result from the coupling between the electrical and thermal properties. Although STO crystals or polycrystalline ceramics remain paraelectric down to 0 K, the ferroelectric phase can be induced by uniaxial stress, an external electrical field, or by doping. Here we develop a nonlinear thermodynamic theory to compute the electrocaloric response of strontium titanate thin films as a function of misfit strain, temperature, electric field strength, and electrode configuration. Our results show that the adiabatic temperature change ΔT of epitaxial (001) STO films can be controlled by the misfit strain and by varying the thermal and electrical boundary conditions. For films in a capacitor configuration on compressive substrates, the transition between paraelectric and strain-induced ferroelectric tetragonal phases produces a large adiabatic temperature change at room temperature. For films on tensile substrates, the transition between the paraelectric and strain-induced ferroelectric orthorhombic phases can also be accessed using inter-digitated electrodes, and the maximum EC response occurs with a [110] orientation.

4:42PM R21.00010 Combined Angle-Resolved Photoemission Spectroscopy and Theoretical Study of the Surface Electronic Structure of $SrTiO_3$, RICHARD C. HATCH, KURT FREDRICKSON, CHUNGWEI LIN, MIRI CHOI, AGHAM B. POSADAS, HOSUNG SEO, ALEXANDER A. DEMKOV, Department of Physics, The University of Texas at Austin, TX 78712, USA — The surface electronic structure of the O $2p$-derived valence band states of (001)-oriented, TiO_2-terminated $SrTiO_3$ is measured along various crystallographic directions using angle-resolved photoemission spectroscopy (ARPES). A comparison of ARPES spectra to *ab initio*, density functional theory (DFT) band structure calculations as well as the theoretical band structure calculated at the tight binding level are in excellent agreement. ARPES measurements also reveal a mid-gap state located roughly 0.5 eV above the valence band which we interpret as a surface state. This interpretation is supported by DFT calculations of an $SrTiO_3$ slab which reveals the existence of a surface state located in the gap roughly 0.5 eV above the projected valence band.

4:54PM R21.00011 Resonant inelastic soft x-ray scattering as a site-specific probe of electron-phonon coupling in one-dimensional edge-shared cuprates , S. JOHNSTON, IFW Dresden, W.S. LEE, B. MORITZ, SLAC National Accelerator Laboratory, J. VAN DEN BRINK, IFW Dresden, Z.-X. SHEN, Stanford University, T. P. DEVEREAUX, SLAC National Accelerator Laboratory — Resonant inelastic x-ray scattering (RIXS) is a powerful probe for studying excitations in strongly correlated systems. With continued advancements of the technique the overall energy resolution has improved to the point of probing low-energy boson excitations near the elastic line. In this talk we present evidence for coupling to an optical oxygen phonon in the RIXS spectrum at the oxygen K-edge of the quasi-1D edge shared cuprate $Ca_{2+x}Y_{2-x}Cu_5O_{10}$. This mode is identified as a compressive mode polarized perpendicular to the chain direction, modulating the Cu-O charge transfer energy and setting the size exchange interaction. By comparing to small cluster calculations we extract a sizable electron-phonon coupling strength in a site-resolved manner, implying a strong integration of the lattice degrees of freedom into the electronic structure.

Wednesday, March 20, 2013 2:30PM - 5:30PM –

Session R22 DCMP: Plasmonics and Optical Interactions in Structured Materials 324 - Eric Stinaff, Ohio University

2:30PM R22.00001 Optimizing coherent Raman scattering with plasmonic nanoparticles , DMITRI VORONINE, XIA HUA, ALEXANDER SINYUKOV, CHARLES BALLMANN, ALEXEI SOKOLOV, MARLAN SCULLY, Texas A&M University — Two commonly used techniques that provide species-specific spectroscopic signals in the form of vibrational fingerprints are surface-enhanced Raman scattering (SERS) and coherent anti-Stokes Raman scattering (CARS) spectroscopies. In order to enhance the signal, SERS takes advantage of the electromagnetic near-field enhancement while CARS employs molecular coherence. We have combined these two techniques to achieve best-of-both-worlds maximum signal enhancement by using optimized laser pulse shaping and time-resolved detection. We applied this new time-resolved surface-enhanced coherent anti-Stokes Raman scattering (tr-SECARS) technique to investigate various molecular complexes in a vicinity of gold nanoparticles. While large signal enhancement has previously been achieved in SERS, surfaced-enhanced coherent signals have shown lower values. We investigate the mechanisms of these effects by analyzing the spatial dependence of the coherent Raman spectra for different hot spots in aggregated plasmonic nanoparticles. Understanding coherence effects in surface-enhanced Raman scattering may lead to improved nanoscale sensors.

2:42PM R22.00002 Complex metallic nanostructures using self-assembled DNA templates for SERS and plasmonic applications , MAURICIO PILO-PAIS, ANNE WATSON, Duke University, THOM LABEAN, North Carolina State University, GLEB FINKELSTEIN, Duke University — We custom-tune the plasmonic resonance of complex metallic nanostructures based on "DNA origami" templates (∼90x70nm). Briefly, 5 nm gold nanoparticles are attached at selected places within a DNA-origami "nano-breadboard" and later enlarged, and even fused, by electroless deposition of silver. By this method, we are able to control the size and topology, and therefore the plasmonic resonance of the resulting metallic nanostructures. We perform SERS measurements of various Raman molecules (i.e. 4-aminobenzenethiol), which are chosen based on the plasmonic resonance frequency of the structure. The flexibility of the design and multiply parallel nature of the method open the road for designing and fabricating optimum structures for a desired plasmonic application.

2:54PM R22.00003 Enhanced surface Raman scattering in gold thin films deposited on large array anti-nanoring template , CHI CHIH HO, Nanoscience and Technology Program, Taiwan International Graduate Program, Institute of Physics, Academia Sinica, Taipei, Taiwan, TZE YANG LEE, Department of Engineering and System Science, National TsingHua University, Hsinchhu, Taiwan, WEI LI LEE, Institute of Physics, Academia Sinica, Taipei, Taiwan, FAN GANG TSENG, Department of Engineering and System Science, National TsingHua University, Hsinchhu, Taiwan — To evenly distribute hot spots over large area is an important subject for realistic applications using surface enhanced Raman scattering (SERS) effect. Here, we utilized a monolayer polymer/nanosphere hybrid to prepare a large area and well-ordered anti-nanoring template for gold thin film deposition. The resulting gold nanostructured thin film, which comprises an antidot network with isolated nano-disk (ND) and nanoring (NR) in each antidot, can be employed as an efficient SERS substrate. From finite difference time domain (FDTD) simulation, hot spots occur at the space between isolated ND and NR giving rise to enhanced surface Raman scattering. We fabricated a series of such gold nanostructured thin films with different thickness and geometry. An optimum condition for maximum SERS was obtained in experiment. Detailed size effect on SERS and comparison to FDTD simulation will be discussed.

3:06PM R22.00004 Ultraviolet surface-enhanced Raman spectroscopy using aluminum plasmonic gratings , ADAM T. ROBERTS, Army Aviation & Missile RDEC, SERKAN BUTUN, KORAY AYDIN, Dept. of Electrical Engineering & Computer Science, Northwestern University, HENRY O. EVERITT, MARK BLOEMER, Army Aviation & Missile RDEC, GIUSEPPE D'AGUANNO, NADIA MATTIUCCI, Aegis Technologies — Surface-enhanced Raman scattering (SERS) has been widely studied both theoretically and experimentally for chemical and biological sensing, primarily in the visible and near-infrared wavelengths. Although in the ultraviolet (UV) plasmonic behavior is limited by metallic dampening, we have theoretically shown that SERS enhancement factors as large as 10^5 can be achieved when the laser is tuned to the plasmonic band edge of an Al metallic grating grown on a sapphire substrate. Using electron beam lithography, aluminum gratings were fabricated whose pitch (150-300 nm), slit widths (64 nm), and thickness (50 nm) were chosen to produce large enhancement factors at wavelengths in the UV. Analytes such as thiophenol were then deposited on the gratings, and UV-SERS spectroscopy was performed to measure the enhancement factors and compare with theoretical estimates. Enhancement factors were measured by comparing the strength of the Raman signal from the grating region with the strength of the Raman signal from adjacent regions without a grating. The dependence of the enhancement factor on laser wavelength relative to the plasmonic band edge for a given grating pitch was explored, as was the effect of using a tapered slit geometry that focuses the local field on the nanoscale.

3:18PM R22.00005 Surfaced Enhanced Raman Spectroscopy in Nanojunctions with Anomalous Polarization Dependence , JOSEPH B. HERZOG, MARK W. KNIGHT, YAJING LI, KENNY EVANS, NAOMI J. HALAS, DOUGLAS NATELSON, Rice University — Several papers have been published on surfaced enhanced Raman spectroscopy (SERS) in nanojunctions, and polarization studies have shown that the strongest SERS enhancement is generated when the incident light is polarized so that the electric field is directed across the interelectrode nanogap. This polarization dependence is certainly true for mesoscale structures such as dimers, but this works show that this is not always the case. Here we create nanogaps both by electromigration and a novel "self-aligned" process, which can be scaled for mass production. Polarization dependent SERS measurements were performed on these junctions and have determined that transverse polarization of incident light generates the strongest SERS enhancement. Cathodoluminescent experiments as well as finite element method calculations have confirmed these findings and together with the experimental results have determined that the enhancements are due to strong localized hybrid modes in the gap which couple to a resonant transverse plasmon mode. This new finding has increased device sensitivity by an order of magnitude and opens the possibility for improved plasmonically-active optoelectronic devices and other nanophotonic applications.

3:30PM R22.00006 Surface-enhanced Raman detection of a vibrational Stark effect in C60-containing molecular junctions , YAJING LI, Department of Physics and Astronomy, MS 61, Rice University, PETER DOAK, JEFFREY NEATON, Molecular Foundry, Lawrence Berkeley National Laboratory, LEEOR KRONIC, Weizmann Institute of Science, Rehovot, Israel, DOUGLAS NATELSON, Department of Physics and Astronomy, MS 61, Rice University — Understanding the interplay of local electric fields and molecular vibrational degrees of freedom is of considerable interest. One nontrivial consequence of this coupling is the vibrational Stark effect, in which vibrational energies are altered through coupling to externally applied electric fields. We investigate this physics through nanoscale Au bowtie structures functioning as surface enhanced Raman(SERS) substrates. Following electromigration, these metal nanostructures possess nanometer-scale interelectrode gaps that support highly localized surface plasmon resonances, resulting in SERS electromagnetic enhancements sufficient for single-molecule studies. These structures have also proven suitable for simultaneous single-molecule electronic transport experiments, in which we observed the vibrational modes of the molecules shift systematically as a function of applied bias. We will present measurements of the electrically driven vibrational energy shifts of C60 in such junctions and compare those with theoretical expectations obtained from DFT calculations.

3:42PM R22.00007 Fractal nanostructures with Hilbert curve geometry as a SERS substrate , ILYA GRIGORENKO, CityTech, CUNY — A new type of substrates for Surface Enhanced Raman Scattering measurements is proposed. The shape of the substrate is based on self-similar fractal space filling curves, which possess properties of both one dimensional and two dimensional geometries. Here I present theoretical studies of the dielectric response of thin film doped semiconductor nanostructures, where conducting electrons are trapped in an effective potential having the geometry of the Hilbert curve. It is found that the system may exhibit the induced charge distributions specific for either two dimensional or one dimensional systems, depending on the excitation frequency. It is also shown that with the increase of the depth of the trapping potential the resonance of the system demonstrates a counter-intuitive shift to lower frequencies.

3:54PM R22.00008 Exciton-plasmon interaction and photo-injection of plasmonic hot carriers in hybrid nanostructures , ALEXANDER GOVOROV, HUI ZHANG, Ohio University, MIN OUYANG, University of Maryland, College Park, YURII GUN'KO, School of Chemistry, University of Dublin, Trinity College — We investigate theoretically the effects of exciton-plasmon interaction and plasmon-assisted carrier injection in a hybrid semiconductor-metal nanostructure under resonant optical excitation. We treat the coupling between the metal and semiconductor nanocrystals using a many-body Fano model and a quantum density-matrix formalism. Hot carriers have a characteristic energy distribution in the plasmon wave function in a metal nanocrystal and participate in tunnel and ballistic injection currents to the neighboring semiconductor nanostructure. The photo-current induced by hot plasmonic electrons in the nanostructure depends on the barrier height, excitation frequency, plasmon energy, relaxation rates, and geometry of a device. The Coulomb exciton-plasmon interaction may also play an essential role in the optical absorption and electron injection. The results obtained in this study can be used to design and describe a variety of plasmonic nanodevices with hot electron injection for photo-catalysis, light-harvesting, and solar cells.

4:06PM R22.00009 Photoconductance measurments of patterned nanocrystal films on gold nanojunctions , KENNETH EVANS, Applied Physics Ph.D. Program, Rice University, SRAVANI GULLAPALLI, MICHAEL WONG, Department of Chemical and Biomolecular Engineering, Rice University, DOUGLAS NATELSON, Department of Physics & Astronomy, Rice University — Large scale production of nanoscale absorbers and emitters based on single, or few, colloidal nanocrystals would be an important advancement for light-based electronics and investigating poorly understood quantum phenomena such as blinking. We present a method for integrating nanocrystals into plasmonically-active gold nanogaps by way of lithographic patterning of nanocrystal films. Initial photoconductance measurements in nanocrystal-based devices are compared with bare gold junctions and the possibility for plasmon-assisted absorption and emission is discussed.

4:18PM R22.00010 Coherent Oscillations in Spoof-Like Plasmonic Ag deposited by PEALD , RYAN COMPTON, Chemistry Division, Naval Research Laboratory, Washington, DC 20375, USA, NRC Postdoctoral Research Associate, SHARKA M. PROKES, OREST J. GLEMBOCKI, Electronic Science Division, Naval Research Laboratory, Washington, DC 20375, USA, JEFFREY C. OWRUTSKY, Chemistry Division, Naval Research Laboratory, Washington, DC 20375, USA — The spoof-like plasmonic properties of Ag thin films produced by plasma enhanced atomic layer deposition (PEALD) were investigated with static and transient spectroscopy. The PEALD process results in a film with cylindrical 2D structures separated by air gaps, giving rise to the plasmonic behavior. Films with thicknesses ranging from 10 to 32 nm were deposited and compared to films of similar thickness produced with traditional e-beam methods. Transmission spectra of the ALD films exhibit a strong surface plasmon resonance (SPR) band at approximately 700 nm, while the e-beam samples were devoid of band structure. The SPR band of the 10 nm ALD sample is blue-shifted (to 550 nm), suggesting morphological differences for the thinnest film. Transient absorption studies with a 400 nm probe revealed electron-phonon coupling times that are similar for both ALD and e-beam films. Transient measurements of the ALD Ag probed near the plasmon band (800 nm), however, feature coherent oscillations attributed to breathing of the cylindrical structures, whereas the e-beam films exhibit no oscillatory behavior. The oscillation period was found to be independent of ALD thickness, except in the 10 nm sample where no oscillations were observed.

4:30PM R22.00011 Optical analogue of quantum spin and dynamic localization in optical waveguides arrays , KIN CHUNG AU YEUNG, KIN WAH YU, The Chinese University of Hong Kong — We have discovered an optical analogue of quantum spin in optical waveguides arrays. Quantum-optical analogy is recently a hot topic. By using special configuration of optical devices, some optical analogues of quantum systems can be realized. Stefano Longhi and coworkers proposed some classical realization of quantum phenomena like the two-site Fermi-Hubbard system [1] and Rabi oscillation [2]. In this work, we propose an optical waveguides arrays system with evanescent couplings according a symmetrized Kac matrix. The system can mimic the quantum spin under different operators like the rotation operator. Also by adding a suitable time-dependent applied potential to the system, dynamic localization of optical signal can be realized along the signal propagation. The system can be extended to mimic any arbitrary angular momentum by increasing the number of optical waveguides arrays. The occurrences of spin under rotation operator and dynamic localization are simulated by a field-evolution analysis using an input Gaussian beam.

4:42PM R22.00012 Comparison of Active and Passive Approaches for Controlling the Near-Field Optical Path of Guided-Light Wave[1] , DANHONG HUANG, US Air Force Research Lab, MICHELLE EASTER, Hunter College of the City University of New York, DAVID WELLEMS, HENRY MOZER, US Air Force Research Lab, ALEXEI MARADUDIN, University of California-Irvine, GODFREY GUMBS, Hunter College of the City University of New York, DAVE CARDIMONA, US Air Force Research Lab — Both active and passive approaches are proposed and compared for controlling the optical path of p-polarized light wave guided through a surface-patterned metallic structure with sub-wavelength features. For active control, the dynamical role of photo-excited electrons in a slit-embedded atomic system with field-induced transparency (FIT) is demonstrated for modulating transmitted-light intensity in the near-field region. Additionally, the strong coupling between the optical transitions within slit-embedded FIT atoms and the surface-plasmon modes in a metallic slit array is found. For passive control, on the other hand, a geometrical effect is demonstrated for focused transmitted light passing through a Gaussian-shaped metallic lens embedded with an array of slits. This geometrical effect is further accompanied by a swing of the light-focusing pattern in the near-field region as the incident angle is increased, as well as by the reduction of an anomalous light refraction due to higher-order diffraction modes at longer wavelengths and larger incident angles.

4:54PM R22.00013 Gain/loss induced localization in low-dimensional PT-symmetric models[1] , FELIX IZRAILEV, Instituto de Fisica, BUAP, Puebla, Mexico, and NSCL and Dept. of Physics and Astronomy, Michigan State University, USA, OMAR O. VASQUEZ-CANDANEDO, Instituto de Fisica, BUAP, Puebla, Mexico — We show that both loss (absorption) and gain (amplification) can induce the localization of eigenstates in low-dimensional models with PT-symmetric potentials. Main results are obtained for 1D tight-binding models and for bi-layered models widely used in optics. We analyze both closed and open models within a unique approach allowing us to reveal the mechanisms responsible for the onset of localization. Specific attention is paid to the interplay between the localization emerging due to weak disorder and the localization induced by gain and loss. The analytical results are compared with the direct computation of the spectrum and eigenstates (for closed models), as well as of the transport characteristics (for open models). Some of the found effects can be observed experimentally in PT-symmetric photonic devices.

5:06PM R22.00014 Generalizing speed-of-light limitations to arbitrary passive linear media , AARON WELTERS, STEVEN JOHNSON, Department of Mathematics, Massachusetts Institute of Technology — We prove that well-known speed of light restrictions on electromagnetic energy velocity can be extended to a new level of generality, encompassing even nonlocal chiral media in periodic geometries, while at the same time weakening the underlying assumptions to only passivity and linearity of the medium (along with a transparency window, which ensures well-defined energy propagation). Surprisingly, passivity alone is sufficient to guarantee causality and positivity of the energy density (with no thermodynamic assumptions), in contrast to prior work which typically assumed the latter properties. Moreover, our proof is general enough to include a very broad range of material properties, including anisotropy, bianisotropy (chirality), nonlocality, dispersion, periodicity, and even delta functions or similar generalized functions. The results in this talk are proved using deep results from linear-response theory, harmonic analysis, and functional analysis.

5:18PM R22.00015 The curvy photonics of squid camouflage , ALISON SWEENEY, AMANDA HOLT, University of Pennsylvania, MORSE DANIEL, University of California, Santa Barbara, DARIUSZ STRAMSKI, University of California, San Diego, Scripps Institute of Oceanography — Cephalopods (squids and octopuses) ubiquitously possess reflective structures in their skin composed of "reflectin" proteins. Although a few simple laminar, Bragg-stack type optical structures have been known in a handful of common squid species for some time, our extensive survey of optically active tissues of exotic deep-sea species has revealed complex, extended curvatures and topologies in dermal reflectors of these rarely-studied animals. Molecular deep-sequencing has revealed these structures also to be composed of reflectin-like proteins. Here we show a survey of some of these deep-sea reflector structures, and present evidence that each novel structure may be a transform of the radiance in the optical niche in the ocean where each of these species live, such that light reflecting off the sides of these animals in their specific ocean habitat resembles the light that would be transmitted through the animals if they were transparent, from many different viewing angles and possible ocean depths.

Session R23 FIAP: Fractional Quantum Hall Theory II 325 - Michael Manfra, Purdue University

2:30PM R23.00001 Interaction induced Landau level mixing in the fractional quantum Hall regime[1]

, INTI SODEMANN, ALLAN MACDONALD, Department of Physics, University of Texas at Austin — We study Landau Level mixing in parabolic bands perturbatively to second order in the ratio of interaction to cyclotron energy, for the lowest ($N = 0$) and first excited ($N = 1$) Landau levels. The mixing is accounted for by constructing an effective Hamiltonian which includes two body and three body interactions. Our study builds upon two previous treatments [1,2], using as a stepping stone the observation that the effective Hamiltonian is fully determined by the 2 and 3 body problems. For the $N = 0$ problem we provide a compact and transparent derivation of the effective Hamiltonian using first quantization which captures a class of virtual processes omitted in earlier calculations of Landau-level mixing corrected Haldane pseudo-potentials. We will comment on potential application of our results for numerical studies.

2:42PM R23.00002 Can Ohmic contact in quantum Hall systems be considered a voltage probe?[1]

, ARTUR SLOBODENIUK, IVAN LEVKIVSKYI, EUGENE SUKHORUKOV, Department of Theoretical Physics, University of Geneva — Ohmic contacts are crucial elements of mesoscopic systems, which have no clear theoretical description yet. We propose a model of the Ohmic contact with a finite capacitance C attached to a quantum Hall edge channel. It is shown that in contrast to naïve expectations the fluctuations of currents originating at such contact have non-equilibrium statistics. Consequently, the Ohmic contact can be considered a "voltage probe" only for certain values of the system parameters. In particular, the distribution function of outgoing electrons is close to the equilibrium one if the contact's temperature is much larger than $e^2/2\pi C$.

2:54PM R23.00003 Hamiltonian Formulation of the Hydrodynamics with Quantum Anomalies

, GUSTAVO MONTEIRO, ALEXANDER ABANOV, Stony Brook University — The hydrodynamic limit of a charged massless chiral spinor under the presence of gauge field in 3 dimensions is consider in [1]. For this system, global gauge symmetry is anomalous. In order to satisfy the second law of thermodynamics, charge current and entropy flow have to be corrected. We present a Hamiltonian formulation of the relativistic hydrodynamics which accounts for these new terms; extending the analysis done in [2]. In this formulation, the limit when particles become massless can be performed in a straightforward way and it has the advantage of being the natural framework to quantization. We show that the Poisson's structure of the hydrodynamics of ideal relativistic fluid allows for a one-parameter deformation. The value of the parameter is fixed by quantum anomalies present in the underlying theory. This formulation allows for generalizations to hydrodynamics of systems with additional conserved quantities, and is found to be a higher dimensional analogous to quantum hall effect. [1] D.T. Son and P. Surowka, Phys.Rev.Lett. 103, 191601 (2009). [2] D.D. Holm and B.A. Kupershmidt, Phys Lett. 101A, 23 (1984)

3:06PM R23.00004 Quantum Hall viscosity of Hierarchy States

, THORS HANS HANSSON, MIKAEL FREMLING, Stockholm University, JUHA SUORSA, Nordita — We describe a strategy for calculating the odd, non-dissipative viscosity for hierarchical QH states. Using previously developed techniques for expressing the wave functions on the plane in terms of conformal blocks, we can in simple cases construct the corresponding torus wave functions and show that they have good modular properties. Under certain assumptions, the QH viscosity can be directly extracted from these wave functions, and in the simplest case of the $\nu = 2/5$ Jain states, we have verified the result numerically. Our results are consistent with the general formula, given by Read, relating the QH viscosity to the average orbital spin of the electrons.

3:18PM R23.00005 Extracting net current from an upstream neutral mode in the fractional quantum Hall regime

, RON SABO[1], ITAMAR GURMAN[2], MOTY HEIBLUM, VLADIMIR UMANSKY, DIANA MAHALU, Weizmann Institute of Science, HEIBLUM'S GROUP TEAM — Upstream neutral modes, counter propagating to charge modes and carrying energy without net charge, had been predicted to exist in some of the fractional quantum Hall states and were recently observed via noise measurements. Understanding such modes will assist in identifying the wavefunction of these states, as well as shedding light on the role of Coulomb interactions within edge modes. In this work, performed mainly in the 2/3 state, we placed a quantum dot a few micrometers upstream of an ohmic contact, which served as a "neutral modes source." We showed the neutral modes heat the input of the dot, causing a net thermo-electric current to flow through it. Heating of the electrons led to a decay of the neutral mode, manifested in the vanishing of the thermo-electric current at T > 100mK. This setup provides a straightforward method to investigate upstream neutral modes without turning to the more cumbersome noise measurements.

[2]equal contribution

3:30PM R23.00006 Phase diagram of the composite fermion Wigner crystals

, ALEX ARCHER, The Pennsylvania State University, KWON PARK, Korea Institute for Advanced Study, JAINENDRA JAIN, The Pennsylvania State University — The energies of the Wigner crystal (WC) phase and the fractional quantum Hall (FQH) liquid have been compared in the past at some special filling factors. We deduce in this work the phase diagram of the WC phase as a function of the general filling factor by considering: (i) the WC of electrons; (ii) WCs of composite fermions (CFs) carrying $2p$ vortices; and (iii) FQH states supporting WC of CF quasiparticles or CF quasiholes. In particular, we find that the re-entrant insulating phase between 1/5 and 2/9 is a WC of composite fermions carrying two vortices. To distinguish the CF Wigner crystal from the electron WC, we compute a number of properties, including shear modulus, magnetophonon and magnetoplasmon dispersions, and melting temperatures. The width dependence of the phase diagram is also studied. A technical innovation that makes these comparisons feasible is to model the WC as the thermodynamic limit of the Thomson crystal on the surface of a sphere, which minimizes the Coulomb energy of classical charged particles.

3:42PM R23.00007 Hierarchy of fractional Chern insulators and competing compressible states , ANDREAS M. LÄUCHLI, Institut für Theoretische Physik, Universität Innsbruck, A-6020 Innsbruck, Austria, ZHAO LIU, Institute of Physics, Chinese Academy of Sciences, Beijing, 100190, China, EMIL J. BERGHOLTZ, Dahlem Center for Complex Quantum Systems and Institut für Theoretische Physik, Freie Universität Berlin, Arnimallee 14, 14195 Berlin, Germany, RODERICH MOESSNER, Max-Planck-Institut für Physik komplexer Systeme, Nöthnitzer Strasse 38, D-01187 Dresden, Germany — We study the phase diagram of interacting electrons in a dispersionless Chern band as a function of their filling. We find hierarchy multiplets of incompressible states at fillings $\nu = 1/3$, 2/5, 3/7, 4/9, 5/9, 4/7, 3/5 as well as $\nu = 1/5$, 2/7. These are accounted for by an analogy to Haldane pseudopotentials extracted from an analysis of the two-particle problem. Important distinctions to standard fractional quantum Hall physics are striking: absent particle-hole symmetry in a single band, an interaction-induced single-hole dispersion appears, which perturbs and eventually destabilizes incompressible states as ν increases. For this reason the nature of the state at $\nu = 2/3$ is hard to pin down, while $\nu = 5/7$, 4/5 do not seem to be incompressible in our system.

3:54PM R23.00008 Fractional Chern Insulators beyond Laughlin states , CECILE REPELLIN, TIANHAN LIU, Laboratoire Pierre Aigrain, ENS and CNRS, 24 rue Lhomond, 75005 Paris, France, B. ANDREI BERNEVIG, Department of Physics, Princeton University, Princeton, NJ 08544, NICOLAS REGNAULT, Laboratoire Pierre Aigrain, ENS and CNRS, 24 rue Lhomond, 75005 Paris, France and Department of Physics, Princeton University, Princeton, NJ 08544 — We report the first numerical observation of composite fermion (CF) states in fractional Chern insulators (FCI) using exact diagonalization. The ruby lattice Chern insulator model for both fermions and bosons exhibits a clear signature of CF states at filling factors $2/5$ and $3/7$ ($2/3$ and $3/4$ for bosons). The topological properties of these states are studied through several approaches. Quasihole and quasielectron excitations in FCI display similar features as their fractional quantum hall (FQH) counterparts. The entanglement spectrum of FCI groundstates shows an identical fingerprint to its FQH partner. We show that the correspondence between FCI and FQH obeys the emergent symmetry already established, proving the validity of this approach beyond the clustered states. We investigate other Chern insulator models and find similar signatures of CF states. However, some of these systems exhibit strong finite size effects.

4:06PM R23.00009 Crystal-symmetry preserving Wannier states for fractional Chern insulators , CHAO-MING JIAN, XIAO-LIANG QI, Department of Physics, Stanford University — Recently, many numerical evidences of fractional quantum anomalous states (FQAH states), i.e. the fractional quantum Hall states (FQH states) on lattice, when a band with non-zero Chern number (We refer to it as a Chern band) is partially filled. Some trial wavefunction of FQAH states can be obtained by mapping the FQH wavefunctions defined in the continuum onto the lattice through the scheme proposed in Ref. [1] in which the single particle Landau orbits in the Landau levels are mapped to the one dimensional Wannier wavefunctions (which is a plane wave on the other direction) of the Chern bands with Chern number C=1. However, this mapping will generically break the lattice rotational symmetry. In this talk, we shall present a modified scheme to accommodate the mapping with the lattice rotational symmetry. The wavefunctions constructed through this modified scheme should serve as better trial wavefunctions to compare with the numerics. The focus of the talk shall be mainly on the C4 rotational symmetry of square lattices. Related issues on C6 symmetry of honeycomb lattice and higher Chern number bands will be discussed. [1] X.-L. Qi, Phys. Rev. Lett. 107, 126803 (2011)

4:18PM R23.00010 Establishing non-Abelian topological order in Gutzwiller projected Chern insulators via Entanglement Entropy and Modular S-matrix , YI ZHANG, Stanford University, ASHVIN VISHWANATH, University of California, Berkeley — We use entanglement entropy signatures to establish non-Abelian topological order in a new class of ground states, the projected Chern-insulator wave functions. The simplest instance is obtained by Gutzwiller projecting a filled band with Chern number C=2 which may also be viewed as the square of the band insulator Slater determinant. We demonstrate that this wave function is captured by the $SU(2)_2$ Chern Simons theory coupled to fermions. In addition to the expected torus degeneracy and topological entanglement entropy, we also show that the modular S-matrix, extracted from entanglement entropy calculations, provides direct access to the peculiar non-Abelian braiding statistics of Majorana fermions in this state. We also provide microscopic evidence for the generalization (expected from the field theory), that the N^{th} power of a Chern number C Slater determinant realizes the topological order of the $SU(N)_C$ Chern Simons theory coupled to fermions, by studying the $SU(2)_3$ and the $SU(3)_2$ wave functions. An advantage of projected Chern insulator wave functions over lowest Landau level wave functions for the same phases is the relative ease with which physical properties, such as entanglement entropy, can be numerically calculated using Monte Carlo techniques.

4:30PM R23.00011 Galilean invariance and linear response theory for Fractional Quantum Hall Effect[1] , ANDREY GROMOV, ALEXANDRE ABANOV, State University Of New York at Stony Brook — We study a general effective field theory of Galilean invariant two-dimensional charged fluid in external electro-magnetic and gravitational fields. We find that combination of the generalized Galilean [1] and gauge invariance implies nontrivial Ward identities between gravitational and electro-magnetic linear responses in the system. This identity appears to hold in all orders of gradient expansion and it generalizes the relation between Hall viscosity and Hall conductivity recently found by Hoyos and Son. We also check the relation in the case of free electrons with integer filling of Landau levels where corresponding linear responses can be calculated directly.

4:42PM R23.00012 Critical behavior of the transport coefficients at the plateau-insulator transition in IQHE[1] , JUNTAO SONG, EMIL PRODAN, Department of Physics, Yeshiva University, New York, NY 10016 — Using the non-commutative Kubo formula for disordered lattice systems, we mapped the conductivity tensor $\sigma(E_F, T)$ as function of Fermi level E_F and temperature T for the disordered Hofstadter model. Convergence and accuracy tests indicate that the simulations can be used to investigate the critical behavior near the plateau-insulator transition. Our analysis provides the first quantitative theoretical confirmation of the well established experimental facts about the critical behavior: 1) The semicircle law for the components of the conductivity tensor; 2) The existence of the quantized Hall insulator state characterized by zero direct and Hall conductivities, but with Hall resistivity quantized at h/e^2; 3) Single scaling behavior with exponents that are consistent with previous studies.

4:54PM R23.00013 Energy Scales of the Reentrant Integer Quantum Hall States in High Landau Levels , NIANPEI DENG, JOHN WATSON, MICHAEL MANFRA, GABOR CSATHY, Purdue University — The reentrant integer quantum Hall states (RIQHS) have been identified with the electronic bubble phases. These bubble phases are exotic electronic solids similar to the Wigner crystal, but have more than one electron per lattice site. Recently we reported the presence of a peak in the temperature dependent magnetoresistence of the RIQHSs and we have associated this peak with the onset of the RIQHSs. We found that, contrary to the predictions of the bubble theory, the onset temperatures of the RIQHSs in the third Landau level are much higher than those in the second Landau level. We have extended such measurements of the onset temperatures to several high Landau levels. In this talk we will discuss the orbital dependence of the onset temperatures of RIQHSs and we will compare these quantitative results to the predictions of the bubble theory. This work was supported by the DOE BES contract no. DE-SC0006671.

5:06PM R23.00014 Boundary degeneracy of topological order states , JUVEN WANG, XIAO-GANG WEN, MIT/Perimeter Institute — It is known that topological ordered states have degenerate ground states on compact space manifold. Its ground state degeneracy on higher genus Riemann surface is encoded by the fusion rules of the fractionalized quasipartcles and the genus number. Here we study topologically ordered states on space manifold with boundary. We find that Bulk-Edge correspondence is not a complete story - edge theory information may not be fully-determined by the bulk theory. Ground state degeneracy of boundary states depends on boundary gapping conditions. Take Abelian topological order as an example, K matrix Chern-Simons theory, the boundary ground state degeneracy counts the number of group elements in a discrete finite quotient group from anyon transport and fusion algebra. We compare this result to Toric code model, Levin-Wen string-net model and flux insertion argument. By glueing the edges of a non-compact manifold to make it compact, we go back to demonstrate bulk ground state degeneracy from edge theory viewpoint, in terms of the Betti number and homology group, such as 2+1 D Chern-Simons or higher dimensional B-F theory.

5:18PM R23.00015 Monte Carlo Study of a $U(1) \times U(1)$ Loop Model with Modular Invariance[1] , SCOTT GERAEDTS, OLEXEI MOTRUNICH, California Institute of Technology — We study a $U(1) \times U(1)$ system in (2+1)-dimensions with long-range interactions and mutual statistics. The model has the same form after the application of operations from the modular group, a property which we call modular invariance. Using the modular invariance of the model, we propose a possible phase diagram. We obtain a sign-free reformulation of the model and study it in Monte Carlo. This study confirms our proposed phase diagram. We use the modular invariance to analytically determine the current-current correlation functions and conductivities in all the phases in the diagram, as well as at special "fixed" points which are unchanged by an operation from the modular group. We numerically determine the order of the phase transitions, and find segments of second-order transitions. For the statistical interaction parameter $\theta = \pi$, these second-order transitions are evidence of a critical loop phase obtained when both loops are trying to condense simultaneously. We also measure the critical exponents of the second-order transitions.

Session R24 DCOMP: Focus Session: Recent Developments in Density Functional Theory I

326 - David Vanderbilt, Rutgers University

2:30PM R24.00001 Density-functional theory: time to move up?[1] , NICOLA MARZARI, Theory and Simulation of Materials, École Polytechnique Fédérale de Lausanne — Materials' simulations based on density-functional theory (DFT) have become an extremely powerful and widely used tool for scientific discovery and technological advancement. Still, in the current approximations, they remain an imperfect tool for predicting materials' properties, with open and urgent challenges in the quest towards qualitative and quantitative accuracy. Several of these challenges stem from the remnants of self-interaction in the electronic-structure framework, leading to qualitative failures in describing some of the fundamental processes involved e.g. in energy applications - from charge-transfer excitations to photoemission spectra to the structure and reactivity of transition-metal complexes. I'll discuss these challenges in realistic case studies, and present a brief overview of some of our suggestions for possible solutions - including constrained DFT, DFT + onsite and intersite Hubbard terms, and Koopmans' compliant energy functionals. In particular, I'll highlight how Koopmans' compliant functionals point to a beyond-DFT formulation where both total energies and spectroscopic properties can be accounted for. Such framework will be illustrated with applications to real systems and with simplified models that can be solved exactly.

[1]Work done in collaboration with Patrick H-L Sit, Heather Kulik, Damian Scherlis, Matteo Cococcioni, Ismaila Dabo, Andrea Ferretti, Nicolas Poilvert, Cheol-Hwan Park, Giovanni Borghi, and Linh Nguyen.

3:06PM R24.00002 Self-Consistent Density Functional Including Long-Range van der Waals Interactions , NICOLA FERRI, ROBERT A. DISTASIO JR., ROBERTO CAR, MATTHIAS SCHEFFLER, ALEXANDRE TKATCHENKO, Fritz-Haber-Institut der MPG, Berlin, Germany and Princeton University, USA — Van der Waals (vdW) interactions are significant for a wide variety of systems, from noble-gas dimers to organic/inorganic interfaces. The long-range vdW energy is a tiny fraction (0.001%) of the total energy, hence it is typically assumed not to change electronic properties. Although the vdW-DF functional includes the effect of vdW energy on electronic structure [1], the influence of "true" long-range vdW interactions is difficult to assess since a significant part of vdW-DF energy arises from short distances. Here, we present a self-consistent (SC) implementation of the long-range Tkatchenko-Scheffler (TS) functional [2], including its extension to surfaces [3]. The analysis of self-consistency for rare-gas dimers allows us to reconcile two different views on vdW interactions: (i) Feynman's view that claims changes in the electron density and (ii) atoms separated by infinite barrier. In agreement with previous work [1], we find negligible contribution from self-consistency in the structure and stability of vdW-bound complexes. However, a closer look at organic/inorganic interfaces reveals notable modification of energy levels when using the SC-TS vdW density functional. [1] Thonhauser et al., PRB (2007). [2] Tkatchenko and Scheffler, PRL (2009). [3] Ruiz et al., PRL (2012).

3:18PM R24.00003 Efficient Oscillator-Based Approach for Polarizability and van der Waals Interactions , VIVEKANAND GOBRE, Fritz-Haber-Institut der MPG, ROBERT A. DISTASIO, JR., ROBERTO CAR, Princeton University, USA, MATTHIAS SCHEFFLER, ALEXANDRE TKATCHENKO, Fritz-Haber-Institut der MPG — The dynamic polarizability measures the response to an applied time-dependent electric field, and its accurate determination is crucial for van der Waals (vdW) interactions and other response properties. First-principles calculations of polarizabilities in principle require a computationally expensive explicit treatment of many-electron excitations, and are only applicable in practice to systems with less than about 100 atoms. In this work, we present an efficient parameter-free approach for calculating accurate frequency dependent polarizabilities for molecules with thousands of atoms, as well as periodic materials. This is achieved by the synergistic coupling of the Tkatchenko-Scheffler method [1], which accurately treats short-range hybridization effects, with the self-consistent screening equation from classical electrodynamics [2,3]. Using only the electron density and free atom reference, we obtain an accuracy of 7% for both static polarizabilities and vdW coefficients for an extensive database of gas-phase molecules and crystals. We analyze the interplay of hybridization and long-range electrostatic screening effects on the polarizability. [1] Tkatchenko and Scheffler, PRL (2009), [2] Felderhof, Physica (1974), [3] Tkatchenko, DiStasio, Car, and Scheffler, PRL (2012).

3:30PM R24.00004 Range-separated approach to the RPA correlation applied to van der Waals bond and to diffusion of defects , FABIEN BRUNEVAL, CEA — The Random Phase Approximation (RPA) is a promising approximation to the exchange-correlation energy of Density Functional Theory (DFT), since it contains the van der Waals (vdW) interaction and yields a potential with the correct band gap. However, its calculation is computationally very demanding. We apply a range separation concept [1] to RPA and demonstrate how it drastically speeds up the calculations without loss of accuracy. The scheme is succesfully applied to a layered system subjected to weak vdW attraction and to address the controversy of the self-diffusion in silicon [2]. We calculate the formation and migration energies of self-interstitials and vacancies taking into account atomic relaxations. The obtained activation energies deviate significantly from the earlier calculations that were affected by the band gap problem and challenge some of the experimental interpretations [3]: the diffusion of vacancies and interstitials have almost the same activation energy.

3:42PM R24.00005 Performance of Common Density Functional Methods for the N-Body Interaction Energies of Water Clusters , KENNETH JORDAN, FANGFANG WANG, University of Pittsburgh — Using an isomer of $(H_2O)_{16}$, which has been the subject of several earlier studies, we demonstrate that, in contrast to the commonly held view, the N-body expansion of the interaction energy evaluated at the MP2 level does not converge monotonically with increasing N. Moreover, comparison of the results of HF and MP2 calculations reveals that this unexpected behavior is primarily due to electron correlation effects. The results of various common density functionals are considered, and the implications of our results for various procedures for correcting DFT for dispersion will be discussed.

3:54PM R24.00006 Chemi- and Physisorption Together from a Semilocal Density Functional: Graphene on Ni (111) , JIANWEI SUN, BING XIAO, ADRIENN RUZSINSZKY, JOHN PERDEW, Tulane University, JOHN PERDEW TEAM — Conventional semilocal approximations of density functional theory at the level of local spin density approximation (LSDA) and generalized gradient approximations (GGA) are thought to lack the ability to describe weak interactions. This is well illustrated by the system of a graphene adsorbed on a Ni (111) surface, in which the graphene can adsorb on the Ni (111) surface chemically or physically at different distances. LSDA, the standard Perdew-Burke-Ernzerhof (PBE) GGA, and its variant designed for solids, PBEsol, miss the physisorption. We show improved descriptions for weak interactions from a newly-developed semilocal meta-GGA (MGGA)—that performs equally well for molecules, surfaces, and solids—by demonstrating its ability to capture both the chemisorption and the physisorption.

4:06PM R24.00007 A generalized gradient approximation for the Coulomb energy , ALBERTO VELA, JORGE LUIS ROSAS-TRIGUEROS, Department of Chemistry, Cinvestav, SAMUEL B. TRICKEY, QTP, Depts. of Physics and Chemistry, University of Florida, JOSÉ L. GAZQUEZ, Department of Chemistry, UAM-Iztapalapa — In this contribution we generate, implement and fully test expressions for the Coulomb energy without explicit dependence of the electron density at two points in space. These approximate expressions depend solely on the density and its derivatives. The starting point is the implementation and testing of the gradient expansions suggested by Bartolotti and Parr that, to the authors' knowledge, have never been tried in molecules. One of the drawbacks of this approach is that its functional derivative diverges in finite systems. To circumvent this deficiency we will show results for a gradient expansion that incorporates several restrictions, among them to have a finite first functional derivative. Since the functionals are derived imposing some restrictions we call these functionals generalized gradient approximations to the Coulomb energy.

4:18PM R24.00008 Analysis of the large reduced density gradient limit for the exchange energy , JOSE GAZQUEZ, Universidad Autonoma Metropolitana-Iztapalapa, JORGE M. DEL CAMPO, Universidad Nacional Autonoma de Mexico, JUAN PACHECO-KATO, Universidad de Guanajuato, SAM TRICKEY, University of Florida, ALBERTO VELA, Cinvestav — Electronic structure calculations have become very important for the analysis, at the microscopic level, of a wide variety of systems in physics, chemistry and biology. The Kohn-Sham version of density functional theory has played a fundamental role in such development. In particular, the generalized gradient approximation (GGA) has proven to be a very useful tool in electronic structure studies of complex systems, because it leads to a reasonable description of many properties, at a moderate computational effort. However, it is desirable to improve beyond the actual limits of accuracy. In this work we will present an analysis of the GGA in the regions of small and large values of the reduced density gradient. Then, taking as starting point the PBE and RPBE functionals, the large reduced density gradient limit will be incorporated, in order to show that it induces small, but subtle changes that lead to a better description of several molecular properties.

4:30PM R24.00009 Laplacian-based generalized gradient approximations for the exchange energy[1] , A.C. CANCIO, Ball State University, CHRIS E. WAGNER, University of Florida — It is well known that in the gradient expansion approximation to density functional theory (DFT) the gradient and Laplacian of the density make interchangeable contributions to the exchange-correlation (XC) energy. This is an arbitrary "gauge freedom" for building DFT models, normally used to eliminate the Laplacian from the generalized gradient approximation (GGA) level of DFT development. We explore the implications of keeping the Laplacian at this level of DFT, in order to develop a model that fits the known behavior of the XC hole, which can only be described as a system average in a conventional GGA. We generate a family of exchange models that obey the same constraints as conventional GGA's, but which in addition have a finite-valued potential at the atomic nucleus unlike GGA's. These are tested against exact densities and exchange potentials for small atoms and finite jellium drops, and for constraints chosen to reproduce the PBEsol and the APBE variants of the GGA. We find that exchange energies of atoms can be reliably reproduced, by breaking the local (but not global) Lieb-Oxford bound.

[1]Work support by National Science Foundation grant DMR-0812195.

4:42PM R24.00010 An Exchange Energy Functional with a Derivative Discontinuity , RICKARD ARMIENTO, Linkoping University, STEPHAN KUEMMEL, Universitat Bayreuth — We explore a way to impose a derivative discontinuity onto a semi-local energy functional in density functional theory, rather than a model potential. The derivative discontinuity is a property of exact exchange that states that the exchange potential may have a uniform discontinuous shift as the particle number passes through an integer. The lack of this property is a known major deficiency of current approximate semi-local exchange functionals. We obtain a closed form expression with a number of attractive properties that can be related to an improved description of charge transfer, overdelocalized orbital states, and band gaps, i.e., deficiencies that are commonly seen in applied use of DFT. Various tests of the construction are presented that clarify the relationship between these issues and the derivative discontinuity.

4:54PM R24.00011 A Kinetic Energy Functional From the Airy Gas Model , ALEXANDER LINDMAA, Linkoping University, ANN MATTSSON, Sandia National Laboratories, RICKARD ARMIENTO, Linkoping University — We present a density functional for the kinetic energy derived from the Airy gas model, which is a model system for an edge electron gas. Electronic edges are the regions in a system where the electronic density changes to become exponentially decaying, and the electron physics requires special consideration. The Airy model describes an electron gas around the classical turning point, where the electrons interact with a uniform forcefield, i.e., an effective linear potential along one of the spatial coordinates. A formally exact energy density is derived in terms of Airy functions and is parametrized to behave correctly in the Thomas-Fermi and von Weizsäcker limits. In contrast to already existing kinetic energy functionals derived from the Airy gas, starting from a closed-form expression yields greater freedom in the choice of parametrization. Comparative tests between our and previous functionals are presented. Improved kinetic energy functionals are highly relevant in the context of orbital-free DFT (OF-DFT) as well as for applications at very high temperature.

5:06PM R24.00012 Constraint-based, Non-empirical Parameterization of Generalized Gradient Approximation Kinetic Energy Functionals[1] , DEBAJIT CHAKRABORTY, SAMUEL TRICKEY, VALENTIN KARASIEV, Department of Physics & Quantum Theory Project, Univ. of Florida — Though we have developed constraint-based "modified conjoint" generalized gradient approximation forms for the orbital-free Kohn-Sham kinetic energy $T_s[n]$, strategies for parameterizing them without use of small training sets have remained elusive[1]. Here we discuss one possible way to eliminate that empiricism. We take the reparameterized Perdew-Burke-Ernzerhof exchange functional PBEmol [2], which is self-interaction free for the Hydrogen atom density n_1. We then constrain the Pauli-term kinetic energy (T_θ in $T_s = T_W + T_\theta$, with T_W the von Weizsäcker KE) to cancel the remaining spurious correlation energy $T_\theta[n_1] + E_{c,PBEmol}[n_1] = 0$.We bound the functional by $T_W + T_{TF}$, with T_{TF} the Thomas-Fermi KE and retain the original constraint that $T_\theta > 0$. We report numerical results and findings for this procedure.

5:18PM R24.00013 Revised Thomas-Fermi Functional for Singular Potentials[1] , JAMES DUFTY, SAMUEL TRICKEY, Univ. Florida — Approximations to the non-interacting free energy density functional that include the Thomas-Fermi (TF) functional, or a local density approximation, lead to singular densities for singular external potentials (e.g. Coulomb). We address this limitation of the TF approximation by a formal map of the exact functional for a given external potential onto a fictitious TF functional for an effective external potential. The latter functional is found to be a "regularized" version of the external singular potential, tempered by convolution with the finite temperature Lindhard response function. The result is a Thomas-Fermi approximation but with the singularity removed. Applications at high and low temperatures are described, including comparison with the Parr-Ghosh cusp-condition procedure for a non-singular TF density at zero temperature.

Session R25 DCOMP: Focus Session: Computational Studies of Heterostructures 327 - Shiwei Zhang, College of William and Mary

2:30PM R25.00001 Competition of magnetism and Kondo physics in heterostructures , SIMONE CHIESA, College of William and Mary — Heterostructures made of atomically thin strongly correlated materials have been the focus of intense experimental and theoretical study. We report on results obtained using an unbiased numerical technique on a simple model of a metal-magnetic insulator interface: a multilayer system governed by a tight-binding Hamiltonian in which the interaction is nonzero on one set of adjacent planes and zero on another. As the interface hybridization is tuned, magnetic and metallic properties undergo an evolution that reflects the competition between antiferromagnetism and (Kondo) singlet formation, in a scenario similar to that occurring in heavy-fermion materials. Remarkably, for a few-layer system at intermediate hybridization, a Kondo insulating phase results, where magnetic order and conductivity are suppressed in all layers. As more insulating layers are added, magnetic order is restored in all correlated layers except the one at the interface and no evidence of long-range magnetic order induced in the metallic layers is found.

3:06PM R25.00002 Mechanisms of Electronic Reconstruction at Oxide Interfaces with 001 and 111 Orientation , ROSSITZA PENTCHEVA, Ludwig Maximilians University Munich — Remarkably rich electronic behavior has been recently discovered at oxide interfaces ranging from two-dimensional conductivity, superconductivity and magnetism to confinement induced metal-to-insulator transitions. Most of the interest so far has been directed at 001 oriented interfaces as e.g. the ones between the two band insulators $LaAlO_3$ and $SrTiO_3$ or in superlattices containing the correlated metal $LaNiO_3$ and the band insulator $LaAlO_3$. However, 111 oriented superlattices promise to host even more exotic, possibly topological phases. Despite the difference in stacking with AO and BO_2 planes of the perovskite ABO_3 structure in 001 oriented superlattices versus AO_3 and B layers in the 111 crystallographic direction, analogous effects such as polar discontinuity arise in both cases when the A and B cations are varied across the interface. Based on density functional theory calculations we will compare mechanisms of electronic reconstruction in 001 and 111 oriented superlattices. We will thereby focus on the effect of confinement, band filling, magnetic coupling, structural distortions and substrate strain. Work in collaboration with David Doennig and Warren E. Pickett. Funding by the German Science Foundation, SFB/TR80, is gratefully acknowledged.

3:42PM R25.00003 Electronic properties of graphene-MoS2 contacts , BRANDON COOK, Oak Ridge National Laboratory, KALMAN VARGA, Vanderbilt University — Single layer MoS_2 is a two-dimensional semiconductor which has attracted interest due to its electronic and optical properties. However, experimental studies of the material are limited by poor contacts. Graphene, a two-dimensional semimetal, is often touted as an ideal contact material. We investigate graphene-MoS_2 contacts with first-principles calculations. The density functional calculations predict the possibility of good charge injection from graphene to the MoS_2.

3:54PM R25.00004 Density of States and Magnetic Correlations at a Metal-Mott Insulator Interface[1]

, MI JIANG, Physics Department, University of California, Davis, California 95616, USA, GEORGE BATROUNI, INLN, Université de Nice-Sophia Antipolis, CNRS; 1361 route des Lucioles, 06560 Valbonne, France, RICHARD SCALETTAR, Physics Department, University of California, Davis, California 95616, USA — The possibility of novel behavior at interfaces between strongly and weakly correlated materials has come under increased study recently. In this paper, we use determinant Quantum Monte Carlo to determine the inter-penetration of metallic and Mott insulator physics across an interface in the two dimensional Hubbard Hamiltonian. We quantify the behavior of the density of states at the Fermi level and the short and long range antiferromagnetism as functions of the distance from the interface and with different interaction strength, temperature and hopping across the interface. Induced metallic behavior into the insulator is evident over several lattice spacings, whereas antiferromagnetic correlations remain small on the metallic side. At large interface hopping, singlets form between the two boundary layers, shielding the two systems from each other.

4:06PM R25.00005 Numerical simulation study of inhomogeneous metal-semiconductor contact with discrete distribution of varying barrier heights patches

, PRIYANKA KAUSHAL, SUBHASH CHAND, Department of Physics, National Institute of Technology, Hamirpur-177005, (HP) India — The Poisson's equation and the drift diffusion equations were solved by numerical simulation to calculate the potential and electron and hole concentrations inside the bulk semiconductor near the metal-semiconductor contact. The current density was then estimated from the calculated potential and electron-hole concentrations using the continuity equations. The current as a function of bias was calculated by imposing external bias through the boundary condition during the numerical simulation using silicon parameters to obtain the current-voltage characteristics of metal-semiconductor contact. From the simulated current-voltage characteristics the diode parameters were extracted by fitting the current-voltage data into the thermionic emission diffusion current equation. The simulations were performed for the inhomogeneous metal-semiconductor contact having randomly distributed patches of varying barrier heights. The patch size was varied to see its effect of the current-voltage characteristics and the derived apparent barrier parameters. The derived barrier parameters were analyzed to study the effect of inhomogeneities on the current-voltage characteristics on metal-semiconductor contact. The simulations were carried out for discrete distribution of barrier height patches at the metal-semiconductor contact. It is observed that the apparent barrier height of the inhomogeneous contact decreases and ideality factor increases with increasing the deviation of barrier heights in the distribution.

4:18PM R25.00006 ABSTRACT WITHDRAWN –

4:30PM R25.00007 Plasma instability and wave propagation in gate-controlled semiconductor conduction channels

, SERGEY RUDIN, GREG RUPPER, U.S. Army Research Laboratory — The plasma wave in the conduction channel of a semiconductor heterostructure high electron mobility transistor is an electron density excitation, possible at frequencies significantly higher than the cut-off frequency in a short channel device. When the electron-electron collision limited mean free path is much smaller than the wavelength of the density variations, the electron gas in the channel can be treated as a two-dimensional fluid. The flow is described by the Navier-Stokes equation and the heat conduction equation. The quality of the plasma resonance is limited by the electron mobility and the viscosity of the electron fluid. We use the hydrodynamic model derived as the balance equations from the quasi-classical Boltzmann equation, starting with a drifted Fermi-Dirac distribution as a zero order term in the expansion of the distribution function in orders of the Knudsen number. The charge flow can become unstable because of plasma wave amplification at the boundaries. The device then can be used as a tunable source of terahertz range radiation. We show that in such configuration the charge flow also develops shock waves due to hydrodynamic nonlinearities.

4:42PM R25.00008 Investigation of the effect of core/shell interface on exciton binding energy and electron-hole recombination probability in CdSe/ZnS quantum dots

, JENNIFER ELWARD, ARINDAM CHAKRABORTY, Department of Chemistry, Syracuse University — The explicitly correlated configuration interaction (XCCI) method is a variational technique in which an explicitly correlated reference wavefunction is used for performing the CI calculations. This work presents a multi-faceted study of the effect of heterojunction in nanoparticles and detailed analysis of various influential factors. The XCCI method was used for the study and the calculations were performed in three stages. In stage 1, the CdSe core was kept at a fixed size and the ZnS shell thickness was increased. In stage 2, the dot size was kept fixed and volume ratio between the core and the shell was varied. In stage 3, the sharpness of the core/shell interface was investigated by performing calculations on a core/alloy/shell system. Exciton binding energy (EB) and electron-hole recombination probability (eh-RP) were computed and the results were compared with CdSe quantum dots with similar radii. The presence of the heterojunction was found to effect the scaling of EB and eh-RP as a function of dot size. It was also found that EB and eh-RP scale very differently with respect to dot sizes. Expectation value of r_{eh} and radial 2-particle eh-reduced density matrix were used for analysis of spatial distribution of the quasiparticles in the multilayered qdots.

4:54PM R25.00009 Effects of Nonlocal Exact Exchange on Electrons in Core/Shell Nanowires

, BRYAN WONG, Materials Chemistry Department, Sandia National Laboratories, Livermore, California, ANDREW LONG, Department of Materials Science and Engineering, University of Illinois at Urbana Champaign, Urbana, Illinois — The unique properties of semiconducting heterostructure nanowires hold great promise for their incorporation in next-generation transistors, circuits, and nanoscale devices. The reduction in dimensionality produced by confining electrons in these heterostructure nanowires results in a dramatic change in their electronic structure, leading to novel properties such as ballistic transport and conductance quantization. In order to understand the formation of electron gases in core-shell nanowires, we developed a new pseudospectral approach for incorporating many-body, nonlocal exact exchange interactions within a self-consistent Schrodinger-Poisson formalism. Our approach is efficiently implemented in the open-source software package PAMELA (Pseudospectral Analysis Method with Exchange & Local Approximations) that can calculate electronic energies, densities, wavefunctions, and band-bending diagrams. Furthermore, in order to present a general-purpose set of tools that both experimentalists and theorists can easily use to predict electron gas formation in core-shell nanowires, we document and provide our efficient and user-friendly PAMELA source code that is freely available at http://alum.mit.edu/www/usagi.

5:06PM R25.00010 Kondo screening and Magnetism at Interfaces

, AXEL EUVERTE, GEORGE BATROUNI, Institut Non-Linéaire de Nice, SIMONE CHIESA, College William & Mary, RICHARD SCALETTAR, Physics Department, UC Davis — As clean heterostructures synthesis and analysis become experimentally accessible, the question of the nature of magnetic and transport properties at correlated interfaces arise. We study a simple Hubbard model of an interface between a metal and an antiferromagnetic insulator using a finite temperature quantum Monte Carlo method. Focusing on the effect of the hybridization at the interface, we show the singlet formation leads in thin systems to an intermediate non-magnetic insulating phase that involves metallic and correlated layers that are not in direct contact with each other. In thicker heterostructures, magnetic proximity effect of correlated layers farther from the interface defeats the formation of that intermediate phase. The large hybridization case is also discussed, showing decoupling of outer layers from the singlet interface.

5:18PM R25.00011 Engineering three dimensional topological insulator in layered heterostructures , T. DAS, LANL, A.V. BALATSKY, LANL and Nordita. Sweden — We show that three dimensional topological insulator can be designed artificially via staking layers of two-dimensional Fermi gases (2DEGs) with finite inter-layer tunneling. The approach is based on stacking bilayers of Rashba-type spin-orbit coupled 2DEG with opposite spin-orbit coupling on opposite planes of bilayers. Spin Orbit interaction locks electronic states with respective spin projections, i.e.+/-a(k*s) with 'a' is the Rashba-spin-orbit coupling strength, 'k' is the momentum, and 's' is Pauli matrices for spin. We find that in the stack of bilayers grown along (001)-direction, a topological phase transition occurs above a critical number of Rashba-bilayers, with formation of a single spin-polarized Dirac cone at the \Gamma-momentum . This approach offers a path to design artificial topological insulators in a set up that takes full advantage of atomic layer deposition approach, is free from crystal geometry, and is tunable. Work is supported by US DOE and Nordita.

Session R26 GQI: Foundations of Quantum Theory 328 - Caslav Brukner, University of Austria

2:30PM R26.00001 Distinct Quantum States Can Be Compatible with a Single State of Reality[1] , PETER LEWIS, DAVID JENNINGS, Imperial College, London, JONATHAN BARRETT, University of Oxford, TERRY RUDOLPH, Imperial College, London — Perhaps the quantum state represents information available to some agent or experimenter about reality, and not reality directly. This view is attractive because if quantum states represent only information, then wave function collapse is possibly no more mysterious than a Bayesian update of a probability distribution given new data. Several other "puzzling" features of quantum theory also follow naturally given this view. In order to explore this idea rigorously, we consider models for quantum systems with probabilities for measurement outcomes determined by some underlying physical state of the system, where the underlying state is not necessarily described by quantum theory. In our model, quantum states correspond to probability distributions over the underlying states so that the Born rule is recovered. More specifically, we consider models for quantum systems where several quantum states are consistent with a single underlying state–i.e., probability distributions for distinct quantum states overlap. Recent work shows that such a model is impossible (e.g. the PBR theorem (Nat. Phys. 8, p.474)). Significantly, our example demonstrates that non-trivial assumptions (beyond those required for a well-defined realistic model) are necessary for the PBR theorem and those like it.

2:42PM R26.00002 ABSTRACT WITHDRAWN –

2:54PM R26.00003 Our Current Concept of Locality May be Incomplete , ARMIN NIKKHAH SHIRAZI, University of Michigan, Ann Arbor — The predictions of Bell's inequalities, and their subsequent experimental verification in the form of correlations between spacelike separated events have led to the prevailing current view that 'nature is non-local'. Here we examine the possibility that our current concept of locality may at present not be sufficiently differentiated, and that by using 'nature' synonymously with 'spacetime' we may have missed an implication of special relativity which by rendering a more complete conception of locality permits such quantum correlations without either hidden variables or violations of locality.

3:06PM R26.00004 No Drama Quantum Theory? , ANDREY AKHMETELI, LTASolid Inc. — Is it possible to offer a "no drama" quantum theory? Something as simple (in principle) as classical electrodynamics - a theory described by a system of partial differential equations (PDE) in 3+1 dimensions, but reproducing unitary evolution of a quantum field theory in the Fock space? The following results suggest an affirmative answer: 1. The scalar field can be algebraically eliminated from scalar electrodynamics; the resulting equations describe independent evolution of the electromagnetic field (EMF). 2. After introduction of a complex 4-potential (producing the same EMF as the standard real 4-potential), the spinor field can be algebraically eliminated from spinor electrodynamics; the resulting equations describe independent evolution of EMF. 3. The resulting theories for EMF can be embedded into quantum field theories. Another fundamental result: in a general case, the Dirac equation is equivalent to a 4th order PDE for just one component, which can be made real by a gauge transform. Issues related to the Bell theorem are discussed. A. Akhmeteli, Int'l Journal of Quantum Information, Vol. 9, Suppl., 17-26 (2011) A. Akhmeteli, Journal of Mathematical Physics, Vol. 52, 082303 (2011) A. Akhmeteli, quant-ph/1111.4630 A. Akhmeteli, J. Phys.: Conf. Ser., Vol. 361, 012037 (2012)

3:18PM R26.00005 A realist, "local," "hidden variable" model of quantum mechanics without observers , WILLIAM SULIS, McMaster University and University of Waterloo — The violation of Bell type inequalities hinges upon the non-Kolmogorov nature of quantum probability structures. I show that a Process theory based, game theoretic formulation of quantum mechanics admits non-Kolmogorov probability structures. This formulation is realist, discrete and local at the level of space-time events while having nonlocal properties at the process level. These nonlocal effects respect relativistic constraints. Solutions to the Schrodinger equation arise through sinc interpolation of local samples generated by local path integral calculations based upon local information. Nonrelativistic quantum mechanics emerges in the continuum limit with perfect information transfer. This model avoids Kochen-Specker type restrictions and violates Bell and Leggett-Garg type inequalities. This formulation will be illustrated with a model of the classical two slit experiment.

3:30PM R26.00006 Quantized Energy Spectrum of a Linear Classical Harmonic Oscillator in Classical Electromagnetic Zero-Point Radiation[1] , WAYNE HUANG, HERMAN BATELAAN, University of Nebraska-Lincoln — Since the early development of Quantum Mechanics, the discrete atomic spectra have been considered as the defining feature of Quantum Mechanics. However, when the classical electromagnetic zero-point radiation is introduced as a modification to Classical Mechanics, our simulation shows that a linear classical harmonic oscillator, when excited by a laser pulse, can exhibit an integer spaced energy spectrum just as its quantum counterpart. This finding may be surprising given the use of a fully classical theory, and it may help us identify the true quantum features in physical systems such as harmonic oscillator and ultimately atoms.

[1]This work is supported by NSF Grant No. 096950.

3:42PM R26.00007 Normalized spacings between zeros of Riemann zeta function follow normalized Maxwell-Boltzmann distribution , SIAVASH SOHRAB, Northwestern University — Through *Planck* relation $\varepsilon = h\nu$ normalized spacings between energy levels of oscillators are related to those between frequencies expressed as *Gauss* clock calculator or *Hensel* p_j-adic numbers. Energy-level spacings are related to spacings between "stationary states" and through *Euler* golden key to zeros of *Riemann* zeta function. The latter are shown to follow normalized *Maxwell-Boltzmann* (NMB) distribution function,

$$\rho_\beta = (8/\pi_\beta)[(2/\sqrt{\pi_\beta})x_\beta]^2 e^{-[(2/\sqrt{\pi_\beta})x_\beta]^2} \tag{4}$$

, hence providing physical explanations of *Montgomery-Odlyzko* law and *Hilbert-Polya* conjecture. Position of the critical line is found to coincide with that of stationary states. Normalized spacing between eigenvalues of GUE of an *Adele* space constructed by superposition of infinite NMB distribution functions will coincide with spacing of zeros of *Riemann* zeta function according to the theory of noncommutative geometry of *Connes*.

3:54PM R26.00008 Shape Invariance in Deformation Quantization[1] , CONSTANTIN RASINARIU, Columbia College Chicago — Shape invariance is a powerful solvability condition, that allows for complete knowledge of the energy spectrum, and eigenfunctions of a system. After a short introduction into the deformation quantization formalism, this work explores the implications of the supersymmetric quantum mechanics and shape invariance techniques to the phase space formalism. We show that shape invariance induces a new set of relations between the Wigner functions of the system, that allows for their direct calculation, once we know one of them. The simple harmonic oscillator and the Morse potential are presented as examples.

[1]I would like to acknowledge a sabbatical leave and grant from Columbia College Chicago that made this work possible.

4:06PM R26.00009 Entangled states associated with N-qubit GHZ paradoxes , MORDECAI WAEGELL, P.K. ARAVIND, Worcester Polytechnic Institute — Many workers have generalized the original GHZ paradox by replacing the qubits in it by qudits and the three observers by an arbitrary number of observers. We point out that if one stays with qubits but allows an arbitrary number of observers, a large number of paradoxes are possible. Some of the paradoxes come in families that extend upwards to all numbers of qubits. The entangled states connected within these paradoxes come in a wide variety. We survey the different types of entangled states that occur and also discuss some of their applications.

4:18PM R26.00010 Logical difficulty from combining counterfactuals in the GHZ-Bell theorems , LOUIS SICA, Chapman University, Orange, CA — Since it depends on predictions of single sets of measurements on three particles, the Greenberger, Horne, Zeilinger (GHZ) theorem eliminates the sampling loophole encountered by the Bell theorem that requires a large number of observations to obtain a relatively small number of useful joint measurements. In evading this problem, the GHZ theorem is believed to have confirmed Bell's historic conclusion that local hidden variables are inconsistent with the results of quantum mechanics. The GHZ theorem depends on predicting the results of sets of measurements of which only one may be performed, i.e., counterfactuals. In the present paper, the non-commutative aspects of these unperformed measurement sequences are critically examined. Three classical examples and the logic of the GHZ construction are analyzed to demonstrate that combined counterfactual results of non-commuting operations may be logically absurd, and in general are logically inconsistent with performed measurement sequences that take non-commutation into account. The Bell theorem is also revisited in the light of this result. It is concluded that negative conclusions regarding local hidden variables do not follow from the GHZ and Bell theorems as historically reasoned.

4:30PM R26.00011 Observation of a Fast Evolution in a Parity-time-symmetric System[1] , CHAO ZHENG, LIANG HAO, GUI LU LONG, Tsinghua University — In the parity-time-symmetric (PT-symmetric) Hamiltonian theory, the optimal evolution time can be reduced drastically and can even be zero. In this letter, we report our experimental simulation of the fast evolution of a PT-symmetric Hamiltonian in a nuclear magnetic resonance quantum system. The experimental results demonstrate that the PT-symmetric Hamiltonian system can indeed evolve much faster than the quantum system, and the evolution time can be arbitrarily close to zero.

[1]China National Natural Science Foundation

4:42PM R26.00012 Second law of thermodynamics for random walk of quantum particle inapresence ofdetectors , IVAN SADOVSKYY, Materials Science Division, Argonne National Laboratory, Argonne, Illinois 60439, USA, GORDEY LESOVIK, L.D. Landau Institute for Theoretical Physics RAS, 117940 Moscow, Russia — We test H-theorem for a several models of particle random walk. We study interaction with a reservoir/detectors and its influence on entropy and found entropy growing in the time for some models and behaving non-monotonically for the others. We discuss the details of the system-reservoir interaction (such as presence of the interference in the system and number of interactions with detector parts) and their impact on the monotonicity of entropy.

4:54PM R26.00013 Analogy between optical interferometry and integer factorization inspires novel mathematical results , GABRIEL SEIDEN, Weizmann Institute of Science — Prime factorization of integers is an outstanding problem in arithmetic with important consequences in a variety of fields, most notably cryptography. We explore the intriguing relationship between prime factorization and optical interferometry with the aim of obtaining novel analytic expressions for number-theoretic functions directly related to prime factorization [1]. [1] G. Seiden, Phys. Rev. A 85, 043842 (2012)

5:06PM R26.00014 Glimpses of the quantal algebra in early papers on quantum mechanics , SAMIR LIPOVACA, None — A closer reading of early papers on quantum mechanics reveals that the quantal algebra lies hidden beneath the surface. We will show from the standpoint of the quantal algebra that, in essence, Heisenberg came across the symmetric product of the quantal algebra in his remarkable 1925 paper, Born and Jordan limited a general Hamiltonian function to a linear form of the terms containing the symmetric product of the quantal algebra, and Dirac found that the most general operation d/dv is the Leibnitz identity of the quantal algebra.

Wednesday, March 20, 2013 2:30PM - 5:30PM –

Session R27 GQI: Focus Session: Quantum Error Correction and Decoherence Control II 329 - Andrew Landahl, Sandia National Laboratories

2:30PM R27.00001 Magic state distillation with low overhead , SERGEY BRAVYI, IBM Watson Research Center — Most of error correcting codes used in fault-tolerant quantum computing permit an efficient implementation of high-fidelity encoded Clifford gates and Pauli measurements. On the other hand, implementation of encoded non-Clifford gates such as the $\pi/8$-rotation T usually requires distillation of certain quantum software states known as "magic states" and substantially increases the space and time overheads. To reduce the distillation overhead we propose a new family of stabilizer codes with an encoding rate $1/3$ that permit a transversal implementation of the T-gate on all logical qubits. The new codes are used to construct protocols for distilling high-quality magic states by Clifford group gates and Pauli measurements. The distillation overhead scales as $O(\log^{\gamma}(1/\epsilon))$, where ϵ is the output accuracy and $\gamma = \log_2(3) \approx 1.6$. Our techniques lead to a two-fold overhead reduction for distilling magic states with accuracy $\epsilon \sim 10^{-12}$ compared with the best previously known protocol.

3:06PM R27.00002 Multilevel distillation of magic states for quantum computing , CODY JONES, Stanford University — We develop a procedure for distilling magic states used in universal quantum computing which requires substantially fewer resources than prior schemes. Our distillation circuit is based on a family of concatenated quantum codes with a transversal Hadamard operation which can distill the eigenstate of the Hadamard operator. A crucial result of this design is that low-fidelity magic states can be consumed to purify high-fidelity magic states to even higher fidelity, which we call "multilevel distillation." We show numerically that there exist multilevel protocols such that the average number of magic states consumed to distill from error rate $\epsilon_{\text{in}} = 0.01$ to ϵ_{out} in the range 10^{-5} to 10^{-40} is about $14\log_{10}(1/\epsilon_{\text{out}}) - 40$; the efficiency of multilevel distillation dominates all other reported protocols when distilling Hadamard magic states from initial infidelity 0.01 to any final infidelity below 10^{-7}. These methods are an important advance for magic-state distillation circuits in high-performance quantum computing.

3:18PM R27.00003 ABSTRACT WITHDRAWN –

3:30PM R27.00004 Direct-to-Toffoli Magic-state Distillation , BRYAN EASTIN, Northrop Grumman Corporation — In recently proposed quantum computing architectures, approximately 90% of the required resources are consumed during the distillation of single-qubit magic-states for use in performing Toffoli gates. In this talk I describe how the overhead for magic-state distillation can be reduced by merging distillation with the implementation of Toffoli gates. The resulting routines distill single-qubit magic-states directly to Toffoli ancillae, each of which can be used without further magic to perform a Toffoli gate.

3:42PM R27.00005 Magic state distillation protocols with noisy Clifford gates[1] , PETER BROOKS, California Institute of Technology — A promising approach to universal fault-tolerant quantum computation is to implement the non-universal group of Clifford gates, and to achieve universality by adding the ability to prepare high-fidelity copies of certain "magic states". By applying state distillation protocols, many noisy copies of a magic state ancilla can be purified into a smaller number of clean copies which are arbitrarily close to the perfect state, using only Clifford operations. In practice, the Clifford gates themselves will be noisy, which can limit the efficiency of state distillation and put a floor on the achievable fidelity with the desired state. Recently, a number of new state distillation protocols have been proposed that have the potential to reduce the required resource overhead. I analyze these protocols and explore the tradeoffs between these different approaches to magic state distillation when noisy Clifford gates are taken into account.

3:54PM R27.00006 Simulating Anyon Interference to Measure the Levin-Wen Plaquette Operator , WEIBO FENG, N.E. BONESTEEL, Department of Physics and NHMFL, Florida State University, DAVID DIVINCENZO, Forschungszentrum Juelich & RWTH Aachen — It may be possible to use the ground states of the Levin-Wen model for Fibonacci anyons as a non-Abelian surface code for fault-tolerant quantum computation [1]. To do this, it will be necessary to repeatedly measure the vertex and plaquette operators of the model to check for errors. Recently, two of us have constructed quantum circuits for performing such measurements [2]. Here we present an alternate measurement scheme based on simulating an interference experiment. This "experiment" can be thought of, roughly, as first inserting a pair of Fibonacci anyons with trivial total topological charge onto one edge of a plaquette, "braiding" one anyon all the way around the plaquette while the other remains fixed, and then either measuring the total topological charge of the two anyons or manipulating their state in a specific way. We construct explicit quantum circuits which can be used to simulate these processes and show how they can be used to measure the Levin-Wen plaquette operator on a quantum computer.

4:06PM R27.00007 Optimal control in presence of decoherence and measurement imperfections: Pure state preparation problem , ALIREZA SHABANI, University of California, Berkeley — Quantum control is a key component in the mathematical toolbox for designing fault-tolerant quantum processors. It becomes important to find optimal control protocols for realistic experimental conditions. In this talk, I focus on quantum feedback control for preparing pure states as ideal resources for quantum computation and communication. I discuss how the optimal protocols under experimental imperfections can be different from the ones found under theoretical simplifications. The problem of our study is motivated by superconducting circuit QED proposals for quantum computation.

4:42PM R27.00008 Surface code with decoherence: An analysis of three superconducting architectures[1] , JOYDIP GHOSH, University of Georgia, AUSTIN G. FOWLER, The University of Melbourne, MICHAEL R. GELLER, University of Georgia — We consider a realistic, multi-parameter error model and develop a methodology to connect logical error rates of a surface code architecture with single qubit coherence time (T1 or T2) for any realistic set of intrinsic parameters, such as state preparation, gate, and readout errors. The amplitude and phase damping are mapped to a diagonal Pauli "depolarization" channel via the Pauli twirl approximation. Three existing superconducting architectures are chosen and a numerical Monte Carlo simulation is performed to obtain the logical error rates. A leading order analytic model is also constructed that estimates the scaling behavior of logical error rates below threshold for small distances. Our results suggest that large-scale fault-tolerant quantum computation should be possible with existing state-of-the-art superconducting devices.

4:54PM R27.00009 Surface Code Threshold in the Presence of Correlated Errors[1] , EDUARDO NOVAIS, Universidade Federal do ABC (Brazil), EDUARDO MUCCIOLO, Uniiversity of Central Florida — We study the fidelity of the surface code in the presence of correlated errors induced by the coupling of physical qubits to a bosonic environment. By mapping the time evolution of the system after one quantum error correction cycle onto a statistical spin model, we show that the existence of an error threshold is related to the appearance of an order-disorder phase transition in the statistical model in the thermodynamic limit. This allows us to relate the error threshold to bath parameters and to the spatial range of the correlated errors.

[1]E.N. was partially supported by INCT-IQ and CNPq (Brazil) and E.M. was supported in part by ONR and NSF (USA).

5:06PM R27.00010 Surface code fidelity decay in the presence of a bosonic bath , PEJMAN JOUZDANI, EDUARDO MUCCIOLO, University of Central Florida, EDUARDO NOVAIS, Universidade Federal do ABC (Brazil) — The surface code is a promising quantum computing environment that provides topological protection against errors, ensuring that the distance of the code grows as the physical sizes of the system increases. It has been recently proposed that a surface code in contact with a bosonic bath experiences an effective evolution that induces an constrained Ising-like interaction between qubits. As the coupling to the bosonic bath increases, the system may undergo a transition where the fidelity decays substantially after one quantum error correction cycle even for non-error syndromes. We investigate the manifestation of such a transition by evaluating numerically the fidelity of a surface code qubit system with the proposed Ising interaction. We carry out exact calculations for small systems and perform a finite-size scaling analysis using a cluster mean-field approach. We find a significant change in the fidelity at coupling constant values compatible with the mean-field transition point. Calculations performed with complex coupling constants yield the same behavior for the fidelity.

5:18PM R27.00011 Fast decoder for local quantum codes using Groebner basis[1] , JEONGWAN HAAH, California Institute of Technology — Based on arXiv:1204.1063. A local translation-invariant quantum code has a description in terms of Laurent polynomials. As an application of this observation, we present a fast decoding algorithm for translation-invariant local quantum codes in *any* spatial dimensions using the straightforward division algorithm for multivariate polynomials. The running time is $O(n \log n)$ on average, or $O(n^2 \log n)$ on worst cases, where n is the number of physical qubits. The algorithm improves a subroutine of the renormalization-group decoder by Bravyi and Haah (arXiv:1112.3252) in the translation-invariant case.

Session R28 GSNP: Interfaces 336 - Mark Robbins, Johns Hopkins University

2:30PM R28.00001 Creep and stress relaxation induced by interface diffusion in metal matrix composites[1] , YINFENG LI, ZHONGHUA LI, Shanghai Jiao Tong University — An analytical solution is developed to predict the creep rate induced by interface diffusion in unidirectional fiber-reinforced and particle reinforced composites. The driving force for the interface diffusion is the normal stress acting on the interface, which is obtained from rigorous Eshelby inclusion theory. The closed-form solution is an explicit function of the applied stress, volume fraction and radius of the fiber, as well as the modulus ratio between the fiber and the matrix. It is interesting that the solution is formally similar to that of Coble creep in polycrystalline materials. For the application of the present solution in the realistic composites, the scale effect is taken into account by finite element analysis based on a unit cell. Based on the solution, a closed-form solution is also given as a description of stress relaxation induced by interfacial diffusion under constant strain. In addition, the analytical solution for the interface stress presented in this study gives some insight into the relationship between the interface diffusion and interface slip.

2:42PM R28.00002 De-lamination and Pro-lamination of adhesive films on curved topographies , BENNY DAVIDOVITCH, EVAN HOHLFELD, UMass Amherst — Attaching a solid film onto a sphere (or other curved shape) generates elastic stresses in the film. If the spherical substrate is totally rigid, the film will delaminate when its area exceeds a small fraction of the curved substrate. In contrast, if the substrate is very soft (such as a liquid drop), it will deform beneath the film, suppressing stresses and avoiding delamination of the film. Our theoretical analysis predicts that for very thin films, another scenario emerges - the film remains attached, developing tiny wrinkles that allow relaxation of stress without macro-scale deformation of the spherical shape of the substrate. Furthermore - as the film gets thinner, this predicted "pro-lamination" effect prevails parameter space, and should be observed for substrates with practically arbitrary stiffness.

2:54PM R28.00003 Elastomer-glass detachment front observation , JOSÉ BICO, PMMH - ESPCI, SUOMI PONCE, PMMH - ESPCI / UPMC, BENOIT ROMAN, CNRS / PMMH - ESPCI — When you peel an elastomeric band from a glass plate, the force needed changes with respect to the peeling angle and it is proportional to the width of the band [1]. As you approach to a zero angle, the process changes abruptly. Here we present the experimental study of a lap-test made on PVS elastomer and glass. We propose a simple imaging technique to observe the detachment front propagation.

[1] K. Kendall, "Thin-film peeling - the elastic term" Journal of Physics D : Applied Physics, vol. 8, p. 1449, Sep 1975.

3:06PM R28.00004 Stick-slip during the peeling of adhesive tape , MARIE-JULIE DALBE, STEPHANE SANTUCCI, Laboratoire de Physique, Ecole Normale Superieure de Lyon, LOIC VANEL, LPMCN, CNRS UMR 5586, PIERRE-PHILIPPE CORTET, Laboratoire FAST, CNRS UMR 7608 — Using a high-speed camera, we study the instable peeling dynamics of an adhesive tape pulled at an imposed controlled velocity - focusing on the stick-slip regime of the peeling. Thanks to high-resolution fast camera, we can observe directly the peeling point motion and thus quantify the details of the stick and slip phases. To study properly the influence of peeling angle on stick-slip dynamics, we have developed an original experimental set-up where we are able to control the peeling angle while peeling the adhesive from a plane substrate. In this geometry, we extracted the stick and slip periods and studied their evolution with the peeling speed V, the length between the detachment zone and the peeling motor L, and the peeling angle θ. We observe that the stick and slip periods increase non-linearly with L. We report various regimes depending on V, with periods of Stick and Slip either independent or proportional to V. These experiments confirmed that the physics of adhesive peeling is strongly dependent on θ, especially in the Stick-Slip regime. This general feature questions the correct fracture criterion to consider at the peeling point in order to model the Stick-Slip adhesive peeling.

3:18PM R28.00005 Crack propagation on curved surfaces , MELISSA FENDER, University of Chicago, VINZENZ KONING, VINCENZO VITELLI, Leiden University, WILLIAM T.M. IRVINE, University of Chicago — We investigate the propagation of cracks on curved surfaces. Using a stretched elastic sheet situated at a fluid interface, we generate a surface with spatially varying curvature and observe the trajectory and dynamics of an induced crack. We interpret the results from our experiments using a combination of numerical simulation and analytical considerations.

3:30PM R28.00006 Static and dynamic friction in sliding colloidal monolayers[1] , ANDREA VANOSSI, CNR-IOM Democritos and SISSA, Trieste, Italy, NICOLA MANINI, Dipartimento di Fisica, Universita' di Milano, Italy, ERIO TOSATTI, SISSA, CNR-IOM Democritos and ICTP, Trieste, Italy — In a recent experimental breakthrough, the controlled sliding of 2D colloidal crystals over perfectly regular, laser generated periodic or quasi-periodic 'corrugation' potentials has been realized in Bechinger's group [1]. Based on realistic MD simulations which reproduce the main experimentally observed features, we explore the potential impact of colloid monolayer sliding in nanotribology [2]. The free motion of edge-spawned kinks and antikinks in smooth incommensurate sliding is contrasted with the kink-antikink pair nucleation at the large static friction threshold in the commensurate case. The Aubry pinning/depinning transition is also demonstrated, e.g., as a function of the corrugation amplitude. Simulated sliding data allow the extraction of frictional work directly from particles coordinates and velocities as a function of classic friction parameters, primarily speed, and corrugation strength. Analogies with sliding charge-density waves, driven Josephson systems, sliding of rare gas islands, and other novel features suggest further experiments and insights, which promote colloid sliding to a novel friction study instrument [3]. 3:42PM R28.00007 Contact mechanics of rough spheres[1] , LARS PASTEWKA, MARK ROBBINS, Department of Physics and Astronomy, Johns Hopkins University, Baltimore, MD 21218 — We use large scale numerical calculations to study the contact mechanics of rough spheres on flat elastic solids. Such geometries are encountered in systems that range from ball bearings to atomic force microscope tips, but the influence of roughness is seldom considered explicitly. Our calculations show that the contact area A grows linearly with load N at small loads and crosses over to Hertzian behavior $A \propto N^{2/3}$ at large loads. The total contact stiffness is defined as $K = dN/dz$ where z is the normal displacement of the sphere. It shows power-law $K \propto N^{\alpha}$ behavior at all loads with an exponent α that is close to the value of $1/3$ expected from Hertzian contact mechanics. The results are discussed in the context of recent theories for flat rough contacts [1] and Greenwood-Williams theory as modified for spherical contacts [2].

3:54PM R28.00008 Effects of atomic-scale geometry in contact of rough surfaces[1] , TRISTAN A. SHARP, LARS PASTEWKA, MARK O. ROBBINS, Johns Hopkins University — There has been great recent progress in continuum models of the effect of roughness on the area, friction, and stiffness of contacts between two solids. This talk will use molecular dynamics simulations to study how atomic scale features on surfaces can affect contact properties. Beginning from the established case of continuum linear elasticity that gives a linear relationship between real contact area and load, we systematically introduce atomic-scale physics to determine the affects on contact. Replacing an ideal linear isotropic elastic medium with a harmonic atomic lattice produces only small changes in the mechanical response. For more realistic interactions, anharmonicity and plasticity typically increase the contact area. The atomic steps present on rough crystal lattices lead to increased plasticity and change the small scale structure of contacts. Depending on the tendency for the material to yield, the presence of steps can increase or decrease the area of very high pressure, but steps always decrease the area of very low pressures. The large scale structure of the contact is the same for all cases. Application of continuum contact theories to surfaces with atomic-scale features will be discussed.

4:06PM R28.00009 Brittle Fracture In Disordered Media: A Unified Theory[1] , ASHIVNI SHEKHAWAT, Cornell University, STEFANO ZAPPERI, Consiglio Nazionale delle Ricerche-IENI, Via R. Cozzi 53, 20125 Milano, Italy, JAMES SETHNA, Cornell University — We present a unified theory of fracture in disordered brittle media that reconciles apparently conflicting results reported in the literature, as well as several experiments on materials ranging from granite to bones. Our renormalization group based approach yields a phase diagram in which the percolation fixed point, expected for infinite disorder, is unstable for finite disorder and flows to a zero-disorder nucleation-type fixed point, thus showing that fracture has mixed first order and continuous character. In a region of intermediate disorder and finite system sizes, we predict a crossover with mean-field avalanche scaling. We discuss intriguing connections to other phenomena where critical scaling is only observed in finite size systems and disappears in the thermodynamic limit. We present a numerical validation of our theoretical results.

4:18PM R28.00010 Molecular dynamics simulation investigations of atomic-scale wear , YUCHONG SHAO, MICHAEL FALK, Johns Hopkins University — Frictional running-in and material transfer in wear take place at the micro- and nano-scale but the fundamental physics remain poorly understood. Here we intend to investigate wear and running-in phenomena in silicon based materials, which are widely utilized in micro/nano electromechanical systems(MEMS/NEMS). We use an atomic force microscopy (AFM) model composed of a crystalline silicon tip and substrate coated with native oxide layers. Molecular dynamics simulation has been performed over a range of temperatures, external loads and slip rates. Results show that adhesive wear takes place across the interface in an atom-by-atom fashion which remodels the tip leading to a final steady state. We quantify the rate of material transfer as a function of the coverage of non-bridging oxygen (NBO) atoms, which has a pronounced change of the system's tribological and wear behaviors. A constitutive rate and state model is proposed to predict the evolution of frictional strength and wear. This work is supported by the National Science Foundation under Award No. 0926111.

4:30PM R28.00011 Elastic instabilities in perfect crystals: from planar dislocation-like modes to diffuse buckling-like modes , AKANKSHA GARG, ASAD HASAN, CRAIG MALONEY, CMU — We perform atomistic computer simulations of a model two dimensional perfect hexagonal crystal subjected to nano-indentation loading. For most crystallographic orientations, we find agreement with previous results for the case where the nearest-neighbor direction was perpendicular to the loading axis (cond-mat/1205.1700). In these orientations, the unstable mode takes the form of a sharply localized pair of atomic planes that slide relative to each other and form what is essentially a dipole of edge dislocations. The pair separation scales with the thickness of the film, L, and radius of the nanoindenter, R, in a non-trivial way that is independent of crystallographic orientation. For some crystallographic orientations with high surface energy, such as when the nearest-neighbor direction is co-incident with the loading axis, we find a new failure mode that emerges for very flat indenters and competes with the dislocation-like mode. The new diffuse failure mode is reminiscent of a buckling instability with a predominantly transverse character but exhibits both a nontrivial spatial extent and dominant wavelength that both depend on L and R.

4:42PM R28.00012 Defect mechanics in crystalline packings of spherical caps[1] , AMIR AZADI, Department of Physics, University of Massachusetts, Amherst, GREGORY M. GRASON, Department of Polymer Science and Engineering, University of Massachusetts, Amherst — Topological defects are ubiquitous in 2D curved crystals. We study the structural features and underlying principals of dislocation mechanics in a crystalline spherical cap. Using nonlinear elasticity, we show that frustration arising from the curvature drives the stability of finite length radial grain boundaries in the ground-state packing. For sufficiently large caps at intermediate Gaussian curvature, linear arrays of dislocations relieve the geometric stresses. The number and length of grain boundaries grows with both the curvature and the size of crystalline patch. We also determine the elastic response of the system subject to radial tension. The interplay between the geometrically induced stresses and the tension leads to inhomogeneous stresses that determines the stability of the grain boundaries. The imposed tension stretching the curved crystal radially destabilizes the curvature-induced compressive zone and decrease the length of the grain boundaries. We characterize the transition from a polycrystalline structure to the perfect packing where all dislocations will be expelled at a critical tension that depends on the system size and the curvature. We find scaling laws for the number and length of minimal configurations of grain boundaries.

4:54PM R28.00013 Stick-slip nanofriction in cold-ion traps[1] , DAVIDE MANDELLI, SISSA, Trieste, Italy, ANDREA VANOSSI, CNR-IOM Democritos, SISSA, Trieste, Italy, ERIO TOSATTI, ICTP, CNR-IOM Democritos, SISSA, Trieste, Italy — Trapped cold ions are known to form linear or planar zigzag chains, helices or clusters depending on trapping conditions. They may be forced to slide over a laser induced corrugated potential, a mimick of sliding friction [1,2]. We present MD simulations of an incommensurate 101 ions chain sliding subject to an external electric field. As expected with increasing corrugation, we observe the transition from a smooth-sliding, highly lubric regime to a strongly dissipative stick-slip regime. Owing to inhomogeneity the dynamics shows features reminiscent of macroscopic frictional behaviors [3]. While the chain extremities are pinned, the incommensurate central part is initially free to slide. The onset of global sliding is preceded by precursor events consisting of partial slips of chain portions further from the center. We also look for frictional anomalies expected for the chain sliding across the linear-zigzag structural phase transition. Although the chain is too short for a proper critical behavior, the sliding friction displays a frank rise near the transition, due to opening of a new dissipative channel via excitations of transverse modes.

5:06PM R28.00014 Electronic friction at the atomic scale: Conduction, electrostatic and magnetic effects[1] , JACQUELINE KRIM, North Carolina State University — We have performed a magnetic probe microscopy study of levitation and atomic-scale friction for Fe on YBCO (Tc = 92.5K) in the temperature range 65 - 293 K, to explore electronic contributions to friction at the atomic scale. The samples were prepared with oxygen-depleted surfaces, with thin semiconducting surface layers present atop the bulk. Below Tc, the friction coefficient was observed to be constant at 0.19 and exhibited no correlation with the strength of superconducting levitation forces observed below Tc. The friction coefficient exhibited a change in slope within experimental error of Tc that increased progressively above Tc and reached 0.33 by room temperature. The results were analyzed within the context of underlying atomic-scale electronic and phononic mechanisms that give rise to friction we conclude that contact electrification and static electricity play a significant role above Tc.

5:18PM R28.00015 A hydrodynamic study of corner flow with leakage to orient dilute suspensions of ellipsoids[1] , JONATHAN BAUER, ERIC FURST, University of Delaware — The macroscopic characteristics of thin films are related to the microscale arrangement of the underlying particles. Directing the assembly of anisotropic colloids through the use of external fields, such as flow fields, can lead to materials with novel catalytic, transport, and optical properties. Such fields are used to bias particle orientation in solution before deposition onto a solid substrate. Corner flow with leakage, akin to the doctor blade used in the pulp and paper industry, is a solution-based, processing technique that has been used to create nanostructured materials. We present an analysis that describes how dilute suspensions of ellipsoids couple to this field. A Lagrangian and Eulerian perspective is necessary to identify regions with not only a high straining component but also a sufficient time scale for alignment. Trajectories that lie completely within these "hot spots" result in a distribution in which greater than 80% of the particles have an angle less than 20° with respect to the flow direction. Our results can be used to describe previously reported trends of particle orientation in literature. Overall, our work gives a broader understanding of some of the difficulties associated with using flow fields to fully align ellipsoids in dilute suspensions

Session R29 GSNP: Granular Materials: Phases, Flow, and Rheology 337 - Mark Shattuck, City College of New York

2:30PM R29.00001 Study on a 2D system of granular particles under a cyclic shear , DOYCHO KARAGYOZOV, ABIGAIL POLIN, JOHN ROYER, PAUL CHAIKIN, New York University — Recent computer simulations of granular material under cyclic shear revealed an interesting phase diagram with ordered and disordered spatial and/or temporal patterns. The transition from reversible to irreversible dynamics in systems of many interacting particles is of a fundamental importance to many-body physics. To investigate these effects experimentally we built a two dimensional version where mono-disperse and poly-disperse disks are periodically driven in a parallelepiped shear cell. We track the particle dynamics and measure local packing changes as a function of shear amplitude and find diffusive behavior, localization of motion, reversibility, and macroscopic and microscopic limit cycles.

2:42PM R29.00002 Avalanche Statistics in a Rotating Drum.[1] , ALINE HUBARD, ZHUSONG LI, MARK SHATTUCK, Levich Institue and Physics Department of the City College of New York, and the Graduate Center of CUNY — We perform experiments in a quasi-two dimensional rotating drum. Two glass plates separated by about one particle diameter confine mono-disperse stainless-steel spheres to a cylindrical region. We rotate the system about the cylinder axis, which is perpendicular to gravity. Using high speed video up to 1000 fps we measure the particle positions during very slow rotation in which the flow is dominated by discrete avalanche events. We measure the avalanche size, duration, and time evolution (shape) for up to 10^5avalanches and compare with DEM simulation and a mean field theory that predicts avalanche shape and a power-law distributions of size and duration.

2:54PM R29.00003 Granular gases of rodlike grains in micro-gravity experiments[1] , KIRSTEN HARTH, KATHRIN MAY, TORSTEN TRITTEL, SANDRA WEGNER, RALF STANNARIUS, Otto-von-Guericke University Magdeburg, Institute of Experimental Physics, Universitätsplatz 2, 39106 Magdeburg — Understanding the dynamics of granular materials is relevant both in fundamental physics and from the technological point of view, but many well-known phenomena are still insufficiently understood. Granular gases are dilute ensembles of macroscopic grains, interacting by inelastic collisions. Permanent energy supply is required to maintain dynamic equilibrium. Granular gases of spherical grains have been widely investigated theoretically and in experiments in 2 dimensions. Microgravity is necessary for maintaining such a gas in 3 dimensions (3D). Only dynamics in the Knudsen-regime and clustering instabilities were accessible in previous experiments. Our experiment with rodlike grains offers access to statistical dynamics in the rod-rod collision dominated regime as well as the oppotunity to measure the rotational degrees of freedom of the particles. We present recent results from sounding rocket and drop-tower experiments. Ensembles of rods are confined in a 3D container, monitored by video cameras. Individual rods are tracked in consecutive frames. We analyse spatial and temporal density fluctuations, translational and rotational velocity distributions, the partition of kinetic energy and the influence of different experimental parameters.

3:06PM R29.00004 Critical Phase Transitions in Vibrated Granular Media , GEERT WORTEL, Leiden University, OLIVIER DAUCHOT, ESPCI ParisTech, MARTIN VAN HECKE, Leiden University — Granular media, such as sand, jam under low stresses but yield and flow when stressed sufficiently. We present experiments that uncover that weak vibrations qualitatively modify the nature of this yielding transition from 1st to 2nd order: when the vibration strength, which plays a role similar to temperature, is raised sufficiently, the yielding transition becomes continuous. At the critical point, we find diverging fluctuations, growing timescales and the emergence of a length scale: hallmarks of criticality never seen before in sand.

3:18PM R29.00005 Collision Dynamics of Levitated Granular Clusters , JUSTIN BURTON, PETER LU, SIDNEY NAGEL, University of Chicago — In a granular gas, inelastic collisions cause an initially homogeneous density of particles to evolve into discrete clusters consisting of many particles [1,2]. Further evolution of the system results from the collisions of particles within the clusters and from collisions between the separate clusters. In all of these regimes, however, experimental data is nearly non-existent due to the difficulty of creating a free gas of particles in a terrestrial environment. Here we report experiments of $\sim$ 200 particles moving on a two-dimensional, 90 x 90 cm, anodized aluminum plate. Our particles are composed of solid CO_2 disks with diameter $\sim$ 1.0 cm. When placed on a heated flat surface, the disks float on a cushion of sublimated gas, so that they move essentially without friction. The experiment is filmed from above so that particle velocities can be tracked. Our analysis from the collision of two clusters of particles reveals a sharp decrease in the total kinetic energy, which is weakly dependent on the restitution coefficient, and different velocity distributions parallel and perpendicular to the direction of impact.

3:30PM R29.00006 The relationship between mechanically stable packings of frictional particles and low-dimensional saddle points of frictionless particles , TIANQI SHEN, Department of Physics, Yale University, COREY O'HERN, Department of Mechanical Engineering and Materials Science, Yale University, MARK SHATTUCK, Benjamin Levich Institute and Department of Physics, City College of New York of the City University of New York — We perform computational studies of static packings of bidisperse frictionless and frictional disks. We show that there is a one-to-one correspondence between highly probable mechanically stable packings of frictional disks and low-dimensional saddle points for hard frictionless disks. To show this, we enumerate static packings of frictionless disks with one less contact than that required for mechanical stability $N_c = N_c^{\rm iso} - 1$. We find that the collection of these states forms lines in configuration space that emanate from the mechanically stable packings. Saddles with two missing contacts form branches that emanate from the one-missing-contact lines, and so on. For each saddle point, we calculate the minimum static friction coefficient $\mu_{\rm min}$ required to make each one mechanically stable. These studies allow us to calculate the allowed mechanically stable packings of frictional particles using MS packings of frictionless particles as a reference.

3:42PM R29.00007 Extensional Rheology of Granular Staples[1] , SCOTT FRANKLIN, Rochester Institute of Technology — Collections of U-shaped granular materials (e.g. staples) show a surprising resistance to being pulled apart. We conduct extensional stress-strain experiments on staple piles with vary arm/spine (barb) ratio. The elongation is not smooth, with the pile growing in bursts, reminiscent of intruder motion through ordinary and rod-like granular materials. The force-distance curve shows a power-law scaling, consistent with previous intruder experiments. Surprisingly, there is significant plastic creep of the pile as particles rearrange slightly in response to the increasing force. There is a broad distribution of yield forces that does not seem to evolve as the pile lengthens, suggesting that each yield event is independent of the pile's history. The distribution of yield forces can be interpreted in the context of a Weibullian weakest-link theory that predicts the maximum pile strength to decrease sharply with increasing pile length. From this interpretation arise length and force scales that may be used to characterize the sample.

3:54PM R29.00008 Particle jamming in the gap between a blade and boundary in a granular mixer , CARL WASSGREN, SHRIKANT SWAMINATHAN, Purdue University, JENNIFER CURTIS, University of Florida, BRUNO HANCOCK, BILL KETTERHAGEN, Pfizer, Inc. — The jamming of particles between the blade of a vertical axis mixer and a cylindrical container wall is examined. A single particle model is developed to understand the factors influencing jamming and experiments are performed to investigate jamming as a function of the mixing blade rotational speed, fill height, and gap width. For the range of angular speeds investigated, the rate at which jamming occurs is independent of the blade speed. The jamming rate is proportional to fill height for level fill heights less than twice the blade height, but remains constant for larger heights. This trend is the result of the blade not being completely covered by the particles for level fill heights less than approximately two blade heights due to the deformation of the surface during operation of the mixer. Jamming is a more complex function of the gap width. For gap widths less than a critical distance, which is a function of the particle-boundary friction coefficient as predicted by the single particle model, no jamming occurs. At the critical width, the rate of jamming increases abruptly to its maximum value. Increasing the gap width further decreases the jamming rate until at a gap width of approximately five particle diameters the jamming rate is zero.

4:06PM R29.00009 Orientation Effects for Ellipses Flowing in a 2D Hopper[1] , JUNYAO TANG, ROBERT BEHRINGER, Duke University, Physics Department — Hopper flow of disks has been extensively studied in the past decades. In this work, we investigate how ellipses (aspect ratio = 2) flow in a hopper. This study address the fact that many real-word examples of granular materials have ellipsoidal shapes. We use a quasi-two-dimensional hopper system with photoelastic ellipses so we can obtain stress/force information during the flow. Through synchronized data of particle tracking and stress, we can quantify the orientation of the force networks relative to the orientation of ellipses. The analysis shows that the ellipses which form the force chains have a strong orientation preference, particularly for force chains that form across the opening of the hopper and cause a jam. More generally, the relative orientation of ellipses plays an important role in controlling the flow rheology of ellipses.

4:18PM R29.00010 Hopper Flow: Experiments and Simulation[1] , ZHUSONG LI, MARK SHATTUCK, CUNY Graduate Center and the Benjamin Levich Institute and Physics Department of The City College of New York — Jamming and intermittent granular flow are important problems in industry, and the vertical hopper is a canonical example. Clogging of granular hoppers account for significant losses across many industries. We use realistic DEM simulations of gravity driven flow in a hopper to examine flow and jamming of 2D disks and compare with identical companion experiments. We use experimental data to validate simulation parameters and the form of the inter particle force law. We measure and compare flow rate, emptying times, jamming statistics, and flow fields as a function of opening angle and opening size in both experiment and simulations.

4:30PM R29.00011 Clogging in hopper flow and the kinetics of jamming , CHARLES THOMAS, DOUGLAS DURIAN, University of Pennsylvania — Understanding the time evolution of a system from an unjammed to a jammed state is a significant and open problem. The clogging of granular materials during hopper discharge is a quintessential example of a system undergoing such a process. When a hopper has a small opening, grains exit until a stable arch forms at the opening and a jamming front propagates up through the system. Conversely, hoppers with large enough openings do not clog. We define the clogging transition as the boundary in parameter space between those systems which can clog and those which will never clog. We have established experimental techniques for locating the clogging transition and describing the grain-scale behavior in hopper flow. We use these methods to study the approach to the clogging transition for a quasi-2D hopper. By tracking particle positions with a high-speed camera, we measure time-averaged velocity fields as well as velocity fluctuations. We have previously shown that systems which can clog exhibit elevated velocity fluctuations. We currently investigate the correlations between velocity fluctuations throughout the hopper as well as the size of dynamical heterogeneties as further promising grain-scale signatures of the approach to the clogging transition and of the kinetics of jamming.

4:42PM R29.00012 Jamming to Clogging Transitions for Systems with Obstacle Arrays , CHARLES REICHHARDT, CYNTHIA REICHHARDT, Los Alamos National Laboratory, ZOHAR NUSSINOV, Washington University — Jamming can occur in systems consisting of collections of particles when the response of the system changes from a fluidlike state that can easily flow to a state that acts like a solid. For a loose collection of grains, jamming can occur as a function of density, where the grains readily flow at low densities but with increasing density undergo a transition to a jammed state at point J. Liu and Nagel have proposed that there may be a universal jamming phase diagram as a function of density, load, or temperature that may also include the glass transition. Here we propose that the density of fixed obstacles or quenched disorder can be considered as a new axis for the jamming phase diagram, since the disorder causes the system to jam at densities below point J. For a small number of obstacles, the system exhibits jamming behavior; however, for higher disorder density, there is a crossover to a behavior that we term clogging rather than jamming since the stuck states are highly heterogeneous, fragile, and exhibit memory effects. Our results imply that clogging is a distinct phenomenon from jamming with very different behaviors. These results are of relevance for particle flow in porous media, depinning transitions, and jamming in crowded environments.

4:54PM R29.00013 Dynamic Jamming in Granular Polymers , LENA LOPATINA, CYNTHIA REICHHARDT, CHARLES REICHHARDT, Los Alamos National Laboratory — We present an extensive study of jamming behavior of two-dimensional granular polymers. In previous work, we showed that the nature of the jamming in granular polymer systems has pronounced differences from the jamming behavior observed for bidisperse two-dimensional disk systems at point J [1,2]. We found that the jamming density decreases with increasing length of the granular chain due to the formation of loop structures, in excellent agreement with experiments [3]. Now we present the response of the granular polymers to shear. At low densities, the system unjams independently of boundary conditions or shear rate. At high densities, for a slip wall the system develops plug flow with velocity equal to shear rate, while for a non-slip wall, the system develops a shear band and finite stress. We show that the stress asymptotes to a value that increases with increasing density and decreases with increasing shear rate. The latter is attributed to shear band changes from wide and migrating at low load to very narrow and localized at high load. [1] C. J. Olson Reichhardt and L. M. Lopatina, Science 326 (5951), 374 (2009). [2] L. M. Lopatina, C. J. Olson Reichhardt, and C. Reichhardt, Phys. Rev. E 84, 011303 (2011). [3] L.-N. Zou et al, Science 326 (5951), 408 (2009).

Session R31 DMP DPOLY DBIO: Focus Session: Assembly & Function of Biomimetic & Bioinspired Materials II 339 - Mark Stevens, Sandia National Laboratories

2:30PM R31.00001 Self-assembly of elastin-like polypeptides diblocks into micelles of various morphologies , WAFA HASSOUNEH, Department of Biomedical Engineering, Duke University, Durham, NC, EKATERINA ZHULINA, Institute of Macromolecular Compounds, Russian Academy of Sciences, St. Petersburg, Russia, MICHAEL RUBINSTEIN, Department of Chemistry, University of North Carolina, Chapel hill, NC, ASHUTOSH CHILKOTI, Department of Biomedical Engineering, Duke University, Durham, NC — Elastin-like polypeptides (ELPs) are a promising class of biopolymers for biomedical applications such as drug delivery. These biopolymers are composed of the pentapeptide repeat VPGXG, where X is any amino acid except proline. ELP diblocks, each block of which contains a different X residue composition, self-assemble into spherical micelles for certain lengths and ratios of hydrophobic and hydrophilic blocks. Our objective is to study morphological transitions, from spherical to cylindrical to lamellar structures, for the ELP diblock system by examining a wider range of diblock ratios and lengths. We employ a model that derives the phase boundaries of spherical-to-cylindrical and cylindrical-to-lamellar by balancing the corona elastic energy, the core elastic energy and the surface tension between the core and corona. Theoretical predictions from the model are compared with experimental results by independently measuring 1) surface tension at the core-corona interface and 2) second virial coefficient of the hydrophilic block monomer-monomer interaction. We report the measurements of these parameters and the initial comparison of experimental and theoretical phase boundaries for the ELP diblock system.

2:42PM R31.00002 Design of biomimetic super-lubricants by hydrogel-biopolymer aggregates , RAYMOND SEEKELL, RACHEL DEVER, YINGXI ZHU, University of Notre Dame — Inspired by the superb lubricity of natural synovial fluids for moving articular cartilage joints, we investigate a biomimetic artificial lubricant based on a hydrogel-biopolymer mixture with optimized rheological properties at a microscopic level. Specifically, we examine the structure and rheological relationship of stimuli-responsive poly (N-isopropylacrylamide) (PNIPAM) hydrogel added with hyaluronic acid (HA) to simulate the complexes of HA with a globule protein, lubricin, which are credited as the two key lubricious constituents in natural synovial fluids. By combined microscopic structural characterization and rheology measurement, we tune the rheological and frictional behaviors of HA solutions by optimizing the content of added micron-sized PNIPAM hydrogel particles to form stable PNIPAM-HA network. In a recent work on using zwitterionic hydrogel particles instead of negatively charged PNIPAM, comparable structure and rheological properties of hydrogel-HA aggregates are observed, which may give insight to design new biocompatible lubricants and lubricious coatings for medical ramification.

2:54PM R31.00003 Forming Self-rotating Pinwheels from Assemblies of Oscillating Gels , DEBABRATA DEB, University of Pittsburgh, Pittsburgh, PRATYUSH DAYAL, Indian Institute of Technology Gandhinagar, OLGA KUKSENOK, ANNA C. BALAZS, University of Pittsburgh, Pittsburgh — By using computational modeling, we show that millimeter-sized polymer gels undergoing the self-oscillating Belousov-Zhabotinsky (BZ) reaction not only respond to a chemical signal from the surrounding solution, but also emit this signal and thus, multiple neighboring gel pieces can spontaneously self-aggregate into macroscopic objects. We also show that the gels' coordinated motion can be regulated by light, allowing us to achieve selective self-aggregation and control over the shape of the gel aggregates, as well as reconfiguration of the entire structure. We find that the aggregated gel pieces can rotate as a unit. For example, four millimeter-sized gels can associate into a structure that resembles a pinwheel and then undergo spontaneous, autonomous rotation. With eight gel pieces, the system can form two pinwheels, which communicate and coordinate their motion. Notably, this communication can be controlled with light. In particular, light can be used to translate the pinwheels and to control the relative rotation of two such clusters. These findings reveal a new route for creating dynamically reconfigurable materials using self-oscillating BZ gels where reconfiguration is achieved by using auto-chemotatic behavior of the gels, and also applying external light.

3:06PM R31.00004 Repairable, nanostructured biomimetic hydrogels[1] , M. FIRESTONE, LANL, S. BROMBOSZ, S. GRUBJESIC, ANL — Proteins facilitate many key cellular processes, including signal recognition and energy transduction. The ability to harness this evolutionarily-optimized functionality could lead to the development of protein-based systems useful for advancing alternative energy storage and conversion. The future of protein-based, however, requires the development of materials that will stabilize, order and control the activity of the proteins. Recently we have developed a synthetic approach for the preparation of a durable biomimetic chemical hydrogel that can be reversibly swollen in water. The matrix has proven ideal for the stable encapsulation of both water- and membrane-soluble proteins. The material is composed of an aqueous dispersion of a diacrylate end-derivatized PEO-PPO-PEO macromer, a saturated phospholipid and a zwitterionic co-surfactant that self-assembles into a nanostructured physical gel at room temperature as determined by X-ray scattering. The addition of a water soluble PEGDA co-monomer and photoinitator does not alter the self-assembled structure and UV irradiation serves to crosslink the acrylate end groups on the macromer with the PEGDA forming a network within the aqueous domains as determined by FT-IR. More recently we have begun to incorporate reversible crosslinks employing Diels-Alder chemistry, allowing for the extraction and replacement of inactive proteins. The ability to replenish the materials with active, non-denatured forms of protein is an important step in advancing these materials for use in nanostructured devices

3:18PM R31.00005 Morphogenesis in Belousov-Zhabotinsky microdroplets[1] , NING LI, NATHAN TOMPKINS, CAMILLE GIRABAWE, IRVING EPSTEIN, SETH FRADEN, Brandeis University, BRANDEIS/MRSEC TEAM — We present experimental evidence for the six cases Alan Turing predicted using linear stability analysis in his 1952 paper "The chemical basis of morphogenesis" in our reaction diffusion system. Our experimental system consists of a microfluidically generated microemulsion consisting of Ru(bipy)3 catalyzed light sensitive BZ aqueous droplets which are diffusively coupled through oil gaps. We observed that some droplets grow and others shrink due to the unequal consumption of chemicals in the droplets which leads to an osmotic pressure change, as Turing predicted in his paper. The initial and boundary conditions of our system were controlled by programmable illumination via the light sensitive catalyst Ru(bipy)3. Simulation and linear stability analysis were performed and compared with the experiments.

