H1.00340 Effect of Subelement Size, Strand Size and RRR on Stability of RRP Nb3Sn Wires

, EMANUELA BARZI, SIMONE MOIO, ALEXANDER ZLOBIN, Fermi National Accelerator Lab, SUPERCONDUCTOR R&D TEAM — Using ample statistics gathered from state-of-the-art Nb3Sn strands of different designs and sizes developed by Oxford Superconductor Technology (OST), the effects on the strand current density of subelement size, Residual Resistivity Ratio (RRR) of the copper matrix, and strand size were measured, analyzed and compared with the predictions of a stability model. The data confirmed a strong dependence of the instability current density on the subelement size, but also hinted at effects of non-uniform current distribution in the wire. The data also show that the instability current relates so weakly to RRR that it is possible to cleanly identify a common instability behavior as a function of subelement size and of strand size despite an ample range of RRR. This analysis was performed both at 4.2 K and 1.9 K.

H1.00341 Physics of ON-OFF Switching Mechanism of ReRAM via Oxygen Vacancy Based Conducting Channels

, KATSUMASA KAMIYA, MOONYOUNG YANG, University of Tsukuba, BLANKA MAGYARI-KOPE, Stanford University, MASAAKI NIWA, University of Tsukuba, YOSHIO NISHI, Stanford University, KENJI SHIRAISHI, University of Tsukuba — Resistive–Random–Access–Memories (ReRAMs) have attracted increased attention as a promising candidate for the next generation of non-volatile memories. It has been pointed out that the ON-OFF switching in ReRAMs is governed by the formation and disruption of oxygen vacancy conducting filaments. However, the origin of this formation-isolation transition is still unclear. We thus studied the ON-OFF switching mechanism of ReRAM using first-principles calculations. We found that electron-captured oxygen vacancies tend to form a cohesive conductive filament ("ON"-state), while the filament is disrupted when electrons are removed from the oxygen vacancies ("OFF"-state). We concluded that this cohesion and isolation transition of the oxygen vacancies upon carrier injection and removal is the physical origin of the ON-OFF switching in ReRAMs. This concept is also applicable for other binary-oxide-based ReRAMs, since the physics is inherently related to the properties of the oxygen vacancies. Based on this physics, we proposed a guiding principle for stack-structures of ReRAMs, which has been very recently shown to improve ReRAM properties drastically.

H1.00342 Evidence of a Liquid-Liquid Phase Transition Hot Dense Hydrogen[1]

, ISAAC SILVERA, VASILY DZYABURA, MOHAMED ZAGHOO, Department of Physics, Harvard University, Cambridge, MA 02138 — We use pulsed laser heating of hydrogen at static pressures in the megabar pressure region generated in a diamond anvil cell to search for the plasma phase transition (PPT) to liquid atomic metallic hydrogen. Heating the sample substantially above the melting line we observe a plateau in a temperature vs laser power curve that otherwise increases with power. This anomaly in the heating curve is closely correlated with theoretical predictions for the PPT, falling within the theoretically predicted range and having a negative slope with increasing pressure. Details will be presented.

H1.00343 Magnetic Properties of nickel hydroxides layers 30A apart obtained by intercalation with dodecyl sulfate ion

, MOHINDAR SEEHRA, VIVEK SINGH, West Virginia University — Magnetic systems with reduced dimensionality make good test beds for checks on theoretical models [1]. Here, changes in the nature of magnetic ordering in quasi-2d system of layered Ni hydroxides (LH-Ni-) with variations in the interlayer spacing c are investigated. Magnetic properties of LH-Ni-DS with c $\approx$ 30 A$^\circ$ synthesized by intercalating dodecyl sulfate ion, $(C_{12}H_{25}OSO_3)^-$ between the layers are compared with those of LH-Ni-Ac (c $\approx$ 8.5 A$^\circ$) containing the acetate (Ac) ligand [2]. Measurements included those of magnetization M vs. T and H, ac susceptibilities (f = 0.1 Hz - 1000 Hz) and EMR (Electron Magnetic Resonance) spectra at 9.28 GHz. Results show that just like LH-Ni-Ac, LH-Ni-DS also orders ferromagnetically but with $T_c \approx 23$ K about 45 % larger than $T_c \approx 16$ K reported for LH-Ni-Ac.[2]. In EMR studies, linewidth is strongly temperature-dependent, decreasing with decreasing T from 300 K, reaching a minimum near 45 K and then increasing sharply for T $<$ 45 K, the latter due to short range magnetic ordering. These results differ with the model of Drillon et al [3] in which interlayer dipolar interaction between clusters of correlated spins in the layers yields T_C nearly independent of c. Roles of magnetic anisotropy and exchange constants in determining T_C in the LH-Ni systems is discussed.

H1.00344 A dictionary of behavioral motifs reveals clusters of genes affecting C. elegans locomotion

, ANDRE BROWN, EVIATAR YEMINI, LAURA GRUNDY, TADAS JUCIKAS, WILLIAM SCHAFER, MRC Laboratory of Molecular Biology — Visible phenotypes based on locomotion and posture have played a critical role in understanding the molecular basis of behavior and development in *C. elegans* and other model organisms. However, it is not known whether these human-defined features capture the most important aspects of behavior for phenotypic comparison nor whether they are sufficient to discover new behaviors. Here we show that four basic shapes, or eigenworms, previously described for wild type worms also capture mutant shapes, and that this representation can be used to build a dictionary of repetitive behavioral motifs in an unbiased way. By measuring the distance between each individual's behavior and the elements in the motif dictionary, we create a fingerprint that can be used to compare mutants to wild type and to each other. This analysis has revealed previously undescribed phenotypes and has allowed clustering of mutants into related groups. Behavioral motifs provide a compact and intuitive representation of behavioral phenotypes.

H1.00345 Effect of solvent on the structure of a protein (H3.1) with a coarse-grained model with knowledge-based interactions[1] , RAS PANDEY, University of Southern Mississippi, BARRY FARMER, Air Force Research Laboratory — Quality of solvent plays a critical role in modulating the structure of a protein along with the temperature. Using a coarse-grained Monte Carlo simulation based on three knowledge-based contact potentials (MJ[1], BT[2], BFKV[3]) we examine the structure and dynamics of a histone (H3.1). The empty lattice sites constitute the effective solvent medium in which the protein is embedded. Residue-solvent characteristic interaction is based on the hydropathy index while the residue-residue interaction is used from the knowledge-based contact matrices derived from ensembles of protein structures in the protein data bank. Large scale simulations are performed to analyze the structure of protein for a range of residue-solvent interaction strength, a measure of the solvent quality with each potential. Unlike the monotonic thermal response, the radius of gyration of the protein exhibits non-monotonic dependence of the solvent strength. Quantitative comparison of the structure and dynamics emerging from three knowledge-based potentials will be presented in this talk.

H1.00346 Thermoelectric properties of $AgSbTe_2$ from first-principles calculations[1] , HADI AKBARZADEH, Department of Physics, Isfahan University of Technology, NAFISEH REZAEI, S. JAVAD HASHEMIFAR, Isfahan University of Technology, KEIVAN ESFARJANI, Rutgers University — Recently, novel thermoelectric materials are extensively investigated for providing sustainable energy resource. In this regard, $AgSbTe_2$ as a p-type semiconductor is widely investigated due to its low lattice thermal conductivity and relatively large Seebeck coefficient. We study electronic, vibrational, and thermoelectric properties of FCC and rhombohedral structures of $AgSbTe_2$ by first-principles calculations. The hybrid HSE03 functional is employed to correct wrong prediction of semimetal behavior in GGA and obtain a band gap of about 0.5 eV. The Seebeck coefficient, electrical conductivity, and electronic part of thermal conductivity are calculated by using a combination of maximally localized Wannier functions and semi-classical Boltzmann equation. By matching the calculated Seebeck coefficient with the experimental data, we predict the carrier concentration and band gap of several experimental samples. Our results indicate that the band gap and hole concentration of pure samples should be in the range of 0.2-0.5 eV and 2-5 $\times$ 10^{19} holes/cm^3. Finally, we use the experimental electrical conductivity and the constant relaxation time assumption to estimate the relaxation time of this compound.

Session J1 DCMP GMAG: Invited Session: Buckley Prize Session Ballroom I - Allan MacDonald, Univesity of Texas at Austin

2:30PM J1.00001 Oliver E. Buckley Condensed Matter Prize Lecture: Transfer of spin momentum between magnets: its genesis and prospect , JOHN SLONCZEWSKI, Retired — Consider two nanoscopic monodomain magnets connected by a spacer that is composed of a non-magnetic metal or a tunnel barrier. Any externally applied electric current flowing through these three layers contributes tiny pseudo-torques to both magnetic moments ($J.S.$ 1989). Such a weak spin-transfer torque (STT) may counteract and overcome a comparably small torque caused by viscous dissipation (*L. Berger* 1996; $J.S.$ 1996). Any initial motion (e. g. excited by ambient temperature) of one moment (or both), may grow in amplitude and culminate in steady precession or a transient switch to a new direction of static equilibrium. In a memory element, the STT effect writes 0 or 1 in a magnetic-tunnel junction. Indeed, world-wide developments of memory arrays and radio-frequency oscillators utilizing current-driven STT today enjoy a nine-digit dollar commitment. But the fact that transfer of each half-unit of spin momentum $h/4\pi$ through a barrier requires the transfer of at least one unit of electric charge limits its efficiency. Arguably, STT should also arise from the flow of external heat, in either direction, between an insulating magnet, of ferrite or garnet (e. g. YIG) composition, and a metallic spacer ($J.S.$ 2010). Whenever s-d exchange annihilates a hot magnon at the insulator/metal-spacer interface, it transfers one unit $h/2\pi$ of spin momentum to the spacer. Conduction electrons within the spacer will transport this spin momentum to the second magnet without requiring an electric current. Such a *thermagnonic* method, modestly powered by a Joule-effect heater, can substantially increase the efficiency of STT. Support for this prediction comes from (1) an estimate of the sd-exchange coefficient from data on spin relaxation in magnetically dilute (Cu,Ag,Au):Mn alloys; (2) a DFT computation (*J. Xiao et al* 2010); and (3) most persuasively, data from spin pumping driven across a YIG/Au interface by ferromagnetic resonance (*B. Heinrich et al* 2011; *C. Burrowes et al* 2012).

3:06PM J1.00002 Oliver E. Buckley Condensed Matter Prize Lecture: S-d Exchange, Spin Accumulation, And The Roots Of Spintronics , LUC BERGER, Carnegie Mellon University, Physics Dept. — The success of spintronics in metals such as nickel, cobalt, Ni-Fe and Ni-Co is based on the existence of high-mobility spin-up 4s electrons at the Fermi level, which carry most of the current. The spin-up Fermi level is located above the top of the 3d band. This basic fact, first recognized by Mott in 1936, was confirmed by the Hall-effect measurements of Pugh et al. (1950-1965), and by data of deviation from Matthiessen's rule by Campbell, Fert and Jaoul (1967-1977). In order to explain giant magnetoresistance and the existence of the spin-transfer torque, an interaction is needed which couples 4s conduction electrons to magnetic 3d electrons. This is the s-d exchange interaction, introduced by Vonsovskii in 1946 and Zener in 1951. Theories of Gilbert damping, based on s-d exchange, were soon developed (Turov (1955), Mitchell (1957)). But a serious problem was caused by the existence of a momentum gap between spin-up and spin-down Fermi surfaces, which prevents spin switching from happening at low T. The problem can be solved if local defects exist which act as extra sources of momentum. One such source is spin-flip scattering (Turov (1961), Heinrich, Freitova and Kambersky (1967)). A second one is the presence of an interface (Slonczewski (1996), Berger (1996)). Spin accumulation is another concept of importance to spintronics. It represents an imbalance between spin-up and spin-down Fermi levels. Introduced by Aronov in 1976, it was developed by Johnson and Silsbee (1985-1993) and by Valet and Fert (1993). It is the hidden agent through which the current "pumps" energy into many spintronics devices. In semiconductor lasers, the same role is played by the difference between conduction-band and valence-band Fermi levels. A momentum gap problem also exists in lasers made of indirect-gap semiconductors, and it is solved similarly.

3:42PM J1.00003 From point contacts to spin-transfer torque[1] , MAXIM TSOI, University of Texas at Austin — Point contacts - nanoscale electrical contacts between conductors - have been around for decades and proved to be unique experimental tools for studying the electronic transport properties of metals. Following the theoretical prediction of spin-transfer torque (STT) by John Slonczewski [1] and Luc Berger [2], point contacts were instrumental for the first experimental demonstration of STT in spin-valve multilayers [3], thanks to extremely high current densities routinely produced in such contacts. In this talk I will briefly review the point-contact technique and its contributions to the field of current-induced control over magnetic nanostructures.

4:18PM J1.00004 to be determined , DANIEL RALPH, Cornell Univ — No abstract available.