3:30PM R31.00006 Dynamic Elasticity Model of Resilin Biopolymers , XIAO HU, SOLOMON DUKI, Department of Physics and Astronomy, Rowan University, Glassboro, NJ 08028, USA — Resilin proteins are 'super elastic rubbers' in the flight and jumping systems of most insects, and can extend and retract millions of times. Natural resilin exhibits high resilience ($> 95\%$) under high-frequency conditions, and could be stretched to over 300% of its original length with a low elastic modulus of 0.1-3 MPa. However, insight into the underlying molecular mechanisms responsible for resilin elasticity remains undefined. We report on the dynamic structure transitions and functions of full length resilin from fruit fly (D. melanogaster CG15920) and its different functional domains. A dynamic computational model is proposed to explain the super elasticity and energy conversion mechanisms of resilin, providing important insight into structure-function relationships for resilins, as well as other elastomeric proteins. A strong beta-turn transition was experimentally identified in the full length resilin and its non-elastic domains (Exon III). Changes in periodic long-range order were demonstrated during this transition, induced either by thermal or mechanical inputs, to confirm the universality of proposed mechanism. Further, this model offers new options for designing protein-based biopolymers with tunable material applications.

3:42PM R31.00007 Stretching silk-elastin-like peptide polymers induces nucleation of amyloid nanofibers: Mechanistic study using time-lapse lateral force microscopy[1] , NITINUN VARONGCHAYAKUL, Department of Materials Science and Engineering, University of Maryland, College Park, MD, USA, TRINA QUABILI, SARA JOHNSON, Fischell Department of Bioengineering, University of Maryland, College Park, MD, USA, JOONIL SEOG, Department of Materials Science and Engineering, University of Maryland, College Park, MD, USA — We studied the nucleation mechanism of silk-elastin-like peptide (SELP) nanofibers using lateral force microscopy. When a single line was repeatedly scanned on SELP coated mica surface, a sudden height increase was observed, indicating that the nucleus of amyloid fiber was formed during lateral scanning. The detailed analysis of frictional force profiles revealed that increase of frictional force was followed by a nucleus formation. The profile of increased frictional force was well fitted with exponential function, suggesting that AFM tip stretches multiple SELP molecules to the scanning direction. The probability of nucleus formation was highly dependent on the maximum level of increased frictional force, implying that the highly stretched SELPs are more likely to form nucleus for nanofiber growth.

3:54PM R31.00008 Biopolymer networks in cells[1] , DAVID WEITZ, Dept. of Physics & SEAS, Harvard University — This talk will discuss the role of biopolymer networks in cells. We probe their properties through measurements of fluctuating motions of particles within the cell. These motions have many similarities to thermal motion and, in fact, are often misinterpreted in the context of passive microrheology. Here, we demonstrate that the motion is, instead, driven by the presence of molecular motors within the cell, and we show how this motion can be interpreted quantitatively to determine the nature of the fluctuating forces in the cell due to the molecular motors.

4:30PM R31.00009 Mechanisms and Dynamics of Collagen Assembly[1] , JINHUI TAO, RAYMOND FRIDDLE, DEBIN WANG, JIM DE YOREO, Lawrence Berkeley National Laboratory — Collagen is the major structural protein of bone, dentine and it template the nucleation of biomineral phases. Both collagen conformation and architecture on substrate are critical for its function. We studied the mechanism of collagen I assembly on mica by in-situ AFM. At acidic condition, assembled architecture evolved from random fibers to co-aligned fibers and finally to bundles as the K^+ concentration increased from 100 to 300mM. XPS and NEXAFS showed the concentration of K^+ within the collagen layer increased and the intensity of absorption peak due to π^*(C=O) resonance decreased with higher K^+ concentration. The magnitude of collagen-mica (C-M) and collagen-collagen (C-C) interactions were measured by dynamic force spectroscopy. The free energy ΔG_b for C-M and C-C at 200mM K^+ were 13.7kT and 1.4kT, while ΔG_b at 300mM K^+ were 5.7kT and 12.3kT, respectively. The switch from co-aligned fibers to 3D bundles is driven by the reversal in the magnitude of C-C and C-M interactions. Our results indicate K^+ complex with C=O of collagen and its effect on the strength of collagen-collagen bridging is the likely source of architecture control.

[1]Authors would like to acknowledge grant no. DK61673 from the National Institutes of Health. Theoretical analysis was supported by Office of Science, Office of Basic Energy Sciences of the U.S. Department of Energy under Contract no. DE-AC02-05CH1123.

4:42PM R31.00010 Atomistic modeling of bio-based polymeric fibers , IN-CHUL YEH, B. CHRISTOPHER RINDERSPACHER, JAN W. ANDZELM, Macromolecular Science and Technology Branch, U.S. Army Research Laboratory, LASHONDA T. CURETON, JOHN LA SCALA, Coatings, Corrosion, and Engineered Polymers Branch, U.S. Army Research Laboratory — We performed molecular dynamics simulations on the amorphous phase of two bio-based polymers, poly (butylene furanamide) and poly (hexamethylene furanamide). Simulations of corresponding petroleum-based polymers, nylon 4, 6 and nylon 6, 6, were also performed. Glass transition temperatures estimated from a series of simulations were in good agreement with experimental measurements. Stress-strain relationships under uniaxial deformation were also analyzed. Bio-based polymers show higher glass transition temperatures and comparable yield points despite having overall weaker hydrogen bonds compared with their counterparts nylons. This result suggests that the furan ring plays an important role in the thermodynamic and mechanical properties of bio-based polymers.

4:54PM R31.00011 Structural Properties of Silk Electro-Gels[1] , A.P. TABATABAI, J.S. URBACH, D.L. BLAIR, Department of Physics, Georgetown University, D.L. KAPLAN, Department of Biomedical Engineering, Tufts University — The interest in *Bombyx Mori* silk emerges from its biocompatibility and its structural superiority to synthetic polymers. Our particular interest lies in understanding the capabilities of silk electro-gels because of their reversibility and tunable adhesion. We create an electro-gel by applying a DC electric potential across a reconstituted silk fibroin solution derived directly from *Bombyx Mori* cocoons. This process leads to the intermolecular self-assembly of fibroin proteins into a weak gel. In this talk we will present our results on the effects of applied shear on electro-gels. We quantify the structural properties while dynamically imaging shear induced fiber formation; known as fibrillogenesis. It is observed that the mechanical properties and microstructure of these materials are highly dependent on shear history. We will also discuss the role of surface modification, through micro-patterning, on the observed gel structure. Our results provide an understanding of both the viscoelastiticity and microstucture of reconstituted silks that are being utilized as tissue scaffolds.

5:18PM R31.00013 DFT-based prediction of geometric and thermodynamic parameters in the ATP to ADP hydrolysis reaction , MARK C. PALENIK, JORGE H. RODRIGUEZ, Department of Physics, Purdue University — Studying covalent (chemical) and noncovalent (physical) mechanisms as well as key structural variations associated with ATP $\rightarrow$ ADP hydrolysis is of interest for understanding a multitude of biophysical and biochemical cellular processes. We have studied geometric variations of the ATP and ADP molecules during their hydrolysis reaction using density functional theory (DFT) with an implicit solvation model. We have computed the change in free energy, ΔG, associated with the hydrolysis reaction and established relationships between key geometric parameters and thermodynamic properties. Our computed values for ΔG were found in good agreement with available experimental data for two different sets of geometric conformations. A link is suggested between these values for ΔG and changes in geometry of the ADP molecule. Of methodological and computational interest, we also determined that, while the conductor-like solvation model in the framework of the polarizable continuum model (C-PCM) was capable of producing biochemically meaningful geometries for ATP and ADP, it also displayed a strong preference for binding between the H^+ and PO_4^{2-} ions formed during hydrolysis.

Session R32 DPOLY: Focus Session: Polymer Liquids and Glasses 340 - Rodney Priestley, Princeton University

2:30PM R32.00001 Scattering and Physical Aging in High-Free-Volume Polymeric Glasses[1] , AMANDA G. MCDERMOTT, Pennsylvania State University, PETER M. BUDD, University of Manchester, NEIL B. MCKEOWN, Cardiff University, CORAY M. COLINA, JAMES RUNT, Pennsylvania State University — Polymers of intrinsic microporosity (PIMs) form glassy, rigid membranes featuring a large concentration of pores smaller than 1 nm, large internal surface area, and high gas permeability and selectivity. Porosity in these materials—equivalent to free volume—arises from an unusual chain structure combining rigid segments with sites of contortion. Like other glasses, PIMs are subject to physical aging, which reduces the permeability of films over time. Although it is possible to derive useful information such as surface areas and pore sizes from the scattering patterns of many porous materials, scattering from PIMs includes some unusual features. A robust interpretation of these features is presented with support from molecular dynamics simulations. The sensitivity of PIM SAXS/WAXS patterns to time, temperature and film thickness is shown to be qualitatively consistent with physical aging. Models for extracting quantitative information about changes in the sizes and volume fraction of pores are also discussed.

[1]Supported by NSF

2:42PM R32.00002 Stress Applied during Vitrification Influencing the Subsequent Physical Aging of Polymer Glasses , LAURA A.G. GRAY, CONNIE B. ROTH, Dept. of Physics, Emory University — How stress and mechanical deformation impart mobility to glasses is an active area of study across a range of glassy systems from polymers and small molecules, to colloids and granular materials. Conceptual frameworks such as the jamming phase diagram have been proposed to investigate if stress acts as another independent variable similar to temperature and density (volume fraction). Existing studies have focused primarily on applying stress or strain to a glassy state that has been formed stress free. Here, we investigate the stability of polymer glasses when stress is applied during the formation of the glassy state. We have constructed a jig to apply a known stress to free-standing polymer films during the thermal quench. Ellipsometry is used to measure the physical aging rate of these stress-quenched polystyrene films transferred onto silicon wafers by quantifying the time-dependent decrease in thickness that results from an increase in average density during aging. We observe a transition to a faster aging rate for stresses applied above a critical threshold. We hypothesize that increased stresses may trap the glassy state into higher, less stable potential energy minima resulting in faster aging rates.

2:54PM R32.00003 Quench, equilibration, and subaging in structural glasses , JOERG ROTTLER, University of British Columbia, MYA WARREN, University of California, San Diego — In the glassy state, structural relaxations become increasingly sluggish with the wait time t_w since vitrification. While most theoretical models of aging predict that the relaxation times t_α should increase linearly with the wait time, results from both experiments and simulations are frequently better described by a sublinear scaling: $t_\alpha \sim t_w^\mu$, with an aging exponent $\mu < 1$. We show with molecular dynamics simulations of a Lennard-Jones glass former at various temperatures that this apparent "subaging" behavior may be explained by crossover effects from the freshly quenched state at short t_w, and into the equilibrated state at long t_w. Additionally, the aging behavior on the molecular level is quantitatively reproduced by a coarse-grained continuous time random walk description over the entire range of temperatures and wait times. Since this model is formally equivalent to the well known trap model of aging, this suggests that the Lennard-Jones glass belongs to the "full" aging class $t_\alpha \sim t_w$.

3:06PM R32.00004 Dynamics and thermodynamics of polymer glasses , DANIELE CANGIALOSI, CSIC — The dynamics and thermodynamics of glass-forming systems have been the subject of intense research in the last decades. Among the variety of aspects that have been analyzed, the following can be included: i) the dramatic slowing down of the dynamics when decreasing temperature often described by a Vogel-Fulcher-Tammann (VFT) law; ii) the possible connection between such slowing down and the thermodynamics of the glass-former. These aspects have been deeply investigated above the laboratory glass transition temperature (T_g). It has been speculated that mere extrapolation of the dynamics and thermodynamics to low temperatures produces a singularity at a finite temperature. In particular, extrapolating the behavior above T_g to low temperatures would imply that: (i) the relaxation time associated to the glassy dynamics shows a divergence; (ii) the entropy of the glass equals that of the crystal. Experimental as well as theoretical efforts in the sub-T_g regime are required to clarify whether this scenario really exists. Recent experimental studies indicate deviations of the relaxation time from the VFT behavior to a milder temperature dependence [1,2] and several theoretical approaches provide a rationale to such deviations [3-7]. In this contribution the temperature range of dynamics and thermodynamics is extended to temperatures as low as T_g-40 K by performing enthalpy recovery experiments on glassy polymers for times up to 10^7-10^8 seconds. We find a single stage recovery behavior for temperatures larger than about T_g-10 K. Interestingly, a double stage recovery is observed for $T < T_g-$ 10 K. In all cases the enthalpy recovered after the two-stage decay approximately equals that extrapolated from the melt. Time-temperature superposition close to each plateau in the enthalpy delivers shift factors containing information on the dynamics below T_g. The following scenario emerges analyzing the temperature dependence of the shift factors: i) In both stages of recovery, Arrhenius temperature dependence of the shift factor is observed; ii) The shift factor corresponding to the first stage recovery exhibits relatively low activation energy (several times smaller than that of the α process at T_g); iii) The second stage exhibits activation energy similar to that of the polymer α relaxation at T_g. These results indicate that divergence of the relaxation time at a finite temperature is likely avoided, whereas the question of a thermodynamic singularity remains open.

3:42PM R32.00005 Molecular mobility measurement during constant strain rate deformation of polymer glasses , BENJAMIN BENDING, KELLY CHRISTISON, M.D. EDIGER, University of Wisconsin-Madison — We use a dye reorientation method to measure the segmental mobility in poly (methyl methacrylate) during active deformation. During constant strain rate deformation at 14 K below the glass transition we observe that mobility initially increases by up to a factor of 500, as compared to the starting undeformed mobility. After the softening regime the mobility remains constant as the strain is increased. Similar qualitative trends have been seen in simulations by Riggleman et al. and in the model of Govaert et al. Comparison of these simulations and model to our experiment will be the focus of this talk. In our previous studies of poly (methyl methacrylate) and polystyrene glasses deformed with a constant stress protocol (creep), at 16 K below the glass transition of the polymers we have seen a hundred-fold enhancement of mobility. Results from all these systems can be plotted on a master plot of mobility as a function of the local strain rate during creep deformation. We have found that this correlation holds for multiple glassy polymer systems, thermal and temporal histories, and with different deformation protocols.

3:54PM R32.00006 Origin of mechanical stress from tensile extension of polymer glasses , PANPAN LIN, SHI-QING WANG, Maurice Morton Institute of Polymer Science and Engineering, University of Akron — During uniaxial extension, polymer glasses undergo elastic deformation, yielding, strain softening, neck propagation, and "strain hardening". Both plasticity and anelasticity emerge under the large deformation, making the origin of the mechanic stress elusive to identify. The present work employs an IR camera to make *in situ* temperature measurements on the extending specimen along with the conventional force measurements. To demonstrate the generality of our findings we studied the ductile polycarbonate as well as two brittle polymers, i.e., PS and PMMA, which can be made ductile by melt extension [1]. We found that the rate of heat generation is only a small fraction of the mechanical power involved in the uniaxial extension of these polymer glasses. Thus, it seems that the origin of the tensile stress is largely intrachain, stemming from straining of the chain network.

4:06PM R32.00007 Observation of yield in a triaxial deformation of a glassy thermoset polymer , GRIGORI MEDVEDEV, JAE-WOO KIM, JAMES CARUTHERS, Purdue University — Yield and post-yield behavior of amorphous polymers in a glassy state have been extensively studied in uniaxial tension and compression. In such geometry, the volume change is relatively small reaching the maximum value of approximately 0.5% at the yield point. To study the role of the volumetric contribution a different geometry is needed. Here we report on the first observation of yield behavior in the longitudinal deformation, where the volume change is an order of magnitude higher than in the uniaxial test. The experiment is performed sufficiently close to Tg to ensure that yielding occurs before brittle failure. To characterize the evolution of the mobility/relaxation rate induced by deforming the glassy material through yield, a series of stress relaxation experiments are carried out at various pre-yield and post-yield strains. These experiments are done in uniaxial tension, compression and, for the first time in a longitudinal deformation. Implications of the observation of yield in a dilatation dominated deformation in addition to the traditional uniaxial and shear yield for the theories of glassy behavior and the development of constitutive models are discussed.

4:18PM R32.00008 Evidence for non-diverging time-scales in glass-forming liquids[1] , GREGORY MCKENNA, Texas Tech University — One perceived important signature of the "ideal" glass transition and of the complex fluid nature of glass-forming liquids remains the apparent divergence of the dynamics at temperatures above zero Kelvin. Recently, however, this perception has been increasingly challenged both through experiments and in new theories of the dynamics of glass forming systems. In this presentation we summarize some of the prior evidence suggesting that time scales actually do not diverge in glasses that are aged into equilibrium, perhaps 15 K below the conventional glass transition temperature T_g. We then show new results from an extremely densified glass, 20 Ma old Jamaican amber, in which we were able to obtain the upper bound to the relaxation times through a step-wise temperature scan in which the stress relaxation response of the amber was measured both below and above the fictive temperature T_F.We find that in the case of the upper bound responses at $T > T_F$,there is a strong deviation of the response from the Super-Arrhenius Vogel-Fulcher behavior and this persists to the fictive temperature which is some 33.8 K below T_g. The results are compared to the parabolic model of Chandler and co-workers and we find the model to be consistent with our results if the value of T_x in the model is taken to be the calorimetric glass transition temperature. The significance of the results will be discussed.

4:54PM R32.00009 Collective effects on activated segmental relaxation in supercooled polymer melts , STEPHEN MIRIGIAN, KENNETH SCHWEIZER, University of Illinois at Urbana-Champaign — We extend the polymer nonlinear Langevin equation (NLE) theory of activated segmental dynamics in supercooled polymer melts in two new directions. First, a well-defined mapping from real monomers to a freely-jointed chain is formulated that retains information about chain stiffness, monomer volume, and the amplitude of thermal density fluctuations. Second, collective effects beyond the local cage scale are included based on an elastic solid-state perspective in the "shoving model" spirit which accounts for longer range contributions to the activation barrier. In contrast to previous phenomenological treatments of this model, we formulate an explicit microscopic picture of the hopping event, and derive, not assume, that the collective barrier is directly related to the elastic shear modulus. Local hopping is thus renormalized by collective motions of the surroundings that are required to physically accommodate it. Using the PRISM theory of structure, and known compressibility and chain statistics information, quantitative applications of the new theory to predict the temperature and chain length dependence of the alpha time, shear modulus, and fragility are carried out for a range of real polymer liquids and compared to experiment.

5:06PM R32.00010 The Relationship of Dynamical Heterogeneity to the Adam-Gibbs and Random First-Order Transition Theories of Glass Formation , FRANCIS STARR, Wesleyan University, Middletown CT, JACK DOUGLAS, NIST, Gaithersburg, MD, SRIKANTH SASTRY, Tata Institute of Fundamental Research, Hyderabad, India — We examine measures of dynamical heterogeneity for a bead-spring polymer melt and test how these scales compare with the scales hypothesized by the Adam and Gibbs (AG) and random first-order transition (RFOT) theories. We show that the time scale of the high-mobility clusters and strings is associated with a diffusive time scale, while the low-mobility particles' time scale relates to a structural relaxation time. The difference of the characteristic times naturally explains the decoupling of diffusion and structural relaxation time scales. We examine the appropriateness of identifying the size scales of mobile particle clusters or strings with the size of cooperatively rearranging regions (CRR) in the AG and RFOT theories. We find that the string size appears to be the most consistent measure of CRR for both the AG and RFOT models. Identifying strings or clusters with the"mosaic" length of the RFOT model relaxes the conventional assumption that the"entropic droplet" are compact. We also confirm the validity of the entropy formulation of the AG theory, constraining the exponent values of the RFOT theory. This constraint, together with the analysis of size scales, enables us to estimate the characteristic exponents of RFOT.

5:18PM R32.00011 Enthalpy Recovery of Polystyrene: Is the Liquid Equilibrium Line Reached? , YUNG P. KOH, SINDEE L. SIMON, Texas Tech University, TEXAS TECH UNIVERSITY TEAM — Glasses are not in thermodynamic equilibrium below the glass transition temperature (T_g), and consequently, their properties such as enthalpy, volume, and mechanical properties evolve toward equilibrium in a process known as structural recovery or physical aging. However, several recent studies have suggested that the equilibrium liquid line is not reached even when properties have ceased to evolve. In this work, we present measurements of the enthalpy recovery of polystyrene at the aging temperature of 15°C below the nominal T_g, for aging times up to 1 year. The results are analyzed in the context of the TNM model of structural recovery. The results show that the equilibrium liquid enthalpy line is indeed reached at temperatures below T_g when enthalpy recovery ceases to evolve. Our results will be discussed and compared to results from works leading to different conclusions. We also use our results to probe the issue of whether or not equilibrium relaxation times diverge from super-Arrhenius behavior below T_g.

Session R33 DMP: Focus Session: Organic Electronics and Photonics - Transport in Small Molecules 341 - Jana Zaumseil, Institute of Polymer Materials, Friedrich-Alexander Universitaet Erlangen

2:30PM R33.00001 Intrinsic transport and photo-physical properties of high-mobility organic single crystals , VITALY PODZOROV, Rutgers University — Small-molecule organic semiconductors form the basis for the emerging field of organic optoelectronics. In order to better understand the intrinsic photo-physical and transport phenomena in this important class of materials, it is necessary to study samples of very high structural order and chemical purity. Such materials exist in the form of molecular single crystals that can be used for fabrication of high-performance prototype devices, such as field-effect transistors, photo-conductors and photo-voltaic cells, in which intrinsic properties of organic semiconductors can be investigated without parasitic effects of disorder (see, e.g., [1,2]). This talk will cover the recent progress in organic single-crystal device electronics. In particular, several phenomena related to the previously discovered long-range triplet exciton diffusion and surface photocurrent generation (see, e.g., [3]) will be discussed.

3:06PM R33.00002 Variation in the Single-Molecule Conductance of Oligothiophenes[1] , BRIAN CAPOZZI, EMMA DELL, KATERI DUBAY, JOSE MORENO, TIMOTHY BERKELBACH, DAVID REICHMAN, LUIS CAMPOS, LATHA VENKATARAMAN, Columbia University — Thiophenes are ubiquitous in organic electronic and photovoltaic applications; yet, they have received minimal attention in single molecule transport studies. Here, we carry out single molecule conductance measurements on a family of methyl sulfide-terminated oligothiophenes using the scanning tunneling microscope based break-junction technique. We find a non-exponential decay in conductance with the number of thiophene units (2 through 6) in the chain, which cannot be explained by a simple tunneling or hopping mechanism. We also find that the oligothiophenes exhibit a rather broad conductance distribution when compared to oligophenyls. Using a combination of experiment and molecular dynamics simulations, we show that this increased breadth is most likely due to different thiophene confomers sampled in the experiments, which do not necessarily maintain conjugation along the backbone. These measurements therefore reinforce the importance of conformation and conjugation effects in thiophene-based organic electronic devices where highly conducting molecular components are required.

[1]The experimental work was funded by NSF-DMR-1206202 and the theory was funded by the EFRC program of the U.S. Department of Energy under Award No. DESC0001085.

3:18PM R33.00003 X-ray Induced Trap States in the Organic Semiconductor Rubrene , TOBIAS MORF, TINO ZIMMERLING, SIMON HAAS, BERTRAM BATLOGG, ETH Zurich — The charge transport in organic semiconductors and thus the device performance is broadly affected by localised electronic states capturing charge carriers. In a controlled irradiation experiment, the formation and microscopic origin of these trap states is studied quantitatively. Rubrene crystals with a low pristine trap density are irradiated with monochromatised CuKα radiation. The spectral density of trap states (DOS) is determined by the well-established SCLC method before and after each exposure step. After irradiation, a well defined additional DOS peak is measured. Its density grows linearly by approximately 10^{17} trap states per Joule of absorbed energy. These new states are closely peaked around 0.3 eV above the HOMO (valence band) mobility level. The results are compared to those of the previous ion-irradiation study. Even though the ionic doses were higher by a factor of 10^3 we find very similar changes in the DOS both with respect to quantity and energy of the trap states. This remarkable result suggests a much higher trap creation efficiency of X-rays as compared to ion radiation. Furthermore, the two different radiation methods seem to cause the same type of microscopic perturbation of the molecular crystal.

3:30PM R33.00004 Trap effects in the analysis of conducting probe AFM current-voltage relations , KANOKKORN PIMCHAROEN, DANIAL OLDS, JIEBING SUN, PENG PENG ZHANG, PHILLIP DUXBURY, Michigan State University — Current-voltage relations of conducting probe AFM (CP-AFM) measurements demonstrate that trap effects are important in nanostructured P3HT thin films, particularly prior to thermal annealing. In order to analyze these measurements, we have developed fully three dimensional continuum device models incorporating the CP-AFM tip geometry and nanoscale morphology of the films. Results will be presented for a variety of trap systems in three dimensional model morphologies including nanofibrous structures and systems with inhomogeneous trap distributions. The simulation results will be compared with experimental data.

3:42PM R33.00005 Wave-packet approach to thermal fluctuation effects on charge transport of organic semiconductors[1] , HIROYUKI ISHII, Institute of Applied Physics, University of Tsukuba, 1-1-1 Tennodai, Tsukuba, Ibaraki 305-8573, Japan., NOBUHIKO KOBAYASHI, Institute of Applied Physics, University of Tsukuba, 1-1-1 Tennodai, Tsukuba, Ibaraki 305-8573, Japan, KENJI HIROSE, NEC Corporation, 34 Miyukigaoka, Tsukuba, Ibaraki 305-8501, Japan. — Organic materials are formed with weak van der Waals interactions between molecules. For typical organic semiconductors, the transfer integrals are small in the range of 10 - 100meV, which is comparable to the dynamical transfer integral modulations originating from the thermal fluctuations of molecular motions. Therefore the fluctuations provide important contributions to the understanding of the transport mechanism. To investigate such effects, we have developed a methodology to calculate the carrier transport coupled with inter- and the intramolecular vibrations of organic semiconductors based on the time-dependent wave-packet diffusion method [1]. In this methodology, we carry out the quantum-mechanical time-evolution calculations of wave packets and the classical molecular dynamics simulations simultaneously. We evaluate the anisotropic mobility of organic semiconductors, such as pentacene crystals. We also clarify the change of temperature dependence of mobility from the thermal activated behavior to the power law behavior. I will talk about these results in my presentation. [1] H. Ishii, K. Honma, N. Kobayashi, K. Hirose, Phys. Rev. B, 85 (2012) 245206.

3:54PM R33.00006 Computational Study of Electron-Phonon Coupling in Crystalline Organic Semiconductors[1] , NENAD VUKMIROVIC, Scientific Computing Laboratory, Institute of Physics Belgrade, University of Belgrade, Belgrade, Serbia, CHRISTOPH BRUDER, VLADIMIR M. STOJANOVIC, Department of Physics, University of Basel, Basel, Switzerland — Despite wide interest in organic molecular crystals and the recognition that electron-phonon (e-ph) coupling strength crucially determines the nature of charge carriers in these materials, ab-initio studies of e-ph coupling elements in these materials are still lacking. In this work [1], we calculated the e-ph coupling elements throughout the whole Brillouin zone in crystalline naphthalene using density functional perturbation theory within the generalized gradient approximation. Fourier-Wannier interpolation scheme [2] was then used to obtain the e-ph coupling constants on a fine k-point grid necessary for accurate evaluation of physical properties. Using the obtained e-ph coupling elements, we evaluated the quasiparticle residues for electrons and holes, obtaining the values of 0.74 and 0.78, respectively. These values suggest that e-ph coupling strength is insufficient for formation of small polarons in crystalline naphthalene and other oligoacene semiconductors. [1] N. Vukmirovic, C. Bruder, and V. 4:06PM R33.00007 Van der Waals epitaxy of organic crystal films on hexagonal boron nitride layers for high-quality organic electronics , CHUL-HO LEE, Department of Physics and Chemistry, Columbia University, New York, New York 10027, United States, THEANNE SCHIROS, Energy Frontier Research Center, Columbia University, New York, New York 10027, United States, SEOK JU KANG, BUMJUNG KIM, Department of Chemistry, Columbia University, New York, New York 10027, United States, KEVIN YAGER, Center for Functional Nanomaterials, Brookhaven National Laboratory, Upton, New York 11973-5000, United States, COLIN NUCKOLLS, Department of Chemistry, Columbia University, New York, New York 10027, United States, PHILIP KIM, Department of Physics, Columbia University, New York, New York 10027, United States — The charge transport in organic field-effect transistors (FETs) is strongly influenced by the dielectric and interface properties because crucial carrier processes including accumulation and transport take place at the interface between dielectric and organic materials. In this sense, hexagonal boron nitride (h-BN), which is a layered van der Waals (vdW) dielectric having atomically flat surface and no surface charge trap states, has great potential for both achieving high-quality organic FETs and investigating the intrinsic carrier transport properties in organic semiconductors. In this talk, we present the direct growth of rubrene crystal films on h-BN layers, demonstrating that there exists vdW epitaxial relation between rubrene and h-BN. Furthermore, charge transport properties in FETs using graphene electrodes will be discussed.

4:18PM R33.00008 Voltage dependent capacitance – a measure of energy level bending in naphthalene-tetra-carboxylic- di-imide based transistors , MATHIAS NYMAN, OSKAR SANDBERG, Abo Akademi University, JOSUE MARTINEZ HARDIGREE, SRINIVAS KOLA, HOWARD KATZ, The Johns Hopkins University, RONALD OSTERBACKA, Abo Akademi University — We demonstrate transient capacitance measurements using charge extraction by a linearly increasing voltage (CELIV) on the small molecule naphthalene-tetra-carboxylic- di-imide (NTCDI) based organic transistors. The OFETs use Aluminum (Al) and Aluminum Oxide (AlO_x) as bottom gate and dielectric, with gold (Au) source and drain electrodes. The Al/AlO_x gate is modified using two different self assembled monolayers, triethoxy(octyl)silane and perfluorooctyltriethoxysilane, in order to tune the turn-on voltage. We have clarified the voltage dependent capacitance in diode structures and found that when the transistor is in the fully on state a charge reservoir is formed at the AlO_x interface and a saturation of the steady-state capacitance is seen, equaling the capacitance of the AlO_x layer. When the transistor is in the fully off state the steady state capacitance saturates to the capacitance of the semiconductor bulk. We interpret this as a build-up of a charge reservoir in the semi conductor bulk when going from the off to the on state making it possible to charge the AlO_x capacitance. By going from the on state towards the off state using a linearly increasing voltage pulse the dynamics of the depletion of the reservoir gives information about the energy level bending in the bulk.

4:30PM R33.00009 Controlling Leakage Currents in Organic Field-Effect Transistors using Molecular Dipole Monolayers on Nanoscale Oxides , JOSUE F. MARTINEZ HARDIGREE, THOMAS DAWIDCZYK, ROBERT IRELAND, GARY JOHNS, BYUNG-JUN JUNG[1], NINA MARKOVIC, HOWARD KATZ, Johns Hopkins University — Self-assembled monolayers (SAM) have been explored as easily-processed, ultrathin interfacial layers in organic field-effect transistors (OFETs) for tuning the threshold voltage (Vt). We investigated the influence of Fermi-level pinning of the gate electrode by SAMs on leakage currents in OFETs fabricated on highly-doped n- and p-type Si gates with an intentionally marginal-quality, high leakage 8 nm SiO_2 dielectric. Two dipolar alkyl SAMs, octyltriethoxysilane (OTS) and its fluorinated analogue (FOTS), were employed under a 40 nm active layer of a naphthalenetetracarboxylic diimide (NTCDI) derivative. Transistors on nSi displayed more positive Vt for OTS (+0.23 V) and FOTS (+1.09 V) than bare oxide (-0.56 V), while OFETs on pSi showed a lower Vt for OTS (+0.26 V) and a higher Vt for FOTS (+1.25 V) devices relative to bare oxide (+1.15 V). Differences in gate and subthreshold leakage between bare and SAM-treated oxides match the trends in Vt. Scanning Kelvin-probe measurements were consistent with this trend, indicating FOTS made both nSi and pSi oxide surfaces more negative relative to bare oxide, while OTS treatment resulted in more positive surface potentials on pSi and more negative surface potentials on nSi.

4:42PM R33.00010 Halogenated contorted hexabenzocoronene derivatives for electron transport in thin-film transistors and organic photovoltaics , ANNA HISZPANSKI, LEO SHAW, Chemical and Biological Engineering Dept., Princeton University, MATTHEW BRUZEK, Chemistry Dept., University of Kentucky, FRANZISKA LUETTICH, ANTOINE KAHN, Electrical Engineering Dept., Princeton University, JOHN ANTHONY, Chemistry Dept., University of Kentucky, YUEH-LIN LOO, Chemical and Biological Engineering Dept., Princeton University — In investigating electron acceptor substitutes for fullerene derivatives in organic photovoltaic applications, we have modified a semiconductor, contorted hexabenzocoronene (HBC), with halogens to increase its oxidative stability and lower its lower unoccupied molecular orbital energy level relative to vacuum level. We synthesized a series of HBC derivatives with increasing fluorine substitution on the peripheral aromatic rings and elucidated the effect of chemical modification on electronic properties. Though we observe a 57 meV shift in both the highest occupied and lowest unoccupied energy levels of the molecules with each progressive addition of fluorine, none of the fluorinated HBC derivatives demonstrate electron transport in thin-film transistors. By substituting chlorine for four of the peripheral fluorines, however, this mixed-halogenated compound exhibits n-transport characteristics. Unoptimized thin-film transistors comprising 8F-8Cl-HBC have demonstrated electron mobilities as high as 0.01 cm^2/Vs, and unoptimized bulk-heterojunction solar cells with poly(3-hexyl thiophene) as the polymer donor have yielded power conversion efficiencies as high as 0.9%.

4:54PM R33.00011 Tellurium-Organic Thin-Films in Hybrid Electronic Platforms , ROBERT IRELAND, HOWARD KATZ, Johns Hopkins University — Vacuum-deposited tellurium (Te) is considered with semiconducting, insulating, and charged organic films for hybrid electronic platforms. Specifically, polycrystalline films of Te and organic semiconductor (OSC) molecules are combined for the first time in bilayer field-effect transistors (FET). Although Te is not ideal for high dynamic range FETs, it serves as a useful test platform in inorganic-organic heterostructures because of high mobility (μ), defined composition, and amenable processing methods. Scanning Kelvin probe microscopy directly confirms the interfacial vacuum level offset for different Te-OSC junctions. By implanting electrostatic charges at the dielectric surface we demonstrate that interfacial fields determine the gate voltage range over which Te shows field-effect in heterostructured FETs. FETs are measured under both continuous and pulsed operation. Pulsed gating influences the measured μ by selectively concentrating charge carriers in semiconductor layers that are farther away from the gate dielectric. FETs comprising various Te-organic junctions gave consistent μ ranging from 0.001 to above 5 $cm^2\ V^{-1}\ s^{-1}$, compared to 2.7 $cm^2\ V^{-1}\ s^{-1}$ for Te deposited on bare silicon dioxide under the same conditions.

5:06PM R33.00012 Spatial dependence of charge photogeneration and transport in an ordered, phase-separated liquid crystalline organic semiconductor , SANJOY PAUL, Department of Physics, Kent State University, SUVAGATA TRIPATHI, Department of Chemistry, Kent State University, BRETT ELLMAN, Department of Physics, Kent State University, ROBERT TWIEG, Department of Chemistry, Kent State University — Bulk heterojunction organic photovoltaic cells depend on charge and exciton physics within, and between, small regions of organic semiconductors. To probe the physics of charge generation and transport in these geometries, we have fabricated patterned, phase-separated mixtures of liquid crystalline (LC) organic semiconductors and photopolymerized polymers. To characterize transport in the LC regions, we have developed "scanning time-of-flight microscopy" (STOFm), whereby spatially resolved TOF and polarized microscopy data are acquired in parallel. We will discuss the technique, as well as our results on efficiency of charge generation, mobility, and trapping in these confined geometries.

5:18PM R33.00013 Probing Polaron Dynamics and Transport in Multiporphyrin Conjugated Arrays by EPR and Optical Spectroscopy , PAUL ANGIOLILLO, Saint Joseph's University, JEFF RAWSON, MICHAEL THERIEN, Duke University — The nature of mobile charge carriers and their transport in organic conducting and semiconducting materials is still an area requiring deeper understanding. Unlike in classical metals, charge carriers are not represented well by bare charges but rather as polarons. Hole and electron polarons were chemically generated in a systematic series of meso-to-meso ethyne-bridged (porphinato)zinc arrays (PZn_n), spanning a linear dimension of 1.4 nm to 7.5 nm. Determination of the spin distribution through the nuclear hyperfine interaction suggest that both hole and electron polarons are extensively delocalized over the extent of the molecule at 298 K. Low temperature studies at 77 K further reveal that the polaronic states maintain their ability to explore the extent of the molecule. Concomitant optical absorption spectroscopy of the hole polaronic states in these oligomers further supports the delocalized nature of the excitation. Electron spin relaxation in organic materials devoid of heavy atoms is dominated by the nuclear hyperfine interaction. This decreased interaction manifest itself in a simultaneous decrease in the spin lattice relaxation rate (increase in spin lattice relaxation time T_1) with oligomer size as determined through progressive microwave saturation with relaxation times on the order of 1μs at 298 K. These data demonstrate exceptional and unprecedented charge dynamics and polaron delocalization lengths.

Wednesday, March 20, 2013 2:30PM - 5:30PM –

Session R34 DPOLY: Thin Films of Block Copolymers and Hybrid Materials: Hierarchical Structures 342 - Fred Phelan, National Institute of Standards and Technology

2:30PM R34.00001 Thin Films of Supramolecular Nanocomposites , TING XU, University of California, Berkeley — Supramolecular nanocomposites, composed of polymers, small molecules and nanoparticles, offer numerous opportunities to achieve nanoparticle assemblies with high spatial precision and to incorporate different built-in functionalities by simply varying building blocks. However, as multi-component systems, building blocks are mixed together without forming covalent bonds. There are different energetic contributions governing their phase behavior in bulk and in thin films. Energetically, these contributions are comparable, typically in the range of a few kcal/mol. This makes it feasible to access a rich library of nanostructured composites and enables one to manipulate dynamic nanoparticle assemblies. However, the rather flat energy landscape also presents challenges to precisely control the assemblies in a predictable manner. Here, we present our recent studies on the phase behavior of supramolecular nanocomposites in thin films. We qualitatively describe the effect of the particle-polymer interaction, the polymer chain conformation, the surface tension of each component and the supramolecular morphology on the nanoparticle assemblies in thin films. These basic studies led to well-defined 3-D nanoparticle assemblies of single type nanoparticle and nanoparticle mixtures in thin films. Furthermore, I will discuss our interesting explorations on the dynamics of nanoparticle assemblies in thin films of supramolecular assemblies.

3:06PM R34.00002 Hierarchical Structuring in Block Copolymer Nanocomposites through Two Phase Separation Processes Operating on Different Time Scales , ROY SHENHAR, ELINA PLOSHNIK, AMIT HALEVI, MEIRAV BEN-LULU, Hebrew University of Jerusalem, AXEL H.E. MUELLER, University of Bayreuth, KAROL M. LANGNER, JOHANNES G.E.M. FRAAIJE, G.J. AGUR SEVINK, Leiden University — The ability to assemble nanoparticles (NPs) hierarchically, with control over their positioning and spacing, is considered an important step toward applications where collective properties are sensitive to the morphology of the NP aggregates. Using block copolymers as matrices for organizing metal and semiconductor NPs through microphase separation leads to hierarchical NP assemblies, but control over NP location within the hosting domains is usually limited to one-dimensional distribution. The presentation will demonstrate by both experimental evidence and mesoscopic simulations that functionalizing the nanoparticles with polymeric ligands that are incompatible with both blocks, but to considerably different extents, leads to hexagonally-packed NP assemblies in every other domain of the copolymer film. Such choice of polymeric components leads to a situation where the microphase separation of the block copolymer precedes the macrophase separation of the NPs from the copolymer. Thus, when the latter finally sets in, it occurs within the confines of the domains hosting the NPs. In the hexagonally-packed arrays formed by this process, the interparticle distances are controlled by the thickness of the nanoparticle coating.

3:18PM R34.00003 Hierarchical pattern formation through photo-induced disorder in block copolymer/additive composite films[1] , LI YAO, JAMES WATKINS, Department of Polymer Science and Engineering, University of Massachusetts Amherst — Segregation strength in hybrid materials can be increased through selective hydrogen bonding between organic or nanoparticle additives and one block of weakly segregated block copolymers to generate well ordered hybrid materials. Here, we report the use of enantiopure tartaric acid as the additive to dramatically improve ordering in poly(ethylene oxide-block-tert-butyl acrylate) (PEO-b-PtBA) copolymers. Phase behavior and morphologies within both bulk and thin films were studied by TEM, AFM and X-ray scattering. Suppression of PEO crystallization by the interaction between tartaric acid and the PEO block enables the formation of well ordered smooth thin films. With the addition of a photo acid generator, photo-induced disorder in PEO-b-PtBA/tartaric acid composite system can be achieved upon UV exposure to deprotect PtBA block to yield poly(acrylic acid) (PAA), which is phase-miscible with PEO. Due to the strong interaction of tartaric acid with both blocks, the system undergoes a disordering transition within seconds during a post-exposure baking. With the assistance of trace-amounts of base quencher, high resolution, hierarchical patterns of sub-micron regions of ordered and disordered domains were achieved in thin films through area-selective UV exposure using a photo-mask.

[1]Funding from Center for Hierarchical Manufacturing (CHM); Facility support from Materials Research Science and Engineering Center at UMass Amherst and Cornell High Energy Synchrotron Source

3:30PM R34.00004 Hierarchical multiscale patterned flexible PDMS elastomeric film and its ice-retarding properties , YING CHEN, The University of Akron, DIYA BANDYOPADHYAY, BASF, ALAMGIR KARIM, The University of Akron — Hierarchical structures in nature inspired development of artificial micro-nano structures in recent years, because these structures exhibit unique properties like tunable adhesion and wetting. We demonstrate a simple yet versatile method to fabricate micro-nano surface based on combination of PDMS nano-imprinting and UVO lithography. Nanoscale patterned PDMS is fabricated by imprinting digital recording media discs (CD/DVD) pattern. The micro pattern was then built by selective densification of patterned PDMS by exposing to UVO through a bigger mask like TEM grid or wire mesh. The nano imprinted pattern remains unaffected during the UVO treatment. We observed that tunable hierarchical structures with height up to 900 nm can be created by simply controlling UVO exposure time. This method provides potential applications in various fields such as superhydrophocity, icephobicity, microfludics and solar cell. We demonstrate that these hierarchical surface exhibits improved icephobicity comparing to flat hydrophobic surface. Icephobocity experiments were carried out in a controlled humidity and temperature chamber. Patterned PDMS film coatings were cooled to -10 ^{o}C at a relative humidity of 65%. Temporal formation of ice was observed under optical microscopy.

3:42PM R34.00005 Theory of Hierarchical Morphologies in Binary Blends of AB/CD Diblock Copolymers , ASHKAN DEHGHAN, McMaster University, WEIQUAN XU, PINGWEN ZHANG, Peking University, AN-CHANG SHI, McMaster University — The self-assembled structures formed in binary blends of AB/CD diblock copolymers are studied using the real space Self-Consistent Field Theory (SCFT), focusing on the cases with attractive A/C and repulsive B/D interactions. The attractive A/C interaction prevents macroscopic phase separation, whereas the repulsive B/D interaction leads to the formation of complex nanoscopic structures. The combination of these features makes the AB/CD blend an ideal model system for the study of hierarchical self-assembly. Our results demonstrate that the B/D separation leads to the emergence of hierarchal alternate lamellar, cylinders and checker board morphologies from the classical lamellar structure. Similar behavior in the cylindrical phase, where an increase in the BD interaction leads to a phase transition from the classical hexagonally packed cylinders to alternating cylinders, has also been predicted. The theoretical predictions are consistent with available experiments and, more importantly, provide an interesting route for the engineering of hierarchically ordered structures using block copolymer blends.

3:54PM R34.00006 Solution Construction of Multigeometry Nanoparticles and Multicompartment Superstructures from Block Copolymer Mixtures , JIAHUA ZHU, Materials Science and Engineering, University of Delaware, SHIYI ZHANG, KAREN WOOLEY, Dept of Chemistry Texas A&M University, DARRIN POCHAN, Materials Science and Engineering, University of Delaware — Novel soft objects with both compositional and geometric complexity at nanoscale have been constructed through solution supramolecular assembly from block copolymer mixtures due to their non-ergodic character. The mixture is composed of two block copolymers with distinctive hydrophobic blocks but the same poly(acrylic acid) hydrophilic block. First, multigeometry nanoparticles, due to segregation of unlike block copolymer molecules into multiple subdomains trapped within the same micelle-like structures, have been assembled in tetrahydrofuran/water solution. Through carefully designed molecular architecture, mixing ratio and pathway kinetics, both size and shape of subdomains can be controlled to produce a novel class of multigeometry nanoparticles, including sphere-sphere, sphere-cylinder, cylinder-cylinder, cylinder-disk, and sphere-disk hybrid nanoparticles. Second, hierarchical multicompartment superstructures including particle chains, rings and other nano to micro cluster formations, have been built up from pre-formed multigeometry nanoparticles by taking advantage of their surface anisotropy and the controlled particle-particle association. The interparticle association can be achieved via either covalent or non-covalent bindings due to different post-polymerization chemical modifications with hydroxyethyl acrylate or crown ether functionalities, respectively.

4:06PM R34.00007 Mixed Solvent Strategy for the Dispersion of PCBM in Block Copolymer Thin Films[1] , ABUL HUQ, MANISH KULKARNI, The University of Akron, KEVIN YAGER, Brookhaven National Laboratory, DETLEF-M. SMILGIES, Cornell High-Energy Synchrotron Source (CHESS), ALAMGIR KARIM, The University of Akron — In this work a model system of self assembling cylinder forming polystyrene-b-poly(ethylene oxide) (PS-*b*-PEO) block-copolymer (BCP) and photosensitive phenyl-C61-butyric acid methyl ester (PCBM) nanoparticles were utilized to study extent of nanoparticle dispersion into BCP thin films. We studied effects of different solvents and mixture of solvents for casting variable amount of PCBM loaded PS-*b*-PEO films on the final morphology of the films. Atomic force microscope (AFM) as well as transmission electron microscope (TEM) was employed to study the dispersion of PCBM into PS-*b*-PEO matrix. We were able to disperse more than fifty percent PCBM (wt./wt.) in the film, which is higher than the percolation threshold of nanoparticles, without forming PCBM clusters. Grazing incidence small angle scattering (GISAXS) results show that the mixed solvent strategy resulted in change of domain sizes of thin films due to change of effective interaction parameters. It was found by AFM scratch test that the film thickness is highly dependent on the casting solvent mixtures and nanoparticle concentration.

4:18PM R34.00008 Dynamics of block copolymer / nanoparticle composites[1] , ANDREI ZVELINDOVSKY, MARCO PINNA, University of Central Lancashire, IGNACIO PAGONABARRAGA, University of Barcelona — We present results of a large scale coarse grained computer simulation for block copolymer nanoparticle composites, Hybrid Cell Dynamics Simulation. Dynamics of the nanoparticles is found to strongly influence block copolymer nanostructure dynamics and vice versa. Different ratios of nanoparticle diameter and block copolymer domain spacing were investigated. The effect of the external fields such as electric or magnetic fields on the dynamics of the particles was incorporated into the computer model and found to influence block copolymer matrix structure. For example, the nanoparticles can controllably induce phase transitions between different block copolymer morphologies. The simulation results gave insights on underlying physical mechanisms in recent experiments on such systems.

4:30PM R34.00009 Precise control of magnetic and dielectric nanoparticle placement within block copolymer templates for the fabrication of 3D magneto-dielectric metamaterials[1] , XINYU WANG, DONGPO SONG, JAMES WATKINS, Polymer Science and Engineering Department at University of Massachusetts Amherst — Magneto-dielectric metamaterials fabricated using high permeability (high-μ) nanoparticles (NPs) with precise control over position and orientation could yield superior electromagnetic properties with low loss. In addition, proper tuning of the effective dielectric constant of the host composite could yield more efficient devices with a wider bandwidth. Lin et al. recently reported the use of strong interactions between NPs and one segment of weakly segregated block copolymer (BCP) systems to drive the assembly of well-ordered morphologies while confining the NPs specifically in the desired spherical, cylindrical or lamellar domains. Here we used this approach to assemble high-μ NPs into well ordered systems. Specifically, FePt nanoparticles functionalized with H-bonding donating ligands were shown to induce strong segregation in weakly segregated BCP systems. In addition, different NP/polymer segment interactions, such as π-π interactions, were introduced to incorporate dielectric NPs in order to tune the effective permittivity of the material. Small-angle X-ray scattering was used to track the morphological evolution of the composite. Transmission electron microscopy was used to investigate the location of the NPs in their respective polymer domains.

4:42PM R34.00010 Morphological studies on supramolecular hybrids comprising a block copolymer and semiconductor nanoparticles[1] , ATSUSHI NORO, KOTA HIGUCHI, YOSHIO SAGESHIMA, YUSHU MATSUSHITA, Nagoya University — Well-ordered periodic nanostructures have been attaining much attention due to their high potential for nano-applications. Nanophase-separated structures of block copolymer/inorganic nanoparticle hybrids are one of good candidates for such applications. Here we report a systematic study on preparation and morphological observation of hybrids composed of a block copolymer and hydroxy-capped cadmium selenide nanoparticles (h-CdSe) via hydrogen bonding. Three polystyrene-*b*-poly(4-vinylpyridine) (PS–P4VP) block copolymers with the same PS chain length but with different P4VP chain length were synthesized for hybrid preparation. Each PS–P4VP was mixed with h-CdSe by varying a weight ratio of PS–P4VP:h-CdSe. A hybrid composed of h-CdSe and PS–P4VP bearing long P4VP blocks represents a single nanophase-separated structure, where domain spacing expansion and morphology transition induced by addition of h-CdSe were observed. On the other hand, macrophase separation accompanied by overflow of h-CdSe from nanophase-separated domains was observed in hybrids which contain PS–P4VP bearing short P4VP blocks. These results are attributed to hydrogen-bonding formation and the stoichiometric balance of functional groups.

4:54PM R34.00011 Nanoparticle distribution in complex block-copolymer morphologies , YONGJOO KIM, HSIEH CHEN, ALFREDO ALEXANDER-KATZ, MIT — We present our work on the distribution of nanoparticles (NPs) having various shapes (sphere, rod or disk) in different types of directed-self-assembled block-copolymer (BCP) morphologies using hybrid particle-field simulations. The BCP patterns are first obtained by modeling a nanoscale template consisting of ordered posts that are attracted to one of the blocks of BCPs. Once a desired pattern is obtained, we run simulations using the pattern as the initial condition while also including nanoparticles with different shapes, sizes and positions. By calculating the mean-field free energy of the entire system, we study the role that chain stretching and nanoparticle shape and size play in the equilibrium location of the NPs in the BCP matrix. Our results can have important implications in directing the self-assembly of multi-component hierarchical materials.

5:06PM R34.00012 Directed Nanorod Assembly Using Block Copolymer-Based Supramolecules

, KARI THORKELSSON, ALEXANDER MASTROIANNI, Materials Science and Engineering, University of California, Berkeley, PETER ERCIUS, National Center for Electron Microscopy, Lawrence Berkeley National Laboratory, TING XU, Materials Science and Engineering, Chemistry University of California, Berkeley; Materials Sciences Division, Lawrence Berkeley National Laboratory — Nanorods display many unique electrical, mechanical, and optical properties unavailable in traditional bulk materials, and are attractive building blocks toward functional materials. The collective properties of anisotropic building blocks often depend strongly on their spatial arrangements, interparticle ordering, and macroscopic alignment. We have systematically investigated the phase behavior of nanocomposites composed of nanorods and block copolymer (BCP)-based supramolecules forming spherical, cylindrical and lamellar morphologies. Initial exploration showed that the nanorods can be readily dispersed in polymeric matrix and the overall morphology of nanorod-containing supramolecular nanocomposite depends on the nanorod-polymer interactions, inter-rod interactions and entropy associated with polymer chain deformation. The energetic contributions from the components of the system can be tailored to disperse nanorods with control over inter-rod ordering and the alignment of nanorods within BCP microdomains.[1] By varying the supramolecular morphology and composition, arrays, sheets, and interconnected networks of nanorods are demonstrated that may prove useful for fabrication of optically and electrically active nanodevices. 1. Thorkelsson, K. et al. Nano letters 2012, 12, 498

5:18PM R34.00013 Morphological Control of Charged Block Copolymer Micelle Complexes in Dilute Aqueous Media

, KOOKHEON CHAR, MISOOK LEE, KYUNG JEE MIN, Seoul National University, JINKEE HONG, Kyunghee University — Amphiphilic block copolymers dispersed in a selective solvent can be self-assembled into various aggregates such as spherical and cylindrical micelles and bilayer vesicles. Block copolymers typically possess hundred repeat units, leading to kinetically stable or trapped assemblies due to the lack of molecular chain exchange between aggregates in solution; thus, aggregated morphologies are highly path dependent. Here, we demonstrate the amphiphilic block copolymer micelle (BCM) complexes with pH-tunable electrostatic interactions between two differently charged corona blocks in aqueous media. The combination of preformed micellization of each BCM with the dissociation control of the corona blocks provides a distinct assembly pathway. This is to say that the sequential mixing of charged BCMs reveals the effects of both corona complexation (through inter-component interactions) and the manipulation of interfacial curvature between core and corona within a micelle (through the intra-molecular block conformations), resulting in unique complex morphologies such as crystal-like hexagonal prisms, hierarchical spheres, and twisted peapods.

Session R35 DCMP: Novel Superconductors I

343 - James Eckstein, University of Illinois at Urbana-Champaign

2:30PM R35.00001 The Introduction of substitutional and non-substitutional dopants into MgB2 in high pressure/Temperature or non-equilibrium regimes[1]

, MIKE SUMPTION, The Ohio State University — In an attempt to study the effect of doping of MgB2 under conditions leading to efficient doping, we used both an high temperature/high pressure induction furnace to dope into MgB2 bulks at temperatures up to 1600 C and 1500 Psi, and thin film, PLD multilayer and mixed layer film fabrication. The high temperature/high pressure formation was used to explore the solubility at high temperatures of various dopants, and the thin film formation was an attempt to use non-equilibrium conditions to inject dopants more effectively. The dopants used were C, Ti, and Zr. C was seen to reach a maximal level at 4 at% C site substituted into MgB2, as evidenced by EPMA and XRD results. Zr, of interest as a possible Mg site substitution in MgB2 was not seen to enter into the MgB2 phase (instead segregating) in the bulk high temperature/high pressure experiments, but was seen to enter in during PLD, as evidenced by STEM and XRD results. Ti additions were attempted in the high pressures and temperature rig, with some evidence for dopant introduction. Critical field measurements on the Zr doped samples where seen to suppress Bc2 for all except very low levels of Ti addition, presumably associated with the much greater doping efficiency.

2:42PM R35.00002 The Penetration Depth of MgB_2 as measured by DC SQUIDs

, DANIEL CUNNANE, KE CHEN, X.X. XI, Temple University — High-speed superconducting circuits may benefit from the high T_c and large superconducting gap of MgB_2. Nb remains the state of the art for superconducting electronics partly because of its small penetration depth and its isotropic nature. A microscopic theory on the penetration depth of multiband superconductors states that a clean MgB_2 sample is nearly isotropic while a sample in the dirty limit is anisotropic. We have made and measured DC SQUIDs using MgB_2 Josephson junctions to determine the inductance of an MgB_2 microstrip. The penetration depth along the c-axis, λ_c, was calculated using the inductance value and dimensions of the microstrip. We have previously reported the absolute value of the penetration depth of our MgB_2 films to be around 40 nm. Now we have made devices with film ranging from the clean limit to the dirty limit by adding defects during the deposition. The absolute value of λ_c at low temperature is compared to the cleanliness of the film. The temperature dependence was also measured which is non-trivial due to the two-gap nature of MgB_2. These results are compared with theory that confirmed our previous results.

2:54PM R35.00003 Superconducting properties of aligned flexible networks and yarns of MgB_2-CNT nanowires[1]

, JULIA BYKOVA, MÁRCIO DIAS LIMA, DERRICK TOLLY, CARTER HAINES, AUSTIN HOWARD, MYRON SALAMON, RAY BAUGHMAN, ANVAR ZAKHIDOV, University of Texas at Dallas — Magnesium diboride (MgB_2) has attracted great interest due to its outstanding superconducting characteristics. Literature reports showed that addition of carbon nanotubes (CNT) to a MgB_2 matrix significantly improves its properties: CNTs can carry extremely high currents and also provide electrical and mechanical connection between MgB_2 grains. Here we present a new method to produce networks of aligned MgB_2-CNT nanowires which can be spinned into flexible yarns. Free-standing, aligned CNT sheets were used as a starting network. A conformal layer of boron was deposited on CNTs by Laser Assisted Chemical Vapor Deposition. The resultant boron-CNT nanowires (thickness of 70 ± 10 nm) were exposed to magnesium vapor and were converted into MgB_2-CNT composites. The MgB_2-CNT arrays are flexible and can be easily bent and even twisted. Critical temperature reaches 37 K and depends on thickness and crystalline structure of nanowires. Critical current and critical fields were shown to be comparable or even better than standard MgB_2 wires. We discuss the correlation of observed two step behavior in electric transport curves with interconnects between MgB_2-CNT nanowires and Josephson junction network formation.

3:06PM R35.00004 Enhancement of lower critical field in thin MgB_2 films and MgB_2/MgO multilayers

, TENG TAN, EVAN JOHNSON, NARENDRA ACHARYA, MICHAEL HAMBE, KE CHEN, Department of Physics, Temple University, ALEX KRICK, STEVEN MAY, Department of Materials Science and Engineering, Drexel University, XIAOXING XI, Department of Physics, Temple University — Magnesium diboride is a conventional superconductor with a high T_c of 39 K, a low residual resistivity of < 0.1 $\mu\Omega$cm (at 42 K), and higher thermodynamic critical field H_c values than Nb. These properties make MgB_2 a promising superconductor as an alternative to Nb for future SRF cavities. However, the lower critical field H_{c1} of MgB_2 is low, and vortex dissipation above H_{c1} can lead to degradation of the quality factor and low RF breakdown field. Here, we report an enhancement of H_{c1} in thin MgB_2 films and MgB_2/MgO multilayers. The value of H_{c1}(5K) is increased from 40 mT in a 300 nm-thick MgB_2 film to 180 mT when the MgB_2 layer thickness is 100 nm either in a single-layer film or in a MgB_2/MgO multilayer with a total MgB_2 layer thickness of 300 nm. Superconducting MgB_2 thin films have been coated *in-situ* on the inner wall of a SRF cavity using the hybrid physical chemical vapor deposition (HPCVD) technique. The characterization of the coating will be presented.

3:18PM R35.00005 Thickness dependence of superconducting properties in magnesium diboride thin films[1]

DOUGLAS BERINGER, The College of William and Mary, CESAR CLAVERO, Lawrence Berkeley National Laboratory, TENG TAN, XIAOXING XI, Temple University, ROSA LUKASZEW, The College of William and Mary — Thin film MgB_2 is a promising material currently researched for improvements in superconducting radio frequency (SRF) technology and applications. At present, bulk niobium SRF accelerating cavities suffer from a fundamental upper limit in maximally sustained accelerating gradients; however, a scheme involving multi-layered superstructures consisting of superconducting-insulating-superconducting (SIS) layers has been proposed to overcome this fundamental material limit of 50 MV/m. The SIS multi-layer paradigm is reliant upon implementing a thin shielding material with a suitably high Hc1 which may prevent early field penetration in a bulk material layer and consequently delay the high field breakdown. It has been predicted that for thin superconducting films — thickness less than the London penetration depth ($\sim$ 140 nm in the case of MgB_2) — the lower critical field Hc1 will be enhanced with decreasing thickness. Thus, MgB_2, with a high bulk Hc1 value is a prime candidate for such SIS structures. Here we present our study on the structure, surface morphology and superconducting properties on a series of MgB_2 thin films and correlate the effects of film thickness and surface morphology on Hc1.

3:30PM R35.00006 High resolution ^{11}B NMR of MgB_2 using cryogenic magic-angle spinning[1]

RAIVO STERN, National Institute of Chemical Physics and Biophysics, Tallinn 12618, Estonia, PETER BECKETT, MARK S. DENNING, School of Chemistry, University of Southampton, Southampton SO17 1BJ, UK, IVO HEINMAA, MUKESH C. DIMRI, National Institute of Chemical Physics and Biophysics, Tallinn 12618, Estonia, EDWARD A. YOUNG, Institute of Cryogenics, School of Engineering Sciences, University of Southampton, Southampton SO17 1BJ, UK, MARINA CARRAVETTA, School of Chemistry, University of Southampton, Southampton SO17 1BJ, UK — Static and magic-angle spinning (MAS) ^{11}B NMR data at 4.7 T and 8.5 T have been obtained under cryogenic conditions on a diluted sample of magnesium diboride powder in the normal and superconducting state. We demonstrate that MAS NMR is possible on type-II superconductors despite the sample rotation. The data provide accurate information on the magnetic shift variation and longitudinal relaxation data down to a temperature of 8 K, with a resolution improvement over the entire temperature range. The onset of superconductivity is unaffected by the sample rotation, as revealed by a steep variation of the magnetic shift just below the critical temperature.

3:42PM R35.00007 The full 3D electronic band structure of MgB2 determined by soft x-ray ARPES

YASMINE SASSA, MARTIN MANSSON, Laboratory for Solid State Physics, ETH Zurich, CH-8093 Zurich, Switzerland, BASTIAN M. WOJEK, Materials Physics, Royal Institute of Technology KTH, S-16440 Kista, Sweden, MASAKI KOBAYASHI, Swiss Light Source, Paul Scherrer Institut, CH-5232 Villigen PSI, Switzerland, OLOF GOTBERG, Materials Physics, Royal Institute of Technology KTH, S-16440 Kista, Sweden, VLADIMIR STROCOV, Swiss Light Source, Paul Scherrer Institut, CH-5232 Villigen PSI, Switzerland, NIKOLAI ZHIGADLO, Laboratory for Solid State Physics, ETH Zurich, CH-8093 Zurich, Switzerland, OSCAR TJERNBERG, Materials Physics, Royal Institute of Technology KTH, S-16440 Kista, Sweden, BERTRAM BATLOGG, Laboratory for Solid State Physics, ETH Zurich, CH-8093 Zurich, Switzerland — MgB_2 is a prototypical multi-band multi-gap superconductor with electron-phonon coupling driving T_c up to 40 K. Surprisingly, the experimental knowledge of the electronic band structure is rather limited. Here, we present the first results of angle-resolved photoelectron spectroscopy (ARPES) studies on high quality MgB_2 single crystals, employing photons in the soft x-ray range with variable energy. We have been able to measure the band dispersion not only in the k_x-k_y plane, but also probe in detail the k_z dependence and thus, the 3D nature of the bands. Furthermore, we have found the ARPES intensities to be strongly polarization dependent and their analysis provides an excellent agreement with the orbital nature of the electronic states. The calculated electronic band structure captures very well all the features revealed in our experiment.

3:54PM R35.00008 Fragile Structure Transition in Mo3Sb7

J.-Q. YAN, University of Tennessee, Oak Ridge National Laboratory, M.A. MCGUIRE, A.F. MAY, Oak Ridge National Laboratory, D.G. MANDRUS, University of Tennessee, Oak Ridge National Laboratory, B.C. SALES, Oak Ridge National Laboratory — Despite a relatively low superconducting transition temperature T_c = 2.08 K, the Zintl compound Mo_3Sb_7 has attracted considerable interest due to the possible involvement of magnetism in superconducting pairing, and promising thermoelectric performance with proper doping. Mo_3Sb_7 crystallizes in a Ir_3Ge_7-type cubic structure with space group Im3m at room temperature. A structure transition from cubic to tetragonal (I4/mmm) was observed at 53 K and this symmetry lowering is accompanied by the opening of a 120 K spin gap. Here, we will present the growth of Mo_3Sb_7 single crystals and our work in exploring the correlation between the low-temperature superconductivity, the structure transition, and the spin gap. The low-temperature superconductivity was observed in both the cubic and tetragonal phases. The structure transition was found to be extremely sensitive to Te or Ru substitution which shifts the Fermi level toward the valence band edge. Work at ORNL was supported by the U.S. Department of Energy, Basic Energy Sciences, Materials Sciences and Engineering Division.

4:06PM R35.00009 Crystal growth, complex phase diagram and high pressure studies of layer compound $PdBi_2$[1]

KUI ZHAO, Texas Center for Superconductivity and Department of Physics, University of Houston, XIYU ZHU, BING LV, YUYI XUE, PAUL CHU[2], Texas Center for Superconductivity and Department of Physics, University of Houston, Houston, TX 77204-5002 — Among the different Pd-Bi Alloys, β-$PdBi_2$, which is crystallized in a layered tetragonal (I4/mmm) structure, has been identified as a superconductor with transition temperature at $\sim$ 5.4K. Band structure calculation indicates that the interlayer Bi-Bi bonds are weak but not negligible, which implies the 3D bonding character of this compound. In order to enhance or weaken the interlayer bonding and ultimately increase the Tc in this system, high pressure measurement, isovalent chemical substitution of Bi with Sb, and chemical intercalation using transition metal Cu and alkali metal Na, are applied to the system. Meanwhile, aliovalent chemical substitution on the Bi site by Pb is also carried out. The magnetic, electrical, and calorimetric properties of these compounds are determined at ambient pressure and compared. The detailed high pressure results and the complete phase diagram of chemical substitution and intercalation will be presented and discussed.

4:18PM R35.00010 Superconductivity with extremely large upper critical fields in $Nb_2Pd_{0.81}S_5$

, QIU RUN ZHANG, GANG LI, DANIEL RHODES, ANDHIKA KISWANDHI, TIGLET BASARA, J SUNG, THEO SIEGRIST, National High Magnetic Field Laboratory, Tallahassee, FL, USA, MICHELLE JOHANNES, Center for Computational Materials Science, Naval Research Laboratory, Washington DC, USA, LUIS BALICAS, National High Magnetic Field Laboratory, Tallahassee, FL, USA — Here, we report the discovery of superconductivity in a new transition metal-chalcogenide compound, i.e. $Nb_2Pd_{0.81}S_5$, with a transition temperature $T_c \cong 6.6$ K. Despite its relatively low T_c, it displays remarkably high and anisotropic superconducting upper critical fields, e.g. $\mu_0 H_{c2}$ ($T \rightarrow 0$ K) > 37 T for fields applied along the crystallographic b-axis. This value is considerably larger than the value reported for the technologically relevant Nb_3Sn compound ($\mu_0 H_{c2} \sim 30$ T, with $T_c = 18$ K)[1,2]. Its ratio of $\mu_0 H_{c2}$ ($T \rightarrow 0$ K) to T_c, is also larger than those of the new Fe based superconductors, e.g. β-FeSe (20 T/8.7 K)[3], $Ba_{1-x}K_xFe_2As_2$ ($\sim$ 70 T/28 K)[4], and even higher than the reported ratio for the Chevrel-phase $PbMo_6S_8$(60T/13.3 K)[5] compound. For a field applied perpendicularly to the b-axis, $\mu_0 H_{c2}$ shows a linear dependence in temperature which coupled to a temperature-dependent anisotropy of the upper critical fields, suggests that $Nb_2Pd_{0.81}S_5$ is a multi-band superconductor. This is confirmed by band structure calculations which reveal nearly cylindrical and quasi-one-dimensional Fermi surface sheets having hole and electron character, respectively.

4:30PM R35.00011 Synthesis, structure, chemical doping and high pressure studies of the $SrPt_3$ P with unique structure features[1] , BENMAAN JAWDAT, BING LV, XIYU ZHU, YUYI XUE, CHING CHU[2], Texas Center for Superconductivity and Department of Physics, University of Houston, Houston, TX 77204-5002 — Superconductivity up to 8.4K was reported by Takayama et al.[3] in APt_3P (A=Sr, Ca and La) in 2012 with structural information based only on X-ray powder refinement. The compounds are suggested to crystallize in an antiperovskite-based structure closely related to that of the heavy fermion superconductor $CePt_3Si$ but are nonpolar unlike $CePt_3Si$. Both small single crystals and polycrystalline samples of $SrPt_3P$, the compound with the highest T_c of this class of materials, are synthesized through solid state reactions. In this presentation, full and detailed structural information will be revealed based on X-ray single crystal analysis. Different chemical doping on different sites and high pressure studies have been carried out on the compound of $SrPt_3P$. The results and its implication will be presented and discussed.

4:42PM R35.00012 Revealing the superconducting state of CaC6 by angle-resolved photoelectron spectrocopy , SHUOLONG YANG, JONATHAN SOBOTA, Stanford Institute for Materials and Energy Science;Geballe Laboratory for Advanced Materials, Department of Physics and Applied Physics, Stanford, CA, CHRIS HOWARD, CHRIS PICKARD, London Centre for Nanotechnology and Department of Physics and Astronomy, University College London, London, UK, MAKOTO HASHIMOTO, DONGHUI LU, Stanford Institute for Materials and Energy Sciences, SLAC, CA, SUNG-KWAN MO, Advanced Light Source, Materials Science Division, Lawrence Berkeley National Laboratory, Berkeley, CA, MARK ELLERBY, London Centre for Nanotechnology and Department of Physics and Astronomy, University College London, London, UK, ZHI-XUN SHEN, Stanford Institute for Materials and Energy Science;Geballe Laboratory for Advanced Materials, Department of Physics and Applied Physics, Stanford, CA — We studied the electronic band structure of CaC_6 using angle-resolved photoelectron spectroscopy (ARPES). We were able to make direct connections to the DFT calculation and identify various electron- and hole-pockets both at the Γ- and K-points. Most importantly, we convincingly observed the interlayer band, which was predicted to be responsible for superconductivity and to display a near-free-electron-like dispersion. The near-circular Fermi surface of the interlayer band is clearly separate from the carbon-derived bands, which enables a pocket-dependent superconducting gap analysis near the Γ-point. Distinct electron-phonon coupling regimes were observed for the interlayer and the carbon-derived bands using self-energy analysis in agreement with previous studies.

4:54PM R35.00013 Superconductivity in layered cobaltates: a functional RG treatment , CHRISTIAN PLATT, MAXIMILIAN KIESEL, WERNER HANKE, Institute for Theoretical Physics, University of Wuerzburg, RONNY THOMALE, Ecole Polytechnique Federale de Lausanne — The superconducting state of water-intercalated cobaltates is still poorly understood. Starting with an effective three orbital model which fits the experimentally observed Fermi surface, we apply the functional renormalization group and study the phase diagram of Na_xCoO_2 as a function of doping. Here, we find ferromagnetic and triplet-pairing tendencies near van-Hove filling as well as $(d+id)$-superconductivity for larger dopings. The calculated gap function in this $(d+id)$-phase reveals a near-nodal behavior, and an increased CoO_2 layer distance promotes the ferromagnetic and triplet-pairing channels. Our findings are consistent with recent experimental observations. The cobaltates thus establish a chiral singlet superconductor based on transition metal oxides.

5:06PM R35.00014 Evidence for phase separation between the co-existing Density Wave and Superconducting orders in $(TMTSF)_2PF_6$, ARJUN NARAYANAN, PAUL CHAIKIN, Physics Department, New York University — Resistance, Thermopower and Angular Dependent Magnetoresistance(AMRO) measurements were used to study the organic conductor $(TMTSF)_2PF_6$ at pressures where co-existence between Superconducting and Spin Density Wave orders occurs. While in other material families such coexistence is poorly understood, in $(TMTSF)_2PF_6$ a clear picture is emerging. Various suggestions had been made regarding the coexistence phase, including homogenous phases showing microscopic coexistence, Soliton walls in Density Waves, and phase separation between normal metal and density wave regions. *We provide strong evidence for the phase separation scenario in $(TMTSF)_2PF_6$.* The existence of domains and their pattern of distribution are unambiguously evidenced by thermopower and resistivity anisotropies. The metallic domains are identified as the regular high pressure metal by various unique signatures such as Field Induced Density Waves(FISDW), AMRO and the superconducting Tc. Some surprising details of the evolution of FISDW and AMRO with pressure in the coexistence phase will also be discussed.

5:18PM R35.00015 Electron correlations in C_{60} and aromatic superconductors , YUSUKE NOMURA, KAZUMA NAKAMURA, RYOTARO ARITA, Department of Applied Physics, University of Tokyo — Recent discovery of superconductivity in fcc/A15 Cs_3C_{60} under pressure and in aromatic compounds (ex. alkali-doped picene) has stimulated a renewed interest in molecular superconductors such as K_3C_{60} and Rb_3C_{60}. To clarify the mechanism of the superconductivity, it is essential to understand low-energy electronic structure of these systems. In the present study, we perform a systematic study for understanding the relation between electronic correlation and superconductivity in C_{60} and aromatic compounds [1]. We derived, from first principles, extended Hubbard models for twelve compounds: fcc K_3C_{60}, Rb_3C_{60}, Cs_3C_{60} (with three different lattice constants), A15 Cs_3C_{60} (with four different lattice constants), doped solid picene, coronene, and phenanthrene. We show that these compounds are strongly correlated and have similar energy scales of their bandwidths and interaction parameters. However, they have a different trend in the relation between the strength of the electronic correlation and superconducting-transition temperature. While the C_{60} compounds have a positive correlation, the aromatic compounds exhibit a negative correlation. [1] Y. Nomura, K. Nakamura, and R. Arita, Phys. Rev. B **85**, 155452 (2012).

Wednesday, March 20, 2013 2:30PM - 5:30PM –

Session R36 DCMP: Superconducting Proximity Effects: Mesoscopic and Related 344 - Zhiqiang Mao, Tulane University

2:30PM R36.00001 Nonlocal correlations in a proximity-coupled normal metal , TAEWAN NOH, SAM DAVIS, VENKAT CHANDRASEKHAR, Northwestern University — We report evidence of large, nonlocal correlations between two spatially separated normal metals in superconductor/normal-metal (SN) heterostructures, which manifest themselves a nonlocal voltage generated in response to a driving current. Unlike prior experiments in SN heterostructures, the nonlocal correlations are mediated not by a superconductor, but by a proximity-coupled normal metal. The nonlocal correlations extend over relatively long length scales in comparison to the superconductng case. At very low temperatures, we find a reduction in the nonlocal voltage for small applied currents that cannot be explained by the quasiclassical theory of superconductivity. We believe is a signature of new long-range quantum correlations in the system.

2:42PM R36.00002 Superconducting proximity effect in MBE grown Nb-InAs junctions[1] , CAROLYN KAN, CHI XUE, STEPHANIE LAW, JAMES ECKSTEIN, University of Illinois, Urbana-Champaign — Several proposals for the realization of Majorana fermions rely on excellent quality proximity coupling between a superconductor and a high-mobility semiconductor. We examine the long-range proximity coupling between MBE-grown InAs and in situ grown superconducting overlayers by fabricating transport devices, and investigate the effect of substrate choice and growth conditions on the quality of the MBE InAs. GaAs is commonly available as a high quality insulating substrate. Overcoming its lattice mismatch with InAs using GaSb and AlSb layers results in locally smooth terraced surfaces, but global spiral dislocation structures also appear and have a negative impact on the InAs mobility. Growing InAs on homoepitaxial GaSb results in improved morphology and increases the mean free path. We compare the proximity effect in devices made both ways.

2:54PM R36.00003 Electrostatic Tuning of the Proximity-Induced Exchange Field in EuS/Al Bilayers[1] , TIJIANG LIU, JOSEPH PRESTIGIACOMO, PHILIP ADAMS, Lousiana State University, LOUSIANA STATE UNIVERSITY COLLABORATION — We demonstrate that the proximity-induced exchange field, H_{ex} in ferromagnetic/paramagnetic bilayers can be modulated with an electric field. An electrostatic gate arrangement is used to tune the magnitude of H_{ex} in the Al component of EuS/Al bilayers. We produced modulations of ~ 30 Oe in H_{ex} with the application of perpendicular electric fields of the order of $\pm 10^6$ V/cm. Several possible mechanisms accounting for the electric field's influence on the interfacial coupling between the Al layer and the ferromagnetic insulator EuS will be discussed.

[1]Authors gratefully acknowledge support from the U.S. DOE.

3:06PM R36.00004 Unbiased Analysis of Super/Ferro Bilayer Physics , THOMAS LEMBERGER, MICHAEL HINTON, JIE YONG, The Ohio State University, ADAM HAUSER, University of California, Berkeley, FENGYUAN YANG, The Ohio State University, JULIA MEYER, SPSMS, UMR-E CEA — S/F bilayer physics has been studied for some time now. With a large number of unknown and seemingly-known parameters, some values are traditionally and understandably assumed to be fixed quantities. In particular, the exchange energy, E_{ex}/k_B, is believed to be comparable to the Curie temperature. We analyze the data assuming only that the Fermi velocity v_F in F and the density of states, $2N_S(0)$, in S are known. Fitting T_c vs. d_F with the dirty-limit theory, we determine the interface resistance, R_b, the ratio $E_{ex}/\rho_F\ell_F$, and the ferromagnetic coherence length ξ_F. For physically plausible values of $\rho_F\ell_F$, the dephasing rate of cooper pairs in F is 10 times smaller than expected from the known Curie temperature of F. We propose that dephasing is mitigated by spin-orbit scattering. We also find that the transmission probability for electrons striking the F/S interface is much less than unity.

3:18PM R36.00005 Exploring the mini-gap state and magnetoresistance in platinum nanowires[1] , DANIEL SLOTCAVAGE, MEENAKSHI SINGH, THOMAS MALLOUK, MOSES CHAN, The Pennsylvania State University — Periodic oscillations in differential magnetoresistance and a superconducting mini-gap state were found in single-crystal gold nanowires [Wang et al., PRL 102, 247003 (2009)]. The oscillations were attributed to motion of individual vortices in the nanowire. We have studied proximity-induced superconductivity in polycrystalline platinum nanowires grown using template-based electrodeposition. Systematic studies of the dependence of the mini-gap state on temperature, magnetic field, and sample morphology and geometry were conducted. We found the mini-gap state to persist in polycrystalline samples. The presence of the mini-gap state in polycrystalline samples demonstrates its robustness with respect to sample morphology. On the other hand, the differential magnetoresistance oscillations was not found in these wires. Future work will focus on determining the conditions required for the occurrence of these oscillations.

3:30PM R36.00006 Unconventional quantum oscillations in mesoscopic rings of spin-triplet superconductor Sr_2RuO_4[1] , XINXIN CAI, YIQUN YING, NEAL STALEY, The Pennsylvania State University, YAN XIN, NHMFL, Florida State University, DAVID FOBES, TIJIANG LIU, ZHIQIANG MAO, Tulane University, YING LIU, The Pennsylvania State University — Spin-triplet superconductor Sr_2RuO_4 has been found to feature exotic vortex physics including the formation of vortex lattices at low fields and most recently, evidence for half-flux quanta trapped in a doubly connected sample. We carried out the magnetoresistance measurements in mesoscopic ring samples of Sr_2RuO_4 fabricated on mechanically exfoliated single crystals of Sr_2RuO_4 by photolithography and focused ion beam. With the magnetic field applied perpendicular to the in-plane direction, thin-wall rings of Sr_2RuO_4 were found to exhibit a large number of full-flux quantum oscillations with pronounced amplitudes unexpected from the conventional Little-Parks effect. Furthermore, in thick-wall rings, two distinct periods were observed in both resistance and critical current oscillations, which we attribute to the effect of vortices, namely, the "lock-in" effect of a vortex lattice in Sr_2RuO_4. No evidence for half-flux-quantum oscillations were identified in any sample measured so far without the presence of an in-plane field. The measurements with an in-plane field are being pursued.

3:42PM R36.00007 Analytic Description of Superconducting-Ferromagnetic Proximity Systems[1] , THOMAS E. BAKER[2], Department of Physics & Astronomy University of California, Irvine, CA 92617, OVIDIU E. ICREVERZI, ADAM K. MOKE, ANDREAS BILL, Department of Physics & Astronomy California State University Long Beach, Long Bech, CA 90840 — We present the exact analytic solution of the Usadel equations for a proximity system made of a superconductor and a ferromagnet in the wide dirty limit, including spin-flip scattering. The solution was found by mathematical analogy to the Jacobi elliptic function description of a classical mechanics system known as the bead on a hoop [1]. We highlight the parallels between the two systems and present an analysis of the solution with special attention to long rage triplet effects and the inverse Fulde-Ferrell-Larkin-Ovchinnikov state. We determine the Josephson critical current and the variation of the critical temperature with spin-flip scattering.

3:54PM R36.00008 Microscopic Study of c-axis Proximity Effect in Cuprate-Manganite Heterostructures[1] , H. ZHANG, I. FRIDMAN, University of Toronto, N. GAUQUELIN, G.A BOTTON, Canadian Centre for Electron Microscopy and McMaster University, J. Y.T. WEI, University of Toronto and Canadian Institute for Advanced Research — Recent studies have reported long-ranged proximity effect in epitaxial thin-film heterostructures of ferromagnetic manganites and superconducting cuprates, with possible origins in novel spin-triplet correlations [1]. A key evidence for this effect is the suppression of the superconducting T_c observed in multilayer films of $La_{2/3}Ca_{1/3}MnO_3/YBa_2Cu_3O_{7-\delta}$ (LCMO/YBCO). However, scanning tunnelling spectroscopy on c-axis LCMO/YBCO bilayers have not seen direct evidence for proximity-induced pairing down to 5nm LCMO thickness [2]. We re-examine the T_c suppression by performing atomically-resolved transmission electron microscopy and resistivity measurements on c-axis YBCO/LCMO films grown by pulsed laser deposition, and relating the microstructure in YBCO with the layer thickness and T_c. The microscopy revealed double CuO-chain intergrowths forming non-stoichiometric YBCO-247 regions that do not appear in x-ray diffraction, but can be related to the T_c suppression. We attribute these intergrowths to heteroepitaxial strain, by comparing all the lattice parameters and symmetries involved. [1] Z. Sefrioui *et al.*, PRB 67, 214511 (2003); C. Visani *et al*, Nat. Phys. 8, 539 (2012). [2]I. Fridman *et al*, PRB 84, 104522 (2011).

4:06PM R36.00009 ABSTRACT WITHDRAWN –

4:18PM R36.00010 New structural features in solution-derived YBCO nanocomposite films responsible for a successful novel pinning mechanism , J. GAZQUEZ, R. GUZMAN, ICMAB-CSIC, Spain, J. SALAFRANCA, Universidad Complutense de Madrid, Spain, R. MISHRA, Vanderbilt University, USA, M. VARELA, Materials Science and Technology Division, ORNL, USA, A. PALAU, V. ROUCO, M. COLL, A. LLORDES, ICMAB-CSIC, Spain, G. DEUTSCHER, Tel Aviv University, Israel, X. OBRADORS, T. PUIG, ICMAB-CSIC, Spain — The optimization of high temperature superconductors calls for a detailed knowledge about the effects of materials' manipulations on the subnanometer scale, since the subtle interplay of a variety of nanoscale defect structures that pin the magnetic flux lattice will dictate the performance of these materials. The outstanding properties of solution deposited-$YBa_2Cu_3O_{7-d}$ nanocomposites arise from the strains associated to the network of $YBa_2Cu_4O_8$ intergrowths emerging from the spontaneously segregated oxide nanoparticles, and a novel pinning mechanism coupling this lattice strain with superconducting pairing [1]. However, $YBa_2Cu_4O_8$ intergrowths involve the addition of an extra CuO chain and their ubiquity may lead to an off-stoichiometry that could jeopardize the superconducting properties of the film. Conversely, we will show, by means of aberration corrected scanning transmission microscopy in combination with electron energy loss spectroscopy, how the system balance this deficiency of Cu through new structural features, previously unforeseen, that may constitute new and effective pinning centers and may be responsible for the novel pinning mechanism proposed.

4:30PM R36.00011 Crossover from Peierls distortion to one-dimensional superconductivity in arrays of (5,0) carbon nanotubes , TING ZHANG, MING YUAN SUN, ZHE WANG, WU SHI, PING SHENG, the Hong Kong University of Science and Technology — We consider the electronic instabilities in (3,3)@(8,8) and (5,0)@(15,0) metallic double wall carbon nanotubes. Using 2rd order renormalization group method, we find that in the single wall (3,3) and (5,0) CNTs, the Peierls transition dominates, while if dressed with metallic outer shell, namely the (8,8) CNT and (15,0) CNT to form double wall carbon nanotube system(DWNT), the screening effect greatly reduces the Coulomb interaction of inner tubes, and superconductivity(SS) instability is identified to be the groud state, although the crossover temperature of which SS response functions take over could be very low.

4:42PM R36.00012 1D to 3D Crossover Transition in a System of Weakly Coupled Superconducting Nanowires , QIHONG CHEN, MING YUAN SUN, ZHI LIN HOU, TING ZHANG, ZHE WANG, WU SHI, ROLF W. LORTZ, PING SHENG, the Hong Kong University of Science and Technology — Recent Results have shown the existence of superconductivity in quasi-one-dimensional systems, e.g., the 4Å superconducting carbon nanotubes embedded in the aligned, linear pores of the aluminophosphate-five (AFI) zeolite. In order to understand theoretically the experimental observations on the thermal specific heat and the electrical resistance variation as a function of temperature, we have carried out Monte Carlo simulations on a Ginzburg-Landau (GL) model of Josephson-coupled superconducting nanowires. The results show that the competition between 1D fluctuations and the weak transverse Josephson coupling between the nanowires can give rise to a 1D-3D crossover transition at a temperature T_C below the mean field T_C^O of the wires. The electrical resistance can experience a sharp drop at T_C, at which point the nanowires become phase coherent. The simulated specific heat exhibits a rounded peak between $T_C$and T_C^O, whereas the phase correlation length within the ab plane diverges at T_C from above, in a manner that is consistent with the occurrence of a BKT-transition in the ab plane. These Monte Carlo simulated behaviors are in excellent agreement with the experimental data.

4:54PM R36.00013 Phase slip in large array superconducting anti-dot thin films[1] , WEI-LI LEE, HSIANG-HSI KUNG, TING-HUI CHEN, CHIA-TSO HSIEH, CHI-CHIH HO, KENG-HUI LIN, WEN-TAU JUAN, Institute of Physics, Academia Sinica — Phase slip is one of the most intriguing phenomena in superconducting nanostructure, which gives rise to a finite resistance below superconducting transition temperature. By using a special technique we developed previously for the preparation of a monolayer polymer/nanosphere hybrid, we fabricated a series of large array niobium antidot thin films with niobium line width ranging from about 36 nm to 90 nm. From the resistance and magnetization measurement, we found that the transition width decreases with increasing magnetic field applied along the normal direction of the antidot thin film, which becomes more significant in samples with smaller niobium line width. We argue that this phenomenon provides an evidence for the existence of thermal activated phase slip effect that was discovered for the first time in superconducting antidot thin film structure. Detailed results and analysis will be discussed.

5:06PM R36.00014 p-wave Superconductor in a Mesoscopic Size Grain , SUNGKIT YIP, BOR-LUEN HUANG, Institute of Physics, Academia Sinica — Motivated by the claim that Sr2RuO4 is a p-wave superconductor with broken time-reversal symmetry in the bulk, and many recent experimental studies of superconductors in mesoscopic size grains, we study theoretically a two-component p-wave superconductor in confined geometries, considering circular disks and rectangular samples, using both Ginzburg-Landau (GL) and quasiclassical (QC) Green function theories. For GL theory with parameters near the weak-coupling limit, we find that a sufficiently small circular disk remains normal. For zero field and intermediate sizes, a disk with sufficiently smooth boundary is in a time-reversal symmetric state, where the order parameter can be represented by a real vector forming a vortex-like structure. Only for larger grains and at lower temperatures can a broken time-reversal state be recovered. For intermediate sizes but with finite external magnetic field, the system can have possibly re-entrant phase transitions. For rectangular samples with sufficiently large aspect ratios, the superconductor near its transition temperature at zero fields has its order parameter vector parallel to the long side of the sample. Within a critical aspect ratio however, the order parameter vector forms a vortex-like structure, much like for the disk.

5:18PM R36.00015 Superconductivity and anomalous magnetic phase in $LuGe_2$ single crystals , NAKHEON SUNG, B.K. CHO, Gwangju Institute of Science and Technology (GIST), Y.J. JO, Kyungpook National University, S.K. CHOI, A.I. COLDEA, University of Oxford, H. KIM, R. PROZOROV, Ames Laboratory and Iowa State University — $LuGe_2$ single crystals ($ZrSi_2$-type orthorhombic structure, C_{mcm}) were synthesized by the high temperature metal flux method. $LuGe_2$ was found to be the type-II superconductivity below superconducting transition temperature, T_c = 2.3 K. An anomalous magnetic and electric phase below T^* = 4 K was found only along b-axis in electrical transport measurement, and confirmed additionally by magnetization and heat capacity measurement. From the heat capacity data, $LuGe_2$ was found to be the weak coupling BCS type superconductivity at T_c, whereas the anomalous phase above T_c seems to have a close correlation with the superconducting state below T_c. Upper critical field, $H_{c2}(T)$, of the superconductivity exhibits significant anisotropy either along b-axis or along a (and c)-axis. Recently, a possible second superconducting state in superconducting $YbSb_2$ single crystals, which has the same structure as $LuGe_2$, was reported. [1] Thus, we will discuss in detail on the anisotropic superconducting properties and the anomalous phase above T_c in terms of the possible second superconductivity as in $YbSb_2$.

Session R37 DMP DCOMP: Focus Session: Fe-based Superconductors: Nematicity and Related Phenomena 345/346 - Andrey Chubukov, University of Wisconsin

2:30PM R37.00001 Effects of competing Neel-type magnetic fluctuations and nematic order on the superconductivity of the iron arsenides[1] , RAFAEL M. FERNANDES, University of Minnesota, ANDREW J. MILLIS, Columbia University — In many iron-based superconductors, the presence of two matching electron pockets displaced by (π, π) gives rise to Neel-type magnetic fluctuations, in addition to the usual stripe-type magnetic fluctuations peaked at $(\pi, 0)$ and $(0, \pi)$. Indeed, recent neutron scattering experiments observed both types of fluctuations in certain hole-doped iron pnictides, which intriguingly do not display superconductivity. In this talk, we employ an Eliashberg approach to address the impact of competing (π, π) and $(\pi, 0)$ fluctuations on the superconducting state of the iron arsenides. We show that, surprisingly, even weak short-ranged Neel fluctuations strongly suppress the $s^{\pm}$ state. The main contribution to this suppression comes from a repulsive $s^{\pm}$ interaction induced by the Neel fluctuations, and not from the inelastic scattering pair-breaking that they promote. Upon enhancing the strength of the Neel fluctuations, a d-wave state appears, preceded by either an intermediate $s + id$ state or a non-superconducting region, forming a two-dome structure. We compare our results to experimental findings, and discuss their implications to the optimal T_c of the iron arsenides, arguing that it can be enhanced via a tetragonal-symmetry breaking induced by nematic order.

2:42PM R37.00002 Divergent nematic charge susceptibility in iron-pnictide[1] , YANN GALLAIS, LUDIVINE CHAUVIÈRE, YANXING YANG, MARIE-AUDE MÉASSON, MAXIMILIEN CAZAYOUS, ALAIN SACUTO, Université Paris Diderot, DOROTHÉE COLSON, SPEC CEA Saclay, PARIS DIDEROT COLLABORATION, CEA COLLABORATION — We report doping dependent low energy Electronic Raman Scattering measurements in the normal state of $Ba(Fe_{1-x}Co_xAs)_2$ stress-free twinned single crystals. The Raman response shows a systematic increase at low energy upon approaching the magneto-structural transition. This quasi-elastic peak displays a distinct symmetry dependence which links it to the nematic charge response in the x^2-y^2 symmetry channel, indicating an incipient tetragonal symmetry breaking instability in the charge sector. The extracted static nematic charge response shows Curie - Weiss behavior above the magneto-structural transition with a characteristic temperature which decreases with doping. These results allow us to disentangle the respective roles of spin, charge and lattice degrees of freedom in the mechanism of tetragonal symmetry breaking in iron-pnictides superconductors.

[1]Funding: ANR Grant "PNICTIDES"

2:54PM R37.00003 Divergent nematic susceptibility in an iron arsenide superconductor , HSUEH-HUI KUO, Stanford University, JIUN-HAW CHU, JAMES ANALYTIS, University of California, Berkeley, IAN FISHER, Stanford University — Within the Landau paradigm of continuous phase transitions, ordered states of matter are characterized by a broken symmetry. Although the broken symmetry is usually evident, determining the driving force behind the phase transition can be complicated by coupling between distinct order parameters. We show how measurement of the divergent nematic susceptibility of the iron pnictide superconductor $Ba(Fe_{1-x}Co_x)_2As_2$ distinguishes an electronic nematic phase transition from a simple ferroelastic distortion. These measurements also indicate an electronic nematic quantum phase transition near the composition with optimal superconducting transition temperature.

3:06PM R37.00004 In-plane structural and electronic anisotropy in de-twinned $CaFe_2As_2$ compounds , ERICK BLOMBERG, M.A. TANATAR, S. RAN, S.L. BUD'KO, P.C. CANFIELD, R. PROZOROV, The Ames Laboratory, Ames, IA 50011, USA — In-plane structural and electronic anisotropy has been studied in a wide range of iron-based superconductors by detwinning via uniaxial stress or strain [1]. In particular, materials based on $BaFe_2As_2$ ("112") are among the most studied systems, where different dopants, annealing protocols and different flux growths were extensively explored. However $CaFe_2As_2$ remains a much less studied compound and it exhibits properties quite different from Ba-based 122's [2]. Here we report polarized-light microscopy and electric transport measurements of strain-detwinned $CaFe_2As_2$ compounds. Our results reveal unusual evolution of the structural, electronic and magnetic properties dependent on annealing, growth from Sn flux vs FeAs flux, and doping, as compared to $BaFe_2As_2$. Among the key observations are the differences in twin domain evolution, and a hysteresis in structural and electronic anisotropy upon warming and cooling. This work was supported by the Department of Energy Office of Science, Basic Energy Sciences under Contract No. DE-AC02-07CH11358.

[1] M. A. Tanatar, E. C. Blomberg, et. al. Phys. Rev. B 81, 184508 (2010).

3:18PM R37.00005 Chasing the nematic phase in detwinned $Ba(Fe_{1-x}Co_x)_2As_2$ with optical investigations , C. MIRRI, S. BASTELBERGER, A. DUSZA, A. LUCARELLI, ETH Zurich, H.-H. KUO, J.-H. CHU, I.R. FISHER, Stanford University, L. DEGIORGI, ETH Zurich, ETH ZURICH TEAM, STANFORD UNIVERSITY COLLABORATION — A renewed interest in the study of symmetry-breaking competing states in complex interacting systems followed the discovery of a broken rotational symmetry, due to stripe or nematic order, in the pseudogap phase of the copper oxide superconductors. The most recent playground in which to address the competition between structural, magnetic and superconducting phases is provided by the iron-pnictide superconductors. In these systems, the non-superconducting parent compounds undergo an antiferromagnetic transition into a broken-symmetry ground state at T_N, which is always preceded by or coincident with a tetragonal-to-orthorhombic structural distortion at T_s. Here, we investigate the optical conductivity with light polarized along the in-plane orthorhombic a- and b-axis of $Ba(Fe_{1-x}Co_x)_2As_2$ for x=0, 2.5% and 4.5% (i.e., in the so-called underdoped regime) under $tunable$ uniaxial pressure across their structural and magnetic transitions. We estimate the dichroism, which extends to high frequencies and temperatures. All together, our results on such single domain specimens reveal a nematic susceptibility as well as the electronic nature of the structural transition.

3:30PM R37.00006 Coupled orthorhombic distortion, antiferromagnetism, and superconductivity in a single twin domain of $Ba(Fe_{1-x}Co_x)_2As_2$ (x=0.047)[1] , QIANG ZHANG, WENJIE WANG, B. HANSEN, N. NI, S.L. BUD'KO, P.C. CANFIELD, R.L. MCQUEENEY, D. VAKNIN, Ames Laboratory, and Department of Physics and Astronomy, Iowa State University, J.W. KIM, Argonne National Laboratory — The interplay between structure, magnetism, and superconductivity in single crystal $Ba(Fe_{1-x}Co_x)_2As_2$ (x=0.047) has been studied using high-resolution X-ray diffraction by monitoring charge Bragg peaks in each twin domain separately. The emergence of superconducting state is correlated with the suppression of theorthorhombic distortion around T_C, exhibiting the competition between orthorhombicity and superconductivity. Above T_S, the Bragg peak widths gradually broaden, possibly induced by orthorhombic (nematic) fluctuations in the paramagnetic tetragonal phase. Upon cooling, anomalies in the peak width are observed at T_S and also T_N indicative of strong magnetoelastic coupling. Using the capability to study individual twin domains, the peak widths in the *ab*-plane are found to exhibit anisotropic behavior along and perpendicular to the stripe-type AFM wave vector. In contrast, the temperature dependencies of the out-of-plane peak width showan anomaly at T_N, reflecting the connection between Fe-As distance and Fe local moment.

[1]Supported by DOE Basic Energy Sciences contract no. DE-AC02-07CH11358.

3:42PM R37.00007 Nematic transition and hidden quantum critical point in iron-pnictide superconductors , SHIGERU KASAHARA, Kyoto University — A central issue in the physics of iron-based superconductivity concerns the origin of the pairing interaction, in which the importance of the spin and orbital degrees of freedoms has been discussed. Clarifying the anomalies inherent to this system and unveiling their connections to the high-temperature superconductivity are of primary importance. Here, we report our investigations on clean single crystals of $BaFe_2(As_{1-x}P_x)_2$ [1]. The observed quantum critical point (QCP) behaviors as represented by non-Fermi liquid transport [1], effective mass enhancement [2], and a sharp peak in the zero-temperature magnetic penetration depth [3] at a critical doping are discussed. In addition, we discuss the development of electronic nematicity, a unidirectional self organized state which breaks the underlying crystal lattice symmetry. Our highly sensitive magnetic anisotropy measurements, together with high resolution synchrotron X-ray diffraction experiments, indicate that electronic nematicity develops in the normal state, far above the magneto-structural and superconducting transitions, resulting in a new phase diagram of iron-based superconductors. The development of electronic nematicity appears to help the emergence of superconductivity whilst the QCP provides the highest superconducting transition temperature.

4:18PM R37.00008 Electronic anisotropy in $Ba(Fe_{1-x}Ru_x)_2As_2$ revealed by ARPES , YOONYOUNG KOH, YEONGKWAN KIM, WONSIG JUNG, Institute of Physics and Applied Physics, Yonsei University, MANJIN EOM, JUNSUNG KIM, Department of Physics, Pohang University of Science and Technology, CHANGYOUNG KIM, Institute of Physics and Applied Physics, Yonsei University — One of the central issues in field of iron pnitides is the origin of electronic anisotropy observed by in-plane resistivity measurement and STM quasi-particle interference patterns. It is believed that it is related to magnetism and plays an important role in superconductivity in iron pnictides. It was argued that the split bands in ARPES data are from two orthogonal bands with dominant d_{xz} and d_{yz} characters, demonstrating the in-plane electronic anisotropy. It appears to be consistent with anisotropy observed by other probes. We performed temperature dependent ARPES measurements on an iron pnictide system, $Ba(Fe_{1-x}Ru_x)_2As_2$, to experimentally verify existence of electronic anisotropy and compare the results with those of $BaFe_2As_2$ and $Ba(Fe_{1-x}Co_x)_2As_2$.

4:30PM R37.00009 Elastic softening of the shear modulus in Fe-based superconductors[1] , C. MEINGAST, A. BOEHMER[2], P. ADELMANN, R. FROMKNECHT, P. SCHWEISS, TH. WOLF, F. HARDY, IFP, Karlsruhe Institute of Technology, Germany, W. SCHRANZ, M. REINECKER, Faculty of Physics, University of Vienna — A strong softening of the elastic shear modulus C_{66} has been observed as one approaches the spin-density-wave (SDW) transition in Ba122 from high temperature [1,2]. A smaller softening is still observed for superconducting Co-doped Ba122 crystals, followed by distinct hardening below T_c [1,2]. This elastic response has been taken as evidence either for electronic-magnetic nematic fluctuations [1], or as evidence for a structural quantum critical point near optimal doping [2]. Here we study the elastic response of various Fe-based superconductors by a recently developed technique based upon a three-point bending experiment in a high-resolution capacitance dilatometer. We measure the temperature dependence of the Young's modulus, which for thin slabs can be shown to be closely related to C_{66} for a given orientation. This is confirmed by measurements on Co-doped Ba122, for which we find very similar results as previously reported [1,2]. We will report on new measurements of the Young's modulus on other Fe-based Ba122 systems in order to study the universality of the elastic response at the SDW and superconducting transitions. [1] R. M. Fernandes, et al., Phys. Rev. Lett. 105, 157003 (2010). [2] M. Yoshizawa, et al., J. Phys. Soc. Jpn. 81, 024604 (2012).

4:42PM R37.00010 Magnetic Origin of Electronic Nematicity in NaFeAs (Part I) , CARLOS J. ARGUELLO, ETHAN ROSENTHAL, ERICK ANDRADE, Department of Physics, Columbia University, RAFAEL FERNANDES, School of Astronomy and Physics, University of Minnesota, ANDREW MILLIS, Department of Physics, Columbia University, CHANGQING JIN, Institute of Physics, Chinese Academy of Sciences, ABHAY PASUPATHY, Department of Physics, Columbia University — Several experiments have shown that the parent states of the iron pnictides display electronic nematicity at high temperature, where the electronic states spontaneously break the rotational symmetry of the crystal lattice. A common feature displayed by many pnictide systems is a tetragonal to orthorhombic distortion on cooling down the system below T_S and a magnetically ordered phase below T_{SDW}. In particular, NaFeAs has a structural to orthorhombic transition (T_S=54K) and a SDW transition (T_{SDW}= 39K). This wide temperature difference between transitions makes it an excellent testing ground for the characterization of the electronic states in each one of these regimes. The electronic states of this material can be directly visualized as a function of temperature using atomic-resolution scanning tunneling microscopy/spectroscopy. Real-space images of the electronic states show domains on the micron scale, with a strong unidirectional character persisting to temperatures well above T_S. These unidimensional features are found to be localized around defects in the system. We will discuss the details of the energy and temperature dependence of these features in both real space and Fourier space, as well as draw differences with the structurally similar LiFeAs.

4:54PM R37.00011 Magnetic Origin of Electronic Nematicity in NaFeAs (Part II) , ETHAN ROSENTHAL, CARLOS ARGUELLO, ERICK ANDRADE, Columbia University, RAFAEL FERNANDES, University of Minnesota, ANDREW MILLIS, Columbia University, CHANGQING JIN, Institute of Physics, Chinese Academy of Sciences, ABHAY PASUPATHY, Columbia University — The characterization of possible broken symmetries is essential to understanding high-temperature superconductivity. The electronic states of many iron-based superconductors have been shown to break rotational symmetry, but the origin of this nematicity remains elusive. We use Scanning Tunneling Microscopy (STM) and Spectroscopy (STS) to directly visualize the spatial structure of electronic states in NaFeAs. Intrinsic defects produce unidirectional spectroscopic features that persist to temperatures well above both the spin density wave (SDW) and orthorombic transitions. By comparing our measurements to angle-resolved photoemission spectroscopy (ARPES) data on the same material, we find that these features arise from quasiparticle interference (QPI) in the presence of magnetic order, indicating the primary role of spin interactions in electronic nematicity.

5:06PM R37.00012 Nematicity driven by hybridization in the iron-based superconductors[1] , VALENTIN STANEV, Materials Science Division, Argonne National Laboratory, Argonne, Illinois 60439, PETER LITTLEWOOD, Physical Sciences and Engineering, Argonne National Laboratory, Argonne, Illinois 60439, USA — We introduce an effective three-orbital model to study the normal state of the iron-based superconductors. It has both itinerant and localized electrons - the former originate from the d_{xz}/d_{yz} iron orbitals, and the latter from the d_{xy} iron orbitals. These distinct degrees of freedom are coupled through hybridization and onsite interactions. On a mean-field level this model has an excitonic instability, driven by the effective delocalization of the d_{xy} electrons. Because of the multiband character of the itinerant Fermi surface the ordered state can spontaneously break the lattice rotation symmetry (and thus is nematic) and generate orbital order. In this scenario the nematic state is induced by the coupling of the d_{xz}/d_{yz} with the d_{xy} iron orbitals, rather than the presence of magnetic order, or the proximity to such. We propose this mechanism as an explanation of the tendency towards nematicity observed in several iron-based compounds, and study some of its experimental consequences.

5:18PM R37.00013 Nematic state of the pnictides induced by the interplay between the spin, orbital, and lattice degrees of freedom , SHUHUA LIANG, ADRIANA MOREO, ELBIO DAGOTTO, Department of Physics, University of Tennessee and Materials Science and Technology Division, ORNL — The nematic state with orthorhombic distortion observed in several iron based superconductors is stabilized in the undoped three-orbital (xz, yz, xy) spin-fermion model [1] via the addition of lattice degrees of freedom. The Monte Carlo simulations show that the electron-phonon coupling is not sufficient to stabilize the experimentally observed lattice distortion. The nematic phase is induced instead by the spin-lattice coupling. The interplay between the coupling strength of the lattice to the magnetic and charge degrees of freedom determines the separation between the structural and the magnetic transitions. Experimental results for the anisotropic behavior of the resistivity and the orbital spectral weight as a function of the temperature are also reproduced by the numerical simulations.[2] [1] S. Liang, G. Alvarez, C. Sen, A. Moreo, and E. Dagotto, Phys. Rev. Lett. 109 047001 (2012) and references therein. [2] S. Liang, A. Moreo, and E. Dagotto, submitted for publication.

Session R38 Focus Session: Scalable Technologies for Photovoltaics I 347 - Sue A. Carter, University of California at Santa Cruz

2:30PM R38.00001 Increasing the band gap of iron pyrite by alloying with oxygen , MATTHEW LAW, Department of Chemistry and Department of Chemical Engineering and Materials Science, University of California, Irvine, California 92697, JUN HU, YANNING ZHANG, RUQIAN WU, Department of Physics and Astronomy, University of California, Irvine, California 92697 — Systematic density functional theory studies and model analyses have been used to show that the band gap of iron pyrite (FeS_2) can be increased from $\sim$ 1.0 to 1.2 -1.3 eV by replacing $\sim$ 10% of the sulfur atoms with oxygen atoms (i.e., $\sim$ 10% O_S impurities). O_S formation is exothermic, and the oxygen atoms tend to avoid O-O dimerization, which favors the structural stability of homogeneous $FeS_{2-x}O_x$ alloys and frustrates phase separation into FeS_2 and iron oxides. With an ideal band gap, absence of $O_S$induced gap states, high optical absorptivity, and low electron effective mass, $FeS_{2-x}O_x$ alloys are promising for the development of pyrite-based heterojunction solar cells that feature large photovoltages and high device efficiencies. Acknowledgement: We thank the NSF SOLAR Program (Award CHE-1035218) and the UCI School of Physical Sciences Center for Solar Energy for support of this work. Calculations were performed on parallel computers at NERSC and at NSF supercomputer centers.

2:42PM R38.00002 Effect of annealing conditions on the healing of sulfur vacancy in pyrite FeS2(100) surfaces[1] , AMANDA WEBER, Department of Chemistry and Department of Chemical Engineering and Materials Science, University of California, Irvine, California 92697, YANNING ZHANG, Department of Physics and Astronomy, University of California, Irvine, CA 92697, NICHOLAS BERRY, MATTHEW LAW, Department of Chemistry and Department of Chemical Engineering and Materials Science, University of California, Irvine, California 92697, RUQIAN WU, Department of Physics and Astronomy, University of California, Irvine, CA 92697 — Through density functional calculations, we investigated the segregation of a sulfur vacancy from interior sites outward to the FeS_2(100) surfaces in different surface conditions in order to provide guidance for the development of iron pyrite in photovoltaics applications. We found that the surfaces with interior S-vacancy are energetically unstable and bulk S-vacancies tend to hop toward the surface, in particular when the surface composition is in the stoichiometric or S-rich side. The segregation process is accompanied by redox reaction near the vacancy site, Fe(2+) + S(1-) $\rightarrow$ Fe(3+) + S(2-), and the activation energy decreases near the surface region. We compare the calculated structural, energetic and electronic properties to experimental data, and provide insights for reduction of vacancy density in optimal annealing conditions.

[1]Work was supported by NSF SOLAR Program (Award CHE-1035218). Calculations were performed on NSF-XSEDE supercomputers.

2:54PM R38.00003 A new paradigm for thin-film solar cells: the case of Earth abundant Cu-N ternary compounds , JULIEN VIDAL, XIUWEN ZHANG, STEPHAN LANY, ANDRIY ZAKUTAYEV, DAVID GINLEY, National Renewable Energy Laboratory, Golden, CO, MINGHUI YANG, AMY ALLEN, FRANCK DISALVO, Department of Chemistry, Cornell University, Ithaca, NY — The design of thin film solar cells is extremely sensitive to the choice of the material forming the absorbing layer. Indeed, many of the limitations of solar cell devices are either directly linked to the intrinsic properties of the absorber such as in CdTe or design-related indirect consequences of this choice such as for SnS-based devices. Most of the design of current thin film solar cells rely on chalcogenide materials as the absorbing layer. We propose a new paradigm based on Earth abundant Cu-N ternary compounds as the absorbing layer. We will present the theoretical and experimental investigation of the electronic properties of two Cu-N compounds with interesting photovoltaic properties namely CuSrN and $CuTaN_2$. We performed state-of-the-art defect calculation and GW-based band structure calculations. $CuTaN_2$ was synthesized by ion exchange and its absorption onset was subsequently characterized with diffusive reflectance. While CuSrN displays interesting p-doped capability and defect immunity similar to Cu(In,Ga)Se_2, $CuTaN_2$ presents very strong absorption with a sharp absorption onset in the optimal range for photovoltaic conversion. Finally, we will address potential pitfalls of such absorbers related to stability with respect to O_2 and H_2O.

3:06PM R38.00004 PLD growth of thin film Zinc Phosphide , RAJESH VADDI, PARAG VASEKAR, CHARLES WESTGATE, BRUCE WHITE, Binghamton University - State University of New York — The development of efficient, low cost solar cells to meet society's growing energy needs has triggered tremendous interest in developing photovoltaics formed from earth abundant materials. Zinc phosphide (Zn3P2) is a promising earth abundant absorber layer for photovoltaic energy conversion with a nearly ideal band gap (1.5eV) and a large absorption coefficient of 10^4/cm. In this work we examine the growth parameters, electrical and optical properties of thin film zinc phosphide produced using pulsed laser deposition (PLD) from a zinc phosphide target at laser fluencies ranging from 1-3 J/cm2. For the laser fluences explored, highly resistive amorphous zinc phosphide thin films were produced with a band gap of approximately 1.7 eV. The thin films could be transformed from amorphous to polycrystalline zinc phosphide by annealing at 400C for 15mins in a N2 atmosphere. High resolution X-ray photoelectron spectroscopy (XPS) is used to examine the binding energies of Zn 2p3/2 and Phosphorous 2p3/2 signals and are in the range of 1021.6 eV and 127.5 eV. Energy Dispersive X-ray Spectroscopy (EDAX) revealed that the Zn3P2 thin films are nearly stoichiometric in composition. Hall mobility in these materials and Zn3P2/ZnS hetrojunction solar cell performance will be discussed.