4:54PM J1.00005 The Spin Torque Lego - from spin torque nano-devices to advanced computing architectures[1] , JULIE GROLLIER, CNRS/Thales laboratory, Palaiseau, France — Spin transfer torque (STT), predicted in 1996 [1], and first observed around 2000, brought spintronic devices to the realm of active elements. A whole class of new devices, based on the combined effects of STT for writing and Giant Magneto-Resistance or Tunnel Magneto-Resistance for reading has emerged. The second generation of MRAMs, based on spin torque writing : the STT-RAM, is under industrial development and should be out on the market in three years. But spin torque devices are not limited to binary memories. We will rapidly present how the spin torque effect also allows to implement non-linear nano-oscillators, spin-wave emitters, controlled stochastic devices and microwave nano-detectors. What is extremely interesting is that all these functionalities can be obtained using the same materials, the exact same stack, simply by changing the device geometry and its bias conditions. So these different devices can be seen as Lego bricks, each brick with its own functionality. During this talk, I will show how spin torque can be engineered to build new bricks, such as the Spintronic Memristor, an artificial magnetic nano-synapse. I will then give hints on how to assemble these bricks in order to build novel types of computing architectures, with a special focus on neuromorphic circuits.

Session J2 DCMP: Invited Session: Topological States and Plasmonics in Graphene Ballroom II - Qian Niu, University of Texas at Austin

2:30PM J2.00001 Topological insulator gap in graphene with heavy adatoms , RUQIAN WU[1], University of California, Irvine — It is important to search an effective approach to expand the spin-orbit coupling gap of graphene for the realization of the two-dimensional topological insulator (TI) state. We found that heavy In or Tl adatoms may dramatically enhance the gap to detectable values of order 7 or 20 meV, large enough for the realization of quantum spin Hall effect in experimental conditions. However, In and Tl atoms may easily coalesce on graphene due to their weak binding energies and shallow segregation barriers. We proposed a new way to produce a two-dimensional spin-orbit coupling gap using the impurity bands that are mediated through graphene. First principles calculations predict that the gaps generated by osmium and iridium exceed 200 meV over a broad range of adatom coverage The position of the Fermi level can be manipulated by using external electric field and co-adsorbates. The mechanism at work is expected to be rather general and may open the door to designing new TI phases in many materials.

3:06PM J2.00002 Engineering topological states in graphene systems , ZHENHUA QIAO[1], Department of Physics, The University of Texas at Austin, Austin, Texas, USA — In this talk, I will introduce our recent progress on engineering various topological states in graphene systems. The presentation includes two parts: (i) We show that in monolayer graphene, Rashba spin-orbit coupling (SOC) together with Zeeman field can open a nontrivial bulk gap to host the quantum anomalous-Hall effect [1]. We further show that this can be realized via doping magnetic metal atoms on graphene [2,3]. In Bernal stacking bilayer graphene, an interlayer potential difference breaks the inversion symmetry and opens a bulk gap to support the quantum valley-Hall effect. We find that Rashba SOC can induce a topological phase transition from the quantum valley-Hall effect to a Z2 topological insulator [4]. When the Zeeman field is further considered, a rich variety of topological phases emerge. (ii) When the mass term (e.g., sublattice potential in monolayer graphene, or interlayer potential difference in bilayer graphene) varies spatially, topologically protected 1D kink states arise along zero lines. We demonstrate that such 1D kink state exhibits zero bend resistance for arbitrary turns in its propagating path [5]. We further point out that similar kink states can be tailored in graphene nanoroads in boron nitride sheets [6]. When the kink current experiences a crossing junction composed of four zero lines, we find the splitting of the 1D kink state at the bifurcation point obeys an explicit law of current partition [7].

3:42PM J2.00003 Giant Rashba effect and spin polarization of Dirac fermions in graphene[1] , OLIVER RADER, Helmholtz-Zentrum Berlin — Graphene in spintronics has so far meant a material with low spin-orbit coupling which could be used as high-performance spin current leads. If the spin-orbit interaction could be enhanced by an external effect, the material could serve also as an active element in a spintronics device such as the Das-Datta spin field effect transistors. We show that by intercalation of Au under graphene grown on Ni(111), a Rashba-type spin-orbit splitting of $\sim$ 100 meV can be created in a wide energy range while the Dirac cone is preserved and becomes slightly p-doped. We discuss different superstructures of Au under the graphene which are observed in the experiment. Ab initio calculations indicate that a sharp graphene-Au interface at the equilibrium distance accounts for only $\sim$ 10meV spin-orbit splitting and enhancement can occur due to Au atoms in the hollow position that get closer to graphene while preserving the sublattice symmetry. For the system graphene/Ir(111) we observe a large splitting of the Dirac cone as well. The large lattice mismatch of this system allows us to investigate properties of the pseudospin that are related to the structure of minigaps that occur at the zone boundary of the superstructure. We also report on the giant Rashba splitting of an Ir(111) surface state which persists underneath the graphene. Finally, we re-investigate with p(1×1) graphene/Ni(111) and Co(0001) typical examples where the sublattice symmetry breaking by the substrate is believed to lead to a large band gap at the Dirac point. We show that this is not the case and the Dirac point of graphene stays instead intact, and we discuss implications of this finding.

4:18PM J2.00004 Infrared nano-imaging and nano-spectroscopy of graphene plasmons , ZHE FEI, University of California, San Diego — Graphene plasmons, which are collective oscillations of Dirac fermions in graphene, are of broad interests in both fundamental research and technological applications. In this talk, we present first nano-imaging and nano-spectroscopy studies of graphene plasmons using scattering-type scanning near-field optical microscope –a unique technique allowing efficient excitation and high-resolution imaging of graphene plasmons. With this technique, we were able to show that common graphene/SiO2/Si back-gated structure support propagating surface plasmons in the infrared frequencies. The observed plasmons are highly confined surface modes with a wavelength around 200nm that are conveniently tunable by the back gate voltages [Nature 487, 82–85 (2012)]. In addition, we performed nano-spectroscopy of graphene over a broad range of mid-infrared frequencies. Our spectroscopy results provide evidence of strong coupling between graphene plasmons and SiO2 optical phonons [Nano Lett. 11(11), 4701-4705 (2011)]. Finally, we were able to map and characterize various types of line defects inside CVD graphene film by exploring real space patterns of propagating surface plasmons. These line defects, including cracks, wrinkles, and even grain boundaries, trigger distinct plasmonic features due to plasmon interference. Further modeling and analysis unveiled unique electronic properties associated with these line defects.