3:18PM R38.00005 The electronic properties of point defects in earth-abundant photovoltaic material Zn_3P_2: A hybrid functional method study , WAN-JIAN YIN, YANFA YAN, University of Toledo — Zinc phosphide (Zn_3P_2) is an attractive and promising semiconductor for thin-film solar cell application because of its earth abundance and ease of thin-film fabrication. The electronic properties of intrinsic and extrinsic defects in Zn_3P_2 are studied by density-functional theory with hybrid functional method. Our results show that undoped Zn_3P_2 should be intrinsically p-type with Zn vacancies as the responsible shallow acceptors. Na or Cu doping is expected to result in improved p-type conductivity as compared to intrinsic Zn_3P_2. S or Al doping may lead to weak n-type Zn_3P_2. Doping of Mg does not produce good n-type Zn_3P_2, consistent with experimental observations. Contradicting to conventional wisdom, an interstitial P in Zn_3P_2 is not a triple-hole acceptor and a P vacancy in Zn_3P_2 is not a triple-electron donor. Instead, we find that the interstitial P is actually a single-hole acceptor and the P vacancy is a single-electron donor. The origins of these unusual behaviors are discussed.

3:30PM R38.00006 Local structure of Cu2S/ZnS multi-layer films prepared using ALD[1] , FRANK BRIDGES, LEILA JEWELL, ANDREW SHORT, GLENN ALERS, SUE A. CARTER, UCSC — We present local structure studies of ZnS, Cu_2S, and ZnS/Cu_2S composite films, using extended x-ray absorption fine structure (EXAFS) technique. The films were prepared using atomic layer deposition (ALD), which can in principle deposit films layer by layer and hence form mesoscopic structures. ZnS and Cu_2S films prepared using ALD are very similar to the bulk material; the main difference is a reduced amplitude for the second neighbor Zn-Zn peak in ZnS, suggesting increased disorder within the film. Relative disorder in the films also increases with decreasing thickness as well as with decreasing deposition temperature. More importantly, multi-layer ZnS/Cu_2S films prepared using the same parameters as for individual films do not produce the expected multi-layer for $\sim$1 nm thick layers. If there is some excess Zn, the multi-layer is predominately ZnS and the Cu_xS fraction is highly disordered, and may include some ZnS:Cu. In contrast if there is a little Cu excess, the film is nearly all Cu_2S and the small Zn fraction is highly disordered ZnS with a shifted Zn-S distance. Consequences for multi-layer formation for solar cell applications will be discussed.

3:42PM R38.00007 Enhancement of solar absorption with black Cu2O Nanostructures[1] , HUI XING, JOHN HATCH, DENGXIN JI, KENNETH KORT, BIPLOB BARMAN, YU TSUNG TSAI, YUELING QIN, SARBAJIT BANERJEE, ATHOS PETROU, QIAOQIANG GAN, HONG LUO, HAO ZENG, SUNY at Buffalo — Cu_2O is a direct gap semiconductor with a band gap of 2.1 eV. It was considered to be a solar absorber material, while the application is hindered by its large band gap and weak stability. Here we report an electrochemical synthesis of Cu_2O. By rationally control the synthetic parameters, we achieved two types of Cu_2O: one of black color and the other "normal" red Cu_2O. Both Cu_2O films were in cubic phase and their crystal structures are almost identical as seen by X-ray diffraction. This is further corroborated by their nearly identical Raman spectra. The scanning tunneling spectrum (STS) revealed a gap in the red Cu_2O around 2.1 eV and a significantly lowered gap of $\sim$ 1.7 eV in the black Cu_2O, indicating that the black color is caused by a change in the electronic structure. The reflectance and transmittance indicated a band gap of $\sim$ 1.7 eV for the black Cu_2O, with a significantly broadened absorption spectrum. While further effort is needed to understand the mechanism for the lowering of the band gap, we believe that our approach demonstrated means to promote earth abundant and nontoxic materials for potential photovoltaic applications through band gap engineering.

3:54PM R38.00008 First-principles electronic structure of β-$FeSi_2$ and FeS_2 surfaces[1] , PENGXIANG XU, TIMO SCHENA, STEFAN BLÜGEL, GUSTAV BIHLMAYER, Peter Gruenberg Institut & Institute for Advanced Simulation, Forschungszentrum Juelich and JARA, 52425 Juelich, Germany — Applying density functional theory in the framework of the full-potential linearized augmented plane-wave (FLAPW) method [1], we investigated electronic structure of potential future photovoltaic materials, β-$FeSi_2$ and FeS_2, for selected surface orientations and terminations. The most stable orientations are determined by comparing their surface energy. Detailed electronic structure calculations show that surface states originating from Fe play an important role and might determine photovoltaic properties. Our results show that anti-ferrimagnetic ordering exists for Fe-terminated surface. Furthermore, we also studied how electronic structure and photovoltaic efficiency are affected by the recently observed structural defects such as stacking fault in β-$FeSi_2$.

4:06PM R38.00009 Photocurrent studies on continuous large area monolayers of WS_2 and MoS_2 , NESTOR PEREA-LOPEZ, ANA LAURA ELIAS-ARRIAGA, Pennsylvania State University, HUMBERTO RODRIGUEZ-GUTIERREZ, University of Lousiville, RUITAO LU, ANDRES CASTRO, Pennsylvania State University, SAIKAT TALAPATRA, SUJOY GHOSH, University of Southern Illinois, AYSE BERKDEMIR, FLORENTINO LOPEZ-URIAS, HUMBERTO TERRONES, MAURICIO TERRONES, Pennsylvania State University, MURI 24 TEAM — Continuous large area monolayers of WS_2 and MoS_2 synthesized by chemical vapor deposition were used as light sensing devices. I-V measurements and photo response measurements were performed on both materials. The photocurrent measurements were carried out from 300 °K down to 10 °K using various visible laser wavelengths (405 nm, 488 nm, 514 nm and 667 nm). A resistance decrease was registered on both materials when illuminated with the laser beam, such change was proportional to the laser photon energy and when the laser energy was lower than the band gap of each material, no photo response was observed. The layered materials were structurally characterized by Raman spectroscopy, atomic force microscopy, scanning electron microscopy and high-resolution transmission electron microscopy. Raman spectra confirms the presence of monolayers and UV-visible spectra revealed the resonance peaks at the energies close to the direct band gap predicted for single layers of WS_2 and MoS_2 (2.05 eV and 1.85 eV). Further experiments on time response and continuous spectral response are now underway and will be presented.

4:18PM R38.00010 Printable CIGS thin film solar cells , XIAOJUAN FAN, Marshall University — Among the various thin film solar cells in the market, CuInGaSe thin film solar cells have been considered as the most promising alternatives to crystalline silicon solar cells because of their high photo-electricity conversion efficiency, reliability, and stability. However, many fabrication methods of CIGS thin film are based on vacuum processes such as evaporation and sputtering techniques which are not cost efficient. This work develops a solution method using paste or ink liquid spin-coated on glass that would be competitive to conventional ways in terms of cost effective, non-vacuum needed, and quick processing. A mixture precursor was prepared by dissolving appropriate amounts of composition chemicals. After the mixture solution was cooled, a viscous paste was prepared and ready for spin-coating process. A slight bluish CIG thin film on substrate was then put in a tube furnace with evaporation of metal Se followed by depositing CdS layer and ZnO nanoparticle thin film coating to complete a solar cell fabrication. Structure, absorption spectrum, and photo-electricity conversion efficiency for the as-grown CIGS thin film solar cell are under study.

4:30PM R38.00011 Crystal structure of Cu_2Te predicted within adaptive genetic algorithm[1] , KAI-MING HO, MANH CUONG NGUYEN, Ames Laboratory, US DOE and Department of Physics and Astronomy, Iowa State University, Ames, Iowa 50011, USA, JINHO CHOI, ICQD, Hefei National Laboratory for Physical Sciences at the Microscale, University of Science and Technology of China, Hefei, Anhui, 230026, China, CAI-ZHUANG WANG, XIN ZHAO, Ames Laboratory, US DOE and Department of Physics and Astronomy, Iowa State University, Ames, Iowa 50011, USA, ZHENYU ZHANG, ICQD, Hefei National Laboratory for Physical Sciences at the Microscale, University of Science and Technology of China, Hefei, Anhui, 230026, China — Cu_2Te is one of the most commonly used conductive back-contacting materials for high-efficiency CdTe-based solar cells. However, the detailed crystal structure of Cu_2Te is still undetermined blocking property investigations of the Cu_2Te-based solar cell systems. Some models have been proposed but all of them have positive formation energy [1]. We have performed adaptive genetic algorithm crystal structure search to find low energy crystal structures of Cu_2Te. We found a new layered-structure edged by Te atoms with negative formation energy from first-principles calculations within local density approximation. This layered structure consists of tilted Cu_2Te ribbon arrays. Structural and electronic properties of the newly found Cu_2Te structure will be discussed in detail.

4:42PM R38.00012 Solution processed solar cells using earth abundant materials for terawatt scale energy production , DAVID MITZI, IBM Research — No abstract available.

5:18PM R38.00013 High photoactivity in ultrathin as-grown hematite films prepared by atomic layer deposition[1] , JEFFREY KLUG, NICHOLAS BECKER, SHANNON RIHA, ALEX MARTINSON, JEFFREY ELAM, MICHAEL PELLIN, THOMAS PROSLIER, Argonne National Laboratory — Nanostructured hematite (α-Fe_2O_3) has been widely studied for use in a variety of thin film applications including solar energy conversion, water oxidation, catalysis, and gas sensing. Among established deposition methods, atomic layer deposition (ALD) is a leading technique for large-scale, controlled synthesis of a wide range of nanostructured materials. In this work, ALD of Fe_2O_3 is demonstrated using $FeCl_3$ and H_2O precursors at growth temperatures between $200 - 350°C$. Self-limiting growth of Fe_2O_3 is observed with a growth rate of ~ 0.06 nm/cycle. As-deposited, films are nanocrystalline with low Cl impurities and a mixture of α- and γ-Fe_2O_3. Post-deposition annealing in O_2 leads to phase-pure hematite with increased out-of-plane grain size. Photoelectrochemical measurements under simulated solar illumination reveal high photoactivity toward water oxidation in both as-deposited and post-annealed films. Planar films deposited at low temperature (235°C) exhibit remarkably high photocurrent densities ~ 0.71 mA/cm^2 at 1.53 V vs. the reversible hydrogen electrode (RHE) without further processing. Films annealed in air at 500°C show current densities of up to 0.84 mA/cm^2 (1.53V vs. RHE).

Session R39 DFD: Pattern Formation and Nonlinear Dynamics 348 - Gregory Eyink, Johns Hopkins University

2:30PM R39.00001 The Peierls Transport Equation — Revised , YI-KANG SHI, GREGORY EYINK, Johns Hopkins University — In 1929 Peierls derived an equation for the joint probability distribution of all wave amplitudes in classical and quantum anharmonic systems, still widely used in quantum transport theory, plasma physics and weak wave turbulence. For uncorrelated amplitudes, it implies the kinetic equation for the wave spectrum/occupation numbers. This equation was rederived by Brout & Prigogine (1956), Zaslavskii & Sagdeev (1967), and recently by Choi et al. (2005) in wave turbulence. We show that these derivations are non-systematic, retaining terms smaller than those neglected. We obtain an equation simpler than Peierls', which still implies the kinetic equation and also a generalized kinetic equation for the distribution of single-mode amplitudes, previously obtained by Choi et al. We show by an H-theorem that the single-mode distributions approach Gaussian, if this equation is valid for all amplitudes. Non-Gaussian statistics can arise if the equation breaks down for large amplitudes/strong nonlinearity. This may explain intermittency observed in laboratory experiments of weak turbulence. Moreover, we show the most general solutions of our revised Peierls equations are statistical ensembles of chaotic solutions of kinetic equations, or "super-turbulence", another source of intermittency.

2:42PM R39.00002 Controlling the position of traveling fronts , JAKOB LÖBER, HARALD ENGEL, ECKEHARD SCHÖLL, Institute for Theoretical Physics, TU Berlin — We present a method to control the position as a function of time of a one-dimensional traveling front solution of a one-component reaction-diffusion system according to a specified protocol of movement. Given this protocol, the control function is found as the solution of a perturbatively derived integral equation. Two cases are considered. First, we derive an analytical expression for the space (x) and time (t) dependent control function $f(x,t)$ valid for arbitrary protocols and arbitrary bistable reaction kinetics. These results for the control agree well with results of an optimal control algorithm. Second, for stationary control the integral equation reduces to a Fredholm integral equation of the first kind. For the Schlögl model, we present an analytical solution of the problem to stop a front at a specified position. All analytical results are in good agreement with numerical simulations of the underlying reaction-diffusion equations. Extensions to two spatial dimensions and other equations supporting traveling wave solutions are considered.

2:54PM R39.00003 Experimental studies of stationary reaction fronts in a chain of vortices with imposed wind[1] , TOM SOLOMON, CARLEEN BOYER, Bucknell University — We present experiments that study the behavior of the excitable Belousov-Zhabotinsky (BZ) reaction in a chain of alternating vortices with an imposed uniform wind. Previous experiments[2] have shown that fronts in this system are pinned for a wide range of imposed wind speeds, propagating neither forward against the wind nor in the downwind direction. We explain this behavior with a recent theory[3] that proposes the existence of *burning invariant manifolds* (BIMs) that act as local barriers to front propagation. Fronts are pinned when a BIM or a combination of BIMs spans the width of the vortex chain, blocking the reaction front. We show experimental measurements of the shape of the pinned front for a range of different wind speeds, and compare these shapes to the BIMs calculated theoretically. We also consider the dependence of the front shape on the location of the initial trigger for the front.

3:06PM R39.00004 Pinning of reaction fronts by burning invariant manifolds in spatially-disordered fluid flows[1] , MAYA NAJARIAN[2], TOM SOLOMON, Bucknell University — We present experiments on the pinning of reaction fronts in spatially-disordered fluid flows with an imposesd wind. The disordered flow is driven by a magnetohydrodynamic forcing technique, and there is a uniform wind imposed on the flow with the use of a translation stage. Reaction fronts are produced using the excitable Belousov-Zhabotinsky chemical reaction. For a wide range of wind speeds, a complicated stationary front forms, pinned to the underlying vortex flow, neither propagating forward against the wind nor being blown backwards. The shape of the front depends significantly on the magnitude of the imposed wind. We propose that the shape of the stationary front is determined by a collection of overlapping BIMs that act as barriers against forward movement of the reaction front. The location of the BIMs can be predicted by integrating a three-dimensional set of ordinary differential equations[3] that describes the dynamics of an element of an evolving reaction front in the fluid flow.

3:18PM R39.00005 Laboratory Scale Simulating of Strange Spiral Plumes in Fluid with Hight Ptandtl Number , ALBERT SHARIFULIN, Perm State Technical University, ANATOLY POLUDNITSIN, Perm State University — We experimentally investigated the appearance of a plumes from local hot spot and study its interaction with cellular flow in closed cavity filled by silicon oil with Prandtl number $\mathrm{Pr} \approx 2 \cdot 10^3$. Convective plume generated by a local heat source, located on the top of the small rubber cylinder, which is located in the center of the bottom of the rectangular cell. To simulate the hot-spot green laser has been used. Roll-type large-scale convective flow was generated by heating of the one vertical sides of cavity. Influence of power of hot point on the shape of plume has been investigated. It is shown that the presence of cellular convective motion may lead to the formation of a strange spiral convective plume. This plume looks like Archimedes spiral replaced on vertical plane. Physical mechanism of the formation of strange spiral plume and application of obtained results for mantle convection problems are discussed.

3:30PM R39.00006 Double-diffusive layers adjacent to cold chimney flows during transient mushy-layer growth , JIN-QIANG ZHONG, TongJi University, Shanghai, China, QIWEI XUE, JOHN WETTLAUFER, Yale University, NewHaven, CT, USA — We examine the cooling effect of chimney flows in the liquid region during transient upward growth of a mushy layer in solidifying aqueous ammonium chloride. Through drainage channels in a mushy layer, cold, relatively fresh fluid is carried into the warm, salt-stratified liquid region. Double-diffusive cells form due to the cooling effect of the chimney flows and evolve into a series of downwelling horizontal layers. Using shadowgraph methods and dyed fluids we demonstrate the vigorous flow circulations and compositional mixing within each layer. Vertical concentration and temperature profiles reveal the double-diffusive staircase structure across the layers. The downward velocity of the layers decreases as they approach to the mush-liquid interface, which is interpreted by a filling-box model representing the momentum and compositional transport of turbulent continuous plumes in a confined region. The present experiment provides insight to evaluate the solute fluxes from growing mushy layers.

3:42PM R39.00007 Connectivity-disorder effect on collective synchronization , JAEGON UM, School of Physics, Korea Institute for Advanced Study, Seoul 130-722, Korea, HYUNSUK HONG, Department of Physics, Chonbuk National University, Jeonju 561-756, Korea, HYUNGGYU PARK, School of Physics, Korea Institute for Advanced Study, Seoul 130-722, Korea — We investigate a system of random frequency oscillators coupled through sparse random networks and explore connectivity-disorder effects on collective synchronization. In particular, we pay attention to how the random quenched disorder in connectivity affects the nature of synchronization transitions. The oscillator frequencies are assigned independently from an unimodal, bimodal, or uniform distribution. Extensive numerical simulations as well as the mean-field analysis have been performed on Erdös-Rényi random networks. We find that the quenched connectivity disorder invalidates the mean-field prediction of distinctive transition natures depending on frequency distributions in random networks. In fact, the same continuous synchronization transition is found for all types of frequency distributions. The physical origin of this unexpected result is discussed.

3:54PM R39.00008 Geometry of branching stream networks , HANSJORG SEYBOLD, ROBERT YI, ALEX PETROFF, OLIVIER DEVAUCHELLE, DANIEL ROTHMAN, MIT — River networks have been a source of fascination for centuries. Yet, how these networks form and create these geometries remains elusive. Recently we have shown that streams branching in a diffusive field bifurcate at a characteristic angle of $\alpha = 2\pi/5 = 72^\circ$. This result is obtained from Lowner dynamics by combining classical results of groundwater hydrology with the hypothesis that streams grow in the direction of maximal water flux into the channel's tip. Our theoretical results are umambigously consistent with field measurements we conducted in a 100 km^2 channel network on the Florida Panhandle. Here we extend our theory to include slope effects and apply our analysis to large drainage basins. We hypothesize that the extension of the network at the tip is driven by a diffusive process leading to a (slope corrected) $2\pi/5$ branching at the leaves of the network.

4:06PM R39.00009 Absence of power-law scaling in the dendritic crystal growth of ammonium chloride , ANDREW DOUGHERTY, Lafayette College — We report measurements of the dendritic crystal growth of NH_4Cl from supersaturated aqueous solution at small supersaturations, with a goal of understanding the origin of the sidebranching structure. The early detection of sidebranches requires measurements of small deviations from the smooth steady state shape, but that underlying shape is not precisely known at the intermediate distances relevant for sidebranch measurements. We find that no simple power law describes the average crystal shape, the average sidebranch amplitude, or the average sidebranch envelope. Instead, the effective power law exponents appear to increase steadily as a function of distance from the dendritic tip. Comparisons of the amplitude of sidebranches with that predicted by models of noise-driven sidebranching require careful measurements of materials parameters such as the capillary length. Previous published estimates for this material varied by over a factor of 20. We report new measurements of the capillary length and find $d_0 = 0.224 \pm 0.005$ nm. Based on those new measurements, we find that the amplitude of the sidebranches in this system is larger than expected from numerical models.

4:18PM R39.00010 ABSTRACT WITHDRAWN –

4:30PM R39.00011 Multistable dynamics in electroconvecting liquid crystals , ZRINKA GREGURIC FERENCEK, JOHN CRESSMAN, George Mason University — Nonlinear driven system can exhibit a diverse range of dynamics, from highly ordered to chaotic. These systems are ubiquitous, from atmospheric phenomena to brain function. Here we study such dynamics in electroconvecting liquid crystals. There applied electric fields create structured roll-like patterns that support the creation, evolution, and annihilation of defects in the rolls. By using a time scale separation algorithm based on diffusion map delay coordinates we have been able to identify a small number of multistable dynamics in this system. We utilize perturbations to control or steer the system between these different dynamics. We will discuss how this method of identification and interaction can be utilized to better interact with a wide range of dynamic systems.

4:42PM R39.00012 Coherent Pattern Prediction in Swarms of Delay-Coupled Agents[1] , LUIS MIER-Y-TERAN-ROMERO, Johns Hopkins University/Naval Research Laboratory, ERIC FORGOSTON, Department of Mathematical Sciences, Montclair State University, IRA SCWARTZ, U.S. Naval Research Laboratory, Nonlinear Systems Dynamics Section, Plasma Physics Division — We consider a general swarm model of self-propelling particles interacting through a pairwise potential in the presence of a fixed communication time delay. Previous work has shown that swarms with communication time delays and noise may display pattern transitions that depend on the size of the coupling amplitude. We extend these results by completely unfolding the bifurcation structure of the mean field approximation. Our analysis reveals a direct correspondence between the different dynamical behaviors found in different regions of the coupling-time delay plane with the different classes of simulated coherent swarm patterns. We derive the spatio-temporal scales of the swarm structures, and also demonstrate how the complicated interplay of coupling strength, time delay, noise intensity, and choice of initial conditions can affect the swarm. In addition, when adding noise to the system, we find that for sufficiently large values of the coupling strength and/or the time delay, there is a noise intensity threshold that forces a transition of the swarm from a misaligned state into an aligned state. We show that this alignment transition exhibits hysteresis when the noise intensity is taken to be time dependent.

4:54PM R39.00013 Structure-Property Relationships for Branched Worm-Like Micelles , GREGORY BEAUCAGE, DURGESH RAI, University of Cincinnati — Micellar solutions can display a wide range of phase structure as a function of counter ion content, surfactant concentration, and the presence of ternary components. Under some conditions, common to consumer products, extended cylindrical structures that display persistence and other chain features of polymers are produced. These worm-like micelles (WLMs) can form branched structures that dynamically change under shear and even in quiescent conditions. The rheology of these branched WLMs is strongly dependent on migration of the branch points, and the dynamics of branch formation and removal. Persistence and other polymer-based descriptions are also of importance. We have recently developed a scattering model for branched polyolefins and other topologically complex materials that can quantify the branching density, branch length, branch functionality and the hyperbranch (branch-on-branch) content of polymers. This work is being extended to study branching in WLMs in work coupled with Ron Larson at UMich to predict rheological properties.

Session R40 DMP: Focus Session: Growth and Pattern Formation on Surfaces 349 - Zhenyu Zhang, University of Science and Technology of China

2:30PM R40.00001 Lateral Charge Transport in Atomically Clean, Ultra-thin Crystalline-Silicon Sheets[1] , WEIWEI HU, SHELLEY SCOTT, R.B. JACOBSON, DONALD SAVAGE, MARK ERIKSSON, MAX LAGALLY, University of Wisconsin — In very thin, atomically clean crystalline-Si sheets ("nanomembranes"), the electrical conductance is controlled by the surface. Conductance can occur either through surface transfer doping or directly in the clean-surface electronic bands. The thinner the sheet, the larger should be the contribution of the surface. We have earlier reported [1] conductance measurements on nanomembranes as thin as 77nm, and have shown that not only is the surface antibonding (π^*) band used to enhance "bulk" conduction in the membrane [2], but also the charges are additionally mobile in this band, providing a significant contribution to the overall conductance. We extend these measurements to thinner nanomembranes, between 64nm and 35nm thick, using a back-gated van der Pauw technique in ultra-high vacuum. The sheet conductance is measured after a high-temperature flash to obtain a high-quality Si(2×1) reconstructed surface, and with H adsorbed on the surface. The maximum sheet resistance for a 64nm sample with H deposited in situ is higher than 24 GΩ.

2:42PM R40.00002 Electronic properties of epitaxial silicene: a LT-STM/STS study , ANTOINE FLEURENCE, CHI-CHENG LEE, TAISUKE OZAKI, YUKIKO YAMADA-TAKAMURA, JAIST, YASUO YOSHIDA, YUKIO HASEGAWA, The Univ. of Tokyo — The astonishing properties of silicene, the Si-counterpart of graphene, together with pioneering experimental observations, triggered in the very recent years, an exponentially increasing interest for this atom-thick material, both at fundamental level and for applications in high-speed electronic devices. We demonstrated, that the spontaneous segregation of silicon on (0001) surface of zirconium diboride (ZrB_2) thin films epitaxied on Si(111) wafers gives rise to a wide-scale uniform two-dimensional silicene sheet [1]. The silicene nature of the honeycomb structure imaged by scanning tunneling microscopy is evidenced by the observation of gap-opened π-electronic bands. The band gap opening is primarily due the specifically imprinted buckling. Here, we present the results of a low-temperature scanning tunneling spectroscopy investigation, which evidences the n-doped nature of silicene. The mapping of the local density of states, together with density functional theory give precious insights into the microscopic origin of the electronic bands of silicene. In particular, it shows the correlation between the degree of sp^2 hybridization of different Si atoms in the internal structure and the character of the electronic bands.

2:54PM R40.00003 A planar-like silicene on ZrB_2(0001) surface revealed by a first-principles study , CHI-CHENG LEE, YUKIKO YAMADA-TAKAMURA, TAISUKE OZAKI, School of Materials Science, Japan Advanced Institute of Science and Technology (JAIST), 1-1 Asahidai, Nomi, Ishikawa 923-1292, Japan — Given that a free standing planar silicene is unstable [1], it is of great interest to understand the mechanism of stability of any existing planar-like structure that would optimize the understanding of the intrinsic difference from its counterpart, graphene. Recently, silicene was epitaxially grown on the ZrB_2(0001) surface and was demonstrated to have $(\sqrt{3}\times\sqrt{3})$-reconstruction due to irregular buckling [2]. While the deviation from the regularly buckled structure is clearly made by experiment, two possible structures revealed by a first-principles calculation are still in the candidate list, neither one is completely ruled out from the possible groundstate structure. The energetically more favorable one possesses a planar-like structure, with all Si atoms residing in a plane except the one on top of a Zr atom becomes higher. However, this structure is less preferable from available experimental data. By studying the binding energy and electronic band structures of these two structures with and without the substrate, we will explain why such a planar-like structure can gain more energy than the regularly buckled-like phases via the interaction of the ZrB_2(0001) surface and why the ground state advocated by density functional theory could become less preferable by experiment. [1] S. Cahangirov *et al.*, Phys. Rev. Lett. **102**, 236804 (2009). [2] A. Fleurence *et al.*, Phys. Rev. Lett. **108**, 245501 (2012).

3:06PM R40.00004 Growth and electronic properties of monolayer and multilayer silicene , BAOJIE FENG, LAN CHEN, KEHUI WU, Institute of Physics, Chinese Academy of Sciences — Silicene, in which Si atoms replace C atoms in a two-dimensional honeycomb lattice in analogue with graphene, has been experimentally realized recently. In this work we report a systematic study of superstructures formed by sub- monolayer and multiple layer silicon grown on Ag(111), by scanning tunneling microscopy (STM) and spectroscopy (STS). We found that, depending on the substrate temperature and silicon coverage, several monolayer superstructures can form on Ag(111). At proper temperature and Si coverage, monolayer and multilayer silicene films were grown [1]. STS at 4K revealed quasiparticle interference (QPI) patterns suggesting intervalley and intravalley scattering of charge carriers, and a linear energy-momentum dispersion relation and a large Fermi velocity were derived [2]. These results unambiguously prove the existence of Dirac fermions in silicene, and provide a solid basis for further studies on the electronic property and device applications of silicene. [1] Nano Letters 12, 3507 (2012), [2]Physical Review Letters 109, 056804 (2012).

3:18PM R40.00005 Quasiparticle Interference in Silicene on Ag(111) Surface , LAN CHEN, KEHUI WU, Institute of Physics, Chinese Academy of Sciences — Silicene, a single sheet of silicon atoms arranged in a honeycomb lattice analogous to graphene, has been successfully prepared on Ag(111) surface recently. The honeycomb atomic structure of silicene has been confirmed experimentally. However, more important details of the electronic structures of silicene, such as pseudospin or chirality of Dirac Fermions and the shapes of the Dirac cones, still remain illusive. Here we performed scanning tunneling microscopy and spectroscopy to investigate the electronic states of silicene on Ag(111) surface. From the quasiparticle interference (QPI) pattern observed in dI/dV maps, we derived linear energy-momentum dispersion and a large Fermi velocity, which prove the existence of Dirac fermion in silicene. Moreover, through mapping the QPI pattern in q space, we found the Dirac cones of silicene are not circular as in graphene, but significantly warped to hexagon. The theoretical calculations prove that the constant energy contours of Dirac cones of silicene are hexagonal warped due to the unique structure of silicene. Our results pave the way for exploiting anisotropic transport behavior and other exotic quantum effects in silicene.

3:30PM R40.00006 Nanostressor growth on Silicon Nanomembranes[1] , FRANK FLACK, BENJAMIN TREML, DONALD SAVAGE, MAX LAGALLY, University of Wisconsin - Madison — Single-crystal semiconductor nanomembranes (NMs) have great potential for microelectronic materials heterointegration. In particular, they allow for the fabrication of custom-strained, dislocation-free growth interfaces. However, thin substrates are extremely compliant and it is, therefore, crucial to understand the added effects of residual processing strain and substrate bonding. We study the strain distributions on silicon NMs transferred to patterned Si substrates such that some NM regions are bonded and others freestanding. As the critical thickness for Stranski-Krastanow growth of quantum dots (QDs) is very strain dependent, we decorate the surface with Ge quantum dots (QDs) and use the resulting distribution as an easily visible indicator of strain. We see dramatic differences between QD distributions on the bound and freestanding regions, and also between the bound regions and the bulk Si substrate, suggesting that the buried interface may influence nanostressor growth.

3:42PM R40.00007 Investigation of Mn-Co surface alloy on Si(100)-2x1[1] , GOPALAKRISHNAN RAMALINGAM, Materials Science and Engineering, University of Virginia, JEAN-FRANCOIS JACQUOT, INAC/SCIB, CEA-Grenoble, ROBERT MOREL, INAC/SP2M, CEA-Grenoble, MATTHIEU JAMET, INAC/NM, CEA-Grenoble, PETRA REINKE, Materials Science and Engineering, University of Virginia — Understanding of magnetic doping of Group-IV semiconductors is critical for the realization of spintronics devices. We present STM investigations of room temperature, sequential and co-deposition of Mn and Co on Si(100)-2x1. Monoatomic Mn-nanowires, which self-assemble on the Si surface, lose their continuity after deposition of 0.04-0.08 ML of Co. This loss in continuity is expressed in the wire length distributions, which are dominated by Mn dimers and ultrashort wires. Protrusions with a height of 0.5-0.8 Å above the surface of the Mn wire are observed, which is evidence for adsorption of Co on wires. The Si defect structure is similar to exclusive Co deposition experiments on Si, and in agreement with the model of subsurface diffusion of Co atoms present in literature. Only 25% of the deposited Co is observed on the surface and the rest are attached to the Mn structures. Wires form even during co-deposition of Mn and Co, indicating stronger Mn-Si and Mn-Mn interaction over Mn-Co interaction. The wire length distribution is dominated by ultrashort wires, similar to sequential deposition. A detailed discussion of the role of Co in breaking up the Mn wires will be presented. SQUID measurements are being performed to study the magnetic properties of Co-Mn-Si structures and will be discussed. DFT calculations for co-deposition of Mn and Co are presented and compared with experimental data.

3:54PM R40.00008 A Level-Set Approach to Simulate Mound Formation during Epitaxial Growth , CHRISTIAN RATSCH, JOE PAPAC, UCLA, FREDERIC GIBOU, UCSB — We have developed an island dynamics model that uses the level-set approach to model epitaxial growth. In recent work we have implemented a numerical scheme to solve the diffusion equation for the adatom concentration with a (mixed) Robin boundary condition. Such a boundary condition properly describes multilayer growth when there is an additional step-edge barrier for atoms to diffuse over a step edge. We will discuss how variations of the boundary condition that correspond to variations of the step edge barrier affect the formation of mounds. We will furthermore discuss how the effect of downward funneling can be implemented within our approach and how it affects the slop of the mounds.

4:06PM R40.00009 How nucleation can cause stacking faults on the GaAs (111) B surface: A DFT study , JOSHUA SHAPIRO, ANDREW LIN, DIANA HUFFAKER, CHRISTIAN RATSCH, UCLA — GaAs grows along the [111] direction much faster than other crystal axes at high growth temperature. In this work, we leverage this anisotropy, using catalyst-free selective-area epitaxy, to grow high-aspect ratio nanopillars. However, we find that the resulting crystal structure exhibits a high density of stacking faults that can have detrimental effects on the electronic and optical properties of the material. Each stacking fault is equivalent to a monolayer of wurtzite embedded in an otherwise zinc-blende lattice. The origins of stacking faults are currently under debate, with both thermodynamic equilibrium arguments and nucleation arguments proposed to explain the segments of wurtzite that appear in the primarily zinc-blende crystal. Here we present a density-functional-theory study of nucleation and island growth on the (111)B surface of GaAs that demonstrates how the smallest stable nucleus can transition and stabilize in either a wurtzite or a zinc-blende orientation.

4:18PM R40.00010 First principles study of Bismuth growth on Nickel (111) surface[1] , QIN GAO, MICHAEL WIDOM, Carnegie Mellon University — A recent experiment (Bollman, et al. 2011) suggests that Bismuth forms flat hexagonally close packed (hcp) films on the Nickel (111) surface, of heights 1, 3, 5 and 7 layers. A quantum size effect (QSE) based on free electrons was proposed in explanation. To test this idea, we calculated the total energy and QSE of Bismuth on Nickel (111) surface using density functional theory. We find the hcp films are destabilized by adding capping atoms which lead to puckering of the hcp layers and covalently bonded structures. Furthermore, we find the rhombohedral films based on the bulk Bi structure are energetically more favorable than the proposed hcp films. These structures also favor odd numbers of layers (a flat wetting layer followed by bulk-like rhombohedral bilayers), but owing to covalent chemical bonding rather than QSE.

4:30PM R40.00011 Absolute surface energies of polar and non-polar planes in GaN[1] , CYRUS E. DREYER, ANDERSON JANOTTI, CHRIS G. VAN DE WALLE, University of California, Santa Barbara Materials Department — Growth of high quality single crystals and epitaxial layers of GaN is very important for producing optoelectronic devices. First principles calculations can help in determining absolute surface energies, which are key quantities that control crystal-growth rates and fracture toughnesses. By means of hybrid functional calculations, we have determined absolute surface energies for the non-polar {11-20} and {10-10} and polar (0001) and (000-1) planes in wurtzite GaN. Low energy reconstructions of the bare and hydrogenated surfaces were considered under various conditions chosen to correspond to growth by molecular beam epitaxy (MBE) or metal-organic chemical vapor deposition (MOCVD). We find that the non-polar planes are close in energy, and lower in energy than the reconstructed (000-1) polar plane under all conditions considered. The reconstructions of the (0001) plane are lower in energy than the (000-1) plane over the whole range of conditions, and lower in energy than the non-polar reconstructions for high-pressure conditions. From these surface energies, lower bounds on the anisotropic fracture toughness of GaN are determined. Surface energies of polar planes for other III-nitrides will be compared to those of GaN.

4:42PM R40.00012 DFT studies of the early stages of growth of Nb on MgO(100)[1] , YUNSIC SHIM, JACQUES G. AMAR, University of Toledo — Using DFT calculations of binding and adsorption energies for various sizes and shapes of Nb clusters on MgO(100) surfaces, we have examined the effects of cluster shape and a neutral O vacancy on the energies and stability of Nb[100] and [110] island structures. Similarly to other cases of metal adsorbates on MgO(100) surfaces, O-vacancy sites tend to act as nucleation sites for Nb adatoms, while the effect of a nearby O vacancy on the binding energy of a Nb cluster is much weaker. In particular, we find that the binding energy for a Nb monomer at an O site (O-vacancy site) is 1.52 eV (2.2 eV) while the energy barrier for Nb monomer diffusion is 0.58 eV. In addition, although both isolated 4-atom Nb [100] and 5-atom Nb [110] islands are isotropic with a slightly higher binding energy for the [100] island, for larger clusters an anisotropic Nb [110] structure is more stable than a square Nb [100] structure, which is in good agreement with a recent experimental result [1].

4:54PM R40.00013 Self Directed Growth of Nanopillar Arrays in Molten Polymer Films: Theory versus Experiment , KEVIN FIEDLER, SANDRA TROIAN, California Institute of Technology, MC 128-95, Pasadena, CA 91125 — It has been known for over a decade that molten polymer films exposed to a large uniform thermal gradient can develop spontaneous arrays of nanopillars. Theoretical predictions based on linear stability theory in the long wavelength approximation suggest that such formations arise from fluctuations either in the electrostatic attraction between the fluid and opposing substrate, acoustic phonon radiation pressure within the film, or thermocapillary forces along the air/polymer interface. Experimental confirmation of the mechanism responsible for such emergent structures requires measurements of the pattern formation process at very early times, a difficult task given that initial thickness fluctuations are of the order of a few nanometers. Here we report results of in-situ microscopy measurements of the dominant wavelength as a function of the applied thermal gradient and initial film thickness. Comparison to all three models indicates closest agreement with the thermocapillary mechanism. However, there remain discrepancies between theory and experiment with regard to the dominant wavelength observed and its corresponding growth rate. We discuss possible origins for the discrepancies, including non-stationary effects and simplified assumptions of the thermocapillary model.

5:06PM R40.00014 Guided Growth of Millimeter-Long Horizontal Nanowires with Controlled Orientations , DAVID TSIVION, MARK SCHVARTZMAN, Department of Materials and Interfaces, Weizmann Institute of Science, RONIT POPOVITZ-BIRO, PALLE VON HUTH, Chemical Research Support, Weizmann Institute of Science, ERNESTO JOSELEVICH, Department of Materials and Interfaces, Weizmann Institute of Science — The large-scale assembly of nanowires (NWs) on surfaces remains one critical challenge toward their integration into practical devices. We report the vapor-liquid-solid growth of perfectly aligned, millimeter-long horizontal GaN [1] and ZnO [2] NWs with controlled orientations on different sapphire planes. The growth directions, crystallographic orientation and faceting of the NWs vary with each surface orientation, as determined by their epitaxial relation with the substrate, as well as by a graphoepitaxial effect that guides their growth along surface steps and grooves. Despite their interaction with the surface, these NWs display few structural defects, exhibiting optical and electronic properties comparable to those of vertically grown NWs. Further control was recently achieved by patterning the catalyst nanoparticles to produce NWs with well-defined locations, orientation and length. This enables the massively parallel integration of NW circuits. The guided growth approach paves the way to highly controlled NW structures with potential applications not available by other means. [1] D. Tsivion, M. Schvartzman, R. Popovitz-Biro,P. von Huth and E. Joselevich, Science **333**, 1003 (2011). [2] D. Tsivion, M. Schvartzman, R. Popovitz-Biro and E. Joselevich, ACS Nano **6**, 6433 (2012).

5:18PM R40.00015 Low-energy Alkali Ion Scattering and X-ray Photoelectron Diffraction Studies of the Structure of Pt-Zn/Pt(111) Bimetallic Surfaces[1] , BRUCE KOEL, JOHN ROSZELL, Princeton University, EDDIE MARTONO, JOHN VOHS, University of Pennsylvania — Pt-Zn alloys have applications in heterogeneous catalysis, and studies on surfaces of well-defined, ordered Pt-Zn alloys, or intermetallic compounds, clarify the origins of changes that occur in catalysis by the alloy. Many stable intermetallic compounds of Pt and Zn occur in bulk materials, but no long-range ordered surface alloys were formed by depositing Zn on a Pt(111) single-crystal substrate in a search over a considerable range of conditions. These results can be contrasted to those from Pt-Sn, where ordered surface alloys were formed. Zn alloys with Pt upon heating, and XPD and ALISS were used to characterize the Pt-Zn alloy created by annealing one monolayer of Zn on Pt(111) to 650 K. This Pt-Zn/Pt(111) surface alloy had a diffuse (1x1) LEED pattern due to formation of a random, substitutional alloy between Pt and Zn with 0.05-monolayer Zn in the topmost layer. Zn atoms are substitutionally incorporated into Pt lattice positions and alloyed Zn atoms in the surface layer are located coplanar with the surface Pt atoms, without any buckling. TPD shows that both CO and NO chemisorb more weakly on the Pt-Zn alloy than on the clean Pt(111) surface, with NO more strongly affected.

5:30PM R40.00016 Positron states and annihilation characteristics of surface-trapped positrons at the oxidized Cu(110) surface[1] , N.G. FAZLEEV, ANTOINE OLENGA, A.H. WEISS, Department of Physics, University of Texas at Arlington — The process by which oxide layers are formed on metal surfaces is still not well understood. In this work we present the results of theoretical studies of positron states and annihilation characteristics of surface-trapped positrons at the oxidized Cu(110) surface. An ab-initio investigation of stability and associated electronic properties of different adsorption phases of oxygen on Cu(110) has been performed on the basis of density functional theory and using DMOl3 code. The changes in the positron work function and the surface dipole moment when oxygen atoms occupy on-surface and sub-surface sites have been attributed to charge redistribution within the first two layers, buckling effects within each layer and interlayer expansion. The computed positron binding energy, positron surface state wave function, and annihilation probabilities of surface trapped positrons with relevant core electrons demonstrate their sensitivity to oxygen coverage, elemental content, atomic structure of the topmost layers of surfaces, and charge transfer effects. Theoretical results are compared with experimental data obtained from studies of oxidized transition metal surfaces using positron annihilation induced Auger electron spectroscopy.

Wednesday, March 20, 2013 2:30PM - 5:30PM –
Session R41 DAMOP: Casimir Forces 350 -

2:30PM R41.00001 Measurement of the Casimir force between ferromagnetic surfaces , UMAR MOHIDEEN, ALEXANDR BANISHEV, Department of Physics and Astronomy, University of California, Riverside, USA, GALINA KLIMCHITSKAYA, VLADIMIR MOSTEPANENKO, Central Astronomical Observatory at Pulkovo of the Russian Academy of Science, St. Petersburg, Russia — We have measured the Casimir interaction between two ferromagnetic boundary surfaces using the dynamic atomic force microscope in the frequency shift technique. The experimental data are found to be in excellent agreement with the predictions of the Lifshitz theory for magnetic boundary surfaces combined with the plasma model approach for the free electrons in the metal. In an important difference from non-magnetic metals, the Drude description of the free electrons leads to a Casimir force that is less than that from the plasma model approach. Thus the role of hypothetical patch potentials will be opposite to that required for reconciliation of the data with the Drude model.

2:42PM R41.00002 Validity of effective medium theories in Casimir force calculations[1] , RAUL ESQUIVEL-SIRVENT, Instituto de Fisica, Universidad Nacional Autonoma de Mexico — Effective medium theories have been used extensively to describe the dielectric response of inhomogeneous media. This is media that is composed of a mixture of materials with different dielectric functions. The possibility of using inhomogeneous media to control or tune Casimir forces has been discussed in the literature. In this paper we present results for the Casimir force between two inhomogeneous plates described by different effective medium models. In particular we show how the force depends on the model used. This has implications on the comparison between theoretical and experimental results. Furthermore, we calculate the force between an inhomogeneous sphere like multi layered nano shells and a plane to study the effects of effective models when using the proximity force approximations. The conditions under which effective medium models can be used in the context of the Casimir force are discussed in detail.

2:54PM R41.00003 Experiments on Sphere Cylinder Geometry Dependence in the Electromagnetic Casimir Effect , SHOMEEK MUKHOPADHYAY, EHSAN NORUZIFAR, JEFFREY WAGNER, ROYA ZANDI, UMAR MOHIDEEN, University of California, Riverside — We report on ongoing experimental investigations on the geometry dependence of the electromagnetic Casimir force in the sphere-cylinder configuration. A gold coated hollow glass sphere which forms one surface is attached to a Silicon AFM cantilever. The cylinder, which is constructed from tapered optical fiber is also gold coated. The resonance frequency shift of the cantilever is measured as a function of the sphere-cylinder surface separation. The sphere-cylinder electrostatic force is used for alignment of the sphere and the cylinder and also for calibrating the system. The results are compared to numerical simulations in the framework of the Proximity Force Approximation (PFA).

3:06PM R41.00004 Sum-over-modes approach to the Casimir effect in dissipative systems , FRANCESCO INTRAVAIA, RYAN BEHUNIN, Theoretical Division, MS B213, Los Alamos National Laboratory, Los Alamos, NM 87545, USA — We show that, within the open-system framework, the sum-over-modes approach à la Casimir leads to the Lifshitz formula for the Casimir free energy. A general result applicable to arbitrary geometries is obtained through the use of Ford, Lewis, & O'Connell's remarkable formula. Additionally, we address the possibility for obtaining the Casimir energy as a sum over complex "modes." We show in this case that the standard sum-over-modes formula must be suitably generalized to avert unphysical complex energies.

3:18PM R41.00005 Influence of Casimir-Lifshitz forces on actuation dynamics of MEMS , WIJNAND BROER, GEORGE PALASANTZAS, JASPER KNOESTER, University of Groningen, VITALY SVETOVOY, University of Twente — Electromagnetic fluctuations generate forces between neutral bodies known as Casimir-Lifshitz forces, of which van der Waals forces are special cases, and which can become important in micromechanical systems (MEMS). For surface areas big enough but gaps small enough, the Casimir force can possibly draw and lock MEMS components together, an effect called stiction, causing device malfunction. Alternatively, stiction can also be exploited to add new functionalities to MEMS architecture. Here, using as inputs the measured frequency dependent dielectric response and surface roughness statistics from Atomic Force Microscopy (AFM) images, we perform the first realistic calculation of MEMS actuation. For our analysis the Casimir force is combined with the electrostatic force between rough surfaces to counterbalance the elastic restoring force. It is found that, even though surface roughness has an adverse effect on the availability of (stable) equilibria, it ensures that those stable equilibria can be reached more easily than in the case of flat surfaces. Hence our results can have significant implications on how to design MEM surfaces. The author would like this abstract to appear in a Casimir related session.

3:30PM R41.00006 Scattering Theory Calculations of Casimir Energies at High Curvature[1] , NOAH GRAHAM, Middlebury College, THORSTEN EMIG, Universite Paris Sud, ADEN FORROW, Middlebury College, ROBERT JAFFE, MEHRAN KARDAR, MOHAMMAD MAGHREBI, Massachusetts Institute of Technology, JAMAL RAHI, Rockefeller University, ALEX SHPUNT, PrimeSense Inc. — Scattering theory provides a powerful tool for capturing the response of an object to electromagnetic charge and field fluctuations. Techniques based on scattering theory have made possible a wide range of new calculations of Casimir energies. In this approach, the Casimir interaction energy for a collection of objects can be expressed in terms of the scattering T-matrices for each object individually, combined with universal translation matrices describing the objects' relative positions and orientations. These translation matrices are derived from an expansion of the free Green's function in an appropriate coordinate system, independent of the details of the objects themselves. This method proves particularly valuable for geometries involving high curvature, such as edges and tips. I will describe this approach in general terms and then give results from several problems to which it has been applied successfully. I will also discuss new developments in scattering theory that have been motivated by these problems.

3:42PM R41.00007 ABSTRACT WITHDRAWN –

3:54PM R41.00008 Investigation of electrostatic "patches" on Au samples: Effects on the Casimir measurements , RICARDO DECCA, GUILLAUME VOISIN, Department of Physics, Indiana University-Purdue University Indianapolis — It has been argued by Behunin and co-workers that the measurements done of the Casimir force on Au coated surfaces could suffer from substantial systematic errors arising from the presence of so called electrostatic "patches" (i.e. an electrostatic potential distribution on the surface of the Au layer). While these effects can be minimized, in principle they cannot be nullified by the application of uniform potential differences between the investigated surfaces. We present Kelvin probe microscopy studies of Au samples on Si. Au samples (about 200 nm thick) were deposited by thermal evaporation and sputtering. A thin (about 10 nm thick) layer of Cr is used as an adhesion layer. We will discuss the methodology used. We will show that that irrespectively of sample deposition method, there is two characteristic scales for the potential distribution: One, with spatial size of about 100 nm, associated with grain sizes and the other one, typical dimension 1 μm, most likely associated with unavoidable sample contamination. The effect of this potentials is found to be too small to affect the conclusions found in precision measurements of the Casimir effect.

4:06PM R41.00009 Casimir effect between Topological Insulators: a proposal for quantum levitation , PABLO RODRIGUEZ-LOPEZ, Universidad Carlos III de Madrid, ADOLFO GRUSHIN, ALBERTO CORTIJO, CSIC — In this talk I will study the Casimir interaction between Topological Insulators (TIs). I will start with a brief description of the TIs, to explain what a TI is, and why they are interesting from a Casimir effect point of view. In particular, a three dimensional Topological Insulator is characterized by its topological magnetoelectric coupling $\theta \neq 0$. We will discuss the electromagnetic response of the TIs, how a magnetoelectric coupling between TE and TM modes appears in this material and its consequences. We will show how, by tuning the parameter θ of the TI, we will be able to change the behavior of the Casimir energy between Tis from attraction to repulsion for all distances, and even the appearance of an equilibrium distance in the system. Then TIs can be potentially used to obtain "quantum levitation" and to avoid the sticking phenomena in NEMS.

4:18PM R41.00010 Three-body Casimir effects and repulsion[1] , KIMBALL MILTON, University of Oklahoma — The Casimir effect arises from quantum fluctuations in the electromagnetic field and results in forces between atoms (van der Waals and Casimir-Polder forces), between atoms and surfaces (Casimir-Polder forces), and between conducting and dielectric surfaces (Casimir-Lifshitz forces). In the past few years, there has been a revolution in our ability to calculate forces between different bodies. Pairwise summation of interatomic forces in general is very inadequate to describe the physics. In particular three-body effects can be large. Two-body forces, for example, between a dielectric sphere and a dielectric plane, can be calculated by a combination of analytic and numerical techniques; non-monotonic effects can occur when three-body interactions are considered. Anisotropic objects with ordinary electrical properties can give rise to repulsive quantum vacuum forces, which might have application in nanotechnology. This talk will focus on the overlap of the three-body force regime and Casimir repulsion, for example, the interaction between an anisotropically polarizable atom and a pair of facing conducting wedges, or two conducting half-planes constituting an aperture.

4:30PM R41.00011 Electromagnetic fluctuation-induced interactions with metallic gratings , DIEGO DALVIT, Los Alamos National Laboratory — In this talk I will discuss electromagnetic equilibrium and non-equilibrium fluctuation-induced interactions involving metallic gratings. In particular, I will describe a modal approach [1] to compute Casimir forces between metallic gratings and discuss the description of a recent Casimir force experiment with nanostructures that shows a strong force reduction. I will also discuss the related non-equilibrium problem of nanoscale heat transfer in metallic gratings from a modal approach point of view [2].

[1] *Quasi-analytical modal approach for computing Casimir interactions in periodic nanostructures*, F. Intravaia, P.S. Davids, R.S. Decca, V.A Aksyuk, D. Lopez, and D.A.R. Dalvit, Phys. Rev. A 86, 042101 (2012).
[2] *Enhanced radiative heat transfer between nanostructured gold plates*, R. Guerout, J. Lussange, F.S.S. Rosa, J.-P. Hugonin, D.A.R. Dalvit, J.-J. Greffet, A. Lambrecht, and S. Reynaud, Phys. Rev. B85, 180301(R) (2012).

4:42PM R41.00012 Fundamental limitations on force sensing due to patch potentials , RYAN BEHUNIN, Los Alamos National Laboratory, LOS ALAMOS NATIONAL LABORATORY COLLABORATION, INDIANA UNIVERSITY-PURDUE UNIVERSITY INDIANAPOLIS COLLABORATION, UNIVERSITY OF BIRMINGHAM COLLABORATION — In this talk I will discuss some of the current methods used for measuring non-Newtonian corrections to gravity at short separation. When polycrystalline metallic test masses are used in these experiments patch potentials may provide a large source of noise. I'll present a simple model to quantify patch effects from which insights may be gained for minimizing deleterious effects on force signal to noise in these experiments.

4:54PM R41.00013 Measurement of the Casimir force between gold surfaces using a Frequency-Modulation technique , JOE GARRETT[1], JEREMY MUNDAY[2], University of Maryland — The Casimir force arises from the interactions between fluctuating dipoles in two media separated by a gap. We measure the derivative of the Casimir force with respect to sample separation between a gold-coated sphere and a gold-coated planar substrate using a non-contact Frequency-Modulation (FM) method of Atomic Force Microscopy (AFM) in a thermally controlled environment. The resonant frequency of the cantilever is tracked as the sphere is brought close to the surface. At each distance from the surface, the bias voltage of the sphere is swept, both to measure the distance between the sphere and the plate and to mitigate the effect of any contact potential difference. We will present recently obtained experimental data and discuss the various artifacts associated with Casimir force measurements.

5:06PM R41.00014 Shape and material effects in Casimir forces , THORSTEN EMIG, LPTMS, CNRS and Universite Paris-Sud, UMR8626, 91405 Orsay, France, GIUSEPPE BIMONTE, Dipartimento di Scienze Fisiche, Università di Napoli Federico II, Via Cintia, 80126 Napoli, Italy, MOHAMMAD MAGHREBI, Physics Department, Massachusetts Institute of Technology, 77 Massachusetts Avenue, Cambridge, MA 02139, NOAH GRAHAM, Department of Physics, Middlebury College Middlebury, VT 05753, ROBERT JAFFE, Center for Theoretical Physics, Massachusetts Institute of Technology, 77 Massachusetts Avenue, Cambridge, MA 02139, MEHRAN KARDAR, Physics Department, Massachusetts Institute of Technology, 77 Massachusetts Avenue, Cambridge, MA 02139 — Casimir forces depend non-trivially on shape and material properties. Using ideas from electromagnetic scattering theory and conformal mappings, we have derived a number of novel analytical and numerical results for Casimir interactions. We shall give a brief overview of the general approach and present explicit results for some generic examples, including short- and long-distance expansions, interaction of perfect conductors with sharp edges and tips, and exact solutions in two and three dimensions. The predictions are compared to recent experiments.

5:18PM R41.00015 Heat transfer and non-equilibrium Casimir force in nanostructured surfaces

, ROMAIN GUÉROUT, SERGE REYNAUD, ASTRID LAMBRECHT, Laboratoire Kastler-Brossel — I'll review recent calculations for Casimir interactions between nanostructured surfaces both at thermodynamic equilibrium and out of equilibrium in the framework of the scattering theory. I'll emphasize on the interplay between the thermal Casimir force and the geometry of the surfaces. We predict an enhancement in the heat transfer between metallic gratings due to the appearance of spoof surface plasmons modes. We also show that the thermal component of the Casimir force arise at shorter separation distance in the case of nanostructured surfaces.

Session R42 DCP: Colloids and Interfaces Hilton Baltimore Holiday Ballroom 3 - Jesse Kern, University of Kansas

2:30PM R42.00001 Curvature-Induced Potential for Colloidal Particles at an Oil-Water Interface

, COLM KELLEHER, PAUL CHAIKIN, New York University — At the micrometer scale, surface tension plays a predominant role in the interactions that occur at fluid interfaces. For example, when a spherical colloidal particle is adsorbed onto a curved oil-water interface, the surface must deform in order to satisfy the requirement of constant contact angle. The energy cost of the deformation depends on the local curvature of the interface, and so a particle sitting on an interface of varying curvature will experience a potential which depends on the particle's position on the interface. We present results from an experiment in which a capillary bridge droplet creates an interface of varying Gaussian curvature. The shape of this interface is obtained by using confocal microscopy. One or more spherical microparticles are then introduced to the interface. We demonstrate that a curvature-induced potential exists for a single wetting particle, which attracts the particle to the most highly curved regions. By tracking the motion of the particle in 3D, we are able to calculate the forces acting on the particle. We can then compare these forces to theoretical and numerical predictions based on the shape of the interface.

2:42PM R42.00002 Self-pinning by colloids confined at a contact line[1]

, BYUNG MOOK WEON[2], JUNG HO JE[3], Pohang University of Science and Technology — Colloidal particles suspended in a fluid usually inhibit complete wetting of the fluid on a solid surface and cause pinning of the contact line, known as self-pinning. We show differences in spreading and drying behaviors of pure and colloidal droplets using optical and confocal imaging methods. These differences come from spreading inhibition by colloids confined at a contact line. We propose a self-pinning mechanism based on spreading inhibition by colloids. We find a good agreement between the mechanism and the experimental result taken by directly tracking individual colloids near the contact lines of evaporating colloidal droplets.

2:54PM R42.00003 Holographic Imaging of Interfacial Mobility at Emulsion Interfaces

, SCOTT PARKER, MELINDA SINDORO, STEVE GRANICK, University of Illinois — The difficulty of achieving nm resolution in the vertical direction has limited prior studies of nanoparticle mobility at the oil-water interface. This can be overcome by techniques of holographic imaging, implemented in this study and applied here to this problem. We have studied both homogeneous and Janus particles with emphasis on what determines the dynamics of surface pinning and desorption. Surprising dependence is found on conditions which govern kinetic depinning and the time scale for desorption.

3:06PM R42.00004 The Effect of Size, Morphology and Composition on Second Harmonic Light Scattering from Colloidal Particles

, GRAZIA GONELLA, HAI-LUNG DAI, Department of Chemistry - Temple University, Philadelphia, PA 19122 — Second harmonic light scattering (SHS) is a coherent second-order optical technique that is specifically surface sensitive and can be performed in-situ [1]. It has also been recently shown to be sensitive to size, shape and composition of metallic (Ag) and dielectric (polystyrene) nano and microparticles with or without adsorbed molecular monolayers. An understanding of how the size, shape, composition, structure, charge and surface chemistry influence the nonlinear optical properties makes SHS a versatile in-situ probe of nano- and/or micro-particle whose importance span from plasmonics to biomedicine [2].

3:18PM R42.00005 Using DNA-directed crystals to template colloidal clusters

, JOHN CROCKER, JAMES MCGINLEY, TALID SINNO, University of Pennsylvania — DNA is a versatile tool for directing the controlled self-assembly of nanoscopic and microscopic objects. We demonstrate a new, scalable method for producing highly ordered clusters of sub-micron colloidal microspheres at high yield. The basic idea is first to form a binary AB-type crystal using DNA-directed assembly, where a small fraction of the A species, A', contains a unique DNA sequence not present on the other A species. If the DNA domain of the A' and A particles that drive their interaction with the B species are identical, then the A' co-crystallize stiochiometrically as an 'impurity' into a well ordered AB lattice. Once formed, a soluble DNA strand is added to the crystals which binds the unique A' sequence and selectively stabilizes the A'-B bonds. When the crystals are then melted by heating, every A' particle yields a cluster surrounded by its nearest B neighbors. We will discuss the different clusters we have formed using this approach, as well as limits to yield and ordering in the clusters.

3:30PM R42.00006 Particle-Size Dependency of Single Molecule Properties in Surface-Tethered Particle Systems by Monte Carlo Simulation

, IAN HAMILTON, MARC ROBERT, Rice University — We consider the behavior of a surface-tethered particle system, comprising a single colloid particle tethered to a flat surface by a single polymer chain. This study is relevant to the interpretation of tethered particle motion experiments, wherein the motion and position of the tethered particle are used as reporters on the conformational properties of the underlying polymer molecule. The dependency of the polymer dimensions on the relative size of the tethered particle at equilibrium is obtained by Monte Carlo simulations with both random walk and self-avoiding walk polymer models. Two local maxima are found in the expansion factors of the polymer tether as a function of particle size, with both models. Comparison of these two models shows that the particle-size effects are separable from expansion by self-excluded volume of the polymer. Furthermore, the non-monotonic behavior persists to very large particle sizes before the expected asymptotic gparallel plate h limit is reached. The maxima are revealed to be due to the rotational entropy of the junction between the polymer and particle.

3:42PM R42.00007 Liquid-vapor interface in two-dimensional colloid-polymer systems , MARIAM NOURI, Rice University, RYAN MCGORTY, VINOTHAN MANOHARAN, Harvard University, MARC ROBERT, Rice University — The phase diagrams of two-dimensional aqueous colloid-polymer systems are determined experimentally. Mixtures of fluorescent polystyrene spheres and polyacrylamide are confined between a glass slide and a coverslip to construct a two-dimensional system. Liquid–vapor phase coexistence between a colloid-rich phase (colloid liquid) and a polymer-rich phase (colloid vapor) occurs at intermediate polymer concentrations, while vapor–solid phase coexistence between a polymer-rich liquid and a colloid-rich solid is observed at high polymer concentrations. For the interface between the coexisting liquid-vapor phases, the interfacial thickness and tension are measured using image analysis and Fourier analysis of the capillary waves. Close to the critical point, the fluctuations of the inteface become large and can no longer be decomposed into waves. It is also observed that the colloid-rich solid and liquid domains coarsen mainly by Ostwald ripening in a short time and long time regime.

3:54PM R42.00008 Tunable Soft Structure in Charged Fluids confined by Dielectric Interfaces , JOS ZWANIKKEN, MONICA OLVERA DE LA CRUZ, Department of Materials Science and Engineering, Northwestern University, 2220 Campus Drive, 60208 Evanston, Illinois, United States — We study the deformation of the local structure in an electrolytic background by micro- and nanoscopic polarizable surfaces, and vice versa, the emergence of induced forces between two surfaces due to the cohesive properties of the background. The range and strength of these forces depend sensitively on the material properties of the charged fluid, and can be varied over decades, offering high tunability and, aided by accurate theory, control in experiments and applications. The attention is directed towards the electrolyte-induced forces between neutral boundaries, to distinguish correlational effects from simple ionic screening. The interplay of thermal motion, short range repulsions, and electrostatic forces is responsible for a typical ordered fluid state, a soft structure, that changes near polarizable interfaces and causes diverse attractions between fluctuation-confining walls that seem well exploited by microbiological systems. We use liquid state theory and classical density functional theory to accurately calculate these interactions and nuance the understanding of double-layer forces, relevant for colloid and emulsion stability, phase-transfer catalysis, and (interface-directed) self-assembly of nanomaterials.

4:06PM R42.00009 Interfacial free energy calculation of a binary hard-sphere fluid at a hard wall by Gibbs-Cahn Integration , JESSE KERN, BRIAN LAIRD, University of Kansas — The interfacial free energy, γ, of fluids at surfaces is a parameter that is central to a number of technologically important phenomena, such as wetting, nucleation and the stability and self assembly of colloidal particles in solution. In recent years, our group has developed techniques to determine γ from atomistic simulation. In this work, we apply one of these methods, Gibbs-Cahn Integration, to determine γ for a model two-component (binary) mixture of hard spheres. Molecular dynamics simulation is used to characterize a hard-sphere fluid mixture in a slit-pore confined geometry as packing fraction, mole fraction, and diameter ratio are varied. We find that recent theoretical predictions from the White Bear II classical density functional theory [Roth et al., J. Phys.: Condens. Matter, *18*, 8413, (2006)] agree well with our computational results We also observe that, for this model system, the preferential adsorption of one particle species over the other contributes negligibly to the interfacial free energy at modest diameter ratios.

4:18PM R42.00010 Understanding the correlation function of the inhomogeneous hard-sphere fluid , JEFF SCHULTE, PATRICK KREITZBERG, CHRIS HAGLUND, DAVID ROUNDY, Oregon State University — We present a new functional for the correlation $g(r)$ at contact for an inhomogeneous distribution of hard spheres. This term is a key input into classical density functional theories developed using Statistical Associating Fluid Theory, a widely used approach for handling complex liquids in which hydrogen bonding plays an important role. We use a thermodynamic approach to derive an exact formula for the correlation expressed as a derivative of the free energy functional. We evaluate this approach using the approximate free energy of the "White Bear" version of Fundamental Measure Theory, and test our approach (and two previously published approximations) against correlation values found from Monte Carlo simulations.

4:30PM R42.00011 Testing "Soft" Fundamental Measure Theory for not-so-hard-sphere fluids , ERIC KREBS, PATRICK KREITZBERG, DAVID ROUNDY, Oregon State University — A standard approach for modelling in-homogeneous distributions of the hard-sphere fluid is the Fundamental Measure Theory (FMT) formulation of classical density functional theory. Due to the paucity of truly hard spheres in the real world, it seems advisable to consider interactions that are not quite so "hard," a challenge tackled by the "Soft" FMT (SFMT) introduced by Schmidt [1]. We apply SFMT to a simple potential describing slightly penetrable spheres, that is, spheres at moderate temperatures—such that the spheres are thermally able to penetrate by a short distance. We compare the predicted equation of state with the result of Monte Carlo simulations, and also compare the free energy and density distribution near a hard wall with simulation.

[1] Schmidt, M. Phys. Rev. E 62(4), 4976 (2000)

4:42PM R42.00012 Nonlinear functional for solvation in Density Functional Theory[1] , DENIZ GUNCELER, RAVISHANKAR SUNDARARAMAN, KATHLEEN SCHWARZ, KENDRA LETCHWORTH-WEAVER, T. A. ARIAS, Cornell University — Density functional calculations of molecules and surfaces in a liquid can accelerate the development of many technologies ranging from solar energy harvesting to lithium batteries. Such studies require the development of robust functionals describing the liquid. Polarizable continuum models (PCM's) have been applied to some solvated systems; but they do not sufficiently capture solvation effects to describe highly polar systems like surfaces of ionic solids. In this work, we present a nonlinear fluid functional within the framework of Joint Density Functional Theory. The fluid is treated not as a linear dielectric, but as a distribution of dipoles that responds to the solute, which we describe starting from the exact free energy functional for point dipoles. We also show PCM's can be recovered as the linear limit of our functional. Our description is of similar computational cost to PCM's, and captures complex solvation effects like dielectric saturation without requiring new fit parameters. For polar and nonpolar molecules, it achieves millihartree level agreement with experimental solvation energies. Furthermore, our functional now makes it possible to investigate chemistry on the surface of lithium battery materials, which PCM's predict to be unstable.

2:30PM R43.00001 Numerically Exact Long Time Magnetization Dynamics Near the Nonequilibrium Kondo Regime[1]

, GUY COHEN, Department of Chemistry, Columbia University, EMANUEL GULL, Department of Physics, University of Michigan, DAVID REICHMAN, Department of Chemistry, Columbia University, ANDREW MILLIS, Department of Physics, Columbia University, ERAN RABANI, School of Chemistry, The Sackler Faculty of Exact Sciences, Tel Aviv University, Israel — The dynamical and steady-state spin response of the nonequilibrium Anderson impurity model to magnetic fields, bias voltages, and temperature is investigated by a numerically exact method which allows access to unprecedentedly long times. The method is based on using real, continuous time bold Monte Carlo techniques—quantum Monte Carlo sampling of diagrammatic corrections to a partial re-summation—in order to compute the kernel of a memory function, which is then used to determine the reduced density matrix. The method owes its effectiveness to the fact that the memory kernel is dominated by relatively short-time properties even when the system's dynamics are long-ranged. We make predictions regarding the non-monotonic temperature dependence of the system at high bias voltage and the oscillatory quench dynamics at high magnetic fields. We also discuss extensions of the method to the computation of transport properties and correlation functions, and its suitability as an impurity solver free from the need for analytical continuation in the context of dynamical mean field theory.

2:42PM R43.00002 Transport and dynamics in multisite subsystems

, MALAY BANDYOPADHYAY, Indian Institute of Technology Bhubaneswar, MANAS KULKARNI, Princeton University, DVIRA SEGAL, University of Toronto — We consider a chain of quantum dots coupled to finite-size reservoirs (prepared out-of-equilibrium) in which each dot is susceptible to decoherence effects or inelastic scattering processes. We observe a ballistic to diffusive crossover in the electronic current. We further investigate the manifestation of this ballistic-diffusive crossover on the dynamics and electron reorganization in the fermionic reservoirs. We find regimes which can be described in a classical framework and regimes whose description is rooted in quantum statistics. Our work can be generalized to understand other multi-site systems and their feedback on the bath degrees of freedom.

2:54PM R43.00003 Possibilities for Observation of Quantum Transport in (RE)$Ba_2Cu_3O_{7-y}$ Perovskites

, PAUL GRANT, W2AGZ Technologies — For y $\approx$ 0, the crystal structure of the "1-2-3" family of rare earth copper oxide perovskites displays several curious "porosity" features. For example, along the b-axis direction of the region usually termed the "CuO chains," one observes a dramatically wide "channel" bounded within a Ba-Cu-O tube. Similar channels can be found in both the b- and a-axes directions contained within RE, Cu and O ion groupings. The cross-sectional area of these channels is roughly that of a single-wall carbon nanotube, suggesting the former may manifest Buettiker-Landauer quantum conductance similar to that observed in the latter. Moreover, by employing various ratios of Pr/Y for the RE component of the host system, the bulk electrical properties of the surrounding host can be tailored from completely insulating to metallic. We test our conjecture predicting ballistic transport down these channels using density functional theory and report our initial findings here along with the likely consequences of paramagnetic spin scattering. We also discuss possible experimental embodiments which could lead to nano-controllable gate structures.

3:06PM R43.00004 The Information Content of Conductance Histogram Peaks: Transport Mechanisms, Level Alignments, and Coupling Strengths

, MATTHEW REUTER, Computer Science and Mathematics Division and Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, PATRICK WILLIAMS, Oak Ridge High School — We develop a theory for describing single channel peaks in conductance histograms by applying probability theory to electron transport. This produces analytical forms for fitting experimental conductance data, where the fitting parameters have physical significance. Depending on the transport mechanism (resonant vs. non-resonant tunneling), the peak's line shape contains information on the level alignment of the channel and the channel-electrode coupling(s). Ultimately, this work provides tools for extracting additional information from experimental data, helping us better understand electron transport processes.

3:18PM R43.00005 Collective Plasmon-Molecule Excitations in Nanojunctions: Quantum Consideration[1]

, ALEXANDER WHITE, University of California San Diego, BORIS FAINBERG, Holon Institute of Technology, MICHAEL GALPERIN, University of California San Diego — We use a pseudoparticle nonequilibrium Green function approach to study the coupling between plasmons and molecular excitons in nonequilibrium molecular junctions. This method is shown to be especially convenient for the calculation of the plasmon absorption spectrum of hybrid plasmon-exciton systems where coherent electron and energy transfer processes and strong system interactions play an important role. The formalism treats the intramolecular interactions and plasmon-exciton coupling exactly, going beyond the standard tool of molecular electronics - the nonequilibrium Green function. We demonstrate the sensitivity of the molecule-plasmon Fano resonance to junction bias, Coulomb repulsion, and intramolecular exciton coupling. We also compare our prediction for non-linear optical effects to previous mean-field equilibrium studies of isolated hybrid plasmon-exciton systems, and demonstrate the advantage of our approach. This study opens a way to deal with strongly interacting plasmon-exciton systems in nonequilibrium molecular devices.

[1]We gratefully acknowledge support by the Department of Energy (M.G., Early Career Award, DE-SC0006422) and the US-Israel Binational Science Foundation (B.D.F. and M.G., grant no. 2008282).

3:30PM R43.00006 Magnetic Field Control of Current through Molecular Ring Junctions[1]

, DHURBA RAI, MICHAEL GALPERIN, Department of Chemistry and Biochemistry, University of California, San Diego, USA, ODED HOD, ABRAHAM NITZAN, School of Chemistry, Tel Aviv University, Ramat Aviv, Israel — We study circular currents driven by voltage bias in molecular wires with ring structures [J. Phys. Chem. C 114, 20583 (2010)]. We revisit magnetic field effects on molecular ring structures presenting conditions under which magnetic field control of molecular ring conduction is realizable. [Phys. Rev. B 85, 155440 (2012)]. We find these conditions to be (a) weak molecule-lead coupling, implying relatively distinct conduction resonances, (b) asymmetric junction structure (e.g., meta or ortho connected benzene ring rather than a para connection), and (c) minimal dephasing (implying low temperature) so as to maintain coherence between multiple pathways of conduction. When these conditions are satisfied, considerable sensitivity to the applied magnetic field normal to the molecular ring plane is found. Although sensitivity to magnetic field is suppressed by dephasing, quantitative estimates indicate that magnetic field control can be observed in suitably constructed molecular ring junctions. We demonstrate control of the spin-flip inelastic electron tunnelling spectroscopy (IETS) signal and discuss spin polarization of total and circular currents in a benzene ring junction with spin impurity [Phys. Rev. B 86, 045420 (2012)].

[1]We gratefully acknowledge support by the National Science Foundation (CHE-1057930), the US-Israel Binational Science Foundation (Grant No. 2008282), and the Hellman Family Foundation.

3:42PM R43.00007 Interaction effects in electric transport through self-assembled molecular monolayers , MARTIN LEIJNSE, Center for Quantum Devices, Niels Bohr Institute, University of Copenhagen — I will discuss a theoretical study of electric transport in molecular electronic devices based on self-assembled molecular monolayers (or other devices involving a large number of mesoscopic conductors contacted in parallel). In contrast to macroscopic conductors, Coulomb interactions between charge carriers being transported through neighboring molecules within the monolayer are large. I show that such inter-molecular Coulomb interactions not only lowers the conductance level, but lead to a correlated current and give rise to distinct signatures in the current-voltage characteristics. If some molecules fail to bond strongly to both electrodes, interactions can even give rise to negative differential resistance. Knowledge of the effects of Coulomb interactions between different conductors is important not only for the functionality of nanoelectronic devices, but also to isolate the genuine single-device properties, for example when trying to interpret a transport experiment using a molecular monolayer device in terms of single-molecule properties. Reference: Martin Leijnse, arXiv:1210.2843

3:54PM R43.00008 Zero-bias anomaly in thiol-bound molecular junction on Ag(111) , KEES FLIPSE, ERWIN ROSSEN, Eindhoven University of Technology, Eindhoven, The Netherlands, JORGE CERDA, Instituto de Ciencia de Materiales de Madrid, Madrid, Spain — Single molecule transistors are widely regarded as the successor of current silicon-based technology. To investigate the electronic properties of single molecules, they must be connected to the macroscopic world via electrodes. The most used linker group to connect the molecule to the metal leads is a thiol group. One feature that is often observed in these systems is a significant reduction (10-20%) in the conductance in a narrow region around the Fermi-level. While most authors choose to ignore this feature, it is in general attributed to excitations of the metal-sulphur mode and phonon interactions in the metal leads. We will discuss the origin of this zero-bias anomaly (ZBA) by presenting ab-initio calculation results in a Scanning Tunnelling Microscopy (STM) geometry for thiophenol molecules adsorbed on Ag(111), indicating the important role of the inelastic contributions of low energy vibrational modes in charge transport.

4:06PM R43.00009 Bi-Stable States in Highly Conductive Pyrazine Molacular Junction , G.P. BRIVIO, C. MOTTA, Department of Materials Science, University of Milano-Bicocca, Milano (Italy), S. KANENKO, M. KIGUCHI, Department of Chemistry, Tokyo Instiutute of Technology, Tokyo (Japan), MILANO-BICOCCA COLLABORATION, TOKYO INSTITUTE OF TECHNOLOGY COLLABORATION — Bi-stable molecular junctions are recently deserving attention for their potential in molecular electronics applications. In the present work, we investigate the bi-stable conductance of highly conductive single-molecule pyrazine/Pt junctions. Break-junction measurements show two distinct conductance states of 1.0 G_0 and 0.3 G_0, G_0 being the quantum of conductance. First-principles calculations reveal that the two states could be assigned to different geometrical configurations of pyrazine exhibiting larger and lower coupling with the electrodes, respectively. Inelastic tunneling electron spectroscopy measurements and theoretical analysis of the system vibrations are able to further characterize the configuration dependent conductance of such junctions. We demonstrate that the controlled torsion of the molecule is capable to switch between the two conducting regimes. This process triggered only by mechanical manipulation of the junction is reversible.

4:18PM R43.00010 Switching of Current in a Molecular Junction[1] , KAMAL DHUNGANA, SUBHASISH MANDAL, RANJIT PATI, Michigan Technological University — Achieving atomic level control at the metal-molecule interface in a single molecule conductance measurement is a difficult task that hinders the progress in molecular electronics. The lack of atomic level structural information of the interface makes the theoretical interpretation of experimental data much harder. Herein, we create an ensemble of device structure by varying metal-molecule binding sites, the orientation of the molecule at the interface, interface distance, and conformational change within the molecule to study junction dependent conductance behavior in Ruthenium-Bis(terpyridine) molecular wire, which has been fabricated and characterized. An orbital dependent DFT in conjunction with a parameter free, single particle Green's function approach is used to study the I-V characteristics. Our calculation for the weakly-coupled ONTOP junction geometry yields a relatively small (OFF state) current value below a threshold voltage (V_{th}). The current value is found to increase at V_{th} and remains flat (ON state) after the threshold value. A similar non-linear I-V curve with a current switching behavior has been reported experimentally.

4:30PM R43.00011 Effect of electron transfer on direct vs. indirect contact of CdSe quantum dots on TiO_2 nanoparticles , TESS R. SENTY, OSHADHA RANASINGHA, SCOTT K. CUSHING, West Virginia University, CONGJUN WANG, NETL, JAMES P. LEWIS, West Virginia University, CHRISTOPHER MATRANGA, NETL, ALAN D. BRISTOW, West Virginia University — CdSe quantum dots (QD) attached to TiO_2 semiconductors (SC) have been extensively studied over the last decade. They have shown promising results for uses as energy materials including capture of light in solar cells [1] and photocatalytic reduction of CO_2 [2]. The length of linker molecules between the QD and SC has been shown to decrease the electron transfer (ET) rate exponentially for an increasing linker length [3]. Studies also indicate that this exponential decrease breaks down for direct contact [4] although the exact mechanism is not fully understood. Through visible and NIR transient absorption spectroscopy we directly probe the electron and hole dynamics of CdSe QDs on TiO_2 nanoparticles comparing intimate contact with mercaptopropionic acid linked QDs. We find that with this direct contact, the ET rate decreases, deviating from previous results. We investigate the mechanisms for this deviation including the effect of oxidation on the QD surface.

4:42PM R43.00012 Surface plasmonic responses in semiconductor and metal nanostructures investigated by ultrafast electron diffraction[1] , KISEOK CHANG, TZONG-RU T. HAN, FEI YUAN, CHONG-YU RUAN, Physics and Astronomy Department, Michigan State University — Incorporating metallic nanostrcutures in the molecular sensing, nanoelectronics, and catalysis devices has often yielded significantly enhanced efficiency, despite many open questions remain. Using ultrafast electron diffraction as a sensitive contact free voltammetry probe, we find the photoinduced voltages across the heterojunctions consisting of nanostructures and semiconductor or metal surfaces can be highly enhanced when the surface plasmon excitation is used as the ponderomotive drive to induce photocurrent. By using the effective circuit model, and aided by the time domain finite difference method, we are able to describe the observed timescales and spectral responses in the context of dielectric coupling, interfacial charge transfer, and strong proximity-field induced at the interfaces between the nanostrcutures, the substrate, and the surrounding medium, which help understand different origins of the surface plasmon enhancement effect.

4:54PM R43.00013 Frontier Orbital Energy Change of Poly(3-Hexylthiophene) Oligomers: Effect of Large Amplitude Torsional Motion[1] , RAM BHATTA, Department of Chemistry, The University of Akron, MESFIN TSIGE, Department of Polymer Science, The University of Akron, DAVID PERRY, Department of Chemistry, The University of Akron — Poly(3-hexylthiophene) (P3HT) and [6,6]-phenyl C61-butyric acid methylester (PCBM) based solar cells remain the most promising organic photovoltaics so far. Despite their promise for organic solar cells, practical application is hindered by low efficiency, associated with poor electron transport from P3HT to PCBM. For isolated P3HT oligomers, we investigate the torsional dependence of electronic properties by performing DFT calculations and extrapolate to the long chain limit. The fully relaxed isolated P3HT oligomers are non-planar with a 47 degree twist angle between each pair of rings and are lower in energy by 0.03 eV per monomer unit than the fully planar oligomers. The non-planarity lowers highest occupied molecular orbital (HOMO) energy by 1 eV and rises lowest unoccupied molecular orbital (LUMO) energy by 0.6 eV compared to the respective orbital energies in a planar P3HT. The shifts in HOMO and LUMO energies increase the band gap from 1.9 eV in planar P3HT up to 3.3 eV when all backbone angles are non-planar and point to a reduced electrical conductivity. The larger band gap in non-planar P3HT accounts for the observed blue shift in the visible P3HT absorption band in P3HT/PCBM mixtures.

5:06PM R43.00014 Effect of geometrical orientation on the charge transfer energetics of supramolecular (tetraphenyl)-porphyrin/fullerens dyads[1] , MARCO OLGUIN, RAJENDRA ZOPE, TUNNA BARUAH, University of Texas at El Paso — We present our study of several low lying charge-transfer (CT) excitation energies for a widely used donor-acceptor system composed of a porphyrin-fullerene pair. The dyad systems consist of C_{60} and C_{70} acceptor systems coupled to tetraphenyl-porphyrin (TPP) and tetraphenyl-(zinc)porphyrin (ZnTPP) donor systems in a co-facial orientation. We find that replacing C_{60} by C_{70} in a given dyad may increase the lowest charge transfer excitation energy by about 0.27 eV, whereas varying the donor in these complexes had marginal effect on the lowest charge transfer excitation energy. Additionally, we examined the effect of geometrical orientation on the CT energy by calculating several CT excited state energies for an end-on orientation of the porphyrin-fullerene dyads. The CT excitation energies are larger for the end-on orientation in comparison to the co-facial orientation by 0.6 eV - 0.75 eV. The difference is attributed to a reduced exciton binding energy in going from the co-facial to the end-on orientation.

5:18PM R43.00015 Electron Transfer Mechanism in Gold Surface Modified with Self-Assembly Monolayers from First Principles[1] , FILIPE C. D. A. LIMA, IF-USP/Brazil, RODRIGO M. IOST, FRANK N. CRESPILHO, IQSC-USP/Brazil, MARÍLIA J. CALDAS, IF-USP/Brazil, ARRIGO CALZOLARI, CNR-NANO/Italia, HELENA M. PETRILLI, IF-USP/Brazil — We report the investigation of electron tunneling mechanism of peptide ferrocenyl-glycylcystamine self-assembled monolayers (SAMs) onto Au (111) electrode surfaces. Recent experimental investigations showed that electron transfer in peptides can occur across long distances by separating the donor from the acceptor. This mechanism can be further fostered by the presence of electron donor terminations of Fc terminal units on SAMs but the charge transfer mechanism is still not clear. We study the interaction of the peptide ferrocenyl-glycylcystamine on the Au (111) from first principles calculations to evaluate the electron transfer mechanism. For this purpose, we used the Kohn Sham (KS) scheme for the Density Functional Theory (DFT) as implemented in the Quantum-ESPRESSO suit of codes, using Vandebilt ultrasoft pseudopotentials and GGA-PBE exchange correlation functional to evaluate the ground-state atomic and electronic structure of the system. The analysis of KS orbital at the Fermi Energy showed high electronic density localized in Fc molecules and the observation of a minor contribution from the solvent and counter ion. Based on the results, we infer evidences of electron tunneling mechanism from the molecule to the Au(111).

Session R44 DBIO: Nucleic Acids: Structure, Function, Protein Interactions Hilton Baltimore Holiday Ballroom 1 - Xiangyun Qiu, Physics department, George Washington University

2:30PM R44.00001 Stretching DNA molecules on a flexible substrate, a polarization-dependent fluorescence microscopy study , KE ZHU, Stony Brook University, Stony Brook, NY, JOHN MELE, Central Islip Senior High School, Central Islip, NY, JULIA BUDASSI, JONATHON SOKOLOV, Stony Brook University, Stony Brook, NY — DNA molecules absorbed and stretched onto surfaces can be used to analyze DNA structure by imaging fluorescence of labeled hybridization probes or enzymes. A recently proposed method for sequencing by electron microscopy requires either adsorbed single-stranded DNAs or untwisted double-stranded DNA. In this experiment, studies were performed on the adsorption of isolated DNA molecules to a flexible PDMS substrate, which permits continuous stretching, until breakage of the DNA molecules. Lambda and T4 DNAs (48.5 and 165.6 kilobase pairs, respectively) were absorbed onto PDMS out of solution by withdrawing a submerged substrate at a rate of 2mm/s, producing linear molecules deposited on the surface. Incident light polarization was varied and fluorescence emission intensity measured as a function of polarization angle and degree of stretching of the DNA. The stretching and breakage properties of lambda and T-4 DNA on the PDMS substrate were determined. The amount of stretching before breakage occurred was found to be up to 40% relative to the as-deposited length. Supported by NSF-DMR MRSEC program.

2:42PM R44.00002 Controlled enzymatic cutting of DNA molecules adsorbed on surfaces using soft lithography[1] , ALYSSA AUERBACH, Yeshiva University High School for Girls, Holliswood, NY, JULIA BUDASSI, Stony Brook University, Stony Brook, NY, EMILY SHEA, Williams College, Williamstown, MA, KE ZHU, JONATHAN SOKOLOV, Stony Brook University, Stony Brook, NY — The enzyme DNase I was applied to adsorbed and aligned DNA molecules (Lamda, 48.5 kilobase pairs (kbp), and T4, 165.6 kbp), stretched linearly on a surface, by stamping with a polydimethylsiloxane (PDMS) grating. The DNAs were cut by the enzyme into separated, micron-sized segments along the length of the molecules at positions determined by the grating dimensions (3-20 microns). Ozone-treated PDMS stamps were coated with DNase I solutions and placed in contact with surface-adsorbed DNA molecules deposited on a 750 polymethylmethacrylate (PMMA) film spun-cast onto a silicon substrate. The stamps were applied under pressure for times up to 15 minutes at 37 C. The cutting was observed by fluorescence microscopy imaging of DNA labeled with YOYO dye. Cutting was found to be efficient despite the steric hindrance due to surface attachment of the molecules. Methods for detaching and separating the cut segments for sequencing applications will be discussed.

2:54PM R44.00003 Localizing the critical point of random RNA secondary structures[1] , WILLIAM BAEZ, RALF BUNDSCHUH, The Ohio State University — Previous numerical studies have found that below the denaturation temperature random RNA secondary structures can exist in one of two phases: a strongly disordered, low-temperature glass phase and a weakly disordered, high-temperature molten phase. The probability of two bases pairing in these phases have been shown to scale with the distance between the two bases as -3/2 and -4/3 in the molten and glass phases, respectively. In this study, we characterize the scaling behavior of various sub-strand lengths within the molecule for a range of temperatures both far from and near the critical point. We anticipate that this approach allows to more accurately determine the critical point and to measure the critical exponents of the system right at the phase transition.

3:06PM R44.00004 Self-assembly of virus particles: The role of genome , GONCA ERDEMCI-TANDOGAN, JEF WAGNER, Department of Physics and Astronomy, University of California, Riverside, RUDOLF PODGORNIK, Department of Physics, University of Ljubljana, ROYA ZANDI, Department of Physics and Astronomy, University of California, Riverside — A virus is an infectious agent that inserts its genetic material into the cell and hijacks the cell's machinery to reproduce. The simplest viruses are made of a protein shell (capsid) that protects its genome (DNA or RNA). Many plant and animal viruses can be assembled spontaneously from a solution of proteins and genetic material in different capsid shapes and sizes. This work focuses on the role of genome in the assembly of spherical RNA viruses. The RNA, a highly flexible polymer, is modeled by mean field approximations. Two RNA models are discussed: (i) A linear polymer model including a pairing affinity between RNA base pairs, and (ii) a branched polymer model. Polymer density and electrostatic potential profiles are obtained, and the relevant free energies are calculated from these profiles. The optimal length of the encapsidated chain is examined as a function of the model parameters. The osmotic pressure of the system is also discussed.

3:18PM R44.00005 Automated building of three-dimensional RNA structures[1] , YUNJIE ZHAO, Department of Physics, Huazhong University of Science & Technology; Department of Physics, George Washington University, ZHOU GONG, YANGYU HUANG, YI XIAO, Department of Physics, Huazhong University of Science & Technology, CHEN ZENG, Department of Physics, George Washington University — RNAs have been found to be involved in many biological processes. Difficulties of experimental determination of tertiary structures of RNA limit our understanding of their biological functions. Therefore, some computational methods of building tertiary structures of RNA have been proposed. However, current algorithms of RNA tertiary structure prediction give satisfactory accuracy only for RNA of small size and simple topology, and most are not fully automatic. Here, we present an automated and efficient program, 3dRNA. Since the organization of RNA structure is largely defined by topological constraints in the secondary structure as well as the tertiary contacts, we build the RNA tertiary structure from the smallest secondary elements (SSEs) by using a two-step procedure. We first assemble the SSEs into hairpins or duplexes and then into complete structure since the tertiary structures of hairpins and duplexes usually can be built with a high accuracy. In a benchmark test with known structures, 3dRNA can give predictions with reasonable accuracy for RNAs of larger size and complex topology.

3:30PM R44.00006 Ion concentration dependent tRNA folding energy landscapes , RONGZHONG LI, Department of Physics, Wake Forest University, SAMUEL CHO, Departments of Physics and Computer Science, Wake Forest University — The RNA folding is highly dependent on the ionic conditions of its environment in the cell because the surrounding ions electrostatically screen the charged phosphates that line the RNA backbone. Recent studies (Cho, Pincus, and Thirumalai, PNAS, 2007; Biyun, Cho, and Thirumalai, JACS, 2011) demonstrated that the coarse-grained model we use accurately captures the RNA folding mechanisms by incorporating a Debye-Huckel potential to screen the electrostatics. We compare the ion-concentration dependent tRNA folding mechanism to the classical thermodynamic melting profiles of Crothers and co-workers, and we observe excellent agreement. We also supported our findings by performing empirical force field MD simulations with CHARMM and AMBER, and we observe remarkably comparable qualitative similarities between the average base-base distances from simulations and the empirically measured base-stacking potentials from the well-known Turner's Rules.

3:42PM R44.00007 Determination of counterion distribution around DNA coated nanoparticles (DNA-AuNP) by small angle X-ray scattering (SAXS)[1] , SUMIT KEWALRAMANI, CHEUKYUI LEUNG, JOS ZWANIKKEN, ROBERT MACFARLANE, MONICA OLVERA DE LA CRUZ, CHAD MIRKIN, MICHAEL BEDZYK, Northwestern University — The interactions between DNA-Au nanoparticles (AuNP) and the surrounding cationic counterion layer critically determine the melting behavior of DNA duplexes on isolated DNA-AuNP and in crystalline assemblies of DNA-AuNPs. Also, the counterion layer is speculated to cause the enhanced stability of DNA-AuNPs against nuclease degradation, as compared to isolated DNAs. This makes DNA-AuNPs attractive for bio-diagnostic and therapeutic applications. To probe the ion cloud around DNA-AuNPs, we apply the isomorphous heavy ion replacement SAXS approach. Specifically, the SAXS measurements are carried out on DNA-AuNPS dispersed in a series of solutions that contain different monovalent ions (Na^+, K^+, Rb^+ or Cs^+). The combined analysis of all four intensity profiles makes it possible to extract, in a model-independent manner, the cation profile contribution I_{cat} (q) from the SAXS intensity that is averaged over the polydispersity of AuNPs. The I_{cat} (q) is found to be consistent with the cation dependent SAXS intensities that are derived on the basis of classical DFT calculations for the counterion distribution around DNA-AuNPs.

3:54PM R44.00008 Ion Competition in Ordered DNA arrays in the Attractive Regime , XIANGYUN QIU, George Washington University, JOHN GIANNINI, KURT ANDRESEN, Gettysburg College — Quantitative knowledge of electrostatic interactions is of fundamental importance for many classes of biomolecules and biological processes. Acquiring such knowledge is challenged by inherent complexities such as the long-range nature of electrostatic forces, the non-linear screening of ubiquitous ions, and the involvement of a large number of solvent molecules. Here we report our recent work to address some of the key questions by interrogating electrostatics-governed ordered nucleic acids arrays and bringing together a set of quantitative tools to elucidate the role of each of the electrostatic factors: ion, water, and charged surface. Specifically, we will present measurements and modeling of the spacings between DNA strands and the numbers of interstitial competing ions in the attractive regime. Our results indicate a linear relation between the partition of interstitial ions and the magnitude of inter-DNA attraction, which will be discussed in the context of current theories of electrostatic interactions.

4:06PM R44.00009 Modeling spatial correlation of DNA deformations: Allosteric effects of DNA protein binding , XINLIANG XU, JIANSHU CAO, Department of Chemistry, MIT, HAO GE COLLABORATION[1], X. SUNNEY XIE COLLABORATION[2] — We report a study of DNA deformations by a coarse grained mechanical model. Recent single molecule experimental studies show that when DNA molecule is deformed by its binding to a protein, the binding affinity of a second protein at distance L away from the first binding site is altered. To explain this observation, the relaxation of deformation along the DNA chain is examined. Our method predicts a general exponentially decaying behavior for differenct deformation modes. As an example, inter-helical distance deformation is studied in details, and is found to decay at a previously unknown lengthscale of 10 base pairs as a result of the balance between inter and intra DNA strand energy. This lengthscale is in good agreement with the said single molecule experimental observation. This model of local deformation relaxation helps us better understand many important issues in DNA such as the enhanced flexibility of DNA at short lengthscales and DNA repair mechanism inside cells.

4:18PM R44.00010 Molecular dynamics simulation of DNA base-pair opening by sharp bending , PEIWEN CONG, Singapore-MIT Alliance, National University of Singapore, LIANG DAI, Singapore-MIT Alliance for Research and Technology, National University of Singapore, JOHAN R.C. VAN DER MAAREL, JIE YAN, Physics, National University of Singapore — Many biological processes require sharp bending of DNA. According to worm-like chain model, the bending energy dominates the free energy cost of those processes containing DNA loops shorter than 40 nm, such as DNA wrapping around histones, Lac repressor looping and virus DNA packaging . However, several recent experimental observations suggest that the WLC model s not applicable under tight bending conditions. In full atom molecular dynamics simulations, a double stranded, 20 base-pairs DNA fragment is forced to bend by an external spring. It is found that one or two AT-rich regions are disrupted for sufficiently small end-to-end distance. The disrupted DNA base-pairs separate and usually stack with the neighbouring base-pairs to form a defect. It is shown that these defects are more bendable than the bending rigidity of the duplex in the regular B-form. The simulation suggests a curvature dependent, non-harmonic bending elasticity of the DNA backbone is necessary to describe the DNA conformation under tight bending conditions.

4:30PM R44.00011 Looping of anisotropic, short double-stranded DNA[1] , HAROLD KIM, TUNG LE, Georgia Institute of Technology — Bending of double-stranded DNA (dsDNA) is associated with fundamental biological processes such as genome packaging and gene regulation, and therefore studying sequence-dependent dsDNA bending is a key to understanding biological impact of DNA sequence beyond the genetic code. Average mechanical behavior of long dsDNA is well described by the wormlike chain model, but sequence-dependent anisotropic bendability and bendedness of dsDNA can in principle lead to abnormally high looping probability at short length scales. Here, we measured the looping probability density (J factor) and kinetics of dsDNA as a function of length and curvature using single-molecule FRET (Förster Resonance Energy Transfer). For theoretical comparison, we calculated the J-factor using a discrete dinucleotide chain model, and also simulated it by Monte Carlo methods. We provide evidences that even when the intrinsic shape of dsDNA is accounted for, the wormlike chain model fails to describe looping dynamics of dsDNA below 200-bp length scale.

[1]Georgia Tech FIRE program

4:42PM R44.00012 DNA looping by a ligase under nanoconfinement , MAEDEH HEIDARPOUR-ROUSHAN, ROBERT RIEHN, North Carolina State University — DNA looping is essential for the function and maintenance of genetic information. We have investigated the kinetic evolution of DNA loops (48500 bp) induced by T4 ligase inside a nanofabricated channel system with a channel cross-section of 100x100 nm2, and a few hundred microns channel length. We found that addition of the ligase profoundly alters the behavior of DNA. In particular, ligase acts to stabilize hairpin geometries in which the extended forward and backward arms of the hairpin scan past each other. From the linear density of DNA inside the channel, we deduce that the effective excluded volume vanishes upon addition of T4 ligase and ATP. We conclude that the two strands are effectively stapled together through a large number of weak bonds involving T4 ligase.

4:54PM R44.00013 Loops determine the mechanical properties of mitotic chromosomes[1] , YANG ZHANG, DIETER W. HEERMANN, Institute for Theoretical Physics, Heidelberg University, Germany — In mitosis, chromosomes undergo a condensation into highly compacted, rod-like objects. Many models have been put forward for the higher-order organization of mitotic chromosomes including radial loop and hierarchical folding models. Additionally, mechanical properties of mitotic chromosomes under different conditions were measured. However, the internal organization of mitotic chromosomes still remains unclear. Here we present a polymer model for mitotic chromosomes and show how chromatin loops play a major role for their mechanical properties. The key assumption of the model is the ability of the chromatin fibre to dynamically form loops with the help of binding proteins. Our results show that looping leads to a tight compaction and significantly increases the bending rigidity of chromosomes. Moreover, our qualitative prediction of the force elongation behaviour is close to experimental findings. This indicates that the internal structure of mitotic chromosomes is based on self-organization of the chromatin fibre. We also demonstrate how number and size of loops have a strong influence on the mechanical properties. We suggest that changes in the mechanical characteristics of chromosomes can be explained by an altered internal loop structure.

[1]YZ gratefully appreciates funding by the German National Academic Foundation (Studienstiftung des deutschen Volkes) and support by the Heidelberg Graduate School for Mathematical and Computational Methods in the Sciences (HGS MathComp).

5:06PM R44.00014 New insights into nucleosome unwrapping , RAZVAN CHEREJI, ALEXANDRE MOROZOV, Rutgers University — Eukaryotic genomes are organized into arrays of nucleosomes, in which stretches of 147 base-pairs (bp) of DNA are wrapped around octameric histones. Recently, a new approach for direct mapping of nucleosome centers at bp resolution was developed [Brogaard et al., Nature 486, 496-501 (2012)] and some intriguing results appeared. About 40% of the inter-dyad distances are smaller than 147 bp, which imply massive nucleosome unwrapping, genome-wide, in vivo. The histogram of the inter-dyad distances presents small oscillations which indicate a step-wise unwrapping of the nucleosomal DNA from the histone. We present a statistical mechanics model for the nucleosome unwrapping, which is able to take into account sequence-dependent binding energies, sequence-independent potential barriers and wells, effective two-body interactions between the nucleosomes, competition between different species, cooperative-binding, and other important factors which dictate the nucleosome distribution along the DNA. We are able to reproduce the distribution of the inter-dyad distances, which cannot be obtained if there is no nucleosome unwrapping. The nucleosome unwrapping model can explain also the variable DNA accessibility and the nucleosome-induced cooperativity, which were observed experimentally.

5:18PM R44.00015 Mechanisms for enhanced protein dissociation driven by nucleosomes[1] , RALF BUNDSCHUH, CAI CHEN, The Ohio State University — When a transcription factor binding site is located within a nucleosome, the DNA in the nucleosome has to unwrap in order for the transcription factor to bind. Thus, it is not surprising that the rate of transcription factor binding is slowed significantly in the presence of a nucleosome. The resulting change in transcription factor binding site occupancy has been known for quite a while as a mechanism for regulation of gene expression via chromatin structure. More surprisingly, recent single molecule experiments have pointed out that not only is the on-rate of transcription factors reduced by the presence of a nucleosome but also is the off-rate increased. There are two possible explanations short of an active role of the nucleosome in pushing the transcription factor off the DNA: (i) the nucleosome can change the equilibrium between binding at the specific binding site and nonspecific binding to the surrounding DNA or (ii) for dimeric transcription factors the nucleosome can change the equilibrium between monomeric and dimeric binding. We explicitly model both scenarios and find that the first mechanism cannot be reconciled with experimental findings. However, we show that the second mechanism can indeed explain increases in off-rate by a factor as high as 100.

Wednesday, March 20, 2013 2:30PM - 5:18PM –

Session R45 DBIO: Focus Session: Physics of the Cytoskeleton II Hilton Baltimore Holiday Ballroom 4 - Timothy Sanchez, Brandeis University

2:30PM R45.00001 Biological Physics Dissertation Award Talk - Self-organization in cytoskeletal mixtures: from synthetic cilia to flowing networks , TIM SANCHEZ, Brandeis University — Inspired by biological functions such as ciliary beating and cytoplasmic streaming, we have developed a highly tunable and robust model system from biological components that self-organizes to produce a broad range of far-from-equilibrium materials with remarkable emergent properties. Using only simple components - microtubules, kinesin motor clusters, and a depletion agent that bundles MTs – we reproduced several essential biological functions, including cilia-like beating, the emergence of metachronal waves in bundle arrays, and internally generated flows in active cytoskeletal gels. The occurrence of these biomimetic functions as self-organized processes provides unique insight into the mechanisms that drive these processes in biology. Beyond these biomimetic behaviors, we have also used the same components to engineer novel active materials which have no biological analogues: active streaming 2D nematics, and finally self-propelled emulsion droplets. These observations exemplify how assemblages of animate microscopic objects exhibit highly sought-after collective and biomimetic properties, challenging us to develop a theoretical framework that would allow for a systematic engineering of their far-from-equilibrium material properties.

3:06PM R45.00002 Nonlinear force propagation, anisotropic stiffening and non-affine relaxation in a model cytoskeleton , DAISUKE MIZUNO, Kyushu University, DAVID HEAD, Leeds University, EMI IKEBE, AKIKO NAKAMASU, SUGURU KINOSHITA, Kyushu University, ZHANG PEIJUAN, Kyushu Univeristy, SHOJI ANDO, Sojo University — Forces are generated heterogeneously in living cells and transmitted through cytoskeletal networks that respond highly non-linearly. Here, we carry out high-bandwidth passive microrheology on vimentin networks reconstituted in vitro, and observe the nonlinear mechanical response due to forces propagating from a local source applied by an optical tweezer. Since the applied force is constant, the gel becomes equilibrated and the fluctuation-dissipation theorem can be employed to deduce the viscoelasticity of the local environment from the thermal fluctuations of colloidal probes. Our experiments unequivocally demonstrate the anisotropic stiffening of the cytoskeletal network behind the applied force, with greater stiffening in the parallel direction. Quantitative agreement with an affine continuum model is obtained, but only for the response at certain frequency $\sim$ 10-1000 Hz which separates the high-frequency power law and low-frequency elastic behavior of the network. We argue that the failure of the model at lower frequencies is due to the presence of non-affinity, and observe that zero-frequency changes in particle separation can be fitted when an independently-measured, empirical nonaffinity factor is applied.

3:18PM R45.00003 Conformational phases of membrane bound cytoskeletal filaments , DAVID A. QUINT, University of California Merced, GREGORY GRASON, University of Massachusetts Amherst, AJAY GOPINATHAN, University of California Merced — Membrane bound cytoskeletal filaments found in living cells are employed to carry out many types of activities including cellular division, rigidity and transport. When these biopolymers are bound to a membrane surface they may take on highly non-trivial conformations as compared to when they are not bound. This leads to the natural question; What are the important interactions which drive these polymers to particular conformations when they are bound to a surface? Assuming that there are binding domains along the polymer which follow a periodic helical structure set by the natural monomeric handedness, these bound conformations must arise from the interplay of the intrinsic monomeric helicity and membrane binding. To probe this question, we study a continuous model of an elastic filament with intrinsic helicity and map out the conformational phases of this filament for various mechanical and structural parameters in our model, such as elastic stiffness and intrinsic twist of the filament. Our model allows us to gain insight into the possible mechanisms which drive real biopolymers such as actin and tubulin in eukaryotes and their prokaryotic cousins MreB and FtsZ to take on their functional conformations within living cells.

3:30PM R45.00004 Athermal Fluctuations of Probe Particles in Active Cytoskeletal Networks , HEEV AYADE, Kyushu University, IRWIN ZAID, Oxford University, DAISUKE MIZUNO, Kyushu University — A reconstituted active cytoskeletal networks consisting of an actin filament network coupled to myosins (motor proteins) have been shown to display rich in dynamical and mechanical behaviors that is often in contrast to passive, equilibrium system. The motor proteins, which spontaneously generate forces, kept the active cytoskeletal network out of equilibrium. The athermal fluctuations observed in the network are linked to the active force generation process by motor proteins which give more relevant information including the interaction with the surrounding materials. In prior studies, only the second moment of the athermal fluctuations has been investigated while the full displacement distribution of the athermal fluctuations in active cytoskeleton recently is found to be far from Gauss when observed with video microrheology. Here, we investigated the nonequilibrium statistics and dynamics of the active network by analyzing the athermal fluctuations of different probe sizes embedded in the same active system. The model developed here is based on truncated Lévy statistics which is generally observed for the force generators whose impact decays as $1/r^2$.

3:42PM R45.00005 Spontaneous Motion in Hierarchically Assembled Active Cellular Materials , DANIEL CHEN, Brandeis University Department of Physics — With exquisite precision and reproducibility, cells orchestrate the cooperative action of thousands of nanometer-sized molecular motors to carry out mechanical tasks at much larger length scales, such as cell motility, division and replication. Besides their biological importance, such inherently far-from-equilibrium processes are an inspiration for the development of soft materials with highly sought after biomimetic properties such as autonomous motility and self-healing. I will describe our exploration of such a class of biologically inspired soft active materials. Starting from extensile bundles comprised of microtubules and kinesin, we hierarchically assemble active analogs of polymeric gels, liquid crystals and emulsions. At high enough concentration, microtubule bundles form an active gel network capable of generating internally driven chaotic flows that enhance transport and fluid mixing. When confined to emulsion droplets, these 3D networks buckle onto the water-oil interface forming a dense thin film of bundles exhibiting cascades of collective buckling, fracture, and self-healing driven by internally generated stresses from the kinesin clusters. When compressed against surfaces, this active nematic cortex exerts traction stresses that propel the locomotion of the droplet. Taken together, these observations exemplify how assemblies of animate microscopic objects exhibit collective biomimetic properties that are fundamentally distinct from those found in materials assembled from inanimate building blocks. These assemblies, in turn, enable the generation of a new class of materials that exhibit macroscale flow phenomena emerging from nanoscale components.

4:18PM R45.00006 Mechanical Models of Microtubule Bundle Collapse in Alzheimer's Disease[1] , AUSTIN SENDEK, RAJIV SINGH, DANIEL COX, UC Davis — Amyloid-beta aggregates initiate Alzheimer's disease, and downstream trigger degradation of tau proteins that act as microtubule bundle stabilizers and mechanical spacers. Currently it is unclear which of tau cutting by proteases, tau phosphorylation, or tau aggregation are responsible for cytoskeleton degradation., We construct a percolation simulation of the microtubule bundle using a molecular spring model for the taus and including depletion force attraction between microtubules and membrane/actin cytoskeletal surface tension. The simulation uses a fictive molecular dynamics to model the motion of the individual microtubules within the bundle as a result of random tau removal, and calculates the elastic modulus of the bundle as the tau concentration falls. We link the tau removal steps to kinetic tau steps in various models of tau degradation.

[1]Supported by US NSF Grant DMR 1207624

4:30PM R45.00007 Properties of intracellular transport: the role of cytoskeleton topology , NICKOLAY KORABEL, University of California Merced, KERWYN C. HUANG, Stanford University, AJAY GOPINATHAN, University of California Merced — The eukaryotic cytoskeleton is composed of polarized filaments forming a complex, intertwined network. Various motor proteins such as kinesins or myosins convert ATP into mechanical work and are able to walk processively or even diffuse along the cytoskeleton. Large organelles such as vesicles or mitochondria can randomly bind and unbind to one or several motors and their transport in the cell can be described as alternating phases of diffusion in the cytoplasm and phases of directed or diffusive transport along the cytoskeletal network. Intracellular transport has been the focus of extensive studies both experimentally and theoretically. However, the impact of the cytoskeleton network structure on transport properties, which is expected to be significant, is not fully understood. We develop a computational model of intracellular transport, and explore the impact of the cytoskeletal structure on transport properties. We show that transport can be enhanced even by diffusional motion along the cytoskeleton after memory effects due to cytoskeletal structure are taken into account. We also explore the influence of the network structure on the first passage time distributions for a cargo to reach the cell membrane after being exported from the nucleus and for transport from the membrane to the nucleus.

4:42PM R45.00008 Active Stresses Drive Random Fluctuations in the Cytoplasm of Cells , MING GUO, ALLEN EHRLICHER, Harvard University, MIKKEL JENSEN, JEFFREY MOORE, Boston University, JENNIFER LIPPINCOTT-SCHWARTZ, NIH, FRED MACKINTOSH, Vrije Universiteit, DAVID WEITZ, Harvard University — The cytoplasm of living cells is a highly dynamic environment with continuous intracellular motion that is essential for life. Some intracellular movements appear directional, and are clearly actively transported. However, most intracellular movement appears random in nature. These random movements have often been interpreted as Brownian motion, and have been used to infer cellular mechanics. Here we describe direct quantifications of the random intracellular motion by using sub-micron beads, and independent micromechanical measurements of the local cellular environment using optical tweezers. We demonstrate that the random intracellular motion is driven by active stress fluctuations in a nearly elastic cytoskeletal matrix. The combination of our two measurements allows us to quantify the frequency spectrum of the intracellular forces, and directly shows that non-thermal active stresses dominate thermal forces in the cellular interior at long time scales ($t>0.1s$), which results in the random intracellular motion. By using the photoconvertible fluorescent protein Dendra2, we also show that the movement of very small particles ($\sim$ nm) are also accelerated by active fluctuations. These active-stress driven movements may be an essential part of rapid transport in life.

4:54PM R45.00009 Microrheology of highly crosslinked microtubule networks is dominated by force-induced crosslinker unbinding , MEGAN VALENTINE, YALI YANG, University of California, Santa Barbara, MO BAI, WILLIAM KLUG, ALEX LEVINE, University of California, Los Angeles — We determine the viscoelastic responses of reconstituted networks of microtubules that have been strongly bonded by labile crosslinkers using a magnetic tweezers device to apply localized forces. At short time scales, the networks respond nonlinearly to applied force, with stiffening at small forces, followed by a reduction in the stiffening response at high forces, which we attribute to the force-induced unbinding of crosslinks. At long time scales, force-induced bond unbinding leads to local network rearrangement and significant bead creep. Interestingly, for rigidly crosslinked networks, the material retains its elastic modulus even under conditions of significant plastic flow, suggesting that crosslinker breakage is balanced by the formation of new bonds. To better understand this effect, we developed a finite element model of such a stiff filament network with crosslinkers obeying force-dependent Bell model unbinding dynamics. The coexistence of dissipation, due to bond breakage, and the elastic recovery of the network is possible because each filament has many crosslinkers. Recovery can occur as long as a sufficient number of the original crosslinkers are preserved under the loading period. When these remaining original crosslinkers are broken, plastic flow results.

5:06PM R45.00010 Microtubules contribute to maintain nucleus shape in epithelial cell monolayer , DOMINIQUE TREMBLAY, LUKASZ ANDRZEJEWSKI, ANDREW PELLING, University of Ottawa — INTRODUCTION: Tissue strains can result in significant nuclear deformations and may regulate gene expression. However, the precise role of the cytoskeleton in regulating nuclear mechanics remains poorly understood. Here, we investigate the nuclear deformability of Madin-Darky canine kidney cells (MDCK) under various stretching conditions to clarify the role of the microtubules and actin network on the mechanical behavior of the nucleus. METHODS: A custom-built cell-stretching device allowing for real time imaging of MDCK nuclei was used. Cells were seeded on a silicone membrane coated with rat-tail collagen I. A nuclear stain, Hoechst-33342, was used to image nuclei during stretching. We exposed cells to a compressive and non-compressive stretching strain field of 25%. Nocodazole and cytochalasin-D were used to depolymerize the microtubules and actin network. RESULTS: Nuclei in control cells stretched more along their minor axis than major axis with a deformation of 5% and 2% respectively. This anisotropy vanished completely in microtubule-deprived cells and these cells showed a very high nuclear deformability along the minor axis when exposed to a compressive stretching strain field. CONCLUSIONS: The microtubules drive the anisotropic deformability of MDCK nuclei in a monolayer and maintain nuclear shape when exposed to compressive strain. Such intrinsic mechanical behavior indicates that microtubules are essential to maintain nuclear shape and may prevent down regulation of gene expression.