4:54PM J2.00005 Quantum Anomalous Hall Effects and Topological Phase Transitions in Silicene , MOTOHIKO EZAWA, Department of Applied Physics, University of Tokyo — Silicene is a monolayer of silicon atoms forming a two-dimensional honeycomb lattice, which is experimentally manufactured this year. The low energy theory is described by Dirac electrons, but they are massive due to a relatively large spin-orbit interaction. I will explain the following properties of silicene: 1) The band structure is controllable by applying an electric field [1]. Silicene undergoes a phase transition from a topological insulator to a band insulator by applying external electric field [1]. 2) The topological phase transition can be detected experimentally by way of diamagnetism [7]. 3) There is a novel circular dichroism and spinvalley selection rules by way of photon absorption [6]. 4) Silicene shows a quantum anomalous Hall effects when ferromagnet is attached onto silicone [3]. 5) Silicene shows a photo-induced quantum Hall effects when we apply strong laser onto silicene [8]. 6) Single Dirac cone state emerges when we apply photo-irradiation and electric field, where the gap is open at the K point and closed at the K' point [8].

Session J3 DCMP GSNP: Invited Session: Colloidal Carbon Nanotubes Ballroom III - Erik K. Hobbie, North Dakota State University

2:30PM J3.00001 Soft Materials Approaches to Carbon Nanotubes: from Gels to Composites[1] , MOHAMMAD ISLAM, Carnegie Mellon University — Carbon nanotubes combine low density with exceptional mechanical, electrical and optical properties. Unfortunately, these nanoscale properties have not been retained in bulk structures. I will describe surface modification assisted self-assembly of single wall carbon nanotube into macroscopic nanotube networks - hydrogels and aerogels. The nanotube networks are ultra-lightweight, electrically conducting and thermally insulating. The shapes and sizes of these nanotube networks are readily tunable and is a tremendous strength of our fabrication method. The interesting properties and structure of these nanotube networks make them suitable for diverse applications. For example, we have used these networks as scaffolds to enhance elastic modulus of polymers by 36,000%. The porous nanotube networks also show high capacitance, and can be impregnated with catalysts nanoparticles at high loading, which can then be simultaneously used as electrodes and catalysts supports in electrochemical cells. A weakness of the nanotube networks is their fragility – but we have recently developed a method to transform these inelastic networks into superelastic materials by coating them with between one and five layers of graphene nanoplates.

[1]This work has been supported by the NSF (DMR-0645596, DMR-0619424 and CBET-0933510), Sloan Foundation, ACS-PRF, the Korea Institute of Energy Research, DARPA, and Bayer Materials.

3:06PM J3.00002 Connectedness percolation of carbon nanotube dispersions: impact of interactions, polydispersity and external fields , PAUL VAN DER SCHOOT, Department of Applied Physics, Eindhoven University of Technology — There is considerable industrial interest in novel flexible, transparent electrodes for electro-optical applications, in part because of dwindling natural reserves of indium, a component of transparent electrodes used, e.g., in LCD display technology. For this purpose, frantic research is currently being conducted worldwide into polymeric composites containing electrically conducting inorganic and metallic nanowires, carbon nanotubes, grafite flakes, graphene and so on. One of the objectives is to get as high as possible a conduction for as low as possible a nanoparticle loading but progress is slow. Unclear is why, e.g., carbon nanotubes dispersed in plastic matrix materials can have such widely diverging electrical percolation thresholds, even when their mean physical dimensions and other characteristics seem very similar. In an effort to shed light on this, we apply continuous space connectedness percolation theory to collections of anisometric particles with arbitrary polydispersity in length, width and levels of conduction between them. We find that the percolation threshold is extremely sensitive to even quite modest degrees of polydispersity and of alignment induced in the processing of the fluid composites before they set and become the final solid product. We find that the way polydispersity influences the percolation threshold depends on whether or not the length and width distributions are coupled or not. Finally, we provide an explanation why composites with graphene filler seems to have a larger percolation threshold than those with carbon nanotubes.

3:42PM J3.00003 Fluid Phases of Carbon Nanotubes and Graphene , MATTEO PASQUALI, Department of Chemical & Biomolecular Engineering and Chemistry, The Smalley Institute for Nanoscale Science and Technology, Rice University — Nanoscale carbon—including Carbon Nanotubes (CNTs) as well as graphene, i.e., graphite in its single layered form—has remarkable electrical, thermal, and mechanical properties, more so than previously known polymer molecules or colloidal particles. Realizing these properties in applications requires understanding and controlling the behavior of fluid phases of CNTs and graphene. Biological and environmental applications are likely to require dilute phases of CNTs and graphene; material processing, e.g., production of coatings and fibers, will require more concentrated phases. Fluid processing is one of the most important frontiers of applied research in CNTs and graphene. Nano-carbon fluids are almost considered an oxymoron because dispersing or dissolving CNTs and graphene into fluid phases is exceedingly difficult. This talk reviews advances in understanding and controlling fluid phases of CNTs and graphene, with specific focus on single-object properties and true solutions. The dynamics of individual CNTs can be studied by fluorescence microscopy, revealing that their translational and rotational motion and bending stiffness can be described well by the semiflexible chain model. Even at low concentrations (few parts per million), CNTs form complex fluid phases with intriguing properties. In strong acids, CNTs as well as graphene dissolve spontaneously. At low concentration, these fluids can be used for making transparent, conducting films and coatings. In crowded environments, CNTs reptate like stiff polymers. At sufficiently high concentrations, CNTs and graphene form liquid crystals that can be spun into well-aligned, macroscopic fibers. Like in polymeric systems, the properties of macroscopic CNT materials depend on the length (molecular weight) of the constituent CNT macromolecules.

4:18PM J3.00004 Field-assisted assembly and orientational order of colloidal ellipsoids , MICHAEL SOLOMON, University of Michigan — Colloidal particles with anisotropy in shape and interactions can potentially be assembled into colloidal crystals with unusual structure and symmetry. Field-assisted assembly is likewise a means to produce structures that are otherwise difficult to achieve by equilibrium self-assembly. Here we show, by means of confocal microscopy direct visualization, how controlled application of electric fields can improve general prospects for assembly of any anisotropic colloid. By studying the model case of ellipsoidal colloidal rods, we find that applied fields can be designed which produce liquid crystal phases of colloids in a simple, versatile manner. By directly visualizing the assembled particles in three dimensions we learn that the quality of orientational order achieved is comparable to that of materials such as liquid crystalline polymers. We understand the results in terms of the underlying electrokinetics of the system as well as connect the observed field-induced orientational order to the equilibrium isotropic-nematic transition predicted for rods with prolate spheroidal shape. Specifically, the applied field generates a force that is balanced by a gradient in osmotic pressure generated by the density dependence of the rod suspension. If the field strength is sufficiently large, the resultant osmotic pressure produces a phase transition. We discuss how the required field conditions for assembly can be tailored based on the shape and size of the anisotropic building block.

4:54PM J3.00005 DNA-wrapped Carbon nanotubes as a model rod-like colloid system , MING ZHENG, National Institute of Standards and Technology — Single-wall carbon nanotubes (SWCNTs) exhibit many fascinating physical behavior as the result of their quasi one-dimensional crystalline structures. SWCNTs can be dispersed into rod-like colloid particles by a few small molecules and polymers, among which the most effect one is single-stranded DNA (**Nature Materials** 2, 338, 2003). The structure of a DNA-SWCNT hybrid is controlled by both the sequence of the wrapping DNA, and the atomic configuration, or chirality, of the SWCNT (**Science** 302, 1545, 2003). This has been exploited by us to purify single-chirality SWCNTs from synthetic mixtures via liquid chromatography (**Nature** 460, 250, 2009; **JACS** 133, 12998, 2011). DNA-SWCNTs have well-defined surface structures, tunable aspect-ratios, and ultra-small diameters. These attributes provide unique advantages to the DNA-SWCNT colloid system in probing inter-particle interactions in crowded and high salt environment (**ACS Nano** 5, 8258, 2011). In this talk, I will present some recent observations we made on DNA-SWCNT clustering that shed new light on the Hofmeister effect.

Tuesday, March 19, 2013 2:30PM - 5:30PM –

Session J4 FIAP: Invited Session: Physics Challenges in Biophysics Ballroom IV - Cha-Mei Tang, Creatv Micro Tech Inc

2:30PM J4.00001 Phase contrast imaging with conventional x-ray sources at acceptable dose levels and exposure times[1] , ALESSANDRO OLIVO, University College London — X-ray Phase Contrast imaging (XPCi) generates image contrast from interference and refraction effects (instead of x-ray attenuation), which leads to enhanced visibility of all details and to the detection of features classically considered "x-ray invisible." XPCi thus has great potential in a wide range of applications, from the earlier diagnosis of lesions in medical imaging to the detection of faint blemishes in non-destructive testing. However, XPCi seemed to require a high level of (at least spatial) coherence, which restricted its use to synchrotron facilities. Microfocal sources can be used but, due to low emitted flux, result in exposure times too long (hours) for most practical applications. Other attempts were based on aperturing/collimating the focal spot of a conventional source to create sufficient spatial coherence, again limiting the source output and resulting in excessive exposure times and/or delivered dose. This talk will present a method, based on appropriately designed x-ray masks, which works with unapertured and uncollimated conventional sources, at acceptable exposure times and delivered doses. It will describe how the method works, explain how quantitative features can be extracted from the images, and provide examples of application in various fields.

3:06PM J4.00002 Diagnostic Applications and Methods to Isolate Circulating Tumor Cells (CTCs) from Blood , CHA-MEI TANG, Creatv MicroTech, Inc. — Each year a million new cancer cases are diagnosed in the United States. Ninety percent of the deaths will be the result of metastasis, not from the primary tumor. Tissue biopsy is a universally accepted tool for cancer diagnosis and determination of treatment. The procedure varies, but is invasive, costly, and can be fatal, and for these reasons is seldom repeated after initial diagnosis. Monitoring of treatment response and for possible relapse is usually done by CT or MRI scan, both of which are expensive and require the tumor to change size perceptibly. Further, cancer can mutate or develop resistance to therapeutics and require modification of the treatment regimen. The initial tissue biopsy often cannot reflect the disease as it progresses, requiring new biopsy samples to determine a change of treatment. All carcinomas, about 80% of all cancer, shed tumor cells into the circulation, most often at the later stages when treatment is more critical. These circulating tumor cells (CTCs) are the cause of metastasis, and can be isolated from patient blood to serve as "liquid biopsy". These CTCs contain a valuable trove of information that help both patient and clinician understand disease status. In addition to counting the number of CTCs (known to be a prognostic indicator of survival), CTCs can provide biomarker information such as protein expressions and gene mutations, amplifications, and translocations. This information can be used to determine treatment. During treatment, the number of intact and apoptotic CTCs can be measured on a repeated basis to measure the patient's response to treatment and disease progression. Following treatment, liquid biopsy can be repeated at regular intervals to watch for relapse. Methods to isolate CTCs can be grouped into three categories: i) immunocapture based on surface markers of CTCs, ii) size exclusion based on CTC size, typically larger than blood cells, and iii) negative selection utilizing red blood cell lysis, white blood cell depletion or FICOLL. Various implementations of the CTC isolation methods will be presented.

3:42PM J4.00003 A Retinal Prosthetic Strategy with the Capacity to Restore Normal or Near-Normal Vision , SHEILA NIRENBERG, Weill Medical College, Cornell University — A pressing problem in neuroscience is determining the neural code. We know that neurons send their signals in the form of trains of action potentials, but we don't know what the code is, that is, we don't know what the unit of information is. Is it the number of spikes per unit time? Is it the individual spike or some pattern of spikes? Getting a clear answer to this affects a great deal of work in neuroscience, both basic and applied. For basic research, it tells us what quantity we need for building models of neural computations (i.e., what spike train features we need). For applied research, it tells us what quantity we need to effectively transmit information from one brain area to another via brain-machine-interfaces or prosthetic devices. Here we describe a strategy for finding neural codes and use it to develop a powerful new kind of prosthetic device for treating blindness.

4:18PM J4.00004 Smart Prosthetics , STUART HARSHBARGER, Contineo Robotics, LLC — No abstract available.

4:54PM J4.00005 Artifical Pancreas , JIANGFENG FEI, JDRF — In 2006, JDRF launched the Artificial Pancreas Project (APP) to accelerate the development of a commercially-viable artificial pancreas system to closely mimic the biological function of the pancreas individuals with insulin-dependent diabetes, particularly type 1 diabetes. By automating detection of blood sugar levels and delivery of insulin in response to those levels, an artificial pancreas has the potential to transform the lives of people with type 1 diabetes. The 6-step APP development pathway serves as JDRF's APP strategic funding plan and defines the priorities of product research and development. Each step in the plan represents incremental advances in automation beginning with devices that shut off insulin delivery to prevent episodes of low blood sugar and progressing ultimately to a fully automated "closed loop" system that maintains blood glucose at a target level without the need to bolus for meals or adjust for exercise.