Session R46 GIMS: Invited Session: Keithley Session: Enabling Sensitive Measurements Beyond the Standard Quantum Limit Hilton Baltimore Holiday Ballroom 5 - Eric Hudson, The Pennsylvania State Unversity

2:30PM R46.00001 oseph F. Keithley Award For Advances in Measurement Science Lecture: Squeezing: the future for gravitational wave detectors , DAVID MCCLELLAND, Australian National University — No abstract available.

3:06PM R46.00002 Joseph F. Keithley Award For Advances in Measurement Science Lecture: Beyond the quantum limit in gravitational wave detection , NERGIS MAVALVALA, Massachusetts Institute of Technology

3:42PM R46.00003 Exploring quantum limits with micro-mechanical membranes , CINDY REGAL, JILA, University of Colorado, Boulder — The pursuit of increasingly sensitive interferometric measurement of mechanical motion has a rich history. This pursuit has resulted in the development and study of seminal ideas on quantum limits of measurement and beyond. In recent years, an interesting class of devices has been developed in which low-mass, high-frequency, and mechanically isolated objects are well-coupled to optical cavities. The large response of these mechanical objects to applied forces makes them an ideal platform to observe the effects of radiation forces, which are integral to the physics of quantum limits to interferometric measurement. Some of these nanomechanical resonators have been recently cooled with electromagnetic radiation to near their quantum mechanical ground state, illustrating the capacity for harnessing coherent optical forces. In this talk I present our recent work on a silicon nitride (SiN) membrane coupled to an optical cavity in a cryogenic environment. We use cavity coupling to significantly damp and cool membrane motion, and we demonstrate a low-absorption cavity with an efficient readout. Building on these capabilities, we observe the effect of a fluctuating radiation pressure force on the membrane resonator due to optical shot noise. Continued work will focus on further removing effects of classical noise in our devices; this will provide a path to measurement at the standard quantum limit as well as to using our optomechanical interface for applications in quantum information science. In particular, we are working on devices that will connect disparate quantum resources via SiN membrane resonators with hybrid functionalization.

4:18PM R46.00004 Approaching the Quantum Limits of Displacement Detection , JOHN TEUFEL, NIST Boulder — While high quality factor mechanical resonators (such as cantilevers and membranes) are routinely used as exquisite sensors, only recently are these engineered devices encountering the fundamental limits and opportunities afforded by quantum mechanics. The standard quantum limit of displacement detection requires a balance between the measurement imprecision and momentum imparted on the object of interest. One promising measurement scheme for achieving, and possibly surpassing, these quantum limits of measurement is that of cavity optomechanics—an architecture in which a mechanical resonator modulates the frequency of a high frequency electromagnetic resonance. Ideally, the quantized nature of the measurement photons will impart backaction in the form of radiation pressure shot noise, but observation of this quantum effect in macroscopic mechanical resonators has proven experimental difficult due to the relatively weak forces of the light. We realize a microwave cavity "opto" -mechanical system by incorporating a freely-suspended membrane in a superconducting microwave resonant circuit, which simultaneously exhibits high quality factor electrical and mechanical modes [1]. The relatively large electomechanical coupling has led to experimental observation of the strong coupling regime [1] as well as sideband cooling of the mechanical mode to its quantum ground state [2]. I will present recent experiments of similar circuits in which the displacement sensitivity goes beyond that at the standard quantum limit by several orders of magnitude. These measurements also clearly show the fundamental trade-off between measurement imprecision and backaction. We observe the radiation pressure shot noise of the microwave photons and show that it can completely overwhelm the classical, thermal motion of the membrane. [1] Teufel et al., Nature 471, 204-208 (2011).

[1] Teufel et al., Nature 475, 359-363 (2011).

4:54PM R46.00005 Quantum Non-Demolition Measurements between a Graphene Nanomechanical Resonator and a Diamond Nitrogen-Vacancy Center[1] , BRIAN D'URSO, University of Pittsburgh — A description of the motion of microscopic particles often requires quantum mechanics, but macroscopic objects are typically observed to follow the predictions of classical mechanics. In the transition from microscopic components to a complex macroscopic system, the distinctive features of quantum mechanics can be hidden by thermal excitations and coupling to the environment. In particular, while individual spins are intrinsically quantum objects, nanomechanical resonators are usually observed as classical damped oscillators. With a careful choice of coupling, these two systems can be made to interact such that they perform quantum non-demolition (QND) measurements on each other, enabling a bridge between the quantum and classical worlds. Through this coupling, the nanomechanical resonator provides a classical readout of the spin, while the spin acts as a probe of the discrete quantum states of the resonator. We present a system consisting of a graphene nanoelectromechanical resonator coupled to a single spin through a uniform external magnetic field. The spin originates from a nitrogen-vacancy (NV) center in a diamond nanocrystal, which is positioned on the resonator. The external magnetic field provides quadratic coupling which results in QND measurements between the spin and resonator. The strength of the quadratic coupling is enhanced by utilizing an avoided level crossing of the coupled spin-resonator system. The low mass of a graphene resonator further increases the sensitivity to the force associated with a single spin. NV centers are chosen as the source of a spin due to their exceptional spin state coherence times, large zero-field splitting, and optical addressability. We will present an analysis of the system and report on the status of experimental measurements with graphene-NV center devices.

Session R47 DFD: Invited Session: Simulation of Interfaces in Two-Fluid Flows Hilton Baltimore Holiday Ballroom 6 - Shahriar Afkhami, New Jersey Institue of Technology

2:30PM R47.00001 Accelerated boundary integral simulations of particulate and two-phase flows , ANNA-KARIN TORNBERG, Royal Institute of Technology (KTH) — In micro-fluidic applications where the scales are small and viscous effects dominant, the Stokes equations are often applicable. The suspension dynamics that is observed already with rigid particles and fibers are very complex also in this Stokesian regime, and surface tension effects are strongly pronounced at interfaces of immiscible fluids. Simulation methods can be developed based on boundary integral equations, which leads to discretizations of the boundaries of the domain only, and hence fewer unknowns compared to a discretization of the PDE. Two main difficulties associated with boundary integral discretizations are to construct accurate quadrature methods for singular and nearly singular integrands, as well as to accelerate the solution of the linear systems, that will have dense system matrices. If these issues are properly addressed, boundary integral based simulations can be both highly accurate and very efficient. We will discuss simulations of periodic suspensions of rigid particles and rigid fibers in 3D, where the simulations are accelerated by a newly developed spectrally accurate FFT based Ewald method, as well as highly accurate simulations of many interacting drops in 2D.

3:06PM R47.00002 Direct Numerical Simulations of Multiphase Flows[1] , GRETAR TRYGGVASON, University of Notre Dame — Many natural and industrial processes, such as rain and gas exchange between the atmosphere and oceans, boiling heat transfer, atomization and chemical reactions in bubble columns, involve multiphase flows. Often the mixture can be described as a disperse flow where one phase consists of bubbles or drops. Direct numerical simulations (DNS) of disperse flow have recently been used to study the dynamics of multiphase flows with a large number of bubbles and drops, often showing that the collective motion results in relatively simple large-scale structure. Here we review simulations of bubbly flows in vertical channels where the flow direction, as well as the bubble deformability, has profound implications on the flow structure and the total flow rate. Results obtained so far are summarized and open questions identified. The resolution for DNS of multiphase flows is usually determined by a dominant scale, such as the average bubble or drop size, but in many cases much smaller scales are also present. These scales often consist of thin films, threads, or tiny drops appearing during coalescence or breakup, or are due to the presence of additional physical processes that operate on a very different time scale than the fluid flow. The presence of these small-scale features demand excessive resolution for conventional numerical approaches. However, at small flow scales the effects of surface tension are generally strong so the interface geometry is simple and viscous forces dominate the flow and keep it simple also. These are exactly the conditions under which analytical models can be used and we will discuss efforts to combine a semi-analytical description for the small-scale processes with a fully resolved simulation of the rest of the flow. We will, in particular, present an embedded analytical description to capture the mass transfer from bubbles in liquids where the diffusion of mass is much slower than the diffusion of momentum. This results in very thin mass-boundary layers that are difficult to resolve, but the new approach allows us to simulate the mass transfer from many freely evolving bubbles and examine the effect of the interactions of the bubbles with each other and the flow. We will conclude by attempting to summarize the current status of DNS of multiphase flows.

3:42PM R47.00003 Advances and Challenges in Modeling Interfacial Flows , MARIANNE FRANCOIS, Los Alamos National Laboratory — Interfacial flows are multi-material flows comprised of two or more immiscible materials demarcated by interfaces. They are encountered in several applications of interest to the Department of Energy. Examples of applications include materials processing (e.g. casting), inertial confinement fusion and solvent extraction. We are interested in the development of accurate numerical methods to simulate with high-fidelity interfacial flows. For such simulation, the position of the interface and interface physics need to be predicted as part of the solution of the flow equations. One of the many techniques is known as the volume tracking method. It is a pure Eulerian method that represents the interface with volume fraction and intrinsically ensures mass conservation. In this talk, I will describe several advances that have been made over the past 25 years and discuss remaining challenges in the context of the volume tracking method.

4:18PM R47.00004 A moment of fluid method for computing solutions to multi-phase/multimaterial flows , MARK SUSSMAN, Florida State University, Department of Mathematics — We combine the multimaterial Moment-of-Fluid (MOF) work of Ahn and Shashkov with the work of Kwatra et al for removing the acoustic time step restriction in order to solve multimaterial flows in which each material might be compressible or incompressible. The mass weights found in the algorithm of Kwatra et al are computed directly from the multimaterial MOF reconstructed interface. We treat the interface(s) between materials as sharp when discretizing the boundary conditions between materials. The combination of the multimaterial MOF reconstruction together with the cell centered formulation devised by Kwatra et al enable us to robustly compute multimaterial flows with large density ratios, stretching and tearing of interfaces and contact line dynamics at the junction of 3 materials with minimal volume fluctuation of each material (if a given material is incompressible). Simulations for multimaterial flows are presented with applications to combustion (atomization and spray) and microfluidics.

Session S19 Funding Opportunities in Europe for Creative Minds from Anywhere in the World 321 -

5:45PM S19.00001 Funding Opportunities in Europe for Creative Minds from Anywhere in the World , GEORGIOS TZAMALIS, European Research Council (ERC) — The European Research Council (ERC) is the first European body to fund bottom up investigator-driven research at the frontiers of knowledge. Launched in 2007, it has been funding excellent science in Europe ever since. Governed by a council of 22 eminent scientists, the ERC is highly regarded by the international research community, and is quickly establishing itself as a world-class research funding agency. Since 2007, the ERC has funded pioneering research, which is now starting to bear fruit. Through highly competitive calls for attractive grants, the ERC encourages both junior and established researchers to pursue their work in Europe in any field of research and regardless of their nationality. The ERC promotes collaborations between scientists working on funded projects in Europe and international groups anywhere in the world including the USA. To date, over 30 000 scientific proposals have been received, and over 3000 researchers have been funded, including several Nobel Prize winners. By challenging Europe's brightest minds, the ERC expects that its grants will help to bring about new and unpredictable scientific and technological discoveries. This session will explain the ERC's funding schemes as well as provide answers to practical questions such as:

-How can the ERC support research careers?
-What are its main features?
-What are the selection criteria and how long is the selection process?
-How does the application process work?
-How many researchers are funded each year?
-What are the chances of success?

Wednesday, March 20, 2013 5:45PM - 7:45PM –

Session S22 NSF: The Status of NSF-DMR in FY13 324 -

5:45PM S22.00001 The status of NSF-DMR in FY13 , MARY GALVIN-DONOGHUE, DMR —

Wednesday, March 20, 2013 5:45PM - 5:57PM –

Session S26 DCOMP: DCOMP Business Meeting 328 -

5:45PM S26.00001 DCOMP Business Meeting –

Wednesday, March 20, 2013 7:30PM - 9:00PM –

Session S48 APS: Special Evening Event Hosted by the Editors of Physics Ballroom IV - Jessica Thomas, Editor, Physics

7:30PM S48.00001 Social Gathering with Pizza and Beer – .

8:00PM S48.00002 Why Condensed Matter Physicists Should Pay Attention to Atomic Physics , WILLIAM D. PHILLIPS, Joint Quantum Institute / NIST — Atomic and molecular (AMO) physics has been revolutionized by the advent of ultracold atomic gases, including quantum degenerate Bose and Fermi gases. Much of the activity with cold atoms brings AMO physics into close contact with condensed matter (CM). Atoms in optical lattices (externally imposed periodic potentials) can mimic the behavior of electrons in crystals, Bose-Einstein condensed gases or Cooper-paired degenerate Fermi gases can mimic superfluid helium or superconducting materials, and atomic gases can exhibit phase transitions that are traditionally studied in solids. These and other atomic phenomena offer possibilities for measurement and control that can be quite different from those available in materials. This talk will explore some of the current intersections of AMO and CM physics and speculate about the future of this relationship.

Wednesday, March 20, 2013 8:00PM - 9:30PM –

Session S50 FHP: A Staged Reading of the Play: Farm Hall Holiday Ballroom 4 -

8:00PM S50.00001 Farm Hall: The Play , DAVID C. CASSIDY, Hofstra University — It's July 1945. Germany is in defeat and the atomic bombs are on their way to Japan. Under the direction of Samuel Goudsmit, the Allies are holding some of the top German nuclear scientists–among them Heisenberg, Hahn, and Gerlach–captive in Farm Hall, an English country manor near Cambridge, England. As secret microphones record their conversations, the scientists are unaware of why they are being held or for how long. Thinking themselves far ahead of the Allies, how will they react to the news of the atomic bombs? How will these famous scientists explain to themselves and to the world their failure to achieve even a chain reaction? How will they come to terms with the horror of the Third Reich, their work for such a regime, and their behavior during that period? This one-act play is based upon the transcripts of their conversations as well as the author's historical work on the subject.

Discussion of the play with the playwright follows after the staged reading.

Thursday, March 21, 2013 8:00AM - 11:00AM –

Session T1 DCMP: Invited Session: Superfluids under Nanoscale Confinement Ballroom I - Jeevak Parpia, Cornell University

8:00AM T1.00001 Topological superfluids confined in a nanoscale slab geometry[1] , JOHN SAUNDERS, Department of Physics, Royal Holloway University of London — Nanofluidic samples of superfluid ^{3}He provide a route to explore odd-parity topological superfluids and their surface, edge and defect-bound excitations under well controlled conditions. We have cooled superfluid ^{3}He confined in a precisely defined nano-fabricated cavity to well below 1 mK for the first time. We fingerprint the order parameter by nuclear magnetic resonance, exploiting a SQUID NMR spectrometer of exquisite sensitivity. We demonstrate that dimensional confinement, at length scales comparable to the superfluid Cooper-pair diameter, has a profound influence on the superfluid order of ^{3}He. The chiral A-phase is stabilized at low pressures, in a cavity of height 650 nm. At higher pressures we observe ^{3}He-B with a surface induced planar distortion. ^{3}He-B is a time-reversal invariant topological superfluid, supporting gapless Majorana surface states. In the presence of the small symmetry breaking NMR static magnetic field we observe two possible B-phase states of the order parameter manifold, which can coexist as domains. Non-linear NMR on these states enables a measurement of the surface induced planar distortion, which determines the spectral weight of the surface excitations. The expected structure of the domain walls is such that, at the cavity surface, the line separating the two domains is predicted to host fermion zero modes, protected by symmetry and topology. Increasing confinement should stabilize new p-wave superfluid states of matter, such as the quasi-2D gapped A phase, which breaks time reversal symmetry, has a protected chiral edge mode, and may host half-quantum vortices with a Majorana zero-mode at the core. We discuss experimental progress toward this phase, through measurements on a 100 nm cavity. On the other hand, a cavity height of 1000 nm may stabilize a novel "striped" superfluid with spatially modulated order parameter.

8:36AM T1.00002 Probing Chirality in Superfluid ^{3}He-A: Free surface as an ideal boundary condition[1] , KIMITOSHI KONO, Low Temperature Physics Laboratory, RIKEN — Superfluid ^{3}He is known as a typical topological superfluid. A recent theoretical investigation suggests Majorana surface states at the free surface of superfluid ^{3}He-B phase [1]. On the other hand, superfluid ^{3}He-A is known as a chiral superfluid. The scattering of quasiparticle from small object is predicted to be skew with respect to an anisotropy axis [2]. We have developed an experimental technique to study transport properties of ions under the free surface of superfluid ^{3}He [3]. By using this technique, we can investigate interaction between elementary excitations in superfluid ^{3}He and small objects under well-controlled conditions. For example, in ^{3}He-B interaction with Majorana surface states, although no interaction is expected, will be investigated, whereas in ^{3}He-A skew scattering of quasiparticle from electron bubbles will be probed. In this paper, we present the recent results of transport properties of electron bubbles trapped below the free surface of superfluid ^{3}He. In particular, experimental evidences of the skew scattering and chirality of superfluid ^{3}He-A will be presented. The skew scattering of quasiparticle in ^{3}He-A from electron bubble results in a bubble transport analogous to the Hall effect, where the anisotropy vector of ^{3}He-A behaves as if it was a magnetic field in the Hall effect. Under experimental conditions, the effect is observed as an analogue of edge magnetoplasmon effect. After the analysis of data, we obtained a reasonable qualitative agreement with the theory [2].

9:12AM T1.00003 Surface Majorana cone of the topological superfluid ^{3}He B phase , RYUJI NOMURA, Tokyo Institute of Technology — Topological superfluids and superconductors are characterized by a non-trivial topological number in the gapped bulk state and gapless edge states on their surfaces. The surface states are proposed to be Majorana fermions as they satisfy the Majorana condition, i.e., a particle and its antiparticle are equivalent, and their linear dispersion is called Majorana cone. It is an urgent issue in condensed matter physics to confirm the realization of the topological matters in nature and their bulk-edge correspondence. Superfluid ^{3}He is a suitable system to reach a definite conclusion since the spin-triplet p-wave symmetry is well established in the bulk state. We measured transverse acoustic impedance of the superfluid ^{3}He B phase changing the boundary condition of a wall from a diffusive scattering up to practically specular limit by coating the wall with thin layers of superfluid ^{4}He. A growth of low-energy peak in the transverse acoustic impedance was observed at higher specularities, which is the clear evidence of low-lying quasiparticle states in the vicinity of the wall. A self-consistent theoretical calculation reproduces the experimental results well and shows that the observed growth of the peak is the reflection of the linear dispersion of the surface Andreev bound states. Thus, we experimentally confirmed Majorana fermions on the surface of the superfluid ^{3}He B phase and showed that the superfluid ^{3}He B phase is truly a topological superfluid with the bulk-edge correspondence.

9:48AM T1.00004 Symmetry Protected Topological Order in Superfluid ^{3}He-B[1] , TAKESHI MIZUSHIMA, Department of Physics, Okayama University and Department of Physics and Astronomy, Northwestern University — The superfluid ^{3}He-B has been recognized as a concrete example of topological superconductors, where the time-reversal symmetry ensures a nontrivial topological number and the existence of helical Majorana fermions. This may indicate that any time-reversal breaking disturbance wipe out the topological nature. In this talk, I will demonstrate that the B phase under a magnetic field in a particular direction stays topological due to a discrete symmetry, that is, in a symmetry protected topological order [1]. Due to the symmetry protected topological order, helical surface Majorana fermions in the B phase remain gapless and their Ising spin character persists. I unveil that the competition between the Zeeman magnetic field and dipole interaction involves an anomalous quantum phase transition where a topological phase transition takes place together with spontaneous breaking of symmetry. Based on the quasiclassical theory, I illustrate that the phase transition is accompanied by anisotropic quantum criticality of spin susceptibilities on the surface, which is detectable in NMR experiments [1,2].

10:24AM T1.00005 Critical Point Coupling and Proximity Effects in He-4 at the Superfluid Transition[1] , FRANCIS GASPARINI, University at Buffalo, SUNY — We report measurements of specific heat and superfluid density for ^{4}He confined in an array of $(2\mu m)^3$ boxes at 2μm separation and linked through a 33 nm film [1]. We find a strong enhancement of the specific heat and the superfluid density relative to control measurements where the boxes are placed farther apart [2]; and, measurements of the film itself in the absence of the boxes. We demonstrate that this coupling is due to the finite-size correlation length associated with the helium in the boxes. The surprising result, however, is that this coupling extends over distances 30-50 times the correlation length. This cannot be understood on the basis of the meaning of the correlation length as the distance over which order propagates in a critical system. These observations have implications in the understanding of experiments with helium confined in heterogeneous media, and, more generally, to other coupled critical systems where competing order is present.

Session T2 DCMP: Invited Session: Valley Polarization Physics: Transition Metal Dichalcogenides and Other Ballroom II - Tony Heinz, Columbia University

8:00AM T2.00001 Valley optoelectronics and spin-valley coupling: from graphene to monolayer group-VI transition metal dichalcogenides[1] , WANG YAO, The University of Hong Kong — The Bloch bands in many crystals have a degenerate set of energy extrema in momentum space known as valleys. The band-edge carriers then have an extra valley index which may also be used to encode information for device applications provided that dynamic control of valley index is possible. In this talk, we show that, when inversion symmetry is broken, a pair of valleys which are equivalent by time-reversal are distinguishable by their magnetic moment and Berry curvature. These quantities give rise to valley Hall effect and circularly-polarized valley optical transition selection rule both in graphene (where inversion symmetry can be broken in a controlled way in gated bilayers), and in monolayer group-VI transition metal dichalcogenides (where the 2D crystal has inherent structural inversion asymmetry). Moreover, in monolayer dichalcogenides, we find the electrons and holes at the band edges are described by massive Dirac Fermions with strong spin-valley coupling, which further results in valley and spin dependent optical selection rule, and coexistence of valley Hall and spin Hall effects. These phenomena make possible dynamic control of valley and spin by electric and optical means for device applications in monolayer dichalcogenides. We will report photoluminescence studies on dichalcogenide thin films, which show the first evidence on valley optical selection rule and optical valley pumping, and signature of the spin-valley coupling.

[1]The work was supported by the Research Grant Council of Hong Kong (HKU706412P). The author acknowledges collaborations with Guibin Liu, Zhirui Gong, Hongyi Yu, Xiaodong Cui, Di Xiao, Qian Niu and Xiaodong Xu.

8:36AM T2.00002 Optical control of exciton valley polarization in MoS_2 , KIN FAI MAK, Cornell University — Atomic monolayers of transition metal dichalcogenides have emerged as an interesting class of 2-dimensional (2D) crystals beyond graphene. In particular, the isoelectronic family of MoS_2, $MoSe_2$, WS_2 and WSe_2 monolayers are direct band gap semiconductors.[1,2] Unlike graphene, because of the lack of inversion symmetry and the presence of strong spin-orbit interactions, the fundamental energy gaps of these compounds are located at two inequivalent high-symmetry valleys in the Brillouin zone (K and K') with coupled valley and spin degrees of freedom.[3] This electronic property makes them unique from conventional semiconductors. In this talk, we will discuss the properties of MoS_2 atomic layers as a prototype. Through characterization of the optical properties of the material as a function of thickness, we show that quantum confinement effects lead to a crossover in MoS_2 from a bulk indirect gap semiconductor to a direct gap semiconductor at monolayer thickness.[4] With this basic property established, we show that complete valley polarization of the excitons in monolayer MoS_2 can be achieved by optical pumping with circularly polarized light.[5] Furthermore, this polarization can be retained for longer than 1ns. Our results thus highlight the great potential of this material family for studies of valley and spin Hall physics.[6]

9:12AM T2.00003 Single-layer MoS_2 - electrical transport properties, devices and circuits[1] , ANDRAS KIS, EPFL — After quantum dots, nanotubes and nanowires, two-dimensional materials in the shape of sheets with atomic-scale thickness represent the newest addition to the diverse family of nanoscale materials. Single-layer molybdenum disulphide (MoS_2), a direct-gap semiconductor is a typical example of these new graphene-like materials that can be produced using the adhesive-tape based cleavage technique originally developed for graphene. The presence of a band gap in MoS_2 allowed us to fabricate transistors that can be turned off and operate with negligible leakage currents. Furthermore, our transistors can be used to build simple integrated circuits capable of performing logic operations and amplifying small signals. I will report here on our latest 2D MoS_2 transistors with improved performance due to enhanced electrostatic control, showing improved currents and transconductance as well as current saturation. We also record electrical breakdown of our devices and find that MoS_2 can support very high current densities, exceeding the current carrying capacity of copper by a factor of fifty. Furthermore, I will show optoelectronic devices incorporating MoS_2 with sensitivity that surpasses similar graphene devices by several orders of magnitude. Finally, I will present temperature-dependent electrical transport and mobility measurements that show clear mobility enhancement due to the suppression of the influence of charge impurities with the deposition of an HfO_2 capping layer.

9:48AM T2.00004 Novel electronic degrees of freedom emerging from symmetry breaking of honeycomb lattices , JI FENG, International Center for Quantum Materials, Peking University — Electrons are central to the society-transforming information technologies. The intrinsic degrees of freedom of an electron, namely, its charge and spin, have been extensively explored in electronic and spintronic devices. As we are approaching the limit of device miniaturization, the exploration of novel electronic degrees of freedom, in terms of theoretical development and materials discovery, is of current interest. In this talk, we will focus on two strategies to break the symmetry of a Fermionic honeycomb lattice that lead to novel degrees of freedom of Bloch electrons. The essential idea in these approaches is to lift the isospin degeneracy a honeycomb lattice by introducing contrasting identities (chemical or magnetic) to the two sublattices. The new indices of Bloch electrons will then arise, corresponding to contrasting responses to external fields, such as in optical selectivity and anomalous electronic transport. Using combined computational, theoretical and experimental approaches, we go on to demonstrate that the proposed physics can be realized in real material systems. In particular, our results indicate that monolayer transition metal chalcogenides, such as non-magnetic MoX_2 and antiferromagnetic $MnPX_3$ (X = S, Se), can indeed exhibit selective circular dichroism. The associated Berry curvature-supported quantum transport will also be discussed.

10:24AM T2.00005 Valley polarization in bismuth , BENOIT FAUQUE, LPEM/ESPCI — The electronic structure of certain crystal lattices can contain multiple degenerate *valleys* for their charge carriers to occupy. The principal challenge in the development of *valleytronics* is to lift the valley degeneracy of charge carriers in a controlled way. In bulk semi-metallic bismuth, the Fermi surface includes three cigar-shaped electron valleys lying almost perpendicular to the high symmetry axis known as the trigonal axis. The in-plane mass anisotropy of each valley exceeds 200 as a consequence of Dirac dispersion, which drastically reduces the effective mass along two out of the three orientations. According to our recent study of angle-dependent magnetoresistance in bismuth [1], a flow of Dirac electrons along the trigonal axis is extremely sensitive to the orientation of in-plane magnetic field. Thus, a rotatable magnetic field can be used as a valley valve to tune the contribution of each valley to the total conductivity. As a consequence of a unique combination of high mobility and extreme mass anisotropy in bismuth, the effect is visible even at room temperature in a magnetic field of 1 T. Thus, a modest magnetic field can be used as a valley valve in bismuth. The results of our recent investigation of angle-dependent magnetoresistance in other semi-metals and doped semiconductors suggest that a rotating magnetic field can behave as a valley valve in a multi-valley system with sizeable mass anisotropy.

Session T3 DCMP DBIO: Invited Session: From Cells to Tissues: The Material Properties of Living Matter Ballroom III - Aaron Mertz, Yale University

8:00AM T3.00001 Spreading and spontaneous motility of multicellular aggregates on soft substrates , FRANÇOISE BROCHARD-WYART, Institut Curie-UPMC — We first describe the biomechanics of multicellular aggregates, a model system for tissues and tumors. We first characterize the tissue mechanical properties (surface tension, elasticity, viscosity) by a new pipette aspiration technique. The aggregate exhibits a viscoelastic response but, unlike an inert fluid, we observe aggregate reinforcement with pressure, which for a narrow range of pressures results in pulsed contractions or shivering. We interpret this reinforcement as a mechanosensitive active response of the acto-myosin cortex. Such an active behavior has previously been found to cause tissue pulsation during dorsal closure of Drosophila embryo. We then describe the spreading of aggregates on rigid glass substrates, varying both intercellular and substrate adhesion. We find both partial and complete wetting regimes. For the dynamics, we find a universal spreading law at short time, analogous to that of a viscoelastic drop. At long time, we observe, for strong substrate adhesion, a precursor film spreading around the aggregate. Depending on aggregate cohesion, this precursor film can be a dense cellular monolayer (liquid state) or consist of individual cells escaping from the aggregate body (gas state). The transition from liquid to gas state appears also to be present in the progression of a tumor from noninvasive to metastatic, known as the epithelial-mesenchymal transition. Finally, we describe the effect of the substrate rigidity on the phase diagram of wetting. On soft gels decorated with fibronectin and strongly cohesive aggregates, we have observed a wetting transition induced by the substrate rigidity: on ultra soft gels, below an elastic modulus Ec the aggregates do not spread, whereas above Ec we observe a precursor film expending with a diffusive law. The diffusion coefficient D(E) present a maximum for E=Em. A maximum of mobility versus the substrate rigidity had also been observed for single cells. Near Em, we observe a new phenomenon: a cell monolayer expands outward from the aggregate apparently under tension. In this tense monolayer, holes nucleate, and lead to a symmetry breaking as the entire aggregate starts to move in a similar fashion as a giant fish keratocyte.

8:36AM T3.00002 Modeling cell-matrix traction forces in Keratinocyte colonies[1] , SHILADITYA BANERJEE, Department of Physics, Syracuse University — Crosstalk between cell-cell and cell-matrix adhesions plays an essential role in the mechanical function of tissues. The traction forces exerted by cohesive keratinocyte colonies with strong cell-cell adhesions are mostly concentrated at the colony periphery. In contrast, for weak cadherin-based intercellular adhesions, individual cells in a colony interact with their matrix independently, with a disorganized distribution of traction forces extending throughout the colony. In this talk I will present a minimal physical model of the colony as contractile elastic media linked by springs and coupled to an elastic substrate. The model captures the spatial distribution of traction forces seen in experiments. For cell colonies with strong cell-cell adhesions, the total traction force of the colony measured in experiments is found to scale with the colony's geometrical size. This scaling suggests the emergence of an effective surface tension of magnitude comparable to that measured for non-adherent, three-dimensional cell aggregates. The physical model supports the scaling and indicates that the surface tension may be controlled by acto-myosin contractility.

9:12AM T3.00003 May the force be with you: Surface tension predicts tissue rearrangement. , RAMSEY FOTY, DUniversity of Medicine and Dentistry of New Jersey, Robert Wood Johnson Medical — No abstract available.

9:48AM T3.00004 Biophysical aspects of embryonic development , LARS HUFNAGEL, European Molecular Biology Laboratory - EMBL, Heidelberg — No abstract available.

10:24AM T3.00005 Forces, waves and emergent dynamics during collective cell migration , XAVIER TREPAT, Institute for Bioengineering of Catalonia — A broad range of biological processes such as morphogenesis, tissue regeneration, and cancer invasion depend on the collective motion of cell groups. For a group of cells to migrate cohesively, it has long been suspected that each constituent cell must exert physical forces not only upon its extracellular matrix but also upon neighboring cells. I will present novel techniques to measure these distinct force components. Using these techniques, we unveiled an unexpectedly rich physical picture in which the distribution of physical forces is dominated by heterogeneity, cooperativity, and jamming. I will show, moreover, that these essential features of inter-cellular force transmission enable the propagation of a new type of mechanical wave during tissue growth. Finally, I will demonstrate that both in epithelial and endothelial cell sheets, forces and waves are mechanically linked to cell velocities through a newly discovered emergent mechanism of innately collective cell guidance: plithotaxis.

Thursday, March 21, 2013 8:00AM - 11:00AM –

Session T4 FIAP: Invited Session: Physics and Applications of Transparent Conducting Oxides

Ballroom IV - Chris Van de Walle, University of California, Santa Barbara

8:00AM T4.00001 Transparent Conducting Oxides as Potential Thermoelectrics[1] , THOMAS MASON, Northwestern University, Evanston, IL — Transparent conducting oxides (TCOs) in their less-doped semiconducting states have potential as thermoelectric oxides or TEOs. They are attractive as TEOs owing to: 1) their good thermochemical stability, 2) their n-type character (to complement existing p-type TEOs), and 3) their high electronic mobilities. The numerator of the TE figure of merit (Z), also known as the "power factor" (PF), is the product of the electronic conductivity and the square of the Seebeck coefficient. An experimental procedure named after its developer, "Jonker" analysis plots Seebeck coefficient vs. the natural logarithm of the electronic conductivity. Data for bulk ceramic specimens just prior to the onset of degeneracy tend to fall on a line of slope, k/e (k=Boltzmann constant, e=charge of the electron). From this line, the doping composition corresponding to the highest power factor can be determined and the PF optimized, based upon data from a few carefully chosen compositions. Subsequently, following a procedure originally derived by Ioffe, the zero-thermopower intercept of these Jonker lines can be directly related to the maximum achievable power factor for a given TEO. So-called "Ioffe" plots allow for meaningful comparisons between candidate TEO materials, and also indicate the minimum thermal conductivity required to achieve a target ZT value at the temperature of measurement. Results for TCO-based TEOs will be discussed for both simple and compound (including layered) materials.

[1]This work was supported by the U.S. Department of Energy, Office of Basic Energy Sciences as part of an Energy Frontier Research Center under grant no. DE-SC0001059.

8:36AM T4.00002 Developing New TCOs for Renewable Applications , DAVID GINLEY, NREL — Transparent conducting oxides are enabling for a broad range of optoelectronic technologies. Not only are conductivity and transparency critical but many other factors are critical including: carrier type, processing conditions, work function, chemical stability, and interface properties. The historical set of materials cannot meet all these needs. This has driven a renaissance in new materials development and approaches to transparent contacts. We will discuss these new developments in general and in the context of photovoltaics specifically. We will present results on new materials and also the development bilayer structrues that enable charge selective contacts. Materials set includes amorphous materials for hybrid solar cells like InZnO and ZnSnO, it includes Nb and Ta doped TiO2 as a high refractive index TCO and it includes the use of thin n- and p-type oxides as electron and hole selective contacts such as has been demonstrated for organic photovotaics.

This work is supported by the U.S. Department of Energy, Office of Science, Basic Energy Sciences, under Contract No. DE-AC36-08GO28308 to NREL as a part of the DOE Energy Frontier Research Center "Center for Inverse Design" and through the US Department of Energy under Contract no. DOE-AC36-08GO28308 through the National Center for Photovoltaics.

9:12AM T4.00003 Fundamental limits on transparency: first-principles calculations of absorption[1] , HARTWIN PEELAERS, Materials Department, University of California, Santa Barbara, CA 93106-5050 — Transparent conducting oxides (TCOs) are a technologically important class of materials with applications ranging from solar cells, displays, smart windows, and touch screens to light-emitting diodes. TCOs combine high conductivity, provided by a high concentration of electrons in the conduction band, with transparency in the visible region of the spectrum. The requirement of transparency is usually tied to the band gap being sufficiently large to prevent absorption of visible photons. This is a necessary but not sufficient condition: indeed, the high concentration of free carriers can also lead to optical absorption by excitation of electrons to higher conduction-band states. A fundamental understanding of the factors that limit transparency in TCOs is essential for further progress in materials and applications. The Drude theory is widely used, but it is phenomenological in nature and tends to work poorly at shorter wavelengths, where band-structure effects are important. First-principles calculations have been performed, but were limited to direct transitions; as we show in the present work, indirect transitions assisted by phonons or defects actually dominate. Our calculations are the first to address indirect free-carrier absorption in a TCO completely from first principles. We present results for SnO_2 [1], but the methodology is general and is also being applied to ZnO and In_2O_3. The calculations provide not just quantitative results but also deeper insights in the mechanisms that govern absorption processes in different wavelength regimes, which is essential for engineering improved materials to be used in more efficient devices. For SnO_2, we find that absorption is modest in the visible, and much stronger in the ultraviolet and infrared.

9:48AM T4.00004 Surface electron accumulation layers in oxide semiconductors[1] , TIM VEAL, University of Liverpool — In contrast to the electron depletion at the surface of almost all n-type semiconductors, electron accumulation has long been known to be observable at ZnO surfaces. It has recently been found to be a characteric of several other oxide semiconductors, including CdO [1,2], In_2O_3 [3] and SnO_2. They all have a significant size and electronegativity mismatch between their cation and anion. As a result, they have a particularly low Γ-point conduction band minimum which is ultimately responsible for the propensity for electron accumulation. In addition to the mere existence of an electron-rich surface layer, it has been found, using angle-resolved photoemission spectroscopy (ARPES), to be quantized into two dimensional subbands [1]. Moreover, the conventional one-electron picture of surface space-charge in semiconductors is shown to be inconsistent with the electronic structure that we observe directly from ARPES, indicating that many-body interactions play a large role in the surface electronic properties of these semiconductors. Such interactions lead to a depth-dependent shrinkage of the semiconductor band gap, resulting in a surface band gap which differs from the bulk value [1]. The most recent studies have focussed on the influence of depositing alkali metals onto the surface of these semiconductors. Many collaborators are acknowledged for samples and ARPES expertise.

10:24AM T4.00005 Low temperature growth of conformal, transparent conducting oxides , ROY GORDON, Harvard University — Transparent conductors (TC) are essential components of many widely-used technologies, including energy conserving low-E windows, electronic displays and solar cells. Currently, TC films are made by chemical vapor deposition (CVD) or by sputtering or evaporation (PVD). CVD has generally required high temperatures (greater than 500 C), so that is not applicable to plastic substrates and some solar cells. PVD makes films with low step coverage, so textured substrates, such as those with narrow holes, cannot be coated uniformly. The most effective PVD films are based on indium, a rare and expensive element. Recently, atomic layer deposition (ALD) processes have been developed that overcome all of these limitations, allowing highly uniform and conformal coating of substrates with very narrow holes even at substrate temperatures below 100 C. The metals used in these ALD TCs are tin and/or zinc, which are abundant and inexpensive elements. In this talk, we will review these ALD processes, along with the optical, structural and electrical properties of the TCs that they produce. Applications of these low-temperature, conformal TCs will also be discussed. Record-breaking solar cells made entirely from Earth-abundant elements were enabled by these ALD processes. Transparent transistors with excellent characteristics can now be made at low temperature even on rough or textured plastic surfaces. Micro-channel plate array detectors are being produced for use in highly sensitive imaging applications.

Thursday, March 21, 2013 8:00AM - 11:00AM –

Session T5 DCMP: Graphene: Transport and Optical Phenomena: Raman and Phonons 301 - Francois Peeters, University of Antwerp

8:00AM T5.00001 Polarization dependence of Raman 2D band in bilayer graphene , JAE-UNG LEE, NGOR MBAYE SECK, Department of Physics, Sogang University, Seoul, Korea, DUHEE YOON, Electrical Engineering Division, Engineering Department, University of Cambridge, Cambridge, UK, HYEONSIK CHEONG, Department of Physics, Sogang University, Seoul, Korea — The Raman intensity of the double-resonance 2D band in sigle-layer graphene has a strong polarization dependence(Yoon et al. Nano Lett.). The intensity is maximum when the excitation and detection polarization are parallel and minimum when they are orthogonal, whereas that of G band is isotropic. This strong polariztion dependence is the consequence of inhomogeneous optical absorption and emission mediated by electron-phonon interactions. Here, the polarization dependence of the Raman 2D band in bilayer graphene. The 2D band of bilayer graphene can be decomposed to 4 Lorentzian peaks corresponding to different scattering process involving 2 conduction and 2 valence bands. The 2D band in bialyer graphene shows a similar polarization dependence as that of single layer. Futhermore, the excitation energy dependence was investigated by using 4 different excitation laser wavelenghths. The polarization ratio of each of the 4 Lorentizan peaks seems to reflect the features of the electronic band structure of bilayer graphene in the energy range of the excitation laser.

8:12AM T5.00002 Undetectable Raman Spectrum of Graphene on Platinum Surface , A. ZETTL, QIN ZHOU, Department of Physics, University of California at Berkeley; Materials Sciences Division, Lawrence Berkeley National Laboratory — Raman spectrometry is often used as a quick and convenient tool to evaluate the growth quality of graphene. Recently there has been growing interest in platinum mediated graphene CVD growth for producing high-quality, large grain size, and highly flat graphene layers. Surprisingly, no Raman signal of graphene can be detected in the as-grown state on platinum substrates, despite using different laser wavelengths from 488 nm to 785nm. This phenomenon is briefly mentioned in earlier literature and has been attributed to strong platinum-graphene interaction. We investigate the disappearance of graphene Raman signatures on metal substrates, by performing Raman spectrum measurements on graphene layers transferred onto various substrates.

8:24AM T5.00003 Raman spectroscopy of single layer graphitic carbon nitride , JOEL THERRIEN, YANCEN LI, ECE Dept UMass Lowell, DANIEL SCHMIDT, Plastics Engineering Dept UMass Lowell, ADAM COLLARD, Physics U. Texas Austin, DANIEL FINKENSTADT, TAYLOR YUST, US Naval Acdemy — Single layer graphitic carbon nitride (referred to as melon) has been synthesized by our group in sizes up to 50 μm across. Raman spectroscopy has been performed on single layer melon and multi layer samples. Much like graphene, melon shows a unique raman spectrum when in single layer form. These experimental results have been compared to theoretical calculations for possible melon structures. Bond counts for feasible structures of hexagonal carbon nitride have been calculated and some possible structures have been eliminated from consideration based on these efforts. Periodic supercells have been built to make sheets based on structures to be modeled via density-functional theory, as implemented using VASP, to calculate thermodynamic and structural stability and frequencies of IR and Raman active modes.

8:36AM T5.00004 Magneto-Raman experiments in single- and multi-layer graphene , F.M. ARDITO, UNICAMP - Univ. Estadual de Campinas, T.G. MENDES DE SA, UFMG - Univ. Federal de Minas Gerais, P.F. GOMES, UNICAMP - Univ. Estadual de Campinas, E. NERY, D.L. MAFRA, UFMG - Univ. Federal de Minas Gerais, F. IIKAWA, M.J.S.P. BRASIL, UNICAMP - Univ. Estadual de Campinas, L.M. MALARD, F. PLENTZ, M.A. PIMENTA, R.G. LACERDA, UFMG - Univ. Federal de Minas Gerais, E. GRANADO, UNICAMP - Univ. Estadual de Campinas — Micro-Raman experiments as a function of magnetic field up to 15 T were performed on a set of natural graphene flakes on Si/SiO_2 substrates and multilayer epitaxial graphene grown on a carbon face of SiC. Pronounced oscillations of the G-band position and linewidth attributed to crossings of this mode with Landau levels were observed in epitaxial graphene. Calculated phonon energy and broadening oscillations obtained from the phonon's Green function show good agreement with the results obtained for SiC samples, in line with a previous report [1]. For graphene flakes, the field evolution of the G-band is strongly sample-dependent, and may also depend on the position of the focal spot. A splitting of G-band in two peaks was observed in some cases for $B > 12$ T. Our results suggest the large sensitivity of graphene electron-phonon interaction to both magnetic field and local conditions. [1] C. Faugeras *et al.*, Phys. Rev. Lett. **103**, 186803 (2009).

8:48AM T5.00005 Transport and Raman measurements in Graphene: Interaction strength and scattering mechanisms , SEBASTIAN REMI, ANNA SWAN, BENNETT GOLDBERG, Boston University — Among the most common techniques for characterization of Graphene materials have been electronic transport and Raman measurements, for instance both can be easily tuned by changing the charge carrier density and electronic screening. In each situation the underlying physics is connected to the interactions and relaxation mechanisms in the material. However it is well known that the electronic scattering time does not necessarily describe the broadening observed in Raman measurements. Here we present micro Raman and transport measurements of single layer graphene field effect devices. We discuss interaction and scattering mechanisms and how these are connected in the different measurements.

9:00AM T5.00006 Raman scattering of 2D materials , TING YU, Division of Physics and Applied, School of Physical and Mathematical Sciences, Nanyang Technological University, Singapore 637371 2, RIICHIRO SAITO, Department of Physics, Tohoku University, Sendai, Miyagi 9808578, Japan, MILDRED DRESSELHAUS, Department of Electrical Engineering and Computer Science; Department of Physics, Massachusetts Institute of Technology, Cambridge, Massachusetts 021 — Motivated by graphene, two-dimensional (2D) materials become the center of current Nanoscience and Nanotechnology. In this talk, I will report our recent works on Raman scattering study of 2D materials such as graphene and MoS2. In detail: the in-plane and out-of-plane arrangement of carbons in graphene layers are identified by both Raman and HRTEM with atomic resolution; the structure evolution of molecules anchored on the surface of graphene is studied by Raman; the behavior of Dirac Fermions of graphene in a magnetic field is probed; the strain effects on MoS2 and the identification of crystallographic orientation of MoS2 are also discussed. The results presented here are highly relevant to the fundamental and applications of graphene and other 2D transition metal dichalcogenides (TMDs)..

9:12AM T5.00007 Temperature-dependent photoluminescence and Raman spectroscopy of single-layer MoS_2 , J.R. SIMPSON, Towson University, R. YAN, Notre Dame, S. BERTOLAZZI, A. KIS, J. BRIVIO, EPFL, M. WATSON, Towson University, H.G. XING, Notre Dame, A.R. HIGHT WALKER, NIST — We report the temperature-dependent photoluminescence (PL) and Raman spectra of single-layer MoS_2. Mechanical exfoliation from bulk MoS_2 provides single-layer flakes which are then transferred to either sapphire (with and without ALD HfO_2 overcoating) or suspended over holes in a Si/Si_3N_4 substrate. We measure the temperature dependence of PL and Raman spectra from (100 to 400) K using HeNe 632.8 nm (PL) and Ar^+-ion 514.5 nm (Raman) laser excitations coupled to a microscope and grating spectrometer. PL shows a single, narrow peak corresponding to a direct-band transition approximately centered at 1.9 eV with a width of 50 meV. The PL peak redshifts and broadens with increasing temperature. Raman spectra reveal two strong phonon vibrational modes, the planar E^1_{2g} and out-of-plane A_{1g}, both of which soften linearly with increasing temperature as a result of anharmonic effects. We extract a linear temperature coefficient for both Raman modes comparable to the G-mode of graphene. A comparison with the dependence of phonon peak position on incident optical power for the suspended sample shows moderate heat flux efficiency. The impact of dielectric and substrate environment on extraction of thermal conductivity will be discussed.

9:24AM T5.00008 Observation of polaronic effects in electron transport in graphene by infrared spectroscopy , KELIANG HE, LIANG ZHAO, JIE SHAN, Case Western Reserve University, KIN FAI MAK, NICK PETRON, JAMES HONE, TONY F. HEINZ, Columbia University, G. LARRY CARR, NSLS, Brookhaven National Laboratory — Polarons, quasi-particles consisting of electrons and the accompanying lattice polarization, are generally considered to be unimportant for the electrical transport properties of nonpolar crystals such as graphene. The distinctive linear dispersion relation found in graphene and the drastically reduced screening of Coulomb interactions associated with the material's reduced dimensionality, however, lead to strong coupling between Dirac electrons and high-energy optical phonons in graphene. In this work, we apply the infrared absorption spectroscopy to investigate the optical conductivity of graphene as a function of electrostatic doping density. We have observed a phonon side band in the intraband optical conductivity with a significant spectral weight transfer from the Drude response, indicating the importance of the polaronic effects. The effects can also be tuned by doping. The conductivity spectra have been analyzed in the framework of the extended Drude model to yield the spectral dependence of the mass enhancement factor (band structure renormalization) and the scattering rate (with an onset for phonon scattering) at different doping levels. Our results are in good agreement with many-body calculations for graphene conductivity with polaronic corrections.

9:36AM T5.00009 Electron-phonon bound states in graphene , JUSTIN ZHU, SAMVEL M. BADALYAN, FRANCOIS PEETERS, Department of Physics, University of Antwerp, Groenenborgerlaan 171, B-2020 Antwerpen, Belgium — We investigate the fine structure of the energy spectrum in graphene induced by electron-optical phonon coupling. Despite the small electron-phonon coupling, perturbation theory is inapplicable in the part of spectrum near the optical phonon emission threshold. In zero magnetic field [1] we derive new dispersion equation, which in the immediate neighborhood below the threshold describes an electron-phonon bound state. We find that the singular vertex corrections beyond perturbation theory strongly inhance the electron-phonon binding energy scale. In quantizing magnetic fields [2], our findings beyond perturbation theory show that the true spectrum near the phonon emission threshold is completely governed by new branches of the spectrum, corresponding to bound states of an electron and an optical phonon with a binding energy of the order of $\alpha\omega_0$ where α is the electron-phonon coupling and ω_0 the phonon energy.

[2] J. Zhu, S. M. Badalyan and F. M. Peeters, arXiv:**1206.5107**.

9:48AM T5.00010 Graphene thermal conductivity from first principles , LUCAS LINDSAY, TOM REINECKE, Naval Research Laboratory, Washington, D.C., DAVID BROIDO, Department of Physics, Boston College — Previous theoretical work based on an optimized Tersoff interatomic potential found that the thermal conductivity of graphene is dominated by out-of-plane phonons in part due to reflection symmetry of the graphene sheet [1,2]. Since empirical potentials can have questionable predictive power, here we present calculations of the thermal conductivity of graphene using interatomic forces determined from *first principles* coupled with a numerical solution to the Peierls-Boltzmann transport equation. We find good agreement with experiment for the calculated phonon dispersion and thermal conductivity of graphene and validate earlier theoretical results which used the optimized empirical potential. [1] J.H. Seol, *et al*, *Science* 328, 213 (2010). [2] L. Lindsay, *et al*, *Phys. Rev. B* 82, 115427 (2010).

10:00AM T5.00011 Thermal transport in low-dimensional systems: the case of Graphene and single layer Boron Nitride , LUIZ FELIPE PEREIRA, DAVIDE DONADIO, Max Planck Institute for Polymer Research — Low-dimensional systems present unusual transport properties in comparison to bulk materials. In contrast with the three-dimensional case, in one- and two-dimensions heat transport models predict a divergence of the thermal conductivity with system size. In reality, in a low-dimensional system the mean-free-path of heat carriers (phonons) becomes comparable to the micrometer size of experimental samples. Recent developments in nanostructure fabrication allow a direct comparison between theory and experiments for such low-dimensional systems. We perform extensive molecular dynamics simulations of heat transport in graphene and single layer BN, in order to clarify the behavior of the thermal conductivity in realistic low-dimensional systems. In particular, we address the influence of system size on the simulation results. Equilibrium molecular dynamics predicts a convergence of the thermal conductivity with system size, even for systems with less than one hundred nanometers and thousands of atoms. Meanwhile, large scale non-equilibrium molecular dynamics shows a divergence of the thermal conductivity with system size up to the micrometer scale. We analyse the discrepancy between methods in terms of perturbations in phonon populations induced by the non-equilibrium regime.

10:12AM T5.00012 Phonon-limited transport coefficients in extrinsic graphene[1] , ENRIQUE MUNOZ, Departamento de Fisica, Pontificia Universidad Catolica de Chile — The effect of electron-phonon scattering processes over the thermoelectric properties of extrinsic graphene was studied. Electron-phonon interaction is formulated in the second quantization language, for chiral Dirac spinor fields and phonon Bose fields, within the deformation potential approximation. Electrical and thermal resistivity, as well as the thermopower, were calculated within the Bloch theory approximations. Analytical expressions for the different transport coefficients were obtained from a variational solution of the Boltzmann transport equation. The phonon-limited electrical resistivity ρ_{e-ph} shows a linear in temperature dependence at high temperatures, and follows a $\rho_{e-ph} \sim T^4$ at low temperatures, in agreement with experiments. The phonon-limited thermal resistivity at low temperatures exhibits a $\sim T$ dependence and achieves a nearly constant value at high temperatures. The predicted Seebeck coefficient at very low temperature is $Q(T) \sim \pi^2 k_B T/(3eE_F)$, which shows a $n^{-1/2}$ dependence with the carrier density, in agreement with experiments.

10:24AM T5.00013 Thermal Conductivity Measurements in Sub-micron Graphene Crystals , SERAP YIGEN, VAHID TAYARI, JAMES PORTER, JOSHUA O. ISLAND, A. R. CHAMPAGNE, Department of Physics, Concordia University, Montreal, QC, Canada — Heat conductivity measurements in graphene using optical spectroscopy have been limited to micron-scale devices, and mostly room temperature and uncontrolled charge densities. We present an electron transport method to measure thermal conductivity, κ, in sub-micron suspended graphene, over a broad range of temperature (50K - 350K), and as a function of charge density. We study suspended two-point graphene devices whose length ranges from 350 nm up to 1.2 micron. We show that the there can be good thermalization of electrons and acoustic phonons in these devices. This enables us to use electron resistivity as a thermometer for electrons or phonons. Our devices are in the near-diffusive regime, permitting Joule heating of the samples and modelling heat transport using a heat equation. We measure an increase of two orders of magnitude in κ over the studied temperature range and crystal lengths. κ is dominated by the electronic heat conductivity in sub-micron devices, and phononic heat conductivity in longer devices. In short devices, we can tune κ by more than a factor of two with charge density, opening the possibility of creating room temperature heat transistors.

10:36AM T5.00014 Electron-Phonon Coupling in Silicene , JIA-AN YAN, Department of Physics, Astronomy, and Geosciences, MEI-YIN CHOU, School of Physics, Georgia Institute of Technology, Atlanta, Georgia 30332, USA and Institute of Atomic and Molecular Sciences, Academia Sinica, Taipe — We report here a first-principles study of the electron-phonon coupling (EPC) in silicene and compare the results to graphene. The E_g mode at Γ and the A_1 mode at K of the first Brillouin zone are shown to exhibit Kohn anomalies, similar to that in graphene. Detailed calculations show that although the EPC matrix elements are much smaller than in graphene, the linear band with smaller slope compensate this effect, resulting in a slightly larger phonon linewidth. Finally, the phonon frequency shift and the linewidth of the E_g mode as a function of the Fermi level E_F have been calculated.

10:48AM T5.00015 Out-of-equilibrium current-induced forces on a suspended graphene sheet , SILVIA VIOLA KUSMINSKIY, Dahlem Center for Complex Quantum Systems - Freie Universität Berlin — We have recently developed a formalism that allows to obtain the current-induced forces that act on the vibrational degrees of freedom of a nanoelectromechanical system, purely from scattering matrix theory [*cf* N. Bode, S. Viola Kusminskiy, R. Egger, F. von Oppen, *Phys. Rev. Lett.* **107**, 036804 (2011) and *Beilstein J. Nanotechnol.* **3**, 144 (2012), and M. Thomas, T. Karzig, S. Viola Kusminskiy, G. Zaránd, F. von Oppen, arXiv:1209.0620 (2012)].The forces are expressed in terms of the frozen electronic scattering matrix and its first non-adiabatic correction, the A-matrix, and the expressions are valid both in and out of thermal equilibrium. We apply our results to study the effects of transport currents on the dynamics of the flexural modes of a suspended graphene sheet. We pay particular attention to the non-equilibrium contributions to the force which occur in the presence of a finite applied bias voltage.

Session T6 DMP: Focus Session: Graphene - Heterostructures, Overlayers 302 - Debdeep Jena, University of Notre Dame

8:00AM T6.00001 Direct Evidence for van der Waals Hetero-epitaxy of Graphene on Hexagonal Boron Nitride , HAOMIN WANG, State Key Laboratory of Functional Materials for Informatics, Shanghai Institute of Microsystem and Information Technology, Chinese Academy of Science, SHUJIE TANG, ANG LI, XIAOMING XIE, MIANHENG JIANG, State Key Laboratory of Functional Materials for Informatics, SIMIT, CAS — We report on direct evidence for van der Waals (vdW) hetero-epitaxy of graphene grown on hexagonal boron nitride (hBN). Rotational misalignment of graphene on hBN produces a moiré pattern detectable by scanning probe microscopy (SPM) as a small modulation of the probe/surface friction. With the help of moiré interferometry and atomic resolution imaging, we obtained a fundamental insight into the growth behavior of single-crystalline graphene grown on h-BN substrates. It is found that the graphene grown by chemical vapor deposition mainly locks into one crystallographic orientation with respect to the h-BN substrate, while the graphene edges are parallel to armchair direction. The Moiré pattern on graphene/h-BN confirms that the rotational misalignment of graphene is definitely less than 0.05 $^\circ$ with respect to h-BN. It is also noticed that the vdW interaction plays a critical role in releasing the interfacial stress in the epitaxial graphene on h-BN. Our work shines light on creating artificial moiré interferometry in nanometer scale, which provides an invaluable scientific tool of atomic analyses on graphene based hetero-junction.

8:12AM T6.00002 DUV-Vis-NIR Structural and Compositional Imaging of Two-Dimensional Heterostructures , ROBIN HAVENER, CHEOL-JOO KIM, LUJIE HUANG, ADAM TSEN, MARK LEVENDORF, JIWOONG PARK, Cornell University — Recent advances have allowed precise stacking and lateral stitching of various two-dimensional materials in complex geometries, but characterizing these structures remains a challenge. Here, we use a DUV-Vis-NIR ($<$ 200-1000 nm) hyperspectral microscope to image composition and structural features in graphene and hexagonal boron nitride (h-BN) heterostructures with micron-scale resolution. We provide high-contrast images of h-BN at its absorption peak (6.1 eV), and map the quantitative full optical functions of single-layer graphene and h-BN in a device geometry. Stacking these materials provides an additional rotational degree of freedom which can produce unique optical signatures, allowing all-optical structural imaging. We characterize the optical response of twisted bilayer graphene, which exhibits an absorption peak whose energy varies with relative rotation angle from the infrared to the DUV ($\sim$ 4.0 eV), by combining hyperspectral imaging with dark-field transmission electron microscopy. By establishing such structure-property relationships, we enable controlled device fabrication on silicon substrates.

8:24AM T6.00003 Fabrication and characterization of graphene/MoS_2 heterojunctions , AMELIA BARREIRO, CHUL-HO LEE, INANC MERIC, LEI WANG, JAMES HONE, KEN SHEPHARD, PHILIP KIM, Columbia University — We have fabricated graphene/MoS_2 /graphene co-laminated heterojunctions using a micromechanical manipulation technique. In order not to mask the transport properties of the heterojunctions, ohmic contact resistances need to be established. With the purpose of avoiding the formation of a Schottky barrier between the metal electrode and the MoS_2, different metals with work functions lower than the MoS_2 are tested. Once having obtained ohmic contacts, we are able to access the intrinsic transport properties of the heterojunctions and form Schottky diodes at the interface of the two layered materials. We will discuss the implications of the stacked heterojunction geometry to build novel transistors.

8:36AM T6.00004 Atomically-Smooth MgO films grown on Epitaxial Graphene by Pulsed Laser Deposition[1] , SEAN STUART, ANDREAS SANDIN, JACK ROWE, DAN DOUGHERTY, North Carolina State University, MARC ULRICH, Army Research Office — The growth of high quality insulating films on graphene is a crucial materials science task for graphene electronic and spintronic applications. It has been demonstrated that direct spin injection from a magnetic electrode to graphene is possible using MgO tunnel barriers of sufficient quality. We have used pulsed laser deposition (PLD) to grow thin magnesium oxide films directly on epitaxial graphene on SiC(0001). We observe very smooth film morphologies (typical rms roughness of $\sim$ 0.4 nm) that are nearly independent of film thickness and conform to the substrate surface which had $\sim$ 0.2 nm rms roughness. Surface roughness of 0.04 nm have been recorded for $\sim$ 1nm films with no pinholes seen by AFM. XPS and XRD data show non crystalline, hydroxylated MgO films with uniform coverage. This work shows that PLD is a good technique to produce graphene-oxide interfaces without pre-deposition of an adhesion layer or graphene functionalization. The details and kinetics of the deposition process will be described with comparisons being made to other dielectric-on-graphene deposition approaches.

8:48AM T6.00005 Initial stages of growth of pentacene on graphene[1] , GVIDO BRATINA, MANISHA CHIKKARA, EGON PAVLICA, University of Nova Gorica, Nova Gorica, Slovenia, ALEKSANDAR MATKOVIC, ANGELA BELTAOŠ, DJORDJE JOVANOVIC, DANKA STOJANOVIC, RADOŠ GAJIC, Institute of Physics, University of Belgrade, Serbia — We have examined by scanning probe microscope submonolayer coverages of pentacene on graphene fabricated by chemical vapor deposition (CVD) and exfoliated graphene. Inherent to CVD-graphene, even upon transferring onto SiO_2 substrates is the presence of varying surface density of folds-grafolds. By means of Kelvin force microscopy we observe about 0.3 eV higher workfunction on multiply-folded grafolds, but within our resolution, observe no change in workfunction for singly folded grafolds. By atomic force microscopy we observe that grafolds act as nucleation centers for pentacene, inducing three-dimensional (3D) morphology of pentacene layers in the nucleation phase of growth. Moreover, the resulting elongated islands exhibit a preferential orientation perpendicular to the dominant direction of a grafold. We associate this behavior in terms of elastic strain and enhanced chemical reactivity of the grafolds. This type of morphology is at strong variance with the morphology of pentacene layers that we observe on exfoliated graphene. There we observe two-dimensional (2D) islands whose height of 1.5 nm corresponds to a thin-film phase of pentacene. We observe the onset of 3D island nucleation on the surface of the 2D islands that have attained a critical size. We interpret this behavior in terms of surface energy of pentacene that depends on the underlying substrate.

9:00AM T6.00006 Intrinsic Electron-Hole Puddles in Graphene on Hexagonal Boron-Nitride , MENNO BOKDAM, TAHER AMLAKI, GEERT BROCKS, PAUL J. KELLY, MESA+ Institute for Nanotechnology, University of Twente, The Netherlands — When graphene is placed on top of hexagonal boron nitride (h-BN), the 1.7% lattice mismatch between the honeycomb lattices of graphene and h-BN leads to the formation of superstructures that are observed as moiré patterns in scanning tunneling microscopy images [1,2]. Using first-principles calculations and ignoring the incommensurability, we observed the formation of a dipole layer at the graphene|h-BN interface [3]. The strength and direction of this dipole layer depends sensitively on the local bonding of the carbon atoms to the substrate i.e. on the details of how the graphene layer is positioned on top of h-BN. The dipole layer is accompanied by a step in the electrostatic potential, which ranges from $+120$ to -30 meV depending on the configuration. Because the lattice mismatch is so small, the local bonding configuration varies slowly in a graphene|h-BN superstructure. We predict that the Dirac cone will follow the slowly varying potential created by the interface dipole layer even when screening effects are included. This then leads to the formation of regions of electron- and hole-doped graphene: intrinsic electron-hole puddles that will limit the mobility in this system. We make a comparison with graphene on molybdenum disulphide (MoS_2) where a dipole layer is also formed but where we do not expect intrinsic electron-hole puddles to be formed. [1] R. Decker et al., Nano Lett. 11, 2291-2295 (2011) [2] J.M. Xue et al., Nature Mat. 10, 282-285 (2011) [3] M. Bokdam et al., Nano Lett. 11, 4631-4635 (2011)

9:12AM T6.00007 Accurate effective model Hamiltonian for non-commensurate graphene on hexagonal boron nitride substrate[1] , JEIL JUNG, ZHENHUA QIAO, ALLAN MACDONALD, The University of Texas at Austin — High quality hexagonal boron nitride (h-BN) crystals have emerged as a promising substrate and barrier-material for graphene nanoelectronic devices. The influence of the h-BN substrate on graphene's electronic properties is sometimes observable, but often extremely weak. We develop a theory of the h-BN graphene interaction that is based on first-principles electron tunneling amplitudes calculated as a function of horizontal displacement between commensurate honeycomb lattices. The effective Hamiltonian we derive is valid for arbitrary rotation angles between adjacent graphene and h-BN sheets.

9:24AM T6.00008 Electronic structure of graphene-topological insulator heterostructures[1] , CHRISTOPHER TRIOLA, JUNHUA ZHANG, ENRICO ROSSI, Department of Physics, College of William and Mary — We have studied the electronic structure of heterostructures consisting of graphene in close proximity to a strong three dimensional topological insulator (3DTI). We find that in the presence of a momentum dependent tunneling the low-energy band structure of graphene is qualitatively modified due to the hybridization of the two-dimensional bands of the 3DTI surface with the bands of graphene. One of the effects of the hybridization is to effectively shift the two spin-degenerate Dirac cones of pristine graphene in opposite directions in momentum space. We also show how, by tuning separately the doping in graphene and the 3DTI surface, some of the qualitative features of the hybridized bands can be controlled.

9:36AM T6.00009 Spin textures in graphene-topological insulator heterostructures[1] , JUNHUA ZHANG, CHRISTOPHER TRIOLA, ENRICO ROSSI, Department of Physics, College of William and Mary — We study the spin texture of the bands of heterostructures formed by graphene and strong three dimensional topological insulators (3DTIs). We find that in these systems, via the proximity effect, graphene can acquire nontrivial spin textures and we identify the conditions for their realization. The presence of spin textures in the graphene layer opens the possibility to realize ideal 2D spin-selective systems with the unique properties of graphene, such as the extremely high room-temperature mobility. In addition, we find that in graphene-3DTI heterostructures some of the spin structures are characterized by the locking of the spin and valley degrees of freedom and should allow the realization of novel valley-spintronics effects.

9:48AM T6.00010 Chiral superfluid states in hybrid graphene heterostructures , ENRICO ROSSI, JUNHUA ZHANG, Department of Physics, College of William and Mary — We study the hybrid heterostructure formed by one sheet of single layer graphene (SLG) and one sheet of bilayer graphene (BLG) separated by a thin film of dielectric material. In general it is expected that interlayer interactions can drive the system to a spontaneously broken symmetry state characterized by interlayer phase coherence. The peculiarity of the SLG-BLG heterostructure is that the electrons in the layers (SLG and BLG) have different chiralities. We find that the difference of chirality between electrons in the two layers causes the spontaneously broken symmetry state to be N-fold degenerate. Moreover, we find that some of the degenerate states are chiral superfluid states, topologically distinct from the usual layer-ferromagnetism. The chiral nature of the ground state opens the possibility to realize topologically protected midgap states.

10:00AM T6.00011 Ab-initio investigation of one-dimensional graphene-silicene superlattices , LARS MATTHES, University of Jena, KARSTEN HANNEWALD, Humboldt University of Berlin, FRIEDHELM BECHSTEDT, University of Jena — Since the two-dimensional (2D) crystal graphene was rediscovered in 2004 by Geim et al. there has been a strong interest in tailoring its properties in order to achieve a broad usability in manifold applications. Furthermore, due to massless electrons appearing in graphene it is also a playground for theoretical physicists for testing basic physical theories of high energy physics in a solid state system. Recently, also a silicon based 2D honeycomb crystal, called silicene, was discovered. Due to the similar crystal structure, silicene shares many properties with graphene, e.g., massless fermions. Here we present first-principles studies of electronic and structural properties of graphene-silicene superlattices. Our investigations provide insights to the physics of heterostructures consisting of materials where both may contain massless fermions and a vanishing electronic gap around the Fermi-energy. Finally, we also discuss the importance of the 1D interface between those 2D crystals [2].

10:12AM T6.00012 Design of Ordered Graphene Oxides by First-Principles based Cluster Expansion Approach , BING HUANG, NREL, HONGJUN XIANG, NREL-Fudan, SUHUAI WEI, NREL — The inhomogeneous phase, which usually exists in graphene oxides (GOs), is a long-standing problem that has severely restricted the use of GOs in various applications. By using first-principles based cluster expansion, we find that the existence of phase separation in conventional GOs is due to the extremely strong attractive interactions of oxygen atoms at different graphene sides. Our Monte Carlo simulations show that this kind of phase separation is not avoidable under the current experimental growth temperature. In this Letter, the idea of oxidizing graphene on single-side is proposed to eliminate the strong double-side oxygen attractions, and our calculations show that well-ordered GOs could be obtained at low oxygen concentrations. These ordered GOs behave as quasi-one-dimensional narrow-gap semiconductors with quite small electron effective masses, which can be useful in high-speed electronics. Our concept could be widely applied to overcome the inhomogeneous phases in various chemically functionalized two-dimensional systems.

10:24AM T6.00013 Electronic and transport properties in graphene oxide frameworks , PAN ZHU, VINCENT MEUNIER, Rensselaer Polytechnic Institute — We report a detailed theoretical study of the electronic and transport properties of a series of graphene oxide frameworks (GOFs) using first-principles calculations based on density functional theory. The pillar molecular structure of GOFs determine that with various linear boronic acid pillars and different pillar concentrations, GOF structures can be fine tuned and exhibit various electronic properties. Based on ideal GOF structures, we predict that GOFs' electronic properties, such as band gap, can be modified controllobly by an appropriate choice of pillaring units and pillar concentration. The quantum transport properties of several systems with various linear boronic acid pillars are also evaluated. The variation of conductance arising from different pillar composition is shown to be potentially useful for practical applications.

10:36AM T6.00014 Dispersions of non-covalently functionalized graphene with minimal stabilizer , DORSA PARVIZ, SRIYA DAS, FAHMIDA IRIN, MICAH GREEN, Department of Chemical Engineering, Texas Tech University — Pyrene derivatives are promising substitutes of surfactants and polymers for stabilization of graphene in aqueous dispersions. We demonstrate that pyrene derivatives stabilize single- to few-layer graphene sheets, yielding exceptionally higher graphene/stabilizer ratio in comparison with conventional stabilizers. Parameters such as stabilizer concentration, initial graphite concentration, type and number of functional groups, counterions, the pH and the polarity of dispersion media were shown to affect the adsorption process and final graphene concentration. The effectiveness of pyrene derivatives is determined by the type, number and electronegativity of functional groups and counterion. It also depends on the distance between functional group and pyrene basal plan, the pH of the dispersion (as shown by zeta potential measurements) and the relative polarity between stabilizer and solvent. Stability of the dispersions against centrifugation, pH and temperature changes and lyophilization was investigated. These dispersions also show promise for applications to polymer nanocomposites, organic solar cells, conductive films, and inkjet-printed electronic devices.

10:48AM T6.00015 Formation of transferable transparent pristine graphene films at water/heptane interface[1] , A.J. OYER, J-M.Y. CARRILLO, S.J. WOLTORNIST, D.H. ADAMSON, A.V. DOBRYNIN, University of Connecticut — We present a method of forming one to four layer thick pristine graphene films on glass substrates. These transparent and electrically conductive films are formed from natural graphite without the use of chemical treatment. The films are initially formed at a water/heptane interface and then transferred to a glass slide. Computer simulations of the graphene sheets at water/heptane interface show that the films are metastable, kinetically trapped assemblies. To evaluate stability of the film we used the Weighted Histogram Analysis Method to calculate the potential of the mean force and the height of the local potential barrier for single sheet and double sheet assembly of the graphene at water/heptane interface. The film structure on a glass slides was analyzed by Raman spectroscopy, optical microscopy, and transmission electron microscopy. These measurements show that the films are composed of overlapping graphene sheets one to four layers thick covering approximately 80% of the substrate. These low cost films are expected to find applications in the economical replacement of current inorganic transparent conductive films.

Session T7 DMP: Focus Session: Carbon Nanotubes: Transport and Electronic Properties 303

- Phillip Collins, University of California, Riverside

8:00AM T7.00001 Electrical Transport in Graphene-Carbon nanotube Junctions , JHAO-WUN HUANG, CHENG PAN, HANG ZHANG, YONGJIN LEE, FENGLIN WANG, LEI JING, MARC BOCKRATH, CHUN NING LAU, Department of Physics and Astronomy, University of California, Riverside — We fabricate suspended graphene-carbon nanotube hybrid junctions by transferring monolayer graphene sheets onto single-walled carbon nanotubes that are synthesized by chemical vapor deposition, and etching in hydrofluoric acid. The devices are measured as a function of magnetic field, gate voltage and electric field. We will present our latest transport data that will be compared with theoretical models.

8:12AM T7.00002 Quasiparticle and exciton renormalization effects in carbon nanotubes near metallic surfaces , CATALIN SPATARU, Sandia National Labs — We study theoretically the influence of a metallic surface on electron excitations (quasiparticles and excitons) in carbon nanotubes. Long-range polarization effects are included in the calculations using many-body *ab initio* approaches such as the GW approximation [2] for the electron self-energy and the Bethe-Salpeter equation [3] for excitonic effects. In the case of semiconducting carbon nanotubes and when charge transfer effects between nanotube and metal are not important, we find that the image charge effect can lead to significant renormalization of the quasiparticle energies in nanotubes even for an apparent height (of the nanotube relative to the metallic surface) of the order of nm (in agreement with experiment [1]). The calculations reveal the important role played by the intrinsic dielectric screening properties of the nanotubes in establishing these renormalization effects. Also, we find that the optical gap of the nanotubes is barely affected by the metallic surface due to the weaker interaction between the exciton transition dipole in the nanotube and its induced image in the metallic surface.. [1] H. Lin et al, *Nature Mater.* **9**, 235 (2010). [2] M.S. Hybertsen and S.G. Louie, *Phys. Rev. B* **34**, 5390 (1986). [3] M. Rohlfing and S.G. Louie, *Phys. Rev. B* **62**, 4927 (2000).

8:24AM T7.00003 Chirality dependence of exciton diffusion in air-suspended single-walled carbon nanotubes[1] , A. ISHII, A. YOKOYAMA, M. YOSHIDA, T. SHIMADA, Y. K. KATO, The University of Tokyo — In single-walled carbon nanotubes, exciton diffusion affects the photoluminescence quantum efficiency through substrate- and defect-induced nonradiative decay of excitons, and therefore quantitative characterization of exciton diffusion is important. In the case of air-suspended nanotubes, exciton diffusion lengths can be determined by analyzing the dependence of photoluminescence intensity on nanotube length.[2] As this method requires $\sim$30 nanotubes for a particular chirality, we have constructed an automated micro-photoluminescence system to characterize air-suspended carbon nanotubes. A three-dimensional programmable stage is used to automatically locate and list the positions of bright nanotubes. Excitation wavelength, intensity, and polarization angle are automatically controlled to fully characterize these nanotubes. Using this system, measurements on hundreds of as-grown air-suspended carbon nanotubes are performed, and data from high quality individual tubes are selected to investigate the chirality dependence of exciton diffusion length.

8:36AM T7.00004 Growth Mechanism of Well Aligned Semiconducting Single-walled Carbon Nanotubes , JIE LIU, Department of Chemistry, Duke University, Durham, NC 27708, USA — Even though the devices made from individual nanotubes have shown outstanding performances such as high mobility, high current, high thermal conductivity, good chemical and mechanical stability, the high hope for the next generation of carbon nanotube based electronics is hampered by several major problems. Among them are the lack of reliable methods to control the alignment and position of nanotubes as well as and perhaps most problematically, the simultaneous growth of nanotubes with different chiralities, yielding random mixtures of metallic and semiconducting nanotubes. Even though the post-growth separation of metallic from semiconducting SWNTs have made good progress, the alignment and assembly of the separated nanotubes into devices are still challenging and not suitable for large scale fabrication. Consequently, a method that can directly produce well aligned arrays of pure semiconducting nanotubes is thought to be the ideal choice for large scale fabrication of nanotubes FETs. In this talk, we show that such a method is not a dream. Recently we have successfully synthesized high-density, horizontally aligned SWNTs on quartz wafers, and the thin-film transistors (TFTs) based on this SWNT array show high on-driving current density (up to $\sim$220 μA/μm). Additionally, through systematic studies, we proposed and confirmed the high growth selectivity originates from the etching effect and chemical reactivity difference of metallic and semiconducting nanotubes. Three important rules were summarized for achieving a high selectivity in growing semiconducting nanotubes by systematically investigating the relationship among water concentration, carbon feeding rate and the percentage of semiconducting nanotubes in the produced SWNT arrays. Furthermore, these three rules can also be applied to the growth of random SWNT networks on silicon wafers. This understanding will help us to develop better method to solve the most difficult problem which limited applications of carbon nanotubes in nanoelectronics the coexistence of metallic and semiconducting nanotubes in samples produced by most, if not all, growth methods. Based on these results, the alignment and density will no longer be the bottlenecks for the surface growth of SWNTs anymore.

9:12AM T7.00005 Exciton diffusion in semiconducting single-wall carbon nanotubes studied by transient absorption microscopy , BRIAN RUZICKA, RUI WANG, Department of Physics and Astronomy, University of Kansas, JESSICA LOHRMAN, SHENQIANG REN, Department of Chemistry, University of Kansas, HUI ZHAO, Department of Physics and Astronomy, University of Kansas — We report a spatially resolved transient absorption study of exciton diffusion in a thin films of isolated semiconducting single-wall carbon nanotubes. Spatiotemporal dynamics of excitons injected by a tightly focused pump pulse are studied by measuring differential reflection and differential transmission of a time-delayed and spatially scanned probe pulse. We observe a bi-exponentially decaying signal with a fast time constant of 0.66 ps and a slower time constant of 2.8 ps. Both constants are independent of the pump fluence. The squared width of the exciton density profile increases linearly with time, as expected for a diffusion process. We measured a diffusion coefficient of 200 $\pm$ 10 cm^2/s at room temperature, which is independent of the pump fluence. We additionally investigated the diffusion coefficient at temperatures of 10 and 150 K and found diffusion coefficients of approximately 300 $\pm$ 10 cm^2/s at both.

9:24AM T7.00006 Intrinsic and Extrinsic Exciton Decay in HIPCO and COMOCAT Carbon Nanotubes , JEREMY ALLAM, TARIQ SAJJAD, ZHONGYANG WANG, SOFIA SIDDIQUE, KONSTANTIN LITVINENKO, ANTONY MORETTI, University of Surrey, DIRK MERSCH, IZABELLA JUREWICZ, University of Surrey, ALAN DALTON, University of Surrey — The luminescence efficiency of semiconducting carbon nanotubes is limited by non-radiative decay of the exciton population. A wide range of quasiexponential and power law decays with different exponents has been reported, and attributed to exciton trapping at defects and exciton-exciton annihilation. The role of diffusion has been controversial and reported diffusion coefficients for carbon nanotubes differ by several orders of magnitude. Here we investigate diffusion-assisted trapping and annihilation processes in HiPco and CoMoCat carbon nanotubes with different defect concentrations. At low excitation, the HiPco nanotubes show quasi-exponential trapping, however at high excitation the population follows a diffusion-limited power law. We attribute this to filling of saturable traps under strong excitation, as demonstrated in Monte Carlo simulations, and at the highest excitation levels the intrinsic behaviour is revealed with distinct regions where decay is limited either by the reaction rate or by Fickian diffusion. In the CoMoCat nanotubes, the same regimes are observed but the diffusion-limited exponent is reduced from -0.5 to -0.3 indicating sub-diffusive transport. We show that this is consistent with a moderate population of shallow traps.

9:36AM T7.00007 Quantum dot in semiconducting single walled carbon nanotube on thin hexagonal boron nitride , ZHENGYI ZHANG, AREND VAN DER SANDE, Department of Mechanical Engineering,Columbia University, MIT-SUHIDE TAKEKOSHI, Department of Physics,Columbia University, XIAO GUO, Department of Mechanical Engineering, Columbia University, PHILIP KIM, Department of Physics,Columbia University, JAMES HONE, Department of Mechanical Engineering, Columbia University — Carbon nanotube(CNT) is one of the best available systems to study the one dimensional physics. However, so far most of the studies are based on the devices made of CNT on SiO_2/Si substrate, which introduces a large amount of trapped charges causing the spatial variation of the Fermi energy of CNT. It separates CNT into multiple islands preventing its formation of single, well defined quantum dot. Recently it is found that suspended metallic nanotube shows 100meV band gap, 20 times compared with the one on SiO_2/Si substrate, which also suggests the trapped charges can obscure many intrinsic properties of CNTs. In this study, we perform the transport measurements of ultra-clean semiconducting CNT transferred on to 5nm thick of hexagonal boron nitride(h-BN) with 10nm thick graphite as back gate. At room temperature, it shows nearly hysteresis free low bias transport. And a clear coulomb blockade feature is observed at 2K in vacuum, which was only obtained in clean suspended nanotubes before. These all suggest that h-BN is an ultraclean and uniform substrate for study of the intrinsic nature of CNT.

9:48AM T7.00008 Poole-Frenkel emission by carbon nanotube defect sites , DENG PAN, ELLIOT J. FULLER, BRAD L. CORSO, OSMAN GUL, PHILIP G. COLLINS, University of California Irvine — Single walled carbon nanotubes (SWCNTs) have a conductance that is particularly sensitive to the presence of defects and disorder. Here, we combine three-terminal transport measurements with Kelvin Probe Force Microscopy (KPFM) to investigate the electronic transmission of individual SWCNT defects. A unique strength of the work is the ability to fully characterize each SWCNT before and after the chemical addition of a particular defect. In transport, the additional resistance caused by a defect is studied as a function of bias, backgate and temperature. KPFM, on the other hand, directly images the spatial, bias-dependent voltage drop in the vicinity of the defect. The two types of measurement agree remarkably well and are consistent with a Poole-Frenkel emission model, in which a shallow trap state has a gate-dependent depth and width. The effective width of a defect trap is determined to be remarkably large and gate dependent, ranging from 400 to 1400 nm. The value might seem unphysical, if not for the fact that KPFM spatially resolves this potential drop and its gradient. Evidently, the SWCNT's very small carrier density and screening lengths lead to anomalously wide effective barriers, helping to explain the extreme sensitivity of SWCNTs to point defects.

10:00AM T7.00009 Impact of charged impurity scattering in carbon nanotubes , RYUICHI TSUCHIKAWA, JONATHAN EDMISTON, DANIEL HELIGMAN, MASAHIRO ISHIGAMI, Department of Physics and Nanoscience Technology Center, University of Central Florida, XIAO GUO, ZHENGYI ZHANG, JAMES HONE, Department of Mechanical Engineering, Columbia University — We have measured the transport property of carbon nanotubes as a function of density of charged impurities. Length-dependent resistance measurements were used to eliminate the contribution from the contact resistance in our data. By knowing the exact density of charged impurities on nanotubes, we measure the scattering cross section of individual adsorbed charge impurity. Measurements on different nanotubes are used to reveal the effect of pseudospin conservation on electronic transport in metallic and semiconducting carbon nanotubes upon addition of long-range impurities experimentally. These findings will be outlined in this talk.

10:12AM T7.00010 Photon Statistics of Single Carbon Nanotubes at Room Temperature , XUEDAN MA, JUAN DUQUE, JARED CROCHET, BENJAMIN MANGUM, STEPHEN DOORN, HAN HTOON, Los Alamos National Laboratory — Different from zero-dimensional systems such as atoms, molecules, and quantum dots, semiconducting single-walled carbon nanotubes (SWNTs) are ideal one-dimensional systems that allow free diffusion of excitons along their length. Studies have also shown that multiple excitons exist within the diffusion length can annihilate via Auger process. Interplay of Auger process and exciton diffusion therefore could have interesting effects on photon emission statistics of SWNTs. Current existing studies [1] on photon emission statistics were conducted at low temperature where excitons were localized to quantum-dot-like states. To this end we conduct room temperature 2^{nd} order photon correlation spectroscopy studies on high quality SWNTs capable of emitting continuous photoluminescence along their length which could extend up to several micrometers. We observed the degree of photon-bunching lower than 0.5 at the lowest pumping powers. We will also present a correlation between the diffusion length and the degree of photon-bunching. Our study could have implications toward utilizing SWNTs as room temperature single photon sources.

10:24AM T7.00011 Optical Behaviors of Single-Wall Carbon Nanotubes in Complex Environments , JUAN G. DUQUE, JARED CROCHET, Los Alamos National Laboratory, BRAHIM LOUNIS, LAURENT COGNET, Bordeaux University, STEPHEN DOORN, Los Alamos National Laboratory — The optical properties of single-walled carbon nanotubes (SWNTs) offer great promises. However, the realization of their potential is limited by degree of interactions with their immediate surroundings. Here, we present an innovative approach to control and manipulate the intrinsic optical properties of SWNTs to develop optical sensors as a direct or indirect means to measure physical changes and convert such a response to a signal. We probe the mechanism of photoluminescence brightening via surfactant restructuring using time-resolved PL measurements and show an original way to visualize complex fluid behaviors controlling the intrinsic optical properties of SWNTs.

10:36AM T7.00012 Optical coupling of air-suspended carbon nanotubes to silicon microdisk resonators[1] , S. IMAMURA, R. WATAHIKI, R. MIURA, T. SHIMADA, Y.K. KATO, The University of Tokyo — Optical coupling of individual air-suspended single-walled carbon nanotubes to whispering-gallery modes in silicon microdisk resonators is studied. We fabricate silicon microdisks with diameters of $\sim$3 μm on SiO_2 supporting posts from silicon-on-insulator substrates, and synthesize carbon nanotubes from patterned catalysts by alcohol chemical vapor deposition to suspend them onto the microdisks. Interactions between carbon nanotubes and evanescent fields of microdisk modes are investigated by microspectroscopy at room temperature. We observe microdisk modes with quality factors of $\sim$3000 at wavelengths longer than those of silicon emission, even at positions that are a few micrometers from the suspended carbon nanotubes. In addition, as microdisk modes also exist at excitation laser wavelengths, the photoluminescence intensity can be resonantly enhanced by tuning the laser wavelength to those modes.

10:48AM T7.00013 Effects of longitudinal electric fields on carbon nanotube photoluminescence[1] , Y. KUMAMOTO, M. YOSHIDA, A. YOKOYAMA, S. YASUKOCHI, Y. K. KATO, The University of Tokyo — We investigate modulation of single-walled carbon nanotube photoluminescence with electric fields along the tube axis by using field-effect transistor structures. The nanotubes are synthesized with chemical vapor deposition, and measurements are performed on as-grown tubes suspended over trenches formed between source and drain electrodes. As gate-voltage induced carrier doping causes peak shifts and quenching of photoluminescence,[2] care must be taken to identify the effects of longitudinal electric fields. In order to suppress the doping effects at the center of the nanotubes, we apply symmetric bias voltages between source and drain while keeping the gate at zero voltage. In addition, we use Si substrates with 1-μm thick oxide layer to reduce the gate effects at the ends of the nanotubes. After identification of individual nanotubes by photoluminescence imaging and excitation spectroscopy, we collect luminescence spectra as a function of bias voltage. As the bias is increased, we observe moderate reduction of emission intensity whose voltage dependence cannot be accounted for by gate-induced quenching. Furthermore, broadening of nanotube emission peak with increasing bias voltage is also observed.

Session T8 DMP: Carbon Nanostructures: Transport and Optical Phenomena 307 - Lilia Woods, University of South Florida

8:00AM T8.00001 Dynamic Negative Compressibility of Few-Layer Graphene, h-BN, and MoS_2[1] , BERNARDO NEVES, ANA PAULA BARBOZA, HELIO CHACHAM, CAMILLA OLIVEIRA, THALES FERNANDES, Universidade Federal de Minas Gerais, ERLON MARTINS FERREIRA, BRAULIO ARCHANJO, Instituto Nacional de Metrologia, RONALDO BATISTA, ALAN OLIVEIRA, Universidade Federal de Ouro Preto — We report a novel mechanical response of few-layer graphene, h-BN, and MoS2 to the simultaneous compression and shear by an atomic force microscope (AFM) tip. The response is characterized by the vertical expansion of these two-dimensional (2D) layered materials upon compression. Such effect is proportional to the applied load, leading to vertical strain values (opposite to the applied force) of up to 150%. The effect is null in the absence of shear, increases with tip velocity, and is anisotropic. It also has similar magnitudes in these solid lubricant materials (few-layer graphene, h-BN, and MoS2), but it is absent in single-layer graphene and in few-layer mica and Bi2Se3. We propose a physical mechanism for the effect where the combined compressive and shear stresses from the tip induce dynamical wrinkling on the upper material layers, leading to the observed flake thickening. The new effect (and, therefore, the proposed wrinkling) is reversible in the three materials where it is observed.[2]

8:12AM T8.00002 Scaling of Non-Saturating Magnetoresistance in HOPG , NICHOLAS CORNELL, MYRON SALAMON, ANVAR ZAKHIDOV, The University of Texas at Dallas — There have been many various resistive and field dependent behaviors observed in Highly Oriented Pyrolytic Graphite (HOPG). We found HOPG samples to vary significatly in their temperature dependent resistances, even between portions of the same sample. All samples exhibit non-saturating magnetoresistance (MR) and, at low temperatures, Shubnikov-de Haas (SdH) oscillations. These oscillations give rise to a mobility $\mu = 1.2$ T^{-1} at 5 K. The MR follows a scaling behavior that is predicted by a model based on the Hall effect in granular materials and that predicts a crossover to linear behavior with a characteristic field H_0 on the order of μ^{-1}, or 0.8 T, in agreement with experiment. Data at higher temperatures can be collapsed to a single curve if $H_0(T)$ increases linearly with temperature. Analysis of the SdH data gives a 2D carrier density in agreement with previous results, and a large mean-free path relative to crystallite size.

8:24AM T8.00003 Mechanical and Electrostatic Properties of Freestanding Graphene Functionalized With Tin Oxide (SnO_2)[1] , MATTHEW ACKERMAN, PENG XU, STEVEN BARBER, KEVIN SCHOELZ, DEJUN QI, PAUL THIBADO, University of Arkansas, LIFENG DONG, JAMES HANSEN, Missouri State University — Polymer/graphene blends have shown promise for building inexpensive and efficient heterojunction solar cells. It has been shown that efficiencies can be enhanced if the graphene membrane is functionalized by n-type inorganic nanocrystals, but it has proved difficult to directly chemically modify graphene. In this talk we present for the first time a two-step solution based technique which directly and uniformly deposits SnO_2 nanoparticles onto a graphene membrane. Films are characterized using X-ray energy dispersive spectrometry (EDS) and field emission scanning electron microscopy (FESEM) to determine elemental composition and density of coverage. A novel technique known as electrostatic manipulation scanning tunneling microscopy (EM-STM) is employed to characterize the affect of the nanoparticles on the mechanical and electrostatic properties of the functionalized graphene relative to pristine membranes. Evidence is presented that during the deposition stage graphene wraps around and encapsulates the nanoparticles.

8:36AM T8.00004 Can graphene allotropes surpass the high thermal conductivity of graphene?[1] , ZACHARIAS FTHENAKIS, ZHEN ZHU, DAVID TOMÁNEK, Michigan State University — Searching for materials with very high thermal conductivity, we explore the possibility that specific carbon allotropes may even surpass the high thermal conductivity of graphene and carbon nanotubes. We focus our study on graphene allotropes including 5-7 or 5-5-8 haeckelites with planar structure and sp^2 graphitic bonding. In contrast to graphene, these anisotropic systems should also conduct heat differently in different directions. Our computational studies use non-equilibrium molecular dynamics simulations based on the valence-bond force field parameterized by Tersoff and a Nose-Hoover thermostat to regulate the temperature. Whereas thermal conductivity of most haeckelite systems is reduced by an order of magnitude in comparison to graphene due to a lower phonon mean-free path, there is a distinct possibility that the isotropic thermal conductivity of graphene may be surpassed at least along particular directions in specific artificial haeckelite superstructures.

8:48AM T8.00005 Radiative heat transfer in low-dimensional systems – microscopic mode[1] , LILIA WOODS, ANH PHAN, DAVID DROSDOFF, Department of Physics, University of South Florida, Tampa, Florida 33620, USA — Radiative heat transfer between objects can increase dramatically at sub-wavelength scales. Exploring ways to modulate such transport between nano-systems is a key issue from fundamental and applied points of view. We advance the theoretical understanding of radiative heat transfer between nano-objects by introducing a microscopic model, which takes into account the individual atoms and their atomic polarizabilities. This approach is especially useful to investigate nano-objects with various geometries and give a detailed description of the heat transfer distribution. We employ this model to study the heat exchange in graphene nanoribbon/substrate systems. Our results for the distance separations, substrates, and presence of extended or localized defects enable making predictions for tailoring the radiative heat transfer at the nanoscale.

9:00AM T8.00006 Van der Waals/Casimir interactions in graphene nanoribbons , DAVID DROSDOFF, LILIA WOODS, University of South Florida — The isolation of graphitic nanostructures and their potential applications for novel devices have spurred new interest in the properties of low dimensionality systems. One important interaction in the sub-micron scale is the van der Waals/Casimir force. The general Casimir force between two planes in terms of the dielectric response of the materials was originally formulated by Lifshitz, which was subsequently generalized to two dimensional systems. In this talk, the formulation of the non-retarded dispersive force in terms of the dielectric response functions for quasi-one dimensional systems will be discussed. Results from the application of the developed theory to the interaction between graphene nanoribbons will be presented.

9:12AM T8.00007 Prediction of ultra-high ON/OFF ratio nanoelectromechanical switches from covalently bound C60 chains: An ab initio study[1] , HAN SEUL KIM, YONG-HOON KIM, KAIST Graduate School of EEWS — Applying a first-principles computational approach combining density-functional theory and matrix Green's function calculations, we analyze the microscopic origin of the switching behavior experimentally observed for the fullerene C_{60} chains oligomerized via [2+2] cycloaddition and propose a scheme to significantly improve the device performance. Considering infinite C_{60} chains, we first confirm that bound C_{60} chains with significant orbital hybridizations and band formation should in principle induce a higher conductance state. However, we find that large metal-C_{60} distances adopted in the scanning tunneling microscope (STM) setup can result in the experimentally observed opposite switching state assignment. The switching ordering and ratio is in fact found to sensitively depend on the STM tip metal species and the associated band bending direction in the C_{60}–STM tip vacuum gap. We demonstrate that a junction configuration in which the C_{60}–STM tip distance is maintained at short distances via nanoelectromechanical tip movement can achieve a metal-independent and drastically improved switching performance based on the intrinsically better electronic connectivity in the oligomerized C_{60} chains.

9:24AM T8.00008 Infrared magneto-optical Kerr and Faraday measurements of carbon nano-onions , M. MURAT ARIK, C.T. ELLIS, ALOK MUKHERJEE, JOHN CERNE, Department of Physics, University at Buffalo, SUNY, A. MOLINA ONTORIA, L. ECHEGOYEN, Department of Chemistry, University of Texas at El Paso, M.N. CHAUR, Departamento de Química Universidad del Valle, Cali (Colombia) — Carbon nano-onions (CNOs) are multilayer fullerenes in the form of concentric spherical graphene shells with diameters on the order of 10 nm. Angular resolved photoemission spectroscopy [1] has shown that the electronic structure of CNOs is more similar to graphite nanocrystals than fullerene molecules. Previously, we have observed rich Landau level structure in planar multilayer graphene using infrared Kerr and Faraday measurements [2], and now apply these techniques to CNOs. We report infrared (100-1000 meV) Faraday and Kerr measurements on CNOs at temperatures down to 10K and magnetic fields up to 7T. These infrared polarization-sensitive magneto-optical measurements allows us to study confinement effects in Dirac and bilayer quasiparticles, interlayer coupling among neighboring graphene shells, as well as inter-CNO coupling between neighboring CNOs. This work is supported by NSF-DMR1006078.

9:36AM T8.00009 The Aharonov-Bohm effect in Möbius rings[1] , ZEHAO LI, L. RAMDAS RAM-MOHAN, Worcester Polytechnic Institute, CENTER FOR COMPUTATIONAL NANOSCIENCE TEAM — Electron transmission through finite-width 2D ring structures is calculated for cylindrical, flat (Aharonov-Bohm), and Möbius rings. In the presence of an external magnetic field, curves of constructive transmission display a pattern similar to that for a 1D ring. The periodicity in the magnetic flux, in units of h/e, is weakly broken on 2D rings of finite width, so that a description with a 1D-path is very acceptable. The unusual states with half-integer values of $\langle L_z \rangle$ observed on Möbius rings, display a different characteristic in transmission. Such resonant states are in constructive interference for transmission at magnetic fields where the contribution from ordinary states with integer $\langle L_z \rangle$ is in destructive interference, and vice versa. This leads to an alternating dominance of the set of half-integer $\langle L_z \rangle$ states and the set of integer $\langle L_z \rangle$ states in transport with increasing magnetic fields. We anticipate that Möbius rings would be synthesized with graphene ribbons in the near future.

9:48AM T8.00010 Electron Transport in Solvated Porous Nanocarbons , ARTEM BASKIN, PETR KRAL, University of Illinois at Chicago — We study electron transport in porous nanocarbons (PNCs) in vacuum, gases, and ionic solutions. Using state of the art electronic structure methods and nonequilibrium Green's functions techniques, we explore the band structures [1] and the current-voltage characteristics of PNCs with different sizes, shapes, positioning and functionalization of pores, edges, and types of electrodes. We find that the presence of ions and molecules around PNCs can largely influence their electron transmissivity. Therefore, PNCs could be used for highly sensitive detection of ions and polar molecules passing around them. [1] A. Baskin and P. Kral, Electronic Structures of Porous Nanocarbons, Sci. Rep. 1, 36 (2011).

10:00AM T8.00011 Exciton Spectra of Two-Dimensional Semiconducting Carbon Structures , SHOUTING HUANG, YUFENG LIANG, LI YANG, Department of Physics, Washington University in St. Louis — We employ the first-principles GW-Bethe-Salpeter Equation (BSE) approach to study excitonic effects on optical absorption spectra of several newly discovered two-dimensional (2D) semiconducting carbon structures. Unique exciton spectra are observed, in which the order of exciton energies and degeneracies are qualitatively different from those of bulk semiconductors. We propose a modified hydrogen-like model that clearly explains their exciton spectra. Our modeling effort gives rise to a convenient way to understand excitonic spectra and estimate the exciton binding energy of 2D semiconductors.

10:12AM T8.00012 First-Principles Studies of the Vibrational Stark Effect in C60 , PETER DOAK, Department of Chemistry, UC-Berkeley, Molecular Foundry, LBNL, YAJING LI, DOUGLAS NATELSON, Department of Physics and Astronomy, Rice University, LEEOR KRONIK, Department of Materials and Interfaces, Weizmann Institute of Science, JEFFREY NEATON, Molecular Foundry, LBNL — C60 has played a central role in molecular and organic electronics, where coupling between charge and vibrational degrees of freedom is of paramount importance. Recent surface-enhanced Raman scattering (SERS) studies of C60-Au junctions have reported significant shifts in vibrational mode frequencies with applied bias. Here we compute the magnitude of the vibrational Stark effect in gas-phase C60 and seek to understand and simulate the shifts in Raman mode frequencies observed in these electromigration junction-SERS experiments. Using density functional theory and a finite-difference approach, we calculate trends in the vibrational Stark effect for different modes of gas-phase C60, comparing directly to experiment and assessing the role of substrate-induced charging and external electric fields. This work supported by DOE and computational resources provided by NERSC.

10:24AM T8.00013 Anomalous response of supported few-layer hexagonal boron nitride to DC electric fields: a confined water effect?[1] , CAMILLA OLIVEIRA, MATHEUS MATOS, MÁRIO MAZZONI, HÉLIO CHACHAM, BERNARDO NEVES, Universidade Federal de Minas Gerais-UFMG — Hexagonal boron nitride (h-BN) is a two-dimensional compound from III-V family, with the atoms of boron and nitrogen arranged in a honeycomb lattice, similar to graphene. Unlike graphene though, h-BN is an insulator material, with a gap larger than 5 eV. Here, we use Electric Force Microscopy (EFM) to study the electrical response of mono and few-layers of h-BN to an electric field applied by the EFM tip. Our results show an anomalous behavior in the dielectric response for h-BN for different bias orientation: for a positive bias applied to the tip, h-BN layers respond with a larger dielectric constant than the dielectric constant of the silicon dioxide substrate; while for a negative bias, the h-BN dielectric constant is smaller than the dielectric constant of the substrate. Based on first-principles calculations, we showed that this anomalous response may be interpreted as a macroscopic consequence of confinement of a thin water layer between h-BN and substrate. These results were confirmed by sample annealing and also also by a comparative analysis with h-BN on a non-polar substrate.

10:36AM T8.00014 Electronic band structure and phonons in V2O5 , CHURNA BHANDARI, WALTER R.L. LAMBRECHT, CWRU — Among the vanadium oxides, V_2O_5 presents special interest as a layered material. As for other layered materials, it is of interest to search for changes in its electronic structure and phonon spectrum in the monolayer modification of this material. For example, reduced screening may modify phonon modes affected by long-range Coulomb interactions. As a preliminary we here present a first-principles study of the bulk electronic band structure and the phonons at the Γ-point. Density functional calculations in the local density approximation were carried out for the electronic band structure and the density functional perturbation method was used for the phonon calculations. We used LDA and norm-conserving pseudopotentials in the abinit code. A group theoretical analysis is used to label the phonon modes. Non-analyticity is included for the LO modes. The band structures are in good agreement with previous work and yield an indirect band gap. Relaxed structural properties are also in good agreement with experiment. Simulated infrared and Raman spectra will be presented. Our results will be compared with experimental and previous theoretical work.

10:48AM T8.00015 Calculation of the optical properties of the nitrogen-vacancy center in diamond , DENIS ANTONOV, Max-Planck-Institut für Festkörperforschung, Heisenbergstraße 1, 70569 Stuttgart, Germany, JÖRG WRACHTRUP, 3rd Institute of Physics, University of Stuttgart, Pfaffenwaldring 57, D-70550 Stuttgart, Germany, GABRIEL BESTER, Max-Planck-Institut für Festkörperforschung, Heisenbergstraße 1, 70569 Stuttgart, Germany — We calculate the optical properties of extended and nanoscale diamond structures with embedded nitrogen-vacancy centers (NV). In particular, the negatively charged NV^- center is a promising candidate for the manipulation of quantum states, quantum processing [1] and high resolution magnetometry [2]. For these applications a precise prediction and understanding of the optical properties of NV^- centers and of coupled NV^- centers, which are less than 10 nm apart, is required. For this task, we derive spin-polarized atomic effective pseudopotentials (AEPs [3]), which deliver results with DFT quality, but allow us to treat the large number of atoms required for the calculation of coupled NV centers. The ensuing wave functions are used in a configuration interaction approach to obtain the correlated excitonic spectra. Our results for the single defect centers are in good agreement with earlier theoretical reports [4]. The experimental zero phonon line (ZPL) and the band gap of the diamond system were reproduced with an error of 0.5%. [1] Bermudez et al., Phys. Rev. Lett. **107**, 150503 (2011) [2] Zhao et al., Nature Nanotechnology **7**,657-662 (2012) [3] J. R. Cárdenas and G. Bester, Phys. Rev. B **86**, 115332 (2012) [4] Gali et al., Phys. Rev. B

Thursday, March 21, 2013 8:00AM - 11:00AM –

Session T9 DAMOP: Invited Session: Thermalization and Non-Equilibrium Dynamics in Isolated Quantum Systems 308 - Marcos Rigol, Georgetown University

8:00AM T9.00001 Non-Equilibrium Thermodynamic Relations in Driven Systems , ANATOLI POLKOVNIKOV, Boston University — In this talk I will review some recent results on non-equilibrium thermodynamic relations, which follow from combining unitary dynamics with the Eigenstate thermalization hypothesis. In particular, I will mention fluctuation theorems, general properties of energy and entropy production in driven systems (both open and thermally isolated), and fundamental limitations on efficiency of non-equilibrium heat engines.

8:36AM T9.00002 Quantum dynamics of a single, mobile spin impurity , STEFAN KUHR, University of Strathclyde, Glasgow — Quantum magnetism describes the properties of many materials such as transition metal oxides and cuprate superconductors. One of its elementary processes is the propagation of spin excitations. Here we study the quantum dynamics of a deterministically created spin-impurity atom, as it propagates in a one-dimensional lattice system. We probe the full spatial probability distribution of the impurity at different times using single-site-resolved imaging of bosonic atoms in an optical lattice. In the Mott-insulating regime, a post-selection of the data allows to reduce the effect of temperature, giving access to a space- and time-resolved measurement of the quantum-coherent propagation of a magnetic excitation in the Heisenberg model. Extending the study to the bath's superfluid regime, we determine quantitatively how the bath strongly affects the motion of the impurity. The experimental data shows a remarkable agreement with theoretical predictions allowing us to determine the effect of temperature on the coherence and velocity of impurity motion. Our results pave the way for a new approach to study quantum magnetism, mobile impurities in quantum fluids, and polarons in lattice systems.

9:12AM T9.00003 Dynamics and description after relaxation of disordered quantum systems after a sudden quench , EHSAN KHATAMI, University of California, Santa Cruz / Georgetown University — After a sudden quench, the dynamics and thermalization of isolated quantum systems are topics that have generated increasing attention in recent years. This is in part motivated be the desire of gaining a deeper understanding of how statistical behavior emerges out of the unitary evolution in isolated quantum systems and in part by novel experiments with ultracold gases. Several studies have found that while unitary dynamics in generic systems lead to thermal behavior of observables after relaxation, the same is not true for integrable systems. The latter need to be described using generalized ensembles, which take into account the existence of relevant sets of conserved quantities. In this talk, we discuss how delocalization-to-localization transitions in integrable and non-integrable disordered quantum systems change the picture above. We find that the relaxation dynamics, whenever relaxation takes place, is close to power law in those systems. In addition, statistical mechanics descriptions break down in the localized regimes. We discuss how this relates to the failure of eigenstate thermalization in the presence of localization.

9:48AM T9.00004 Conduction properties of strongly interacting Fermions , JEAN-PHILIPPE BRANTUT, ETH Zürich — We experimentally study the transport process of ultracold fermionic atoms through a mesoscopic, quasi two-dimensional channel connecting macroscopic reservoirs. By observing the current response to a bias applied between the reservoirs, we directly access the resistance of the channel in a manner analogous to a solid state conduction measurement. The resistance is further controlled by a gate potential reducing the atomic density in the channel, like in a field effect transistor. In this setup, we study the flow of a strongly interacting Fermi gas, and observe a striking drop of resistance with increasing density in the channel, as expected at the onset of superfluidity. We relate the transport properties to the in-situ evolution of the thermodynamic potential, providing a model independant thermodynamic scale. The resistance is compared to that of an ideal Fermi gas in the same geometry, which shows an order of magnitude larger resistance, originating from the contact resistance between the channel and the reservoirs. The extension of this study to a channel containing a tunable disorder is briefly outlined.

10:24AM T9.00005 Analytical methods for studying quantum quenches in integrable models , FABIAN ESSLER, Oxford University — I consider the non-equilibrium time evolution in integrable models after a quantum quench. For the case of a magnetic field quench in the transverse field Ising chain I present detailed results for the time evolution of local observables, which are shown to relax to a generalised Gibbs ensemble (GGE) [2] at late times. More generally, the reduced density matrix of a subsystem is shown to relax to a GGE in a power-law fashion in time. Dynamical response functions are studied as a function of the time after the quench and are shown to approach values given by the GGE as well. Finally generalizations to the sine-Gordon model [3] are discussed.

Thursday, March 21, 2013 8:00AM - 11:00AM –

Session T10 GQI DCMP: Invited Session: Superconducting Qubits 309 - Matthias Steffen, IBM

8:00AM T10.00001 A strand of a surface code fabric with superconducting qubits[1] , JERRY CHOW, IBM T.J. Watson Research Center — Quantum error correction will be a necessary component towards realizing scalable quantum computers with physical qubits. Theoretically, it is possible to perform arbitrarily long computations so long as the error rate is below a threshold value. The two-dimensional surface code permits relatively high fault-tolerant thresholds at the $\sim 1\%$ level, and only requires a latticed network of qubits with nearest-neighbor interactions. I will discuss our implementation of a sub-section of the larger fabric using three transmon qubits and two linking microwave resonators. We demonstrate high-fidelity control over the sub-section surface code strand, verified via quantum prcoess tomography and randomized benchmarking experiments. Our fixed-frequency qubit approach relies on the two-qubit cross-resonance microwave driving interaction, which is now one of many microwave-based entangling gate protocols. I will also discuss the prospects to scale to surface code plaquette level experiments.

[1]We acknowledge support from IARPA under contract W911NF-10-1-0324

8:36AM T10.00002 Recent progress of the fluxonium qubit[1] , MICHEL DEVORET, Applied Physics Department, Yale University — Superconducting artificial atoms are all based on the purely dispersive non-linearity of a Josephson tunnel junction, which provides anharmonicity for a microwave oscillator mode. In the fluxonium qubit [1], the microwave oscillator crucially involves a superinductor, built with a linear array of several tens of "large" Josephson junctions. As the flux threading the loop formed by the superinductor and the tunnel junction is swept from zero to half a flux quantum, the g-e transition frequency varies between a sweet spot around 10GHz and another sweet spot at a few hundreds of MHz. By optimizing the fabrication and parameters of this superinductor [2], we have eliminated spurious phase slips through the array, and ensured that its self-resonance frequency lies above the frequency of the qubit. The improved relaxation times of this multi-junction circuit are promising for the design of a novel mesoscopic artificial atom, in which large anharmonicity, long coherence times and fast coupling rate to a cavity bus would all be compatible.

9:12AM T10.00003 Are materials good enough for a superconducting quantum computer? , JOHN MARTINIS, UC Santa Barbara — Recent developments of surface codes now place superconducting quantum computing at an important crossroad, where "proof of concept" experiments involving small numbers of qubits can be transitioned to more challenging and systematic approaches that could actually lead to building a quantum computer. Although the integrated circuit nature of these qubits helps with the design of a complex architecture and control system, it also presents a serious challenge for coherence since the quantum wavefunctions are in contact with a variety of materials defects. I will review both logic gate design and recent developments in coherence in superconducting qubits, and argue that state-of-the-art devices are now near the fault tolerant threshold. Future progress looks promising for fidelity ten times better than threshold, as needed for scalable quantum error correction and computation.

9:48AM T10.00004 Overhead considerations of surface codes , AUSTIN FOWLER, The University of Melbourne — How big would a commercially relevant superconducting quantum computer making use of the surface code need to be? What is the simplest experiment required to conclusively demonstrate that arbitrarily reliable quantum computation is technologically feasible? In this talk, we discuss the current state-of-the-art of the surface code and answer these two questions according to the latest available results. We describe ongoing research to bring down the overhead associated with quantum computation.

10:24AM T10.00005 Scaling up with superconducting qubits , ALEXANDRE BLAIS, Universite de Sherbrooke — There have been significant developments in the field of superconducting qubits since the first observation, almost 15 years ago, of coherent oscillations in a superconducting electrical circuit. One key number could summarize this progress: the coherence time. Indeed, this quantity has increased by about 5 orders of magnitude since the first experiments. Characterizing this progress with a single number is, however, too simplistic. It does not capture the many improvements that the field has witnessed and, in the same way, hides many of the challenges that lie ahead. Indeed, with many ingredients having to come together and work just right, quantum computation is about more than long coherence times. A much better (yet incomplete) measure is the error rate of single- and two-qubit logical gates. Recent experiments show this rate approaching the level required for fault-tolerant quantum computation, a requirement for a scalable quantum computer architecture. In parallel, much effort has been invested in using superconducting qubits as artificial atoms to explore quantum optics with microwaves and in unconventional parameter ranges. With an emphasis on theoretical work, in this talk I will present an overview of the recent achievements in the field and present some challenges that will have to be overcome.

Session T11 DPOLY DBIO: Invited Session: Self-Assembly, Physical Properties and Functionalities of Amyloid Fibrils 310 - Raffaele Mezzenga, ETH-Zurich

8:00AM T11.00001 Folding and mis-folding of proteins , CHRISTOPHER DOBSON, University of Cambridge, UK — No abstract available.