Tuesday, March 19, 2013 2:30PM - 5:30PM –

Session J5 DMP DCOMP: Focus Session: Computational Discovery and Design of New Materials: Graphene 301 - Richard Hennig, Cornell University

2:30PM J5.00001 Electronic structure and lattice matching in graphene/h-BN stacked thin films[1] , YUKI SAKAI, Department of Physics, Tokyo Institute of Technology and Department of Physics, University of California, Berkeley, SUSUMU SAITO, Department of Physics, Tokyo Institute of Technology, MARVIN COHEN, Department of Physics, University of California, Berkeley and Materials Science Division, Lawrence Berkeley National Laboratory — In this work, we study the electronic structure and possibility of lattice matching of thin films composed of graphene and hexagonal boron nitride (h-BN) within the framework of the density functional theory. Since graphene and h-BN have different in-plane lattice constants intrinsically, we first study relative stabilities of commensurate thin films with lattice matching and incommensurate thin films without lattice matching by comparing total energies in order to clarify the stable geometries of graphene/h-BN thin films. As a result, we find some stacking patterns where commensurate thin films are more stable than incommensurate thin films. We also find that the energy gain due to interlayer interaction depends on the number of layers in thin films. In addition, we report electronic properties of these thin film systems. Some commensurate thin films are found to possess finite band gaps, while induced band gaps should be almost canceled out in incommensurate phases. We also discuss the electric field effect on the electronic properties of graphene/h-BN thin films.

[1]This work was partially supported by NSF Grant No. DMR-10-1006184, DOE under Contract No. DE-AC02-05CH11231, and by the Global Center of Excellence Program by MEXT, Japan. Y. S. also acknowledges the funding from JSPS.

2:42PM J5.00002 Accessing the Strong-Coupling Regime in Graphene on hBN Substrate , ANDREY SHYTOV, University of Exeter, JUSTIN SONG, LEONID LEVITOV, Massachusetts Institute of Technology — Recent experiments [1,2] report on an insulating behavior at charge neutrality in single-layer graphene on hBN substrate. Ref.[1] attributed this behavior to weak localization due to residual short-range disorder. However, in Ref.[2] a much stronger insulating behavior was observed at a larger separation between graphene and the gates, in the regime when interactions are largely unscreened. This suggests that interactions play a decisive role in the observed phenomena, ruling out the weak localization scenario. We propose an alternative mechanism in which a gap opens up due to a combined effect of sublattice modulation in hBN [3] and electron-electron interactions. We argue that sublattice modulation in hBN amplifies the effective fine structure constant enhancing electron-electron interactions. In this regime, a weak gap induced by sublattice modulation can be strongly enhanced by interactions, giving rise to near-spontaneous excitonic order.

2:54PM J5.00003 Observation of a Massive Dirac Spectrum in Monolayer Graphene on Boron Nitride , BENJAMIN HUNT, JAVIER D. SANCHEZ-YAMAGISHI, ANDREA F. YOUNG, Massachusetts Institute of Technology, T. TANIGUCHI, K. WATANABE, National Institute for Materials Science, PABLO JARILLO-HERRERO, RAYMOND ASHOORI, Massachusetts Institute of Technology — Graphene on hexagonal boron nitride (hBN) has emerged as the new standard for high-mobility graphene devices. However, the role of the hBN substrate in modifying the electronic properties of the graphene has only recently been investigated, with particular attention paid to the effects of the Moire produced by the interplay between the graphene and hBN lattices. Here we show that the hBN substrate can have a dramatic effect on the electronic structure of monolayer graphene, leading to the formation of superlattice Dirac points (SLDPs) and an insulating state at charge neutrality in zero magnetic field. The SLDPs imply that the insulator is related to the presence of a long-wavelength Moire. In samples which show the zero-field insulator, we also observe incompressible features associated with fractional quantum Hall (FQH) states at filling fractions $\nu=\pm 5/3$. Their absence in previous measurements has been attributed to the presence of low-energy valley excitations; in our measurement we find the strength of the $\nu=5/3$ gap is comparable to that of all other observed FQH states. Taken together, these observations imply that for small twist angles between the graphene and hBN substrates, the appropriate low-energy theory describing monolayer graphene features a mass.

3:06PM J5.00004 Ideal strength and phonon instability of atomically-thin materials under strain , ERIC B. ISAACS, CHRIS A. MARIANETTI, Department of Applied Physics and Applied Mathematics, Columbia University — Recent *ab initio* calculations suggest that the ideal strength of graphene is limited by a finite-wavevector phonon instability [1]. In order to understand the origin and generality of phonon instabilities in two-dimensional crystals, we investigate the ideal strength of other monolayer materials including boron nitride (BN) and molybdenum disulfide (MoS_2) with density functional theory calculations. We find a soft phonon mode at the K-point of the Brillouin zone leading to mechanical failure for both BN and MoS_2 under biaxial tensile strain, which suggests that Fermi surface nesting cannot be a universal explanation for this type of phonon instability in monolayer materials since BN and MoS_2 have substantial band gaps. While BN distorts similarly to graphene upon mechanical failure, MoS_2 undergoes a more complex phase transformation with both in- and out-of-plane atomic displacements. We discuss general features of phonon instabilities in monolayer materials under strain and make connection to results from nanoindentation experiments when available. [1] C. A. Marianetti and H. G. Yevick, Phys. Rev. Lett. **105**, 245502 (2010).

3:18PM J5.00005 First-Principles Study of Multilayer Lithium and Graphene Compounds for Battery Applications , ALPER BULDUM, GULCIN TETIKER, Department of Physics, The University of Akron, Akron, OH — Recently, graphene and graphene based materials have attracted great interest for energy storage applications such as rechargable Li-ion batteries and supercapacitors. However, recent experiments showed that these materials may have different electrochemical mechanism compared to graphite. Porosity and presence of single or few layers of graphene play important roles in carbon based anode materials in lithium ion batteries. In this work, a study of different multilayer lithium-graphene compounds is performed using first-principles density-functional theory(DFT). Relaxed structures are determined, adsorption energies, density of states and charge density are calculated. Possible multilayer structures for energy storage are discussed.

3:30PM J5.00006 Self-assembly mechanisms and even/odd disparity of short atomic chains on graphene[1] , V. ONGUN OZCELIK, SALIM CIRACI, Bilkent University — Self-assembly mechanisms of carbon chains on boron nitride and short BN chains on graphene are investigated using first-principles plane wave calculations. Once a C_2 nucleates on h-BN, the insertion of each additional carbon at its close proximity causes a short segment of carbon atomic chain to grow by one atom at a time in a quaint way: The existing chain leaves its initial position and subsequently is attached from its bottom end to the top of the carbon ad-atom. The electronic, magnetic and structural properties of these chains depend on the number of carbon atoms in the chain, such that they exhibit an even-odd disparity. An individual carbon chain can also modify the electronic structure with localized states in the wide band gap of h-BN. As a reverse situation, the growth of short BN atomic chains on graphene is also examined. These results reveal the interesting self-assembly behavior short atomic chains. Furthermore, we find that these atomic chains enhance the chemical activity of h-BN and graphene sheets by creating active sites and can act as pillars between two and multiple sheets of these honeycomb structures leaving wider spacing between them to achieve high capacity storage of specific molecules.