8:36AM T11.00002 Molecular Self-Assembly of Short Aromatic Peptides: From Biology to Nanotechnology and Material Science , EHUD GAZIT, Tel Aviv University — The formation of ordered amyloid fibrils is the hallmark of several diseases of unrelated origin. In spite of grave clinical consequence, the mechanism of amyloid formation is not fully understood. We have suggested, based on experimental and bioinformatic analysis, that aromatic interactions may provide energetic contribution as well as order and directionality in the molecular-recognition and self-association processes that lead to the formation of these assemblies. This is in line with the well-known central role of aromatic-stacking interactions in self-assembly processes. Our works on the mechanism of aromatic peptide self-assembly, lead to the discovery that the diphenylalanine recognition motif self-assembles into peptide nanotubes with a remarkable persistence length. Other aromatic homodipeptides could self-assemble in nano-spheres, nano-plates, nano-fibrils and hydrogels with nano-scale order. We demonstrated that the peptide nanostructures have unique chemical, physical and mechanical properties including ultra-rigidity as aramides, semi-conductive, piezoelectric and non-linear optic properties. We also demonstrated the ability to use these peptide nanostructures as casting mold for the fabrication of metallic nano-wires and coaxial nano-cables. The application of the nanostructures was demonstrated in various fields including electrochemical biosensors, tissue engineering, and molecular imaging. Finally, we had developed ways for depositing of the peptide nanostructures and their organization. We had use inkjet technology as well as vapour deposition methods to coat surface and from the peptide "nano-forests". We recently demonstrated that even a single phenylalanine amino-acid can form well-ordered fibrilar assemblies.

9:12AM T11.00003 Amyloid at the nanoscale: AFM and single-molecule investigations of early steps of aggregation and mature fibril growth, structure, and mechanics[1] , VINOD SUBRAMANIAM, MIRA Institute for Biomedical Technology and Technical Medicine, University of Twente — Misfolding and aggregation of proteins into nanometer-scale fibrillar assemblies is a hallmark of many neurodegenerative diseases. We have investigated the self-assembly of the human intrinsically disordered protein alpha-synuclein, involved in Parkinson's disease, into amyloid fibrils. A particularly relevant question is the role of early oligomeric aggregates in modulating the dynamics of protein nucleation and aggregation. We have used single molecule fluorescence spectroscopy to characterize conformational transitions of alpha-synuclein [1], and to gain insights into the structure and composition of oligomeric aggregates of alpha-synuclein [2]. Quantitative atomic force microscopy [3, 4] and nanomechanical investigations [5, 6] provide information on amyloid fibril polymorphism and on nanoscale mechanical properties of mature fibrillar species, while conventional optical and super-resolution imaging have yielded insights into the growth of fibrils and into the assembly of suprafibrillar structures.

9:48AM T11.00004 Amyloid Self Assembly , TUOMAS KNOWLES, University of Cambridge — No abstract available.

10:24AM T11.00005 Designing biomaterials exploiting beta-sheet forming peptides self-assembly , ALBERTO SAIANI, The University of Manchester — The use of non-covalent self-assembly to construct materials has become a prominent strategy in material science offering practical routes for the construction of increasingly functional materials for a variety of applications ranging from electronic to biotechnology. A variety of molecular building blocks can be used for this purpose, one such block that has attracted considerable attention are de-novo designed peptides. The library of 20 natural amino acids offers the ability to play with the intrinsic properties of the peptide such as structure, hydrophobicity, charge and functionality allowing the design of materials with a wide range of properties. The beta-sheet motif is of particular interest as short peptides can be designed to form beta-sheet rich fibres that entangle and consequently form hydrogels. These hydrogels can be further functionalised using specific biological signals or drugs by synthesising functionalised peptides that are incorporated into the hydrogel network during the self-assembling process. This functionalisation approach is very attractive has it does not require any chemistry avoiding therefore the use of additional potentially toxic chemicals. It also offers the possibility to introduce multiple functionalities in a straightforward fashion. The hydrogels can also be made responsive through the use of enzymatic catalysis and/or conjugation with responsive polymers. In this presentation we will discuss the design opportunities offered by these peptides to create new functional biomaterials.

Session T12 DMP GERA FIAP: Focus Session: Thermoelectrics Materials I 314 - Michael McGuire, ORNL

8:00AM T12.00001 Emergent nanoscale fluctuations in high rock-salt PbTe[1] , SIMON BILLINGE, Brookhaven National Laboratory and Columbia University — Lead Telluride is one of the most promising thermoelectric materials in the temperature range just above room temperature. It is a narrow band gap semiconductor with a high Seebeck coefficient and a low thermal conductivity. It is structurally much simpler than many other leading candidates for high performance thermoelectrics being a binary rock-salt, isostructural to NaCl. The thermoelectric figure of merit, ZT, can be markedly improved by alloying with various other elements by forming quenched nanostructures. The undoped endmember, PbTe, does not have any such quenched nanostructure, yet has a rather low intrinsic thermal conductivity. There are also a number of interesting and non-canonical behaviors that it exhibits, such as an increasing measured band-gap with increasing temperature, exactly opposite to what is normally seen due to Fermi smearing of the band edge, and an unexpected non-monotonicity of the band gap in the series PbTe - PbSe - PbS. The material is on the surface simple, but hides some interesting complexity. We have investigated in detail the PbTe endmember using x-ray and neutron diffraction and neutron inelastic scattering [1]. To our surprise, using the atomic pair distribution function (PDF) analysis of neutron powder diffraction data we found that an interesting and non-trivial local structure that appears on warming. with the Pb atoms moving off the high-symmetry rock-salt positions towards neighboring Te ions. No evidence for the off-centering of the Pb atoms is seen at low temperature. The crossover from the locally undistorted to the locally distorted state occurs on warming between 100 K and 250 K. This unexpected emergence of local symmetry broken distortions from an undistorted ground-state we have called emphanisis, from the Greek for appearing from nothing. We have also investigated the lattice dynamics of the system to search for a dynamical signature of this behavior and extended the studies to doped systems and I will also describe the results of these experiments. This work gives key insights into PbTe, the possible origin of its anomalous electronic structure properties, and why it is such an attractive parent compound for nanostructured high performance thermoelectric materials. I would like to acknowledge the excellent collaborations that occurred during this work, including Emil Bozin at Brookhaven National Laboratory, Mercouri Kanatzidis and Christos Malliakas at Northwestern University and Argonne National Laboratory, Kirsten Jensen from U. Aarhus, Steve Shapiro at Brookhaven National Laboratory, Matt Stone and Mark Lumsden at Oak Ridge National Laboratory, Nicola Spalding at ETH Zurich and Petros Souvatzis at Los Alamos National Laboratory. I would also like to acknowledge the support of the national user facilities and their staff where the work was done. [1] E.S. Bozin et al., Science v330, pp1660 (2010).

[1]Financial support for this work was from DOE office of Basic Energy Sciences through award DE-AC02-98CH10886.

8:36AM T12.00002 Thermoelectric properties of FeSb2: A first principles study , MOMAR DIAKHATE, MATTHIEU VERSTRAETE, Universite de Liege — The development of new types of thermoelectric materials with a large figure of merit is strongly driven by the need for sustainable and clean energy. In this respect first-principles study of thermoelectric properties can help to achieve a better understanding of microscopic mechanisms in transport, which provides insight for discovering new materials. To study the thermoelectrical properties, we combine the well known Boltzmann transport theory with the predictive power of density functional calculations. With the exception of the lattice thermal conductivity, all of the required transport coefficients can be obtained using the BoltzTrap code, based simply on the electronic band energies. With a constant relaxation time, we predict the Seebeck coefficient of bulk FeSb2, which showed colossal negative value at 12K experimentally. The calculated peak position is consistent with the observation, while the amplitude is underestimated. The inclusion of contributions from phonon drag effect and the exact calculation of the electronic density of states around Fermi level may better describe the experimentally observed phenomena.

8:48AM T12.00003 Large Seebeck Effect in $CrSb_2$ Single Crystals , BRIAN SALES, ANDREW MAY, MICHAEL MCGUIRE, DAVID SINGH, Oak Ridge National Laboratory, DAVID MANDRUS, University of Tennessee — $CrSb_2$ is a narrow gap semiconductor (E_g = 0.14 meV) that orders antiferromagnetically at T_N = 273 K. Resistivity, Hall effect, Seebeck coefficient, thermal conductivity, heat capacity, and magnetic susceptibility data are reported for $CrSb_2$ single crystals. In spite of some unusual features in electrical transport and Hall measurements below 100 K, only one phase transition occurs (T_N) in the temperature range from 2 to 750 K. Many of the low temperature properties can be explained by the thermal depopulation of carriers from the conduction band into a low mobility impurity band about 16 meV below the conduction band edge. The Seebeck coefficient, S, is large and negative from 2 to 300 K, ranging from -70 μV/K at 300 K to -4500 μV/K at 18 K. The large magnitude of S at 18 K is likely due to phonon drag, with the large decrease in the magnitude of S below 18 K due to the thermal depopulation of the high mobility conduction band. The $CrSb_2$ Seebeck data are compared to some of the data reported for $FeSb_2$ and FeSi. This research was supported by the U. S. Department of Energy, Basic Energy Sciences, Materials Sciences and Engineering Division.

9:00AM T12.00004 Magnon gap formation and charge density wave effect on thermoelectric properties in SmNiC2 compound , JIN-HEE KIM, JONG-SOO RHYEE, Department of Applied Physics, Kyung Hee University, YONG SEUNG KWON, Department of Emerging Materials Science, Daegu Gyeongbuk Institute of Science and Technology — We studied the magnetic, electrical, and thermal properties of polycrystalline compound of SmNiC2. The electrical resistivity and magnetization measurement show the interplay between the charge density wave at T_{CDW} = 157 K and the ferromagnetic ordering of Tc = 18 K. Below the ferromagnetic transition temperature, we observed the magnon gap formation of 4.3 $\sim$ 4.4 meV by ρ(T) and C_p(T) measurements. The charge density wave is attributed to the increase of Seebeck coefficient resulting in the increase of power factor $S^2\sigma$. The thermoelectric figure-of-merit ZT significantly increases due to the increase of power factor at T_{CDW} = 157 K. Here we argue that the competing interaction between electron-phonon and electron-magnon couplings exhibits the unconventional behavior of electrical and thermal properties. This research was supported by Basic Science Research Program (2011-0021335), Nano-Material Technology Development Program (2011-0030147), and Mid-career Research Program (Strategy) (No. 2012R1A2A1A03005174) through the National Research Foundation of Korea (NRF) funded by the Ministry of Education, Science and Technology.

9:12AM T12.00005 New insights into rare-earth intermetallic alloys for cryogenic Peltier cooling[1] , STEPHEN BOONA, DONALD MORELLI, Department of Chemical Engineering and Materials Science, Michigan State University — Strongly correlated materials such as intermediate valence $CePd_3$ have long been considered attractive candidates for cryogenic Peltier cooling due to the combination of metallic electrical resistivity concurrent with Seebeck coefficient values on the order of 100 μ V/K at low temperatures. This behavior is a direct result of the strong hybridization of localized 4f states with delocalized conduction electrons, which gives rise to several unusual structural, electronic, thermal, and magnetic properties. Our recent work on this compound has helped to unravel some of the complex ways in which these properties are correlated, and we have successfully utilized this improved understanding to enhance ZT up to 0.3. We present a broad overview of these new insights and provide suggestions for how they may be exploited to achieve enhanced thermoelectric performance in other strongly correlated materials.

9:24AM T12.00006 Low Temperature Specific Heat Study on Type I Clathrates , JIAZHEN WU, Graduate school of science, Tohoku University, JINGTAO XU, WPI-AIMR, Tohoku University, GANG MU, DWI PRANANTO, HIDEKAZU SHIMOTANI, Graduate school of science, Tohoku University, YOICHI TANABE, WPI-AIMR, Tohoku University, SATOSHI HEGURI, Graduate school of science, Tohoku University, KATSUMI TANIGAKI, Graduate school of science, Tohoku University; WPI-AIMR, Tohoku University — Zintl phase clathrates, which are featured by the cage framework with guest atoms accommodated inside, are considered as good candidates of thermoelectric materials mainly due to the low thermal conductivity caused by large scattering of the acoustic phonons via the rattling phonons arising from the guest motions [1,2]. The fact has been known so far that, in clathrate $Sr_8Ga_{16}Ge_{30}$ showing off-centered displacement of encapsulated elements, thermal conductivity is suppressed even stronger via the scattering of acoustic phonons by anharmonic rattling phonons. Consequently, further detailed understanding on the anharmonic potentials realized in clathrates is important. In this meeting, we will present our recent studies on low temperature specific heat of type I $Ba_8Ga_{16}Sn_{30}$ and $K_8Ga_8Sn_{38}$ in addition to those of $Ba_8Ga_{16}Ge_{30}$ and $Sr_8Ga_{16}Ge_{30}$ reported previously [2]. The discussion will mainly focus on the separation of the apparent linear temperature dependent terms of anharmonic rattling phonons from those of conduction electrons. The electron phonon interaction strength and the tunneling density of anharmonic potentials will be described on a basis of the analyses. [1] J. Tang, *et al., Phys. Rev. Lett.,* 105, 176402 (2010). [2] J.-T. Xu, *et al., Phys. Rev. B,* 82, 085206 (2010).

9:36AM T12.00007 Surface Modification induced Double Decoupling in Transport Properties of Polycrystalline Bi , JIAN HE, POOJA PUNEET, RAMAKRISHNA PODILA, SONG ZHU, MALCOLM SKOVE, TERRY TRITT, APPARAO RAO, Department of Physics and Astronomy, Clemson University, Clemson, SC, United States 29634 — Nanostructured thermoelectric (TE) materials have gained major interest due to their ability to offer better control of electronic and thermal transport properties. Such nanostructures, with increased surface-to-volume ratio, lead to pronounced surface effects on various transport properties. In this study, we used the spark plasma sintering (SPS) process as a densification and surface modification technique for nano-structured Bi. Several samples were prepared with varying the DC pulse times and durations to tailor interface/surface properties. As a result, a complete decoupling of electrical and thermal transport (*double decoupling*) in nano-structured Bi was observed with enhanced (greater than six-fold) power factor. This is a very significant improvement that goes beyond partial decoupling. Details of the TE properties will be presented.

9:48AM T12.00008 The microstructure network and thermoelectric properties of bulk (Bi,Sb)2Te3 , HYE JUNG KANG, Clemson University, WENJIE XIE, Clemson University, Wuhan University of Technology, DALE HITCHCOCK, JIAN HE, Clemson University, XINFENG TANG, Wuhan University of Technology, MARK LAVER, Technical University of Denmark, University of Copenhagen, Paul Scherrer Institut, BOUALEM HAMMOUDA, National Institute of Standards and Technology — We report small-angle neutron scattering studies on the microstructure network in bulk (Bi,Sb)2Te3 synthesized by the melt-spinning (MS) and the spark-plasma-sintering (SPS) process. We find that rough interfaces of multiscale microstructures generated by the MS are responsible for the large reduction of both lattice thermal conductivity and electrical conductivity. Our study also finds that subsequent SPS forms a microstructure network of 10 nanometer thick lamellae and smooth interfaces between them. This nanoscale microstructure network with smooth interfaces increases electrical conductivity while keeping a low thermal conductivity, making it an ideal microstructure for high thermoelectric efficiency.

10:00AM T12.00009 Electronic structure of Mn and Fe impurities in Bi-Sb-Te , BYUNGKI RYU, KYUNGHAN AHN, SANG MOCK LEE, KYU HYOUNG LEE, Samsung Advanced Institute of Technology — Bi_2Te_3-based thermoelectric materials are well known room temperature thermoelectric materials. Here we present a density-functional study of the electronic structure of Mn and Fe doped p-type Bi-Sb-Te (p-BST) to investigate the effect of metal impurities on the thermoelectronic properties. Our calculations show that, for both Mn and Fe, the substitutional impurity at the Bi/Sb-site is the most stable geometry. Mn is a single acceptor, whereas Fe is an isovalent defect. The metal d bands are located within the host bands, not in the band gap. Due to the octahedral symmetry of the Bi/Sb-site, the metal d bands of Mn and Fe are split into three t_{2g} and two e_g^* states in the high spin configuration. The electronic charge distribution analysis reveals that occupied e_g^* states are well resonant with the host valence bands. As the e_g^* states are located near the valence band maximum, Mn and Fe impurities are expected to enhance the p-type Seebeck coefficient of BST.

10:12AM T12.00010 Transport Properties of Ce, Sm, and Ho Doped Bismuth Antimony[1] , K.C. LUKAS, H. ZHAO, Z.F. REN, C.P. OPEIL, Boston College — $Bi_{88}Sb_{12}$ alloy has been doped with Ce, Sm, and Ho prepared under two different fabrication conditions. The first being ball milled for 12 hours and a hot pressed at 240 ^{o}C and the second ball milled for 6 hours and hot pressed at 200 ^{o}C. It is found that Ce, Sm, and Ho dopants all have a similar impact on the transport properties. A ZT enhancement is seen due to doping which is an effect of an enhanced Seebeck coefficient as a result of a decrease in the carrier concentration most likely caused by a widening band gap. The alteration of the band gap does not appear to be caused by the magnetic moments of Ce, Sm, and Ho based on the similar change to the gap size with the widely varying magnetic moments of the dopants. Also, similar results were not obtained with Fe doped samples, where Fe has a magnetic moment similar to Ce and greater than Sm.

10:24AM T12.00011 Low Temperature Transport Properties of $Bi_{2-x}Tl_xTe_3$ Single Crystals[1] , HANG CHI, CTIRAD UHER, University of Michigan, USA, PETR LOSTAK, CESTMIR DRASAR, University of Pardubice, Czech Republic — We show that Tl-doping progressively changes the electrical conduction of $Bi_{2-x}Tl_xTe_3$ (x =0−0.30) single crystals from p-type ($0 \leq x \leq 0.08$) to n-type ($0.12 \leq x \leq 0.30$), which is observed via measurements of both the Seebeck coefficient and the Hall effect performed in the crystallographic *ab*-plane in the temperature range of 2K-300K. The temperature dependent electrical resistivity in the *ab*-plane of $Bi_{2-x}Tl_xTe_3$ maintains its metallic character with the decreasing hole density at low doping levels of $0 \leq x \leq 0.05$. Heavier Tl-doping with $0.08 \leq x \leq 0.12$ drives the electrical resistivity into a prominent non-metallic regime, associated with characteristic metal-insulator-metal transitions upon cooling down from 200K. For even more Tl-doped samples, $0.20 \leq x \leq 0.30$, the system reverts back into the metallic state. Thermal conductivity measurements of $Bi_{2-x}Tl_xTe_3$ single crystals reveal a progressively stronger point defect scattering of phonon with the increasing Tl content. The systematic evolution of transport properties suggests that the Fermi level of Bi_2Te_3 which initially lies in the valence band (for x =0), is gradually shifted, with increasing Tl-doping, toward the top of the valence band (for $0.01 \leq x \leq 0.05$), then into the band gap (for $0.08 \leq x \leq 0.10$), and eventually into the conduction band (for $0.20 \leq x \leq 0.30$).

[1]This work is supported by CSTEC, a U.S. DOE EFRC, under Award Number DE-SC0000957.

10:36AM T12.00012 Valence band structure of Bi2Se3[1] , YI-BIN GAO, Department of Mechanical and Aerospace Engineering, Ohio State University, Columbus, Ohio 43210, DAVID PARKER, Oak Ridge National Laboratory, 1 Bethel Valley Road, Oak Ridge, Tennessee 37831, JOSEPH P. HEREMANS, Department of Mechanical and Aerospace Engineering, Department of Physics, Ohio State University, Columbus, Ohio 43210 — Bi2Se3 is an interesting candidate for thermoelectric application because Se is a more abundant element than Te, which is commercially used in Bi2Te3-based Peltier coolers. However, intrinsic Se vacancies dominate in Bi2Se3 and dope the material n-type. Due to unfavourable conduction band structure, n-type Bi2Se3 does not have a high power factor. Recently, it has been calculated [1] that Bi2Se3 has a favourable valence band structure for thermoelectric application. In this presentation, high-quality p-type Bi2Se3 single crystals are prepared and Shubnikov de Haas measurement are carried out on them to characterize the band structure. Cross-sectional areas of Fermi surface are mapped out and compared with the theoretical calculation. Reference: [1] Phys. Rev. X 1, 021005 (2011)

10:48AM T12.00013 Electronic and structural properties of superionic Cu_2Se from density functional theory[1] , MIKAEL RÅSANDER, LARS BERGQVIST, ANNA DELIN, KTH - Royal Institute of Technology — The superionic high temperature phase of Cu_2Se has been found to yield high thermoelectric efficiency due to an interesting combination of low thermal conductivity and a rather high power factor. The low thermal conductivity has been found to be due to the quasi-liquid behaviour of the superionic Cu atoms (Liu et al., Nature Materials, **11**, 422-425 (2012)). Here we will present results obtained using density functional theory calculations of the electronic and structural properties of the superionic Cu_2Se phase. We will especially address how the inclusion of non-local exchange by the use of hybrid density functionals as well as how localization of the Cu 3d-states affect the electronic structure of Cu_2Se.

Session T13 DMP: Focus Session: Topological Materials - Quasi 1-dimensional 315 - Joel Moore, University of California, Berkeley

8:00AM T13.00001 Transition from fractional to Majorana fermions in Rashba nanowires , JELENA KLINOVAJA, PETER STANO, DANIEL LOSS, Department of Physics, University of Basel — We study hybrid superconducting-semiconducting nanowires in the presence of Rashba spin-orbit interaction as well as helical magnetic fields.[1] We show that the interplay between them leads to a competition of phases with two topological gaps closing and reopening, resulting in unexpected reentrance behavior. Besides the topological phase with localized Majorana fermions (MFs) we find new phases characterized by fractionally charged fermion (FF) bound states of Jackiw-Rebbi type. The system can be fully gapped by the magnetic fields alone, giving rise to FFs that transmute into MFs upon turning on superconductivity. We find explicit analytical solutions for MF and FF bound states and determine the phase diagram numerically by determining the corresponding Wronskian null space. We show by renormalization group arguments that electron-electron interactions enhance the Zeeman gaps opened by the fields.

8:12AM T13.00002 Majorana fermions in topological insulator nanoribons with multiband occupancy , PIYAPONG SITTHISON, TUDOR STANESCU, Department of Physics, West Virginia University — We present the phase diagram of a topological insulator nanoribbon with proximity-induced superconductivity as function of the chemical potential and the Zeeman field applied parallel to the ribbon. We find that, in doped topological insulator systems, both surface-like and bulk-like states contribute to the low-energy physics and that proximity-induced quantities, such as the induced superconducting pair potential, have different energy scales in these channels. We study the effect of this band-specific proximity coupling on the properties and the stability of Majorana zero-energy bound states in multiband topological insulator nanoribbons.

8:24AM T13.00003 Time Reversal Invariant Topological Superconductors and Majorana Pairs , FAN ZHANG, EUGENE MELE, CHARLES KANE, Department of Physics and Astronomy, University of Pennsylvania, Philadelphia, PA 19104 — We propose a feasible route to engineer two dimensional (2D) and one dimensional (1D) time reversal invariant topological superconductors via proximity effects. At a boundary of the 2D (1D) topological superconductor, a time reversal pair of Majorana edge (bound) states emerge as the localized midgap states. We analyze how the Majorana pair evolves in the presence of a Zeeman field, as the superconductor undergoes the symmetry class change as well as the topological phase transitions. A fractional Josephson effect with time reversal symmetry occurs in the presence of a mirror symmetry, realizing a topological crystalline superconducting state. We also briefly discuss the possible realization in materials and the unique signature in experiments.

8:36AM T13.00004 Ripple modulated electronic structure of a 3D topological insulator , VIDYA MADHAVAN, Boston College — Many of the unusual properties of topological insulators can only be realized through a delicate tuning of the Dirac surface state rendering their detection thus far elusive. We have discovered that the surface state dispersion of a prototypical topological insulator can be continuously tuned via a novel topographical route. STM images of Bi_2Te_3 show one-dimensional (striped) ripples with 100nm periodicity. By combining information from Landau level spectra [1] and Fourier transform of interference patterns [2] we show that the ripples induce spatial modulations in the surface state dispersion. We describe how the ripples create topological channels for chiral spin modes at the boundaries such that placing the Fermi energy between the Landau levels of these periodic stripes would result in the first experimental realization of the ideal 1D dissipationless quantum wire. This ability to tune the surface state dispersion locally opens the door to a host of new phenomena in topological insulators.

9:12AM T13.00005 Novel giant Rashba spin splitting of holes in semiconductor nanowires for Majorana Fermions[1] , JUN-WEI LUO, LIJUN ZHANG, National Renewable Energy Laboratory, ALEX ZUNGER, CU Boulder, USA — Majorana Fermions (MFs) are particles identical to their own antiparticles that have been first theoretical predicted and then experimentally observed in hybrid superconductor-semiconductor nanowire devices. The appearance of MFs requires (spin-orbit-induced) giant nanowire spin splitting (SS) to exceed the topological superconductor gap, a condition realized by tuning the magnetic field. Because the SS due to the conventional Dresselhaus or Rashba mechanisms is inversely proportional to the wire diameter, these mechanisms contribute but vanishing SS ($\ll 1$ meV Å) for wide (~ 100 nm) wires that are appropriate to device uses–a significant disadvantage of nanowire for this application. Our atomistic pseudopotential calculation predicted a novel large Rashba SS in GaAs/AlAs wires under electric field [1], which increases as the wire diameter to the potential benefit of nanowire MF device. This emerged automatically when the ordinary Schrödinger equation is solved in the presence of spin-orbit interaction. We will report such giant Rashba SS coefficient of the order of ~ 200 meVÅ in a number of semiconductor wire materials ~ 100 nm wide.

9:24AM T13.00006 Classification of the 2D topological insulator/ superconductors through their 1D Dirac edge Hamiltonians , YI-TING HSU, ABOLHASSAN VAEZI, EUN-AH KIM, Cornell University — Ref [1] analyzes the consequences of discrete symmetries for 1D Dirac Hamiltonians as candidate description of 2D topological insulators/superconductors(TI/TS), formally revealed that there are multiple inequivalent representations of time reversal symmetry as required by $\mathbf{T}^\dagger H T = H^*$. This is special to 1D Dirac edge Hamiltonians and leads to additional possibilities in the classification of 2D TI/TS. In this talk, we present physical implications of the multiple representations through additional hidden symmetries X_i implicit in the 1D Dirac Hamiltonians. When X_i do not commute with any of the existing discrete symmetries, it is necessary to consider X_i alone as individual symmetries for the purpose of classifying the edge theory which usually extends its classification. Graphene-based topological insulators are physical examples of a resulting new Z-type topological phase obtained through imposing an additional $U(1)$ symmetry due to the absence of inter-valley scattering. [1] D. Bernard, E.-A. Kim, and A. LeClair, ArXiv:1202.5040 (2012)

9:36AM T13.00007 Topological pi Josephson effect and Majorana states in Rashba wires , TEEMU OJANEN, Aalto University — Rashba-based topological superconductor nanowires, where the spin-orbit coupling may change its sign, support three topological phases protected by chiral symmetry. When a superconducting phase gradient is applied over the interface of the two nontrivial phases, the Andreev spectrum is qualitatively phase shifted by π compared to usual Majorana weak links. The topological π-junction has the striking property of exhibiting maximum supercurrent in the vicinity of vanishing phase difference.The studied system could be realized by local gating of the wire or by an appropriate stacking of permanent magnets in synthetic Rashba systems.

9:48AM T13.00008 Majorana fermions in hybrid superconductor-semiconductor nanowire devices , VINCENT MOURIK, KUN ZUO, DAVID VAN WOERKOM, Delft University of Technology, SERGEY FROLOV, University of Pittsburgh, SEBASTIEN PLISSARD, ERIK BAKKERS, Eindhoven University of Technology, LEO KOUWENHOVEN, Delft University of Technology — Our recent experiment carried out in hybrid superconductor-semiconductor nanowire devices gave the first experimental evidence for the existence of Majorana fermions [1]. However, some open questions need to be answered. Majorana fermions have to come in pairs, but before we were only capable of probing one Majorana fermion. Besides, Majorana fermions should be fully gate controllable, which could not be demonstrated very convincingly. Furthermore the observed conductance peak was only at 5% of the theoretically expected height of 2eˆ2/h. Currently we are performing new experiments in similar but improved devices. We study three terminal normal-superconductor-normal InSb nanowire devices. This enables the possibility to simultaneously probe both Majorana fermions occurring at the ends of the superconducting contact by using tunneling spectroscopy from normal to superconducting contact. Furthermore, the devices have an improved gate design enabling more efficient gating under the superconducting contact. The first measurements already give a larger peak amplitude and the peak is visible in a larger magnetic field range. [1] V. Mourik, K. Zuo et al., Science, Vol. 336 no. 6084 pp. 1003-1007

10:00AM T13.00009 Detecting Majorana fermions in quasi-1D topological phases using non-local order parameters , YASAMAN BAHRI, ASHVIN VISHWANATH, University of California, Berkeley — There has been much recent interest in realizing Majorana fermions in solid-state or cold atom systems. A primary goal has been to identify the topological phases which host them and propose routes towards their experimental detection. Such topological phases cannot be distinguished via local order parameters. Instead, we propose non-local string order parameters to distinguish 1D topological phases hosting Majorana zero modes. We also discuss potential cold atom measurements of string order, based on recent experimental developments, as a new and alternative route towards their detection. We further consider N identical chains of interacting fermions and use the group cohomology approach to construct non-local order parameters to distinguish topological phases of this quasi-1D system.

10:12AM T13.00010 Gate-defined wires in HgTe quantum wells as a robust Majorana platform[1] , JOHANNES REUTHER, JASON ALICEA, Department of Physics, Caltech, AMIR YACOBY, Department of Physics, Harvard — We propose a new quasi-1D platform for Majorana zero-modes based on gate-defined wires in HgTe. Due to the Dirac-like band structure for HgTe such wires exhibit several remarkable properties. Most strikingly, modest gate-tuning allows one to modulate the Rashba spin-orbit energy from zero up to $\sim 30K$, and the effective g-factor from zero up to giant values of ~ 600. The large achievable spin-orbit coupling and g-factor together allow one to access Majorana modes in this setting at exceptionally low magnetic fields while maintaining robustness against disorder. Moreover, gate-defined wires may facilitate the fabrication of networks required for realizing non-Abelian statistics and quantum information devices. The exquisite tunablity of parameters further suggests applications in spintronics.

10:24AM T13.00011 Hints of hybridizing Majorana fermions in a nanowire coupled to superconducting leads[1] , A.D.K. FINCK, D.J. VAN HARLINGEN, P.K. MOHSENI, K. JUNG, X. LI, University of Illinois at Urbana-Champaign — It has been proposed that a nanowire with strong spin-orbit coupling that is contacted with a conventional superconductor and subjected to a large magnetic field can be driven through a topological phase transition. In this regime, the two ends of the nanowire together host a pair of quasi-particles known as Majorana fermions (MFs). A key feature of MFs is that they are pinned to zero energy when the topological nanowire is long enough such that the wave functions of the two MFs do not overlap significantly, resulting in a zero bias anomaly (ZBA). It has been recently predicted that changes in external parameters can vary the wave function overlap and cause the MFs to hybridize in an oscillatory fashion. This would lead to a non-monotonic splitting or broadening of the ZBA and help distinguish MF transport signatures from a Kondo effect. Here, we present transport studies of an InAs nanowire contacted with niobium nitride leads in high magnetic fields. We observe a number of robust ZBAs that can persist for a wide range of back gate bias and magnetic field strength. Under certain conditions, we find that the height and width of the ZBA can oscillate with back gate bias or magnetic field.

10:36AM T13.00012 Using InAs quantum wells to navigate the Majorana parameter space , PETER O'MALLEY, PEDRAM ROUSHAN, YU CHEN, BROOKS CAMPBELL, BORZOYEH SHOJAEI, JAVAD SHABANI, BRIAN SHULTZ, CHRIS PALMSTROM, JOHN MARTINIS, University of California, Santa Barbara — Although superconducting contacts laid down on self-assembled nanowires have produced impressive experimental results, the desire to build complex and scalable devices using Majorana modes leads us to want to develop lithographically defined nanowires. Our strategy is to deposit a superconducting layer in situ on an MBE-grown InAs 2DEG, and etch nanowires in subsequent microfabrication. This allows control over nanowire properties as well as the ability to vary the superconductor-semiconductor coupling strength in a precise manner. We plan to present measurements of both Nb coupled to an InAs 2DEG and nanowires fabricated out of two-dimensional InAs systems. We then discuss where these measurements put our system in the parameter space needed to observe the Majorana fermion, and propose a path forward.

10:48AM T13.00013 High-Performance Topological Insulator Bi_2Se_3 Nanowire Field Effect Transistors[1] , HAO ZHU, GMU, CURT RICHTER, NIST, ERHAI ZHAO, HUI YUAN, HAITAO LI, DIMITRIS IOANNOU, QILIANG LI, GMU, GEORGE MASON UNIVERSITY TEAM, NIST TEAM — Single crystal topological insulator Bi_2Se_3 nanowires were synthesized by Vapor-Liquid-Solid (VLS) mechanism. Bi_2Se_3 NW field-effect transistors were fabricated by using self-alignment method with HfO_2 as the gate dielectric. Bi_2Se_3 NWFETs were measured in vacuum at different temperatures. Excellent MOSFET characteristics were achieved: smooth and well-saturated output characteristics, large On/Off ratio (10^7), zero Off-state current and good subthreshold slope in transfer characteristics. We have observed linear behavior of the saturation current extracted from the I_{ds}-V_{ds} curves as a function of the overthreshold voltage (V_g-V_{th}), which indicated the main role of the metallic surface conduction at Bi_2Se_3 nanowire channel. Both effective mobility and field-effect mobility have been extracted. Very good effective mobility ($>$ 5000 $cm^2V^{-1}s^{-1}$ at 77 K) was obtained under a low gate voltage. From off-state current we calculated the band gap of bulk about 0.33 eV, which is in a good agreement with reported value of 0.35 eV.

Session T14 GMAG DMP: Focus Session: Magnetic Vortices 316 - Kristen Buchanan, Colorado State University

8:00AM T14.00001 Reproducible control of the magnetic vortex chirality on a nanosecond timescale[1] , VOJTĚCH UHLÍŘ, Center for Magnetic Recording Research, University of California, San Diego — Magnetic vortices are curling magnetization structures which represent the lowest energy state in sub-micron size magnetic disks or polygons. The vortex core, a singularity at the vortex center, features magnetization pointing either up or down perpendicular to the disk plane. The binary character of the chirality of the curl and the polarity of the vortex core leads to four possible stable magnetization configurations that can be utilized in a multi-bit memory cell. Both the vortex polarity and chirality are stable against static magnetic fields. It has been shown that when excited with ultrafast magnetic field or current stimuli, the core polarity can be reversed on a 100 ps timescale. We demonstrate ultrafast switching of vortex chirality using nanosecond magnetic field pulses by imaging the process with full-field x-ray transmission microscopy. The dynamic reversal process is controlled by far-from-equilibrium gyrotropic precession of the vortex core and the reversal is achieved at significantly reduced field amplitudes when compared to quasi-static switching. Controlled switching of the chirality requires removing the vortex core out of the disk and then reforming the vortex with opposite chirality. This can be achieved by using a static magnetic field and exploiting a geometric asymmetry in the object. However, scaling this process down in time, using nanosecond and shorter magnetic field pulses, necessarily introduces complex magnetization dynamics that might prevent efficient and reproducible switching of the vortex chirality. We show that these issues can be overcome by selecting magnetic disks of an appropriate geometry along with the field pulse parameters. Finally we discuss that faster switching rates can be achieved by scaling down the disk size.

8:36AM T14.00002 Interacting magnetic nanodisks pairs , JOAO PAULO SINNECKER, HELMUNT EDUARDO VIGO COTRINA, ERICO NOVAIS, Centro Brasileiro de Pesquisas Físicas, Rio de Janeiro, Brasil, FLÁVIO GARCIA, Laboratorio Nacional de Luz Sincrotron, Campinas, Brasil, ALBERTO PASSOS GUIMARAES, Centro Brasileiro de Pesquisas Físicas, Rio de Janeiro, Brasil — Nanodots with magnetic vortex configuration are considered as promising elements of recording media [1]. When vortices are excited from their equilibrium position and allowed to relax, they perform a motion called gyrotropic, with a characteristic frequency. When two magnetic disks are close to one another there arises a frequency splitting due to the dynamic interaction [1]. Expressions for the magnetic vortex excitation frequencies and coupling constants in a pair of coupled identical circular disks were obtained previously by Shibata et al. [2]. The goal of this work is to calculate analytically the frequency of the dynamic excitation of coupled vortices in a pair of disks with different radii, with the same thickness. We considered a magnetostatic interdot interaction using the linearized Thiele's equations of motion of the vortex core, neglecting the damping term. Through micromagnetic simulation, we have investigated the interaction of these pairs of nanodisks using a recently developed tool, the magnetic vortex echoes (MVE) [3]. An analytical model of the MVE is presented.

8:48AM T14.00003 Element Specific Observation of Ferromagnetic Interlayer Exchange Coupled Dual Vortex Core Nano Systems , JAVIER PULECIO, DARIO ARENA, Brookhaven National Laboratory, PETER WARNICKE, Swiss Light Souce, MI-YOUNG IM, Lawrence Berkeley National Laboratory, SHAWN POLLARD, Brookhaven National Laboratory, PETER FISCHER, Lawrence Berkeley National Laboratory, YIMEI ZHU, Brookhaven National Laboratory — We report on the magnetic evolution of magnetic vortices in nanoscale and multilayer disk structures. The tri-layer structure consists of Co and Permalloy (Py) layers, coupled across a thin (1nm) Cu spacer that provides strong coupling between the Co and Py layers. Element-resolved full-field XMCD microscopy is combined with ultra-high resolution Lorentz transmission electron microscopy, permitting measurement of both layer-resolved domain patterns and the vortex structure averaged across the tri-layer. We examine the evolution of the vortex structure while the nanostructure is cycled through the M-H hysteresis loop. In particular we will discuss the effects of strong interlayer exchanged coupling on a dual vortex core system, including analysis of the layer-resolved coercivity, and the evolution, deformation, annihilation, and nucleation of the vortices.

9:00AM T14.00004 Configurational Anisotropy and Single Domain Behavior in Sub-Micron Square Nickel Dots[1] , DANIEL ENDEAN, E. DAN DAHLBERG, University of Minnesota — Magnetic thin films patterned as regular polygons discourage the formation of a vortex magnetic state in favor of single domain behavior due to the presence of sharp corners. We report on measurements of the magnetic properties of Nickel films patterned as isolated square dots with side lengths varying from 1 micron down to 100 nm and thicknesses of 10 nm. The magnetic field dependence of the dot magnetization is probed using a 4-terminal resistance measurement through the anisotropic magnetoresistance (AMR) effect. By measuring the resistance analog of a hysteresis loop, we observe single domain behavior consistent with the presence of 4-fold configurational anisotropy energy. Using a Stoner-Wohlfarth model, we quantify the magnitude of the anisotropy through the easy axis coercivity and the rotational hysteresis and compare to micromagnetic simulations.

9:12AM T14.00005 Resonant-spin-ordering of vortex cores in interacting mesomagnets[1] , SHIKHA JAIN, Materials Science Division, Argonne National Laboratory — The magnetic system of interacting vortex-state elements have a dynamically reconfigurable ground state characterized by different relative polarities and chiralities of the individual disks; and have a corresponding dynamically controlled spectrum of collective excitation modes that determine the microwave absorption of the crystal. The development of effective methods for dynamic control of the ground state in this vortex-type magnonic crystal is of interest both from fundamental and technological viewpoints. Control of vortex chirality has been demonstrated previously using various techniques; however, control and manipulation of vortex polarities remain challenging. In this work, we present a robust and efficient way of selecting the ground state configuration of interacting magnetic elements using resonant-spin-ordering approach. This is achieved by driving the system from the linear regime of constant vortex gyrations to the non-linear regime of vortex-core reversals at a fixed excitation frequency of one of the coupled modes. Subsequently reducing the excitation field to the linear regime stabilizes the system to a polarity combination whose resonant frequency is decoupled from the initialization frequency. We have utilized the resonant approach to transition between the two polarity combinations (parallel or antiparallel) in a model system of connected dot-pairs which may form the building blocks of vortex-based magnonic crystals. Taking a step further, we have extended the technique by studying many-particle system for its potential as spin-torque oscillators or logic devices.

9:48AM T14.00006 Magnetization manipulation in ferromagnetic nanoscale disks[1] , WENMING JU, UMass Amherst, MADELINE SHORTT, MINA KHAN, JESSICA BICKEL, KATHY AIDALA, Mount Holyoke College, MARK TUOMINEN, UMass Amherst — A ferromagnetic nanodisk, several hundred nanometers in radius and several tens of nanometers in thickness, has in-plane curling magnetization distribution around the center and out-of-plane magnetization vortex core at the center. Here, permalloy disks were patterned by electron-beam lithography. We investigated the in-plane curling magnetization direction (i.e., clockwise or counter-clockwise) by applying a uniform external magnetic field and observing the motion of vortex core via Magnetic Force Microscopy (MFM). We conducted experiments to reverse the in-plane curling direction for the magnetization by applying a circular magnetic field around the disk center with a conducting AFM tip [1]. Micro-magnetic simulations were performed to give a comparison and better understanding of the experimental work.

10:00AM T14.00007 Calculation of energy barriers for magnetic vortices in sub-100 nm dots , PAVEL LAPA, ANDREW KING, IGOR V. ROSHCHIN, Texas A&M University — Interest in switching of magnetic vortices in nanodots is stimulated by their potential application for magnetic memories and nano-oscillators. By combining analytical and micromagnetic techniques, we calculated energy barriers for vortex switching in 20 nm-thick iron dots as a function of applied in-plane field and dot diameter. Using analytical formula for magnetization distribution in the vortex[1], we performed micromagnetic calculations of the dot energy for different vortex core positions. In contrast to the "rigid body approximation," the core size and core shape in our calculations were varied to achieve the energy minimum for every core displacement. The energy barriers required for vortex nucleation and annihilation were calculated as a function of magnetic field. By comparing these barriers to the thermal energy k_BT we obtained the temperature dependences of the vortex nucleation and annihilation fields in good agreement with the experiment.[2] Work is supported by Texas A&M University, TAMU-CONACyT Collaborative Research Program.

10:12AM T14.00008 ABSTRACT WITHDRAWN –

10:24AM T14.00009 Nanomechanical Detection of Magnetic Hysteresis of a Single-crystal Yttrium Iron Garnet Micromagnetic Disk , JOSEPH LOSBY, ZHU DIAO, JACOB BURGESS, SHAWN COMPTON, FATEMEH FANI SANI, Dept. of Physics, University of Alberta and National Institute for Nanotechnology, TAYYABA FIRDOUS, Dept. of Physics, University of Alberta, DOUGLAS VICK, MIRO BELOV, National Institute for Nanotechnology, WAYNE HIEBERT, MARK FREEMAN, Dept. of Physics, University of Alberta and National Institute for Nanotechnology — A micromagnetic disk was milled from a monocrystalline yttrium iron garnet film using a focused ion beam and micromanipulated onto a nanoscale torsional resonator. Nanomechanical torque magnetometry results show a unipolar magnetic hysteresis characteristic of a magnetic vortex state. Landau-Lifshitz-Gilbert-based micromagnetic simulations of the disk show a rich, flux-enclosed, three-dimensional domain structure. On the top and bottom faces of the disk, a skewed vortex state exists with a very small core. The core region extends through the thickness of the disk with a smooth variation in core diameter reaching a maximum along the midplane of the disk. The single crystalline nature of the disk lends to an observed absence of Barkhausen-like steps in the magnetization-versus-field curves, qualitatively different in comparison to the magnetometry results of an individual polycrystalline permalloy microdisk. Prospects for the mechanical detection of spin dynamical modes in these structures will also be discussed.

Thursday, March 21, 2013 8:00AM - 11:00AM –

Session T15 GMAG DMP: Focus Session: Spin Ice and Weakly Disordered Pyrochlores 317 -

Michel Gingras, University of Waterloo

8:00AM T15.00001 Challenges in the collective behaviour of spin ice materials , CLAUDIO CASTELNOVO, TCM group, Cavendish Laboratory, University of Cambridge, RODERICH MOESSNER, Max Planck Institute for the Physics of Complex Systems, GABRIELE SALA, Department of Physics, Royal Holloway University of London, SHIVAJI SONDHI, Department of Physics, Princeton University — The opportunity to observe magnetic monopoles in spin ice materials has driven a significant theoretical and experimental research effort over the past few years. While a broad class of experimental results have confirmed the monopole picture, some experiments continue to present tantalising puzzles which have not yet been possible to resolve via straightforward application of Coulomb liquid theories a la Debye-Hückel. This is illustrated perhaps most strikingly by the departure from the expected asymptotic Arrhenius behaviour of the characteristic relaxation time scales observed at very low temperatures in magnetisation and magnetic susceptibility measurements. Here we investigate some of these phenomena and attempt to identify the necessary extensions of existing theories.

8:12AM T15.00002 NMR relaxation in spin ice at low temperature due to diffusing emergent monopoles[1] , CHRISTOPHER L. HENLEY, Cornell University — At low temperatures, spin dynamics in ideal spin ice is due mainly to dilute, thermally excited magnetic "monopole" excitations. I consider how these will affect the longitudinal (T1) and dephasing (T2) relaxation functions of a nuclear spin in the spin-ice pyrochlore Dy2Ti2O4. Up to the time scale for nearby monopoles to be rearranged, a stretched-exponential form of the relaxation functions is expected, due to averaging over nuclei that have different local environments. ror the dephasing (T2) relaxation, the power of time in the stretched exponential is 3/2 in the case of diffusing monopoles, but 1/2 in the case of fixed, fluctuating magnetic impurities. The flip rate and density of fluctuating spins (whatever their nature) can be extracted from the measured relaxation times T_1 and T_2, and from known parameters. However, the actual experimental relaxation measured by Kitagawa and Takigawa becomes temperature independent in the very low T limit, and the T2 has a power $t^{1/2}$ in the exponential, neither of which can be explained by monopoles. I suggest the very low T behavior could be due to magnetic impurities on the (normally nonmagnetic) Ti sites.

[1]Supported by NSF grant DMR-1005466.

8:24AM T15.00003 Impurities in Spin Ice Crystals , GABRIELE SALA, TCM group, Royal Holloway University of London and ISIS Facility, CLAUDIO CASTELNOVO, TCM group, Cavendish Laboratory, University of Cambridge, JON GOFF, Royal Holloway University of London, MATTHIAS GUTMANN, Rutherford Appleton Laboratory (ISIS Facility), PRABHAKARAN DHARMALINGAM, CM group, Claredon Laboratory, University of Oxford — Spin ice crystals (and pyrochlore oxides in general) have raised a lot of interest of late thanks to their exotic properties, including emergent gauge symmetries, possible spin liquid behavior, and magnetic monopole excitations. Theoretical and experimental efforts in the study of these materials have benefited from the relative ease of growth of large clean single crystals. Even in such clean systems, however, impurities can play a crucial role in determining the properties at very low temperatures (see e.g., C. Henley, http://arxiv.org/abs/1210.8137). Here we investigate this issue both experimentally and theoretically. We study how controlled non-magnetic Y-dilution in $Dy_2Ti_2O_7$ gradually alters the effective monopole description and the thermodynamic properties of the system at low temperature (extending earlier work by other authors to regimes that have not been investigated so far). We also study how oxygen deficiency affects spin ice samples, and we discuss how the oxygen stoichiometry can be quantified and controlled experimentally.

8:36AM T15.00004 Impurity and boundary effects on magnetic monopole dynamics in spin ice , J.B. KYCIA, H.M. REVELL, L.R. YARASKAVITCH, J.D. MASON, Department of Physics and Astronomy, University of Waterloo, Waterloo, Ontario, N2L 3G1, Canada, K.A. ROSS, H.M.L. NOAD, H.A. DABKOWSKA, B.D. GAULIN, Department of Physics and Astronomy, McMaster University, Hamilton, ON, L8S 4M1, Canada, P. HENELIUS, Dept. of Theoretical Physics, Royal Institute of Technology, SE-106 91 Stockholm, Sweden — Using a SQUID magnetometer, we measure the time-dependent magnetic relaxation in Dy2Ti2O7 and find that it decays with a stretched exponential followed by a very slow long-time tail. In a Monte Carlo simulation governed by Metropolis dynamics we find that surface effects and a very low level of stuffed spins (0.30%) - magnetic Dy ions substituted for non-magnetic Ti ions - can explain these signatures in the relaxation. We find that the additional spins trap the magnetic monopole excitations and provide the first example of how defects in a spin-ice material can obstruct the flow of monopoles.

8:48AM T15.00005 Low temperature specific heat measurements of the spin ice material $Dy_2Ti_2O_7$, D. POMARANSKI, Department of Physics and Astronomy, University of Waterloo, Waterloo, Ontario, Canada N2L 3G1, L.R. YARASKAVITCH, University of Waterloo, S. MENG, Department of Physics and Astronomy, University of Waterloo, Waterloo, Ontario, Canada N2L 3G1, K.A. ROSS, H.M.L. NOAD, H.A. DABKOWSKA, B.D. GAULIN, Department of Physics and Astronomy, McMaster University, Hamilton, Ontario, Canada L8S 4M1, J.B. KYCIA, Department of Physics and Astronomy, University of Waterloo, Waterloo, Ontario, Canada N2L 3G1 — Recent work on low temperature magnetization [1] and ac-susceptibility [2] of the spin ice $Dy_2Ti_2O_7$ has revealed a number of inconsistencies with earlier magneto-caloric [3] and thermal relaxation [4] measurements. These unsolved puzzles have motivated us to re-investigate the low temperature specific heat of this material. By measuring the thermal relaxation of $Dy_2Ti_2O_7$, we extract magnetic spin relaxation times and compare them to previous results in the literature.

9:00AM T15.00006 Dipolar Hyperkagome Spin Ice[1] , TRAVIS E. REDPATH, University of Manitoba, JOHN M. HOPKINSON, Brandon University, University of Manitoba, MATTHEW ENJALRAN, PATRICK CARTER, Southern Connecticut State University — Non-magnetic doping of the Pyrochlore spin ices $Dy_2Ti_2O_7$ and $Ho_2Ti_2O_7$ has been shown[2] to exhibit a nonmonotonic residual entropy per spin as a function of doping, with an increase near one quarter doping. Hyperkagome corresponds to a disorder-free one quarter doping of the Pyrochlore lattice with a large residual Pauling entropy $S/N = 1/3\ln(9/2)$. In this talk we discuss the physics of local Ising spins coupled through antiferromagnetic nearest neighbour exchange and a long range dipolar interaction. We generalize the phase diagram[3] of dipolar Pyrochlore spin ice to the Hyperkagome case, finding a crossover to a spin ice state followed by a transition to a charge ordered state and finally a transition to an ordered ground state, as first seen on the Kagome lattice[4]. We show that our hybrid single spin flip/loop algorithm Monte Carlo simulations agree with analytical results for small sizes, and present results for systems as large as $12 * L^3$ spins with $L = 4$.

9:12AM T15.00007 Disordered Quantum Spin Ice Ground State of $Tb_2Sn_{2-x}Ti_xO_7$, JIMIN ZHANG, McMaster University, B.D. GAULIN, McMaster University, Canada, M.L. DAHLBERG, M.J. MATTHEWS, Pennsylvania State University, USA, F. BERT, E. KERMARREC, Universite Paris-Sud 11, France, K. FRITSCH, McMaster University, G.E. GRANROTH, Oak Ridge National Laboratory, USA, P. JIRAMONGKOLCHAI, Princeton University, USA, A. AMATO, C. BAINES, Paul Scherrer Institut, Switzerland, R.J. CAVA, Princeton University, USA, P. MENDELS, Universite Paris-Sud 11, France, P. SCHIFFER, Pennsylvania State University, USA — Inelastic neutron scattering, AC magnetic susceptibility and μSR measurements have been performed on polycrystalline solid solutions of the pyrochlore magnet, $Tb_2Sn_{2-x}Ti_xO_7$ for seven samples with x between 0 and 2. These measurements probe the crystal field states, low energy spin dynamics and phase behavior to temperatures less than 0.1K. $Tb_2Ti_2O_7$ is proposed to display a quantum variant of the spin ice ground state, stabilized by virtual excitations between the Tb^{3+} crystal field ground state doublet and its low lying excited state doublet. Isostructural, $Tb_2Sn_2O_7$, displays "soft" spin ice order and its Tb^{3+} ground and excited crystal field states are known to be interchanged relative to those in $Tb_2Ti_2O_7$. These measurements of the solid solutions of $Tb_2Sn_{2-x}Ti_xO_7$ focus on crystal field excitations between 1meV and 50meV, and show greatly enhanced spin dynamics at low energies for samples with intermediate x. All magnetic order is absent for x>0.1, leaving behind a highly fluctuating, disordered spin ice ground state.

9:24AM T15.00008 Antiferromagnetic Spin Ice Correlations at (1/2,1/2,1/2) in the Ground State of the Pyrochlore Magnet $Tb_2Ti_2O_7$, K. FRITSCH, Dept. of Physics and Astronomy, McMaster Univ., K.A. ROSS, McMaster Univ., now Johns Hopkins Univ. and NCNR NIST, Y. QIU, J.R.D. COPLEY, NCNR NIST, T. GUIDI, R.I. BEWLEY, ISIS, H.A. DABKOWSKA, Brockhouse Institute for Materials Research, B.D. GAULIN, Dept. of Physics and Astronomy, McMaster Univ., and Brockhouse Institute for Materials Research — The ground state of the candidate spin liquid pyrochlore magnet $Tb_2Ti_2O_7$ (TTO) has been long debated. Despite theoretical expectations of magnetic order below 1K based on classical Ising-like Tb spins, muSR and neutron scattering experiments show no long range order down to 50mK. Two theoretical scenarios have been put forward to account for this: the quantum spin ice scenario and a non-magnetic singlet ground state, but no clear consensus has been reached. We present neutron scattering measurements on TTO at 70mK that reveal elastic scattering intensity at (1/2,1/2,1/2) positions in reciprocal space[1]. The corresponding spin configuration can be modeled as a short-range antiferromagnetically ordered spin ice, in which spins obey a variant of the ice rules in each unit cell, and flip directions between adjacent cells. At low temperatures, this elastic scattering is separated from low-lying magnetic inelastic scattering by $\sim$0.05meV. The elastic signal disappears under the application of small magnetic fields and upon elevating temperature. Pinch-point-like elastic diffuse scattering is observed, which together with the elastic spin ice correlations strongly supports the quantum spin ice picture for TTO. [1] K. Fritsch et al., arXiv:1210.1242[cond-mat.str-el]

9:36AM T15.00009 Low-Temperature Low-Field Phases of the Pyrochlore Quantum Magnet $Tb_2Ti_2O_7$, LIANG YIN, JIAN SHENG XIA, YASU TAKANO, NEIL SULLIVAN, University of Florida, QIU JU LI, XUE FENG SUN, University of Science and Technology of China — By means of ac magnetic-susceptibility measurements, we have found evidence for a new magnetic phase of $Tb_2Ti_2O_7$ below about 140 mK in zero magnetic field. In magnetic fields parallel to [111], this phase—exhibiting frequency- and amplitude-dependent susceptibility and an extremely slow spin dynamics—extends to about 70 mT, at which it gives way to another phase. The field dependence of the susceptibility of this second phase, which extends to about 0.6 T, indicates the presence of a weak magnetization plateau below 50 mK, as has been predicted by a single-tetrahedron four-spin model, giving support to the underlying proposal that the disordered low-field ground state of $Tb_2Ti_2O_7$ is a quantum spin ice.

9:48AM T15.00010 Glassiness in single crystalline $Y_2Mo_2O_7$[1] , CHRISTOPHER WIEBE, University of Winnipeg/University of Manitoba — The spin glass transition at $T_g = 22$ K in the pyrochlore $Y_2Mo_2O_7$ has remained an enigma in condensed matter physics for over two decades. Despite the results of many experiments which indicate a freezing of the Mo^{4+} spins at low temperatures, a consistent theoretical framework has not been reached to describe how this can occur in the absence of large amounts of chemical disorder. We report on the synthesis of the world's first high quality single crystal of this compound, and its characterization using a variety of thermodynamic and scattering probes. Some of the new results include a non-linear magnetic heat capacity at low temperatures, the presence of liquid-like elastic scattering within the glassy state, and high-Q scattering consistent with orbital or chemical disorder. Possible candidates for the low-T ground state will be discussed.

[1]Support for this work is acknowledged from NSERC, CFI, the CRC program, the NSF and the DOE.

10:24AM T15.00011 Monopole Hopping through Quantum Spin Tunnelling in Spin Ice , BRUNO TOMASELLO, University of Kent & ISIS, GABRIELE SALA, Royal Holloway University of London & ISIS, JORGE QUINTANILLA, University of Kent & ISIS, CLAUDIO CASTELNOVO, Cambridge University, Royal Holloway University of London & ISIS, SEAN GIBLIN, Cardiff University & ISIS, RODERICH MOESSNER, Max Planck Institute for the Physics of Complex Systems — The low temperature dynamics in spin ice materials is governed by the density and mobility of elementary excitations that behave as emergent magnetic monopoles. The diffusion of such monopoles proceeds via flipping of large electronic spins with Ising-like anisotropy (due to their crystal field environment). Experimental evidence suggests that, at temperatures relevant for spin ice physics, this flipping occurs as a quantum-mechanical tunnelling through a large anisotropy barrier. Here we investigate this process at the microscopic, single-ion level by computing the quantum dynamics resulting from the interplay between the crystal field Hamiltonian and the Zeeman coupling with magnetic fields (either applied or due to other spins). We interpret our results in terms of monopole hopping rates, and we compare our predictions with existing experiments for both Ho2Ti2O7 and Dy2Ti2O7.

10:36AM T15.00012 Numerical Study of Perturbations in Dipolar Spin Ice , TAORAN LIN, University of Waterloo, JAAN ALTOSAAR, McGill University, PATRIK HENELIUS, KTH Royal Institute of Technology, MICHEL GINGRAS, University of Waterloo — Competing interactions in geometrically frustrated magnets can lead to highly degenerate and non-trivially correlated ground states. One topical example, the spin ice compound $Dy_2Ti_2O_7$, exhibits such a ground state which possesses a Pauling's residual entropy analogous to that of water ice. At temperatures well below the temperature scale set by the frustrated and dominant dipolar interactions, the material displays a classical spin liquid like state. As a result, small perturbations may become significant for the low temperature physics. In this project we consider perturbations from further neighbor interactions and from stuffing impurities in an attempt to account for some of the observed experimental low temperature behaviors. In particular, we determine the third neighbor interactions using Monte Carlo (MC) simulations by fitting to experimental data in a magnetic field near the [112] direction. The effects on the zero-field specific heat due to variation of the exchange parameters are studied using a cumulant method in conjunction with the MC simulations. We also studied the effects of stuffing Dy magnetic ions on the Ti site, which can trigger large variations in the equilibrium value of the specific heat below temperatures of 0.5K.

10:48AM T15.00013 Synthesis and Characterization of New Germanate Pyrochlores, $A_2Ge_2O_7$ (A = Tb, Yb, Er) , ALANNAH HALLAS, Department of Chemistry, University of Manitoba, HAIDONG ZHOU, Department of Physics and Astronomy, University of Tennessee, ANGEL AREVALO LOPEZ, University of Edinburgh, HARLYN SILVERSTEIN, Department of Chemistry, University of Manitoba, J. PAUL ATTFIELD, University of Edinburgh, CHRISTOPHER WIEBE, Department of Chemistry, University of Winnipeg — The titanate pyrochlores, $A_2Ti_2O_7$, have yielded some of the most well-studied geometrically frustrated magnetic materials. A new class of pyrochlores with germanium on the B-site is now being investigated. The germanates, which in many cases share ground states with their titanate analogues, are far more highly correlated due to the smaller B-site cation. Two germanate pyrochlores, $Ho_2Ge_2O_7$ and $Dy_2Ge_2O_7$, were previously synthesized and characterized as new spin ice compounds [1-3]. We now present the new germanate pyrochlores, $A_2Ge_2O_7$ with A = Tb, Yb, and Er. Based on the titanates, three distinctly different magnetic ground states can be expected for these materials: $Er_2Ti_2O_7$ has an "order-by-disorder" mechanism, $Yb_2Ti_2O_7$ is a quantum spin ice and $Tb_2Ti_2O_7$ is a spin liquid. Preliminary measurements on $Tb_2Ge_2O_7$ indicate that it too is a spin liquid down to at least 0.35 K. We will present the characterizations of $A_2Ge_2O_7$ (A = Tb, Yb, Er) and compare them to the titanates.

Session T16 GPC DFD: Climate Physics / Instabilities and Turbulence 318 - James Brasseur, Pennsylvania State University

8:00AM T16.00001 Simultaneous measurement of sphericity and scattering phase functions from single atmospheric aerosol particles in Las Cruces, NM , SEAN MARTIN, KEVIN APTOWICZ, West Chester University, YONG-LE PAN, US Army Research Laboratory, RICHARD CHANG, Yale University, RONALD PINNICK, US Army Research Laboratory — We report upon the collection of elastic light scattering patterns with high angular resolution and large angular coverage from single atmospheric aerosol particles in Las Cruces, NM. Radiative forcing due to aerosols is a primary source of uncertainty in climate models. Characterization of tropospheric aerosols is carried out by inversion of optical measurements made remotely by land-based instruments and satellites. An integral part of the retrieval procedure is accounting for particle shape (i.e. nonsphericity). In-situ and laboratory measurements of aerosol particles play a critical role in validating and constraining the inversion procedure used in climate models. In this work, we utilize high angular resolution and large angular coverage scattering patterns to simultaneously calculate particle sphericity and the scattering phase of individual atmospheric particles. We examine the relationship between a particle's sphericity and its phase function. In addition, we explore the differences in phase function between nonspherical particles that have high sphericity (i.e. complex particles with overall round shape) and spherical particles. We conclude by commenting on the possible impacts of our findings on inversion procedures used in aerosol characterization.

8:12AM T16.00002 Measurement of aerosol optical properties by integrating cavity ring-down spectroscopy and nephelometery[1] , GETACHEW TEDELA, SUJEETA SINGH, MARC FIDDLER, SOLOMON BILILIGN, North Carolina A&T State University — Accurate measurement of optical properties of aerosols is crucial for quantifying the influence of aerosols on climate. Aerosols that scatter and absorb radiation can have a cooling or warming effect depending on the magnitude of the respective scattering and absorption terms. One example is black carbon known for its strong absorption. The reported refractive indices for black carbon particles range from 1.2+0i to 2.75+1.44i. Our work attempts to measure extinction coefficient, and scattering coefficient of black carbon particles at different incident beam wavelengths using a cavity ring-down spectrometer and a Nephelometer and compare to Mie theory predictions. We report calibration results using polystyrene latex spheres and preliminary results on using commercial black carbon particles.

8:24AM T16.00003 Non-Condensable Gas Absorption by Capillary Waves , MATTHIEU A. ANDRE, PHILIPPE M. BARDET, The George Washington University — Oceans and atmosphere are constantly exchanging heat and mass; this has a direct consequence on the climate. While these exchanges are inherently multi-scales, in non-breaking waves the smallest scales strongly govern the transfer rates at the ocean-atmosphere interface. The present experimental study aims at characterizing and quantifying the exchanges of non-condensable gas at a sub-millimeter scale, in the presence of capillary waves. In oceans, capillaries are generated by high winds and are also present on the forward face of short gravity waves. Capillary waves are thus present over a large fraction of the ocean surface, but their effect on interphase phenomena is little known. In the experiment, 2D capillary waves are generated by the relaxation of a shear layer at the surface of a laminar water slab jet. Wave profile is measured with Planar Laser Induced Fluorescence (PLIF) and 2D velocity field of the water below the surface is resolved with Particle Image Velocimetry (PIV). Special optical arrangements coupled with high speed imaging allow 0.1 mm- and 0.1 ms- resolution. These data reveal the interaction of vorticity and free surface in the formation and evolution of capillaries. The effect of the capillaries on the transfer of oxygen from the ambient air to anoxic water is measured with another PLIF system. In this diagnostic, dissolved oxygen concentration field is indirectly measured using fluorescence quenching of Pyrenebutyric Acid (PBA). The three measurements performed simultaneously -surface profile, velocity field, and oxygen concentration- give deep physical insights into oxygen transfer mechanisms under capillary waves.

8:36AM T16.00004 The relation between the statistics of open ocean currents and the temporal correlations of the wind-stress , GOLAN BEL, YOSEF ASHKENAZY, Ben-Gurion University of the Negev — We study the statistics of wind-driven open ocean currents. Using the Ekman layer model for the integrated currents, we investigate, analytically and numerically, the relation between the wind-stress distribution and its temporal correlations and the statistics of the open ocean currents. We find that temporally long-range correlated wind results in currents whose statistics is proportional to the wind-stress statistics. On the other hand, short-range correlated wind leads to Gaussian distributions of the current components, regardless of the stationary distribution of the winds, and therefore, to a Rayleigh distribution of the current amplitude, if the wind-stress is isotropic. We find that the second moment of the current speed exhibits a maximum as a function of the correlation time of the wind-stress for a non-zero Coriolis parameter. The results were validated using an oceanic general circulation model.

8:48AM T16.00005 Stochastic Parameterization of Ocean Mesoscale Eddies , LAURE ZANNA, LUCA MANA, University of Oxford — Processes smaller than the model resolution or faster than the model time step are parameterized in climate simulations using deterministic closure schemes. Yet, several subgrid-scale processes are turbulent and potentially best represented by stochastic closures. The goal of our study is to construct a stochastic parameterization of mesoscale eddies in ocean models. The output of a quasi-geostrophic model in a double-gyre configuration with horizontal resolution of 7.5 km (eddy-resolving resolution) is used as the "truth". A coarse-graining methodology is employed on this output to compute "eddy fluxes" tendencies appropriate to the grid scale of a coarse resolution model. The tendencies are binned into different ranges of mean flow and mean shear strength related to the eddy life cycle in order to obtain probability distribution functions (PDFs). The PDFs for the coarse-grained tendencies show that the temporal and spatial eddy fluxes cannot be captured by current downgradient deterministic parameterizations. We rely on the PDFs to implement a novel stochastic parameterization into a coarse resolution model. We show and discuss the impact of this new parameterization on the mean flow and its fluctuations.

9:00AM T16.00006 Nonlinear Scale Interactions and Energy Pathways in the Ocean , HUSSEIN ALUIE, MATTHEW HECHT, LANL, GEOFFREY VALLIS, KIRK BRYAN, Princeton/GFDL, MATHEW MALTRUD, ROBERT ECKE, BETH WINGATE, LANL — Large-scale currents and eddies pervade the ocean and play a prime role in the general circulation and climate. The coupling between scales ranging from $O(10^4)$ km down to $O(1)$ mm presents a major difficulty in understanding, modeling, and predicting oceanic circulation and mixing, where the energy budget is uncertain within a factor possibly as large as ten. Identifying the energy sources and sinks at various scales can reduce such uncertainty and yield insight into new parameterizations. To this end, we refine a novel coarse-graining framework to directly analyze the coupling between scales. The approach is very general, allows for probing the dynamics simultaneously in scale and in space, and is not restricted by usual assumptions of homogeneity or isotropy. We apply these tools to study the energy pathways from high-resolution ocean simulations using LANL's Parallel Ocean Program. We examine the extent to which the traditional paradigm for such pathways is valid at various locations such as in western boundary currents, near the equator, and in the deep ocean. We investigate the contribution of various nonlinear mechanisms to the transfer of energy across scales such as baroclinic and barotropic instabilities, barotropization, and Rossby wave generation.

9:12AM T16.00007 Suppressing Rayleigh-Taylor Instability with rotation[1] , MATTHEW SCASE, RICHARD HILL, KYLE BALDWIN, University of Nottingham — The stabilizing effects of rotation upon many instabilities are well known. We demonstrate how the Rayleigh-Taylor instability (RTI) in a two-layer fluid may be stabilized by rotating the fluid, and present a critical rotation rate for such stabilization. We show that, in contrast to non-rotating RTI, there is a fundamental difference between placing heavy fluid above a light fluid (unstable arrangement) and simply accelerating a stable arrangement (light above heavy) at a rate greater than gravity vertically downwards. We propose to show novel experiments, conducted using high-powered superconducting magnets (18.7 T), supporting the theoretical predictions. We believe these to be the first experiments to investigate the effects of rotation upon RTI and they exploit the use of the magnetic field that removes the need for a physical barrier when initializing the experiment. Potential applications for the research lie not only in fundamental fluid mechanics, but also in astrophysical applications where RTI is observed (e.g. Crab Nebula) and other strategic applications.

[1]Supported under EPSRC Grant EP/K50354X/1.

9:24AM T16.00008 Inverse Energy cascade in 3D Navier-Stokes eqs , LUCA BIFERALE, University of Rome "Tor Vergata", Italy, STEFANO MUSACCHIO, CNRS-Nice, France, FEDERICO TOSCHI, Applieed Physics, TUE, The Netherlands, ICTR COLLABORATION — We study the statistical properties of homogeneous and isotropic three-dimensional (3D) turbulent flows. We show that all 3D flows in nature possess a subset of possible non-linear evolution leading to a reverse energy transfer: from small to large scales. Up to now, such inverse cascade was only observed in flows under strong rotation and in quasi two-dimensional geometries under strong confinement. We show here that energy flux is always reversed when mirror symmetry is broken leading to a distribution of helicity in the system with a well defined sign at all wavenumbers. Our findings broaden the range of flows where inverse energy cascade may be detected and rationalize the role played by helicity in the energy transfer process showing that both 2D and 3D properties naturally coexist in all flows in nature.

9:36AM T16.00009 Rotation rate of tracer and long rods in turbulence , SHIMA PARSA, GREG VOTH, Wesleyan University — We study the rotational dynamics of single rod-like particles ranging from tracer rods to long rods and quantify the effects of length of rod on its rotation rate in turbulent flow. The orientation and position of rods are measured experimentally using Lagrangian particle tracking with images from multiple cameras in a flow between two oscillating grids. Rods rotate due to the velocity gradient of the flow and also develop alignment with the directions of the velocity gradient tensor as they are carried by the flow. Small tracer rods rotate due to the velocity gradient of the smallest eddies that produce the largest shear rate while longer rods average over length-scales smaller than their size to eddies order of their own length-scales. The rotation rate variance gets smaller as the length of the rod increases.

9:48AM T16.00010 ABSTRACT WITHDRAWN –

10:00AM T16.00011 Intermittency in 2D Turbulence , WALTER GOLDBURG, RORY CERBUS, Department of Physics and Astronomy, University of Pittsburgh — The existence of intermittency in three-dimensional turbulence is generally accepted, although with a variety of interpretations. However, the issue of intermittency in two- dimensional turbulence is unresolved. By measuring the velocity in a flowing soap film, we show that there is significant intermittency in both the enstrophy and energy cascades. The intermittency is characterized by the scaling exponents of velocity structure functions $S_n(r)$ as well as the flatness F of velocity derivatives. Both show a strong Reynolds number dependence. However, unlike turbulence in three dimensions, the intermittency decreases with increasing Reynolds number. This work is supported by NSF grant No. 1044105, a Mellon fellowship, and the Okinawa Institute of Science and Technology.

10:12AM T16.00012 From a Desingularized Vortex Sheet Model to a Turbulent Mixing Layer , UJJAYAN PAUL, RODDAM NARASIMHA, Jawaharlal Nehru Centre for Advanced Scientific Research (JNCASR) — The temporal mixing layer is studied using the model of a slightly perturbed vortex sheet which is unstable and tends to roll-up in a spiral. The flow is inviscid and incompressible. A point vortex model tends to evolve into a chaotic cloud of point vortices instead of a smooth double branched spiral. The vortex sheet model is derived (in closed form) from the basic equations of vortex dynamics. The problem of finite time singularity is handled by a technique that invokes longitudinal circulation density diffusion along the sheet at singular points. The present model uses linear segments to interpolate the sheet. Although it is computationally involved compared to point vortices, the vortex sheet does not get distorted and rolls-up into a smooth double branched spiral. The accuracy of such simulations can be independently verified by using the laws of vortex dynamics and conserved quantities. We observe the growth of the two-dimensional shear layer with time and the merger of vortex like structures. The dependence of the mixing layer on the initial conditions is studied in detail and tries to answer the question whether the vortex sheet model yields a turbulent mixing layer.

10:24AM T16.00013 Return to isotropy in high Reynolds number turbulent shear flow , CHERYL KLIPP, US Army Research Laboratory — Given that turbulence decays from large scales to smaller scales, and that large scales are anisotropic and the smallest scales are isotropic, can the results of return to isotropy experiments be applied to the cascade of turbulence from large scales to small scales? If energy is added to the system only at larger scales, then probably yes. For atmospheric flow over relatively open and flat terrain (Kansas), the 'decay' of turbulence progresses from fairly anisotropic at the large scales (maximum turbulent kinetic energy) toward pure isotropy at smaller scales via pancake-like axisymmetry. The smallest scale resolvable by the instrumentation is on the order of 1m, so dissipation scales are not evaluated. The flows with cigar-like axisymmetry occur inside an urban canyon. In these cases it is not clear if turbulence is generated at only the maximum turbulent kinetic energy scale. The turbulence at larger scales possesses a strong cigar-like axisymmetry, but can often progress to pancake-like axisymmetry at smaller scales.

10:36AM T16.00014 Information Content of Turbulence , RORY CERBUS, WALTER GOLDBURG, Department of Physics and Astronomy, University of Pittsburgh — This work is one of the few attempts to treat turbulence as an information source that can be controlled experimentally. As the Reynolds number Re is increased, more degrees of freedom are excited and participate in the turbulent cascade. One might therefore expect that on raising Re, the system becomes more random, thereby increasing the Shannon entropy H. However, because the excited modes are correlated, H is a *decreasing* function of Re, as is experimentally shown in a study of turbulence in a flowing soap film. A parallel analysis was made of the logistic map, where H is calculated as a function of the control parameter r in the equation $x_{n+1} = rx_n(1-x_n)$. There, as expected, H is an increasing function of r. This work is supported by NSF grant No. 1044105, a Mellon fellowship, and the Okinawa Institute of Science and Technology.

10:48AM T16.00015 A hypothesis on nanodust as a source of energy for extreme weather events and climate changes , SIMON BERKOVICH, The George Washington University — There are many phenomena that attract energy, the source of which cannot be unerringly identified. Among those are: excess heat alleged to nuclear processes, sonoluminescence, wire fragmentation under high voltage pulses, diverse biophysical experiences, and some atmospheric effects, like ball lightning and terrestrial gamma rays. Destructive atmospheric events associated with intense air movements, such as hurricanes and tornadoes, expend huge amounts of energy equivalent to very many nuclear bombs. Our paper [1] indicates a possibility for a new source of energy due to the so-called "hot-clocking" effect related to the holographic mechanism of the Universe that establishes the exclusive property of nonlocality. This may uncover energy in various unusual appearances, particularly, in the suspected trend of global warming as a direct contribution to the extreme weather events. The surmised clocking impacts from holographic reference beam can reveal themselves through gaseous aerosols and suspended contaminants that may have been increased with human technogenesis. According to recent EPRI report nanopowder for Ni-Pd alloys in the size range of 5–10 nm was found to cause small amounts of excess power, about 4 watt per gram. So, using a minimal norm of contamination (20 micrograms per cubic meter) as an approximate guide, we could estimate that the whole atmosphere would thus generate dozens of terawatts, a contribution comparable to that of the Sun. [1] S.Berkovich, "Generation of clean energy by applying parametric resonance to quantum nonlocality clocking", **Nanotech,** 2011 Vol. 1, pp.771-774

Thursday, March 21, 2013 8:00AM - 11:00AM –

Session T17 GMAG: Magnetic Alloys and Multilayers 319 - Masatoshi Onoue, Northwestern University

8:00AM T17.00001 Phase stability, ordering, and magnetism of single-phase fcc Fe-Au alloys , JOONHEE M. AN, University of Nebraska-Lincoln, SERGEY V. BARABASH, Intermolecular Inc., KIRILL D. BELASHCHENKO, University of Nebraska-Lincoln — Motivated by experimental evidence of $L1_0$ ordering in single-phase fcc Fe-Au nanoparticles, we study the structural thermodynamics of Fe-Au alloys. First, separate cluster expansions for fcc and bcc lattices are constructed for fully optimized ferromagnetic structures using density functional theory calculations. The optimized structures were assigned to fcc or bcc lattice by a structural filter. Although the lowest formation enthalpy at 50% Au is reached in the bcc lattice, the fcc lattice is preferred for the random alloy. Dynamical stability of specific orderings strongly depends on the magnetic configuration. To analyze the ordering tendencies of the fcc alloy, we restrict uniform lattice relaxations and separate the contributions of chemical interaction and local relaxations. By using the effective tetrahedron model (Ruban *et al.*, Phys. Rev. B 67, 214302 (2003)) and explicit calculations for ordered and special quasi-random structures, we find that the local relaxation energies depend weakly on the magnetization. Although the $L1_0$ ordering is the ground state at 50% Au on the ideal lattice, local relaxations make it unfavorable compared to the random alloy. Moderate compression due to the size effect tends to slightly stabilize the $L1_0$ ordering.

8:12AM T17.00002 First-principles study of magnetic properties of Fe-Ni based alloys[1] , M. ONOUE, G. TRIMARCHI, A.J. FREEMAN, Northwestern U., Evanston (IL) — Investigations of the magnetic properties of Fe-Ni based alloys are important from the fundamental as well as technological points of view. Furthermore, the magnetization at saturation and Curie temperature ($T_{\rm C}$) of FeNi can be tuned for specific applications by alloying with other metallic species. We have performed electronic structure calculations on Fe-Ni-M alloys, where M are 3d transition metals, to determine how the magnetization depends on the species M and alloy composition. Electronic band structure and total energies are calculated by the Korringa-Kohn-Rostoker method within the coherent-potential-approximation (KKR-CPA). For the KKR-CPA calculations, we use the generalized gradient approximation of the exchange and correlation functional. In the case of $Fe_{0.50}Ni_{0.45}M_{0.05}$ (M=Sc, Ti, V, Cr, Mn, and Co), the early 3d atoms have antiparallel magnetic moments to the Fe or Ni, whereas the late ones, Mn and Co, have a parallel magnetic moment.

[1]Supported by the NU-Boeing Alliance

8:24AM T17.00003 FeCo-based permanent magnet materials search by genetic algorithm , CAI-ZHUANG WANG, MANH CUONG NGUYEN, XIN ZHAO, KAI-MING HO, Ames Laboratory, US DOE and Department of Physics and Astronomy, Iowa State University, Ames, Iowa 50011, USA — FeCo alloy is well-known soft magnetic material with high magnetic moment, 2.5 μ_B/atom at $\sim$ 30 wt. % Co. However, doping FeCo alloys with heavy 5d transition metal and mix FeCo phase with nomagnetic structure of AlNi (e.g., Alnico) would increase the coercivity of the alloys. In order to gain more insight into the enhancement of the magnetic anisotropy in FeCo by doping or mixing, we have investigated the stable and metastable crystal structures of Fe-Co-W and Fe-Co-Al-Ni systematically over a wider range of composition by adaptive genetic algorithm method. Our search results show that the Fe-rich FeCoW alloys are all in bcc structures with W prefer substituting Fe sites. The Fe-Co-Al-Ni structures are also found to be in bcc lattice with broad chemical variation across the FeCo and AlNi interface. The magnetic properties in these stable and metastable structures are also calculated and the microscopic mechanism for the enhancement of magnetic anisotropy is discussed.

8:36AM T17.00004 Unusually sharp paramagnetic phase transition in thin film Fe_3Pt invar , JASPER DRISKO, JOHN CUMINGS, University of Maryland — Invar alloys, typically 3d transition metal rich systems, are most commonly known for their extremely low coefficients of thermal expansion (CTE) over a wide range of temperatures close to room temperature. This anomalous behavior in the CTE lends Invar to a variety of important applications in precision mechanical devices, scientific instruments, and sensors, among others. Many theoretical models of Invar have been proposed over the years, the most promising of which is a system described by two coexisting phases, one high-spin high-volume and the other low-spin low-volume, that compete to stabilize the volume of the material as the temperature is changed. However, no theory has yet been able to explain all experimental observations across the range of Invar alloys, especially at finite temperature [1]. We have fabricated thin films of a Fe_3Pt Invar alloy and investigate them using Lorentz Transmission Electron Microscopy (TEM). 23nm films are deposited onto SiN membrane substrates via radio-frequency magnetron sputtering from a pure Fe target decorated with Pt pieces. We observe novel magnetic domain structures and an unusually sharp phase transition between ferromagnetic (FM) and paramagnetic (PM) regions of the film under a temperature gradient. This sharp transition suggests that the FM-to-PM transition may be first order, perhaps containing a structural-elastic component to the order parameter. However, electron diffraction reveals that both the FM and PM regions have the same FCC crystal structure.

8:48AM T17.00005 Predicting magnetostructural trends in equiatomic FeRh-based ternary systems[1] , RADHIKA BARUA, FELIX JIMENEZ-VILLACORTA, LAURA H. LEWIS, Department of Chemical Engineering, Northeastern University, NANOMAGNETISM GROUP TEAM — A phenomenological model is proposed to predict the influence of elemental substitution on the magnetostructural transition temperatures and Curie temperatures of nominally-equiatomic FeRh-based compounds with the B2 (CsCl)-type crystal structure. Clear trends in the characteristic magnetic transition temperatures, as reported in the literature, are found as a function of the averaged weighted valence band electrons ($(s+d)$ electrons/atom) in compounds of composition $Fe(Rh_{1-x}M_x)$ or $(Fe_{1-x}M_x)Rh$ (M = $3d$, $4d$ or $5d$ transition metals). Substitution of $3d$ or $4d$ elements ($\leq$ 6.5 atomic %) into B2-type FeRh causes the magnetostructural transition temperature T_t to increase to a maximum around a critical valence band electron concentration of 8.5 electrons/atom and then decrease. Substitution of $5d$ transition metal atoms echoes this trend but shifts it to higher transition temperatures. These data and associated trends allow deductions that the stability of the ground state antiferromagnetic phase of the FeRh-based system depends both on the size of the constituent atoms as well as the character of the valence electrons.

9:00AM T17.00006 Development of Magnetic Materials Based on the Ordered $Fe_{50}Ni_{50}$ Phase: Methodologies and Results[1] , ERIC POIRIER, MEDA Engineering and Technical Services, MISLE M. TESSEMA, Optimal CAE, MARTIN S. MEYER, FREDERICK E. PINKERTON, General Motors Global RD — The $L1_0$ FeNi structure known as tetrataenite, usually found in meteorites, is reported to possess significant magnetocrystalline anisotropy suitable for hard magnetic properties. As part of the ongoing Advanced Research Project Agency-Energy project on FeNi-based magnets, melt-spinning was used to synthesize new FeNi precursors. The melt-spinning conditions were established in terms of wheel speed, ejection pressure, and atmosphere composition and pressure. The as-spun ribbons have a cubic crystal structure with a=3.584 $\pm$ 0.002 Å, and (100) preferred grain orientation perpendicular to the ribbon. They also behave like soft magnetic materials, with coercitivities below 0.3 kOe. DSC response curves were essentially featureless, except for a thermal signature at about 515 °C associated with the Curie temperature. In contrast, melt-spun FeNi ribbons that were subsequently ball-milled and annealed exhibited a more complex thermal behavior compared to the as-spun ribbons with a weak endotherm in the 300-350 °C range followed by an exotherm at higher temperatures. These results are discussed in the context of a search for an order-disorder phase transition associated with the $L1_0$ phase, and preferred properties for permanent magnet applications. Although $L1_0$ phase formation was not observed at this point, the techniques established for processing FeNi will be further studied on modified FeNi alloys as a promising route to obtain the $L1_0$ phase.

9:12AM T17.00007 Combinatorial Approach for High-efficiency Magnetization Measurements of Co-Fe-Ni Alloys with a Scanning Hall Probe Microscope , GIRFAN SHAMSUTDINOV, DEBABRATA MISHRA, BORIS NADGORNY, Wayne State University, PENG ZHAO, JI-CHENG ZHAO, Ohio State University, SREENIVAS BHATTIPROLU, Oxford Instruments America Inc. — A Scanning Hall Probe Microscope with a submicron scale Hall probe (HP) was used for high efficiency measurements of magnetic properties of Co-Fe diffusion couples. Co-Fe couples were made by placing Co and Fe blocks in an intimate contact and annealing at high temperature to allow thermal interdiffusion to create solid-solution with a composition varying gradually from pure Fe to pure Co. The magnetic field in the vicinity of these variable composition Fe-Co alloys, with the width of approximately 400 microns, was measured continuously as the HP was scanned across the interdiffusion region. Using a simple model, we determined the composition dependent saturation magnetizations of Co-Fe alloys. The values of the saturation magnetization were in good agreement with the known values for pure Fe and Co. The composition variation and the crystal structure along the scan line were measured independently using Energy Dispersive X-ray Spectroscopy (EDS) and Electron Backscatter Diffraction (EBSD). Similar measurements were performed for the Fe-Ni and Co-Ni interfaces. This study demonstrates that Scanning Hall microscopy can be used for high efficiency and high accuracy measurements of saturation magnetization in variable composition alloys.

9:24AM T17.00008 Tuning magnetic anisotropy in Fe/Pt multilayers on Pt(001) by surface charging , PEDRO RUIZ-DIAZ, VALERI STEPANYUK, Max Planck Institute of Microstructure Physics, Weinberg 2, 06120 Halle (Saale), Germany — Magnetic anisotropy of nanoscale systems has recently received considerable attention from both experimentally and theoretically perspectives. Diverse ways of manipulating the anisotropy have been sought and found. Those include alloying, external electric field exposure and electrolyte charging. However, the hunt for a system that would exhibit a large anisotropy and be easy to manipulate at the same time is still on. By using density functional theory tools, we study the magnetic anisotropy of Fe/Pt multilayers on Pt(001). Our fully relativistic *ab initio* calculations demostrate that the value of magnetic anisotropy energy (MAE) strongly depends on the composition of Fe/Pt multilayers, achieving remarkable large values for systems featuring Fe layers capped with Pt. For instance, positive charging of a Fe slab capped with Pt enhances significantly the MAE. More intriguing is the behavior of Fe bilayers, for which surface charging does not only change the value of the anisotropy but can also lead in the switching of the easy axis. To understand the physics underlying this behavior of MAE, we analyze the electronic structure of the system by means of the second-order perturbation theory linking MAE to the local density of electronic states near the Fermi level.

9:36AM T17.00009 ABSTRACT WITHDRAWN –

9:48AM T17.00010 Investigation of the atomic structure of Zr_2Co_{11} , XIN ZHAO, MANH CUONG NGUYEN, LIQIN KE, VLADIMIR ANTROPOV, CAI-ZHUANG WANG, KAI-MING HO, Ames Laboratory, US DOE and Department of Physics and Astronomy, Iowa State University, Ames, Iowa 50011, USA — The compound known as Zr_2Co_{11} is a ferromagnet with high uniaxial anisotropy. Although a lot of experimental work has been done on this compound, its crystal structure is still unsolved. We performed adaptive Genetic Algorithm (GA) search on its atomic structure, in order to have a better understanding of this compound. The validity of our method was verified by locating all the stable phases in Zr-Co alloy system. The search for Zr_2Co_{11} was performed with up to 117 atoms per unit cell and a narrow composition window near 15.38% Zirconium was explored. We found that Zr_2Co_{11} compound has a structure derived from $CaCu_5$ prototype and complex mixed phases can be formed. Simulated XRD and TEM patterns of our models are in agreement with the experimental results. Calculated magnetic properties provide explanations of the high uniaxial anisotropy in this system.

10:00AM T17.00011 Atomic structure and magnetic properties of $HfCo_7$ alloy , MANH CUONG NGUYEN, XIN ZHAO, LIQIN KE, VLADIMIR ANTROPOV, CAI-ZHUANG WANG, KAI-MING HO, Ames Laboratory, US DOE and Department of Physics and Astronomy, Iowa State University, Ames, Iowa 50011, USA — Low energy atomic structures of $HfCo_7$ alloys were searched by adaptive generic algorithm with unit cell up to 48 atoms. We found some different motifs existing in other magnetic systems in low energy structures for unit cell with 16 and 32 atoms. When the unit cell size is bigger than 40 atoms, we observed structures with phase separation into pure hcp Co and Hf_2Co_7 in agreement with phase diagram. Magnetic properties calculations were performed to investigate the relationship between the structure motifs and magnetic properties. The magnetization and Curie temperature of low energy structures are close to those of hcp Co and for some structures, a magnetic anisotropy larger than that of hcp Co were found. We will discuss more on how calculated intrinsic magnetic properties can explain the observed permanent magnet properties and how to improve the magnetic properties of $HfCo_7$ alloy.

10:12AM T17.00012 Magnetic properties of doped Ce_2Co_{17} alloys , LIQIN KE, DENIS KUKUSTA[1], VLADIMIR ANTROPOV, Ames Laboratory USDOE, Ames, IA 50011 — Substitutional alloys $Ce_2Co_{17-x}T_x$, where T is $d-$atom or Al, Si, Ga, have been analyzed using electronic structure calculations with a focus on the influence of doping on such properties as magnetization, magnetic anisotropy and Curie temperature. A complication arises because we need to improve all three of these key properties of magnets. We found that a system with small levels of doping has a strong site preference effect. This effect, when combined with site decomposition of magnetic anisotropy and Curie temperature leads to the specific scenario of producing desirable new magnetic materials with better properties as permanent magnets. We show that in order to obtain a better set of these three key magnetic properties, one has to consider dopings by two elements, with one element responsible for changes to magnetic anisotropy and another for improving the magnetization and Curie temperature. Obtained theoretical results have been compared favorably with a large amount of available experimental data for certain systems.

10:24AM T17.00013 Ferromagnetism in Single Crystal MoS_2[1] , SIMA SAEIDI VARNOOSFADERANI, Department of Physics, University of Florida, SEFAATTIN TONGAY, Department of Material Science and Engineering, University of California, Berkeley, BILL APPLETON, Nanoscience Institute for Medical and Engineering, University of Florida, JUNQIAO WU, Department of Material Science and Engineering, University of California, Berkeley, ARTHUR HEBARD, Department of Physics, University of Florida — We report on the magnetic properties of MoS_2 flakes measured from room temperature down to 10 K and magnetic fields up to 5 Tesla. Molybdenum disulfide (MoS_2) is one of the most stable layered transition metal dichalcogenides, which has a finite band gap and is regarded as a complementary (quasi-) 2D material to graphene. We find that single crystals of MoS_2 display ferromagnetism superimposed onto a large temperature-dependent diamagnetism and observe that ferromagnetism persists from 10 K up to room temperature. We attribute the existence of ferromagnetism partly to the presence of zigzag edges in the magnetic ground state at the grain boundaries. Since the magnetic measurements are relatively insensitive to the interlayer coupling, these results are expected to be also valid in the single layer limit.

10:36AM T17.00014 Structural and electronic properties of the half-Heusler phases PtFeBi, PtMnBi, PdFeBi and PdMnBi , XIAOFANG WANG, XIAOSHUANG CHEN, Shanghai Institute of Technical Physics, Chinese Academy of Sciences, CHINGYAO FONG, Department of Physics, University of California, Davis, WENCHAO HUANG, WEI LU, Shanghai Institute of Technical Physics, Chinese Academy of Sciences — First-principles calculations based on density functional theory have been performed to study the structural and electronic properties of the PtFeBi, PtMnBi, PdFeBi and PdMnBi half-Heusler alloys. The results reveal that all the alloys show metallic properties at the ground state configuration. We further investigated the dependence of electronic band structures by applying hydrostatic pressure. It is found that the PtMnBi and PdMnBi are half-metallic with the same magnetic moment of 4.0 μB per formula-unit when their lattice constants are reduced (from -3.0% to -11.2% and -6.1% to -7.9%, respectively). For PtMnBi, its band gap of the minority spin channel increases with compression due to the noticeable strong p-d hybridization, which is the reason for the formation of bonding and antibonding states. It is obvious that the high spin polarization of PtMnBi is over a large range of its lattice constant and with a wide band gaps in the PtMnBi. However, the PdFeBi and PtFeBi are quasi-half-metallic with magnetic moment to be 3.0 μB at -6.9% and -8.3% uniform strain, respectively. They are sensitive to the changes of lattice constants.

10:48AM T17.00015 Complex magnetic ordering and spin glass behavior as a driving mechanism of multifunctional properties of Heusler alloys from first principles , ANNA GRUENEBOHM, PETER ENTEL, HEIKE C. HERPER, MARKUS E. GRUNER, ALFRED HUCHT, DENIS COMTESSE, Faculty of Physics and CENIDE, University of Duisburg-Essen, 47048 Duisburg, Germany, RAYMUNDO ARROYAVE, Department of Mechanical Engineering, Texas A&M University, College Station, Texas 77843, USA — First-principles calculations are used to study the structural, electronic and magnetic properties of (Pd, Pt)-Mn-Ni-(Ga, In, Sn, Sb) alloys which display multifunctional properties like the magnetic shape-memory, magnetocaloric and exchange bias effect. The ab initio calculations give a basic understanding of the underlying physics which is associated with the complex magnetic behavior (also spin glass) arising from competing ferro- and antiferromagnetic interactions with increasing number of Mn excess atoms in the unit cell. This information allows to optimize, for example, the magnetocaloric effect by using the strong influence of compositional changes on the magnetic interactions. Thermodynamic properties can be calculated by using the ab initio magnetic exchange parameters in finite-temperature Monte Carlo simulations. We present guidelines of how to improve the functional properties. For Pt-Ni-Mn-Ga alloys, a shape memory effect with 14% strain can be achieved in an external magnetic field.

Session T18 GMAG DMP FIAP: Focus Session: Spin-Dependent Phenomena in Semiconductors - Magnetic Semiconductors 320 - Jairo Sinova, Texas Agricultural and Mechanical University

8:00AM T18.00001 Spin transistor action via tunable Landau-Zener transitions in magnetic semiconductor quantum wells[1] , DIETER WEISS, Institute of Experimental and Applied Physics, University of Regensburg, D-93040 Regensburg, Germany — Spin-transistors, employing spin-orbit interaction like Datta-Das prototypes [1], principally suffer from low signal levels due to limitations in spin injection efficiency, fast spin relaxation and dephasing processes. Here we present an alternative concept to implement spin transistor action where efficiency is improved by keeping spin transport adiabatic [2]. To this end a helical stray field B, generated by ferromagnetic Dysprosium stripes, is superimposed upon a two-dimensional electron system in (Cd,Mn)Te, containing Mn ions with spin 5/2. Due to the giant spin splitting, occurring at low temperatures and small B in (Cd,Mn)Te quantum wells, the B-helix translates into a spin-helix and the electron spins follow adiabatically the imposed spin texture. Within this approach the transmission of spin-polarized electrons between two contacts is regulated by changing the degree of adiabaticity, i.e. an electron's ability to follow the spin helix. This is done by means of a small applied homogeneous magnetic field while the degree of adiabaticity is monitored by the channel resistance. Our scheme allows spin information to propagate efficiently over typical device distances and provides an alternative route to realize spintronics applications. We note that our concept is not restricted to a particular choice of materials, temperature, methods of spin injection, manipulation as well as detection.

Work done in cooperation with Christian Betthausen, Institute of Experimental and Applied Physics, University of Regensburg, D-93040 Regensburg, Germany; Tobias Dollinger, Henri Saarikosi, Institute of Theoretical Physics, University of Regensburg, D-93040 Regensburg, Germany; Valeri Kolkovsky, Grzegorz Karczewski, Tomasz Wojtowicz, Institute of Physics, Polish Academy of Sciences, PL-02668 Warsaw, Poland; and Klaus Richter, Institute of Theoretical Physics, University of Regensburg.

8:36AM T18.00002 Disorder in Mn doped InSb studied at the atomic scale by cross-sectional STM

, PAUL KOENRAAD, SAMUEL MAUGER, JUANITA BOCQUEL, Eindhoven University of Technology, CAITLIN FEESER, NIDHI PARASHAR, BRUCE WESSELS, Northwestern University — We present an atomically resolved study of MOVPE grown Mn doped InSb. Both topographic and spectroscopic measurements have been performed by X-STM. The measurements show a perfect crystal structure and reveal that Mn acts as a shallow acceptor. The Mn concentration obtained from the cross-sectional STM data compares well with the intended doping concentration. While the pair correlation function of the Mn atoms showed that their local distribution is uncorrelated beyond the STM resolution for observing individual dopants, disorder in the Mn ion location is noted. This inhomogeneous distribution is proposed to play an important role in the magnetic behavior.

8:48AM T18.00003 Giant magnetoresistance in InMnAs/InAs heterojunctions and its composition and temperature dependence[1]

, JOHN PETERS[2], CHRISTOPHER GARCIA, BRUCE WESSELS[3], Materials Research Center, Northwestern University, Evanston IL — The transport properties of magnetic semiconductors play a central role in spintronics as they provide an effective insight into spin related phenomena. Motivated by predictions of large magnetoresistance effects in dilute magnetic semiconductor heterojunctions, the electronic and magnetotransport properties of narrow gap heterojunction diodes have been demonstrated. We report here on the positive magnetoresistance of $p-\mathrm{In_{1-x}Mn_xAs}/n-\mathrm{InAs}$ magnetic semiconductor heterojunctions and its dependence on Mn concentration and temperature. The junction magneto-conductance is well described by an analytical expression for the total conductance G_{tot} of two spin-split bands. From the junction magneto-conductance an effective g-factor due to a giant Zeeman effect was determined for varying Mn concentration. The effective g-factor increased with increasing Mn concentration from 98 to 131 for x_{Mn} =0.01 to x_{Mn} =0.06. /newline /newline Use of the Center for Nanoscale Materials at Argonne National Laboratory was supported by the U. 9:00AM T18.00004 Magnetism of IV-VI compound based DMS

, HITOSHI FUJII, TETSUYA FUKUSHIMA, KAZUNORI SATO, HIROSHI KATAYAMA-YOSHIDA, Graduate School of Engineering Science, Osaka University — The electronic structure and the magnetic properties of Mn doped GeTe, which is IV-VI compound semiconductor based dilute magnetic semiconductors (DMS), are calculated from first principles. Although the ferromagnetism was discovered in GeMnTe before III-V compound DMS systems [1], IV-VI DMS have not been so popular in DMS community due to the low Curie temperature and the incompatibility with present electronic materials. However, the carrier concentration and hence the magnetic properties can be controlled easily by forming Ge vacancies. In this work, in order to discuss potentiality of IV-VI DMS systems as semiconductor spintronics materials, the electronic structure are calculated based on the local density approximation and we use the Korringa-Kohn-Rostoker coherent potential approximation method [2]. The magnetic exchange interactions between Mn impurities are calculated by using the Lichitenstein's method [3]. Based on the calculation results, we will also discuss the Curie temperature by using Monte Carlo simulations.

9:12AM T18.00005 All-optical ultrafast control of the four-state memory of ferromagnetic semiconductors by using coherent trains of femtosecond optical pulses

, ILIAS PERAKIS, Department of Physics, University of Crete and IESL/FORTH, Heraklion, Crete, Greece — We present a many-body theoretical framework based on density matrix equations of motion for investigating ultrafast all-optical manipulation of ferromagnetism in magnetic semiconductors. We develop a theory of collective spin dynamics triggered by femtosecond photoexcitation and demonstrate non-thermal control of magnetization switchings between the four metastable magnetic states of (Ga,Mn)As by using sequences of linearly-polarized optical pulses. We study the influence of such pre-designed coherent pulse trains on the four-state magnetic memory and demonstrate its full ultrafast control by tuning of relative phase, intensity, and frequency. We show the development of a light-induced magnetization tilt governed by suitable quantum-mechanical superpositions of conduction and valence band states created during the optical pulse. This femtosecond magnetization dynamics is followed by a distinct picosecond temporal regime governed by the magnetic anisotropy of thermal holes. We address the fundamental question of how spins couple to transient optical coherences during time intervals shorter than the photo-excitation and elucidate the role of the competition between magnetic exchange and spin-orbit interactions. Our results indicate the possibility of reading/writing magnetic states at THz speed and propose protocols for multiple switchings between the four metastable states.

9:48AM T18.00006 Calculated x-ray linear dichroism spectra for Gd-doped GaN

, TAWINAN CHEIWCHANCHAMNANGIJ, WALTER LAMBRECHT, Department of Physics, Case Western Reserve University — Gd doped GaN has been claimed to be a dilute magnetic semiconductor with colossal magnetic moments. However, the origin of huge magnetic moments is still controversial. The x-ray linear dichroism (XLD) spectrum of the Gd L3 edge and the multiple scattering calculations from Ney et al. (J. Magn. Magn. Mater. 322, 1162 (2010)) suggested that about 15% of Gd atoms should be on antisites. In contrast, our first principle calculations indicate that once the Gd is put on the N site, it will move to the interstitial site and cause large structure relaxation. The formation energy of the system is, therefore, in the order of 10 eV per Gd atom which is extremely large. We show that XLD spectra for L-edges can be analyzed in terms of suitable linear combinations of the partial densities of states of the Gd d-electrons. Core-hole effects are also included. The XLD spectra extracted from our calculations of Gd on the Ga site is shown to fit the experimental spectrum and no Gd on the N site is needed.

10:00AM T18.00007 Achieving Room-temperature Ferromagnetism in N-doped ZnO with Inhomogeneity , VIVIAN TRAN, Department of Materials Science and Engineering, University of California, Berkeley; and Graduate School of Engineering Science, Osaka University, MASAYOSHI SEIKE, TETSUYA FUKUSHIMA, KAZUNORI SATO, HIROSHI KATAYAMA-YOSHIDA, Graduate School of Engineering Science, Osaka University — Wide-gap semiconductors, such as ZnO, are attractive host materials for dilute magnetic semiconductors (DMS) due to potential applications in optoelectronic and magneto-optical devices. Recent experiments on N-doped ZnO DMS have reported room-temperature ferromagnetism (RTFM) under a homogeneous distribution of N-dopants. However, analogies to the previously studied transition-metal-doped ZnO systems suggest that RTFM originates from inhomogeneity in the system. Through first-principles calculations, we show that the N-dopants tend to cluster and that RTFM in N-doped ZnO DMS can be achieved by controlling the inhomogeneity in the system. That is, Monte Carlo simulations indicate that self-organized N-rich nanostructures form under layer-by-layer growth conditions. Furthermore, our calculations show that these nanostructures have strong ferromagnetic coupling between N-atoms within each nanostructure in addition to high blocking temperature, assuming a homogeneous distribution of dopants within each nanocluster. These self-organized nanostructures have potential applications to high-density magnetic memory.

10:12AM T18.00008 Electronic bulk and surface transport in n- and p-InAs films on GaAs substrates[1] , YAO ZHANG, V. SOGHOMONIAN, J.J. HEREMANS, L.J. GUIDO, Virginia Tech — We experimentally studied magnetotransport of bulk carriers and surface electrons in InAs MOCVD-grown on GaAs, as well as the spin interaction between surface carriers and transition metal ions. Hall and Shubnikov-de Haas data show the existence of 3 carrier types: interface carriers at the GaAs/InAs interface, bulk carriers and surface state carriers. In n-type samples total density n and total mobility μ increase with increasing n-doping. At a threshold doping level, transport in the system changes from multi-carrier to single-carrier. In p-type InAs, n and μ show a strong temperature dependence, partly due to carrier freeze-out. The p-type InAs also shows GaAs/InAs interface carriers. At low temperatures and low magnetic fields, weak antilocalization (AL) is observed due to spin-orbit interaction, mostly from electrons with Rashba spin-orbit interaction in the surface accumulation layer. Due to its sensitivity to spin phenomena AL can be used as a sensitive probe of interactions between the surface electrons and local magnetic moments. The magnetic species modify the surface electron spin-flip scattering and spin-orbit scattering. Spin-orbit scattering is seen to be increased by Co^{2+} and Ni^{2+}, while suppressed by Fe^{3+}.

10:24AM T18.00009 Coexistent Ferromagnetic and Semiconducting behavior in CoO/ZnO Multilayer Films[1] , FRANCES HELLMAN, HYEON-JUN LEE, CATHERINE BORDEL, MICHALIS CHARILAOU, JULIE KAREL, Department of Physics, University of California, Berkeley and LBNL Materials Sciences Division — Ferromagnetic semiconductor behavior up to just below 300 K is shown in CoO/Al-doped ZnO (AZO) multilayers, shown by magnetic measurements and anomalous and ordinary Hall effect. The magnetism oscillates with odd versus even number of Co layers in the insulating antiferromagnetic CoO and (separately) with the thickness of the doped semiconducting AZO layers, and vanishes if AZO is replaced by undoped insulating ZnO. Magnetization is attributed to uncompensated (111) ferromagnetic planes of insulating CoO for odd numbers of atomic planes per layer which are coupled together via RKKY exchange mediated by electron carriers in the non-magnetic AZO layers. The period of the oscillation with AZO thickness qualitatively matches the Fermi wavevector calculated from the carrier concentration measured by ordinary Hall effect. Magnetic polarization of the AZO carriers is confirmed via anomalous Hall effect which is proportional to the magnetization. X-ray magnetic circular dichroism confirm magnetic properties.

10:36AM T18.00010 Interaction of Mn with Ge-quantum dot surfaces and its impact on quantum dot growth and morphology[1] , PETRA REINKE, CHRISTOPHER NOLPH, JOSEPH KASSIM, JERROLD FLORO, University of Virginia — The magnetic doping of Ge-quantum dots (QD) and Ge thin film materials has garnered considerable interest due their anticipated use in nanoscale spintronics device structures. In this study we probe with scanning tunneling microscopy the interaction of Mn with the growth surfaces in strain-driven synthesis of Ge-QDs on Si(100)-(2x1). The growth surfaces are the Ge-QD{105}facet and the Ge(100) surface of the wetting layer (WL). Mn interactions with the QD{105}facet is particularly interesting, and shows the formation of Mn-islands with a geometry bounded by the surface reconstruction, and a backbonding of Mn-d electrons into the surface states of the rebonded Ge{105}facet. Annealing introduces ($<$570 K) dramatic changes in bonding, and initiates intermixing of Ge and Mn. Further increase in the temperature drives the Mn-surface diffusion and leads to the formation of germanide clusters. In the co-deposition of Mn and Ge with 2-23 at% of Mn, the morphology of the Ge QDs is gradually modulated, QDs are significantly smaller for high Mn concentrations, with a concurrent thickening of the WL. We will discuss the co-deposition process in the framework of surface processes in the Mn-Ge-QD system.

10:48AM T18.00011 Spin-gating an antiferromagnetic semiconductor conductivity , XAVIER MARTI, University of California, Berkeley, IGNASI FINA, Institut de Ciencia de Materials de Barcelona ICMAB-CSIC, DI YI, JIAN LIU, CLAUDY RAYAN-SERRAO, JIUN-HAW CHU, University of California, Berkeley, SIRIYARA JAGANNATHA SURESHA, Lawrence-Berkeley National Laboratory, JAKUB ZELEZNY, JAN MASEK, TOMAS JUNGWIRTH, Institute of Physics, Academy of Sciences Czech Republic, RAMAMOORTHY RAMESH, University of California Berkeley — Magnetic semiconductors entwine two of the most successful concepts in both fundamental physics and industrial applications where ferromagnetic materials have played an undismissable role. Recently antiferromagnets have been proposed as alternative material systems [1,2]. Antiferromagnetic spintronics have been demonstrated by the fabrication of tunnel devices [3,4], atomic-size proof-of concepts [5], even devices without auxiliary ferromagnetic layers [6]. Here we present the control of the electrical conductivity of an antiferromagnetic semiconductor by manipulating the magnetic state of a contiguous ferromagnetic layer acting as a spin-based gate. We present an oxide-based fully epitaxial heterostructure, its structural characterization and the electrical measurements showing a direct link between state of the ferromagnetic gate and ohmic resistance of the semiconductor, even displaying distinct remnant resistance states. Session T19 DCMP: Metal-Insulator Transitions I 321 - Nandini Trivedi, The Ohio State University

8:00AM T19.00001 Importance of subleading corrections for the Mott critical point[1]

, A.-M.S. TREMBLAY, Universite de Sherbrooke, Quebec, Canada, and Canadian Institute for Advanced Research, PATRICK SEMON, Universite de Sherbrooke — The interaction-induced metal-insulator transition should be in the Ising universality class. Experiments on layered organic superconductors suggest instead that the observed critical endpoint of the first-order Mott transition in $d = 2$ does not belong to any of the known universality classes for thermal phase transitions. In particular, it is found that $\delta = 2$. Given the quantum nature of the two phases involved in the transition, we use dynamical mean-field theory and a cluster generalization to investigate whether the new exponents could arise as transient quantum behavior preceding the asymptotic critical behavior. In the cluster calculation, a canonical transformation that minimizes the sign problem in continuous-time quantum Monte Carlo calculations allows previously unattainable precision. Our results show that there are important subleading corrections in the mean-field regime that can lead to an $apparent$ exponent $\delta = 2$. Experiments on optical lattices could verify our predictions for double occupancy. P. Sémon and A.-M.S. Tremblay, Phys. Rev. B 85, 201101(R)/1-5 (2012).

8:12AM T19.00002 Quantum critical Mott transition in triangular lattice Hubbard model

, ZI YANG MENG, Department of Physics and Astronomy, Ceneter for Computation and Technology, Louisiana State University, KUANG SHING CHEN, Department of Physics and Astronomy, Louisiana State University, UNJONG YU, GIST-college, Gwangju Institute of Science and Technology, Korea, SHUXIANG YANG, Department of Physics and Astronomy, Louisiana State University, JUANA MORENO, MARK JARRELL, Department of Physics and Astronomy, Center for Computation and Technology, Louisiana State University — Using large-scale dynamical cluster quantum Monte Carlo simulations, we study the correlation-driven metal-insulator transition in the half-filled Hubbard model on a triangular lattice, with the interaction strength (U/t) and temperature as control parameters. We compute spectral and transport properties and estimate the Mott transition to occur at the critical interaction strength Uc/t=8.5+/-0.5. From the metallic side, the van Hove singularity in the density of states moves towards the Fermi level with increasing U/t and eventually collapses at the Mott transition, above which the Mott gap opens. In the quantum critical region above the transition point, the system exhibits a marginal Fermi liquid behavior. Due to the competition between electronic correlations and geometric frustrations, we observe non-trivial transport properties across the transition such as a universal jump in the resistivity, consistent with recent quantum field theory proposals. Implications for experiments on the layered triangular lattice organic material k-(BEDT-TTF)2Cu2(CN)3 and EtMe3Sb[Pd(dmit)2]2 are also discussed.

8:24AM T19.00003 Mott criticality in electric transport of triangular lattice Hubbard model

, TOSHIHIRO SATO, KAZUMASA HATTORI, HIROKAZU TSUNETSUGU, Institute for Solid State Physics, University of Tokyo — We numerically study electric transport near the Mott metal-insulator transition for the half-filled Hubbard model on a triangular lattice. Our approach is a cellular dynamical mean field theory (CDMFT) with a continuous-time QMC solver and we calculate optical conductivity including vertex corrections. The main issue is the variation of optical conductivity upon controlling Coulomb repulsion U for various temperatures. Near the Mott critical end point, a Drude peak on the metallic side smoothly continues to an "ingap" peak emerging within the Hubbard gap on the insulating side. We find a critical power-law behavior in their U-dependence near the critical point. The obtained critical exponent $1/\delta = 0.15$ of the optical weight differs from the exponent $1/\delta = 1/3$ of the order parameter (double occupancy) in the CDMFT calculations. This discrepancy suggests that conductivity does not have the same scaling behavior as that for the order parameter[1]. [1]T. Sato, K. Hattori, and H. Tsunetsugu, J. Phys. Soc. Jpn. **81**, 083703 (2012).

8:36AM T19.00004 Self-localization of a single hole in Mott antiferromagnets

, ZHENG ZHU, Institute for Advanced Study, Tsinghua University, Beijing, 100084, China, HONG-CHEN JIANG, Kavli Institute for Theoretical Physics, University of California, Santa Barbara, CA, 93106-4030, U.S.A., YANG QI, CHUN-SHUN TIAN, ZHENG-YU WENG, Institute for Advanced Study, Tsinghua University, Beijing, 100084, China — Anderson localization - quantum suppression of carrier diffusion due to disorders - is a basic notion of modern condensed matter physics. Here, we report a novel localization phenomenon totally contrary to this common wisdom. Strikingly, it is purely of strong interaction origin and occurs without the assistance of disorders. Specifically, by combined numerical (density matrix renormalization group) method and analytic analysis, we show that a single hole injected in a quantum antiferromagnetic ladder is generally self-localized even though the system respects the translational symmetry. The localization length is found to monotonically decrease with the increase of leg number, indicating stronger self-localization in the two-dimensional limit. We find that a peculiar coupling between the doped charge and the quantum spin background causes quantum interference among different hole paths. The latter brings the hole's itinerant motion to a halt, a phenomenological analogy to Anderson localization. Our findings are opposite to the common belief of the quasiparticle picture for the doped hole and unveil a completely new paradigm for lightly doped Mott insulators.

8:48AM T19.00005 Emergent Metal in Disordered Two Dimensional Mott Insulator[1]

, OINAM NGANBA MEETEI, NANDINI TRIVEDI, Ohio State University, ELIAS LAHOUD, AMIT KANIGEL, Technion - Israel Institute of Technology — We show that disordering a two dimensional Mott insulator leads to an insulator-metal transition, even in the absence of any doping. For disorder strengths comparable to the interaction, the Mott gap closes and extended states develop at the chemical potential. Further increase in disorder drives the emergent metal into a gapless localized insulating phase. We make detailed comparisons of our theoretical predictions on the emergent metal with transport and APRES data on 1T-TaS_2 intercalated by Cu. The parent compound 1T-TaS_2 is a Mott insulator at low temperature ($T < 180K$). In the commensurate charge density wave (CCDW) phase, the "star of David" unit cells with 13 Ta atoms form a commensurate triangular lattice with a single half filled band crossing the Fermi energy. Strong interaction produces a Mott gap in the half filled band. Disorder introduced by intercalating Cu atoms between TaS_2 layers closes the Mott gap and drives the material into a metallic phase without destroying the CCDW order in good agreement with theory. Our work presents the first evidence of such an insulator-metal transition in a disordered two-dimensional Mott insulator.

9:00AM T19.00006 Configuration Interaction as an Impurity Solver: Benchmark Dynamical Mean-Field Theory for the Hubbard Model[1]

, ARA GO, ANDREW J. MILLIS, Department of Physics, Columbia University — The configuration interaction technique has been widely used in quantum chemistry to solve quantum many body systems with lower computational costs than exact diagonalization and was introduced by Dominika Zgid, Emanuel Gull, and Garnet Kin-Lic Chan [Phys. Rev. B **86**, 165128 (2012)] as a solver for the impurity models of dynamical mean field theory. We extend their work, demonstrating for the one and two dimensional Hubbard model how the method reproduces the known results and allows convergence with bath size to be studied in cluster dynamical mean field theory. As an example of the power of the method, cluster dynamical mean field studies of the three band copper-oxygen model are presented.

9:12AM T19.00007 Periodic Anderson model with Holstein phonons on the conduction band

, PENG ZHANG, PETE REIS, KA-MING TAM, MARK JARRELL, JUANA MORENO, FAKHER ASSAAD, ANDY MCMAHAN, None — The volume collapse of Cerium is a long standing problem in condensed matter physics. Recent interest has been attracted to this problem by the experimental discovery that lattice vibrations play an important role in the entropy change of such a first-order phase transition. Using Continuous Time Quantum Monte Carlo as impurity solver of Dynamical Mean Field Theory, the Periodic Anderson Model with Holstein phonons coupling to the conduction band is investigated. Above a certain electron-phonon coupling, we find two coexisting phases separated by a first order transition line, which ends at a second order terminus. One of the coexisting phases is a Kondo Singlet phase with polaronic features while another is local moment phase with bipolaronic features.

9:24AM T19.00008 Spontaneuous symmetry breaking in matrix models[1] , FABIO FRANCHINI, Massachusetts Institute of Technology & SISSA — Matrix models with rotational invariant weights provide, in the large N limit, a robust universality of correlated eigenvalues. Here, we want to argue that a weight that breaks the eigenvalue distribution into disjoint supports, further induces a spontaneous breaking of the rotational symmetry. This SSB of the $U(N)$ can potentially be used as a toy model to study the eigenstate distribution at the Anderson Metal/Insulator Transition.

9:36AM T19.00009 Solving a puzzle in the Anderson transition with long-range correlated potentials[1] , GREG PETERSEN, NANCY SANDLER, Ohio University — The conditions for an Anderson transition in 1D systems has been an open question since it's discovery a half century ago. Although scaling theory predicts localization in this case, it has been shown that a transition exists in the presence of some form of long-range correlations in the on-site energies. One of the most widely used examples are disorder potentials generated by $1/k^{\alpha}$ spectral densities [1] that, with an appropriate short range cutoff, result in vanishing correlation functions in the thermodynamic limit. However, these results are in direct contradiction to work by Kotani et. al. [2] that argues for the existence of a metallic state only when infinite range correlations are non-zero. In this talk we will show that there is no contradiction between the two results as the correlation function generated from numerical techniques is staunchly different from analytic expectations. Furthermore, we will present the exact analytic expression for the correlation function in the thermodynamic limit. Finally, we will discuss the role played by short- and long-range features of the correlation function in the Anderson transition.

9:48AM T19.00010 Momentum Space Signatures of Anderson Localization[1] , CONRAD MOORE, CHINEDU EKUMA, Louisiana State University, HANNA TERLETSKA, Brookhaven National Laboratory, ZIYANG MENG, JUANA MORENO, MARK JARRELL, Louisiana State University — The ensemble averaged density of states is commonly used as an order parameter to distinguish between a metal and insulator. However, for disordered electronic systems this is not the case: the disorder averaged density of states exhibits no singular behavior as the mobility edge between extended and localized states is crossed. In addition, recent work on rare events in the Anderson model further complicate this characterization with "resonant states" becoming significant in the tails of the density of states. In this work, we present exact diagonalization results of the Anderson model and review two quantities that measure the localization transition: the inverse participation ratio and the typical (geometrically averaged) density of states. We also examine the log-normal distribution of the local density of states in real and momentum space. In particular, the results in momentum space provide a justification for the systematic extension of the single site typical medium theory to a momentum coarse grained Dynamical Cluster Approximation where the non-local effects can be included systematically.

10:00AM T19.00011 Anderson localization in one-dimension with Levy-type disorder , DAVID MAYETT, JENNIFER SCHWARZ, Syracuse University — Abstract: Quantum transport through disordered systems has been the subject of extensive research since Anderson's seminal theory of localization. Motivated by experimental realizations of light transport across media exhibiting Levy-type fluctuations, we study the one-dimensional Anderson model where the random site energies are governed by a probability distribution with a broad tail, otherwise known as Levy-type. We numerically compute the Lyapunov exponent and its variance. This exponent is a self-averaging quantity whose inverse in certain cases can be used to define the localization length. Furthermore, we check for the validity of single parameter scaling (SPS), and its dependence on the Levy index.

10:12AM T19.00012 Interactions produce strongly non-Gaussian spatial correlations of the screened random potential , H. JAVAN MARD, Department of Physics and National High Magnetic Field Laboratory, Florida State University, Tallahassee, FL, E.C. ANDRADE, Technische Universitaet Dresden, Dresden, Germany, E. MIRANDA, Univ. of Campinas,Campinas,SP,Brazil, V. DOBROSAVLJEVIĆ, Department of Physics and National High Magnetic Field Laboratory, Florida State University, Tallahassee, FL — We perform variational studies of the interaction-localization problem[1], by using both the Hartree-Fock and the Gutzwiller (slave boson) approximations to describe the interaction-induced renormalizations of the effective (screened) random potential seen by quasiparticles. Here we present results of careful finite-size scaling studies for the conductance of disordered Hubbard chains at half-filling and zero temperature. While our results indicate that quasiparticle wavefunctions remains exponentially localized even in presence of moderate to strong repulsive interactions, we find surprisingly strong enhancement of the conductance of finite size systems. In particular, we show that interactions produce a strong decrease of the characteristic conductance scale g^* signaling the onset of strong localization. We show that this effect, which cannot be captured by a simple renormalization of the disorder strength, instead reflects a peculiar *non-Gaussian form for the spatial correlations* of the screened disordered potential, a so-far neglected mechanism to suppress the role of Anderson localization (interference) effects.

10:24AM T19.00013 Verwey Metal-Insulator Transition in Magnetite from the Slave-Boson Approach , MOHAMMAD SHERAFATI, SASHI SATPATHY, Department of Physics and Astronomy, University of Missouri, Columbia, Missouri, USA, DIX PETTEY, Department of Mathematics, University of Missouri, Columbia, Missouri, USA — We study the Verwey metal-insulator transition in magnetite (Ref.1) by solving a three-band extended Hubbard Hamiltonian for spinless fermions using the slave-boson approach, which also includes coupling to the local phonon modes. This model is suggested from the earlier density-functional studies of magnetite.(Ref.2) We first solve the 1D Hubbard model for the spinless fermions with nearest-neighbor interaction by both Gutzwiller variational and slave-boson methods and show that these two approaches yield different results unlike in the case of the standard Hubbard model, thereby clarifying some of the discrepancies in the literature (Ref.3), then we extend the formalism to three-band Hamiltonian for magnetite. The results suggest a metal-insulator transition at a critical value for the intersite interaction.

10:36AM T19.00014 Thoery of Charge Order and Heavy-Electron Formation in the Mixed-Valence Compound KNi_2Se_2[1] , JAMES MURRAY, ZLATKO TESANOVIC[2], Department of Physics and Astronomy, Johns Hopkins University — The material KNi_2Se_2 has recently been shown to posses a number of striking physical properties, many of which are apparently related to the mixed valency of this system, in which there is on average one quasi-localized electron per every two Ni sites. The material exhibits a charge density wave (CDW) phase that disappears upon cooling, giving way to a low-temperature coherent phase characterized by an enhanced electron mass, reduced resistivity, and an enlarged unit cell free of structural distortion. Starting from an extended periodic Anderson model and using the slave-boson formulation, we develop a model for this system and study its properties within mean-field theory. We find a reentrant first-order transition from a CDW phase, in which the localized moments form singlet dimers, to a heavy Fermi liquid phase as temperature is lowered. The magnetic susceptibility is Pauli-like in both the high- and low-temperature regions, indicating the absence of free local moments, which are typically present in heavy-fermion materials at temperatures above the coherence temperature.

Session T20 DMP: Focus Session: Electron, Ion, and Exciton Transport in Nanostructures - Resistive Switching Phenomena 322 - Luca Larcher, Universita di Modena e Reggio Emilia

8:00AM T20.00001 X-ray Irradiation Induced Colossal Resistance Change in Pt/TiO2/Pt cellss , SEO HYOUNG CHANG, Materials Science Division, Argonne National Laboratory, JUNGHO KIM, Advanced Photon Source, Argonne National Laboratory, SEONG KEUN KIM, CHEOL SEONG HWANG, WCU Hybrid Materials Program, Department of Materials Science and Engineering and Inter-university Semiconductor Research Center, Seoul National Univ., KENNETH D'AQUILA, JEFFREY A. EASTMAN, Materials Science Division, Argonne National Laboratory, JIYOON KIM, Department of Materials Science and Engineering, KAIST, SEUNGBUM HONG, Center for Nanoscale Materials, Argonne National Laboratory and Department of Materials Science and Engineering, KAIST — Interaction between x-ray and matters has been drawing much attention due to its scientific interests as well as technological applications. In particular, synchrotron-based x-ray has been used as a powerful diagnostic tool to unveil nanoscale phenomena in functional materials. However, understanding of how the functional materials respond to the brilliant x-ray is far from complete. Here we report the x-ray-induced colossal resistance change in 40 nm thick TiO_2 films sandwiched by Pt top and bottom electrodes. We observe that the resistance level is modulated in a few orders of magnitude by the intensity of impinging x-ray. In addition, this photovoltaic-like effect can trigger an irreversible resistance change by another few orders of magnitude. We will discuss the physical mechanism behind the emergent phenomenon. Work at the APS, Argonne is supported by a U.S. Department of Energy Office of Science laboratory, is operated under Contract No. DE-AC02-06CH11357.

8:12AM T20.00002 Effect of metallic buffer at electrode-oxide interface on current-voltage characteristics of resistive random access memories (ReRAMs): A first-principles study , TAKEHIDE MIYAZAKI, HISAO NAKAMURA, KENGO NISHIO, AIST-NRI, HISASHI SHIMA, HIROYUKI AKINAGA, AIST-ICANN, YOSHIHIRO ASAI, AIST-NRI — We present the electric current (I)-voltage (V) characteristics (-1.0 eV $< V <$ +1.0 eV) for a model of ReRAM devices with metal-oxide-metal structures, based on first principles nonequilibrium Green's function (NEGF) theory [1]. We choose TiN and hafnia (HfO_2) for the electrode and oxide materials, respectively, because this combination has been widely known in literature. We investigate the I-V characteristics for two different compositions of the TiN/HfO_2 interface, (a) with and (b) without the Ta buffer layer between TiN and HfO_2. We assume cubic HfO_2 layers for simplicity. For case (a), a clear distinction between the "ON" and "OFF" states appears depending on the occurrence and absence of the oxygen vacancies (V_Os), respectively. For case (b), however, little electric current flows even when the V_Os exist in hafnia. In the latter, the O atoms abstracted from hafnia are strongly bound to N, leading to substantial separation of TiN from HfO_2. In contrast, in the former, the Ta buffer not only absorbs the O atoms but also bridges TiN and HfO_2 to secure the occurrence of the "ON" state. [1] H. Nakamura et al., J. Phys. Chem. C 115, 19931 (2011).

8:24AM T20.00003 Identifying and Measuring the State Variables in TaOx Memristors , PATRICK MICKEL, MATTHEW MARINELLA, CONRAD JAMES, Sandia National Laboratories — We present evidence of the identification and characterization of new state variables in TaOx memristors. Thus far, the state variable controlling the resistive switching has been believed to be the oxygen concentration in the conducting Ta filament. However, using voltage pulse measurements sensitive to small changes in resistance, we identify three distinct switching regimes governed by three unique state variables. Oxygen concentration in the Ta filament is shown to control the memristor resistance for low resistances, after which we observe a clear crossover to the area state variable dominated resistance range, and finally a large non-linear resistance range governed by the thickness of a developing insulating layer. The amplitude and time-scale of the applied tuning voltage pulses is investigated, providing insight into thermal properties of the device during switching.

8:36AM T20.00004 Atomic Level Design Rule for Ta-based Resistive Switching devices , SEO HYOUNG CHANG, Materials Science Division (MSD), Argonne National Laboratory (ANL), S. HONG, Center for Nanoscale Materials, ANL, M.-J. LEE, Y.-B. KIM, Semiconductor Device Laboratory, Samsung Advanced Institute of Technology, S. CHATTOPADHYAY, T. SHIBATA, CSRRI-IIT, Physics Dept., Illinois Institute of Technology (IIT) and MRCAT, Advanced Photon Source (APS), B. MAGYARI-KOPE, Dept. of Electrical Engineering, Stanford University, J.A. KADUK, Chemistry dept., IIT, J.A. EASTMAN, MSD, ANL, J. KIM, APS, ANL — Understanding resistive switching phenomena is a prerequisite to realizing the next generation of information storage systems. Ta-based resistive switching devices have been extensively investigated due to their fast switching and reliable endurance among other materials. Despite extensive recent interests, there is still a lack of fundamental understanding of electronic structure and local structure of the Ta-based device. Here, we investigated Ta_2O_5 powder, $Ta_2O_{5-\delta}$ and TaO_x thin films and devices using synchrotron x-ray studies at the Advanced Photon Source, combining resonant x-ray inelastic scattering (RIXS), extended x-ray absorption spectroscopy (EXAFS) and density functional theory based *ab initio* calculations. We found that there are strong correlations between critical values of band gap energies and local atomic environments around Ta atoms. These studies can provide vast possibilities to create new materials based on atomic level design rather than the traditional trial-error methods. Work at the APS, Argonne is supported by a U.S. Department of Energy Office of Science laboratory, is operated under Contract No. DE-AC02-06CH11357.

8:48AM T20.00005 First-principles modeling of the electron and ion transport in TiO_2 ReRAM , LIANG ZHAO, BLANKA MAGYARI-KOPE, YOSHIO NISHI, Department of Electrical Engineering, Stanford University — Transition metal oxide ReRAM is a promising candidate for next generation non-volatile memories. One of the key challenges in modeling ReRAM operations is the prediction of conduction behaviors. The conduction mechanism was found to vary from metallic in ON state, to quantum tunneling/hopping in OFF state. Since resistive switching is a gradual transition between the two, quantitative prediction of I-V characteristics through arbitrary oxygen vacancy (V_O) configuration is desirable. Here we systematically calculated the electron transport properties of pristine and defective TiO_2, by introducing isolated and clustered V_O in a TiN/TiO_2/TiN device structure. The relaxed atomic structures were obtained from density functional theory (DFT) calculations, and the transport behaviors were calculated by DFT-based non-equilibrium Green's function (NEGF) approach. The I-V characteristics of both ON and OFF states can be well reproduced. It was also found that oxygen diffusion into to the vacancy sites is strongly affected by the interface with metal electrodes. Based on the results of transport calculations, a 3D analytical model is parameterized to allow the detailed prediction of device characteristics.

9:00AM T20.00006 Nanoionic Memristive Switches – From Fundamentals to Applications , RAINER WASER, Forschungszentrum Jülich, Peter Grünberg Institut, RWTH Aachen University and JARA-FIT, Germany — A potential leap beyond the limits of Flash (with respect to write speed, write energies) and DRAM (with respect to scalability, retention times) emerges from nanoionic redox-based switching effects encountered in metal oxides (ReRAM). A range of systems exist in which highly complex ionic transport and redox reactions on the nanoscale provide the essential mechanisms for memristive switching. One class relies on mobile cations which are easily created by electrochemical oxidation of the corresponding electrode metal, transported in the insulating layer, and reduced at the inert counterelectrode (so-called electrochemical metallization memories, ECM, also called CBRAM). Another important class operates through the migration of anions, typically oxygen ions, towards the anode, and the reduction of the cation valences in the cation sublattice locally providing metallic or semiconducting phases (so-called valence change memories, VCM). The electrochemical nature of these memristive effects triggers a bipolar memory operation. In yet another class, the thermochemical effects dominate over the electrochemical effects in metal oxides (so-called thermochemical memories, TCM) which leads to a unipolar switching as known from the phase-change memories. In all systems, the defect structure turned out to be crucial for the switching process. The presentation will cover fundamental principles in terms of microscopic processes, switching kinetics and retention times, and device reliability of bipolar ReRAM variants. Passive memory arrays of ReRAM cells open up the paths towards ultradense and 3-D stackable memory and logic gate arrays.

9:36AM T20.00007 Nanoionic switching in metal oxide nanostructures , DANIELE IELMINI, Politecnico di Milano — Ion migration in oxide nanostructures is a key process in information storage technologies, where the logic data are stored as nanoscale conductive filaments [1]. Due to the inherently nanoscale size of the ionic switching location (few cubic nanometers), the local electric field and current density induce extremely high temperatures as a result of Joule heating [2,3]. To develop and design advanced nanoionic materials and devices with improved performance and reliability, the ion migration phenomena in metal oxides must be carefully understood and modeled. This talk will address the modeling of ionic migration and the consequent switching in HfO_x layers of RRAM devices [4]. The model solves drift/diffusion equations for thermally-activated hopping of positive ion, such as oxygen vacancies (V_O^+) and metal cations (Hf^+), in presence of intense Joule heating and electric field. The impact of the ion distribution on the local conductivity is described physics-based models of defect-assisted electronic conduction in semiconductors [5,6]. Microscopic parameters, such as the energy barrier for ion hopping, are directly inferred from the experimental switching kinetics at variable voltages. The simulation results picture the filament growth/depletion with time and account for the observed switching characteristics, such as the progressive opening of a depleted gap and the possibility of electrode-to-electrode migration of ions. Finally, new phenomena, such as switching variability at atomic-size filaments and stress-induced symmetric switching, will be discussed.

10:12AM T20.00008 Finite Element Modeling of Ag Transport and Reactions in Chalcogenide Glass Resistive Memory , HUGH BARNABY, ASU, ARTHUR EDWARDS, ARFL, DAVID OLEKSY, MICHAEL KOZICKI, ASU — Silver-based electrochemical memories show potential for non-volatile applications. While several groups have made significant strides in device development and process integration, challenges remain to improve function and reliability. The central problem is the large variability of operational parameters and programmed resistance. To understand these variabilities, we need to grasp the physics of conducting filament formation and dissolution. In this paper the mechanisms of Ag transport and reactions are modeled using a finite element device simulator. The ChG film is modeled as a wide-bandgap semiconductor with material constants (e.g., bandgap, permittivity, electron affinity) extracted from data reported in literature and the results of first principles density functional theory calculations. Active and inert electrodes are modeled as ideal metals with specified workfunctions. The code solves carrier statistics and transport equations (continuity, drift-diffusion, and Poisson) and, simultaneously, performs ion transport and reaction calculations. The chemistry captured by the simulator are the reduction/oxidation (RedOx) reactions, incorporated as generation (G) and recombination (R) terms in the continuity equations for both ionic and neutral Ag species in the ChG film. The results show how neutral Ag builds up in the film under applied bias. The simulations also reveal that the neutral Ag density is left unchanged once the bias is removed, which enables memristive action.

10:24AM T20.00009 Electronic Structure of Cu_2N, a Thin-film Insulating Surface , SAREH HEIDARI, ANDREW J. FISHER, Department of Physics & Astronomy, University College London, UK; London Centre for Nanotechnology, UK. — Thin-film insulators on metals have been used extensively as substrates when studying single molecule magnets (e.g. $DyPc_2$) and magnetic atoms (e.g. Co) using inelastic tunneling spectroscopy (IETS). They decouple the states of the adsorbed molecule from the underlying metallic bulk, which is necessary for IETS measurements [C. F. Hirjibehedin *et al.*, *Science* 312, 1021, (2006)] and also leads to higher resolution imaging of molecular states [J. Repp *et al.*, *Phys. Rev. Lett.* 9, 026803, (2005)]. The Cu_2N-Cu(100) surface has been shown by STM measurements to have insulating character, however the origin of the insulating behaviour has not been determined. By using Density Functional Theory calculations, we investigate the electronic structure of this surface. We show that the apparent insulating behaviour arises from a strong suppression of the Cu 4s density of states near the Fermi energy in the Cu_2N thin film.

10:36AM T20.00010 Giant piezoresistive response in SmSe thin films under uniaxial strain , MARCELO KURODA, MATT COPEL, THOMAS SHAW, XIAO HU LIU, GLENN MARTYNA, DENNIS NEWNS, IBM T.J. Watson Research Center — Mixed valence compound SmSe shows a continuous insulator to metal transition which has been widely studied in bulk materials during the 1970's and 1980's. Here we report that the effect remains observable experimentally in SmSe films as thin as 12 nm. Our results indicate that the resistivity of film (when subject to uniaxial strain) reduces by about three orders of magnitude under a 4% change volume. This piezoresistive response in SmSe thin films is nearly half of that reported for bulk crystals [Jayamaran et al., PRL **25**, 1430, (1970)]. The experiments are quantified using a combination of finite-element and first-principles (FP-LAWP) calculations. We compare the cases of isotropic and uniaxial strain along specific directions in SmSe crystals and discuss its impact in electronic transport. The results demonstrate the potential of rare-earth monochalcogenides as promising materials for new generation of electronic switches and MEMs [Newns et al., Adv. Mat. **24**, 3672 (2012)].

10:48AM T20.00011 Resistive and Capacitive Memory Effects in Oxide Insulator/ Oxide Conductor Hetero-Structures , RENE MEYER, Rambus, Sunnyvale, California, MAOSHENG MIAO, University of California, Santa Barbara, California, JIAN WU, CHRISTOPHE CHEVALLIER, Rambus, Sunnyvale, California — We report resistive and capacitive memory effects observed in oxide insulator/ oxide conductor hetero-structures. Electronic transport properties of $Pt/ZrO_2/PCMO/Pt$ structures with ZrO_2 thicknesses ranging from 20A to 40A are studied before and after applying short voltage pulses of positive and negative polarity for set and reset operation. As processed devices display a non-linear IV characteristic which we attribute to trap assisted tunneling through the ZrO_2 tunnel oxide. Current scaling with electrode area and tunnel oxide thickness confirms uniform conduction. The set/reset operation cause an up/down shift of the IV characteristic indicating that the conduction mechanism of both states is still dominated by tunneling. A change in the resistance is associated with a capacitance change of the device. An exponential relation between program voltages and set times is found. A model based on electric field mediated non-linear transport of oxygen ions across the $ZrO_2/PCMO$ interface is proposed. The change in the tunnel current is explained by ionic charge transfer between tunnel oxide and conductive metal oxide changing both tunnel barrier height and PCMO conductivity. DFT techniques are employed to explain the conductivity change in the PCMO interfacial layer observed through capacitance measurements.

Session T21 DMP: Focus Session: Lattice Dynamics and Surface Chemistry 323 - Kevin Garrity, Rutgers University

8:00AM T21.00001 Phonon dynamics near high temperature phase transition in $Na_{1/2}Bi_{1/2}TiO_3$, LING CAI, JEAN TOULOUSE, Lehigh University, WEI TIAN, Oak Ridge National Laboratory — In this report, we present recent inelastic neutron scattering results on the disordered perovskite system $Na_{1/2}Bi_{1/2}TiO_3$(NBT). NBT exhibits the relaxor ferroelectric behavior (strong frequency dispersion of the dielectric constant) between 850K and 600K. X-ray and neutron diffraction has shown that the structural transition occurs at Tc≈820K corresponds to the in-plane tilting of oxygen octahedral associated with the softening of a zone boundary acoustic mode. Inelastic neutron scattering was measured in the (002) and (220) Brillouin zones, both above and below the high temperature transition. Transverse acoustic and transverse optic phonon modes were mapped out in these two Brillouin zones. The key observations of the study are: 1) the zone boundary soft mode behavior of both TA and TO modes in (002) zone, 2) the critical TA-TO coupling anomaly around q=0.15 (r.l.u.). The latter phenomenon has been well studied in other perovskite systems such as $KTaO_3$ where a pronounced kink is observed in the dispersion curve of the TA and TO branches at a critical q value. Our results on NBT suggest an anti-crossing type coupling of the TA and TO branches in the dispersion curves.

8:12AM T21.00002 Investigation of relaxations and central peaks in the Raman spectra of NBT , DANIEL JACKSON, JEAN TOULOUSE, Physics Dept. Lehigh University — Raman spectroscopic measurements of sodium bismuth titanate ($Na_{0.5}Bi_{0.5}TiO_3$ or NBT) have been carried out from 80 K to 1000 K using an Ar^+ ion laser at 514.5 nm, with a particular emphasis on its two transitions. Full spectral deconvolution has been performed to examine the temperature evolution of the "central features" and low frequency phonons below 100 cm^{-1}. The central intensity profile is found to be composed of two well-defined Lorenzian peaks, one narrow and the other broad. The temperature dependence of the two central peaks reveals the presence of fluctuations/relaxations in both M and R-point rotations of the oxygen octahedra coupled to the cation displacements, the latter giving rise to polar nano-domains (PND's) and the relaxor behavior. These fluctuations/relaxations are shown to not follow the Bose thermal occupancy factor, similar to central peaks in glasses.

8:24AM T21.00003 Dynamical Properties of PbTiO3 Under Pressure, Stress and Strain[1] , KEVIN MCCASH, INNA PONOMAREVA, University of South Florida — Ferroelectric perovskites have been in the focus of attention for many years owing to their remarkable properties and variety of applications. Of notable importance is the manner in which external stimuli alter the properties and dynamics of such materials. Here we take advantage of first principles based molecular dynamics simulations to probe the dynamics of $PbTiO_3$ at finite temperature and under the application of pressure, stress and strain. Our simulations show that the complex dielectric response and soft-mode dynamics of $PbTiO_3$ can be tuned by the application of pressure, stress and strain over a range of values available in a laboratory setting. This tunability can lead to the use of $PbTiO_3$ and other polar perovskite oxides in novel applications.

8:36AM T21.00004 Phonon dispersion relation in $PbTiO_3$[1] , IZUMI TOMENO, Akita University, JAIME FERNANDEZ-BACA, KAROL MARTY, ORNL, KUNIHIKO OKA, AIST, YORIHIKO TSUNODA, Waseda University — The phonon dispersion relations for cubic $PbTiO_3$ (T_c =763 K) have been determined along the high symmetry directions at T =793 K using inelastic neutron scattering. A set of the TO branches drops significantly toward the zone center. This is quite different from the soft mode anomaly in the Pb-based relaxors, named as the waterfall phenomenon. The zone-center TO mode energy softens with decreasing temperature from 1173 to 793 K. The TA branch along $[\xi, \xi, \xi]$ shows significant softening around ξ =0.25 and 0.5. These two anomalies persist up to 1173 K and are weakly temperature dependent. Moreover, the TA branches along [1,0,0] and [1,1,0] soften in the entire q range as the temperature approaches T_c. Although the phonon softening occurs simultaneously, the softening of the zone center TO mode plays an important role in the single phase transition. The phonon dispersion relations for cubic and tetragonal $PbTiO_3$ are discussed in connection with $BaTiO_3$, $KTaO_3$, $Pb(Zn_{1/3}Nb_{2/3})O_3$, and $Pb(Mg_{1/3}Nb_{2/3})O_3$.

[1]U.S.-Japan cooperative program on neutron scattering

8:48AM T21.00005 Static and dynamic properties of $PbTiO_3$ at finite temperatures[1] , BRAJESH MANI, INNA PONOMAREVA, Department of Physics, University of South Florida, Tampa, Florida 33620, USA — The ABO_3-type perovskite crystals are key to several important technological applications. To mention a few, electro-optics, waveguides, laser frequency doubling and high capacity computer memory cells. In this work, we develop a route to first-principles parametrization of effective Hamiltonian for ferroelectric ferovskites [1] which allows an accurate description of both static and dynamic properties of such materials. We use this method to examine softening of the transverse optical mode in both paraelectric and ferroelectric phases of $PbTiO_3$. The computed static and dynamic properties are in good agreement with the available theoretical and experimental data. Our study also predicts a crossover between a displacive to an order-disorder transition near the Curie point.

9:00AM T21.00006 Raman Spectroscopy Study of Phase Transition in Layered Ferroelectric $PbK_2LiNb_5O_{15}$, OLEKSIY SVITELSKIY, Colgate University, Hamilton, NY 13346, YAOVI GAGOU, MIMOUN EL MARSSI, Université de Picardie, Amiens, France — PKLN is a novel material with lattice structure resembling that of tetragonal tungsten bronze. Below 640 K it assumes ferroelectric-ferroelastic orthorhombic phase of Pba2 space group. At high temperature the material is known to possess paraelectric properties characterized by tetragonal P4/mbm structure with one-dimensional electric conductivity. In order to clarify the mechanism of the transition between these two symmetries, we carried out a detailed exploration of temperature dependencies of Raman scattering spectra in five scattering geometries in the broad temperature range between 800 and 300 K, completely covering the region where the phase transformation occurs. Our data indicate that lowering the temperature, pre-transitional phenomena in the form of soft behavior of peaks start at least at 700 K that is well above the transition temperature. While most of the peaks soften towards 640 K, some of them soften towards 680K. Below both of these temperatures many peaks demonstrate splitting. The observed phenomena reveal presence either of an intermediate phase or long-living relaxations in the pretransitional temperature range.

9:12AM T21.00007 ABSTRACT WITHDRAWN –

9:24AM T21.00008 Lattice dynamics of $Bi_2M_2O_7$ (M=Sn, Ti, and Hf) from first principles , JIANGANG HE, CRAIG J. FENNIE, School of Applied and Engineering Physics, Cornell University — Insulating bismuth pyrochlores with mixed cations randomly distributed on the B site, $Bi_2MM'O_7$, have been of interest primarily for their dielectric properties. As a way of helping to elucidate the effects of cation disorder from that of the highly polarizable Bi^{3+} lone pair cation, systems like $Bi_2M_2O_7$ (M=Sn, Ti, and Hf) have beed studied. Far from being simple model systems, these single B-site cation materials have been show to display surprisingly complex and local structural distortions. While $Bi_2Sn_2O_7$ and $Bi_2Hf_2O_7$ undergo three and four different phases (where the ground state structure has 352 atoms), $Bi_2Ti_2O_7$ does not show any coherent structural distortions but rather the Bi_2O' simply becomes disordered. In this talk we will present a comparative first-principles study of the lattice instabilities throughout the BZ of the cubic prototype structures of $Bi_2M_2O_7$ (M=Sn, Ti, and Hf) . We then use the eigenvectors of the identified unstable force constants to perform a systematic search over all possible subgroup structure, performing full structural relaxations thereby constructing a picture of the energy landscape. Finally we studied the effect of biaxial strain along [100], [110], and [111].

9:36AM T21.00009 NO_x Binding and Dissociation: Enhanced Ferroelectric Surface Chemistry by Catalytic Monolayers[1] , ARVIN KAKEKHANI, SOHRAB ISMAIL-BEIGI, Yale University — NO_x molecules are regulated air pollutants produced during automotive combustion. As part of an effort to design viable catalysts for NO_x decomposition operating at higher temperatures that would allow for improved fuel efficiency, we examine NO_x chemistry on ferroelectric perovskite surfaces. Changing the direction of ferroelectric polarization can modify surface electronic properties and may lead to switchable surface chemistry. Here, we describe our recent work on potentially enhanced surface chemistry using catalytic RuO_2 monolayers on perovskite ferroelectric substrates. In addition to thermodynamic stabilization of the RuO_2 layer, we present results on the polarization-dependent binding of NO, O_2, N_2, and atomic O and N. We present results showing that one key problem with current catalysts, involving the difficulty of releasing dissociation products (especially oxygen), can be ameliorated by this method.

9:48AM T21.00010 Optical detection of adsorbed CO_2 and other gases on ferroelectric surfaces using second harmonic generation (SHG) , GUERAU CABRERA, DISHENG CHEN, West Virginia University, KARTHIK JAMBUNATHAN, RUIJUAN XU, University of Illinois, ALEJANDRO CABRERA, P. Universidad Catolica de Chile, LANE MARTIN, University of Illinois, MIKEL HOLCOMB, West Virginia University — Due to their polar surfaces, ferroelectrics may provide an ideal way to detect and collect gas molecules, useful for applications such as gas sensing and pollution mitigation. Since ferroelectric materials have a high reliability (at least 10^9 switching cycles) these sensors could be used for prolonged periods of time without failure. Second harmonic generation (SHG) allows us to determine the spatial orientation of surface adsorbates and to monitor in realtime the kinetics of adsorption/desorption. In preliminary experiments we see a variation of SHG signal from the surface of $PbZrTiO_3$ (PZT) (100 nm film 20% Zr, 80% Ti) when dosed with 1 atm of N_2 or CO_2. There is a 21% increase in signal when dosed with N_2 with respect to signal in vacuum and there is a 19.9% increase in signal when dosed with CO_2 with respect to signal in vacuum. Further studies will be performed to determine the orientation of these molecules on the surface of this device. Experiments will also be performed while polarizing the device with an external electric field to determine the effect of polarization on adsorption/desorption of molecules.

10:00AM T21.00011 AFM Analysis of Photcatalyzed Deposition of Silver Particles on Perovskite Surfaces , BENJAMIN BEIN, Department of Physics and Astromomy, Stony Brook University, JOSEPH MAGEE, Department of Chemistry, Brookhaven National Laboratory, SARA CALLORI, JOHN SINSHEIMER, MATTHEW DAWBER, Department of Physics and Astromomy, Stony Brook University — Photocatalyzed deposition of silver from a silver-nitrate solution onto well-defined perovskite surfaces was investigated using an atomic force microscope (AFM). The different materials were grown in a RF-off-axis sputter deposition chamber. Grown films have atomically flat surfaces with unit cell high step edges. Different particle accumulation structures were encountered, and the distribution of particles was analyzed. The photocatalyzed deposition of silver is a suitable proxy reaction for water splitting, and development of a technique that will allow precise determination of the catalytic ability of surfaces and specific sites on those surfaces is a priority in our group's efforts to develop new ferroelectric photocatalysts.

Thursday, March 21, 2013 8:00AM - 11:00AM –

Session T22 DCMP: Strongly Correlated Electron Theory III 324 - Adrian del Maestro, University of Vermont

8:00AM T22.00001 Lifshitz Transition in the Two Dimensional Hubbard Model , KUANG-SHING CHEN, Department of Physics and Astronomy, Louisiana State University, ZIYANG MENG, Department of Physics and Astronomy, Center for Computation and Technology, Louisiana State University, THOMAS PRUSCHKE, Institute for Theoretical Physics, University of Göttingen, Germany, JUANA MORENO, MARK JARRELL, Department of Physics and Astronomy, Center for Computation and Technology, Louisiana State University — Using large-scale dynamical cluster quantum Monte Carlo simulations, we study the Lifshitz transition of the two dimensional Hubbard model with next-nearest-neighbor hopping (t'), chemical potential and temperature as control parameters. At $t' \leq 0$, we identify a line of Lifshitz transition points associated with a change of the Fermi surface topology at zero temperature. In the overdoped region, the Fermi surface is complete and electron-like; across the Lifshitz transition, the Fermi surface becomes hole-like and develops a pseudogap. At (or very close to) the Lifshitz transition points, a van Hove singularity in the density of states crosses the Fermi level. The van Hove singularity occurs at finite doping due to correlation effects, and becomes more singular when t' becomes more negative. The resulting temperature dependence on the bare d-wave pairing susceptibility close to the Lifshitz points is significantly different from that found in the traditional van Hove scenarios.

8:12AM T22.00002 Density Matrix Embedding Theory of Strongly Correlated Models , QIAONI CHEN, GERALD KNIZIA, GARNET KIN-LIC CHAN, Princeton University — We apply the recently developed density matrix embedding theory(DMET), to the honeycomb Hubbard model and the cuprate p-d model. DMET is based on the density matrix rather than the Green's function, thus all computations are frequency independent and of much lower cost than in DMFT. In DMET large clusters can be treated with similar accuracy but lower cost than in DMFT. (i) In the honeycomb Hubbard model, QMC calculations suggested a spin-liquid between a metal and insulator, but suffered from potential finite size errors. Using cluster DMET we find only a second-order phase transition near $U = 3.3$ between the metal and insulator, with no spin-liquid. Our thermodynamic data allows direct comparison to QMC calculations, highlighting the finite size errors. (ii) Three band model calculations with large cluster DMFT are infeasible, however cluster DMET calculations are very affordable. Earlier DMFT calculations place the metal-insulator transition at an unphysical d-occupancy. Using cluster DMET treatments, we show that the transition between metal and insulator shifts into the physical regime due to our ability to include large cluster correlations.

8:24AM T22.00003 Diagrammatic Monte Carlo for Fermions with Spin-Dependent Hopping Anisotropy , JAN GUKELBERGER, Theoretische Physik, ETH Zurich, EVGENY KOZIK, CPHT, Ecole Polytechnique , LODE POLLET, Department Physik, LMU Munich, KRIS VAN HOUCKE, Department of Physics and Astronomy, Ghent University, NIKOLAY PROKOF'EV, BORIS SVISTUNOV, Department of Physics, University of Massachusetts, MATTHIAS TROYER, Theoretische Physik, ETH Zurich — We study attractively interacting fermions on a square lattice whose Fermi surfaces exhibit a spin-dependent anisotropy. Such a system was proposed to harbor several exotic phases, most notably a Cooper-pair Bose-metal featuring a gap for fermionic excitations but gapless, uncondensed pair excitations along a Bose surface in momentum space. We present unbiased numeric results obtained with Diagrammatic Monte Carlo, a new technique for correlated fermionic systems based on sampling Feynman diagrammatic series directly in the thermodynamic limit. For the relevant regime of intermediate coupling strength our data show that the Fermi surface mismatch indeed suppresses the BCS transition to superfluidity. At strong anisotropy we find no sign of an ordering transition down to very low temperature suggesting existence of a quantum-phase transition from the conventional superconductor to an uncondensed state driven by the Fermi surface anisotropy.

8:36AM T22.00004 Non-Equilibrium Conductivity at Quantum Critical Points , ANDREW BERRIDGE, London Centre for Nanotechnology, M.J. BHASEEN, King's College London, A.G. GREEN, London Centre for Nanotechnology — The behaviour of quantum systems driven out of equilibrium is a field in which we are still searching for general principles and universal results. Quantum critical systems are useful in this search as their out of equilibrium steady states may inherit universal features from equilibrium. While this has been shown in some cases, the calculational techniques used often involve simplified models or calculational tricks, which can obscure some of the underlying physical processes. Here we use a Boltzmann transport approach to study the steady-state non-equilibrium properties - conductivity and current noise, of the Bose-Hubbard model head-on. We must explicitly consider heat-flow and rate limiting processes in the establishment of the steady-state to show that it can indeed be universal. Our analysis reveals the importance of the hydrodynamic limit and the limitations of current approaches.

8:48AM T22.00005 Quantum criticality of reconstructing Fermi surfaces , JUNHYUN LEE, PHILIPP STRACK, SUBIR SACHDEV, Harvard University — We present a functional renormalization group analysis of a quantum critical point in a two-dimensional metal involving Fermi surface reconstruction due to the onset of spin density wave order. The critical theory is controlled by a fixed point in which the order parameter and fermionic quasiparticles are strongly coupled, and acquire spectral functions with a common dynamic critical exponent. We obtain results for critical exponents, and for the variation in the quasiparticle spectral weight around the Fermi surface.

9:00AM T22.00006 Electric polarization in correlated insulators , REZA NOURAFKAN, GABRIEL KOTLIAR, Department of Physics & Astronomy, Rutgers University, Piscataway, NJ 08854-8019, USA, CONDENSED MATTER THEORY TEAM — We derive a formula for the electric polarization of interacting insulators, expressed in terms of the full Green's functions of the system. We use the formula to investigate changes in the electric polarization of the half-filled ionic Hubbard model. Correlations work in favor of covalency and a small lattice deformation can trigger substantial changes in the electric polarization. At the onset of the anti-ferromagnetic phase, a small lattice distortion suppresses the staggered magnetization and simultaneously the electric polarization has a higher variation. This behavior is absent when the anti-ferromagnetic phase is fully established. We also find that the quasi-particle approximation is a reliable approximation for weak to intermediate interaction strengths.

9:12AM T22.00007 Multiple energy scales and emerging quasiparticles in a doped Mott insulator , WENHU XU, GABRIEL KOTLIAR, Department of Physics and Astronomy, Rutgers University — We recognize two temperature scales relevant to formation of quasiparticles but distinct from the Brinkman-Rice scale in a doped Mott insulator. T_{qp} marks the formation of incoherent quasiparticles, while a smaller scale T_{FL} indicates the onset of Fermi-liquid coherence. Below T_{qp}, the scattering rate evolves linearly with temperature and the quasiparticle weight is also strongly T-dependent. Furthermore, the imaginary part of self energy is particle-hole asymmetric at low energy. These facts lead to non-Fermi liquid behaviors in transport properties. The Fermi liquid scale T_{FL} is characterized by a smooth saturation of quasiparticle weight and emerging particle-hole symmetry in self energy. We compute transport properties and find that non-Fermi liquid behavior of longitudinal and Hall resistivity persist down to well below T_{FL} while Hall angle and Nernst effect have revealed Fermi-liquid behavior above T_{FL}. We also discuss the validity of relaxation time approximation in interpreting non-Fermi liquid behaviors.

9:24AM T22.00008 Strongly enhanced thermal transport in a lightly doped Mott insulator[1] , VELJKO ZLATIC, Institute of Physics, Zagreb, JIM FREERICKS, Physics Department, Georgetown University — We discuss the charge and heat transport of a "bad metal" described by the Falicov-Kimball model near half-filling, using DMFT. For a lightly doped Mott insulator, the exact solution gives transport coefficients of a universal form at low, $T \leq T_0$, and high temperatures, $T \geq T_\mu$. These characteristic temperatures are such that, for $T \leq T_0$, transport is not affected by the excitations across the gap and that, for $T \geq T_\mu$, the chemical potential is at the center of the gap. At intermediate temperatures, $T_0 \leq T \leq T_\mu$, the chemical potential moves in the gap and the Wiedemann-Franz law doesn't hold. Here, the increased asymmetry of the electron and hole currents can very much enhance the thermopower S(T) and the figure of merit ZT. At a small doping and U$\gg$1 we find ZT$\geq$100. Above T_μ, the electron-hole symmetry is restored and S(T) drops to small values. For U>1 and moderate doping, there is a broad temperature interval in which ZT>1, even though the electronic thermal conductivity and the effective Lorenz number are not small. In this regime, the phonons might be less adverse to ZT. Large ZT is also obtained for a three-dimensional cubic lattice. Similar effects could not be obtained with non-interacting electrons or a Fermi liquid.

9:36AM T22.00009 Strongly Correlated Transport in the Falicov Kimball Model , GREG BOYD, JIM FREERICKS, Georgetown University, VELJKO ZLATIC, Institute of Physics, Zagreb, Croatia — Many materials like the cuprates, heavy fermions, and strongly correlated oxides, are non-Fermi liquid "bad metals", with linear or quasi-linear resistivity as a function of temperature. The low-energy excitations are quasiparticle-like near the Fermi surface, but their lifetimes are short, so they are not coherent or free-particle-like, as in conventional Fermi-liquids (whose quasi-particle lifetimes diverge at the Fermi energy). It turns out that this kind of behavior is ubiquitous in a wide range of different strongly correlated models, as long as the temperature is above the Fermi-liquid scale. To illustrate this, we investigate the strongly correlated transport in the Falicov-Kimball model using dynamical mean-field theory (DMFT) – which is exactly solvable in the limit of infinite coordination number. We show results for the resistivity as a function of temperature, the quasiparticle lifetime, and the spectral function. These results are quite similar to those recently found for the Hubbard model, illustrating that this high temperature behavior is seen in many different models of strong electron correlations.

9:48AM T22.00010 Charge density wave melting in a correlated system: real-time dynamics in the Hubbard-Holstein model , BRIAN MORITZ, Northern Illinois University and the University of North Dakota, CHENG-CHIEN CHEN, Advanced Photon Source, Argonne National Laboratory, THOMAS P. DEVEREAUX, SIMES and Division of Materials Science, SLAC National Accelerator Laboratory, MICHEL VAN VEENENDAAL, Northern Illinois University and the Advanced Photon Source, Argonne National Laboratory — Strongly correlated materials exhibit an intricate interplay between multiple degrees of freedom that can lead to competing phases with distinct broken symmetry. We study this interplay via the real-time dynamics in the photo-induced melting of the charge density wave state of the Hubbard-Holstein model. Using small cluster sparse matrix exact diagonalization and Krylov subspace techniques, we simulate the temporal evolution of the many-body wavefunction to reveal both the charge and lattice dynamics as a function of electron-electron and electron-phonon interaction strength. We study the behavior in proximity of the transition to the competing antiferromagnetic phase and comment on the character of the photo-induced transient state.

10:00AM T22.00011 Variational Monte Carlo Study of Heisenberg Model in Honeycomb Lattice with Six Spin Interactions , NILADRI SENGUPTA, Louisiana State University, SANDEEP PATHAK, UC Santa Cruz, KA-MING TAM, JUANA MORENO, MARK JARRELL, Louisiana State University — We investigate the possible nature of the spin liquid phase proposed by Quantum Monte Carlo simulation on the Hubbard model in a Honeycomb lattice. We consider the effective spin half Heisenberg model including the nearest neighbors, next nearest neighbors and six sites exchange interactions. Variational Monte Carlo simulations are performed by using the Gutzwiller projected BCS or resonating valence bond wavefunction. Different kind of symmetries (s,p+ip,d,d+id) in the pairing function are considered in order to investigate the effects of higher order exchange interactions.

10:12AM T22.00012 Representing vertex function in inhomogeneous frequency grid and its application in parquet formalism , KA-MING TAM, SHUXIANG YANG, JUANA MORENO, MARK JARRELL, Louisiana State University — Representing two-particle vertices has always been a central issue in computational many body methods such as the parquet formalism, a self-consistent two-particle field theory. Despite the great effort over the past two decades, its application is very limited. This is predominately due to two crucial factors–the stability of the iteration and the size of the memory allocation for representing the vertex. We previously demonstrated that the stability problem may be alleviated by explicitly restoring the crossing symmetry, making simulations beyond weak coupling for the Hubbard model feasible [1,2]. The next step for the practical applications of parquet formalism is to compress the memory required to represent the vertex. In this work, we elaborate a scheme which invokes an inhomogeneous frequency grid replacing the homogeneous Matsubara frequency grid, and thereby reducing the memory by over a order of magnitude. This may represent a crucial step towards the practical applications of the parquet formalism for large cluster sizes.

10:24AM T22.00013 Effect of Electron-Phonon Interaction Range for a Half-Filled Band in One Dimension , MARTIN HOHENADLER, University of Würzburg, FAKHER ASSAAD, University of Wüzburg, HOLGER FEHSKE, University of Greifswald — We demonstrate that fermion-boson models with nonlocal interactions can be simulated at finite band filling with the continuous-time quantum Monte Carlo method. We apply this method to explore the influence of the electron-phonon interaction range for a half-filled band in one dimension, covering the full range from the Holstein to the Fröhlich regime. The phase diagram contains metallic, Peierls, and phase-separated regions. Nonlocal interactions suppress the Peierls instability, and thereby lead to almost degenerate power-law exponents for charge and pairing correlations.

10:36AM T22.00014 ABSTRACT WITHDRAWN –

10:48AM T22.00015 Fluctuation-induced pair density wave state in itinerant ferromagnets near to quantum criticality , ANDREW G. GREEN, London Centre for Nanotechnology, GARETH CONDUIT, TCM, Canvendish Laboratory, University of Cambridge, CHRISTOPHER P. PEDDER, London Centre for Nanotechnology — Magnetic fluctuations near to itinerant ferromagnetic quantum criticality can have profound effects. It has long been realised - since the understanding of superfluidity in helium-3 - that ferromagnetic fluctuations can drive p-wave superconductivity. Near to quantum criticality, fluctuations lead to characteristic scaling with temperature and, ultimately, to a reconstruction of the phase diagram by the fluctuation-driven formation of spatially modulated magnetic order. Here, we show that near to the putative quantum critical point, these two effects become intertwined leading to a fluctuation-driven pair density wave. Moreover, describing this physics from the quantum order-by-disorder perspective reveals a fundamentally common origin of the two effects.

Session T23 FIAP: Semiconductors: Thermodynamic & Transport Properties (Experimental)

325 - Ernesto Marinero, Hitachi Global

8:00AM T23.00001 Hall Effect Measured Using a Waveguide Tee , JOYCE COPPOCK, JAMES ANDERSON, University of Maryland, College Park, Maryland, WILLIAM JOHNSON, Laboratory for Physical Sciences, College Park, Maryland — We describe a simple microwave apparatus to measure the Hall effect in semiconductor wafers. The advantage of this technique is that it does not require contacts on the sample, unlike the Van der Pauw method.[1] Our method consists of placing the semiconductor wafer into a slot cut in an X-band waveguide tee and placing the tee in the center of an electromagnet. The next step is to inject power into two arms of the tee and to balance the output so that no power comes out of the third arm of the tee at zero magnetic field. Application of a nonzero magnetic field gives a Hall signal that is linear in the magnetic field and which reverses phase when the magnetic field is reversed. We use a network analyzer to measure the ratio of the Hall signal to the input power. This method yields the semiconductor mobility in the wafer, which we can compare for calibration purposes with mobility data from our Van der Pauw measurements. This talk presents data for silicon and germanium samples doped with boron or phosphorus. Preliminary measurements on doped III-V semiconductor samples will also be presented.

8:12AM T23.00002 Compositional Distribution in Semiconductor Ternary Quantum Dots and Its Effects on Their Optoelectronic Properties , XU HAN, University of Massachusetts-Amherst, SUMEET PANDEY, Micron Technology Inc., DIMITRIOS MAROUDAS, University of Massachusetts-Amherst — We present a systematic theoretical and computational analysis of compositional distribution in semiconductor ternary quantum dots (TQDs) and the resulting effects on the TQDs' electronic band structure. The analysis is based on a hierarchical modeling approach that combines first-principles density functional theory calculations and classical Monte Carlo simulations with a continuum model of species transport in spherical nanocrystals. In many cases of TQD composition, the model predicts the formation of core/shell-like structures characterized by the formation of concentration boundary layers near the nanocrystal surfaces. A systematic analysis over the size-composition parameter space generates a database of transport properties that is used to design post-growth thermal annealing processes to establish thermodynamically stable compositional distributions in TQDs. We explore the impact of compositional distribution on the TQDs' electronic band gaps and find that TQDs with thermodynamically stable compositional distributions allow for precise band-gap tuning. Our findings lead to a proposal for an efficient one-step TQD synthesis method followed by annealing to promote self assembly of the thermodynamically stable configuration, for optimal optoelectronic function in devices.

8:24AM T23.00003 Weak localization and low temperature transport in MoS_2 flakes , ADAM T. NEAL, HAN LIU, YUCHEN DU, PEIDE YE, Purdue University, Birck Nanotechnology Center — With the recent identification of the indirect to direct bandgap transition for monolayer MoS_2 [1] and the use of MoS_2 in field-effect transistors [2,3], this material has attracted recent interest in the physics and nanotechnology communities. We report studies of transport in MoS_2 at low temperature from 1K up to 70K, characterized by Hall mobility and weak localization. We find that the mobility at T=400mK in this few-layer MoS_2 flake varies from 50cm^2/Vs to 300cm^2/Vs as electron density varies from 6x10^{12} cm^{-2} to 1.2x10^{13} cm^{-2} via the back gate bias. Additionally, we find that the mobility decreases with increasing temperature as a power law with a characteristic exponent of 1.6 at a carrier concentration of 1.2x10^{13} cm^{-2}. Magneto-transport measurements reveal weak localization in this MoS_2 sample up to temperatures as high as 10K. The phase coherence length in MoS_2 is estimated to be about 40nm at 1K for a carrier concentration of 1.2x10^{13} cm^{-2}.

8:36AM T23.00004 Ionic-Liquid Gated Few-layer MoS_2 Field-Effect Transistors[1] , MEEGHAGE PERERA, MING-WEI LIN, HSUN-JEN CHUANG, BHIM CHAMLAGAIN, CHONGYU WANG, XUEBIN TAN, MARK MING-CHENG CHENG, ZHIXIAN ZHOU, Wayne State University — We report the electrical characterization of ionic-liquid-gated bilayer and few-layer MoS_2 field-effect transistors. The extrinsic mobility of our ionic-liquid-gated devices exceeds 70 $cm^2V^{-1}S^{-1}$ at 250 K, which is 1-2 orders of magnitude higher than that measured in the Si back-gate configuration (without ionic liquid). These devices also show ambipolar behavior with a high ON-OFF current ratio of $> 10^7$ for electrons and $> 10^6$ for holes, and a near ideal subthreshold swing (SS) of $\sim$ 50 mV/decade at 250 K for the electron channel. More significantly, we show that the mobility increases from $\sim$ 100 $cm^2V^{-1}S^{-1}$ at 180 K to $\sim$ 220 $cm^2V^{-1}S^{-1}$ at 77K as the temperature decreases following a $\mu \sim T^{-\gamma}$ dependence with $\gamma \approx 1$, indicating that the intrinsic phonon-limited mobility can be achieved in few-layer MoS_2 FETs. We attribute the enhanced device performance to the drastic reduction of the Schottky barrier width (thus higher tunneling efficiency) via highly efficient band bending at the MoS_2/metal interface afforded by the extremely large electrical double layer capacitance of the ionic liquid.

8:48AM T23.00005 Phonon-Limited Electron Transport in Back-Gated Few-layer $MoSe_2$ Field-Effect Transistors , BHIM CHAMLAGAIN, Wayne State University, QING LI, Oak Ridge National Lab, HSUEN-JEN CHUANG, MEEGHAGE MADUSANKA PERERA, MING-WEI LIN, Wayne State University, MINGHU PAN, Oak Ridge National Lab, DI XIAO, Carnegie Mellon University, JIAQIANG YAN, NIRMAL JEEVI GHIMIRE, DAVID MANDRUS, The University of Tennessee & Oak Ridge National Lab, ZHIXIAN ZHOU, Wayne State University — The ultrathin body of monolayer (and few-layer) semiconducting transition-metal-dichalcogenides (TMDs) in conjunction with their highly desirable surface properties makes them excellent candidates for the ultimate downscaling of digital electronics. We have fabricated field effect transistors (FETs) of mechanically exfoliated few-atomic- layer-thick $MoSe_2$, a member of the semiconducting TMD family; and measured their device characteristics as a function of temperature. We find that the field-effect mobility of the devices increases with the applied back-gate voltage, which can be attributed to the Schottky barrier reduction via band bending at the contacts. In the limit of high back-gate voltages, the mobility increases from $\sim$ 135 cm^2/V.s at room temperature to over 300 cm^2/V.s at 200 K following the power law of $\mu \sim T^{-2.1}$, indicating that the mobility is chiefly limited by phonon scattering rather than charged impurity scattering. We attribute the high mobility and its temperature dependence to the extremely low density of defects and/or impurities in the starting $MoSe_2$ crystals as verified by low temperature scanning tunneling microscopy/spectroscopy (STM/STS) measurements.

9:00AM T23.00006 Electrical Transport Properties of Liquid Phase Exfoliated MoS_2 Thin Films[1] , SUJOY GHOSH, ANDREW WINCHESTER, Southern Illinois University, Carbondale, IL, ANA ELIAS, Penn State University, University Park, PA, NIHAR PRADHAN, LUIS BALICAS, National High Magnetic Field Lab, Tallahassee, FL, MAURICIO TERRONES, Penn State University, University Park, PA, SAIKAT TALAPATRA, Southern Illinois University, Carbondale, IL — In this presentation we will report the electrical transport properties of thin films consisting of liquid phase exfoliated MoS_2 flakes. The D.C electrical transport properties will be discussed in the light of 2D VRH model. Our preliminary investigations on the A.C transport properties on these materials indicate similar found in disordered semiconductors. These results will be discussed based different existing charge transport mechanisms under the application of an A.C field.

9:12AM T23.00007 Electrical transport and contact characteristics of single layer MoS_2 devices , JEN-RU CHEN, PATRICK ODENTHAL, ROLAND KAWAKAMI, Membership Pending — MoS_2 and related metal dichalcogenides ($MoSe_2$, WS_2, WSe_2) are layered two dimensional materials with analogous structure to graphene. The monolayer MoS_2, where the Mo layer is sandwiched between two sulfur layers, is a semiconductor with a direct band gap (1.8 eV) at valley K and K' points. These materials are of significant technological interest for nanoscale electronic devices with high on off ratio, opto-electronics, and gas sensing. Also, due to giant spin-orbit coupling and spin splitting ($\sim$ 150 meV) in the valence band of monolayer MoS_2, monolayer MoS_2 has great potential for fascinating spin behavior, including the intrinsic spin Hall effect. Towards investigating spin transport in monolayer MoS_2, we have investigated ferromagnetic metal contacts on monolayer MoS_2. Through transport measurements, we are able to determine the Schottky barrier height between the Co contact electrodes and monolayer MoS_2 with characteristic temperature dependence.

9:24AM T23.00008 Investigating the thermal stability of electron transport properties in modulation-doped semiconductor heterostructure systems[1] , IAN PILGRIM, BILLY SCANNELL, University of Oregon, ANDREW SEE, University of New South Wales, RICK MONTGOMERY, PETER MORSE, MATT FAIRBANKS, COLLEEN MARLOW, University of Oregon, HEINER LINKE, Lund University, IAN FARRER, DAVID RITCHIE, Cavendish Laboratory, ALEX HAMILTON, ADAM MICOLICH, University of New South Wales, LAURENCE EAVES, University of Nottingham, RICHARD TAYLOR, University of Oregon — Since the 1950s, materials scientists have pursued the fabrication of solid-state heterostructure (HS) devices of sufficient purity to replicate electron interference effects originally observed in vacuum. The ultimate goal of HS engineering is to create a semiconductor "billiard table" in which electrons travel ballistically in a 2-D plane—that is, with scattering events minimized such that the electron's mean free path exceeds the device size. For the past two decades, the modulation-doped (MD) HS architecture has yielded devices supporting very high electron mobilities. In this architecture, ionized dopants are spatially removed from the plane of the electrons, such that their influence on electron trajectories is felt through presumably negligible small-angle scattering events. However, we observe that thermally induced charge redistribution in the doped layers of AlGaAs/GaAs and GaInAs/InP MD heterostructures significantly alters electron transport dynamics as measured by magnetoconductance fluctuations. This result demonstrates that small-angle scattering plays a far larger role than expected in influencing conduction properties.

9:36AM T23.00009 High temperature conductivity measurement of La and Sb doped BaSnO3 thin films , CHULKWON PARK, USEONG KIM, HYUKWOO KWON, HOONMIN KIM, KOOKRIN CHAR, Department of physics in Seuol National University, MDPL TEAM — We have recently found that doped $BaSnO_3$ (BSO) system offers great potential for scientific investigations as well as technical applications due to its transparency, high mobility and chemical stability. We investigated the temperature dependent conductivity in two differently n type doped BSO, La doped $BaSnO_3$ (BLSO) and Sb doped $BaSnO_3$ (BSSO), at high temperatures in O_2 and Ar atmosphere. Firstly, by switching gas atmosphere, we have measured the diffusion constant of oxygen atoms in BSO thin films from the time dependent conductivity measurement much lower than those of other oxides exhibiting its stable oxygen stoichiometry. Secondly, although both BLSO and BSSO are n typed doped, slight different behavior in temperature dependent conductivity was found; while the BLSO thin films showed expected results that the conductivity decreased as increasing temperature, the BSSO films displayed increasing conductivity as the temperature increased above 500C. In that high temperature region the BLSO and BSSO films also showed different behavior when the gas atmosphere was exchanged between O_2 and Ar. We will present possible explanations for the observation of the different behavior of BLSO and BSSO in high temperature region by taking into consideration the role of the dopant site and threading dislocations in conductivity of BSO system.

9:48AM T23.00010 Time-Resolved Electroabsorption Measurement of Electron Velocity in InGaN Heterostructures due to Internal Electric Fields , BLAIR CONNELLY, CHAD GALLINAT, NATHANIEL WOODWARD, RYAN ENCK, GRACE METCALFE, RANDY TOMPKINS, SHUAI ZHOU, KENNETH JONES, HONGEN SHEN, MICHAEL WRABACK, US Army Research Laboratory — Carrier transport was measured in c-plane, p-down, n-GaN/i-$In_{1-x}Ga_xN$/p-GaN solar cell heterostructures using a time-resolved electroabsorption pump-probe technique with sub-picosecond resolution. Large built-in electric fields are present in the InGaN region associated with the termination of large polarization at hetero-interfaces. The change in transmission of a probe beam (tuned for maximum sensitivity to changes in the band edge) due to the transport of photogenerated carriers under the built-in field is monitored to determine the electron transit time and average electron velocity. Time-domain THz measurements indicate the direction of electron transport is dominated by drift towards the n-GaN. Samples with a 200-nm $In_{0.13}Ga_{0.87}N$ layer show a change in signal rise time with carrier density. At the lowest injection level, an $\sim$ 1.5-ps rise time is observed, which corresponds to an average electron velocity of 6.7x10^6 cm/s for an average distance of travel of 100 nm in an internal field of $\sim$ 135 kV/cm. This velocity is significantly smaller than in GaN with a similar field, which may be indicative of transport through compositional inhomogeneities.

10:00AM T23.00011 Measurement of the phonon mean free path spectra and the universality in the high temperature limit , KEITH REGNER, JUSTIN FREEDMAN, Carnegie Mellon University, ZLATKO SITAR, North Carolina State University, JACOB LEACH, Kyma Technologies, ROBERT DAVIS, JONATHAN MALEN, Carnegie Mellon University — Here, we use broadband frequency domain thermoreflectance (BB-FDTR) to measure thermal conductivity accumulation functions ($k_{\rm accum}$) of Si, GaAs, GaN, AlN, and SiC at temperatures of 80 K, 150 K, 300 K, and 400 K and show that they collapse to a universal accumulation function ($k_{\rm univ}$) in the high temperature limit. BB-FDTR is a novel technique developed to measure the spectral contributions of phonons to bulk thermal conductivity as a function of phonon MFP i.e., $k_{\rm accum}$. BB-FDTR uses a heterodyne approach allowing for continuous resolution of the phonon MFP spectrum spanning two orders of magnitude (0.3 - 8 μm in Si at $T = 300$ K). Results in Si and GaAs compare favorably to numerical predictions (Esfarjani, et al., PRB, 2011) (Luo et al., arXiv, 2012) and show that phonons with long MFPs (>1 μm) contribute significantly to the bulk thermal conductivity at $T = 300$ K. Next, we present a method to predict $k_{\rm accum}$ as the temperature of the material approaches its Debye temperature. Using the measured spectra at $T = 400$ K and assuming Umklapp scattering as the dominant scattering mechanism, $k_{\rm univ}$ was found to exist in GaAs, GaN, and Si after normalizing the phonon MFP. The existence of $k_{\rm univ}$ suggests that the phonon MFP spectrum is a universal feature of matter in the high temperature limit, and can be used to predict $k_{\rm accum}$ for any crystalline semiconductor near its Debye temperature.

10:12AM T23.00012 Thermometry and Refrigeration using Quantum Dots , AQUILA MAVALANKAR, CHARLES SMITH, SIMON CHORLEY, JONATHAN GRIFFITHS, GEB JONES, IAN FARRER, DAVID RITCHIE, Semiconductor Physics Group, Department of Physics, JJ Thomson Avenue, Cambridge CB3 0HE — The 2D electron gas in GaAs/AlGaAs heterostructures has diverse applications at cryogenic temperatures, but is heated by unintended noise in the measurement set up. Our work involves the fabrication of a quantum dot refrigerator (QDR) which can cool the gas to below the ambient lattice temperature [1]. Lithographically defined gates define three quantum dots tunnel-coupled to an enclosed, macroscopic reservoir of electrons 100 μm^2 in area. Energy selective transport of electrons via the discrete energy levels of two quantum dots through the electron reservoir modifies its Fermi-Dirac distribution, thus cooling it. The third quantum dot (the 'thermometer') probes the temperature of the reservoir being cooled by monitoring the current flowing through an adjacent quantum point contact. We have demonstrated measuring electronic temperatures in the range 100 mK to 300 mK, with an estimated error of about 10%. We have also investigated the variation in electron temperature as a function of the energies of the entrance and exit dots. Our results are consistent with cooling an area of 64μm^2 by 30 mK, starting from 150mK, and agree qualitatively with theory [2].

10:24AM T23.00013 Structures, electronic and magnetic properties of transition metal doped MoS2 intercalation compounds[1] , HONG-DAO LI, TAI-SING WU, HORNG-TAY JENG, Department of Physics, National Tsing Hua University, Taiwan, SHIH-LIN CHANG, National Synchrotron Radiation Research Center, Taiwan, YUN-LIANG SOO, Department of Physics, National Tsing Hua University, Taiwan — Molybdenum disulfide (MoS2) has recently attracted much attention due to its potential applications in high efficiency hydrogen storage, catalysts, and nanoelectronic devices. While intrinsic MoS2 bulk is a well-known diamagnetic material, zigzag nanoribbons of MoS2 have been predicted by density functional theory (DFT) to be metallic and ferromagnetic. The effects of transition metal (TM) doping on the magnetic properties of MoS2 appear to be a very interesting issue. In this work, we have synthesized a series of TM (Co,Ni,Cu) doped MoS2 intercalation compounds by an exfoliation/restacking method with different TM concentration (0.01-10 at. %) and annealed at various temperatures (300-1000K). Raman spectra and x-ray diffraction (XRD) data show that the synthesized TM-MoS2 intercalation compounds are in 2H-MoS2 structure with average size $\sim$100 nm. The average distance between MoS2 host layers strongly depends on the TM concentration. XANES and EXAFS reveal that TM atoms are located on tetrahedral sites between the MoS2 sheets with valence number +1. A series of DFT simulations indicate that Co-MoS2 may exhibit half-metallic ferromagnetic states while ferromagnetism is absent in Cu-MoS2 and Ni-MoS2. Experimental data obtained from magnetic measurements will also be presented.

10:36AM T23.00014 NRG study of the transmission phase shift through a two-level quantum dot with Kondo correlations , ARNE ALEX, ANDREAS WEICHSELBAUM, JAN VON DELFT, Arnold Sommerfeld Center, LMU Munich — The transmission phase shift through a Kondo quantum dot has been predicted to take the universal value $\pi/2$ in the center of the Kondo valley[1]. Several experimental studies using a quantum dot embedded in an Aharonov-Bohm ring have aimed to check this prediction, which was finally verified in [2]. A recent experiment[3] has obtained particularly clean results for the transmission phase shift by eliminating the effect of backscattering. We provide a Numerical Renormalization Group study of a two-level quantum that shows very good qualitative agreement with these new experimental results. The effect of the second level, with width different from the first, is crucial for accounting for some of the observed experimental details.

10:48AM T23.00015 Transmission phase shift across a Kondo correlated quantum dot , SHINTARO TAKADA, (1)Department of Applied Physics, University of Tokyo, Bunkyo-ku, Tokyo 113-8656, Japan, CHRISTOPHER BÄUERLE, (2)Institut Néel - CNRS and Université Joseph Fourier, 38042 Grenoble, France, MICHIHISA YAMAMOTO, KENTA WATANABE, (1), SYLVAIN HERMELIN, TRISTAN MEUNIER, (2), ANDREAS D. WIECK, (3)Lehrstuhl für Angewante Festkörperphysik, Ruhr - Universität Bochum, D-44780 Bochum, Germany, SEIGO TARUCHA, (1) — We report on measurements of the transmission phase across a quantum dot embedded in an original two-path interferometer both in the strong and weak Kondo regime. The Kondo effect is a well known many-body phenomenon, which is characterized by a single energy scale, the Kondo temperature $T_{\rm K}$. In the strong Kondo regime at low temperatures ($T/T_{\rm K}$ <1) we found that the transmission phase is locked to $\pi/2$ in the Kondo valley when the single level spacing $\delta$is significantly larger than the level broadening Γ. When Γ is relatively large, on the other hand, the phase smoothly shifts by π across two peaks on both ends of the Kondo valley without showing any plateau. As the temperature is increased exceeding $T_{\rm K}$, the Kondo correlation becomes lifted and then the phase shift looks similar to that in the Coulomb blockade regime, where the phase evolves π across a Coulomb peak followed by a π-phase lapse in the Coulomb valley. In such a weak Kondo regime ($T/T_{\rm K}$ >1) we observed asymmetric phase evolution about the valley center, which is linked to the orbital parity relation between the levels of interest.

11:00AM T23.00016 Scanning probe microscopy measurements of charge in PbS quantum dot (sub)monolayers , JASON P. MOSCATELLO, PAWANA SHRESTHA, QINXIA WANG, KATHERINE E. AIDALA, Mount Holyoke College — Nanocrystal quantum dots (NQDs) are of intense interest because their optical and electronic properties can be tuned by altering the dot size and material. Transport in arrays of NQDs is generally dominated by disorder, and strongly influenced by the immediate environment. Fully understanding transport through arrays of NQDs would allow the design of improved devices, such as LEDs, photodetectors and lasers. The goal of our study is to use electrostatic force microscopy techniques to study charge transport in (sub)monolayers of NQDs. These 2D PbS NQD arrays are achieved by spin-coating the NQDs between lithographically patterned electrodes, and the measurements take place in a custom-built nitrogen environment cell for our AFM.

Thursday, March 21, 2013 8:00AM - 11:00AM –

Session T24 DCOMP: Focus Session: Recent Developments in Density Functional Theory II

326 - Timo Thonhauser, Wake Forest University

8:00AM T24.00001 Comparing Exact Charge Gaps to Exact DFT and DFT Approximations for Extended 1D Continuum Systems[1] , EDWIN MILES STOUDENMIRE, LUCAS O. WAGNER, STEVEN R. WHITE, KIERON BURKE, UC Irvine — With recent technical advances, the density matrix renormalization group (DMRG) can solve model electronic structure systems with long-range interactions in the 1D continuum exactly. We have been studying these systems as a laboratory for understanding and improving density functional theory (DFT). In this setting we can compute both the exact Kohn-Sham (KS) system and implement key DFT approximations. I will present exact data for charge gaps of extended chains of atoms and molecules driven through metal-insulator transitions, then compare various methods for computing these gaps in DFT. For example, we can compute the KS band gap exactly then compare to the KS band gap or integer gap computed within approximations such as LDA or LDA+U. Our results clarify how KS-DFT captures, or fails to capture, weakly and strongly correlated insuators and highlights the key challenges for improving approximate functionals.

[1]Supported by the Dept. of Energy

8:12AM T24.00002 Development of accurate electron-hole exchange-correlation functional for calculation of exciton binding energy and electron-hole recombination probability in quantum dots , ARINDAM CHAKRABORTY, CHRISTOPHER BLANTON, Syracuse University — Development of electron-hole exchange-correlation functional (eh-Exc) is challenging because of various factors such as distance dependent dielectric function, different effective masses, and presence of core/shell interfaces. Calculation of eh-recombination probability is also challenging because of its sensitivity to the form of the wavefunction at small electron-hole separation. This talk will focus on systematic development of eh-Exc to address these challenges. In this approach an orbital based functional is constructed by combining the strategy of direct minimization of the optimized effective potential (OEP) with the OEP-MBPT method. The eh-Exc functional was used for computational of exciton binding energy and eh-recombination in a series of CdSe qdots. Comparison of the eh-Exc results with pseudopotential+CI calculations, Kohn-Sham perturbation theory calculations, and experimental values will be presented. The results indicate that the search for the ground state densities can be restricted to a set of N-representable densities which satisfy the electron-hole Kato cusp condition. Assessment and benchmarking of the quality of the eh-recombination probability will be presented by comparing eh-Exc results with explicitly correlated methods such as PIMC and QMC calculations.

8:24AM T24.00003 A DFT-based method of calculating optical properties of transition metal oxide materials , JOHN E. COULTER, Florida State University, ADAM GALI, Institute for Solid State Physics and Optics - Hungarian Academy of Sciences, MANOUSAKIS EFSTRATIOS, Florida State University — As part of an ongoing investigation of optical properties of transition metal oxide materials, we have examined the optical properties of Vanadium Dioxide using an *ab-initio* method. Starting from hybrid DFT, we apply the GW approximation and solve the Bethe-Salpeter Equation (BSE) on the wavefunctions obtained from the DFT starting point. We find that the hybrid functional is not fully satisfactory for description of the optical spectrum of VO2, and that corrections are required. The hybrid functional results may be a good starting place for many-body perturbation theory. We apply the GW approximation and then solve the BSE from that starting point. We show that including single particle-hole quasiparticles is not sufficient for the optical spectrum, and that two-particle-two-hole effects must be included via the BSE to give agreement between the integrated strength of the optical spectrum at low energies and the experimental spectrum. We also find that a large number of high energy states must be included for a convergent description of the low energy optical spectrum.

8:36AM T24.00004 Quasiparticle Spectra from a Nonempirical Optimally Tuned Range-Separated Hybrid Density Functional , SIVAN REFAELY-ABRAMSON, Weizmann Institute of Science, Israel, SAHAR SHARIFZADEH, Lawrence Berkeley National Laboratory, USA, NIRANJAN GOVIND, Pacific Northwest National Laboratory, USA, JOCHEN AUTSCHBACH, University at Buffalo, State University of New York, USA, JEFFREY B. NEATON, Lawrence Berkeley National Laboratory, USA, ROI BAER, Institute of Chemistry, Hebrew University, Israel, LEEOR KRONIK, Weizmann Institute of Science, Israel — We present a method for obtaining outer-valence quasiparticle excitation energies from a density-functional-theory-based calculation, with an accuracy that is comparable to that of many-body perturbation theory within the GW approximation. The approach uses a range-separated hybrid density functional, with an asymptotically exact and short-range fractional Fock exchange. The functional contains two parameters, the range separation and the short-range Fock fraction. Both are determined nonempirically, per system, on the basis of the satisfaction of exact physical constraints for the ionization potential and many-electron self-interaction, respectively. The accuracy of the method is demonstrated on four important benchmark organic molecules: perylene, pentacene, 3,4,9,10-perylene-tetracarboxylic dianhydride (PTCDA), and 1,4,5,8-naphthalene-tetracarboxylic dianhydride (NTCDA). We envision that for finite systems the approach could provide an inexpensive alternative to GW, opening the door to the study of presently out of reach large-scale systems (Phys. Rev. Lett., in press).

8:48AM T24.00005 Plasmon-pole models affect band gaps in GW calculations , PAUL LARSON, ZHIGANG WU, Colorado School of Mines — Density functional theory calculations have long been known to underestimate the band gaps in semiconductors. Significant improvements have been made by using GW calculations that uses the self energy, defined as the product of the Green function (G) and screened Coulomb exchange (W). However, many approximations are made in the GW method, specifically the plasmon-pole approximation. This approximation replaces the integration necessary to produce W with a simple approximation to the inverse dielectric function. Four different plasmon-pole approximations have been tested using the tight-binding program ABINIT: Godby-Needs, Hybertsen-Louie, von der Linden-Horsch, and Engel-Farid. For many materials, the differences in the GW band gaps for the different plasmon-pole models are negligible, but for systems with localized electrons, the difference can be larger than 1 eV. The plasmon-pole approximation is generally chosen to best agree with experimental data, but this is misleading in that this ignores all of the other approximations used in the GW method. Improvements in plasmon-pole models in GW can only come about by trying to reproduce the results of the numerical integration rather than trying to reproduce experimental results.

9:00AM T24.00006 Many-body effects on the zero-point renormalization of diamond: a frozen-phonons approach , GABRIEL ANTONIUS, Université de Montréal, SAMUEL PONCÉ, Université Catholique de Louvain, MICHEL CÔTÉ, Université de Montréal, XAVIER GONZE, Université Catholique de Louvain — Electron-phonon interaction has a sizeable effect on the electronic structure of materials. Even at zero temperature, the zero-point renormalization (ZPR) can reduce the band gap of insulators by several hundreds of meV. The method of choice to compute this effect is based on the AHC theory, performing perturbative calculations with DFT wavefunctions and energies, possibly with a scissor shift. However, previous studies suggest that inclusion of many-body effects might change substantially the DFT electron-phonon coupling coefficients. We study the ZPR of the optical band gap of diamond, using a frozen-phonons method. This allows us to perform G_0W_0 and self-consistent quasi-particle GW calculations on the distorted lattice, thus including many-body effects in the electron-phonon coupling coefficients. The frozen-phonons method also allows us to study other neglected components of the AHC theory, such as the non-diagonal Debye-Waller term, and the anharmonic effects.

9:12AM T24.00007 Going beyond Kohn and Sham (KS): determining accurate ground and first excited states , LUIZ FERREIRA, Universidade de Sao Paulo, MARCELO MARQUES, LARA TELES, RONALDO PELA, Instituto Tecnologico de Aeronautica — The Total energy in KS is written as

$$E = \frac{1}{2}\sum\int \nabla\psi^* \cdot \nabla\psi + \frac{1}{2}\int \frac{\sum \psi^*\psi(r)\sum \psi^*\psi(r')}{(r-r')} + \int \sum \psi^*\psi V_{nuclei} + Exc$$

The KS procedure continues by minimizing the energy with respect the wavefunctions ψ. The equation for the wave functions is similar to the one-particle Schroedinger equation. In our talk we will present results obtained in the following way: we add an external potential V_{add} to the nuclei potential V_{nuclei} and, after the calculation is completed, we subtract what we added, namely. $-\int\sum \psi^*\psi V_{add}$. The result is a calculation according to the Eq. above but with wavefunctions not satisfying the KS equations. If the exchange-correlation term were reliable one would expect that the calculated energy would be larger than the KS energy. The added potential V_{add} is what is being used in the *LDA-1/2* method and is dependent on a cut-off parameter C. Making the extremization of the total energy with respect to C we obtain (1) a point of maximum, which frequently will be shown to be the first excited state, (2) a minimum, with an energy lower than the KS ($C = 0$) ground state and with improved lattice parameter.

9:24AM T24.00008 Efficient optimal effective potential approach for pe- riodic plane-wave density functional theory[1] , FLORIAN LIBISCH, JOHANNES M. DIETERICH, CHEN HUANG, EMILY A. CARTER, Department of Mechanical and Aerospace Engineering, Princeton University, Princeton, New Jersey 08544, USA — Kohn-Sham (KS) density functional theory (DFT) formulates equations for non-interacting electrons subject to a mean-field KS potential. The exchange and correlation (XC) between electrons are accounted for by density-based XC-functionals. The introduction of orbital-dependent functionals allows for a more accurate treatment of exchange and correlation, a prominent example being the exact treatment of Hartree-Fock exchange. Such a construction, however, is not straightforward in KS DFT, as all Kohn Sham orbitals fulfill the same KS equation. For a given orbital-dependent functional, direct solutions to find the corresponding KS potential are numerically cumbersome or even unstable. By extending and combining previous approaches [Phys. Rev. B 62, 15521 (2000), Phys. Rev. B 84, 165122 (2011)], we introduce a momentum-space based formulation that allows for an efficient treatment of orbital-dependent functionals. We include the full spin degrees of freedom, as well as periodic boundary conditions and k-point sampling. We show that for the spin-free case, our formulation becomes similar to the orbital-shift approach [Phys. Rev. B 68, 035103 (2003)] but numerically better suited for implementation in plane-wave DFT codes. Finally, we discuss practical applications.

9:36AM T24.00009 Reliability of the Tran-Blaha functional in predicting band gaps and widths , GIAN-MARCO RIGNANESE, WAROQUIERS DAVID, AURÉLIEN LHERBIER, ANNA MIGLIO, MARTIN STANKOVSKI, SAMUEL PONCE, Institute of Condensed Matter and Nanosciences, Université Catholique de Louvain, MICAEL OLIVEIRA, Center for Computational Physics, University of Coimbra, Portugal, MATTEO GIANTOMASSI, XAVIER GONZE, Institute of Condensed Matter and Nanosciences, Université Catholique de Louvain — For a set of oxides and semiconductors, we compute the electronic band structures (gaps and widths) within Density-Functional theory (DFT) using the Tran-Blaha (TB09) functional [Phys. Rev. Lett. **102**, 226401 (2009)]. We compare them with those obtained from (i) DFT using the local-density approximation (LDA), (ii) many-body perturbation theory (MBPT), and (iii) experiments. TB09 leads to band gaps in much better agreement with experiment than the LDA. However, the valence (and conduction) band widths are often underestimated (noticeably more than in LDA). MBPT corrections are obtained peforming one-shot GW calculations using DFT eigenenergies and wavefunctions as starting point (both LDA and TB09 are considered). These corrections lead to a much better agreement with experimental data for the band widths. The MBPT band gaps obtained starting TB09 are close to those from quasi-particle self-consistent GW calculations, at a much reduced cost. Finally, we explore the possibility to tune a semi-empirical parameter present in the TB09 functional aiming to obtain simultaneously better gaps and band widths. We find that these requirements are conflicting.

9:48AM T24.00010 Construction of a spin-density functional for models of strongly correlated systems: including spin improves the description of charge , KLAUS CAPELLE, UFABC, DANIEL VIEIRA, Universidade do Estado de Santa Catarina, VIVIAN FRANCA, Albert Ludwigs Universität — An explicit spin-dependence is built into a class of previously developed density functionals for models of strongly correlated systems. As a side effect of accounting for the spin-degrees of freedom, the functional also provides an improved description of the charge-degrees of freedom. In particular, unlike earlier proposals, the present parametrization correctly predicts a positive Mott gap at half filling for any repulsive interaction. Applications to spatially inhomogeneous models, e.g. in the presence of impurities, external fields or trapping potentials are worked out and results are shown to be in excellent agreement with independent many-body calculations, at a fraction of the computational cost. See New J. Phys. 14 073021 (2012).

10:00AM T24.00011 Transverse spin gradient functional for non-collinear Spin Density Functional Theory[1] , F.G. EICH[2], G. VIGNALE, Department of Physics, University of Missouri-Columbia, Columbia, Missouri 65211, USA, E.K.U. GROSS, Max-Planck-Institut fuer Mikrostrukturphysik, Halle, Germany — The ab-initio description of non-collinear magnetism is essential for the search of new materials suitable for the construction of spintronic devices. We present a novel functional explicitly constructed for the description of non-collinear magnetism. It is formulated in terms of a Spin Gradient Extension (SGE) to the Local Spin Density Approximation, which introduces a dependence on the transverse gradients of the spin magnetization. While collinear Generalized Gradient Approximations provide a dependence on longitudinal spin gradients the SGE takes into account that longitudinal and transverse variations of the spin magnetization affect the energy differently. The explicit dependence on the transverse gradients is obtained from a reference systems which exhibits non-collinearity, i.e., the spin-spiral-wave state of the uniform electron gas. The inclusion of transverse spin gradients yields exchange-correlation magnetic fields that are non-collinear w.r.t. the spin magnetization. This implies that the spin-current density of the Kohn-Sham system does not vanish even if no external magnetic field is applied. As an example we present the application of the SGE to the non-collinear $120°$-Néel state of a Chromium mono-layer.

10:12AM T24.00012 Angular Momentum Dependent Orbital Free Density Functional Theory , YOUQI KE, FLORIAN LIBISCH, JUNCHAO XIA, Department of Mechanical and Aerospace Engineering, Princeton University, Princeton, New Jersey 08544, USA, LIN-WANG WANG, Material Science Division, Lawrence Berkeley National Laboratory, Berkeley, California 94720, USA, EMILY A. CARTER, Department of Mechanical and Aerospace Engineering, Princeton University, Princeton, New Jersey 08544, USA — We report a novel and general formalism for linear scaling, angular momentum dependent (AMD) orbital free (OF) density functional theory (DFT) to advance the accuracy and applicability of OFDFT. To introduce angular momentum dependence in OFDFT, we devise a hybrid scheme by partitioning the system into muffin-tin spheres and an interstitial region: the electron density inside the spheres is expressed by a set of Kohn-Sham (KS) DFT derived atom-centered basis functions combined with an on-site density matrix N_R. A general OFDFT total energy functional is introduced with a crucial nonlocal energy term E^{NL} which is neglected in conventional implementations of OFDFT. E^{NL} corrects the errors due to the use of approximate kinetic energy density functionals and local pseudopotentials for ion-electron interactions. We approximate E^{NL} to include AMD contributions inside the spheres: as a first step, a linear dependence on the N_R is considered with a set of AMD energies E^l_R. E^l_R are determined by fitting a small set of bulk properties to KSDFT. We find AMD-OFDFT offers substantial improvements over conventional OFDFT, as we show for various properties of the transition metal Ti and its alloys (Ti_xAl_{1-x}).

10:24AM T24.00013 Non-Empirical Orbital-Free Approximations from Semiclassical Approaches[1] , STEFANO PITTALIS, Department of Chemistry, University of California, Irvine, California 92697, USA, A. CANGI, Max-Planck-Institut fuer Mikrostrukturphysik, Weinberg 2, D-06120 Halle, Germany, C.R. PROETTO, Centro Atomico Bariloche and Instituto Balseiro, 8400 San Carlos de Bariloche, Rio Negro, Argentina, E.K.U. GROSS, Max-Planck-Institut fuer Mikrostrukturphysik, Weinberg 2, D-06120 Halle, Germany, K. BURKE, Department of Chemistry and Department of Physics, University of California, Irvine, California 92697, USA — We present a selection of results up to exchange effects obtained from semiclassical approximations aiming at enabling non-empirical and accurate orbital-free methods in models of electronic nanostructures. Insights for improving or better understanding popular density-functional theory approximations will be analyzed.

10:36AM T24.00014 The piecewise-linearity of approximate density functionals revisited: implications for frontier orbital energies , ELI KRAISLER, LEEOR KRONIK, Department of Materials and Interfaces, Weizmann Institute of Science, Rehovoth 76100, Israel — In the exact Kohn-Sham density-functional theory (DFT), the total energy versus the number of electrons is a series of linear segments between integer points. However, commonly used approximate density functionals produce total energies that do not exhibit this behavior. As a result, many system properties can be poorly described. In particular, the ionization potential theorem, equating the highest occupied eigenvalue with the ionization potential, can be grossly disobeyed. Here, we offer a generalization of all energy terms of an arbitrary density functional to systems with a fractional electron number, based on the ensemble form of DFT. Using the local density approximation as an illustrative example, we find that this generalization significantly reduces the deviation from piecewise linearity, while introducing neither empiricism nor further correction terms. With the generalized form, the total energy at integer electron numbers remains intact, but the eigen-energies change and the ionization potential theorem is much more closely obeyed.

10:48AM T24.00015 Curvature and frontier orbital energies in density functional theory , LEEOR KRONIK, Weizmann Institute of Science, Israel, TAMAR STEIN, Hebrew University of Jerusalem, Israel, JOCHEN AUTSCHBACH, University of Buffalo, NY, USA, NIRANJAN GOVIND, Pacific Northwest National Laboratory, WA, USA, ROI BAER, Hebrew University of Jerusalem, Israel — Perdew et al. [Phys. Rev. Lett 49, 1691 (1982)] discovered and proved two different properties of exact Kohn-Sham density functional theory (DFT): (i) The exact total energy versus particle number is a series of linear segments between integer electron points; (ii) Across an integer number of electrons, the exchange-correlation potential may "jump" by a constant, known as the derivative discontinuity (DD). Here, we show analytically that in both the original and the generalized Kohn-Sham formulation of DFT, the two are in fact two sides of the same coin. Absence of a derivative discontinuity necessitates deviation from piecewise linearity, and the latter can be used to correct for the former, thereby restoring the physical meaning of the orbital energies. Using selected small molecules, we show that this results in a simple correction scheme for any underlying functional, including semi-local and hybrid functionals as well as Hartree-Fock theory, suggesting a practical correction for the infamous gap problem of DFT. Moreover, we show that optimally-tuned range-separated hybrid functionals can inherently minimize both DD and curvature, thus requiring no correction, and show that this can be used as a sound theoretical basis for novel tuning strategies.

Thursday, March 21, 2013 8:00AM - 11:00AM –

Session T25 GQI: Superconducting Qubits: Qubit Design 327 - Jamie Kerman, Massachusetts Institute of Technology

8:00AM T25.00001 Dispersive measurement of a metastable phase qubit using a tunable cavity , JED WHITTAKER, University of Colorado at Boulder, MICHAEL ALLMAN, KATARINA CICAK, FABIO DA SILVA, NIST, ADAM SIROIS, University of Colorado at Boulder, JOHN TEUFEL, JOE AUMENTADO, RAY SIMMONDS, NIST — A metastable phase qubit was measured using a tunable cavity by two methods: a tunneling measurement followed by magnetometry readout by the cavity, and a non-destructive dispersive measurement of the qubit by the cavity. The cavity was also used to directly observe the photons radiated by a tunneling measurement. Using a tunable cavity to dispersively measure a metastable phase qubit avoids tunneling measurement radiation and allows for further post-measurement qubit manipulations, two characteristics useful in a quantum processor. The tunable nature of the cavity allows it to be detuned during any single qubit or multi-qubit gate operations in order to main long qubit lifetimes by avoiding loss via the Purcell Effect. This architecture is readily expanded for multiplexed readout of many qubits.

8:12AM T25.00002 Large Dispersive Shift of Cavity Resonance Induced by a Superconducting Flux Qubit in the Straddling Regime[1] , KUNIHIRO INOMATA, RIKEN Advanced Science Institute, Japan, TSUYOSHI YAMAMOTO, NEC Smart Energy Research Laboratories and RIKEN, Japan, PIERRE-M. BILLANGEON, ZHIRONG LIN, RIKEN Advanced Science Institute, Japan, YASUNOBU NAKAMURA, The University of Tokyo and RIKEN, Japan, JAW-SHEN TSAI, NEC Smart Energy Research Laboratories and RIKEN, Japan, KAZUKI KOSHINO, Tokyo Medical and Dental University, Japan — We demonstrate enhancement of the dispersive frequency shift in a coplanar waveguide resonator induced by a capacitively coupled superconducting flux qubit in the straddling regime. The magnitude of the observed shift, 80 MHz for the qubit-resonator detuning of 5 GHz, is quantitatively explained by the generalized Rabi model which takes into account the contribution of the qubit higher energy levels. By applying the enhanced dispersive shift to the qubit readout, we achieved 90% contrast of the Rabi oscillations which is mainly limited by the energy relaxation of the qubit. We also discuss the qubit readout using a Josephson parametric amplifier.

[1]This work was supported by the MEXT Kakenhi "Quantum Cybernetics", the JSPS through its FIRST Program, and the NICT Commissioned Research.

8:24AM T25.00003 Strong Coupling of a Scannable Transmon to a Coplanar Waveguide Resonator , WILL SHANKS, DEVIN UNDERWOOD, JAMES RAFTERY, ANDREW HOUCK, Princeton Unversity — We report measurements of the coupling between a superconducting microwave resonator and a transmon qubit fabricated on a separate chip and mounted to a three-dimensional cryogenic translation stage. The qubit-resonator system reached the strong coupling regime with a coupling strength in excess of 180 MHz, while qubit and resonator linewidths were roughly 0.4 and 10 MHz respectively. We map out the coupling strength in the plane of the resonator and find good agreement with finite element simulation. Such a scannable qubit could be used as a part of a local probe of a large array of microwave cavities and superconducting qubits.

8:36AM T25.00004 Circuit QED with multi-pole microwave cavity filters , LEV BISHOP, JQI and CMTC, University of Maryland, College Park, P. C. REINHOLD, D. I. SCHUSTER, Physics Department and James Franck Institute, University of Chicago — Circuit QED has proven to be a successful architecture for quantum computing and quantum optics. In this architecture multiple superconducting qubits are coupled to a high-Q microwave resonator, allowing for control, coupling and readout of qubit states. However, as we scale to larger systems and longer coherence times, reducing residual couplings become more important. We discuss multi-pole cavity filters as isolating elements between qubits, used as a technique for producing improved gates.

8:48AM T25.00005 Characterization of Multipole Microwave Cavity Filters , PHILIP REINHOLD, DAVID SCHUSTER, University of Chicago, LEV S. BISHOP, University of Maryland — An essential requirement for a quantum information processor is the ability to controllably couple and decouple individual qubits with each other. With superconducting circuit QED, this can be implemented by coupling multiple qubits to a transmission line cavity bus, and can be controlled by moving the qubit frequencies in and out of resonance with the bus. As coherence times increase, and the number of qubits attached to a bus grows larger, the problem of spurious coupling while detuned will become more important. We propose using principles from microwave filter design to create new couplers with higher contrast ratios in the effective qubit-qubit coupling. We present progress towards circuit implementations of multipole qubit coupling architectures.

9:00AM T25.00006 Extracting an Effective Jaynes-Cummings Model for an LC Filtered dc SQUID , B.K. COOPER, R.P. BUDOYO, V. ZARETSKEY, C.J. BALLARD, J.R. ANDERSON, C.J. LOBB, F.C. WELLSTOOD, University of Maryland — Spectroscopy of an Al/AlOx/Al dc SQUID phase qubit revealed peaks suggestive of dispersive photon shifts in a Jaynes-Cummings model, where the role of the resonator is played by an on-chip rf LC filter. A lumped element analysis of the filter-qubit system reveals qubit and resonator modes at the expected frequencies (330 MHz and 8.7 GHz) but an isolation junction mode at ∼100 GHz and qubit-filter coupling that is smaller than observed. As an alternative to the lumped element picture, we examine a transmission line model of the SQUID and the first order correction to the lumped element model. We discuss Jaynes-Cummings approximations to these various models.

9:12AM T25.00007 rf Photon Peaks of a dc SQUID Phase Qubit Coupled to On-Chip LC Filter[1] , R.P. BUDOYO, B.K. COOPER, Joint Quantum Institute and Center for Nanophysics and Advanced Materials, Dept. of Physics, University of Maryland, College Park, MD, V. ZARETSKEY, Dept. of Physics, University of Maryland and Laboratory for Physical Sciences, College Park, MD, C.J. BALLARD, J.R. ANDERSON, C.J. LOBB, F.C. WELLSTOOD, Joint Quantum Institute and Center for Nanophysics and Advanced Materials, Dept. of Physics, University of Maryland, College Park, MD — We have fabricated and tested an Al/AlO_x /Al dc SQUID phase qubit on a sapphire substrate. The qubit is shunted by an interdigitated capacitor and isolated from the bias leads by an inductive isolation network using a larger Josephson junction. Additional high frequency filtering is provided by an on-chip LC filter which consists of square spiral inductors and parallel plate SiN_x capacitors, with ∼330 MHz cutoff frequency. Spectroscopy of the qubit transition frequency at 8.7 GHz shows multiple equally spaced subpeaks. These subpeaks are caused by coupling between the qubit and the LC filter, forming a system that can be described by Jaynes-Cummings model. The individual subpeaks correspond to transitions with different photon numbers in the LC filter.

9:24AM T25.00008 Quantum Superinductor with Tunable Nonlinearity[1] , MATTHEW BELL, IVAN SADOVSKYY, LEV IOFFE, Rutgers University, ALEXEI KITAEV, Caltech, MICHAEL GERSHENSON, Rutgers University — We report on the realization of a superinductor, a dissipationless element whose microwave impedance greatly exceeds the resistance quantum R_Q. The design of the superinductor, implemented as a ladder of nanoscale Josephson junctions, enables tuning of the inductance and its nonlinearity by a weak magnetic field. The Rabi decay time of the superinductor-based qubit exceeds 1 μs. The high kinetic inductance and strong nonlinearity offer new types of functionality, including the development of qubits protected from both flux and charge noises, fault tolerant quantum computing, and high-impedance isolation for electrical current standards based on Bloch oscillations.

9:36AM T25.00009 Long-lived, radiation-suppressed superconducting quantum bit in a planar geometry , MARTIN SANDBERG, MICHAEL VISSERS, national institute of standards and technology, THOMAS OHKI, Raytheon BBN technologies, JIANSONG GOA, JOSE AUMENTADO, national institute of standards and technology, MARTIN WEIDES, Karlsruhe institute of technology, Germany, DAVID PAPPAS, national institute of standards and technology — We present a superconducting qubit design that is fabricated in a 2D geometry over a superconducting ground plane to enhance the lifetime. The qubit is coupled to a microstrip resonator for readout. The circuit is fabricated on a silicon substrate using low loss, stoichiometric titanium nitride for capacitor pads and small, shadow-evaporated aluminum/aluminum-oxide junctions. We observe qubit relaxation and coherence times (T_1 and T_2) of 11.7 ± 0.2 μs and 8.7 ± 0.3 μs, respectively. Calculations show that the proximity of the superconducting plane suppresses the otherwise high radiation loss of the qubit. A significant increase in T_1 is projected for a reduced qubit-to-superconducting plane separation.

9:48AM T25.00010 Towards Tunable Transitions in 2-D Transmons , Z.K. KEANE, Laboratory for Physical Sciences, College Park, MD, B. SURI, S. NOVIKOV, Laboratory for Physical Sciences, College Park, MD; Department of Physics, University of Maryland, J.E. ROBINSON, Laboratory for Physical Sciences, College Park, MD, F.C. WELLSTOOD, Department of Physics, University of Maryland, B.S. PALMER, Laboratory for Physical Sciences, College Park, MD — We have developed a design for a tunable transmon qubit with an on-chip flux bias. The transmon is fabricated with two sub-micron Al/AlO_x/Al tunnel junctions and coupled to a superconducting planar lumped-element resonator. A coplanar transmission line provides flux coupling and tuning of the qubit's transition energies. We will discuss the design and fabrication strategy and present preliminary measurements of coherence and tunability in these devices.

10:00AM T25.00011 Tuning qubit interactions with asymmetric transmons , MATTHEW WARE, DANIELA F. BOGORIN, J.D. STRAND, B.L.T. PLOURDE, Syracuse University — Superconducting transmon qubits have been used in numerous key experiments in the field of quantum information processing. We are exploring a variation of this circuit, the asymmetric transmon, where the two Josephson junctions making up the qubit have substantially different critical currents. This results in a second sweet spot with respect to magnetic flux at odd half-integer flux-quantum bias points. The corresponding reduction in energy-modulation depth makes the qubit less sensitive to dephasing due to flux noise for bias points away from the sweet spots. At the same time, the tunability of the qubit energy allows for novel qubit-cavity processes, including flux-driven sideband transitions, as well as adjustable interactions between multiple qubits.

10:12AM T25.00012 Investigation of Single and Coupled Flux Qubit Energy Spectra Using Tunneling Spectroscopy , ANTHONY PRZYBYSZ, TREVOR LANTING, ANDREW BERKLEY, RICHARD HARRIS, ANATOLY SMIRNOV, MOHAMMAD AMIN, D-Wave Systems Inc., NEIL DICKSON, Side Effects Software Inc., EMILE HOSKINSON, FABIO ALTOMARE, ANDREW WILSON, ELENA TOLKACHEVA, PAUL BUNYK, MARK JOHNSON, GEORDIE ROSE, D-Wave Systems Inc. — We present the results of our investigation of the energy levels of systems of flux qubits using tunneling spectroscopy. Tunneling spectroscopy is a technique by which we use macroscopic resonant tunneling processes of a neighboring qubit to probe the energy spectrum of a system of flux qubits. We used this technique to measure the energy gap of a single qubit near its degeneracy point where it is in a superposition of left and right circulating current states. Furthermore, we applied this technique to systems of up to 8 coupled qubits that were biased at degeneracy and observed energy spectra that agree with theoretical predictions based on independently determined device parameters.

10:24AM T25.00013 Phase versus flux coupling between resonator and superconducting flux qubit[1] , J.S. BIRENBAUM, S.R. O'KELLEY, S.M. ANTON, UC Berkeley, C.D. NUGROHO, V. ORLYANCHIK, A.H. DOVE, Z.R. YOSCOVITS, G.A. OLSON, D.J. VAN HARLINGEN, J. ECKSTEIN, University of Illinois at Urbana-Champaign, D.A. BRAJE, R.C. JOHNSON, W.D. OLIVER, MIT Lincoln Laboratory, JOHN CLARKE, UC Berkeley — The dispersive coupling of qubits to microwave resonators has become widely used for qubit readout. Recent advances in coupling qubits to 3D resonators have demonstrated the importance of the nature of the qubit-resonator coupling in determining the qubit relaxation and decoherence times, T_1 and T_2^*. We study the effect of phase versus flux coupling on flux qubits coupled to planar resonators. Using an aluminum shadow evaporation technique we fabricate a low-loss planar resonator, consisting of a meandering inductor and interdigitated capacitor, and a flux qubit, all in a single processing step. Whereas the qubit and resonator are always flux coupled via a geometric mutual inductance, a phase coupling can be added by including a shared trace between the qubit and resonator. This technique allows us to control both the magnitude and nature of the qubit-resonator coupling without significantly affecting either the qubit or resonator design. We characterize the dependence of the qubit parameters T_1, T_2^*, and spin echo time T_{echo} on the resonator coupling parameters to gain insight into possible sources of decoherence and loss.

10:36AM T25.00014 Solid-state quantum metamaterials , RICHARD WILSON, MARK EVERITT, SERGEY SAVELIEV, ALEXANDRE ZAGOSKIN, Department of Physics, Loughborough University — Quantum metamaterials provide a promising potential test bed for probing the quantum-classical transition. We propose a scalable and feasible architecture for a solid-state quantum metamaterial. This consists of an ensemble of superconducting flux qubits inductively coupled to a superconducting transmission line. We make use of fully quantum mechanical models which account for decoherence, input and readout to study the behaviour of prototypical 1D and 2D quantum metamaterials. In addition to demonstrating some of the novel phenomena that arise in these systems, such as "quantum birefringence," we will also discuss potential applications.

10:48AM T25.00015 Development of superconducting transmission-line metamaterials , HAOZHI WANG, FRANCISCO ROUXINOL, B.L.T. PLOURDE, Syracuse University — In recent years, various metamaterials have received substantial attention for their ability to exhibit simultaneous negative permittivity and permeability. Such systems are commonly referred to as left-handed materials and display a variety of counterintuitive properties. We are investigating one-dimensional metamaterials consisting of superconducting circuit elements that operate in the microwave regime. In this talk, we will discuss our efforts to develop a superconducting left-handed transmission line (LHTL) coupled to a coplanar waveguide resonator (right-handed line –RHTL) to create a composite transmission line. Such a structure is predicted to exhibit an intriguing mode structure and we will discuss possible schemes for coupling superconducting qubits to these metamaterials.

Thursday, March 21, 2013 8:00AM - 11:00AM –

Session T26 GQI: Focus Session: Semiconductor Qubits - Charge Qubits, Measurement, and Noise 328 - Matthew Borselli, HRL Laboratories, LLC

8:00AM T26.00001 LeRoy Apker Award Lecture: Coherent control of a semiconductor charge qubit[1] , YULIYA DOVZHENKO, Department of Physics, Princeton University, New Jersey, 08544 — A charge qubit is formed in a GaAs double quantum dot containing one electron. The two basis states of the qubit correspond to the electron residing in either the left or the right dot. In order to drive coherent rotations of the qubit state, 100 ps timescale voltage pulses are applied to the depletion gates forming the double dot. The resulting charge state is detected by a nearby quantum point contact charge sensor. In contrast with previous work, where a single non-adiabatic pulse was applied for quantum control,[2] we apply multiple pulses working towards dynamic decoupling.[3] Data for Ramsey and charge echo pulse sequences are obtained and compared with numerical simulations of the charge qubit evolution.[4] Coherent multi-pulse control of a semiconductor charge qubit demonstrated in this experiment is an essential requirement for future work in understanding charge noise in semiconductor qubits and improving the fidelity of spin qubit operations.

8:36AM T26.00002 Spectroscopy of a many-electron InAs spin-orbit qubit[1] , J. STEHLIK, M.D. SCHROER, K.D. PETERSSON, M. JUNG, J.R. PETTA, Department of Physics, Princeton University, Princeton, NJ 08544, USA — The ability to perform arbitrary single spin rotations is a crucial ingredient for solid state quantum computation using electron spins. However, achieving rapid and selective single spin rotations has been challenging. Strong spin-orbit materials are very promising in this regard, as the spin-orbit interaction can turn a periodic electric driving field into an effective oscillating magnetic field through a process called electric dipole spin resonance (EDSR). In this work we explore EDSR in an InAs nanowire spin-orbit qubit. The qubit is implemented using a many-electron double quantum dot (DQD) and is configured in Pauli-blockade, where electron transport is highly sensitive to processes that rotate spin. We use EDSR to probe the detailed level structure of the DQD. We find a strong current response in several regions of the parameter space, raising the prospects for fast spin rotations.

[1]Research supported by the Sloan and Packard Foundations, the NSF, and the Army Research Office.

8:48AM T26.00003 Pulse-gated quantum dot hybrid qubit[1] , S.N. COPPERSMITH, TECK SENG KOH, JOHN KING GAMBLE, M.A. ERIKSSON, MARK FRIESEN, Department of Physics, University of Wisconsin-Madison — A quantum dot hybrid qubit formed from three electrons in a double quantum dot has the potential for great speed, due to presence of level crossings where the qubit becomes charge-like. Here, we show how to exploit the level crossings to implement fast pulsed gating. We develop one- and two-qubit dc quantum gates that are simpler than the previously proposed ac gates [1]. We obtain closed-form solutions for the control sequences and show that the gates are fast (sub-nanosecond) and can achieve high fidelities.

9:00AM T26.00004 Enhanced Coherence and High Figure of Merit in a Silicon Charge qubit , ZHAN SHI, CHRISTIE SIMMONS[1], DANIEL WARD, JONATHAN PRANCE[2], TECK SENG KOH, JOHN GAMBLE, XIAN WU, DONALD SAVAGE, MAX LAGALLY, MARK FRIESEN, SUSAN COPPERSMITH, MARK ERIKSSON, University of Wisconsin - Madison — Coherent manipulation of a charge qubit is an essential step in the use of pulsed gate voltages [1] to manipulate a quantum dot hybrid spin qubit [2]. Here, we demonstrate coherent manipulation of a charge qubit in Si/SiGe double quantum dot. We perform Larmor oscillations (x-rotations on the Bloch sphere) between the (2,1) and (1,2) charge states, measuring a T_2* time of 2.1 ns at the charge degeneracy point. We find an increased coherence time (3.7 ns) and higher figure of merit (37) away from the charge degeneracy point, arising from a second charge anti-crossing involving a low lying excited state in the right dot – the desired structure for a hybrid spin qubit. We also observe Ramsey fringes (z-rotations on the Bloch sphere) and measure a T_2* of 179 ps at detunings away from any protective energy level structures.

9:12AM T26.00005 Multi-electron double quantum dot spin qubits , ERIK NIELSEN, Sandia National Laboratories, JASON KESTNER, University of Maryland, Baltimore County, EDWIN BARNES, SANKAR DAS SARMA, University of Maryland — Double quantum dot (DQD) spin quits in a solid state environment typically consist of two electron spins confined to a DQD potential. We analyze the viability and potential advantages of DQD qubits which use greater then two electrons, and present results for six-electron qubits using full configuration interaction methods. The principal results of this work are that such six electron DQDs can retain an isolated low-energy qubit space that is more robust to charge noise due to screening. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

9:24AM T26.00006 Charge noise and dynamical decoupling in singlet-triplet spin qubits[1] , GUY RAMON, Santa Clara University — We consider theoretically the effects of an ensemble of fluctuating charges on the coherence of a singlet-triplet qubit in gate-defined double quantum dots. We predict a crossover behavior of the system between non-Gaussian noise and 1/f spectrum, going from mesoscopic single-qubit devices to multi-qubit larger devices. With increasing size of the fluctuator ensemble we find a narrowed distribution of qubit dephasing times that result from random sets of fluctuators. At the same time the noise becomes Markovian with a characteristic Gaussian spectrum and it is dominated by a large collection of weakly-coupled fluctuators. The efficiency of dynamical decoupling pulse sequences in restoring coherence is examined as a function of the qubit's working position and the fluctuator ensemble size. Analytical solutions for qubit dephasing in the limits of weak and strong qubit-fluctuator coupling shed light on the distinct dynamics at different parameter regimes.

9:36AM T26.00007 Relaxation in quantum dots due to evanescent-wave Johnson noise from a metallic backgate[1] , LUKE LANGSJOEN, AMRIT POUDEL, MAXIM VAVILOV, ROBERT JOYNT, University of Wisconsin - Madison — This talk will present a study of decoherence in charge and spin qubits due to evanescent-wave Johnson noise (EWJN) in a laterally coupled double quantum dot and single quantum dot, respectively. The high density of evanescent modes in the vicinity of metallic gates causes energy relaxation and a loss of phase coherence of electrons trapped in quantum dots. These energy relaxation rates are derived, and EWJN is shown to be a dominant source of decoherence for spin qubits held at low magnetic fields. Previous studies in this field approximated the charge or spin qubit as a point dipole. Ignoring the finite size of the quantum dot in this way leads to a spurious divergence in the relaxation rate as the qubit approaches the metal. Our approach goes beyond the dipole approximation and remedies this unphysical divergence by taking into account the finite size of the quantum dot.