3:42PM J5.00007 Ab initio Study of the Interactions between Single Vacancies in Graphene[1] , MAHMOUD HAMMOURI, IGOR VASILIEV, New Mexico State University — Graphene is a promising material for nanoelectronic and spintronic applications. The introduction of point defects such as vacancies can turn graphene into a magnetic material. We present a first-principles computational study of the interactions between single vacancies in graphene. The total energies, lattice deformation energies, and spin magnetic moments of the interacting vacancies are calculated using the SIESTA density functional electronic structure code combined with the generalized gradient approximation for the exchange correlation functional. We discuss the variation of the total energy and the total magnetic moment of defective graphene as a function of the separation distance between vacancies. Our calculations show that the magnetic moment of graphene disappears when the vacancies are located within a certain distance from each other.

3:54PM J5.00008 Ab Initio Study of the Interactions between Dopant Atoms and Vacancies in Graphene[1] , TAREK TAWALBEH, NSMU, IGOR VASILIEV, NMSU — We apply a first-principles computational method based on density functional theory to study the interaction of substitutional boron and nitrogen atoms with single vacancies in graphene. Our calculations are carried out using a pseudopotential technique combined with the generalized gradient approximation for the exchange-correlation functional implemented in the SIESTA electronic structure package. The equilibrium geometries, total energies, electronic structures, magnetization, and spin-polarized densities of states of doped and defective graphene sheets are examined as a function of the separation distance between dopant atoms and vacancies. Our study shows the presence of attractive interaction between dopant atoms and vacancies. Furthermore, we found that boron dopants enhance the magnetism of graphene sheets containing single vacancies, whereas nitrogen dopants reduce it. The influence of dopant site location on both the interaction energy and magnetization is discussed.

4:06PM J5.00009 Doping of graphene nanomeshes by ion-chelation , AHMED MAAROUF, IBM T.J. Watson Research Center & Egypt Nanotechnology Center, RAZVAN NISTOR, ALI AFZALI, MARCELO KURODA, DENNIS NEWNS, GLENN MARTYNA, IBM T.J. Watson Research Center — Graphene nanomeshes (GNM's) are formed by the creation of a superlattice of pores in graphene. Depending upon the pore shape, size, superlattice constant and symmetry, GNM's can be semimetallic, or semiconducting with a fractional eV band gap, allowing them to be fruitfully employed in applications that pristine graphene cannot. In this work, first principles calculations are used to study the doping of semiconducting GNM's using a chemically motivated approach. It is shown that *ion-chelation* leads to a stable doping of the GNM's, and that it occurs within a rigid band doping picture. Such chelated or "crown" GNM structures are thus stable, high mobility semiconducting materials which can serve as building blocks for novel graphene-based nanoelectronics applications.

4:18PM J5.00010 Magnetism of single and divacancies in graphene nanoflakes[1] , SILVIA FERNANDEZ-SABIDO, M.E. CIFUENTES-QUINTAL, CARLOS RAMOS, ROMEO DE COSS, Centro de Investigaciones y de Estudios Avanzados del Instituto Politécnico Nacional - Unidad Mérida — Vacancy-induced magnetism in graphene is a recent topic of great scientific relevance because of the potential applications of spin-polarized graphene-based systems. In this work, we have studied by means of DFT calculations, the structural, electronic and magnetic properties of single and divacancies in hexagonal zigzag graphene nanoflakes $C_{6n^2}H_{6n}(n = 2, \ldots, 7)$. We have found that, when a single carbon atom is removed, the structure undergoes a magnetic 5-9 reconstruction where the interatomic distances depend on the nanoflake size. The charge density distribution suggests that there is not a complete bond reconstruction in the vacancy zone, however, the existence of a partial bond is sufficient to conclude that only two electrons remain unpaired, resulting in the $2\mu_B$ spin moment. The spin moment is equally distributed over the localized-sp^2 and delocalized-p_z orbitals. For a carbon-divacancy, we have varied the distance between the vacancies and we have found magnetic structural reconstructions (9-4-9, 5-9-9-5, 5-9-6-5) which have not been reported for graphene layer with magnetic moments between 2 and $4\mu_B$; although the most stable is the nonmagnetic 5-8-5 reconstruction.

4:30PM J5.00011 Scattering by periodic defect lines in graphene[1] , J.N.B. RODRIGUES, Universidade do Porto, N.M.R. PERES, Universidade do Minho, J.M.B. LOPES DOS SANTOS, Universidade do Porto — Recently, Tsen et al. [1] demonstrated how one can probe the electric properties of a single grain boundary in graphene. Following this remarkable possibility, we study, from a theoretical point of view, the electronic transport across periodic defect lines in graphene. In the continuum low-energy limit, such defects act as infinitesimally thin stripes separating two regions where the Dirac Hamiltonian governs the low-energy phenomena. The behaviour of these systems is determined by the boundary condition imposed by the defect on the massless Dirac fermions. We demonstrate how this low-energy boundary condition can be computed from the tight-binding model of the defect line. We illustrate this procedure by considering a simple zigzag oriented defect line solely composed by pentagons: the $pentagon\text{-}only$ defect line. The recently observed $zz(558)$ defect line [2], as well as the $zz(5757)$ defect line will also be considered [3].

4:42PM J5.00012 First-Principles Investigation of Mn and Co Doped Trilayer Graphene , XUAN LUO, National Graphene Research and Development Center, North Springfield, VA 22151 — First-principles calculations were performed through ABINIT to investigate trilayer graphene for spintronics materials. We studied two stacking orders for trilayer graphene: Bernal (ABA) and rhombohedra (ABC) by using interstitial and substitution transition metal Mn and Co doped trilayer graphene. We found that the ABC stacking order exhibits larger band gap than that of ABA, the Co doped ABC trilayer graphene possesses a band gap and is ferromagnetic. This results show that interstitial Co doped ABC stacking trilayer graphene has potential applications in spintronics.