9:48AM T26.00008 Charge noise and spin noise in a semiconductor qubit , RICHARD WARBURTON, ANDREAS KUHLMANN, JULIEN HOUEL, Department of Physics, University of Basel, Switzerland, ARNE LUDWIG, ANDREAS WIECK, Ruhr University Bochum, Germany — Developing semiconductor spin qubits involves dealing with noise. Spin noise arising from the fluctuating nuclear spins results in electron spin dephasing and decoherence. Charge noise also results in dephasing and decoherence via the spin-orbit interaction and the electric field dependence of the g-factors. We have used resonance fluorescence from a single optically-active quantum dot as a local, minimally-invasive probe of the noise. Our technique is sensitive to 4 decades of noise over 6 decades of frequency. We present a method which allows us to distinguish between charge noise (a fluctuating electrostatic potential) and spin noise (a fluctuating effective magnetic field): we show how the two noise sources result in different optical signatures. The charge noise dominates at low frequencies, the spin noise at higher frequencies. The charge noise spectrum following neither a Lorentzian nor a 1/f-behaviour can be understood by considering an ensemble of 2-level fluctuators located close to the quantum dot. Crucially, both sources of noise decrease rapidly with increasing frequency. The consequences for the quantum dot are profound: at high frequencies (above 10 kHz) the noise is sufficiently small that we achieve ideal optical linewidths (the Fourier transform limit).

10:00AM T26.00009 Leakage-current lineshapes from inelastic cotunneling in the Pauli spin blockade regime[1] , FARZAD QASSEMI, Inst for Quantum Computing, University of Waterloo, Waterloo, Canada, BILL COISH, Department of Physics, McGill University, Montreal, Canada — We find the leakage current through a double quantum dot in the Pauli spin blockade regime accounting for inelastic (spin-flip) cotunneling processes. Taking the energy-dependence of this spin-flip mechanism into account allows for an accurate description of the current as a function of applied magnetic fields, gate voltages, and an inter-dot tunnel coupling. In the presence of an additional local dephasing process or nonuniform magnetic field, we obtain a simple closed-form analytical expression for the leakage current giving the full dependence on an applied magnetic field and energy detuning. This work is important for understanding the nature of leakage, especially in systems where other spin-flip mechanisms (due, e.g., to hyperfine coupling to nuclear spins or spin-orbit coupling) are weak, including silicon and carbon-nanotube or graphene quantum dots.

10:12AM T26.00010 Reweighting of charge occupation in charge stability diagrams due to finite temperature effect and asymmetric tunnel rates in a silicon MOS double quantum dot[1] , KHOI NGUYEN, MICHAEL LILLY, NATHANIEL BISHOP, ERIK NIELSEN, RAJIB RAHMAN[2], JOEL WENDT, JASON DOMINGUEZ, TAMMY PLUYM, JEFF STEVENS, GREG TEN EYCK, MALCOLM CARROLL, Sandia National Laboratories, Albuquerque, NM 87185 — The combination of asymmetric tunnel rates and finite temperature can shift the average charge occupation within a double quantum dot (DQD) stability diagram. DQD charge sensing shows the transitions in electron occupation dependence on gate bias. Applied source-drain bias further introduces shifts in the charge transition lines including the formation of bias triangles. In some material systems, tunnel barrier uniformity can be difficult to achieve. Asymmetry in tunnel barriers can lead to vanishingly small transitions in regions. Finite temperature effects with asymmetric barriers further leads to kinks in the stability diagram. In this talk we present measurements of DQDs with asymmetric barriers and compare them to simulation of stability diagrams using a capacitance network including the rate equation and temperature dependent tunneling. The model provides quantitative insight about finite temperature effects as well as the vanishing charge transition lines that is not readily available in the literature.

10:24AM T26.00011 Integration of on-chip FET switches with dopantless Si/SiGe quantum dot structures for high throughput testing , DANIEL WARD, DONALD SAVAGE, MAX LAGALLY, SUSAN COPPERSMITH, MARK ERIKSSON, University of Wisconsin-Madison — In the last few years, significant research on dopantless Si/SiGe planar quantum dot structures has occurred. One of the limiting factors is that typically only a single double-dot structure can be cooled down in a dilution refrigerator at time due to the limited number of electrical connections available. We report on our recent work to create samples with four sets of double-dots on a single chip that can all be tested in a single cool down through the introduction of on-chip FET switches. In our samples the four double-dot structures have their depletion gates and ohmic contacts connected in parallel, minimizing the number of connections. We energize accumulation gates for the device under test such that the other dot structures do not contribute to the measurements. Our double-dot structures require five accumulation gates, which limits scaling due to limited fridge wiring capacity. To alleviate this problem and to test integration approaches for cryogenic quantum dot devices we fabricated a series of on-chip FET switches to form a multiplexer for the accumulation gates. Using the multiplexer we can wire up four double-dot structures using just 23 connections instead of the 34 required without it. As more devices are added the scaling benefits increase exponentially.

10:36AM T26.00012 Electron transport on ultra thin helium , MAIKA TAKITA, E.Y. HUANG[1], S.A. LYON, Department of Electrical Engineering, Princeton University — Electrons floating on the surface of superfluid helium have been suggested as promising mobile spin qubits, and they have shown extremely efficient transport above micron-sized helium-filled channels. While the calculated spin decoherence and relaxation times on helium are long, no experimental measurements have been made. Efficient thermalization of the spins is necessary for ESR measurements of their coherence, and a lack of thermalization has hindered these experiments. Bringing electrons onto a thin helium film above a metallic layer will speed spin relaxation due to Johnson noise current in the metal. At the same time, higher electron densities can be supported by thin helium films. Ideally, the electrons could be thermalized on the thin helium film coating a metal surface, and then moved to a helium-filled channel for electrical measurements of their density and the spin measurements. However roughness of the metal surface severely limits the electron mobility. Preliminary work show that electrons can be transported from one channel, across a helium-coated metal layer, and to the neighboring channel, by creating a smooth transition from the channel to the thin film.

10:48AM T26.00013 Implementation and test of an Levitov's n-electron coherent source[1] , D. CHRISTIAN GLATTLI, JULIE DUBOIS, THIBAUT JULLIEN, PREDEN ROULLEAU, FABIEN PORTIER, P. ROCHE, Service de l'Etat Condense CEA Saclay — Injecting a controlled number of electrons in a quantum conductor opens the way to new quantum experiment. It is known that a voltage biased contact applied on a single mode quantum conductor, such as a perfectly transmitting Quantum Point Contact (QPC), continuously injects single electrons at a rate eV/h. Here we consider the injection of n electrons using a short time voltage pulse with $\int eV(t)dt = nh$. When the voltage pulse has a Lorentzian shape, L. Levitov et al. [1] have shown that the n-electron injection is free of extra neutral electron-hole pairs and is a minimal excitation state. We present the first realization of Levitov's proposal. Using periodic voltage pulses applied on a contact of a 2DEG, a coherent train of n-electrons is send to a QPC which acts as an electron beam splitter. By measuring the shot noise resulting from the partitioning of all excitations we demonstrate that Lorentzian pulses are minimal excitation states. This is complemented by energy domain study of the excitations using shot noise spectroscopy and by a time-domain study using shot noise in a Hong-Ou-Mandel like n-electron collision experiment.

Session T27 GQI: Focus Session: Superselection and Quantum Reference Frames 329 - Ian Durham, Saint Anselm College

8:00AM T27.00001 Quantum frameness for charge-parity-time inversion symmetry[1] , BARRY SANDERS[2], University of Calgary — Physical laws are invariant under simultaneous charge-parity-time (CPT) inversion, which is due to relativistic Lorentz covariance and the linearity of quantum mechanics. We show that CPT-superselection can be circumvented by employing a system that possesses CPT frameness, and we construct such resources in two cases: for massive spin-zero particles and for Dirac-spinors. In the case of spin-zero particles, we explicitly construct and quantify all resourceful pure states. Our approach is to treat CPT inversion unitarily by considering the aggregate action of the CPT transformation, rather than sequentially composing a unitary and two anti-unitary transformations, thereby overcoming a major drawback of circumventing time-inversion symmetry alone using an anti-unitary transformation [G. Gour, P. S. Turner and B. C. Sanders, J. Math. Phys. 50, 102105 (2009)]. We discuss an explicit example using pionic communication to overcome CPT superselection.

8:36AM T27.00002 The capacity to transmit classical information via black holes , CHRISTOPH ADAMI, Michigan State University, GREG VER STEEG, University of Southern California — One of the most vexing problems in theoretical physics is the relationship between quantum mechanics and gravity. According to an argument originally by Hawking, a black hole must destroy any information that is incident on it because the only radiation that a black hole releases during its evaporation (the Hawking radiation) is precisely thermal. Surprisingly, this claim has never been investigated within a quantum information-theoretic framework, where the black hole is treated as a quantum channel to transmit classical information. We calculate the capacity of the quantum black hole channel to transmit classical information (the Holevo capacity) within curved-space quantum field theory, and show that the information carried by late-time particles sent into a black hole can be recovered with arbitrary accuracy, from the signature left behind by the stimulated emission of radiation that must accompany any absorption event. We also show that this stimulated emission turns the black hole into an almost-optimal quantum cloning machine, where the violation of the no-cloning theorem is ensured by the noise provided by the Hawking radiation. Thus, rather than threatening the consistency of theoretical physics, Hawking radiation manages to save it instead.

8:48AM T27.00003 Constructing holographic spacetimes using entanglement renormalization[1] , BRIAN SWINGLE, Harvard — We elaborate on our earlier proposal connecting entanglement renormalization and holographic duality in which we argued that a tensor network can be reinterpreted as a kind of skeleton for an emergent holographic space. Here we address the question of the large N limit where on the holographic side the gravity theory becomes classical and a non-fluctuating smooth spacetime description emerges. We show how a number of features of holographic duality in the large N limit emerge naturally from entanglement renormalization, including a classical spacetime generated by entanglement, a sparse spectrum of operator dimensions, and phase transitions in mutual information. We also address questions related to bulk locality below the AdS radius, holographic duals of weakly coupled large N theories, Fermi surfaces in holography, and the holographic interpretation of branching MERA. Some of our considerations are inspired by the idea of quantum expanders which are generalized quantum transformations that add a definite amount of entropy to most states. Since we identify entanglement with geometry, we thus argue that classical spacetime may be built from quantum expanders (or something like them).

9:00AM T27.00004 Quantifying asymmetry of quantum states using entanglement[1] , BORZU TOLOUI[2], Departments of Physics and Astronomy, Haverford College — For open systems, symmetric dynamics do not always lead to conservation laws. We show that, for a dynamic symmetry associated with a compact Lie group, one can derive new selection rules from entanglement theory. These selection rules apply to both closed and open systems as well as reversible and irreversible time evolutions. Our approach is based on an embedding of the system's Hilbert space into a tensor product of two Hilbert spaces allowing for the symmetric dynamics to be simulated with local operations. The entanglement of the embedded states determines which transformations are forbidden because of the symmetry. In fact, every bipartite entanglement monotone can be used to quantify the asymmetry of the initial states. Moreover, where the dynamics is reversible, each of these monotones becomes a new conserved quantity.

9:36AM T27.00005 How hard is it to decide if a quantum state is separable or entangled? , MARK WILDE, PATRICK HAYDEN, KEVIN MILNER, McGill University — Suppose that a physical process, described as a sequence of local interactions that can be executed in a reasonable amount of time, generates a quantum state shared between two parties. We might then wonder, does this physical process produce a quantum state that is separable or entangled? Here, we give evidence that it is computationally hard to decide the answer to this question, even if one has access to the power of quantum computation. In order to address this question, we begin by demonstrating a two-message quantum interactive proof system that can decide the answer to a promise version of this problem. We then prove that this promise problem is hard for the class "quantum statistical zero knowledge" (QSZK) by demonstrating a polynomial-time reduction from the QSZK-complete promise problem "quantum state distinguishability" to our quantum separability problem. Finally, we consider a variant of this question, in which a given physical process accepts a quantum state as input, and the question is to decide if there is an input to this process which makes its output separable across some bipartite cut. We prove that this latter problem is a complete promise problem for the class QIP of problems admitting quantum interactive proof systems.

9:48AM T27.00006 Operator extension of strong subadditivity of entropy , ISAAC KIM, California Institute of Technology — We prove an operator inequality that extends strong subadditivity of entropy: after taking a trace, the operator inequality becomes the strong subadditivity of entropy.

10:00AM T27.00007 Measuring Entanglement via SICs and 2-designs[1] , MATTHEW GRAYDON, University of Waterloo, Perimeter Institute for Theoretical Physics, Institute for Quantum Computing, MARCUS APPLEBY, Perimeter Institute for Theoretical Physics — We consider measuring entanglement via the classical quadratic Rényi entropy of joint probability distributions over the measurement outcomes associated with tensor products of elements of local positive operator valued measures (POVMs). We examine the case of pure $d \times d$ bipartite quantum states and identical local POVMs. In this case, we prove that if the local POVMs are rank 1, then the classical quadratic Rényi entropy of such a distribution (denoted by H) is independent of the underlying Schmidt bases if and only if the local POVMs are equivalent to spherical 2-designs. We also prove that if the local POVMs admit a cardinality equal to the composite Hilbert space dimension, then H is independent of the underlying Schmidt bases if and only if the local POVMs are symmetric informationally complete POVMs of arbitrary rank. We show that different degrees of entanglement correspond to distinct spheres within the corresponding joint probability simplexes. Furthermore, we derive a separability criterion for mixed isotropic quantum states in terms of probabilities for outcomes of generalized quantum measurements constructed from tensor products of elements of local POVMs formed from spherical 2-designs.

10:12AM T27.00008 Do emergent entangled coherent Glauber states violate the no-signaling theorems of quantum theory? , JACK SARFATTI, ISEP — Quantum information theory assumes entanglement cannot be used as a direct stand-alone-communication channel without a light speed limited retarded signal key to unlock the message encrypted in the correlation pattern. This pre-supposes orthogonal base states for the entangled subsystems. Macro-quantum coherent Glauber states emerge as ground/vacuum states in spontaneous broken symmetries that describe the Higgs-Goldstone fields of many real/virtual particles. They are distinguishably non-orthogonal and over-complete. In the bipartite case, Alice's two distinguishable non-orthogonal sender Glauber coherent base states are entangled with Bob's two orthogonal receiver Q-BIT base states. The Born rule for strong von-Neumann projection measurements using the orthodox constant $\sqrt{2}^{-1}$ normalization gives an entanglement signal

$$S_{Bob}\,(0/1) = \underset{Alice}{\mathsf{Tr}} \left\{ |\rangle_{Bob\ Bob} \langle (0)1| \, |\rangle \langle Bob, Alice| \right\}$$
$$= \tfrac{1}{2} \left(1 + \left| {}_{Alice} \left\langle \sqrt{\langle n \rangle} e^{\theta} \;\middle|\; \sqrt{\langle n' \rangle} e^{\theta'} \right\rangle_{Alice} \right|^2 \right)$$

Emergent spontaneous symmetry breakdown violates the probability interpretation of orthodox quantum theory. It represents an extension of quantum theory in the same way that gravity required an extension of special relativity limiting it to coincident local inertial frames.

10:24AM T27.00009 Entanglement witnesses for many qubit systems , JUSTYNA ZWOLAK, Oregon State University, DARIUSZ CHRUŚCIŃSKI, Nicolaus Copernicus University — Entanglement is one of the essential features of quantum physics and is fundamental to future quantum technologies. The characterization of entanglement has been shown to be equivalent to the characterization of positive, but not completely positive, maps (PnCP) over matrix algebras. In the cases of 2×2 and 2×3 dimensional spaces does there exist complete characterization of the separability problem (due to the celebrated Peres-Horodecki criterion). However, for increasingly higher dimensions this task becomes more and more difficult. There has been a considerable effort devoted to constructing PnCP, but a general procedure is still not known. Recently we were able to generalize the Robertson map in a way that naturally meshes with $2N$ qubit systems, i.e., its structure respects the 2^{2N} growth of the state space. We proved that this map is positive, but not completely positive, indecomposable and optimal, and as such can be used to detect (bipartite) entanglement. We also determined the relation our maps to entanglement breaking channels. We will discuss these new classes of entanglement witnesses.

10:36AM T27.00010 Measurement-Induced Non-locality in an n-partite quantum state , PRAMOD JOAG, Professor, Department of Physics, University of Pune, ALI HASSAN, Associate Professor Department of Physics, University of Amran — We generalize the concept of measurement-induced non-locality (MiN) to n-partite quantum states. We get exact analytical expressions for MiN in an n-partite pure and n-qubit mixed state. We obtain the conditions under which MiN equals geometric quantum discord in an n-partite pure state and an n-qubit mixed state. We obtain an exact (computable) relation between MiN and entanglement (concurrence) for a bipartite pure state.

10:48AM T27.00011 Zitterbewegung in Cold Atoms[1] , POLIANA PENTEADO, J. CARLOS EGUES, Institute of Physics of São Carlos, University of São Paulo — In condensed matter systems, the coupling between spatial and spin degrees of freedom through the spin-orbit (SO) interaction offers the possibility of manipulating the electron spin via its orbital motion. The proposal by Datta and Das [1,2] of a 'spin transistor' for example, highlights the use of the SO interaction to control the electron spin via electrical means. Recently, arrangements of crossed lasers and magnetic fields have been used to trap and cool atoms in optical lattices and also to create light-induced gauge potentials [3], which mimic the SO interactions in real solids. In this work, we investigate the Zitterbewegung in cold atoms by starting from the effective SO Hamiltonian derived in Ref. [4]. Cross-dressed atoms as effective spins can provide a proper setting in which to observe this effect, as the relevant parameter range of SO strengths may be more easily attainable in this context. We find a variety of peculiar Zitterbewegung orbits in real and pseudo-spin spaces, e.g., cycloids and ellipses - all of which obtained with realistic parameters.

Session T28 GSNP: Focus Session: Shells, Plates, and Thin Films 336 - Katia Bertoldi, Harvard University

8:00AM T28.00001 Buckling in 2D periodic, soft and porous structures: effect of pore shape and lattice pattern , SICONG SHAN, KATIA BERTOLDI, JONGMIN SHIM, JOHANNES T.B. OVERVELDE, SUNG HOON KANG, School of Engineering and Applied Sciences, Harvard University — Adaptive structures allowing dramatic shape changes offer unique opportunities for the design of responsive and reconfigurable devices. Traditional morphing and foldable structures with stiff structural members and mechanical joints remains a challenge in manufacturing at small length scales. Soft structures where the folding mechanisms are induced by a mechanical instability represent a new class of novel adaptive materials which can be easily manufactured over a wide range of length scales. More specifically, soft porous structures with deliberately designed patterns can significantly change their architecture in response to diverse stimuli, opening avenues for reconfigurable devices that change their shapes to respond to their environment. While so far only two-dimensional periodic porous structures with circular holes arranged on a square or triangular lattice have been investigated, here we investigate both numerically and experimentally the effects of pore shape and lattice pattern on the macroscopic properties of the structures. Our results show that both the pore shape and lattice pattern can be used to effectively design desired materials and pave the way for the development of a new class of soft, active and reconfigurable devices over a wide range of length scales.

8:12AM T28.00002 Localization in thin shells under indentation , ALICE NASTO, Massachusetts Institute of Technology, AMIN ADJARI, Northeastern University, ARNAUD LAZARUS, Massachusetts Institute of Technology, ASHKAN VAZIRI, Northeastern University, PEDRO REIS, Massachsuetts Institute of Technology — We perform a hybrid experimental and numerical investigation of deformation in thin spherical elastic shells under indentation. Past the initial linear response, an inverted cap develops as a Pegorelov circular ridge. For further indentation, this ridge loses axis-symmetry and sharp points of localized curvature form, which we refer to as 's-cones' (for shell-cones), in contrast with their developable cousins in plates, 'd-cones'. We quantify how the formation and evolution of s-cones is affected by systematically varying the indenter's curvature. In our precision model experiments, rapid prototyping is used to fabricate elastomeric shells and rigid indenters of various shapes. The mechanical response is quantified through load-displacement comparison tests and the deformation process is further characterized through digital imaging. In parallel, the experimental results are contrasted against nonlinear Finite Element simulations, which enable us to explore the role of friction at the shell-indenter contacts and characterize the relative strain energy focusing properties at different loci of localization. Our combined experimental and computational approach allows us to gain invaluable physical insight towards rationalizing this geometrically nonlinear process.

8:24AM T28.00003 Eggstreme Mechanics of Thin Shells , PEDRO REIS, Massachusetts Institute of Technology — I will present a series of experimental explorations on the rich mechanical behavior of thin elastic shells, subject to different forms of loading. First, I will discuss the geometry-induced rigidity of non-spherical pressurized shells under indentation, that can be used for non-destructive testing. I will proceed by characterizing the emergence and evolution of point and linear-like loci of localization on thin shells indented well into the nonlinear regime. I will then present a new mechanism that utilizes the compression of a thin-shell/soft-core system for switchable and tunable wrinkling on curved surfaces, that can be exploited for active aerodynamic drag control. Finally, I shall introduce the framework for buckling-induced folding (or "Buckligami") that involves functional structural transformations of patterned shells that can be excited to achieve encapsulation, flexure and twist. The main common feature underlying these series of examples is the prominence of geometry in dictating the complex mechanical behavior of slender soft structures, thereby making our results relevant and applicable over a wide range of length scales. Moreover, our findings suggest that we rethink our relationship with mechanical instabilities which, rather than modes of failure, can be embraced as opportunities for functionality that are scalable, reversible, and robust.

9:00AM T28.00004 Buckling Instability of Dielectric Elastomeric Plates for Soft, Bio-Compatible Microfluidic Pumps , BEHROUZ TAVAKOL, Virginia Tech, MICHAEL BOZLAR, GUILLAUME FROEHLICHER, CHRISTIAN PUNCKT, HOWARD A. STONE, ILHAN AKSAY, Princeton University, DOUGLAS HOLMES, Virginia Tech — Dielectric elastomers are well-known for their superior stretchability and permittivity. A fully-clamped thin elastomer will buckle when it is compressed by applying sufficient electric potentials to its sides. When embedded within soft, silicone rubbers, these advanced materials can provide a means for a bio-compatible pumping mechanism that can be used to inject bio-fluids with desired flow rates into microfluidic devices, tissues, and organs of interest. We have incorporated a dielectric film that is sandwiched between two thin, flexible, solid electrodes into a microfluidic device and utilized a voltage-induced out-of-plane buckling instability for pumping of fluids. We experimentally quantify the voltage-induced plate buckling and measure the fluid flow rate when the structure is embedded in a microchannel. Additionally, we offer an analytical prediction that uses plate buckling theory to estimate the flow rate as a function of applied voltage.

9:12AM T28.00005 Ordering in a crumpled elastic sheet , ANNE DOMINIQUE CAMBOU, NARAYANAN MENON, Physics Dept UMass, Amherst — We experimentally study the conformations of polydimethylsiloxane (PDMS) sheets crumpled in a cylinder at volume fractions ranging from 3% to 40%. The PDMS sheets show no plasticity, and slide with low friction as they are immersed in an index-matching fluid to allow imaging in the interior. We crumple the sheet either axially with a piston, or radially by shrinking the radius of the cylinder. We focus on the development of local nematic order created by facets stacking together. Either the flat piston or the curved cylindrical wall promotes global alignment of these stacks. We compare our results to previous experiments on aluminum foil confined in a sphere to understand the role of plasticity and friction on the ordering in crumpled sheets.

9:24AM T28.00006 Whirling Skirts , JAMES HANNA, University of Massachusetts, Amherst, JEMAL GUVEN, Universidad Nacional Autónoma de México, MARTIN MICHAEL MÜLLER, Université de Lorraine — Steady wave patterns may be observed on a rotating skirt. These patterns display a well-defined dihedral symmetry and are marked by strikingly sharp features. We capture these with a minimal model of traveling waves on an inextensible, flexible, rotating generalized-conical sheet. Conservation laws associated with the dynamics are used to reduce the Euler-Lagrange equations to a quadrature describing a particle in a potential. Analytical solutions are obtained; these are quantized by the extrinsic closure of the skirt. Coriolis forces play an essential role in establishing these configurations.

9:36AM T28.00007 Mechanical response of creases network in thin sheets , BENJAMIN THIRIA, PMMH-ESPCI, FRÉDÉRIC LECHENAULT, MOKTHAR ADDA-BEDIA, LPS-ENS, PMMH/LPS COLLABORATION — In a recent study [Thiria & Adda-Bedia, PRL, 2011], it has been shown that the local plastic zone (crease) created during thin-film folding exhibits a logarithmic mechanical response typical to aging. It was found that the related relaxation processes could be described by an Arrhenius law with a typical time scale intrinsic to the material. Here we present an extension to this study by adding collective behaviors and topology (or geometry) to the system . The systems considered consist in in-line series of folds and origami-like 2D patterns. We present the global behavior and mechanical properties (aging, rigidity) of multi-folded thin sheets as a function of the experimental parameters (material, thickness, fold preparation and geometrical characteristic).

9:48AM T28.00008 Folding of thin film on a highly pre-strained elastomer , ATSUSHI TAKEI, HIROYUKI FUJITA, University of Tokyo — Multi-layered systems composed of a rigid thin film and an elastomeric base are ubiquitous in Nature and technology. When the rigid thin film is deposited on the stretched elastomeric base, periodical patterns appear on its surface in releasing the pre-strain. If the pre-strain is small ($\sim$ 10%), sinusoidal wavy patterns appear entirely on the surface as known in literature. On the other hand, with the large pre-strain ($\sim$ 50%), the deformation is localized, and foldings are engendered. We studied this phenomenon experimentally using a balloon structure composed of a PDMS chamber and a thin organic membrane Parylene. Firstly the chamber is filled with oil and inflated like a balloon. Then, keeping its pressure, the organic membrane is deposited on the surface. By changing the pressure inside the chamber during the deposition, the pre-strain can be ranged over 50%. In this study, we demonstrate the pre-strain dependency on the morphology in one dimensional and two dimensional models. We also present that with the balloon structure the surface roughness can be tuned by changing the pressure and that it can be applied to a tunable hydrophobic surface.

10:00AM T28.00009 Experiments with a particle film: Evidence for force chain buckling , ANDREW B. CROLL, BEKELE J. GURMESSA, North Dakota State University, DAVID CAREY, ANTOINETTE TORDESILLAS, University of Melbourne — Granular materials are a unique state of matter that, when loaded, focus stress on a small subset of their total volume. Accurate modeling of the regions of high stress, the force chains, is critical to understanding the overall material behaviour. Progress in modeling the transition from static to fluid has recently been made by considering the onset of the transition as originating with the buckling and failure of a force chain. There is currently little direct experimental evidence for such behaviour. Here we use a simplified model system in which a set of solid particles, packed into a monolayer, is adhered to a soft substrate and compressed. We observe buckling and the emergence of a single dominant lengthscale, much in analogy to the well known "wrinkling" instability of a continuum plate. However, several tests show the behaviour observed in our system to be uniquely granular in nature. Finally, we show how many features of our experiment are in agreement with recent predictions of the force chain buckling model.

10:12AM T28.00010 Mechanics without Muscles: Fast Motion of the Venus flytrap and Bio-inspired Robotics[1] , ZI CHEN, Washington University in St. Louis, QIAOHANG GUO, Washington University, HUANG ZHENG, Fujian Radio and Television University, WEI LI, Fuzhou University, YITING DING, Tsinghua University, GUIPING SU, JUNJIE LIN, Fujian Institute of Technology, YUXIN LIU, Wuhan Foreign Languages School, WENZHE CHEN, Fujian Institute of Technology, LARRY TABER, Washington University — The rapid motion of plants has intrigued scientists for centuries. Plants have neither nerves nor muscles, yet the Venus flytrap can move in a fraction of a second to capture insects. Darwin did a first systematic study on the trap closure mechanism, and called this plant "one of the most wonderful in the world". Several physical mechanisms have since been proposed, such as the rapid loss of turgor pressure, an irreversible acid-induced wall loosening mechanism, and tsnap-through instability, but no unanimous agreement is reached. We propose a coupled mechanical bistable mechanism that explains the rapid closure of the Venus flytrap, consistent with experimental observations. Such bistable behaviors are theoretically modeled and validated with experiments. Biomimetic flytrap robots are also fabricated according to the learnt principles. It is thus promising to design smart bio-mimetic materials and devices with snapping mechanisms as sensors, actuators, artificial muscles and biomedical devices.

10:24AM T28.00011 Auto-origami with liquid crystal elastomers: a simulation study[1] , ANDREW KONYA, ROBIN SELINGER, Kent State University — Liquid crystal elastomers (LCE) undergo shape transformations induced by stimuli such as heating/cooling or illumination. When a non-uniform director field is imposed on a sample during crosslinking, it encodes a complex actuation trajectory which may include a combination of bends, twists, and folds along with changes in Gaussian curvature. Taking a materials-by-design approach, we perform finite element simulations to explore director geometries which produce such auto-origami behavior. By cataloging and assembling a variety of basic motifs including those identified by Modes and Warner [1], we design director geometries that yield a variety of target structures. Assembling a sample with domains of two LCE materials with different isotropic-nematic transition temperatures provides a means for sequencing steps in the resulting actuation choreography on heating/cooling. 10:36AM T28.00012 Mechanics of morphogenesis during cell sheet movements[1] , GLENN EDWARDS, HENG LU, ADAM SOKOLOW, DAN KIEHART, Duke University — We have been investigating the mechanics of dorsal closure, a stage of *Drosophila* embryogenesis. Over 2-3 hours a "hole" in the dorsal surface changes its 2-D geometry from an ellipse to an eye shape, which eventually closes edge to edge. This hole initially is filled with a monolayer of amnioserosa cells, a transient tissue under tension. Beyond the dorsal hole are two flanks of epithelial tissue, also under tension, which are zipped together at each "corner of the eye." The net result of dorsal closure is to form a continuous epithelium on the outer surface of the embryo. High-resolution, *in vivo* images of amnioserosa cells will be presented. Experimental time series of apical shape changes have been assessed with the methods of signal analysis to quantify a band of reversible oscillations and a set of ingression processes. A generalized-force model was formulated to account for changes in cross-sectional areas. High-resolution, 3-D images of dorsal closure also will be presented. The amnioserosa was observed to bulge outwards, where the asymmetric dome was analyzed with Laplace's formula to quantify the turgor pressure. The 3-D zipping process includes substantial remodeling of tissue interfaces and significant intracellular remodeling.

Session T29 GSNP: Focus Session: Jamming: Marginal Solids I 337 - Corey S. O'Hern, Yale University

8:00AM T29.00001 From Crystals to Point J: how changing the order affects disordered systems , CARL GOODRICH, ANDREA LIU, University of Pennsylvania, SIDNEY NAGEL, University of Chicago — The theory of crystalline solids is well established as the basis for our understanding of periodically ordered materials. While less developed, much progress has been made in understanding solids that lack periodic order. Specifically, the jamming transition of idealized soft spheres is a critical point that corresponds to the opposite limit of the fully disordered solid–the epitome of disorder. We seek to bridge the gap between these two extreme limits–the completely disordered solid and the perfect crystal–to understand how partially ordered systems behave. Can they always be considered as perturbations away from these two limits, or are they fundamentally different? We find that systems with intermediate bond orientational order exist but that most systems display either very high or very low order. We study mechanically stable configurations that are very ordered but whose contact number is not far from the marginal value. Despite their ordered structure, these states show the same excess low-frequency modes, elastic properties and scalings typically associated with systems near the jamming transition. This suggests that the signatures of the jamming transition are more robust than previously thought and sheds light on the physical mechanism that makes jamming unique.

8:12AM T29.00002 The equilibration of temperature-like variables in jammed granular subsystems[1] , KAREN DANIELS, NC State University, JAMES PUCKETT, Yale University — Although jammed granular systems are athermal, several thermodynamic-like descriptions have been proposed which make quantitative predictions about the distribution of volume and stress within a system and provide a corresponding temperature-like variable. We perform experiments with an apparatus designed to generate a large number of independent, jammed, two-dimensional configurations. Each configuration consists of a single layer of photoelastic disks supported by a gentle layer of air. New configurations are generated by alternately dilating and re-compacting the system through a series of boundary displacements. Within each configuration, a bath of particles surrounds a smaller subsystem of particles with a different inter-particle friction coefficient than the bath. The use of photoelastic particles permits us to find all particle positions as well as the vector forces at each inter-particle contact. By comparing the temperature-like quantities in both systems, we find compactivity (conjugate to the volume) does not equilibrate between the systems, while the angoricity (conjugate to the stress) does. Both independent components of the angoricity are linearly dependent on the hydrostatic pressure, in agreement with predictions of the stress ensemble.

8:24AM T29.00003 Shape effect on dynamical properties of granular materials[1] , SOMAYEH FARHADI, Duke University, Department of Physics, ROBERT P. BEHRINGER, Duke University — We have investigated the effect of shape on dynamical and rheological properties of granular materials through Couette shear and cyclic isotropic compression experiments. We track the evolution of our systems by measuring the mean velocity local density, orientational order, and local stress. This set of experiments which were performed on systems of bidisperse disks and identical ellipses at exactly same conditions, reveals striking differences between the dynamics of disks and ellipses. In particular we observe a very slow relaxation in various dynamical quantities for systems of ellipses. We also demonstrate that the strain history of the system (i.e. shear vs. compression) highly impacts the aging process.

8:36AM T29.00004 Fracture mechanics and crack propagation in fragile matter , BRYAN CHEN, STEPHAN ULRICH, NITIN UPADHYAYA, VINCENZO VITELLI, Leiden University — Using simulations and theory, we investigate fracture processes and the formation of cracks in near-isostatic networks derived from jammed packings in both the quasi-static limit and with molecular dynamics. We study how localized cracks in networks with high coordination number become randomly distributed and isolated bond breakages near the isostatic point and suggest that this may be related to the scaling of the size of the process zone with characteristic lengths from jamming.

8:48AM T29.00005 Evolution of Triangle Decomposition During Jamming[1] , MARK KANNER, Levich Institute and Physics Department at City College and CUNY Graduate Center, NING XU, University of Science and Technology of China, COREY O'HERN, Yale University Departments of Mechanical Engineering & Materials Science and Physics, MARK SHATTUCK, Levich Institute and Physics Department at City College and CUNY Graduate Center — We use simulations of soft 2D bidisperse disks to determine the properties of jammed packings and investigate the statistical mechanics of these systems. We have created a novel method for the classification of structural subunits of a packing and use the subunits to calculate relevant physical quantities. The classification scheme is based on a 20 type decomposition of the Delaunay triangles extracted from the centers of the particles. The distribution of triangle types evolve as systems are jammed by compression or as they are sheared. We analyze the statistics of the triangle types and identify specific transition events during compression, jamming, and shear.

9:00AM T29.00006 Network and Dynamical System Analysis of a Granular Stick-Slip Experiment[1] , DAVID W. WALKER, ANTOINETTE TORDESILLAS, University of Melbourne, M. SMALL, Hong Kong Polytechnic University, R. P. BEHRINGER, Duke University — We describe analysis of stick-slip behavior in a granular material under shear from a slider that is pulled across the granular surface. We extend previous statistical analysis, focusing on size distributions of failure events by applying nonlinear time series analysis, including surrogate data, and complex network methods. Local dimension measures suggest a robust evolution law of stick-slip dynamics needs at least 4 to 6 degrees of freedom. Surrogate methods indicate that individual stick-slip events may contain more complex nonlinear determinism periodic dynamics, although models with periodic dynamics are adequate for some cases. Within each stick-slip "cycle", we found evidence of nonlinear determinism but no long term memory across cycles. Representing the observed time series as a complex network, however, revealed that despite no evidence for long term dynamical correlations between distinct stick-slip events there is consistency in the structure of individual subnetworks associated with the onset of each slip event, possibly reflecting a single driving mechanism of failure, i.e. dynamics of force chains. When the data is representated as a complex network, it appears to present a new stratification of system dynamics with a previously unreported ranking, or genus,

9:12AM T29.00007 On the local construction of jamming graphs , JORGE LOPEZ, Syracuse University, LIANG CAO, None, JENNIFER SCHWARZ, Syracuse University — We extend the concept of minimal rigidity to particulate systems, or nonbonded networks, in two-dimensions with the introduction of the jamming graph. The jamming graph is a planar Laman graph with each vertex satisfying the Hilbert local stability requirement. In other words, the jamming graph contains both property of global and local mechanical stability at the onset of rigidity for the model system of frictionless, repulsive soft spheres. We demonstrate how such graphs can be constructed using purely local moves interestingly enough. To make comparisons with the model system, we first associate springs with the edges of the graph and then associate shapes with each vertex and determine various mechanical properties as the spring density, or particle packing fraction, is increased. The jamming graph not only provides for a rigorous starting point for the onset of rigidity, the local rules used to construct it can be easily modified to account for friction and/or particle shapes beyond spheres so that a more general framework for the onset of rigidity in particulate systems may ultimately be established.

9:24AM T29.00008 The crossover from random close to random loose packings of frictional disks[1] , STEFANOS PAPANIKOLAOU, Yale University — Mechanically stable packings of frictionless disks with contact interactions form through fast quenches at random close packing (RCP). However, for frictional particles with static friction coefficient μ greater than μ*, the packing density slides toward random loose packing (RLP) at large friction. We elucidate the crossover from random close to random loose packing through simulations of bidisperse disks using the geometric asperity (GA)[1] and Cundall-Strack (CS) friction models. We demonstrate that a change takes place in the structure of allowed mechanically stable packings in configuration space: From uncorrelated points at zero friction to linear and other low-dimensional structures at small friction to higher dimensional structures at large friction. Further, we use the GA model to study dynamical mechanical properties without ad hoc assumptions for sliding contacts, and we find that low-frequency vibrational modes with significant rotational content display a strong peak below μ*. Their rotational content drastically changes from co-rotating contacting particles for low friction to counter-rotating, gear-like, for μ greater than μ* and the groups of particles with gear-like dynamical contributions percolate at μ*. Finally, the very existence of the low-frequency vibrational peak gives rise to a change in the scaling of the static shear modulus with pressure compared to the frictionless behavior.

[1]DTRA Grant No. 1-10-1-0021

10:00AM T29.00009 Vibrational modes of jammed and unjammed packings , THIBAULT BERTRAND, Department of Mechanical Engineering and Materials Science, Yale University, CARL F. SCHRECK, Department of Physics, Yale University, COREY S. O'HERN, Department of Mechanical Engineering and Materials Science, Yale University, MARK D. SHATTUCK, Benjamin Levich Institute and Department of Physics, City College of the City University of New York — We showed previously that granular packings composed of frictionless particles with repulsive contact interactions are strongly nonharmonic. Weakly vibrated packings possess well-defined average positions that differ from those of the unvibrated packing and other nearby static packings, and when excited along a single vibrational mode from the dynamical matrix energy quickly leaks to other modes during vibration due to contact breaking. We now measure the displacement correlation matrix for weakly vibrated systems and the velocity autocorrelation function averaged over fluctuations to extract the associated density of vibrational modes. We find that there is an increase in the number of low-frequency eigenmodes of the displacement matrix compared to that for the dynamical matrix in linear response, and these modes provide a more accurate description of the dynamics. The new set of modes from the displacement correlation matrix persists over several orders of magnitude in the input energy of the vibrations. Futhermore, the new vibrational modes are insensitive to pressure, i.e. packings prepared above and below jamming yield the same set of vibrational modes. We also perform vibration experiments as a function of amplitude and frequency, and compare our findings.

10:12AM T29.00010 Energy Transfers in Coupled Ordered Granular Chains with No Precompression[1] , ALEXANDER VAKAKIS, ARIF M. HASAN, University of Illinois, YULI STAROSVETSKY, Technion, LEONID I. MANEVITCH, Institute of Chemical Physics, Russian Academy of Science — We study the dynamics of coupled one-dimensional granular chains mounted on elastic foundations. No dissipative effects, such as plasticity or dry friction effects are taken into account in our analysis. Assuming no pre-compression between beads, the dynamics of the system under consideration is strongly nonlinear and, in an acoustic analogy they can be viewed as 'sonic vacua'. Sources of strong nonlinearity in these systems are nonlinearizable Hertzian interactions between adjacent beads in compression, and also possible separations between beads in the absence of compressive forces leading to bead collisions. We find that demonstrate that in weakly coupled granular chains there can occur strong energy exchanges in the form of nonlinear beat phenomena of spatially periodic traveling waves, stationary breathers or propagating breathers. We employ analytical techniques to study these dynamical phenomena.

10:24AM T29.00011 Rearrangements in 2D packings , MERLIJN VAN DEEN, JOHANNES SIMON, MARTIN VAN HECKE, Kamerlingh Onnes Lab, Universiteit Leiden, SIMON DAGOIS-BOHY, LEOPOLDO GOMEZ, BRIAN TIGHE, ZORANA ZERAVCIC, Instituut-Lorenz, Universiteit Leiden — Using computer simulations of frictionless, harmonic, packings, we have investigated the effects of global shear deformations on a local scale. We have focused on the making and breaking of contacts between particles, as a change in the contact network signals a departure from linear response. We show the deformation at which the first contact change happens can be predicted, using simple scaling arguments, from the initial pressure and the number of particles. In addition, we show the also probability of creating versus breaking a contact can be understood. Finally, we are able to show the locality of the rearrangements in the packing.

10:36AM T29.00012 Lattice model of correlated forces in granular solids near jamming , JING CAO, Penn state University, JILLIAN NEWHALL, University of Illinois, SCOTT MILNER, Penn state University — We have devised a lattice model to study force correlations in granular solids as the isostatic limit is approached. We apply biased Monte Carlo simulations to the Tighe "wheel move" model to progressively starve the system of force-bearing bonds. Increasingly long-ranged correlations are visible as point J is approached, not in the structure of the network of force-bearing bonds, but in the spatial extent of perturbations of the forces consistent with a given starved network. The correlation length so defined diverges as the isostatic point is approached, as a power law $\xi = \delta Z^{-4.78}$. This divergence is much stronger than for the length scale of "soft modes" observed in jammed systems approaching point J from above. We can relate the correlated regions we observe to a certain definition of percolation clusters. The probability distribution of cluster sizes, and the bulk and surface fractal dimensions of the clusters, all scale analogously to classical percolation, but with distinctly different scaling exponents.

10:48AM T29.00013 Tuning with tension: Controlling elasticity in nearly isostatic spring networks , BRIAN TIGHE, RENE PECNIK, Delft University of Technology — We show that the shear stiffness of random spring networks can be controlled by exploiting their strong susceptibility to tensile loading. Unstressed networks below the isostatic point are floppy and cannot sustain shear. But floppiness can be "pulled out" with tension, rendering the loaded system rigid. Using scaling arguments and computer simulations, we determine the dependence of stretched networks' shear modulus on tension and show how this effect can be leveraged to generate "smart networks" with tunable stiffness.

Session T30 DCMP: Disordered and Glassy Systems (non-polymeric) 338 - Nicolas Giovambattista, Brooklyn College

8:00AM T30.00001 Two-State "Hopping" Dynamics in Molecular Liquids and Glasses[1] , MARCUS CICERONE, QIN ZHONG, MADHUSUDAN TYAGI, JOSEPH CURTIS, National Institute of Standards and Technology, DEVIN AVERETT, University of Wisconsin-Madison, JUAN DE PABLO, University of Chicago — Hopping has long been suspected as an important mode of transport in supercooled liquids at temperatures below T_c. It has been observed in model systems, but until now, has not been directly observed in molecular liquids. We show that incoherent quasi-elastic neutron scattering (QENS) reveals a two-state scenario where, on a 1 ps timescale, molecules are either confined to motion on a lengthscale of 0.05 r_H, or free to undergo motion on a much larger lengthscale of roughly 0.3 r_H, where r_H is the hydrodynamic radius. The motion executed by the less-constrained molecules fits the description of hopping motion observed in model simulations and colloid experiments. The population free to he latter giving rise to hopping at low temperature where the mobile states are long-lived. We show also that this two-state scenario holds well above T_c, where the mobile state lifetime exhibits apparently universal behavior, and transport appears to proceed by both small-step diffusion and larger-step "hopping" processes. Our interpretation of the neutron scattering data is confirmed by atomistic MD simulations, which reveal additional richness, and suggest that this very short-time two-state behavior may be the precursor to dynamic heterogeneity as observed on longer timescales.

8:12AM T30.00002 Models of two level systems for anisotropic glassy materials[1] , DRAGOS-VICTOR ANGHEL, IRINA MIHAELA DUMITRU, ALEXANDRU GEORGE NEMNES, Horia Hulubei National Institute of Physics and Nuclear Engineering, DMITRII CHUROCHKIN, Faculty of Mathematical and Physical Sciences, University of Chile — We use an extended version of the standard tunneling model to explain the sound absorption in anisotropic glassy materials and heat transport in mesoscopic slabs and bridges. The glassy properties are determined by an ensemble of two level systems (TLS). In our model a TLS is characterized by a 3×3 symmetric tensor, $[T]$, which couples to the strain field, $[S]$, through a $3 \times 3 \times 3 \times 3$ tensor of coupling constants, $[[R]]$. The structure of $[[R]]$ reflects the symmetry of the host lattice. We also propose microscopic theoretical methods and models of TLS by which we test some of the most well known models of glassy materials, together with our own model.

8:24AM T30.00003 ABSTRACT WITHDRAWN –

8:36AM T30.00004 Configurational excitations of simple liquids , TAKUYA IWASHITA, University of Tennessee, TAKESHI EGAMI, University of Tennessee and Oak Ridge National Laboratory — The dynamics of glass-forming liquids has not been fully understood at the atomic-scale level, even for normal liquids because the basic mechanism regarding to liquid dynamics remain unknown. An elementary process of liquids, in which an atom loses or gains one of its nearest neighbors, was studied using MD simulations of various metallic liquids at high temperatures. The result was presented in terms of Maxwell relaxation time, represented by viscosity/G, and the lifetime of local topology of atomic connectivity. Above crossover temperature, TA, the Maxwell relaxation time is almost equal to the lifetime of local topology, suggesting the topological excitation as the elementary excitation in high temperature liquid metal. We also showed that the TA may be associated with the propagation of transverse sound wave beyond an atomic shell. Below TA the Maxwell relaxation time becomes larger than the lifetime of local topology. This result implies an importance of the interaction between local configulational excitations in the supercooled state.

8:48AM T30.00005 Supercooled Liquids with Enhanced Orientational Order[1] , MICHAEL WÜBBENHORST, SIMONA CAPPONI, KU Leuven, Belgium, SIMONE NAPOLITANO, Universite Libre de Bruxelles, Belgium — The nature of the glass transition, the transformation of a liquid into a disordered solid, still remains one of the most intriguing unsolved problems in materials science. Recent models rationalize crucial features of vitrification with the presence of medium-range ordered regions coexisting with the isotropic liquid. In lines with this prediction, here we report an extraordinary enhancement in bond orientational order (BOO) in ultrathin films of supercooled polyols, grown by physical vapour deposition. By varying the deposition conditions and the molecular size, we could tune the kinetic stability of the liquid phase enriched in BOO towards conversion into the ordinary liquid phase. We observed a strong increase in the dielectric strength with respect to the ordinary supercooled liquid and slower structural dynamics, suggesting the existence of a metastable liquid phase with improved orientational correlations[1]. 9:00AM T30.00006 The Kinetics of the Glass Transition and Physical Aging in Germanium Selenide Glasses[1] , HAOYU ZHAO, YUNG KOH, SINDEE SIMON, Texas Tech University, SABYASACHI SEN, UC Davis, MAREK PYDA COLLABORATION — The kinetics associated with the glass transition is investigated using differential scanning calorimetry (DSC) for germanium selenide glasses with Ge content ranging from 0 to 30 atom% Ge and mean coordination numbers ranging from 2.0 to 2.6. As Ge content increases, the glass transition region broadens and the step change in heat capacity at Tg decreases. As a result of physical aging, enthalpy overshoots are observed in DSC heating scans and the corresponding change in enthalpy can be calculated as a function of aging time. The enthalpy loss on aging linearly increases with the logarithm of aging time and then levels off at an equilibrium value that increases with decreasing aging temperature. The time required to reach equilibrium increases with decreasing aging temperature and, at a given temperature, with decreasing germanium content. The results indicate that all samples show expected physical aging behavior, and no evidence for a Boolchand intermediate phase characterized by high stability and absence of physical aging is found.

9:12AM T30.00007 Dynamical and structural heterogeneities close to liquid-liquid phase transitions: The case of gallium[1] , ALEX ANTONELLI, SAMUEL CAJAHUARINGA, MAURICE DE KONING, Universidade Estadual de Campinas — Liquid-liquid phase transitions (LLPT) have been proposed in order to explain the thermodynamic anomalies exhibited by some liquids. Recently, it was found, through molecular dynamics simulations, that liquid elemental gallium, described by a modified embedded-atom model, exhibits a LLPT between a high-density liquid (HDL) and a low-density liquid (LDL), about 60 K below the melting temperature. In this work [1], we studied the dynamics of supercooled liquid gallium close to the LLPT. Our results show a large increase in the plateau of the self-intermediate scattering function (β-relaxation process) and in the non-Gaussian parameter, indicating a pronounced dynamical heterogeneity upon the onset of the LLPT. The dynamical heterogeneity of the LDL is closely correlated to its structural heterogeneity, since the fast diffusing atoms belong to high-density domains of predominantly 9-fold coordinated atoms, whereas the slow diffusing ones are mostly in low-density domains of 8-fold coordinated atoms. The energetics suggests that the reason for the sluggish dynamics of LDL is due to its larger cohesive energy as compared to that of the HDL. [1] S. Cajahuaringa, M. de Koning, and A. Antonelli, J. Chem. Phys. **136**, 064513 (2012).

9:24AM T30.00008 Pressure Dependence of the Glass Transition Temperature in the Fragile Glass Former Cumene , TIM RANSOM, WILLIAM OLIVER, University of Arkansas Department of Physics — The glass transition temperature, T_g, is one of the most important characteristics of glassy systems. While T_g has been measured for many systems at atmospheric pressure, direct measurement of the glass transition is difficult at high pressures due to small sample sizes and long time scales. T_g(P) measurements to date mostly involve extrapolations of high-pressure viscosity or relaxation data to $\eta = 10^{13}$ P or t = 100 s, respectively. In this study we present direct measurement of T_g at pressures up to several GPa through a combination of pressure gradient tracking and observation of increases in the thermal expansion coefficient upon heating from the glass to the viscous liquid state. High pressures are attained through the use of a diamond anvil cell and precise temperatures are maintained via custom heating and cryogenic systems. By directly mapping this phase boundary, we can compare models for T_g(P). In addition, high-pressure analysis requiring knowledge of T_g at pressure will be greatly aided.

9:36AM T30.00009 Average Oscillator Strength Per State of a one-dimensional disordered Frenkel exciton system in the Coherent Potential Approximation[1] , ABDELKRIM BOUKAHIL, Physics Department, University of Wisconsin-Whitewater, Whitewater, WI 53190, ROBERT SIEMANN, Department of Mathematics, University of Wisconsin-Whitewater, Whitewater, WI 53190, DAVID HUBER, Physics Department, University of Wisconsin-Madison, Madison, WI 53706 — We report the results of studies of the low energy side of the Average Oscillator Strength Per State $f(E) = F(E)/\rho(E)$, where $F(E)$ is the line shape function and $\rho(E)$ is the density of states function of one dimensional Frenkel excitons in the Coherent Potential Approximation (CPA). A Gaussian distribution of the transition frequencies with rms width σ ($0.07 \leq \sigma \leq 0.4$) is used. Our CPA theory predicts that on the low energy side of the peak the tails are short and independent of the disorder parameter σ; implying a behavior consistent with the Urbach rule. Our CPA results are in excellent agreement with previous investigations.

9:48AM T30.00010 Atomistic Modeling of Mechanical Loss in Amorphous Oxides[1] , RASHID HAMDAN, JONATHAN TRINASTIC, HAI-PING CHENG, University of Florida — The mechanical and optical loss in amorphous solids, described by the internal friction and light scattering susceptibility are investigated using classical, atomistic molecular dynamics simulation. We implemented the trajectory bisection method and the non-local ridge method in DL-POLY molecular dynamics simulation software. These methods were used to locate the different local potential energy minima that a system visits through an MD trajectory and the transition state between any two consecutive minima. From the distributions of the barrier height and asymmetry, and the relaxation time of the different transition states we calculated the internal friction of pure amorphous silica and mixed oxides.

[1]Acknowledgment: NSF/PHYS

10:00AM T30.00011 The nature of the β-peak in the loss modulus of amorphous solids , YOSSI COHEN[1], Department of Chemical Physics, The Weizmann Institute of Science, Rehovot 76100, Israel, SMARAJIT KARMAKAR, Dept of Physics, Universita di Roma La Sapienza, Piazale Aldo Moro 2, Rome, Italy, ITAMAR PROCACCIA, Department of Chemical Physics, The Weizmann Institute of Science, Rehovot 76100, Israel, KONRAD SAMWER, Dept of Physics, University of Gottingen, Germany — Glass formers exhibit, upon an oscillatory excitation, a response function whose imaginary and real parts are known as the loss and storage moduli respectively. The loss modulus typically peaks at a frequency known as the α frequency which is associated with the main relaxation mechanism of the super-cooled liquid. In addition, the loss modulus is decorated by a smaller peak, shoulder or wing which is referred to as the β-peak. The physical origin of this secondary peak had been debated for decades, with proposed mechanisms ranging from highly localized relaxations to entirely cooperative ones. Using numerical simulations, we expose a clear and unique cooperative mechanism for the said β-peak which is distinct from that of the α-peak.

10:12AM T30.00012 Density of Surface States in a-Si/Ge Using a Two Parameter Hamiltonian , ELIEZER RICHMOND, Retired — To rigorously investigate the contribution of surfaces to the density of electronic states of a-Si/Ge and the effect of the topology on the density of surface states (DOS), a surface for amorphous homopolar tetrahedral solids is defined. The density of unsaturated bonds is 0.106 bonds/Å^2. Reconstruction enables a 88% reduction in the density of unsaturated bonds. The effects on the DOS in the valence band and energy gap is investigated using a two parameter Hamiltonian. The local and configuration DOS are computed for the unsaturated bond and the four back bond hybrids. The ring structure effects the DOS in the valence band, but not the more localized energy gap states. The spectral feature due to surface atoms with only one unsaturated bond is affected by the topology. The antibonding spectral feature in the energy gap deriving from surface atoms with 2 or 3 unsaturated bonds is independent of all topological effects while the bonding spectral feature from these same surface atoms is not. Comparison with empirical results verifies the contribution of the unsaturated bonds to ESR signals and elucidates the origin of the subtle valence band features in UPS spectra.

10:24AM T30.00013 Fluctuating Mobility Generation and Transport in Glasses , APIWAT WISITSORASAK, PETER WOLYNES, Rice University — Complex spatiotemporal structures developing in glasses during aging and heating processes involve the interplay between fluctuating mobility generation and transport. To understand these structures, we extend mode-coupling theory to inhomogeneous system and combine the theory with activated events within the framework of Random-First Order Transition theory of glasses. We explore using numerical methods the process of fluctuating mobility generation and transport in glasses as the glasses age after cooling and as they rejuvenate after heating. This scheme allows us to investigate the dynamical heterogeneity in glasses below the glass transition temperature. We found a growing length scale and an increasing relaxation time upon the aging process. On the contrary, in the rejuvenating process, the mobility propagates from the high mobility at free surfaces into the bulks which resembles flame front propagation in combustion theory.

10:36AM T30.00014 Many-body localization in one dimension as a dynamical renormalization group fixed poin , RONEN VOSK, EHUD ALTMAN, Weizmann Institute of Science — We formulate a dynamical real space renormalization group approach to describe the time evolution of a random spin-1/2 chain, or interacting fermions, initialized in a state with fixed particle positions. Within this approach we identify a many-body localized state of the chain as a dynamical infinite randomness fixed point. Near this fixed point our method becomes asymptotically exact, allowing analytic calculation of time dependent quantities. In particular we explain the striking universal features in the growth of the entanglement seen in recent numerical simulations: unbounded logarithmic growth delayed by a time inversely proportional to the interaction strength. Lack of true thermalization in the long time limit is attributed to an infinite set of approximate integrals of motion revealed in the course of the RG flow, which become asymptotically exact conservation laws at the fixed point. Hence we identify the many-body localized state with an emergent generalized Gibbs ensemble. Within the RG framework we show that long range resonances are irrelevant at strong randomness, and formulate a criterion for when they do become relevant and may cause a delocalization transition.

Session T31 DPOLY DBIO: Biopolymers: Dynamics of Molecules Under Confinement, Networks, and Proteins 339 - Ting Xu, University of California, Berkeley

8:00AM T31.00001 Tales told by tails: watching DNA driven through a random medium , JUAN GUAN, BO WANG, SUNG CHUL BAE, STEVE GRANICK, U of Illinois - Urbana Champaign — DNA ligation is used to label separately the ends and centers of monodisperse DNA 16 μm in contour length, and 2-color fluorescence microscopy is used to follow with nm resolution how chains migrate through agarose networks driven by electric fields, at both whole chain and segment level. We observe that the leading segment is always a physical chain end which stretches and pulls out slack in the still-quiescent remainder of the chain until the other end is taken up. Heads and tails behave strikingly differently: the leading end of migrating chains migrates more smoothly, whereas motion of the trailing end shows intermittent pauses and jerky recoil. None of the mechanisms imagined classically for this situation - chain reptation, hooking or entropic trapping, appears to fully describe these data obtained from single-molecule visualization.

8:12AM T31.00002 A localized transition in the size variation of circular DNA in nanoslits , ELIZABETH A. STRYCHALSKI, SAMUEL M. STAVIS, JON GEIST, National Institute of Standards and Technology — We observe a localized transition in the size variation of circular DNA between strong and moderate regimes of nanofluidic slitlike confinement. We applied a rigorous statistical analysis to our recent experimental measurements of DNA size for linear and circular topologies in nanoslits with depths around $\approx$2p, where p is the DNA persistence length [E. A. Strychalski, J. Geist, M. Gaitan, L. E. Locascio, S. M. Stavis. Macromolecules, 45, 1602-1611 (2012)]. Our empirical approach revealed a localized transition between confinement regimes for circular DNA at a nanoslit depth of $\approx$3p but detected no such transition for linear DNA with a similar contour length. These results provide the first indication of the localized influence of polymer topology on size variation across changing nanoslit depths. Improved understanding of differences in polymer behavior due to topology in this controversial system is of fundamental importance in polymer science and will inform new nanofluidic methods for biopolymer analysis.

8:24AM T31.00003 Analysis of conflicting experimental studies of DNA size in nanofluidic slits , SAMUEL M. STAVIS, NIST/CNST, ELIZABETH A. STRYCHALSKI, NIST/MML, BRIAN J. NABLO, JON GEIST, NIST/PML — Recent experimental studies have reported conflicting accounts of the size variation of DNA in nanofluidic slitlike confinement; [Bonthuis et al., Physical Review Letters 101, 10, 108303 (2008)], [Tang et al., Macromolecules 43, 17, 7368 (2010)], [Strychalski et al., Macromolecules 45, 3, 1602 (2012)], [Lin et al., Macromolecules 45, 6, 2920 (2012)], [Dai et al., Soft Matter 8, 10, 2972 (2012)]. In an effort to resolve this controversy, these studies are analyzed by a reductive as opposed to predictive approach. Minimum references for DNA size (baselines) are simulated by a Monte Carlo methodology and quantitatively compared to measured and inferred DNA sizes. The measurements of Tang et al., Strychalski et al., and Lin et al. are consistent with the related baselines and in semi-quantitative agreement with each other. The inferences of Tang et al. and Dai et al. are consistent with the related baseline and in qualitative agreement with the measurements of Tang et al., Strychalski et al., and Lin et al. The measurements of Bonthuis et al. are inconsistently larger than the related baseline and the other experimental measurements and inferences of DNA size around the transition from moderate to weak slitlike confinement. A variety of physical and chemical differences between the experimental systems are examined in detail to elucidate this inconsistency. Detailed analyses of the baseline distribution and variation clarify several core physical attributes of the system related to excluded volume effects and chain dimensionality.

8:36AM T31.00004 Universal Regimes of Semiflexible Polymers Confined in a Channel , DOUGLAS TREE, University of Minnesota, YANWEI WANG, Soochow University, KEVIN DORFMAN, University of Minnesota — The problem of a semiflexible polymer confined in a tube was considered solved almost 30 years ago, until a measurement of the extension of DNA in nanochannels challenged these classical results in polymer physics. Moreover, emerging genomics methods that take advantage of confined DNA have provided a strong motivation for reconciling theory and experiment in this field. As a result, there are a number of simulations and experiments aimed at examining the equilibrium extension of confined DNA as a function of the channel size. While these results have shed some light on the problem, a complete theoretical description for a confined semiflexible polymer still does not exist. We will present a combination of scaling theory and simulation results using an implementation of the Pruned-Enriched Rosenbluth method (PERM) that provides such a description in terms of both the confinement free energy and the extension of very long chains. In doing so, we provide clear evidence that a Gaussian-like regime emerges for stiff chains in between the classic Odijk and de Gennes regimes. The observation of this regime leads to our key conclusion that confined, semiflexible chains are best understood in the context of a rod-to-coil transition, which is directly analogous to its bulk counterpart.

8:48AM T31.00005 Fluctuations, structural transitions, and escape of confined biopolymers[1] , AIQUN HUANG, ANIKET BHATTACHARYA, University of Central Florida — Conformation, dynamics, and escape of semi-flexible biopolymers confined in narrow-slits are studied using Langevin dynamics simulation in two dimensions (2D). Along with chain the length and the slit width, we vary the chain stiffness and study how internal modes of the individual chain segments are affected by chain stiffness. In addition to the usual measurements of gyration radii, end to end distance, persistence length, *etc*., we plan to report a detailed analysis of the sub-chain conformations and relaxation of the confined biopolymers both in de Gennes and Odjik limit We also study escape of confined semi-flexible biopolymers through narrow slits.

9:00AM T31.00006 Complex effects of molecular topology on diffusion in entangled biopolymer blends[1] , RAE M. ROBERTSON-ANDERSON, University of San Diego, COLE D. CHAPMAN, University of California, San Diego, SACHIN SHANBHAG, Florida State University, DOUGLAS E. SMITH, University of California, San Diego — By combining single-molecule tracking with bond-fluctuation model simulations, we show that diffusion is intricately linked to molecular topology in blends of entangled linear and ring biopolymers, namely DNA. Most notably, we find a previously unreported non-monotonic dependence of the self-diffusion coefficient for linear DNA on the fraction of linear DNA comprising the ring-linear blend, which we argue arises from a second-order effect of ring DNA molecules being threaded by varying numbers of linear DNA molecules. Results address several debated issues regarding molecular dynamics in biopolymer blends, which can be used to develop novel tunable biomaterials.

9:12AM T31.00007 Direct imaging of entangled actin solutions , CHI HANG BOYCE TSANG, LINGXIANG JIANG, KEJIA CHEN, BO WANG, STEVE GRANICK, University of Illinois at Urbana-Champaign — It is well known that the traditional tube theory of entangled polymer cannot provide a full picture of microscopic heterogeneity. However, problems on modern topics such as nanocomposites and cell motility require us to understand microscopic details of such systems. In order to study their dynamics, direct imaging of entangled biopolymer, F-actin, was carried out. With our experimental technique it was possible to achieve sub-diffraction resolution on sparse points of a polymer, and simultaneously to observe the geometry of the contour. This enabled quantification without assumption about structure factor or the specific type of dynamical model. Preliminary results show that diffusion along the chain contour shows distinct variations according to spatial position even at constant polymer length. This may imply that, on a single polymer level, effects from heterogeneities could override mean field descriptions.

9:24AM T31.00008 Casimir interactions between crosslinkers in semiflexible networks , DEVIN KACHAN, ROBIJN BRUINSMA, ALEX LEVINE, University of California, Los Angeles — The equilibrium phase behavior of solutions of semiflexible filaments such as F-actin and cross-linking proteins is complex. As a function of both crosslinker density and the preferred filament crossing angle imposed by the cross-linker, one may observe a plethora of complex ordered phases in addition to bundles. Simulations report both the formation lamellar network structures and the aggregation of cross-linkers in thermal equilibrium. These complex phases result from an effective interaction between cross-linkers mediated by the filaments to which they are bound. In this talk, we explore interactions between labile cross-linking proteins bound to semiflexible filaments mediated by the effect of crosslinking on the thermal fluctuation spectrum the filaments involved. Such fluctuation induced interactions are of the Casimir type, which we study using a path integral formulation of the partition function of the crosslinked filaments. We also make predictions for the spatial organization of crosslinkers along semiflexible filaments and in complex semiflexible networks based on this Casimir interaction.

9:36AM T31.00009 Rheology of rigid rod – flexible chain composite networks , MEENAKSHI PRABHUNE, Third Institute of Physics - Biophysics, Georg August University, Göttingen, KNUT HEIDEMANN, Department for Numerical and Applied Mathematics, Georg August University, Göttingen, FLORIAN REHFELDT, Third Institute of Physics - Biophysics, Georg August University, Göttingen, MAX WARDETZKY, Department for Numerical and Applied Mathematics, Georg August University, Göttingen, CHRISTOPH SCHMIDT, Third Institute of Physics - Biophysics, Georg August University, Göttingen — Living cells are governed by active cellular processes such as cell division, adhesion and migration that depend on the cytoskeleton. The cytoskeleton is a composite cross-linked polymer network of cytoskeletal filaments ranging from rod-like microtubules and actin bundles to semi-flexible actin filaments and softer intermediate filaments. Single-component *in vitro* networks have been studied, but well defined composites are more difficult to construct and are not yet well understood. Here, we have generated heterogeneous networks *in vitro* by cross-linking microtubules and ds DNA via a heterobifunctional cross-linker (sulpho SMCC). DNA as a cross-linker has the unique advantage of having a well-defined length, which we vary in our experiments. We have measured the shear-elastic response in these networks by macrorheology experiments at varying strains and frequencies. The nonlinear response was also characterized using differential stiffness measurements in a macrorheometer. Simultaneously, we compare the experimental data to numerical simulations that we have developed for networks of stiff slender rods connected by semi-flexible linkers (see talk by Knut Heidemann).

9:48AM T31.00010 Cooperativity and redundancy in the mechanics of compositely crosslinked branched anisotropic cytoskeletal networks , J. M. SCHWARZ, TAO ZHANG, Syracuse University, MOUMITA DAS, Rochester Institute of Technology — At the leading edge of a crawling cell, the actin cytoskeleton extends itself in a particular direction via a branched crosslinked network of actin filaments with some overall alignment. This network is known as the lamellipodium. Branching via the complex Arp2/3 occurs at a reasonably well-defined angle of 70 degrees from the plus end of the mother filament such that Arp2/3 can be modeled as an angle-constraining crosslinker. Freely-rotating crosslinkers, such as alpha-actinin, are also present in lamellipodia. Therefore, we study the interplay between these two types of crosslinkers, angle-constraining and free-rotating, both analytically and numerically, to begin to quantify the mechanics of lamellipodia. We also investigate how the orientational ordering of the filaments affects this interplay. Finally, while role of Arp2/3 as a nucleator for filaments along the leading edge of a crawling cell has been studied intensely, much less is known about its mechanical contribution. Our work seeks to fill in this important gap in modeling the mechanics of lamellipodia.

10:00AM T31.00011 Sacrificial bonds and hidden length in biomaterials – a kinetic description of strength and toughness in bone , CHARLES K. C. LIEOU, AHMED E. ELBANNA, JEAN M. CARLSON, University of California, Santa Barbara — Sacrificial bonds and hidden length in structural molecules account for the greatly increased fracture toughness of biological materials compared to synthetic materials without such structural features, by providing a molecular-scale mechanism of energy dissipation. One example of occurrence of sacrificial bonds and hidden length is in the polymeric glue connection between collagen fibrils in animal bone. In this talk, we propose a simple kinetic model that describes the breakage of sacrificial bonds and the revelation of hidden length, based on Bell's theory. We postulate a master equation governing the rates of bond breakage and formation, at the mean-field level, allowing for the number of bonds and hidden lengths to take up non-integer values between successive, discrete bond-breakage events. This enables us to predict the mechanical behavior of a quasi-one-dimensional ensemble of polymers at different stretching rates. We find that both the rupture peak heights and maximum stretching distance increase with the stretching rate. In addition, our theory naturally permits the possibility of self-healing in such biological structures.

10:12AM T31.00012 Selectively Structural Determination of Cellulose and Hemicellulose in Plant Cell Wall[1] , SHIH-CHUN HUANG, Department of Chemical Engineering, Pennsylvania State University, YONG BUM PARK, DANIEL COSGROVE, Department of Biology, Pennsylvania State University, JANNA MARANAS, Department of Chemical Engineering, Pennsylvania State University, JANNA MARANAS TEAM, DANIEL COSGROVE TEAM — Primary plant cell walls support the plant body, and regulate cell size, and plant growth. It contains several biopolymers that can be categorized into three groups: cellulose, hemicellulose and pectin. To determine the structure of plant cell wall, we use small angle neutron scattering in combination with selective deuteration and contrast matching method. We compare the structure between wild Arabidopsis thaliana and its xyloglucan-deficient mutant. Hemicellulose in both samples forms coil with similar radii of gyration, and weak scattering from the mutant suggests a limited amount of hemicellulose in the xyloglucan-deficient mutant. We observe good amount of hemicellulose coating on cellulose microfibrils only in wild Arabidopsis. The absence of coating in its xyloglucan-deficient mutation suggests the other polysaccharides do not have comparable interaction with cellulose. This highlights the importance of xyloglucan in plant cell wall. At larger scale, the average distance between cellulose fibril is found smaller than reported value, which directly reflects on their smaller matured plant size.

10:24AM T31.00013 Glass micro-wire tracks for guiding kinesin-powered gliding motion of microtubules , K. KIM, WPI-AIMR, Tohoku Univ, A. L. LIAO, WPI-AIMR, Tohoku Univ; Materials Science and Engineering, Texas A&M Univ, A. SIKORA, D. OLIVEIRA, WPI-AIMR, Tohoku Univ, M. UMETSU, WPI-AIMR, Tohoku Univ; Dept of Biomolecular Engineering, Tohoku Univ, I. KUMAGAI, Dept of Biomolecular Engineering, Tohoku Univ, T. ADSCHIRI, WPI-AIMR, Tohoku Univ, W. HWANG, Materials Science and Engineering and Dept of Biomedical Engineering, Texas A&M Univ, W. TEIZER, WPI-AIMR, Tohoku Univ; Materials Science and Engineering and Dept of Physics and Astronomy, Texas A&M Univ — Kinesin, an enzyme molecule found in eukaryotic cells, walks on specific paths, namely microtubules. These microtubules, self-assembled *in-vitro*, cooperate with kinesin molecules by playing the role of either a track for the molecular motors or a lengthy cargo lorry driven by the motor molecules. One of major challenges in utilization of the latter case, which is particularly advantageous for practical applications because of the longer cruising range and the higher carrying capacity of the bio-transporter, is herding the gliding microtubules. A general approach to achieve this goal is aligning motor molecules along a track. In previous attempts such tracks were physically and/or chemically patterned on a glass surface. We use a kinesin-coated glass wire to demonstrate kinesin-powered gliding movement of microtubules confined by the wire-like structure. This new approach distinguishes itself in that the glass wire track is an independent entity, being separable from a two-dimensional surface in principle. We will also discuss quantitative analysis of the guided motility and potential applications.

10:36AM T31.00014 Nanotransport Using The Kinesin Motor Protein , A. SIKORA, J. RAMON-AZCON, D. OLIVEIRA, K. KIM, WPI-AIMR, Tohoku University, Japan, A.L. LIAO, WPI-AIMR, Tohoku University, Japan and Materials Science and Engineering, Texas A&M University, M. UMESTU, T. ADSCHIRI, WPI-AIMR, Tohoku University, Japan, I. KUMAGAI, Department of Biomolecular Engineering, Tohoku University, Japan, W. HWANG, Materials Science and Engineering; Department of Biomedical Engineering, Texas A&M University, W. TEIZER, WPI-AIMR, Tohoku University, Japan; Materials Science and Engineering and Department of Physics and Astronomy, Texas A&M University — The kinesin motor protein is one of the major contributors in cell division and intracellular transportation of cargo. Kinesin converts chemical energy into mechanical work with a yield greater than 50% and it can transport large size cargo along several micrometers, moving on a biopolymer track called microtubule. The kinesin-microtubule system has been studied *in vitro*. Two main configurations exist. In the first one, the gliding mode, microtubules are propelled by kinesin proteins bound to a substrate. In the second one, the kinesin molecules "walk" on the microtubule. Kinesin can be engineered in order to allow binding of specific cargo. In this study, we are using biotinated kinesin which allows strong non-covalent binding with streptavidin, which can cover any nano object. Using fluorescence microscopy, transport of quantum dots has been studied. Velocities have been analyzed and the results are in good agreement with data from the literature. New approaches using multiwall carbon nanotube tracks, aligned by dielectrophoresis, have also been investigated.

10:48AM T31.00015 On the assembly of kinesin-based nanotransport systems , DANIEL OLIVEIRA, WPI-AIMR, Tohoku University, Japan, DOMYOUNG KIM, Department of Biomolecular Engineering, Tohoku University, Japan, MITSUO UMETSU, Department of Biomolecular Engineering, Tohoku University, Japan; WPI-AIMR, Tohoku University, Japan, TADAFUMI ADSCHIRI, WPI-AIMR, Tohoku University, Japan, WINFRIED TEIZER, Department of Physics and Astronomy, Texas A&M University, USA; WPI-AIMR, Tohoku University, Japan — The ongoing pursuit to construct an artificial functional nanorobot has been preceded by biological equivalent long ago. Many proteins act at the nano-scale as biological motors for rotation or translation, being responsible for many fundamental processes. Among these proteins, kinesin is considered a promising tool in the development of synthetic nano-machines. The kinesin protein is a well known naturally occurring molecular machine capable of cargo transport upon interaction with cytoplasmic systems of fibers, known as microtubules. Conversion of chemical energy into mechanical work, harnessed by the hydrolysis of ATP, propels kinesin along microtubules. Even though recent efforts were made to engineer tailor-made artificial nanotransport systems using kinesin, no systematic study investigated how these systems can be built from the bottom up. Relying on the Surface Plasmon Resonance technique, we will show for the first time that it is possible to quantitatively evaluate how each component of such nanoscopic machines is sequentially assembled by monitoring the individual association of its components, specifically, the kinesin association to microtubule as well as the cargo-kinesin association.

Thursday, March 21, 2013 8:00AM - 11:00AM –

Session T32 DPOLY: Focus Session: Charged and Ion Containing Polymers 340 - Lilin He, Oak Ridge National Labs

8:00AM T32.00001 Puzzle of the Electrostatic Persistence Length[1] , A.V. DOBRYNIN, J.-M.Y. CARRILLO, University of Connecticut — Electrostatic interactions play an important role in controlling properties of synthetic and biological polyelectrolytes. The change in the ionic environment in such systems can significantly influence their conformational properties. For semiflexible polyelectrolyte chains with ionic groups interacting via the screened Debye-Huckel potential the electrostatic contribution to the chain persistence length scales quadratically with the Debye screening length (OSF model). However, recent computer simulations of flexible polyelectrolyte chains with explicit counterions and salt ions show that in the wide interval of the solution ionic strengths the electrostatic contribution to chain persistence length is proportional to the Debye screening length, r_D. To understand the crossover between flexible and semiflexible chain behavior and elucidate the effect of explicit ions on chain conformations we performed molecular dynamics of polyelectrolyte chains with degree of polymerization N =300 and different values of the chain bending rigidity varying between K =1 and K =160. Our simulations have shown that the bond-bond correlation function describing chain's orientational memory can be approximated by a sum of two exponential functions manifesting the existence of the two characteristic length scales. One describes the chain's bending rigidity at the distances along the polymer backbone shorter than r_D while another controls the long-length scale chain's orientational correlations. The long-length scale bending rigidity is proportional to r_D for chains with bending rigidity smaller than a crossover bending rigidity K^*.

[1]NSF DMR-1004576

8:12AM T32.00002 Theory of complexation of polyelectrolytes onto curved surfaces , HAMIDREZA SHOJAEI, MURUGAPPAN MUTHUKUMAR, University of Massachusetts — We have derived analytically the critical conditions for the complexation of flexible polyelectrolytes onto curved interfaces, in terms of the various experimental variables characterizing the interface, the polymer, and the electrolyte condition of the medium. We have used the WKB method and the calculated results will be compared with the previously known results from the variational method. Although the results from both methods are qualitatively similar, the WKB method avoids ad hoc choice of trial functions for the monomer density profile. Implications of our results in the context of experimental situations will be discussed.

8:24AM T32.00003 Complexation Between Weakly Basic Dendrimers and Linear Polyelectrolytes: Effects of Chain Stiffness, Grafts, and pOH , THOMAS LEWIS, GUNJA PANDAV, AHMAD OMAR, VENKAT GANESAN, University of Texas at Austin — The unique architecture and high charge density of dendrimer molecules have attracted interest for their utilization in gene delivery applications. The strong binding affinity of cationic dendrimers to genetic materials make them effective gene delivery vectors not only by shielding the nucleic acid (NA) material from degradative enzymes in the blood stream, but also by reducing the overall negative charge of the dendrimer-NA material complex, which in turn creates more favorable interaction with the anionic cell membrane. However, the high cytotoxicities of cationic dendrimers have motivated the development of polyethylene glycol (PEG) conjugated dendrimer molecules, which have been shown to reduce dendrimer cytotoxicity while still retaining transfection ability. In order to gain insight into how the addition of neutral grafts affects the binding affinity and conformations of dendrimer-NA material complexes, we have developed and numerically solved a Self-Consistent Field Theory approach for both grafted and non-grafted annealed charged dendrimer molecules in the presence of linear polyelectrolyte molecules. Specifically, this work examines the effect of linear polyelectrolyte stiffness, grafting chain length, and solution pOH.

8:36AM T32.00004 Self-organization of multivalent counterions in polyelectrolyte brushes , JIANZHONG WU, University of California, Riverside — The structure and interfacial properties of a polyelectrolyte brush (PEB) depend on a broad range of parameters such as the polymer charge and grafting density, counterion valence, salt concentration, and solvent conditions. These properties are of fundamental importance in technological applications of PEBs including colloid stabilization, surface modification and lubrication, and in functioning of biological systems such as genome packaging in single-strand DNA/RNA viruses. Despite intensive studies by experiments, molecular simulations, and myriad analytical methods including scaling analyses, self-consistent-field theory, and most recently density functional theory, the behavior of PEBs in the presence of multivalent counterions remains poorly understood. In this talk, I will present a density functional method for polyelectrolyte brushes and discuss self-organization of multivalent counterions within highly charged polyelectrolyte brushes. The counterion-mediated attraction between polyions leads to a first-order phase transition similar to that for a neutral brush in a poor solvent. The self-organization of multivalent counterions results in a wavelike electrostatic potential and charge density that oscillate between positive and negative values.

9:12AM T32.00005 Linear Viscoelastic and dielectric behavior of Phosphonium Ionomers , QUAN CHEN, SIWEI LIANG, U HYEOK CHOI, JAMES RUNT, RALPH H. COLBY, Department of Materials Science and Engineering, The Pennsylvania State University — Linear viscoelastic (LVE) and dielectric (DRS) responses were examined for polysiloxane-based phosphonium-ionomers with fractions of ionic monomers $f = 0$ to 0.3; the other monomers have short poly(ethylene oxide) side chains. LVE of these samples shows a glassy relaxation followed by a terminal polymer relaxation that is increasingly delayed with increase of f. The glassy relaxation broadens when $f > 0.1$. DRS of these samples shows a segmental α process associated with motion of monomers, followed by an additional $\sim$ 100X slower α_2 process before electrode polarization. A detailed comparison between LVE and DRS reveals that the α_2 relaxation in DRS corresponds to a characteristic modulus of $k_{\mathrm{B}}T$ per ionic group in LVE. This result strongly suggests that the molecular origin of the α_2 relaxation is the dissociation/association of the ionic groups from/into the ionic clusters, consistent with the observed magnitude of the α_2 relaxation increasing with ion content. Based on this molecular view, we can predict the terminal polymer relaxation from the α_2 relaxation time obtained in DRS, assuming this is the lifetime of ionic associations in a sticky Rouse model. Meanwhile, the broadening of glassy mode distribution with increasing $f > 0.1$ is attributed to an enhanced cooperation for motion of glassy segments. This enhancement is possibly due to decrease of distance between the ionic groups with increasing f, leading to stronger overlap of polarizability volumes.

9:24AM T32.00006 Ionic Conductivity of Nanostructured Block Copolymer Electrolytes in the Low Molecular Weight Limit , ALEXANDER TERAN, RODGER YUAN, University of California, Berkeley, INNA GUREVITCH, Lawrence Berkeley National Laboratory, NITASH BALSARA, University of California, Berkeley — Nanostructured block copolymer electrolytes containing an ion-conducting block and a modulus-strengthening block are of interest for applications in solid-state lithium metal batteries. Previous work using symmetric polystyrene-block-poly(ethylene oxide) mixed with a lithium salt has demonstrated that the ionic conductivity increases with increasing molecular weight of the poly(ethylene oxide) block in the high molecular weight regime due to an increase in the width of the conducting channel. Our current study extends the previous work to the low molecular weight limit. Small angle X-ray scattering, differential scanning calorimetry, and ac impedance spectroscopy experiments help identify the opposing forces influencing the conductivity in these materials. We also examine the annealing process for these materials, whose ion transport characteristics are well known to be influenced by sample preparation and thermal history. The conductivity appears to be influenced by the conductive channel width as well as the glass transition temperature of the insulating block, which also plays an important role in the annealing process.

9:36AM T32.00007 Aggregation Behavior of Charged Surfactants and their Mixtures in Ionic Liquids[1] , LANG CHEN, HARRY BERMUDEZ, University of Massachusetts Amherst — Room-temperature ionic liquids (ILs) have been recently explored as extraordinary solvent with potential opportunities for numerous applications. We set out to obtain a better understanding of the aggregation behavior of charged surfactants within ILs. From phase diagrams and isotherms in several distinct ILs, a connection between solubility of the surfactant and the physical properties of the underlying ionic liquid was established. We conclude that the interfacial energy is crucial in determining aggregation behavior while electrostatic interactions can be largely ignored. This study was extended to include mixtures of cationic and anionic surfactants where our data further demonstrate near-complete charge screening. Mixtures of charged surfactants in ILs can therefore be considered as nearly ideal, in sharp contrast to aqueous solutions. The results here give insight into the nature of self-assembly of surfactants in ILs and the interaction between solutes and IL solvents.

[1]MRSEC

9:48AM T32.00008 Morphology and Aggregate Local Structure of Precise Polyolefins with Associating Pendant Groups , FRANCISCO BUITRAGO, University of Pennsylvania, DAN BOLINTINEANU, MARK STEVENS, AMALIE FRISCHKNECHT, Sandia National Laboratories, KAREN WINEY, University of Pennsylvania, WINEY GROUP TEAM, FRISCHKNECHT/STEVENS GROUP TEAM — Polyolefins containing acid and/or ionic pendant groups have specific interactions that produce complex and hierarchical morphologies providing a remarkable set of properties. Despite the widespread industrial use of such materials, rigorous morphology-property relationships remain elusive due to structural heterogeneities in the available copolymers. Recently, linear polyethylenes with associating pendant groups separated by a precisely controlled number of carbon atoms have been synthesized by acyclic diene metathesis (ADMET) polymerization. At room temperature, X-ray scattering shows that the molecular uniformity of these materials results in periodic morphologies of the microphase separated ionic groups. Above their transition temperatures ($\mathrm{T_g}$, $\mathrm{T_m}$), loss of the periodic structures occurs due to polyethylene crystals melting. The morphologies of precise ionomers at elevated temperatures were further investigated via atomistic molecular dynamics (MD) simulations. The simulations complement the X-ray scattering experiments by providing a clear picture of the aggregate shape and size as a function of counterion type, neutralization level and spacer length.

10:00AM T32.00009 Plasticizer Influence on Ionic Morphology and Transport in PEO Ionomers , MICHAEL O'REILLY, University of Pennsylvania, HANQING MASSER, DANIEL KING, PAUL PAINTER, RALPH COLBY, JAMES RUNT, Pennsylvania State University, KAREN WINEY, University of Pennsylvania — Sulfonated poly(ethylene oxide) ionomers have been blended with a miscible, oligomeric poly(ethylene glycol) in order to study the effect of plasticizers on ionomer performance. Plasticizers can increase ionic conductivity in ionomers by depressing the glass transition temperature and dissolving ionic aggregates. In this study, the relative volume fractions of ionic aggregates in various blend compositions is investigated by curve fitting the X-ray scattering aggregate peak. Two fitting parameters are utilized to quantify aggregate composition, peak area and peak position. Fitting results conclude that plasticizer content dilutes and dissolves ionic aggregates, providing higher conducting ion density than comparable neat ionomers. Dielectric relaxation spectroscopy data confirms that ionic conductivity improves with plasticizer content. Similar curve fitting methods were executed for FT-IR signals, and quantification of aggregate structure is compared with X-ray scattering.

10:12AM T32.00010 Predicting the Solution Morphology of a Sulfonated Pentablock Copolymer in an Arbitrary Solvent Mixture , JAMIE FORD, WILLIAM KYEI-MANU, KAREN WINEY, University of Pennsylvania — Block copolymers self assemble into a wide array of morphologies in solvents. To predict the solution morphology of the polymer, we assess the interactions between the individual blocks and the solvent or solvents. Here, we use the Hansen solubility parameters to calculate the interactions between a library of solvents and an ABCBA pentablock copolymer with non-polar A and B blocks and a polar, sulfonated C block to predict the expected morphology for a given solvent and compare it to our small-angle X-ray scattering data. In non-polar solvents, we observe micelles with a C core and an A-B corona. We observe inverted micelles in polar solvents – an A-B core with a C corona. We extended our methodology to mixed polar/non-polar solvent systems to predict the solvent ratios corresponding to the transition from micelles to inverted micelles.

10:24AM T32.00011 Morphology and Dynamics of Ion Containing Polymers using Coarse Grain Molecular Dynamics Simulation , MONOJOY GOSWAMI, BOBBY SUMPTER, Oak Ridge National Laboratory — Ion containing polymers are of particular interest in polymer batteries and membranes for separation chemistry applications. With the increasing interest in this field, novel and modern experimental techniques have been developed to design better materials, however, the fundamental understanding of these polymers, their morphology and ion/counterion dynamics are still not very well understood. We present a coarse grain simulation study to understand the structural detail and physics of ion/counterion dynamics. We do implicit as well as explicit solvent calculation to observe the effect of dielectric constant and temperature on dynamics of polymer chain and ion/counterion. The results are then compared with the small angle neutron scattering experiments. These works will help design better materials for future applications.

10:36AM T32.00012 Packing of charged chains on toroidal geometries?[1] , ZHENWEI YAO, MONICA OLVERA DE LA CRUZ, Northwestern University — We study sequential Langmuir adsorption of a flexible charged polyelectrolyte chain on tori. In the regime of monomer-monomer electrostatic interaction dominating over thermal fluctuations, it becomes a generalized Thomson problem. Various patterns of adsorbed chain are found including double spirals, disclination-like structures, Janus tori and uniform wrappings, arising from the long-range electrostatic interaction and the toroidal geometry. Their broken mirror symmetry and energetics are analyzed. In particular, we find a power law for the electrostatic energy; the dependence of the power on the geometry of tori implies a geometric origin. Furthermore, in the regime of large thermal fluctuation, we systematically study random walks on tori that generate chain configurations; the features associated with the toroidal geometry are discussed.

10:48AM T32.00013 Quantum mechanical calculation of ion chains in Poly(ethylene oxide)-based Sulfonate Ionomers[1] , HUAI-SUEN SHIAU, MICHAEL JANIK, RALPH COLBY, Pennsylvania State University, DOE LI+ BATTERY ENERGY PROJECT TEAM — Ion-containing polymers are of interest as single-ion conductors for use as electrolytes in electrochemical devices, including lithium ion batteries. Current ion conductivities of the best ionomers are roughly 100X too small for practical applications and have a small fraction of their Li^+ counterions participating in conduction. *Ab initio* methods are used to investigate the dissociation/association of ionic chain aggregates. The binding energy as a function of distance between ions is explored, in which the energy at each separation is optimized with respect to the number and location of solvating ether oxygen moieties. We study the barrier between the solvated and bound states as a function of distance between the ions, including the barrier to break ion chain aggregates in different positions along the chain. This is prerequisite to mesoscale simulations capable of reproducing the equilibrium between various ion chain aggregates, with realistic dynamics, from which conductivity pathways can be investigated.

Session T33 DMP: Focus Session: Organic Electronics and Photonics - Transport in Polymers

341 - Vitaly Podzorov, Rutgers University

8:00AM T33.00001 Top contact approach to the nanoscale organic electronic systems using novel stencil lithography technique[1] , HOYEOL YUN, HAKSEONG KIM, SANG WOOK LEE, Division of Quantum Phases & Devices, School of Physics, Konkuk University, Seoul, Korea, SANGWOOK KIM, SEUNGMOON PYO, Department of Chemistry, Konkuk University, Seoul, Korea, JUN SUNG KIM, Department of Physics, Pohang University of Science and Technology, Seoul, Korea — In this presentation, we proposed a widely adaptable fabrication method to form a nanoscale organic electronic system with top contact electrodes using a Poly(methyl methacrylate) (PMMA) shadow mask which has a transparency, flexibility and high resolution electrode pattern. The stencil lithography technique with the PMMA mask was developed by the combination of the standard electron beam lithography and the micro transfer printing technique. Firstly, this technique was applied to fabricate nanoscale pentacene field effect transistor (FET) which has top contact source and drain electrodes. The configurations of pentacene layer such as position, width and length were controlled by a PMMA shadow mask which was pre-transferred onto a target substrate. Another PMMA shadow mask with electrode pattern was precisely aligned on the pre-deposited pentacene layer and the pairs of gold electrode were defined after the thermal evaporation followed by mechanical detachment of the mask. The channel length of the transistor was varied from 5um to 500nm and placed at regular intervals along the pentacene layer. The electrical performance of the pentacene FET was statistically analyzed according to the channel length variation.

8:12AM T33.00002 ABSTRACT WITHDRAWN –

8:24AM T33.00003 Infrared spectroscopy of narrow gap donor-acceptor polymer-based ambipolar transistors , OMAR KHATIB, University of California, San Diego, JONATHAN YUEN, University of California, Santa Barbara, JIM WILSON, University of California, San Diego, RAJEEV KUMAR, Nano Terra, MASSIMILIANO DI VENTRA, University of California, San Diego, ALAN HEEGER, University of California, Santa Barbara, DIMITRI BASOV, University of California, San Diego — Donor-acceptor (D-A) copolymers have recently emerged as versatile materials for use in a large variety of device applications. Specifically, these systems possess extremely narrow band gaps, enabling ambipolar charge transport when integrated in solution-processed organic field-effect transistors (OFETs). However, the fundamentals of electronic transport in this class of materials remain unexplored. We present a systematic investigation of ambipolar charge injection in a family of narrow-gap D-A conjugated polymers based on benzobisthiadiazole (BBT) using infrared (IR) spectroscopy. We observe a significant modification of the absorption edge in polymer-based OFETs under the applied electric field. The absorption edge reveals hardening under electron injection and softening under hole injection. Additionally, we register localized vibrational resonances associated with injected charges. Our findings indicate a significant self-doping of holes that is modified by charge injection. Observations of both electron and hole transport with relatively high carrier mobility strongly suggest an inhomogeneous, phase-separated conducting polymer.

8:36AM T33.00004 Improving Ambipolar Charge Injection in Polymer FETs with Carbon Nanotubes , JANA ZAUMSEIL, Institute of Polymer Materials, Friedrich-Alexander Universität Erlangen-Nürnberg, Martensstraße 7, D-91058 Erlangen (Germany) — Efficient charge injection is a key issue for organic field-effect transistors (FET). Various methods can be used to optimize injection of either holes or electrons, for example, by modifying the workfunction of metallic electrodes with self-assembled monolayers. For ambipolar FETs this is much more difficult because injection of both charge carriers has to be improved at the same time. Here we demonstrate a simple process to significantly improve ambipolar charge injection in bottom contact/top gate polymer field-effect transistors by adding single-walled carbon nanotubes (SWNT) to the semiconducting polymer at concentrations well below the percolation limit. Such polymer/carbon nanotube hybrid systems are easily produced by ultrasonication and dispersion of SWNT in a conjugated polymer solution. Even at very low nanotube concentrations the charge injection of both holes and electrons, for example, into poly(9,9-dioctylfluorene-co-benzothiadiazole) (F8BT) and poly(9,9-dioctylfluorene) (PFO) is significantly enhanced leading to lower contact resistances and threshold voltages than in FETs with pristine polymer films. This method can be extended to other semiconductors like n-type naphthalene-bis(dicarboximide)-based polymers (e.g. P(NDI2OD-T2)) for which hole injection was greatly enhanced. The proposed mechanism for this effect of carbon nanotubes on injection is independent of the polarity of the charge carriers. It can be maximized by patterning layers of pure carbon nanotubes onto the injecting electrodes before spincoating the pristine polymers leading to almost ohmic contacts for polymers, which usually show only strongly Schottky-barrier-limited injection. This improved injection of holes and electrons allows for a wider range of accessible polymers for ambipolar and thus also light-emitting transistors.

9:12AM T33.00005 Elucidating Bias Stress in Vertical and Lateral Charge Transport in Organic Electronics , HE WANG, Princeton University, CHERNO JAYE, ZUGEN FU, DANIEL FISCHER, National Institute of Standards and Technology, YUEH-LIN LOO, Princeton University — Bias stress, during which a reduction in source-drain current is observed under continuous application of gate voltage in organic thin-film transistors, originates from trapped mobile charges. Organic semiconductors often exhibit tail states that extend into their band gap; these tail states can act as traps to immobilize charge. Alternatively, defects at the organic semiconductor-dielectric interface can also trap charge. Whether bias stress originates from impurities or defects in the bulk of the organic semiconductor or at the organic semiconductor-dielectric interface, however, remains unclear. By building and testing organic single-carrier diodes having different active layer thicknesses, we can infer the trapping contributions in the bulk of the organic semiconductor relative to those at the organic semiconductor-electrode interface. In conjunction with device characteristics of organic thin-film transistors having different dielectrics, we found that the broad distribution of tail states that is present in poly(3-hexyl thiophene), P3HT, is responsible for bias stress in P3HT-comprising devices. On the other hand, traps at the [6,6]-phenyl-C61-butyric acid methyl ester, PCBM,-dielectric interface are more dominant than those in the bulk in PCBM-containing devices.

9:24AM T33.00006 Low-temperature transport in metallic polyaniline[1] , EVAN KANG, EUNSEONG KIM, Center for Supersolid & Quantum Matter Research and Department of Physics, KAIST, Korea — Since the first observation of true metallic transport in polyaniline (PANI) [Lee et al. Nature, 441, 65 (2006)], one of the outstanding properties of metallic state in PANI, the positive temperature dependence of resistance has not been systematically investigated. We studied the underlying mechanism of the intriguing low-temperature transport in PANI synthesized with self-stabilized dispersion polymerization. [Lee et al. Adv. Funct. Mater. 15, 1495 (2005)] The positive temperature dependence was successfully reproduced at all range of low temperatures. More disordered samples showed negative temperature dependence, indicating disorder-induced metal-insulator transition. In addition, the charge-density-dependent transport in PANI will be presented for profound understanding of this metallic state.

9:36AM T33.00007 Role of Morphology on Carrier Transport in Conjugated Polymer Thin Films , HENGXI YANG, BINGYUAN HUANG, PETER GREEN, University of Michigan — The effects of morphology on the out-of-plane hole mobility in poly(3-hexylthiophene) (P3HT) films were examined using impedance spectroscopy (IS), time-of-flight (ToF) and charge extraction by a linearly increasing voltage (CELIV). IS was used for the first time to measure the hole mobilities, μ, of P3HT films; μ was found to be film thickness dependent, increasing over an order of magnitude with increasing film thickness from 100 to 700 nm. These results are in excellent agreement with those measured using ToF and CELIV. IS has an added advantage over ToF and CELIV, as it also provides dc conductivity $\sigma_{\rm dc}$ and charge carrier density n. Both $\sigma_{\rm dc}$ and n are shown to decrease appreciably with increasing h, over the same thickness range. The thickness dependent trends in μ, $\sigma_{\rm dc}$ and n are consistent with changes in the morphology of these films.

9:48AM T33.00008 Charge Transport in Trehalose-Derived Sugar Glasses , LOUIS NEMZER, Nova Southeastern University, MAHANTESH NAVATI, JOEL FRIEDMAN, Albert Einstein College of Medicine, ARTHUR EPSTEIN, Ohio State University — Trehalose is a naturally occurring disaccharide with a well-known ability to preserve the biological function of proteins and cell membranes during periods of stress, including dehydration, by stabilizing the conformations of the macromolecules within a glassy matrix. This phenomenon makes use of the propensity of trehalose to interact strongly with protein functional groups and solvating water molecules via hydrogen bonding. Recently, it has been shown that trehalose sugar glasses also support long range charge transport in the form of oxidation-reduction reactions occurring between spatially separated donors and acceptors. Based on an Arrhenius conductivity analysis, along with IR-absorption and dielectric spectroscopy data, we propose that a Grotthuss-like proton hopping mechanism is responsible for the high charge carrier mobility and observed bias-dependent apparent activation energy. The possibility is raised for novel redox reactions to be performed on proteins constrained to specific 3D conformations. This could lead to a deeper understanding of biological processes, such as anhydrobiosis, as well as the development of new biomimetic photovoltaic devices.

10:00AM T33.00009 ABSTRACT WITHDRAWN –

10:12AM T33.00010 Aliphatic Polymers Bearing Pendant Radical Groups as Charge Carrying Moieties in Organic Electronic Applications , BRYAN BOUDOURIS, LIZBETH ROSTRO, ADITYA BARADWAJ, School of Chemical Engineering, Purdue University — The implementation of highly conjugated polymers has led to an explosion of high-performance organic electronic devices; however, many important synthetic, physical, and mechanical properties of these macromolecules still lag behind polymers with non-conjugated backbones. In order to implement the positive aspects of both macromolecular classes, we have synthesized radical polymers ($i.e.$, where a pendant stable radical group is present on each repeat unit of the polymer) using controlled polymerization mechanisms. We demonstrate that these next-generation conducting polymers have thermal and physical properties similar to that of aliphatic polymers while still retaining charge transport properties akin to those of well-studied conjugated polymer systems. Specifically, we characterize the charge transport ability of radical polymers using a model radical polymer, poly(2,2,6,6-tetramethylpiperidinyloxymethacrylate), and propose a mechanism for charge transport in these molecules. Furthermore, because of the low optical absorption in the visible spectrum associated with non-conjugated polymers, radical polymers are utilized as anodic modifiers in organic photovoltaic devices and show promise in being more stable to environmental conditions than traditional anode-modifying materials.

10:24AM T33.00011 Violation of the Wiedemann-Franz law in Conducting Polymers , NELSON COATES, Molecular Foundry, Lawrence Berkeley National Laboratory, JIANFENG LIU, BRYAN MCCULLOCH, Chemical Engineering Dept. University of California, Berkeley, SHANNON YEE, Mechanical Engineering Dept. University of California, Berkeley, JEFFREY URBAN, Molecular Foundry, Lawrence Berkeley National Laboratory, RACHEL SEGALMAN, Chemical Engineering Dept. University of California, Berkeley, XIAOJIA WANG, DAVID CAHILL, Dept. of Materials Science and Engineering, University of Illinois, Urbana-Champaign — The free-electron gas model proposed by Drude and Sommerfeld has been enormously successful at describing the electronic and thermal properties of highly electrically conducting materials. A prediction of the free-electron gas model is that the ratio of the electronic component of the thermal conductivity to the electrical conductivity is proportional to a constant multiplied by the absolute temperature. This prediction is known as the Wiedemann-Franz law, and has been widely validated across various classes of materials. The validity of this law however has not been extensively studied in conducting polymer systems, primarily due to the challenges associated with fabricating highly electrical conductivity polymer devices for which both the electrical and thermal conductivity could be measured. Here, we investigate the relationship between thermal and electronic transport in conjugated polymers across a wide range conductivities, and find that the Wiedemann-Franz law is strongly violated. These results demonstrate that the link between charge transport and heat transport is fundamentally different in conjugated polymer systems than in the vast majority of high-conductivity materials.

10:36AM T33.00012 Ab initio modeling of electronic properties of DNA: Comparison to experiments , JIANQING QI, University of Washington, SURANGA EDIRISINGHE, Georgia State University, ANANT ANANTRAM, University of Washington — In this work, we model the zero-bias conductance for four DNA strands that were used in Ref. [1]. Our approach consists of three elements: (i) experimental data, (ii) ab initio calculations of DNA and (iii) two parameters to determine the decoherence rates. We find that the coherent conductance is much smaller than the experiments [2]. To understand the reason, we look at the effect of decoherence. By including decoherence, we show that our model can rationalize the measured conductance of the four strands. We find that decoherence on $G:C$ base pairs is crucial in getting agreement with the experiments. However, the decoherence on $G:C$ base pairs alone does not explain the experimentally determined dependence of conductance in strands containing a number of $A:T$base pairs. Including decoherence on $A:T$ base pairs is also essential. By fitting the experimental magnitudes of the conductance for the four DNA molecules, we estimate for the first time that the deocherence rate is 6 *meV* for $G:C$ and 1.5 *meV* for $A:T$ base pairs. [1] Ajit K Mahapatro, et al., Nanotechnology, **18**, 195202 (2007) [2] Jianqing Qi, et al. http://www.ee.washington.edu/faculty/anant/publications/JianqingQiPaper.pdf.

10:48AM T33.00013 Various Magnetoresistance of a New Copolymer, $FeCl_3$ doped Poly(Phenylenevinylene-EDOT-Vinylene) , KYUNG HO KIM, Department of Physics and Astronomy, Seoul National University, AJEONG CHOI, WCU Flexible Nanosystems, Korea University, JUN-MO PARK, Department of Chemistry, Seoul National University, SUNG JU HONG, MIN PARK, Department of Physics and Astronomy, Seoul National University, EUN SANG CHOI, National High Magnetic Field Laboratory, Tallahassee, FL, TAE-LIM CHOI, Department of Chemistry, Seoul National University, YUNG WOO PARK, Department of Physics and Astronomy, Seoul National University — We synthesized a new alternating copolymer in which ethylenedioxythiophene (EDOT) and phenylene are alternatively linked by vinylene unit (PPVEDOTV). Temperature dependence of conductivity of the $FeCl_3$ doped PPVEDOTV films followed Coulomb gap variable range hopping (VRH). However magnetoresistance (MR) showed different behaviors despite their similar temperature dependence of conductivity. Among the 4 samples, the MR of the most conducting sample was such that initially positive and decreased as the magnetic field increased and upturned as the field increased further (Type A). 2 other samples showed initially negative MR and it crossed over to positive MR (Type B). Lastly the most insulating sample showed monotonic positive MR (Type C). The MR of type B and C were analyzed as the sum of forward quantum interference (FQI) and wavefunction shrinkage (WS) effects and WS effect only, respectively. For the MR of type A, we propose that the initial positive MR is attributed to FQI in less disordered systems.

Session T34 DPOLY: Thin Films of Block Copolymers and Hybrid Materials: Directed Assembly II

342 - Gila Stein, University of Houston

8:00AM T34.00001 Coupling Dynamic Thermal Shear Field to Block Copolymer Molecular Ordering for Highly Oriented and Hierarchically Patternable Nanostructures , GURPREET SINGH, The University of Akron, KEVIN YAGER, Brookhaven National Laboratory, HO-CHEOL KIM, Almaden Research Center, ALAMGIR KARIM, The University of Akron — Dynamic thermal field processing of block copolymer (BCP) thin film is a highly attractive roll-to-roll directed self-assembly method for molecular level organization of BCP nanostructures over large areas without requiring physical or chemical guiding templates. Previously, we discovered that a sharp temperature gradient >30 ^{o}C/mm flips BCP cylinders from horizontal to vertical orientation with respect to the substrate such that tuning the dynamic thermal sweep rate to the BCP's terminal relaxation time is critical for optimal hexagonally-packed vertical order. We now exploit the dynamic thermal field to induce a directional gradient soft-shear field via a thermally expanding elastomeric overlayer that yields highly oriented and hierarchically patternable horizontal BCP cylinders. BCP thin films confined under a flat or patterned elastomeric overlayer and translated across the dynamic thermal field experience directional elastomer expansion-contraction in the heating-cooling zone as a single oscillatory shear cycle that aligns the BCP films. We successfully characterize the molecular level ordering mechanism and create unidirectionally aligned single crystal cylindrical BCP thin films over a wide range of thicknesses and processing speeds. Excitingly, the BCP cylinder alignment is fully decoupled from the PDMS mold pattern direction and dimensions.

8:12AM T34.00002 Strongly segregated polydisperse block copolymer near the order-disorder transition , ADAM SCHMITT, MAHESH MAHANTHAPPA, University of Wisconsin-Madison — Newer polymerization techniques afford polydisperse block polymers comprised of functional monomers with interesting potential applications as membranes for selective transport applications. As a result of their molecular chain length dispersity, the melt-phase behavior of these polymeric materials differs from that of well-studied monodisperse block copolymers. Extending our previous work dealing with weakly segregated poly(styrene-b-1,4-butadiene-b-styrene) (SBS) copolymers with a polydisperse middle block, we have examined the morphological consequences of increasing the segmental incompatibility between the copolymer segments. We will specifically outline recent studies of the melt phase behavior of highly segregated poly(lactide-b-1,4-butadiene-b-lactide) (LBL) triblock copolymers with a polydisperse center segment near the order-disorder transition. Comparison of the thermodynamics of SBS & LBL copolymer self-assembly suggests additional order parameters that characterize the phase behavior of these complex polymer mixtures.

8:24AM T34.00003 Shear-alignment of metal-containing block copolymer thin films for nanofabrication , SO YOUN KIM, RICHARD REGISTER, Princeton University, JESSICA GWYTHER, IAN MANNERS, University of Bristol, PAUL CHAIKIN, New York University — Cylinder-forming block copolymers can be used as etch masks for the fabrication of nanowire grids, with both fine resolution and scalability. However, achieving a high aspect ratio in these nanostructures, where reactive ion etching is employed for pattern transfer, requires strong etch contrast between two blocks of the copolymer. We achieve this strong contrast by using metal-containing block copolymers: materials which either contain metal as synthesized, or which can be selectively metallized after deposition as thin films. In the first case, iron-containing polystyrene-b-poly(ferrocenylisopropylmethylsilane) (PS-PFS) forming PFS cylinders was employed, and a spin-coated film was aligned by shearing with a polydimethylsiloxane pad. In the second case, polystyrene-b-poly-2-vinylpyridine (PS-P2VP) was deposited as a film, shear-aligned, and then platinum was selectively sequestered within the P2VP cylinders by brief soaking in an aqueous solution of a Pt salt. In both cases, shear stress produced alignment over centimeter-scale areas; this alignment was retained for PS-P2VP during the selective metallization. The line pattern in these aligned block copolymer thin films is then transferred via reactive ion etching into amorphous silicon deposited onto a quartz wafer to fabricate silicon nanowire grid polarizers which can operate at deep ultraviolet wavelengths.

8:36AM T34.00004 High Aspect Ratio Sub-15 nm Silicon Trenches From Block Copolymer Templates , XIAODAN GU, University of Massachusetts Amherst, ZUWEI LIU, Oxford Instrument, ILJA GUNKEL, DEIRDRE OLYNICK, Lawrence Berkeley National Lab, THOMAS RUSSELL, University of Massachusetts Amherst, UNIVERSITY OF MASSACHUSETTS AMHERST COLLABORATION, OXFORD INSTRUMENT COLLABORATION, LAWRENCE BERKELEY NATIONAL LAB COLLABORATION — High-aspect-ratio sub-15 nm silicon trenches are fabricated directly from plasma etching of a block copolymer (BCP) mask. Polystyrene-b-poly(2-vinyl pyridine) (PS-b-P2VP) 40k-b-18k was spin coated and solvent annealed to form cylindrical structures parallel to the silicon substrate. The BCP thin film was reconstructed by immersion in ethanol and then subjected to an oxygen and argon reactive ion etching to fabricate the polymer mask. A low temperature ion coupled plasma with sulfur hexafluoride and oxygen was used to pattern transfer block copolymer structure to silicon with high selectivity (8:1) and fidelity. The silicon pattern was characterized by scanning electron microscopy and grazing incidence x-ray scattering. We also demonstrated fabrication of silicon nano-holes using polystyrene-b-polyethylene oxide (PS-b-PEO) using same methodology described above for PS-b-P2VP. Finally, we show such silicon nano-strucutre serves as excellent nano-imprint master template to pattern various functional materials like poly 3-hexylthiophene (P3HT).

8:48AM T34.00005 Fabrication of 3 Dimensional SERS substrate using block copolymer confined AAO template , JIN KON KIM, DUESIK BAE, Pohang University of Science and Technology — We fabricated alternatively stacked lamellar microdomains of polystyrene (PS) and poly(methyl methacrylate) (PMMA) by confining PS-b-PMMA copolymer within anodic aluminum oxide (AAO) template modified by neutral brush. The size of stacked lamellar microdomains was easily controlled by changing the molecular weights of the block copolymers. We also deposited silver with 10 nm height selectively on the PS microdomains. The distance of neighboring silver was changed by microdomain size, height and diameter of the AAO template. The fabricated surface enhanced Raman scattering (SERS) substrates showed high sensitivity and reliablity.

9:00AM T34.00006 Silver based SERS substrates fabricated from block copolymer thin film , XIN ZHANG, WONJOO LEE[1], SEUNG YONG LEE[2], Department of Materials Sci. & Eng., Univ. of Maryland, College Park, MD, ZHENGHAN GAO, Biophysics Program, Univ. of Maryland, College Park, MD, ODED RABIN[3], R.M. BRIBER[4], Department of Materials Sci. & Eng., Univ. of Maryland, College Park, MD — Poly (styrene-block-4-vinyl pyridine) (PS-b-P4VP, Mw = 47-b-10 kDa, PDI=1.10) thin films were used to form large-scale long range ordered self-assembled hexagonal patterns of vertically P4VP oriented cylinders in a PS matrix on Si substrates. The P4VP cylindrical domains were crosslinked and quaternized using 1,4-dibromobutane. Negatively charged 15nm gold nanoparticles were attached to the quaternized P4VP domains through Coulombic interactions. Silver was then grown on the gold seeds to create nanometer scale gaps between the nanoparticles. The gap between the nanoparticles was fine tuned by controlling the silver growth time. The substrates showed large enhancement factors in the Raman scattering signal for a broad range of incident wavelengths.

9:12AM T34.00007 3D Nanoparticle Assemblies in Thin Films of Supramolecular Nanocomposites , JOSEPH KAO, PETER BAI, VIVIAN CHUANG, UC Berkeley, ZHANG JIANG, Advanced Photon Source, PETER ERCIUS, National Center for Electron Microscopy, TING XU, UC Berkeley — Nanocomposite thin films containing hierarchically-ordered nanoparticle assemblies are highly desirable to modulate the collective properties of nanoparticles to meet material requirements for nanodevice fabrication. Block copolymer-based supramolecules have shown great potential in directing the assembly of ordered nanoparticle arrays for a wide range of nanoparticles in bulk. Here, I will describe systematic studies on the phase behavior of supramolecular nanocomposites in thin films using a model system that forms parallel cylindrical morphology. By tailoring the conformational entropy of the comb block of the supramolecule, a rich library of nanoparticle assemblies including 1D chains, 2D lattices, 3D arrays and networks with precisely controlled inter-particle ordering can be obtained. Furthermore, the entropic contributions in the assembly process can be tuned by varying nanoparticle size. This enables one to achieve 3D hybrid arrays of metallic and semiconductor nanoparticles in thin films. The comprehensive studies on the thermodynamics and kinetics of the nanoparticle assemblies in supramolecular nanocomposite thin films opens up a new avenue for the fabrication of next-generation nanoparticle-based devices.

9:24AM T34.00008 Interfacial roughness of self-assembled lamellae in cross-linkable block copolymer thin films , CHUNLIN HE, MARK STOYKOVICH, CU-Boulder — Although diblock copolymers are attractive for fabricating structures with 5-50 nm dimensions, the ability of such materials to self-correct or "heal" nanoscale defects is of equal importance for future lithographic applications. Reduced interfacial roughness and enhanced dimensional control have been demonstrated to occur at the molecular-level when the block copolymers are directed to self-assemble on chemically patterned surfaces or in topographic structures. Here we demonstrate that cross-linking in self-assembled block copolymer domains can also significantly reduce interfacial roughness caused by thermal fluctuations. Lamellar-forming block copolymer/homopolymer blends, with and without cross-linkable components, were directed to self-assemble on chemically patterned substrates and processed by solvent-annealing at room temperature. The lamellae were subsequently thermally-processed or exposed to UV light to perform a cross-linking reaction in a step distinct from the self-assembly process. Spectral analysis of the interfacial roughness was compared between the cross-linkable and uncross-linkable block copolymer materials, and the cross-linked system was quantified to have lower interfacial roughness due to a tighter coupling between neighboring interfaces.

9:36AM T34.00009 Ordered Deposition of Block Copolymer Thin Films and Its Continuous Growth by Electrospray , HANQIONG HU, CHINEDUM OSUJI, Yale Univ. — Ordering of block copolymer thin films have been studied extensively using different approaches primarily as a post-deposition step. Here we show that well-ordered block copolymer thin films can be continuously deposited through electrospray. Under appropriate conditions, fine particles are generated and sub-attoliter quantities of material is delivered and equilibrated with heated substrate in the presence of solvent-mediated interface. Ordered film formation is predicated on fast thermal equilibration relative to the rate of deposition. We investigate the effects of process parameters that underpin film morphology including solvent selectivity, substrate temperature, flow rate of electrospray feed solution and wetting conditions in a couple of material systems, such as PS-b-PEO, PS-b-PMMA and PS-b-P4VP. We've demonstrated that at relative fast deposition rate ($\sim$ 5nm/min), solvent assists ordering of the film and its selectivity plays an important role in determining the film morphology as it mediates the interface preference regardless of the wetting conditions. We also observe wide temperature and flow rate windows for the film to be ordered. Cylinders were found to align with their long axes perpendicular to the film-air interface at optimal spray conditions. When the material is delivered free of solvent at relative slow deposition rate ($\sim$ 10nm/h), templated substrate or neutral wetting conditions becomes key to ordering of the film and continuity of perpendicular growth is expected under such.

9:48AM T34.00010 Process-dependent Nanostructure and Crystallinity Competition in All-Conjugated Poly(3-hexylthiophene) Block Copolymers , YEN-HAO LIN, RAFAEL VERDUZCO, Rice University, VERDUZCO LAB TEAM — The nanostructure of active layer in organic photovoltaic (OPV) is critical to charge transfer and power conversion efficiency (PCE). This study elucidates a model example of crystallinity competition and process-dependent nanostructures in various composition of an all-conjugated block copolymer, poly(3-hexylthiophene)-*b*-poly(9′,9′-dioctylfluorene) (P3HT-*b*-PF) synthesized from a combination of Grignard metathesis and Suzuki-Miyaura polycondensation. In contrast to previous studies of P3HT-based all-conjugated block copolymer where P3HT typically dominates the final morphology through crystallization. Grazing-incidence X-ray scattering (GIXS) measurements verify that thermally annealed P3HT-b-PF spun-cast films show a morphology dominated by crystallization of P3HT or PF, depending on the size of block ratios. However, all solvent annealed films show primarily an out-of-plane stacking ($q \sim 0.15n$ Å^{-1} where n =1,2,3,4,5,6,7) on the substrate and with strong (020) π-stacking parallel to substrate surface. This expanded small lamellar domain is about 4 nm which is designated to alkyl-chain stacking within block copolymer. Subsequent thermal annealing at high temperatures results in loss of the expanded spacing, indicating that the observed orientation and structure of P3HT-*b*-PF is in non-equilibrium status so that proper processing condition is important in determining final nanostructure and potentially enhanced PCE in all-polymer OPVs.

10:00AM T34.00011 Evaporation-induced ordering in solution-cast block copolymer thin films , SEAN PARADISO, KRIS DELANEY, HECTOR CENICEROS, CARLOS GARCIA-CERVERA, GLENN FREDRICKSON, UC Santa Barbara — Block copolymer thin films are currently being investigated for a wide variety of applications, ranging from separation membranes to organic photovoltaics and lithographic masks. Over the last decade or so, there has been mounting interest in using solvent casting techniques to control morphology selection in thin films either through spin coating, drop casting, or simple annealing under a mixture of solvent vapors. While these added degrees of freedom and process variables offer the promise of enhanced morphology control, they necessarily add extra dimensions and inter-dependencies between parameters that must be sorted out before this control can be effectively exercised. To this end, we have adapted a dynamical extension of Self-Consistent Field Theory to study the dynamics of ordering from a dilute copolymer solution to a dry, ordered thin film. This talk will offer a visual summary of the range in behavior available to a single copolymer + neutral solvent system in both 2D (lamella-forming) and 3D (cylinder-forming) environments. In addition, a brief analysis will be presented on the competing time scales, equilibrium, and non-equilibrium effects that appear to govern the initiation event and propagation of evaporation-induced ordering fronts.

10:12AM T34.00012 Coarse Grained Monte Carlo Simulations of Solvent Annealed Block Copolymer Thin Films , GURDAMAN KHAIRA, SU-MI HUR, JUAN DE PABLO, University of Chicago — Solvent annealing has been shown to provide an effective means for controlling the self assembly of block copolymer thin films. However, the current theoretical understanding of solvent annealing processes is limited. We have developed a particle based coarse-grained model to study the solvent annealing and the effect of process variables on the self assembled structure of block copolymer thin films. For bulk materials, our model is shown to reproduce the phase behavior reported in experiments. In thin films, our approach enables us to mimic the experimental process, while accessing the large length and time scales relevant to applications in directed self assembly. In this presentation, we will discuss the effects of solvent-polymer interactions, solvent vapor pressure and solvent evaporation rate on the morphology of ordered domains.

10:24AM T34.00013 Morphology driven spinodal decomposition of film topography in symmetric diblock copolymer thin films , ROBERT D. PETERS, Department of Physics & Astronomy and the Brockhouse Institute for Materials Research, McMaster University, Hamilton, ON, Canada, L8S 4M1, PAWEL STASIAK, MARK W. MATSEN, School of Mathematical and Physical Sciences, University of Reading, Whiteknights, Reading, UK, KARI DALNOKI-VERESS, Department of Physics & Astronomy and the Brockhouse Institute for Materials Research, McMaster University, Hamilton, ON, Canada, L8S 4M1 — At equilibrium, symmetric diblock copolymer thin films will microphase separate into lamellae oriented parallel to the substrate. If a film is not exactly commensurate, the free surface will form regions of two different film heights separated by one characteristic lamellar bilayer height. Though this equilibrium morphology has been well studied, the intermediate morphologies formed along the ordering pathway as the film transitions from a disordered melt to an equilibrated film with a terraced topography has received relatively little attention.Using atomic force microscopy we probe the topology and morphology evolution at the free surface of maximally incommensurate poly(styrene-b-methyl methacrylate) films during annealing.The film initially develops lamellae at the free surface with a perpendicular orientation, followed by the continuous growth in amplitude of fluctuations in film surface topography, indicating a spinodal process.Using self-consistent field theory we confirm that this spinodal decomposition of film topography is induced by an unstable mixed morphology intermediate state consisting of parallel lamellar domains at the substrate, and perpendicular lamellae at the free surface.

10:36AM T34.00014 Controlled Porous Nanostructure on Gold-Decorated Block Copolymer Microspheres , MINSOO KIM, KANG HEE KU, HYEONG JUN KIM, KAIST, GI-RA YI, Sungkyunkwan University, BUMJOON KIM, KAIST, GI-RA YI COLLABORATION — Hollow block copolymer microspheres (HPMs) with controlled porous nanostructures were simply prepared from gold decorated block copolymer microspheres (GPMs). First, the GPMs were fabricated by emulsifying polystyrene-*b*-poly(4-vinylpyridine) (PS-*b*-P4VP) micelle solution with gold precursors into surfactant solution. Then, the HPMs were prepared by adding cetyl trimethylammonium bromide (CTAB) into the GPMs suspension. Selective dissolution of gold precursors by CTAB resulted in the formation of porous nanostructures on the GPMs. The porous nanostructures can be controlled by molecular weight of block copolymers and the amounts of gold precursors incorporated to P4VP core in the micelle, of which both factors tuned sizes of the surface nanostructures in the HPMs. In addition, we demonstrated that increasing amounts of gold precursors resulted in increasing the pore depth. The detail pore morphology in the HPMs was investigated by SEM, AFM and cross-sectional TEM measurements.

10:48AM T34.00015 Microwave- assisted Rapid Self- Assembly of Lamellar Forming Poly (styrene-b- lactic acid) (PS-b-PLA) Block Copolymer for Fabrication of Silicon Nanowires , PARVANEH MOKARIAN-TABARI, (1) Department of Chemistry, University College Cork and Tyndall National Institute, Cork, Ireland (2) Centre for Research on Adaptive Nanostructures, CIAN CUMMINS, (1) Department of Chemistry, University College Cork and Tyndall National Institute, Cork, Ireland, SOZARAJ RASAPPA, JUSTIN D. HOLMES, MICHAEL M. MORRIS, (1) Department of Chemistry, University College Cork and Tyndall National Institute, Cork, Ireland (2) Centre for Research on Adaptive Nanostructures — Photolithography has been a fundamental process in the production of integrated circuits, but it is reaching its physical limit for generating ultra-small feature sizes. Block copolymers have a great potential as mask templates for fabricating nano features. Although ordered sub 20 nm features utilising BCPs have been achieved, lengthy annealing times (hours to days) are currently employed. Here we use microwave annealing, a new emerging technique, to achieve lateral phase separation in a lamellar forming PS-b-PLA. Having optimised the microwave conditions such as power, temperature, anneal holding time, solvents etc, a long range order line pattern was formed in less than two minutes on Si, Ge and Al substrates. The etched pattern (PLA removed by Ar/O_2 RIE) was transferred to silicon substrate resulting in 18nm Si nanowires.

Thursday, March 21, 2013 8:00AM - 11:00AM –

Session T35 DMP: HTSC: Mostly Superconductor-insulator Transition and Quantum Oscillations 343 - Herbert Fotso, Georgetown University

8:00AM T35.00001 Magnetic field driven superconductor-insulator transition in $La_{2-x}Sr_xCuO_4$

, BRIGITTE LERIDON, CNRS, UMR8213/LPEM - ESPCI ParisTech - UPMC, 10 rue Vauquelin, 75005 Paris, JOHAN VANACKEN, VICTOR MOSHCHALKOV, INPAC, KULeuven, Celestijnenlaan 200 D, B-3001 Heverlee, Belgium, BAPTISTE VIGNOLLE, CNRS/LNCMI, 143 Avenue de Rangueil, 31400 Toulouse, France, RAJNI PORWAL, RAMESH BUDHANI, NPL, CSIR, New Delhi 110012, and IIT Kanpur, Kanpur 208016, India — The magnetic field driven superconductor/insulator transition is studied in a large variety of $La_{2-x}Sr_xCuO_4$ thin films of various Sr dopings. Temperature dependence of the resistivity down to 4.2 or 1.5 K under high pulsed magnetic field (up to 57 T) is analyzed. In particular, the existence of plateaus in the resistance versus temperature curves for given values of the magnetic field is carefully investigated. For underdoped samples, these plateaus, that are observable only in a limited range of temperatures, are shown to be associated to scaling behaviour of the resistance versus magnetic field curves, evocative of the presence of a quantum critical point. A three-dimensional (H,x,T) phase diagram is proposed, taking into account the intrinsic lamellar nature of the materials by the existence of a temperature crossover from quantum-two-dimensional to three-dimensional behavior.

8:12AM T35.00002 Magnetic-field-driven superconductor-insulator transition in underdoped $La_{2-x}Sr_xCuO_4$[1]

, XIAOYAN SHI, PING V. LIN, DRAGANA POPOVIĆ, Dept. of Phys. & Natl. High Magnetic Field Lab., Florida State Univ., G. LOGVENOV, MPI-FKF & Brookhaven Natl. Lab., A. BOLLINGER, I. BOZOVIC, Brookhaven Natl. Lab., T. SASAGAWA, Tokyo Inst. of Tech. — We use magnetotransport measurements to probe the magnetic-field-driven superconductor-insulator transition in both an MBE-grown thin film ($x = 0.07$ and $T_c = 4$ K) and a single crystal ($x = 0.06$ and $T_c = 6$ K) underdoped $La_{2-x}Sr_xCuO_4$ samples in T range of 0.1–30 K and fields up to 35 T. Surprisingly, it is possible to perform scaling analysis in both low- and high-temperature regions, where two different scaling exponents and scaling functions are obtained. These results and a detailed analysis of the temperature dependence of the resistivity suggest that a possible intermediate state exists between the superconducting state at zero field and the insulating state at high fields. This intermediate state may be related to the existence of a large region with superconducting fluctuations in (T, H) parameter space. Furthermore, the insulating state in high fields shares similar 2D variable-range hopping behavior as non-superconducting samples with lower doping.

8:24AM T35.00003 Penetration Depth Measurements of Electrostatically Doped High T_c Superconductors[1]

, JOE KINNEY, University of Minnesota, JAVIER GARCIA-BARRIOCANAL, Universidad Complutense de Madrid, BOYI YANG, ALLEN GOLDMAN, University of Minnesota — The application of field effect transistor concepts to electrostatically dope strongly correlated electron systems has been the focus of intense research [C. H. Ahn et al., Rev. Mod. Phys. 78, 1185 (2006)]. In recent years, we have used this technique to successfully examine magneto-transport properties of $YBa_2Cu_3O_{7-x}$ and $La_2CuO_{4+\delta}$ [X. Leng et al., Phys. Rev. Lett. 107, 027001 (2011)] [X. Leng, et al., Phys. Rev. Lett. 108, 060074 (2012)] [J. Garcia-Barriocanal et al arXiv:1210.7458]. In the work presented here we extend this to include measurements of the penetration depth using a two coil mutual inductance technique. This probe provides an additional window into the underlying properties of the superconducting state as it is electrostatically tuned across the superconductor-insulator phase transition.

8:36AM T35.00004 Comparison of Resistivity and Superfluid Response in Thin CaYBCO Films[1]

, STANLEY STEERS, ADAM AHMED, THOMAS LEMBERGER, The Ohio State University — Resistivity drops to negligible levels at temperatures significantly above those at which superfluid density appears for two-dimensional samples of Ca-doped YBCO. The temperature offset between the disappearance of resistivity and the onset of superfluid density, as measured by low-frequency mutual inductance experiments, depends upon T_c as measured by the appearance of superfluid density, getting bigger as T_c decreases and reaching a maximum as superfluid response disappears near the superconductor-insulator transition while still exhibiting a resistive transition. The offset vanishes at the maximum T_c.

8:48AM T35.00005 Multiple Quantum Phase Transitions in a two-dimensional superconductor

, NICOLAS BERGEAL, J. BISCARAS, S. HURAND, C. FEUILLET-PALMA, J. LESUEUR, ESPCI ParisTech-CNRS, R.C. BUDHANI, A. RASTOGI, IIT Kanpur, S. CAPRARA, M. GRILLI, Universita di Roma "La Sapienza" — We studied the magnetic field driven Quantum Phase Transition (QPT) in electrostatically gated superconducting LaTiO3/SrTiO3 interfaces [1,2]. Through finite size scaling analysis, we showed that it belongs to the (2+1)D XY model universality class. The system can be described as a disordered array of superconducting islands coupled by a two dimensional electron gas (2DEG). Depending on the 2DEG conductance tuned by the gate voltage, the QPT is single (corresponding to the long range phase coherence in the whole array) or double (one related to local phase coherence, the other one to the array). By retrieving the coherence length critical exponent ν, we showed that the QPT can be "clean" or "dirty" according to the Harris criteria, depending on whether the phase coherence length is smaller or larger than the island size [2]. The overall behaviour is well described by a model of coupled superconducting puddles in the framework of the fermionic scenario of 2D superconducting QPT [3].

9:00AM T35.00006 Pseudogap and zero-bias anomaly due to fluctuation suppression of quasiparticle tunneling[1]

, ANDREAS GLATZ, Argonne National Laboratory and Northern Illinois University, ANDREY VARLAMOV, CNR-SPIN, University of Rome, Italy, VALERII VINOKUR, Argonne National Laboratory — In this talk, I will present our study of the effect of superconducting fluctuations on the tunnel current-voltage characteristics of disordered superconducting films placed in a perpendicular magnetic field in the whole field-temperature phase diagram outside the superconducting region. This tunnel-current is experimentally accessible by STM measurements and therefore directly relevant for the interpretation of experimental results, in particular the pseudogap state. We derived a complete expression for the tunneling current (and the tunneling conductance) for arbitrary fields and temperatures and discovered an important nonlinear contribution, which appears due to dynamic fluctuation modes and results in the formation of a strong zero-bias anomaly on the scale at small voltages. At large voltages, fluctuations form a pseudogap maximum.

9:12AM T35.00007 Understanding the superconducting state in SrTiO3 interfaces: Possible two-band superconductivity , J.T. HARALDSEN, Los Alamos National Laboratory, R.M. FERNANDES, Los Alamos National Laboratory and Columbia University, P. WOELFLE, University of Karlsruhe, A.V. BALATASKY, Los Alamos National Laboratory and NORDITA — We examine the possibility of multi-band superconductivity in $SrTiO_3$ interfaces by investigating the effects of a two-dimensional two-band model. In undoped $SrTiO_3$, one of the bands is occupied, while the upper band is empty. As the chemical potential shifts, due to doping by negative charge carriers or application of an electric field, the second band becomes occupied, giving rise to a strongenhancement of the transition temperature and a sharp feature in the gap functions, which is manifested in the local density of states spectrum. By comparing our results with tunneling experiments in Nb-doped $SrTiO_3$, we find that intra-band pairing dominates over inter-band pairing, unlikeother known multi-band superconductors. Given the similar transition temperature and band structure of $LaAlO_3/SrTiO_3$ heterostructures, we speculate that thesuperconductivity observed in $SrTiO_3$ interfaces may be similar in nature to that of bulk $SrTiO_3$,involving multiple bands with distinct electronic occupations.

9:24AM T35.00008 Disordered bosons in one dimension: from weak to strong randomness criticality[1] , FAWAZ HRAHSHEH, THOMAS VOJTA, Missouri University of Science and Technology — We investigate the superfluid-insulator quantum phase transition of one-dimensional bosons with off-diagonal disorder by means of large-scale Monte-Carlo simulations. For weak disorder, we find the transition to be in the same universality class as the superfluid-Mott insulator transition of the clean system. The nature of the transition changes for stronger disorder. Beyond a critical disorder strength, we find nonuniversal, disorder-dependent critical behavior. We compare our results to recent perturbative and strong-disorder renormalization group predictions. We also discuss experimental implication as well as extensions of our results to other systems.

9:36AM T35.00009 Scaling disparity between superconducting and pseudogap states in very low-T_c Bi-2201 cuprates , VLADIMIR KRASNOV, Department of Physics, Stockholm University, AlbaNova University Center, SE-10691 Stockholm, Sweden — Interplay between the normal state pseudogap (PG) and superconductivity in cuprates remains a controversial issue. In this respect it is instructive to compare homologous series of cuprates with a different number of CuO planes. They have similar Fermi energies, resistivities and anisotropies, but exhibit a large variation of T_c. Since thermal fluctuations vanish at $T = 0$, they are less significant at $T \sim T_c$ in low-T_c cuprates. In this work we compare intrinsic tunneling characteristics of double-layer Bi-2212 (T_c=95 K) and single-layer Bi-2201 with a very low $T_c \sim 4$ K. We observe that: (i) The PG characteristics of both cuprates are identical despite a large difference in T_c. Thus, the PG phenomenon is universal irrespective of superconducting properties. (ii) In the low-T_c Bi-2201, all superconducting characteristics scale down with T_c in the same proportion as for high-T_c cuprates. This leads to a dramatic disparity between superconducting ($T_c = 4$ K, energy gap < 1 meV, $H_{c2} \sim 10$ T) and pseudogap (onset $T^* = 90 - 300$ K, PG energy ~ 40 meV, PG suppression field $H^* \sim 250$ T) characteristics in the studied low-Tc cuprate. The observed disparity of the superconducting and pseudogap scales clearly reveals their different origins.

9:48AM T35.00010 Visualizing antinodal pair decoherence in a high T_c cuprate , YANG HE, Harvard Univeristy, YI YIN, Zhejiang University, ANJAN SOUMYANARAYANAN, MARTIN ZECH, TESS WILLIAMS, Harvard Univeristy, MICHAEL BOYER, Clark University, W. D. WISE, KAMALESH CHATTERJEE, Massachusetts Institute of Technology, TAKESHI KONDO, Ames Lab, TSUNEHIRO TAKEUCHI, HIROSHI IKUTA, Nagoya University, ERIC HUDSON, Penn State University, JENNIFER HOFFMAN, Harvard Univeristy — The relationship between the pseudogap phase and superconductivity in the cuprate superconductors remains mysterious. We use Fourier transform scanning tunneling spectroscopy to study the pseudogap in the cuprate superconductor $Bi_{2-x}Pb_xSr_2CuO_{6+\delta}$. We discover a new type of quasiparticle interference in the antinodal regions, presumed to be dominated by the pseudogap. Magnetic field induced spectral weight transfer shows that the pseudogap suppresses superconducting coherence but does not affect d-wave pairing at the antinode.

10:00AM T35.00011 Fermi surface geometry of $YBa_2Cu_4O_8$[1] , NEIL HARRISON, Los Alamos National Labs., SUCHITRA SEBASTIAN, GILBERT LONZARICH, Cambridge University UK, FEDOR BALAKIREV, Los Alamos National Labs., S. SABOK, B. DABROWSKI, Argonne National Labs. — Since the discovery of magnetic quantum oscillations in the underdoped high T_c cuprates, one lingering question concerns whether the Fermi surfaces of $YBa_2Cu_4O_8$ and $YBa_2Cu_3O_{6.5}$ are similar or different. To pursue this question we utilize magnetic fields extending to 100 tesla that are now available at the National High Magnetic Field Laboratory. We find magnetic fields of this strength are essential for determining the geometry of the Fermi surface of $YBa_2Cu_4O_8$ in angle-resolved measurements. Our findings enable us to clarify the origin of the Fermi surface pockets in $YBa_2Cu_4O_8$ and $YBa_2Cu_3O_{6.5}$.

[1]We acknowledge DOE BES funding "Science at 100 tesla"

10:12AM T35.00012 Quantum oscillations in $YBa_2Cu_3O_{6+\delta}$ from period-8 d-density wave order[1] , ZHIQIANG WANG, JONGHYOUN EUN, SUDIP CHAKRAVARTY, University of California, Los Angeles — We consider quantum oscillation experiments in $YBa_2Cu_3O_{6+\delta}$ from the perspective of an incommensurate Fermi surface reconstruction using an exact transfer matrix method and the Pichard-Landauer formula for the conductivity. The specific density wave order responsible for reconstruction is a period-8 d-density wave in which the current density is unidirectionally modulated, which is also naturally accompanied by a period-4 charge order, consistent with recent nuclear magnetic resonance experiments. This scenario leads to a natural explanation as to why only oscillations from a single electron pocket of a frequency of about 500 T is observed, and a hole pocket of roughly twice the frequency as dictated by the two-fold commensurate order and the Luttinger sum rule is not observed. In contrast period-8 d-density wave leads to a hole pocket of roughly half the frequency of the electron pocket. The observation of this slower frequency will require higher, but not unrealistic, magnetic fields than those commonly employed. There is already some suggestion of the slower frequency in a measurement in fields as high as 85 T.

10:24AM T35.00013 Quantum oscillations, phase fluctuations and competing orders in a d-wave vortex liquid[1] , SHIZHONG ZHANG, Department of Physics, The University of Hong Kong, SUMILAN BANERJEE, MOHIT RANDERIA, Department of Physics, The Ohio State University — The observation of quantum oscillations in underdoped cuprates has generated intense debate about the nature of the field-induced resistive state and its relation to the "normal" state of high T_c superconductors. Quantum oscillations suggest a Fermi liquid state at high magnetic fields H and low temperatures, in contrast to the high-temperature, zero-field pseudogap state. Motivated by recent high-field heat capacity measurements, we present a theoretical analysis [1] of the electronic excitations in a vortex-liquid state, with pairing correlations that are short-ranged in both space and time. We show that this permits us to reconcile the various seemingly contradictory experimental observations. We show that phase fluctuations that give insight into the pseudogap in the high temperature classical regime also lead to a large and singular (square root of H) density of states (DOS) suppression at low temperatures. In addition, the DOS shows quantum oscillations with a period determined by a Fermi surface reconstructed by a possible competing order parameter in the vortex liquid. We also comment on possible implications of our results for thermal conductivity and c-axis optical conductivity in such a state. [1] S. Banerjee, S. Zhang, and M. Randeria, arXiv:1210.2466.

10:36AM T35.00014 Multi-orbital Fermi surfaces in metallic layered nickelate , MASAKI UCHIDA, Cornell University, K. ISHIZAKA, M. SAKANO, R. ARITA, S. SHIN, Y. TOKURA, University of Tokyo, P. HANSMANN, A. TOSCHI, K. HELD, Vienna University of Technology, X. YANG, Nanyang Technological University, J. MIYAWAKI, Y. TAKATA, M. OURA, A. CHAINANI, RIKEN SPring-8 Center, Y. KANEKO, RIKEN CMRG and CERG, O. ANDERSEN, Max-Planck-Institut — The three-dimensional Fermi surface structure of hole-doped metallic layered nickelate $Eu_{2-x}Sr_xNiO_4$ ($x = 1.1$), an important counterpart to the isostructural superconducting cuprate $La_{2-x}Sr_xCuO_4$, is investigated by energy-dependent soft-x-ray angle-resolved photoemission spectroscopy. In addition to a large cylindrical hole Fermi surface analogous to the cuprates, we observe a Gamma-centered $3z^2 - r^2$-derived small electron pocket. This finding demonstrates that in the layered nickelate the $3z^2 - r^2$ band resides close to the $x^2 - y^2$ one in energy. The resultant multi-band feature with varying orbital character as revealed may strongly work against the emergence of the high-temperature superconductivity.

10:48AM T35.00015 Possible evidence of electron pockets beyond optimal doping , JAMES STOREY, MacDiarmid Institute for Advanced Materials and Nanotechnology, JEFFERY TALLON, Industrial Research Limited — In recent years the possibility of electron pockets in the Fermi surface of underdoped high-T_c cuprates has become of considerable interest, spawned by quantum oscillations, Hall effect and thermopower measurements of strongly underdoped samples where stripe order is known to be present. Direct proof of their existence and location in momentum space would put significant constraints on the origin of the mysterious pseudogap and possibly the origin of superconductivity in these materials. In contrast, several Fermi surface reconstruction models predict electron pockets appearing with the onset of the pseudogap in the slightly overdoped regime before disappearing at lower dopings. We have calculated the thermopower from the resonating valence bond spin liquid model developed by Yang, Rice and Zhang, and a spin density wave model. Comparing the results with experimental data, we find evidence for electron pockets in the slightly overdoped regime.

Thursday, March 21, 2013 8:00AM - 11:00AM –

Session T36 DCMP: Ruthenates, Iridates, and p-wave Superconductivity

344 - Harald Jeschke, Universitat Frankfurt

8:00AM T36.00001 Theoretical study of novel superconductivity in Ir oxides with large spin-orbit coupling , HIROSHI WATANABE, TOMONORI SHIRAKAWA, SEIJI YUNOKI, RIKEN, CREST, COMPUTATIONAL CONDENSED MATTER PHYSICS LABORATORY, RIKEN ASI TEAM, CREST, JAPAN SCIENCE AND TECHNOLOGY AGENCY TEAM, COMPUTATIONAL MATERIALS SCIENCE RESEARCH TEAM, RIKEN AICS TEAM — Recently, the $5d$ transition metal oxide Sr_2IrO_4 has attracted much attention. In this material, three t_{2g} orbitals of Ir atoms are hybridized with each other by the spin-orbit coupling of $5d$ electrons. As a result of the quantum entanglement of spin and orbital degrees of freedom, an anomalous $J_{\rm eff}$=$|L - S| = 1/2$ state is realized, which causes interesting properties. To clarify the properties of this system, we have studied the ground state of the three-orbital Hubbard model with a spin-orbit coupling term using variational Monte Carlo method. Here, we study the electronic states when carriers are doped in this three-orbital system and discuss the possibility of superconductivity. The obtained ground state phase diagram reveals the antiferromagnetic state, stable around the electron density $n = 5$, is destabilized by carrier doping and the ground state turns to be superconducting under a certain condition. Similar to the high-T_c cuprates, a large asymmetry between electron doping ($n > 5$) and hole doping ($n < 5$) is also observed. Due to the large spin-orbit coupling, the spin is no longer a good quantum number. Instead, the pseudospins form a Cooper pair and a $d_{x^2-y^2}$-wave "pseudospin-singlet" superconductivity is realized.

8:12AM T36.00002 Observation of strong spin-orbital entanglement in Sr_2RuO_4 , ANDREA DAMASCELLI, C.N. VEENSTRA, Z.-H. ZHU, B. LUDBROOK, A. NICOLAOU, M. RAICHLE, I.S. ELFIMOV, Quantum Matter Institute, UBC, Canada, M.W. HAVERKORT, MPI, Stuttgart, Germany, B. SLOMSKI, G. LANDOLT, J.H. DIL, PSI, Switzerland, S. KITTAKA, Y. MAENO, Kyoto University, Japan — Sr_2RuO_4 stands out even amongst the unconventional superconductors. The relativistic spin orbit interaction causes a momentum dependent entanglement of orbital and spin quantum numbers. Using circularly polarized light combined with spin and angle resolved photoemission spectroscopy, we directly observe this entanglement in good agreement with relativistic band-structure calculations. The presence of spin-charge entangled states inherently has a profound influence on the description of the superconducting state. These entangled states are not well described by a product of an orbital and spin wave-function, thereby blurring the distinction between triplet and singlet states.

8:24AM T36.00003 Dislocations and the enhancement of superconductivity in odd-parity superconductor Sr_2RuO_4[1] , YIQUN YING, NEAL STALEY, XINXIN CAI, YING LIU, Department of Physics and Materials Research Institute, The Pennsylvania State University, University Park, Pennsylvania 16802, USA, YAN XIN, National High Magnetic Field Laboratory, Florida State University, Tallahassee, Florida 32306, USA, KAI SUN, Department of Physics, University of Michigan, Ann Arbor, Michigan 48109, USA, DAVID FOBES, TIJIANG LIU, ZHIQIANG MAO, Department of Physics, Tulane University, New Orleans, Louisiana 70118, USA — We investigated the 3-K phase of spin-triplet, odd-parity superconductor Sr_2RuO_4, which was usually referred to the eutectic phase of Ru and Sr_2RuO_4 featuring Ru islands embedded in single crystalline Sr_2RuO_4. Using single-crystal flakes of Sr_2RuO_4 of mesoscopic size free of Ru, we observed an enhancement of superconducting transition temperature (T_c) up to about twice of that of the bulk when lattice dislocations were found in the samples, a surprising result given the well known sensitivity of superconductivity in Sr_2RuO_4 to disorder. We formulated a phenomenological theory taking into account the crystalline as well as the pairing symmetry of Sr_2RuO_4 and showed that the enhanced T_c can be attributed to symmetry reduction in superconductors with a two-component order parameter. We found that our experimental results are consistent with the theoretical predictions.

[1]The work is supported by DOE under Grant No. DE-FG02-04ER4615

8:36AM T36.00004 Numerical study of the stability of half-quantum vortices in superconducting Sr_2RuO_4[1] , KEVIN ROBERTS, RAFFI BUDAKIAN, MICHAEL STONE, University of Illinois at Urbana-Champaign — We numerically solve the coupled Landau-Ginzburg-Maxwell equations for a model of a $p_x + ip_y$ superconductor in which whole or half-quanta of flux threads through a hole. We recover the pattern of stable and unstable regions for the half-flux observed in the experiments of Jang et al [1].

[1] J. Jang, et al, Observation of half-height magnetization steps in Sr_2RuO_4, *Science*, **331**, 186-188(2011)

[1]NSF Grant No. DMR 09-03291

8:48AM T36.00005 Unravelling the Surface-to-Bulk Progression of the Electronic Structure in Sr_2RuO_4 , CHRISTIAN N. VEENSTRA, Z.-H. ZHU, B. LUDBROOK, M. CAPSONI, G. LEVY, A. NICOLAOU, J.A. ROSEN, R. COMIN, I.S. ELFIMOV, A. DAMASCELLI, Quantum Matter Institute, UBC, Canada, S. KITTAKA, Y. MAENO, Kyoto University, Japan — We revisit the normal-state electronic structure of Sr_2RuO_4 by angle-resolved photoemission spectroscopy (ARPES) with improved data quality, as well as ab-initio band structure calculations in the local-density approximation (LDA) with the inclusion of spin-orbit coupling (SO). We find that the current model of a single surface layer $(\sqrt{2} \times \sqrt{2})$R45° reconstruction does not explain all detected features. The observed depth-dependent signal degradation, together with the close quantitative agreement with LDA+SO slab calculations based on the surface crystal structure as determined by low-energy electron diffraction (LEED), reveal that – at a minimum – the subsurface layer also undergoes a similar although weaker reconstruction. This model accounts for all features – a key step in understanding the electronic structure - and indicates a surface-to-bulk progression of the electronic states driven by structural instabilities, with no evidence for other phases stemming from either topological bulk properties or the interplay between SO and the broken symmetry of the surface.

9:00AM T36.00006 Quantifying covalency and metallicity in pyrochlore ruthenates undergoing metal-insulator transitions , ASHISH CHAINANI, RIKEN Harima Institute, AYAKO YAMAMOTO, RIKEN Advanced Science Institute, MASAHARU MATSUNAMI, RITSUKO EGUCHI, MUNETAKA TAGUCHI, YASUTAKA TAKATA, RIKEN Harima Institute, HIDENORI TAKAGI, RIKEN Advanced Science Institute, SHIK SHIN, YOSHINORI NISHINO, MAKINA YABASHI, KENJI KENJI TAMASAKU, TETSUYA ISHIKAWA, RIKEN Harima Institute — We use bulk-sensitive hard x-ray photoelectron spectroscopy to investigate the electronic structure of the cubic pyrochlore ruthenates $Tl_2Ru_2O_7$ and $Hg_2Ru_2O_7$, which show first-order temperature(T)-dependent metal-insulator transitions(MITs). Ru 3d core-level spectroscopy shows drastic changes as a function of T. The metallic-origin features in core-level spectra get quenched upon gap formation in valence band spectra. The results establish temperature-driven Mott-Hubbard MITs in three-dimensional ruthenates and reveals three energy scales : (a) $4d$-electronic changes occur on the largest (∼eV) energy scale, (b) the band gap energies/charge gaps (E_g ∼160-200 meV) are intermediate, and (c) the lowest energy scale corresponds to the transition temperature T_{MIT}(∼10 meV), which is also the spin gap energy of $Tl_2Ru_2O_7$ and the magnetic-ordering temperature of $Hg_2Ru_2O_7$. The results identify and quantify the role of covalency and metallicity in the pyrochlore ruthenates undergoing T-dependent metal-insulator transitions.

9:12AM T36.00007 Weak-coupling analysis of quasiparticle excitations in strontium ruthenate , JOHN DEISZ, TIM KIDD, Department of Physics, University of Northern Iowa — We report FLEX calculations for the quasiparticle properties of pure and electron-doped strontium ruthenate. Through self-consistent calculations of energy- and band-dependent linewidths and effective masses, the specific heat coefficient and superconducting T_c, we assess the effectiveness of this weak coupling approach for consistently describing the electron-electron correlations in this material. We also analyze the impact of the momentum dependence of the electron self-energy in describing the significant correlation effects observed in strontium ruthenate.

9:24AM T36.00008 Theory of edge currents in Sr_2RuO_4: effects of topology and gap anisotropy[1] , SAMUEL LEDERER, SRINIVAS RAGHU, Stanford University — Substantial experimental evidence suggests that Sr_2RuO_4 is a chiral p-wave superconductor. Depending on bandstructure, such a system may exhibit topologically protected edge modes, and in general would exhibit intrinsic edge currents. The latter, however, have not been observed in sensitive scanning probe measurements. A possible resolution to this apparent contradiction has been offered by Raghu et al.[1]. They show that, in weak coupling, superconductivity is dominant not on the 2D γ band as commonly believed, but on the quasi-1D α and β bands, leading to a topologically trivial state, presumably with suppressed currents. They also show that the favored order parameter has sharp gap minima on the Fermi surface. We present calculations of edge currents incorporating these features using two different methods: self-consistent Bogoliubov-de Gennes equations, and Ginsburg-Landau theory. We find that, contrary to expectation, the existence and character of topological edge modes have no effect on edge currents. Multiband effects and gap anistropy yield quantitative reductions, but order 1 edge currents are a generic consequence of chiral p-wave superconductivity at low temperature in Sr_2RuO_4.

9:36AM T36.00009 Superconductivity in Weyl Semimetals , VIVEK AJI, HUAZHOU WEI, University of California Riverside, SUNG-PO CHAO, NTHU Taiwan — Weyl fermions are linearly dispersing massless particles in three dimensions. They are chiral in that the projection of their spin along their momenta is a conserved quantum number. Interest in these particles in the condensed matter context was piqued by the possibility of their emergence in the low energy sector of Pyrochlore Iridates. Since then a number of other systems have been suggested that also support such excitations. We discuss the nature of the superconducting phases that arise for chemical potential at the Weyl nodes. Since the density of states vanishes a finite coupling strength is needed to nucleate these phases. Among the possibilities are the finite momentum pairing state (FFLO) and the conventional BCS state.

9:48AM T36.00010 Quantum quench in a p+ip superfluid: non-equilibrium topological gapless state , MATTHEW FOSTER, Rice University, MAXIM DZERO, Kent State University, VICTOR GURARIE, University of Colorado at Boulder, EMIL YUZBASHYAN, Rutgers University — Ground state "topological protection" has emerged as a main theme in quantum condensed matter physics. A key question is the robustness of physical properties including topological quantum numbers to perturbations, such as disorder or non-equilibrium driving. In this work we investigate the dynamics of a p+ip superfluid following a zero temperature quantum quench. The model describes a 2D topological superconductor with a non-trivial (trivial) BCS (BEC) phase. We work with the full interacting BCS Hamiltonian, which we solve exactly in the thermodynamic limit using classical integrability. The non-equilibrium phase diagram is obtained for generic quenches. A large region of the phase diagram describes strong to weak-pairing quenches wherein the order parameter vanishes in the long-time limit, due to pair fluctuations. Despite this, we find that the topological winding number survives for quenches in this regime, leading to the prediction of a gapless topological state. We speculate on potential realizations, including a proximity effect quench on the surface of 3D topological insulator.

10:00AM T36.00011 Phases in two dimensional $p_x + ip_y$ superconducting systems with interactions beyond nearest-neighbor[1] , ANTONIO RUSSO, SUDIP CHAKRAVARTY, University of California, Los Angeles — A $p_x + ip_y$ superconducting system with longer range hopping and pairing terms is considered. Chern numbers are calculated numerically, and in a simple, visual way by considering weak superconductor order parameter which is still in the same topological phase. Using nearest, second nearest, and third nearest hoppings and pairings, we find Chern numbers 0 through 4, including 3 which, unlike the other Chern numbers, must be thought of in terms of combinations of different range interactions. These Chern numbers are interpreted as phases, with different properties, in particular, the number of edge states created when a cut is introduces. We also explore the effect of introducing magentic flux (in the extreme type-II limit) through flux tubes (which are vortices in the 2D system). In particular, we look at the effect of varying distances between these vortices on the lowest excitation energies of the system.

10:12AM T36.00012 Intra-valley Spin-triplet p+ip Superconducting Pairing in Lightly Doped Graphene[1]

, JIANHUI ZHOU, Carnegie Mellon University, TAO QIN, International School for Advanced Studies, Italy, JUNREN SHI, Peking University, China — We analyze various possible superconducting pairing states and their relative stabilities in lightly doped graphene. We show that, when inter-sublattice electron-electron attractive interaction dominates and Fermi level is close to Dirac points, the system will favor intra-valley spin-triplet $p + ip$ pairing state. Based on the novel pairing state, we further propose a scheme for doing topological quantum computation in graphene by engineering local strain fields and external magnetic fields.

10:24AM T36.00013 Edge currents in multiband chiral p-wave superconductors[1]

, WEN HUANG, McMaster University, CATHERINE KALLIN, McMaster University and Canadian Institute for Advanced Research, EDWARD TAYLOR, McMaster University — The superconducting phase of Sr_2RuO_4 is believed to be a time-reversal symmetry breaking state with spontaneous supercurrents at the edge or domain walls of the sample. Yet Scanning SQUID and related probes have so far failed to detect any signature of such edge currents. Recent theoretical work suggests that the active superconducting bands in Sr_2RuO_4 are the two quasi-1D bands associated primarily with the d_{xz} and d_{yz} orbitals of Ru^{4+}. This contrasts with the more conventional picture in which chiral p-wave superconductivity is primarily a single-band effect, with the γ band being the active superconducting band. Based on Bogoliubov-de-Gennes calculations for tight-binding models, we study the implications of two-band chiral p-wave order on the edge current. The two-band model includes inter-orbital hopping and spin-orbit coupling. In general, the two-band model predicts a net edge current that is at least about an order of magnitude smaller than that from the one-band model. In particular, comparable magnitudes of inter-orbital hopping and spin-orbit coupling lead to substantial reduction of edge current. Also presented are finite temperature calcuations involving all three bands.

10:36AM T36.00014 Low-lying electronic structure and possible intrinsic gap control in J = 1/2 Mott insulating perovskite iridate $Sr_3Ir_2O_7$[1]

, CHANG LIU, SU-YANG XU, NASSER ALIDOUST, MADHAB NEUPANE, M. ZAHID HASAN, Joseph Henry Laboratory and Department of Physics, Princeton University, Princeton, New Jersey 08544, USA, TAY-RONG CHANG, HORNG-TAY JENG, Department of Physics, National Tsing Hua University, Hsinchu 30013, Taiwan, HSIN LIN, ROBERT MARKIEWICZ, ARUN BANSIL, Department of Physics, Northeastern University, Boston, Massachusetts 02115, USA, CHETAN DHITAL, SOVIT KHADKA, YOSHINORI OKADA, VIDYA MADHAVAN, STEPHEN WILSON, Department of Physics, Boston College, Chestnut Hill, Massachusetts 02467, USA — Using angle resolved photoemission spectroscopy, the ground state of perovskite iridate $Sr_3Ir_2O_7$ is found to be in close vicinity to a metal-to-insulator transition. Photoemission data reveal two bands extending up to surprisingly small binding energies around the Brillouin zone corner X, followed by a van Hove-like flat portion at the top of the valence bands. One of these bands form a saddle point while the other shows apparent spectral weight suppression along the the in-plane antiferromagnetic vector direction (Γ-Σ), signaling a possible electronic response to the additional long range order. The energy scale of the Mott insulating gap shows considerable sample-to-sample variation, which points to possible intrinsic control of low temperature resistivity by apical oxygen deficiency - a process suggested by transport experiments and, importantly, similar to the doping process of the cuprates that gives rise to high temperature superconductivity.

10:48AM T36.00015 Orbital angular momentum textures in perovskite oxide materials

, WONSIG JUNG, WONSIG KYUNG, YOONYOUNG KOH, Institute of Physics and Applied Physics, Yonsei University, Seoul 120-749, Korea, YOSHIYUKI YOSHIDA, National Institute of Advanced Industrial Science and Technology, Tsukuba 305-8568, Japan, Y.J. CHOI, Institute of Physics and Applied Physics, Yonsei University, Seoul 120-749, Korea, MASASHI ARITA, KENYA SHIMADA, Hiroshima Synchrotron Radiation Center, Hiroshima University, Higashi-Hiroshima, Hiroshima 739-0046, Japan, C. KIM, Institute of Physics and Applied Physics, Yonsei University, Seoul 120-749, Korea — We measured electronic structures of perovskite oxide materials Sr_2MO_4 (M=Rh, Ru, Ir) with angle-resolved photoemission spectroscopy using circular dichroism (CD) method to investigate orbital characters. We observe large CD which shows complicated orbital structures of Sr_2MO_4. CD signal comes from obital angular momentum induced from inversion symmetry breaking at cleaved surfaces. We compare results from various orbitals of 3-, 4- and 5-d.

Session T37 DMP DCOMP: Focus Session: Fe-based Superconductors: Spectroscopic Probes

345/346 - Ruihua He, Boston College

8:00AM T37.00001 ARPES studies of underdoped (Ba,K)Fe2As2 iron-based superconductors

, MING YI, Stanford Institute for Materials and Energy Sciences, Stanford University, DONGHUI LU, SSRL, SLAC National Accelerator Laboratory, YONGTAO CUI, Stanford Institute for Materials and Energy Sciences, Stanford University, MAKOTO HASHIMOTO, SSRL, SLAC National Accelerator Laboratory, BRIAN MORITZ, Stanford Institute for Materials and Energy Sciences, Stanford University, HAIHU WEN, Nanjing University, THOMAS DEVEREAUX, ZHI-XUN SHEN, Stanford Institute for Materials and Energy Sciences, Stanford University — Phase competition is a topic of high interest in the high temperature superconductivity (HTSC) field as HTSC occurs in proximity to competing phases in both cuprates and iron pnictides. In the pnictides, phase competition to superconductivity takes form in both a tetragonal to orthorhombic structural transition and a collinear spin-density wave transition. In this talk, I will present our ARPES studies of underdoped (Ba,K)Fe2As2, in which distinct spectroscopic signatures associated with all three transitions (structural, SDW, and superconductivity) are observed. The interaction of these three order parameters will be discussed.

8:12AM T37.00002 Orbital Dependent Band Renormalization in $Fe_{1+y}Te_{1-x}Se_x$

, ZHONGKAI LIU, MING YI, Stanford University, DONGHUI LU, SLAC National Accelerator Laboratory, RUIHUA HE, Boston College, JIN HU, Tulane University, MAKOTO HASHIMOTO, SLAC National Accelerator Laboratory, SUNG-KWAN MO, Lawrence Berkeley National Laboratory, TOM DEVEREAUX, SLAC National Accelerator Laboratory, ZHIQIANG MAO, Tulane University, ZAHID HUSSAIN, Lawrence Berkeley National Laboratory, ZHI-XUN SHEN, Stanford University, STANFORD UNIVERSITY TEAM, SLAC NATIONAL ACCELERATOR LABORATORY TEAM, LAWRENCE BERKELEY NATIONAL LABORATORY TEAM, BOSTON COLLEGE COLLABORATION, TULANE UNIVERSITY COLLABORATION — One of the important factors in understanding the Fe-based superconductor is their multi-orbital nature. In this study we present ARPES results on the iron chalcogenide $Fe_{1+y}Te_{1-x}Se_x$ (known as the 11 system), the structurally simplest member in Fe-based superconductors. Our result shows that as Te substitutes Se, the Fe dxy orbital has seen a significant increase in the band renormalization while the other orbitals stay unchanged. Our discovery indicates that different orbitals in Fe-based superconductors have different correlation levels, evolve distinctively with crystal parameters and may play different roles in the emergence of superconductivity.

8:24AM T37.00003 Iron Selenide thin films studied with ARPES , FELIX SCHMITT, R.G. MOORE, SLAC Nat'l Accelerator Laboratory, J.J. LEE, Stanford University, W. LI, M. HASHIMOTO, Z.-X. SHEN, SLAC Nat'l Accelerator Laboratory — Dimensionality and length scales play an important role in material properties and their phases. Recently, superconductivity was discovered in a thin film of Iron Selenide just 1 unit cell thick. We have grown Iron Selenide films of different thickness with molecular beam epitaxy and measured these films in situ with angle-resolved photoemission spectroscopy (ARPES). The ability to measure films in situ eliminates the need for Se capping and provides high quality ARPES data. We will discuss these results, among them what changes can be observed in the band structure between films of different thicknesses.

8:36AM T37.00004 Laser ARPES study of optimally doped $FeTe_{0.6}Se_{0.4}$, KOZO OKAZAKI, YOSHIAKI ITO, YUICHI OTA, YOSHINORI KOTANI, Institute for Solid State Physics, University of Tokyo, TAKAHIRO SHIMOJIMA, Department of Applied Physics, University of Tokyo, TAKAYUKI KISS, Graduate School of Engineering Science, Osaka University, SHUNTARO WATANABE, Research Institute for Science and Technology, Tokyo University of Science, CHUANGTIAN CHEN, Beijing Center for Crystal R&D, Chinese Academy of Science, SEIJI NIITAKA, TETSUO HANAGURI, HIDENORI TAKAGI, RIKEN Advanced Science Institute, ASHISH CHAINANI, RIKEN SPring-8 Center, SHIK SHIN, Institute for Solid State Physics, University of Tokyo — We have studied the electronic structure of optimally doped $FeTe_{0.6}Se_{0.4}$ (T_c = 14.5 K), using laser-excited angle-resolved photoemission spectroscopy (laser ARPES). We observe sharp superconducting coherence peaks in the hole band slightly shifted from the Γ point at $T = 2.5$ K. In contrast to earlier ARPES studies but consistent with thermodynamic results, the momentum dependence shows a $\cos(4\varphi)$ modulation of the SC-gap anisotropy. In addition, we found an electron band at the Γ point, lying just above E_F. This electron band also shows a sharp superconducting coherence peak with gap formation below T_c. The hole and electron bands show significantly different values of superconducting gap Δ and Fermi energy ϵ_F , while the associated Bogoliubov quasiparticle dispersions get merged. The results suggest composite superconductivity in an iron-based superconductor, consisting of strong-coupling Bose-Einstein condensation (BEC) in the electron band while the hole band superconductivity lies closer to the weak-coupling Bardeen-Cooper-Schrieffer (BCS) limit.

8:48AM T37.00005 Thermodynamic signatures of quantum criticality in $BaFe_2(As_{(1-x)}P_x)_2$, P. WALMSLEY, C. PUTZKE, L. MALONE, University of Bristol, S. KASAHARA, T. SHIBAUCHI, Y. MATSUDA, Kyoto University, A. CARRINGTON, University of Bristol — Iron based superconductors are one of many classes of material where superconductivity occurs in the vicinity of a magnetic quantum critical point (QCP). The degree to which the QCP drives or otherwise influences the high temperature superconductivity is however still a matter of debate. In this context it is useful to determine experimentally, the degree to which the quasiparticle effective mass diverges at the QCP and how this is reflected in various physical properties. Here we will report measurements of the specific heat γ and the de Haas-van Alphen effect which quantify these effects. Far from the QCP the enhancement of the mass as measured by γ, dHvA and the magnetic penetration depth λ are all consistent. However, very close to the QCP significant differences are found which likely result from finite temperature and/or multi-band effects.

9:00AM T37.00006 Anisotropic superconducting gap distribution in the presence of spin density wave in Co-doped NaFeAs[1] , QINGQIN GE, ZIRONG YE, MIN XU, YAN ZHANG, JUAN JIANG, BINPING XIE, Fudan University, YU SONG, CHENGLIN ZHANG, The University of Tennessee, PENGCHENG DAI, The University of Tennessee and Chinese Academy of Sciences, DONGLAI FENG, Fudan University — The coexisting regime of spin density wave (SDW) and superconductivity in the iron pnictides represents a novel ground state. We have performed high resolution angle-resolved photoemission measurements on $NaFe_{1-x}Co_xAs$ ($x = 0.0175$) in this regime and revealed its distinctive electronic structure, which provides some microscopic understandings of its behavior. The SDW signature and the superconducting gap are observed on the same bands, illustrating the intrinsic nature of the coexistence. However, because the SDW and superconductivity are manifested in different parts of the band structure, their competition is non-exclusive. Particularly, we found that the gap distribution is anisotropic and nodeless, in contrast to the isotropic superconducting gap observed in an SDW-free $NaFe_{1-x}Co_xAs$ (x=0.045), which puts strong constraints on theory.

[1]This work is supported in part by the National Science Foundation of China and National Basic Research Program of China (973 Program) under the grant Nos. 2012CB921400, 2011CB921802, 2011CBA00112.

9:12AM T37.00007 Evidence of competing s and d-wave pairing channels in iron-based superconductors , FLORIAN KRETZSCHMAR, BERNHARD MUSCHLER, THOMAS BÖHM, ANDREAS BAUM, RUDI HACKL, Walther Meissner Institute, Bavarian Academy of Sciences and Humanities, 85748 Garching, Germany, HAI-HU WEN, National Laboratory of Solid State Microstructures and Department of Physics, Nanjing University, Nanjing 210093, China, VLADIMIR TSURKAN, JOACHIM DEISENHOFER, ALOIS LOIDL, Experimental Physics 5, Center for Electronic Correlations and Magnetism, Institute of Physics, University of Augsburg, 86159 Augsburg, Germany — Superconductivity is determined by the interactions that drive Cooper pairing. However, experimental access to the pairing potential $V_{\mathbf{k},\mathbf{k}'}$ becomes increasingly complicated upon going from conventional metals to complex systems such as the cuprates, some heavy fermion compounds or the iron-based superconductors. We show that electronic Raman scattering affords a window into the essential properties of $V_{\mathbf{k},\mathbf{k}'}$ of iron-based superconductors. In $Ba_{0.6}K_{0.4}Fe_2As_2$ we observe band dependent energy gaps along with excitonic Bardasis-Schrieffer modes characterizing, respectively, the dominant and subdominant pairing channel. The $d_{x^2-y^2}$ symmetry of all excitons allows us to identify the subdominant channel to originate from the interaction between the electron bands. Consequently, the dominant channel driving superconductivity results from the interaction between the electron and hole bands and has the full lattice symmetry. The results in $Rb_{0.8}Fe_{1.6}Se_2$ along with earlier ones in $Ba(Fe_{0.939}Co_{0.061})_2As_2$ highlight the influence of the Fermi surface topology on the pairing interactions.

9:24AM T37.00008 A de Haas-van Alphen study of the Fermi surface of LiFeP[1] , C. PUTZKE, A. CARRINGTON, I. GUILLAMON, University of Bristol, A. COLDEA, M. WATSON, University of Oxford, D. VIGNOLLES, D. LEBOEUF, LNCMI, Toulouse, A. MCCOLLAM, HFML Nijmegen, I.I. MAZIN, Naval Research Laboratory, Washington, S. KASAHARA, T. TERASHIMA, T. SHIBAUCHI, Y. MATSUDA, Kyoto University — We report de Haas-van Alphen (dHvA) measurements of the Fermi surface of the 111 iron based superconductor LiFeP with $T_c \approx 5$ K. Comparison of our experimental results to density functional theory band-structure calculations show good agreement. As in other iron-based superconductors we find that the electron and hole bands are quasi-nested. The effective masses, determined individually for the different Fermi surface sheets (orbits) generally show significant enhancement. The smallest hole pocket sheet is an exception to this and shows a very small enhancement. This difference in the many body interaction suggest a suppression of electron-hole scattering for this sheet which may result from its different orbital character. This might be the reason why LiFeP has nodes in its superconducting gap whereas its sister compound LiFeAs does not.

[1]This work is supported by EPSRC (UK), EuroMagNET II under the EU Contract No. 228043, and KAKENHI from JSPS. A portion of this work was performed at the National High Magnetic Field Laboratory, which is supported by National Science Foundation Cooperative

9:36AM T37.00009 Optical conductivity and Raman scattering of iron superconductors , MARIA J. CALDERON, BELEN VALENZUELA, GLADYS LEON, ELENA BASCONES, Instituto de Ciencia de Materiales de Madrid, Consejo Superior de Investigaciones Cientificas, ICMM-CSIC (Spain) — Raman and optical conductivity are very useful techniques to analyze the electronic properties of strongly correlated electron systems. Optical conductivity experiments have provided very valuable information on the reorganization of the spectral weight and the opening of gaps in many materials. In cuprates the use of different polarizations in Raman scattering has allowed to disentangle the different physics of the nodal and the antinodal electronic states. The multiband character of iron superconductors complicates the analysis of their Raman and optical conductivity spectra. We discuss how to analyze the optical conductivity and Raman spectrum of multi-orbital systems using velocity and Raman vertices in a similar way Raman vertices were used to disentangle nodal and antinodal regions in cuprates. We apply this method to iron superconductors in the magnetic and non-magnetic state, including the orbital differentiation regime. We also show that the Drude weight anisotropy in the magnetic state is sensitive to small changes in the lattice structure.

9:48AM T37.00010 Non-Resonant Raman Scattering in an effective single orbital model of Iron based superconductors , CHANDAN SETTY, JIANGPING HU, Purdue University — We investigate non-resonant Raman response of the 122-type Iron pnictide and chalcogenide superconductors using the framework of an effective single orbital model that was recently proposed to capture the essential electronic and magnetic properties of Iron based superconductors. We compute the momentum matrix elements and the resulting Raman vertices exactly (within the tight- binding approximation) for different polarization geometries of the hole/electron doped 122 pnictide and electron overdoped 122 chalcogenide. Our calculations, performed with a simple coskxcosky form for the gap, find good agreement with data reported by Kretzschmar et. al and Muschler et.al

10:00AM T37.00011 Nonlinear optical study of surface electrons on $Ba(Fe_{1-x}Co_x)_2As_2$, CHANGMIN LEE, FAHAD MAHMOOD, JAMES MCIVER, MIT, G.F. CHEN, J.L. LUO, N.L. WANG, Institute of Physics, Chinese Academy of Sciences, NUH GEDIK, MIT — We report second harmonic generation (SHG) measurements on single crystals of $Ba(Fe_{1-x}Co_x)_2As_2$. SHG from $Ba(Fe_{1-x}Co_x)_2As_2$ is dominated by surface contributions due to the broken inversion symmetry at the surface. By varying the polarization of incident ultrafast laser pulses, we demonstrate that SHG reveals the tetragonal crystal structure of $Ba(Fe_{1-x}Co_x)_2As_2$ at ambient conditions. We will discuss prospects of using SHG as a probe of the surface electrons, the in-plane anisotropy, and the dichotomy between surface and bulk superconductivity in iron-based superconductors.

10:12AM T37.00012 Infrared Faraday measurements on $Ba(Fe_{1-x}Co_x)_2As_2$ superconductors , ALOK MUKHERJEE, CHASE T. ELLIS, M. MURAT ARIK, JOHN CERNE, Dept. of Physics, University at Buffalo, The State University of New York, Buffalo, NY, HIKARU SATO, HIDENORI HIRAMATSU, HIDEO HOSONO, Materials and Structures Laboratory, Tokyo Institute of Technology, Tokyo, Japan — We report infrared Faraday measurements on electron-doped $Ba(Fe_{1-x}Co_x)_2As_2$ superconducting films, which are grown by pulsed laser deposition. The complex Faraday angle θ_F is proportional to the difference of the sample's response to right and left circularly polarized light, making it a highly sensitive tool to probe electronic structure, electron-electron correlations, and magnetic ordering. We measure θ_F for normal and superconducting states in the 110-1400 meV range at temperatures down to 10K and magnetic fields up to 7T. This work is supported by NSF-DMR1006078.

10:24AM T37.00013 Shallow pockets and very strong coupling superconductivity in $FeSe_xTe_{1-x}$, AMIT KANIGEL, Physics Department, Technion-Israel Institute of Technology, Haifa 32000, Israel — The celebrated BCS theory has been successful in explaining metallic superconductors, yet many believe that it must be modified to deal with the newer high temperature superconductors. A possible extension is provided by the BCS-BEC theory, describing a smooth evolution from a system of weakly-interacting pairs to a BEC of molecules of strongly-bounded fermions. Despite its appeal, spectroscopic evidence for the BCS-BEC crossover was never observed in solids. Here we report electronic structure measurements in $FeSe_xTe_{1-x}$ showing that these materials are in the BCS-BEC crossover regime. Above T_c we find multiple bands with remarkably small values for the Fermi energy ε_F. Yet, in the superconducting state, the gap Δ is comparable to ε_F. The ratio $\Delta/\varepsilon_F \approx 0.5$ is much larger than found in any previously studied superconductor, resulting in an anomalous dispersion of the coherence peak very similar to that found in cold Fermi gas experiments, in agreement with the predictions of the BCS-BEC crossover theory.

Thursday, March 21, 2013 8:00AM - 11:00AM –

Session T38 DMP GERA FIAP/DCOMP: Renewable Fuels 347 - Peter Zapol, Argonne National Laboratory

8:00AM T38.00001 First Principles Study for Proton Transport and Diffusion Behavior in Hydrous Hexagonal WO3 , CHI-PING LIU, FEI ZHOU, VIDVUDS OZOLINS, Materials Sciences Engineering, UCLA, QPAM TEAM — Proton transport is of great importance in biological species and energy storage and conversion systems. Previous studies have shown fast proton conduction in liquids and polymers but seldom in inorganic materials. In this work, first principles density functional theory (DFT) reveals that the formation of hydronium and water chains inside the hexagonal channels plays the key roles for the anomalously fast proton transport, by following modified Grotthuss mechanism. Our DFT study shows the detailed microscopic proton diffusion mechanism along the channel in hydrous WO3 with 50% water composition, which is proper for water chain formation. The water chain in the channel serves as a possible diffusion media for hydronium (H3O+). With the continuous formation and cleavage of hydrogen bonds in the channel, the hydronium diffuses by hydrogen bonds exchange between water molecules. This mechanism is very similar with Grotthuss relay mechanism for proton transport in liquid. The possible proton diffusion were studied for hydronium is either far away from the water chain bond defect or next to H2O defect at the end of water chain. The diffusion barriers for both conditions are around 150 meV to 200 meV, and water defects reorganization in the chain is the rate-limited step for proton diffusion. These small diffusion barriers could explain the fast 1-D proton transport in hydrous WO3 channel. Further studies about fast proton transport in other inorganic materials could be an important topic in not only biochemistry but also clean energy applications like fuel cell applications.

8:12AM T38.00002 Density functional theory study of triple phase boundaries of solid oxide fuel cells , ANGELO BONGIORNO, MASSIMO MALAGOLI, Georgia Institute of Technology — In this work, we present a modeling study of triple phase boundary regions of solid oxide fuel cells (SOFCs) based on a density functional theory approach. In particular, we consider the following solid oxide electrolytes, yttrium-doped barium zirconate (BZY) and yttrium-doped barium cerate (BCY), and the following metallic catalysts, palladium, nickel, and copper. Thus, we use density functional theory calculations to construct the energy landscape for a hydrogen species crossing triple phase boundaries based on the materials above. This study focuses, in particular, on the role played by the metal-oxide interface in controlling the proton transfer from the catalyst to the electrolyte component of triple phase boundaries. Our results are discussed in light of the hydrogen spilling process occurring at triple phase boundaries based on nickel and yttria-stabilized zirconia.

8:24AM T38.00003 Electronic and Optical Properties of Tungsten Oxide and Copper Tungstate for Water Oxidation[1]

, YUAN PING, Department of Chemistry, University of California, Davis, YAN LI, Computational Science Center, Brookhaven National Laboratory, JAMES C. HILL, Department of Chemistry, Purdue University, KYOUNG-SHIN CHOI, Department of Chemistry,University of Wisconsin-Madison,Madison, GIULIA GALLI, Department of Chemistry and department of Physics, University of California, Davis — We report first principles calculations of the electronic and optical properties of tungsten oxide clathrates [1,2] and copper tungstate solid solutions, which are considered to be promising materials for oxygen evolution in photo-electrochemical cells. In particular, we considered WO3 intercalated with rare gas atoms and small closed shell molecules, and CuW xMo1-xO4 solid solutions. Although relatively efficient photoanode materials, WO3 and CuWO4 are poor light absorbers, due to their band gap above 2.3 eV. In the case of WO3, we found that intercalation with Xe, N2 and CO may lead to a substantial decrease of the optical gap, mostly due to structural modifications of the oxide lattice. Our results for dinitrogen provided an interpretation of recent experiments [1]. In the case of CuWO4, we observed a 0.5-0.6 eV decrease of the gap when doping with Mo (50% to 75% concentration), in agreement with recent measurements. The gap decrease originates from a downward shift of the conduction band minimum. A detailed discussion of how intercalation and doping affect the electronic properties of tungsten oxide and copper tungstates will be presented. [1] Q. Mi et al, J. Am. Chem. Soc. 2012, DOI: 10.1021/ja3067622 [2] Y. Ping et al, Chem. Mat. 2012, DOI:10.1021/cm3032225

8:36AM T38.00004 Surface Hydroxyl Groups of Anodized TiO2 Nanotube for More Efficient Photoenergy Conversion[1]

, CHIUNG-YUAN LIN, JING-NENG YAO, National Chiao Tung University, Department of Electronics Engineering — Experimentalists can apply a hydrothermal crystallization method to the anodized TiO_2 nanotube-array. Structural transformation of the nanotubes is easily induced if the tubes are treated by hydrothermal solutions of different pH levels. Such transformation under the treatment of basic solutions, if not damaging the nanotubes, will in turn strongly enhance the anchoring of the carboxyls to the tube surface, and consequently improve the performance of the dye-sensitized solar cells with the TiO2 nanotubes being the photoelectrodes. In this work, we perform density-functional calculations of such nanotubes with different H^+ and OH^- attaching to the tube surface. The results provide a great deal of additional details of the tube morphology that is not accessible by the experiments, and reproduce the stability observed experimentally under the attachment of different functional groups.

8:48AM T38.00005 Theoretical and Experimental Co K-edge XAS of Layered Cobalt Oxides Catalysts[1]

, MICHAL BAJDICH, Joint Center for Artificial Photosynthesis, LBL, CA, DANIEL FRIEBEL, SLAC National Accelerator Laboratory, CA, JCAP, BOON S. YEO, Dept. of Chem. and Bio. Eng., UCB, CA, MARY LOUIE, JCAP, UCB, DANIEL J. MILLER, SLAC, HERNAN S. CASALONGUE, SLAC , JCAP, FELIX MBUGA, Stanford U., CA, TSU-CHIEN WENG, DENNIS NORDLUND, DIMOSTHENES SOKARAS, SLAC, ALEXIS T. BELL, JCAP, UCB, ANDERS NILSSON, SLAC, JCAP — The efficient water oxidation for fuel production from sunlight, with the use of earth-abundant catalysts, is of high importance to photo-fuel cell research. Recent experimental investigations of Co-oxide based catalysts under active conditions of water oxidation show evidence for layered cobalt-oxide structures with possible cation intercalation from electrolyte. To gain insight into our experimentally measured Co K-edge x-ray absorption spectra of Co-oxide anodes compared to spectra of powder standards such as CoOOH, $Co(OH)_2$ and Co_3O_4, we perform theoretical investigations of these spectra. We employ density functional theory plus U (DFT+U) calculations of K-edge x-ray absorption spectra using core-hole approach which has been shown to accurately capture the pre-edge features of similar α-$LiCoO_2$ [1]. We consider β-CoOOH, α-$KCoO_2$, γ-$K_{0.5}CoO_2$ structures as possible candidates.

9:00AM T38.00006 Accelerated discovery of materials for solar fuel cells at JCAP[1]

, SLOBODAN MITROVIC, EARL CORNELL, JOHN GREGOIRE, JOEL HABER, KEVIN KAN, SEAN LIN, XIAONAO LIU, MARTIN MARCIN, EDWARD SOEDARMADJI, SANTOSH SURAM, CHENGXIANG XIANG, JIAN JIN, Joint Center for Artificial Photosynthesis, California Institute of Technology — High-Throughput Experimentation group at the Joint Center for Artificial Photosynthesis has a formidable mission: provide accelerated discovery of new photon absorbers and heterogeneous (photo)catalysts for solar fuel cells at the rate far beyond anything attempted in material science to date. The HTE pipeline includes material synthesis, screening and characterization. Within the first year of operations, our fabrication capabilities have risen to 100,000 samples per day using combinatorial inkjet-printing. Such high rate of sample production is setting daunting requirements on screening methods. We are developing and testing methods for fast bandgap measurements, using colorimetry and uv-vis spectroscopy. Material thickness and roughness is determined by confocal chromatic spectroscopy. Catalytic activity is screen through a massively parallel bubble screen and a fast scanning droplet (photo)electrochemical cell. Concurrently, we are developing protocols for high-throughput determination of phase and structure (XRD), surface composition and chemistry (XPS), surface area measurement, etc. on the characterization side of the pipeline.

9:12AM T38.00007 First-Principles Study of Photochemical Activation of CO_2 by Ti-based Oxides

, HAIYING HE, PETER ZAPOL, LARRY CURTISS, Materials Science Division, Argonne National Laboratory, Argonne, IL 60439 — The photochemical conversion of CO_2 and H_2O into energy-bearing hydrocarbon fuels provides an attractive way of mitigating the green-house gas CO_2 and utilizing solar energy as a sustainable energy source. However, due to the high reduction potential and chemical inertness of CO_2 molecules, the conversion rate of CO_2 is impractically low. The activation of CO_2 is critical in facilitating further reactions. By carrying out first-principles calculations of reaction pathways from CO_2 to CO_2^- anions on Ti-based oxides including zeolites in the presence of photoexcited electrons, we have studied the initial step of CO_2 activation via 1e transfer. It is shown that the CO_2 reactivity of these surfaces strongly depends on the crystal structure, surface orientation, and presence of defects. This opens a new dimension in surface structure modification to enhance the CO_2 adsorption and reduction on semiconductor surfaces.

9:24AM T38.00008 Computational Modeling of Photocatalysts for CO2 Conversion Applications

, DE NYAGO TAFEN, National Energy Technology Lab - URS Corp., 1450 Queen Ave. SW, Albany, OR 97321, CHRISTOPHER MATRANGA, National Energy Technology Lab, 626 Cochrans Mill Road, Pittsburgh, PA 15236 — To make photocatalytic conversion approaches efficient, economically practical, and industrially scalable, catalysts capable of utilizing visible and near infrared photons need to be developed. Recently, a series of CdSe and PbS quantum dot-sensitized TiO_2 heterostructures have been synthesized, characterized, and tested for reduction of CO_2 under visible light [1]. Following these experiments, we use density functional theory to model these heterostructured catalysts and investigate their CO_2 catalytic activity. In particular, we study the nature of the heterostructure interface, charge transport/electron transfer, active sites and the electronic structures of these materials. The results will be presented and compared to experiments. The improvement of our understanding of the properties of these materials will aid not only the development of more robust, visible light active photocatalysts for carbon management applications, but also the development of quantum dot-sensitized semiconductor solar cells with high efficiencies in solar-to-electrical energy conversion.

9:36AM T38.00009 Predicting a new quaternary metal oxide and the study of its structural, electronic, and optical properties by density functional theory

, PRANAB SARKER, MUHAMMAD N. HUDA, Department of Physics, University of Texas at Arlington — Our recent theoretical and computational research work of a new quaternary metal oxide $CuBiW_2O_8$ and its electronic properties will be presented. Our density functional theory (DFT) total energy calculation using mineral database of relevant oxides determines the crystal structure of $CuBiW_2O_8$ to be a triclinic structure, which agrees with the experimental result. $CuBiW_2O_8$ has a calculated band gap of 1.43 eV suitable for solar-to-hydrogen conversion technology through photoelectrochemical (PEC) approach. The band structure calculation reveals that $CuBiW_2O_8$ possesses indirect band gap. In addition to this, partial DOS plot calculation demonstrates how Cu 3d plays a major role in band gap reduction and why favorable p-d electron transition is likely although band edges are mostly dominated by d orbital electrons. Finally, we find this material is optically anisotropic.

9:48AM T38.00010 Comparison Between Crystalline and Amorphous Surfaces of Transition Metal Oxide Water Oxidation Catalysts: a Theoretical Perspective[1]

, JONATHAN H. SKONE, Department of Chemistry, University of California, Davis, GIULIA GALLI, Department of Chemistry and Department of Physics, University of California, Davis — Amorphous films of transition-metal oxide water oxidation catalysts (WOCs) often show an enhanced catalytic activity compared to their crystalline counterparts [1-4]. In particular, in the case of cobalt-oxide based WOCs the observed similarity in their electrochemical properties and catalytic activity, under oxidative conditions, has been correlated with the formation of similar amorphous surface morphologies, suggesting the presence of a common, catalytically active amorphous structural motif [3,4]. We present ab initio calculations of cobalt oxide based material surfaces and we compare the electronic properties of crystalline and amorphous surfaces, with the aim of identifying differences related to their different catalytic activity.

10:00AM T38.00011 Ab initio study on microscopic properties of III-V/water interfaces for photoelectrochemical hydrogen production

, BRANDON WOOD, WOON IH CHOI, ERIC SCHWEGLER, TADASHI OGITSU, LLNL — Photoelectrodes made of III-V semiconductors are known to exhibit very high solar-to-hydrogen conversion efficiency (from solar energy to chemical energy as H_2 bond); however, photocorrosion of the electrode in electrolyte solution remains an issue. Based on ab-initio molecular dynamics simulations, we study the structure, stability, and chemical activity of GaP/InP(001) semiconductor electrodes in contact with water. We will show how surface oxygen and hydroxyl change the electronic and chemical properties of water at the interface, leading to the formation of a strong hydrogen-bond network where fast surface hydrogen transport seems to be realized. Implications from our findings will be discussed in detail at the presentation. This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52- 07NA27344.

10:12AM T38.00012 Decarboxylation of furfural on Pd(111): Ab initio molecular dynamics simulations[1]

, WENHUA XUE, HONGLI DANG, DARWIN SHIELDS, YINGDI LIU, The University of Tulsa, FRIEDERIKE JENTOFT, DANIEL RESASCO, The University of Oklahoma, SANWU WANG, The University of Tulsa — Furfural conversion over metal catalysts plays an important role in the studies of biomass-derived feedstocks. We report *ab initio* molecular dynamics simulations for the decarboxylation process of furfural on the palladium surface at finite temperatures. We observed and analyzed the atomic-scale dynamics of furfural on the Pd(111) surface and the fluctuations of the bondlengths between the atoms in furfural. We found that the dominant bonding structure is the parallel structure in which the furfural plane, while slightly distorted, is parallel to the Pd surface. Analysis of the bondlength fluctuations indicates that the C-H bond is the aldehyde group of a furfural molecule is likely to be broken first, while the C=O bond has a tendency to be isolated as CO. Our results show that the reaction of decarbonylation dominates, consistent with the experimental measurements.

[1]Supported by DOE (DE-SC0004600). Simulations and calculations were performed on XSEDE's and NERSC's supercomputers.

10:24AM T38.00013 Ab initio study on the dynamics of furfural at the liquid-solid interfaces[1]

, HONGLI DANG, WENHUA XUE, DARWIN SHIELDS, YINGDI LIU, The University of Tulsa, FRIEDERIKE JENTOFT, DANIEL RESASCO, University of Oklahoma, SANWU WANG, The University of Tulsa — Catalytic biomass conversion sometimes occurs at the liquid-solid interfaces. We report *ab initio* molecular dynamics simulations at finite temperatures for the catalytic reactions involving furfural at the water-Pd and water-Cu interfaces. We found that, during the dynamic process, the furan ring of furfural prefers to be parallel to the Pd surface and the aldehyde group tends to be away from the Pd surface. On the other hand, at the water-Cu(111) interface, furfural prefers to be tilted to the Cu surface while the aldehyde group is bonded to the surface. In both cases, interaction of liquid water and furfural is identified. The difference of dynamic process of furfural at the two interfaces suggests different catalytic reaction mechanisms for the conversion of furfural, consistent with the experimental investigations.

[1]Supported by DOE (DE-SC0004600). Simulations and calculations were performed on XSED's and NERSC's supercomputers

10:36AM T38.00014 Analysis of Enzymatic Degradation of Cellulose Microfibrils using Quantitative Surface Plasmon Resonance Imaging , KYLE REITER, ADAM RAEGEN, SCOTT ALLEN, AMANDA QUIRK, ANTHONY CLARKE, JACEK LIPKOWSKI, JOHN DUTCHER, University of Guelph — Cellulose is the largest component of biomass on Earth and, as a result, is a significant potential energy source. The production of cellulosic ethanol as a fuel source requires conversion of cellulose fibers into fermentable sugars. Increasing our understanding of the action of cellulose enzymes (cellulases) on cellulose microfibrils is an important step in developing more efficient industrial processes for the production of cellulosic ethanol. We have used a custom designed Surface Plasmon Resonance imaging (SPRi) device to study the action of cellulases from the *Hypocrea jecorina* secretome on bacterial cellulose microfibrils. This has allowed us to determine the rates of action and extent of degradation of cellulose microfibrils on exposure to both individual cellulases and combinations of different classes of cellulases, which has allowed us to investigate synergistic interactions between the cellulases.

10:48AM T38.00015 Advances in Surface Plasmon Resonance Imaging enable quantitative measurement of laterally heterogeneous coatings of nanoscale thickness , ADAM RAEGEN, KYLE REITER, University of Guelph Department of Physics, ANTHONY CLARKE, University of Guelph Department of Molecular and Cellular Biology, JACEK LIPKOWSKI, University of Guelph Department of Chemistry and Biochemistry, JOHN DUTCHER, University of Guelph Department of Physics — The Surface Plasmon Resonance (SPR) phenomenon is routinely exploited to qualitatively probe changes to the optical properties of nanoscale coatings on thin metallic surfaces, for use in probes and sensors. Unfortunately, extracting truly quantitative information is usually limited to a select few cases – uniform absorption/desorption of small biomolecules and films, in which a continuous "slab" model is a good approximation. We present advancements in the SPR technique that expand the number of cases for which the technique can provide meaningful results. Use of a custom, angle-scanning SPR imaging system, together with a refined data analysis method, allow for quantitative kinetic measurements of laterally heterogeneous systems. We first demonstrate the directionally heterogeneous nature of the SPR phenomenon using a directionally ordered sample, then show how this allows for the calculation of the average coverage of a heterogeneous sample. Finally, the degradation of cellulose microfibrils and bundles of microfibrils due to the action of cellulolytic enzymes will be presented as an excellent example of the capabilities of the SPR imaging system.

Session T39 DCMP: Metals Alloys and Metallic Structures 348 - David Parker, Oak Ridge National Laboratory

8:00AM T39.00001 Spin-lattice coupling in BCC iron , JUNQI YIN, MARKUS EISENBACH, DON NICHOLSON, Oak Ridge National Laboratory — For empirical iron potentials, the magnetic contribution is usually implicitly considered, and the spin-lattice coupling is simply neglected. From first principle calculations, we proposed a Heisenberg type of exchange for BCC iron that couples the spin and lattice degrees of freedom. The parameterization is based on quantities already employed in embedded-atom potentials. Therefore, the model is a natural augmentation of the existing iron potentials, and is applicable to molecular dynamics simulations. Our model built on Dudarev potential can reproduce iron's specific heat from the Curie temperature down to about 400K, and the estimate of the spin-lattice contribution indicates that it is significant near the transition. We applied our model to studying a $< 111 >$ screw dislocation in BCC iron, and found evidences that the dislocation core has a local transition temperature different from the bulk one. Work is sponsored by the U.S. DOE, Office of Basic Energy Sciences, Materials Sciences and Engineering Division (M. E., D. M. N.), and by Office of Advanced Scientific Computing Research (J. Y.). This research used resources of the Oak Ridge Leadership Computing Facility at the ORNL, which is supported by the Office of Science of the U.S. DOE under Contract No. DE-AC05-00OR22725.

8:12AM T39.00002 The modification of core structure and Peierls barrier of $1/2< 111 >$ screw dislocation in bcc Fe in presence of Cr solute atoms , GERMAN SAMOLYUK, YURI OSETSKY, ROGER STOLLER, DON NICHOLSON, GEORGE MALCOLM STOCKS, Oak Ridge National Laboratory — Mobility of screw dislocations controls low temperature plasticity in bcc metals including ferritic alloys. Density functional theory (DFT) is an effective tool in providing parameter-free information on the energetic and magnetic properties of defects including screw dislocations. We summarize DFT calculations on atomic properties of $1/2< 111 >$ screw dislocations in Fe-Cr system. The periodic quadrupole approach was applied to model the core dislocation structure, core interaction with Cr solute atoms and to estimate their effect on Peierls stress and barrier. The binding energy of Cr impurity atoms with a screw dislocation and its effect on the dislocation core structure are discussed and the importance of magnetism in the effects of Cr on screw dislocation mobility is demonstrated. This work was supported by the Center for Defect Physics, an Energy Frontier Research Center funded by the US Department of Energy, Office of Science, Office of Basic Energy Sciences.

8:24AM T39.00003 Formation Energies and Electronic Properties of Vanadium Carbides Found in High Strength Steel Alloys , KRISTA LIMMER, JULIA MEDVEDEVA, Missouri University of Science and Technology — Carbide formation and stabilization in steels is of great interest owing to its effect on the microstructure and properties of the Fe-based alloys. The appearance of carbides with different metal/C ratios strongly depends on the carbon concentration, alloy composition as well as the heat treatment. Strong carbide-forming elements such as Ti, V, and Nb have been used in microalloyed steels; with VC showing an increased solubility in the iron matrix as compared with TiC and NbC. This allows for dissolution of the VC into the steel during heating and fine precipitation during cooling. In addition to VC, the primary vanadium carbide with cubic structure, a wide range of non-stoichiometric compositions VCy with y varying from 0.72 to 0.88, has been observed. This range includes two ordered compounds, V8C7 and V6C5. In this study, first-principles density functional theory (DFT) is employed to examine the stability of the binary carbides by calculating their formation energies. We compare the local structures (atomic coordination, bond distances and angles) and the density of states in optimized geometries of the carbides. Further, the effect of alloying additions, such as niobium and titanium, on the carbide stabilization is investigated. We determine the energetically preferable substitutional atom location in each carbide and study the impurity distribution as well as its role in the carbide formation energy and electronic structure.

8:36AM T39.00004 A computational study of high entropy alloys , YANG WANG, Pittsburgh Supercomputing Center, Carnegie Mellon University, MICHAEL GAO, National Energy Technology Laboratory, MICHAEL WIDOM, Department of Physics, Carnegie Mellon University, JEFF HAWK, National Energy Technology Laboratory — As a new class of advanced materials, high-entropy alloys (HEAs) exhibit a wide variety of excellent materials properties, including high strength, reasonable ductility with appreciable work-hardening, corrosion and oxidation resistance, wear resistance, and outstanding diffusion-barrier performance, especially at elevated and high temperatures. In this talk, we will explain our computational approach to the study of HEAs that employs the Korringa-Kohn-Rostoker coherent potential approximation (KKR-CPA) method. The KKR-CPA method uses Green's function technique within the framework of multiple scattering theory and is uniquely designed for the theoretical investigation of random alloys from the first principles. The application of the KKR-CPA method will be discussed as it pertains to the study of structural and mechanical properties of HEAs. In particular, computational results will be presented for $Al_xCoCrCuFeNi$ (x = 0, 0.3, 0.5, 0.8, 1.0, 1.3, 2.0, 2.8, and 3.0), and these results will be compared with experimental information from the literature.

8:48AM T39.00005 First-principles Calculations on the Stability of High Entropy Alloy[1] , M. CLAUDIA TROPAREVSKY, Department of Materials Science and Engineering, the University of Tennessee, PAUL KENT, JAMES R. MORRIS, G. MALCOLM STOCKS, Materials Science and Technology Division, Oak Ridge National Laboratory — High entropy alloys (HEAs) constitute a new class of materials comprised of four or more elements in equimolar or near equimolar ratio, which tend to form simple solid solutions, mainly FCC or BCC. Despite extensive attention due to their potential applications as structural materials little is known about why these compounds are stable with respect to phase separation. We study the structural and thermodynamic properties of HEAs composed of Cr, Pd, Mn, Fe, Co, and Ni using density functional theory. We investigate the minimum energy structures of several alloys as well as the competing intermetallic compounds in an effort to assess the stability of the HEAs with respect to phase separation. We find that the enthalpy of formation of the alloys is frequently insufficient to explain their stability and that the entropy of mixing can in some cases account for the stability of these compounds. However, for some five-component alloys this does not appear to be sufficient. In this presentation, we will discuss the degree to which the entropy of mixing can stabilize these alloys.

[1]Work Supported by DOE-BES Materials Sciences and Engineering Division

9:00AM T39.00006 Non-local first-principles calculations in Cu-Au, Ag-Au and Cu-Ag , YONG-SHENG ZHANG, Department of Materials Science & Engineering, Northwestern University, GEORG KRESSE, Faculty of Physics, Center for Computational Materials Science, Universitat Wien, CHRISTOPHER WOLVERTON, Department of Materials Science & Engineering, Northwestern University — Cu-Au is the prototypical alloy system used to exemplify ordering and compound formation, and serves as a testbed for all new alloy theory methods. Yet, despite the importance of this system, conventional density functional theory (DFT) calculations with semi-local approximations (GGA) have two dramatic failures in describing the energies of this system: 1) DFT predicts incorrect ordered ground states for Au-rich compositions, and 2) DFT formation energies of the observed Cu_3Au and CuAu compounds are nearly a factor of two smaller in magnitude than experimental values. Here, we show how modern extensions of DFT based on non-local interactions can rectify both of these failures. Using the self-consistent non-local HSE06 functional, the formation energies of Cu_3Au and CuAu are -71 and -91 meV/atom, respectively, which are in excellent agreement with the experimental measurements. The semi-local GGA predicted $CuAu_2$ is not a stable phase in the HSE06 calculations, and $CuAu_3$ with the $L1_2$ structure is theoretically predicted as a stable phase. For Ag-Au, both semi-local GGA and non-local HSE06 functionals give similar formation energies. The electronic structures are used to explain these different phenomena in Cu-Au and Ag-Au.

9:12AM T39.00007 Stress dependent defect energetics in Tungsten from first-principles , MD. HOSSAIN, California Institute of Technology, JAIME MARIAN, Lawrence Livermore National Laboratory — Tungsten (W) is an important material for high temperature applications due to its refractory nature. However, like all transition metals from the VI-A group, W suffers from low-temperature brittleness and lack of ductility, which poses serious questions for its use as a structural material. Tungsten's mechanical properties can be enhanced by alloying with elements with d-electrons, such as Re, which has resulted in successful commercial alloys. In this work, we obtain the formation and migration energetics of Re solute atoms in terms of their interaction with vacancies and dislocations. To explore the influence of external stresses on Re transport properties, we examine the role of hydrostatic and shear deformation on the vacancy formation energy (VFE) and migration energy barrier (Em) in BCC W from first-principles calculations by developing a pseudopotential with 6s2, 6p0, 5d4, and 5f0 electronic states for the valence electrons. We find that under hydrostatic deformation, increase or decrease of vacancy formation energy depends on the type of deformation – tensile or compressive, while for shear deformation it decreases irrespective of the magnitude of applied deformation. On the other hand, migration energy barrier always decreases under hydrostatic deformation, but shows path-length dependent behavior under shear deformation. This talk will discuss the underlying principles and possible routes for enhancing mechanical strength from a physics perspective.

9:24AM T39.00008 ABSTRACT WITHDRAWN –

9:36AM T39.00009 First Principles Calculation of Elastic Properties of Early-Late Transition Metal Alloys , WILLIAM HUHN, MICHAEL WIDOM, Carnegie Mellon University — Amorphous metals are of practical interest in applications requiring high strength materials. We choose to examine the elastic properties of crystalline phases to understand the elastic properties of amorphous solids. In this talk, we discuss our work using first principles methods to calculate elastic properties for crystalline alloys in various chemical families containing transition metals, specifically early (Ta,W) and late (Fe,Co,Rh,Ni,Cu,Zn) due to their good glass forming ability, as well as select borides. Certain Laves phases, which are known to have local chemical ordering similar to amorphous solids, are focused on. We analyze trends in the elastic properties of chemical families based on computed enthalpies of formation, elastic properties of pure elemental phases, and electronic and structural information. In particular, we use effective medium theories and enthalpies of formation to predict trends in bulk moduli. This information can be used to predict future candidate systems for high-strength amorphous metals.

9:48AM T39.00010 Structural transformations in the physical mixture of Pd and Cu nanoparticles , VINEETHA MUKUNDAN, Purdue University, JUN YIN, CHUAN-JIAN ZHONG, SUNY, Binghamton, OANA MALIS, Purdue University — Pd-Cu bimetallic nanoparticles have the potential to replace palladium, the second most active metal having important applications as a catalyst in fuel cell and hydrogen storage reactions. We investigated the temperature-induced transformations in physical mixtures of Pd and Cu nanoparticles, using in-situ real-time synchrotron based x-ray diffraction. These nanoparticle mixtures undergo coalescence and structural phase transformations at relatively low temperature, and sinter at higher temperature. They form alloys with ordered bcc (B2) structure at low temperature (300C). At higher temperature (450C), it transforms into a disordered fcc (alloy) structure. The structural parameters probed are size, phase, composition and morphology. Grain growth was modeled with growth laws proposed for nanocrystalline materials and the diffusion mechanism driving sintering was explored. The effect of elemental compositions, different substrates and annealing atmospheres on the evolution of the PdCu alloy nanoparticles was also explored.

10:00AM T39.00011 Twinning in nanocrystalline fcc and bcc metals , VLADIMIR S. BOYKO, ROMAN YA. KEZERASHVILI, Physics Department, New York City College of Technology, The City University of New York — The deformation twinning in nanocrystalline (nc) face-centered cubic (fcc) metals, body-centered cubic (bcc) metals, and in nc Si is analyzed. The phenomenological approach is used to make a bridge between microscopical mechanisms of twin nucleation and macroscopical characteristics of twinning with different crystal structures and to calculate the grain size range of the twinning propensity, the requisite external stress for twinning propagation in nc polycrystals, and the grain size at which the slip begins to prevail over the twinning. The developed approach allows to derive analytical expressions and estimate lower and and upper limits of grain sizes at which a twinning propensity is occurred. Results of calculations for the nc fcc metals Al, Cu, Ni, Pd, Au, nc bcc metals Ta, Fe, Mo, W, Nb, and nc diamond-cubic Si are compared with the experimental data, otherwise predictions are made.

10:12AM T39.00012 Irradiation-induced formation of nano-crystallites with C15 Laves phase structure in bcc iron , MIHAI-COSMIN MARINICA, FRANÇOIS WILLAIME, JEAN-PAUL CROCOMBETTE, CEA Saclay — The thermal diffusion of defects as vacancies or interstitials is the main process which drives the material towards equilibrium after or in parallel to the damage production. A three dimensional periodic structure is proposed for self-interstitial clusters in body-centered-cubic metals, as opposed to the conventional two dimensional loop morphology [1]. The underlying crystal structure corresponds to the C15 Laves phase. The new three dimensional structures generalize previous observations [1, 2]. By systematic exploration of the energy landscape performed using an Eigenvector Following method [3] and Density Functional Theory calculations, we demonstrate that in α–iron these C15 aggregates are highly stable and immobile and that they exhibit large antiferromagnetic moments. These clusters form directly in displacement cascades and they can grow by capturing self-interstitials. This new morphology of self-interstitial clusters thus constitutes an important element to account for when predicting the microstructural evolution of iron base materials under irradiation.

10:24AM T39.00013 Composition fluctuation, local clustering, and crystallization in multi-component systems , MINGLEI WANG, KAI ZHANG, STEFANOS PAPANIKOLAOU, JAN SCHROERS, COREY S. O'HERN, Yale University — We perform molecular dynamics simulations of model multi-component metallic liquids to study mechanisms for non-polymorphic crystallization. We measure local concentration fluctuations, nucleation rates, and clustering as a function of the cooling rate for different size ratios, stoichiometries, and attraction strengths. In preliminary studies, we find that over a wide range of particle size ratios and cooling rates, small particles cluster in the interstices of contact networks formed by the large particles. These studies are important for understanding which systems are prone to crystallization and which are good glass-formers.

10:36AM T39.00014 Ab-initio study of the structure and dynamics of bulk liquid Cadmium and its liquid-vapour interface[1] , DAVID J. GONZALEZ, Dpt. Fisica Teorica, Universidad de Valladolid, Valladolid, SPAIN, LAZARO CALDERIN, Materials Research Institute and Research Computing and Cyberinfrastructure, The Pennsylvania State University, Pennsylvania 16802, USA, LUIS E. GONZALEZ, Dpt. Fisica Teorica, Universidad de Valladolid, Valladolid, SPAIN — Several static and dynamic properties of bulk liquid cadmium at a thermodynamic state near its triple point have been calculated by *ab-initio* molecular dynamics simulations. The calculated static structure shows a very good agreement with the available experimental data. The dynamical structure reveals collective density excitations with an associated dispersion relation which points to a small positive dispersion. Results are also reported for several transport coefficients. Additional simulations have also been performed in order to study the structure of the free liquid surface. The ionic density profile shows an oscillatory behavior with two different wavelengths as the spacing between the outer and first inner layer is different from that between the other inner layers. The calculated reflectivity shows a marked maximum whose origin is related to the surface layering along with a shoulder located at a much smaller wave-vector transfer.

Session T40 DAMOP: Strongly Interacting Quantum Gases 349 - Qi Zhou

8:00AM T40.00001 Symmetry methods for harmonically trapped, interacting particles , NATHAN HARSHMAN, Department of Physics, American University — We present a new method for exploiting the symmetries of interacting few-body systems trapped in harmonic potentials to achieve efficient numerical calculations of energy eigenstates. Precision experiments with ultracold atoms trapped in deep optical wells, as well as connections to recombination loss rates in trapped BECs, have driven experimental interest in this topic. Our method has two key elements. First, transformations from the particle observables into the center-of-mass/Jacobi observables can be implemented using the $\mathrm{U}(Nd)$ symmetries of N harmonic oscillators in d dimensions. Second, particle exchange symmetries are realized geometrically as orthogonal transformations in Jacobi relative hypercoordinates. Despite this apparent mathematical complexity, the results are easy to implement and interpret, and the method provides simple classifications of particle clustering in configurations and eigenstates. As a side benefit, the entanglement spectroscopy of few-body systems with tunable interactions can be explored.

8:12AM T40.00002 Unitary thermodynamics calculated from thermodynamic geometry , GEORGE RUPPEINER, New College of Florida — Degenerate atomic Fermi gases of atoms near a Feshbach resonance show universal thermodynamic properties, which are here calculated with the geometry of thermodynamics, and the thermodynamic curvature R. Unitary thermodynamics is expressed as the solution to a pair of ordinary differential equations, a "superfluid" one valid for small entropy per particle $z \equiv S/Nk_B$, and a "normal" one valid for large z. These two solutions are joined at a second-order phase transition at $z = z_c$. Define the internal energy per particle in units of the Fermi energy as $Y = Y(z)$. For small z, $Y(z) = y_0 + y_1 z^\alpha + y_2 z^{2\alpha} + \cdots$, where α is a constant exponent, y_0 and y_1 are scaling factors, and the series coefficients y_i $(i \geq 2)$ are determined uniquely in terms of (α, y_0, y_1). For large z the solution follows uniquely if, in addition, we specify z_c, with $Y(z)$ diverging as $z^{5/3}$. The four undetermined parameters (α, y_0, y_1, z_c) were determined by fitting the theory to experimental data taken by a Duke University group on ^{6}Li in an optical trap with a Gaussian potential. The best fit of this theory to the data has $\chi^2 \sim 1$.

8:24AM T40.00003 Density and particle-hole fluctuation effects on the position of Feshbach resonances in atomic Fermi gases[1] , QIJIN CHEN, Zhejiang University — Feshbach resonances have been the key to achieve tunable effective pairing interaction strength in atomic Fermi gases. Most important experiments, as well as their theoretical explanations, rely on precise determination of the locations of these resonances. For the extensively studied ^{6}Li and ^{40}K Fermi gases, the positions of the widely used s-wave Feshbach resonances have been regarded as being measured with high precision. In this talk, we show that due to inevitable particle-hole fluctuations, there is a significant density effect on the resonance locations. For a ^{6}Li gas with a realistic $T_F = 1$ μK, the shift in location in terms of magnetic field can be as high as 8G at low temperature T, and this effect does not necessarily go away at high T. This will cause important consequences as to whether and how the scattering length taken from the literature need to be re-calibrated for the concrete parameters specific to a given experiment. 8:36AM T40.00004 Scale Invariance in 2D BCS-BEC Crossover[1] , RAJDEEP SENSARMA, Tata Institute of Fundamental Research, EDWARD TAYLOR, Mcmaster University, MOHIT RANDERIA, The Ohio State University — In 2D BCS-BEC crossover, the frequency of the breathing mode in a harmonic trap , as well as the lower edge of the radio frequency spectroscopy response, show remarkable scale-invariance throughout the crossover regime, i.e. they are independent of the coupling constant. Using functional integral methods, we study the behaviour of these quantities in the 2D BCS-BEC crossover and comment on the possible reasons for this scale independence.

8:48AM T40.00005 Apparent Low-Energy Scale Invariance in Two-Dimensional Fermi Gases[1] , EDWARD TAYLOR, McMaster University, MOHIT RANDERIA, The Ohio State University — Recent experiments on a 2D Fermi gas find an undamped breathing mode oscillating at twice the trap frequency over a wide range of parameters [1]. To understand this seemingly scale-invariant behavior in a system with an energy scale, the dimer binding energy, we derive two exact results valid across the entire BCS-BEC crossover at all temperatures [2]. We relate both the shift of the mode frequency from its scale-invariant value as well as a sum rule characterizing the low-energy spectral weight in the bulk viscosity to a single parameter. This parameter characterizes the deviation from scale invariance at low energies and remarkably, vanishes exactly at zero temperature within mean-field BCS theory. Only thermal and quantum fluctuations contribute a nonzero value for this parameter and hence, break the low-energy, effective scale invariance. We discuss reasons why, in 2D with an interaction that depends logarithmically on the density, these fluctuations contribute very weakly.

9:00AM T40.00006 Probing the Contact Locally in a Trapped Unitary Fermi Gas , RABIN PAUDEL, YOAV SAGI, TARA DRAKE, DEBORAH JIN, JILA, NIST and the University of Colorado, and the Department of Physics, University of Colorado, Boulder — The inherent density inhomogeneity of a trapped gas can complicate interpretation of experiments and can wash out sharp features. This is especially important for a Fermi gas, where interaction effects as well as the local Fermi energy, or Fermi momentum, depend on the density. We report on experiments that use optical pumping with shaped light beams to spatially select the center part of a trapped gas for probing. This technique is compatible with momentum resolved measurements. For a weakly interacting Fermi gas of ^{40}K atoms, we present measurements of the momentum distribution that reveal for the first time a sharp Fermi surface. We then apply this technique to a strongly interacting Fermi gas at the Feshbach resonance, where we measured the temperature dependence of the Tan's contact locally in the trapped gas.

9:12AM T40.00007 Magnetic properties and pseudogap phenomenon in an ultracold Fermi gas with population imbalance , TAKASHI KASHIMURA, RYOTA WATANABE, YOJI OHASHI, Department of Physics, Keio University — We discuss the magnetic properties of an ultracold Fermi gas with population imbalance. In the unpolarized case, the photoemisson spectroscopy have observed a gap-like (pseudogap) structure in the normal state above the superfluid phase transition temperature, such an anomalous structure has not been detected in the highly-polarized regime. In this talk, we discuss how the poseudogap phenomenon is affected by the polarization of the system. Within the framework of an extendend T-matrix theory, we calculate the polarization dependence of DOS to show that the pseudogap gradually disappeas with increasing the polarization rate. In a highly-polarized regime, the system is simply described as a gas of long-lived quasiparticles. We also show that the calculated polarization as a function of an effective "magnetic" field $h = (\mu_\uparrow - \mu_\downarrow)/2$ agrees well with the experimental data [where μ_σ is the chemical potential of atoms with pseudospin $\sigma(=\uparrow, \downarrow)$].

9:24AM T40.00008 Spin Diffusion in a Cold Fermi Gas Close to Unitarity , HUA LI, KEVIN BEDELL, Boston College, JASON JACKIEWICZ, New Mexico State University — We study the transport properties of a normal two component Fermi gas with strong attractive interactions close to the unitary limit. In particular, we compute its spin diffusion coefficient in the extreme low temperature limit. To calculate the spin diffusion coefficient we need the scattering amplitudes. The scattering amplitudes are calculated from the Landau parameters. These parameters are obtained from the local version of the induced interaction model for computing Landau parameters. The leading order finite temperature corrections to the spin diffusion coefficient are also calculated. At temperatures close to the BCS transition temperature, pairing fluctuations are considered in calculating the scattering amplitudes. A minimum is found on the calculated temperature dependent spin diffusion coefficient curve. The position and magnitude of this minimum is sensitive to the Landau parameter F0a. Upon choosing a proper value of F0a, we are able to present a good match between the theoretical result and the experimental measurement which has a minimum with a value of order h/m being observed at some finite temperature below the Fermi temperature.

9:36AM T40.00009 Fulde-Ferrell-Larkin-Ovchinnikov states in Fermi-Fermi mixtures[1] , JIBIAO WANG, QIJIN CHEN, Zhejiang University — Fulde-Ferrell-Larkin-Ovchinnikov (FFLO) states have been of great interest in the study of population imbalanced atomic Fermi gases. It has been known that the phase space of FFLO states for an equal-mass Fermi gas in three dimension (3D) is rather small and thus has not been observed experimentally. In this talk, we will explore possible effects of mass imbalance as in a Fermi-Fermi mixture on the FFLO phases for a 3D homogeneous case. In particular, we will use a pairing fluctuation theory in which incoherent pairing fluctuations constitute a key ingredient of the theory and thus lead naturally to the appearance of a pseudogap when the pairing interaction becomes strong. We will present various phase diagrams related to the FFLO states at both zero and finite temperatures, throughout the BCS-BEC crossover, and show that a large mass ratio may indeed enhance FFLO type of pairing and make it easier to detect such states experimentally. 9:48AM T40.00010 Observation of Feshbach resonances between ultracold Na and Rb atoms , FUDONG WANG, DEZHI XIONG, XIAOKE LI, DAJUN WANG, Department of Physics, The Chinese University of Hong Kong — Absolute ground-state ^{23}Na^{87}Rb molecule has a large electric dipole moment of 3.3 Debye and its two body exchange chemical reaction is energetically forbidden at ultracold temperatures. It is thus a nice candidate for studying quantum gases with dipolar interactions. We have built an experiment setup to investigate ultracold collisions between Na and Rb atoms as a first step toward the production of ground state molecular samples. Ultracold mixtures are first obtained by evaporative cooling of Rb and sympathetic cooling of Na. They are then transferred to a crossed dipole trap and prepared in different spin combinations for Feshbach resonance study. Several resonances below 1000 G are observed with both atoms prepared in either $|F = 1, m_F = 1\rangle$ or $|F = 1, m_F = -1\rangle$ hyperfine states. Most of them are within 30 G of predicted values[§] based on potentials obtained by high quality molecular spectroscopy studies. This work is supported by RGC Hong Kong.

10:00AM T40.00011 Quantum Phase Transitions in a Bose-Fermi Mixture[1] , ERIC DUCHON, The Ohio State University, SHIZHONG ZHANG, The University of Hong Kong, SOON-YONG CHANG, MOHIT RANDERIA, NANDINI TRIVEDI, The Ohio State University — Motivated by the recent experimental realization of stable Bose-Fermi mixtures with broad Feshbach resonances, we investigate possible quantum phases and phase transitions in this system using variational Monte Carlo. Within a single-channel model appropriate near broad Feshbach resonances, we show that as the boson-fermion coupling increases, the Bose-Einstein condensate disappears and the atomic Fermi surface is destroyed while the Fermi surface of the composite molecules emerges. We calculate the momentum distribution of atomic and molecular fermions and demonstrate that the atomic fermion's quasi-particle weight Z vanishes at a critical coupling.

10:12AM T40.00012 From the Cooper problem to canted supersolids in Bose-Fermi mixtures , LODE POLLET, Department of Physics, LMU Munich, Germany, PETER ANDERS, Theoretische Physik, ETH Zurich, Switzerland, PHILIPP WERNER, Department of Physics, University of Fribourg, Switzerland, MATTHIAS TROYER, MANFRED SIGRIST, Theoretische Physik, ETH Zurich, Switzerland — We calculate the phase diagram of the Bose-Fermi Hubbard model on the $3d$ cubic lattice at fermionic half filling and bosonic unit filling by means of single-site dynamical mean-field theory (DMFT). For fast bosons, this is equivalent to the Cooper problem in which the bosons can induce s-wave pairing between the fermions. We also find miscible superfluid and canted supersolid phases depending on the interspecies coupling strength. In contrast, slow bosons favor fermionic charge density wave structures for attractive fermionic interactions. These competing instabilities lead to a rich phase diagram within reach of cold gas experiments.

10:24AM T40.00013 Closed Channel Amplitude in a Many Body Feshbach System , NICOLAS LOPEZ, University of California Riverside, EDDY TIMMERMANS, Los Alamos National Lab, SHAN-WEN TSAI, University of California Riverside — Near a narrow Feshbach resonance (with magnetic field width 10 mG or smaller) the ultra-cold atom interactions acquire an effective range that can be comparable to the average inter-particle distance. Although requiring a more accurate magnetic field control than their broad counterparts, the narrow Feshbach resonances can free cold atom physics from its straightjacket of the contact interaction paradigm. The finite-range effects can give rise to roton features in the phonon dispersion of dilute Bose-Einstein condensates (BEC's) and BEC's can support a ground state with modulated density patterns that breaks translational symmetry. We show that the finite range interaction is the consequence of the time-delay in atom-atom collisions. The narrow regime is also the parameter region in which the interacting atoms can spend a significant fraction of their time in the spin-rearranged (also called "closed") channel. To study the interaction physics we describe two atoms in a harmonic trap, interacting near a narrow resonance. We find the fraction of time that the atoms spend in the closed channel at fixed magnetic field and we extend this result to estimate the fraction of time that a distinguishable atom moving through a BEC spends in the closed channel state, quasibound to BEC-atoms.

Session T41 GQI DAMOP: Focus Session: Nano/Optomechanics III 350 - John Teufel, National Institute of Standards and Technology

8:00AM T41.00001 Surprises in three-mode quantum optomechanics: adiabatic quantum state transfer and entanglement by dissipation , AASHISH CLERK, Department of Physics, McGill University — The canonical quantum optomechanical system involves a single mechanical resonator interacting with photons in a single mode of a resonant cavity. Attention has recently turned to the additional rich physics possible in systems with many interacting vibrational and photonic modes. In this talk, I'll discuss theoretical work looking at the simplest step in this direction, optomechanical systems with three modes (2 photonic and one mechanical or vice-versa). With appropriate driving, the existence of a "mechanical dark mode" in such systems can allow for efficient quantum state transfer that is resilient against mechanical dissipation, similar to adiabatic population transfer schemes in atomic physics. With an alternate choice of driving, the same system can be used to generate a surprisingly large amount of entanglement. This occurs via a dissipative mechanism, where one mode in the system acts as an effective bath for the two modes that are to be entangled.

8:36AM T41.00002 Optomechanical transducer for microwave-to-optical photon conversion[1] , J. BOCHMANN, A. VAINSENCHER, D.D. AWSCHALOM, A.N. CLELAND, Department of Physics and California Nanosystems Institute, University of California, Santa Barbara — Mechanical resonators with highly confined optical and mechanical modes exhibit strong interaction between phonons and photons. At GHz mechanical frequencies and low temperature, nanomechanical resonators enter the quantum regime and can be interfaced with superconducting quantum circuits [2]. Here, we present the concept of a quantum transducer between microwave and optical photons. In our approach, the piezoelectric effect maps microwave quantum states to nanomechanical excitations which are up-converted to optical photons by optomechanical interaction. The exceptional properties of aluminum nitride allow the required photonic, nanomechanical and piezoelectric functionality to be integrated in one platform. Experimental progress towards this goal will be presented.

8:48AM T41.00003 State Transfer between a Mechanical Oscillator and Itinerant Microwave Fields , TAUNO PALOMAKI, JENNIFER HARLOW, JILA, National Institute of Standards and Technology and the University of Colorado, JOHN JOHN TEUFEL, RAYMOND SIMMONDS, National Institute of Standards and Technology, Boulder, KONRAD LEHNERT, JILA, National Institute of Standards and Technology and the University of Colorado — We demonstrate that the state of an itinerant microwave field can be coherently transferred into, stored in, and retrieved from a mechanical oscillator. The mechanical oscillator is coupled to a microwave resonator such that the coupling Hamiltonian is capable of exchanging microwave photons and mechanical phonons by applying a detuned microwave pulse. By shaping the envelope of the detuned microwave pulse, we can ideally capture and release itinerant microwave fields with a particular temporal mode. Crucially, the time to capture and to retrieve the microwave state is shorter than the quantum state lifetime of the mechanical oscillator. Here we demonstrate protocols for optimal transfer and measure their efficiency using coherent states with energy at the single quantum level.

9:00AM T41.00004 Electro-optical transduction via a mechanical membrane , COREY STAMBAUGH, JOHN LAWALL, NIST — Both cavity opto-mechanics and cavity electro-mechanics have been studied as means to achieve ground state cooling of mechanical systems. Recent focus has turned to hybrid systems that attempt to convert photons between microwave and optical frequencies through mechanical transduction. This should allow quantum information stored in an electrical cavity to be transferred optically over longer distances. In this talk we describe our hybrid system, a silicon nitride membrane that is coupled to a piezoelectric element and placed within a high finesse Fabry-Perot cavity. This setup allows us to both sense and perturb the mechanical motion of the membrane. Results regarding the coupling between the different domains and the design strategies to optimize these couplings will be discussed.

9:12AM T41.00005 Dispersive optomechanical coupling between a SiN nanomechanical oscillator and evanescent fields of a silica optical resonator , CHUNHUA DONG, THEIN HTAY OO, VICTOR FIORE, HAILIN WANG, Department of Physics and Oregon Center for Optics University of Oregon, Eugene, Oregon 97403, USA — Tensile stressed SiN nanostrings can feature a picogram effective mass and a mechanical Q-factor exceeding a million. These remarkable nanomechanical oscillators can be dispersively-coupled to an ultra-high finesse optical microresonator via its evanescent field [1]. This composite optomechanical system can potentially lead to a cooperativity that far exceeds that of monolithic optomechanical resonators. Here, we report an experimental study coupling a SiN nanostring to evanescent fields of a whispering gallery mode (WGM) in a silica microsphere. The slight deformation of the microsphere enables us to use free-space optical excitation to probe the optomechanical coupling. The dispersive coupling between a nanostring and the evanescent field of a WGM is generally expected to lead to a red shift in the resonance frequency of the WGM [1]. Our experiments, however, reveal a blue frequency shift of the WGM. Detailed experimental studies and possible physical mechanisms for the blue shift will be presented. 1. G. Anetsberger, et al, Nat. Phys. **5**, 909-914 (2009).

9:24AM T41.00006 Cavity optomechanics with silicon nitride sub-wavelength grating membranes , UTKU KEMIKTARAK, MATHIEU DURAND, MICHAEL METCALFE, Joint Quantum Institute, University of Maryland and National Institute of Standards and Technology, JOHN LAWALL, National Institute of Standards and Technology — In the interest of developing a high frequency, low mass, and high reflectivity optomechanical system, we pattern silicon nitride membranes as sub-wavelength diffraction gratings. This allows us to achieve mechanical quality factors reaching $Q = 10^6$, at room temperature, and reflectivities close to $R = 99.8\%$, while simultaneously decreasing the mass of the membrane. We explore the optomechanical interactions, both in the self-oscillation and cooling regimes. In the former regime, we observe a number of mechanical modes competing for self-oscillation and the dynamics of mode competition is determined by the intrinsic damping rates of the mechanical modes and their coupling strengths to the optical mode. In the latter regime, we cool a mechanical mode at 190 kHz from room temperature to below 1 K.