4:54PM J5.00013 Oxygen plasma etching of graphene: A first-principles dynamical inspection of the reaction mechanisms and related activation barriers[1] , KENICHI KOIZUMI, The University of Tokyo, MAURO BOERO, University of Strasbourg and CNRS, YASUTERU SHIGETA, Osaka University, ATSUSHI OSHIYAMA, The University of Tokyo, DEPT. OF APPLIED PHYSICS TEAM[2], INSTITUTE OF PHYSICS AND CHEMISTRY OF STRASBOURG (IPCMS) COLLABORATION, DEPARTMENT OF MATERIALS ENGINEERING SCIENCE COLLABORATION[3] — Oxygen plasma etching is a crucial step in the fabrication of electronic circuits and has recently received a renovated interest in view of the realization of carbon-based nanodevices. In an attempt at unraveling the atomic-scale details and to provide guidelines for the control of the etching processes mechanisms, we inspected the possible reaction pathways via reactive first principles simulations. These processes involve breaking and formation of several chemical bonds and are characterized by different free-energy barriers. Free-energy sampling techniques (metadynamics and blue moon), used to enhance the standard Car-Parrinello molecular dynamics, provide us a detailed microscopic picture of the etching of graphene surfaces and a comprehensive scenario of the activation barriers involved in the various steps.

5:06PM J5.00014 Simulating Lattice Image of Suspended Graphene Taken by Helium Ion Microscopy[1] , YOSHIYUKI MIYAMOTO, Nanosystem Res. Labs., AIST, HONG ZHANG, College of Physical Science and Technology, Sichuan University, ANGEL RUBIO, Department of Materials Science, University of the Basque Country — Atomic scale image in nano-scale helps us to characterize property of graphene, and performance of high-resolution transmission electron microscopy (HRTEM) is significant, so far. While a tool without pre-treatment of samples is demanded in practice. Helium ion microscopy (HIM), firstly reported by Word $et.\ al.$ in 2006, was applied for monitoring graphene in device structure (Lumme, $et.\ al.$, 2009). Motivated by recent HIM explorations, we examined the possibility of taking lattice image of suspended graphene by HIM. The intensity of secondary emitted electron is recorded as a profile of scanned He^+-beam in HIM measurement. We mimicked this situation by performing electron-ion dynamics based on the first-principles simulation within the time-dependent density functional theory. He^+ ion collision on single graphene sheet at several impact points were simulated and we found that the amount of secondary emitted electron from graphene reflected the valence charge distribution of the graphene sheet. Therefore HIM using atomically thin He-beam should be able to provide the lattice image, and we propose that an experiment generating ultra-thin He^+ ion beam (Rezeq $et.\ al.$, 2006) should be combined with HIM technique.

[1]All calculations were performed by using the Earth Simulator.

5:18PM J5.00015 Electronic structures and transport properties of silicene on Ag surface , YUN-PENG WANG, HAI-PING CHENG, Physics Department of Physics and the Quantum Theory Project, University of Florida — It has been predicted from first-principle that "silicene", a two-dimensional buckled honeycomb structure of silicon, is thermally stable and has a graphene-like band structure. In experiments, epitaxial silicene were observed to form at hexagonal Ag(111) and $ZrB_2(0001)$ surfaces. However, electronic structure and transport properties related to silicene have not been thoroughly studied. In this work, we have studied band structures of silicene on top of Ag surface using density-functional theory. The effective band structure mapped onto 1×1 unit cell of monolayer silicene on Ag(111) surface could be compared directly with Angle-Resolved Photoemission Spectra (ARPES). We have also studied electronic transport property across monolayer and bilayer silicene sheets using the Non-Equilibrium Green's Function (NEGF) method. The transmission curve shows a maximum at Fermi energy for the monolayer silicene case, but shows a minimum for the bilayer silicene case, which can be explained by their band structures.

Tuesday, March 19, 2013 2:30PM - 5:30PM –

Session J6 DMP: Growth, Structure, Properties, and Defects 302 - Paola Barbara, Georgetown University

2:30PM J6.00001 Temperature Dependence of the Raman Spectra of CVD-grown Monolayer MoS_2 , A. GLEN BIRDWELL, FRANK J. CROWNE, TERRANCE P. O'REGAN, PANKAJ B. SHAH, MADAN DUBEY, U.S. Army Research Laboratory, Sensors and Electron Devices Directorate, 2800 Powder Mill Rd, Adelphi, MD 20783, USA, SINA NAJMAEI, ZHENG LIU, PULICKEL M. AJAYAN, JUN LOU, Department of Mechanical Engineering and Materials Science, Rice University, Houston, TX 77005, USA, RUSEN YAN, HUILI GRACE XING, Department of Electrical Engineering, University of Notre Dame, Notre Dame, IN 46556, USA — We investigated the temperature dependence of the E^1_{2g} and A_{1g} peaks in the Raman spectra of monolayer MoS_2 grown by chemical vapor deposition (CVD) on Si/SiO_2 substrates. Micro-Raman spectroscopy was carried out using the 532 nm laser excitation over the temperature range from 30 to 175 °C. The extracted values of the temperature coefficient of these modes are χ = -0.013 $cm^{-1}/°C$ and χ = -0.016 $cm^{-1}/°C$, respectively. The obtained results may shed light on the anomalous behavior of these modes observed in laser power dependent studies of monolayer MoS_2.

2:42PM J6.00002 Grains and grian boundaries in highly-crystalline monolayer molybdenum disulfide , AREND M. VAN DER ZANDE, Energy Frontier Research Center, Columbia University, PINSHANE Y. HUANG, Cornell University, DANIEL A. CHENET, YUMENG YOU, TIMOTHY C. BERKELBACH, GWAN-HYOUNG LEE, DAVID R. REICHMAN, Columbia University, DAVID A. MULLER, Cornell University, TONY F. HEINZ, JAMES C. HONE, Columbia University — Recent progress in large-area chemical vapor deposition (CVD) synthesis of monolayer molybdenum disulfide, a new two-dimensional direct-bandgap semiconductor, is paving the way for applications in atomically thin electronics. Little is known, however, about the microstructure of this material. Here we have refined CVD synthesis to grow highly crystalline islands of monolayer molybdenum disulfide up to 120 micrometers in size with optical and electrical properties comparable or superior to exfoliated samples. Using transmission electron microscopy, we correlate lattice orientation, edge morphology, and crystallinity with island shape to demonstrate that triangular islands are single crystals. The crystals merge to form faceted tilt and mirror boundaries that are stitched together by lines of 8- and 4- membered rings. Density functional theory reveals localized mid-gap states arising from these 8-4 defects. The knowledge gained about grain structure enables systematic studies of the optical, mechanical, and electronic properties of grain boundaries.

2:54PM J6.00003 Synthesis Single Layer Transition Metal Dichalcogenides with Chemical Vapor Deposition , YI-HSIEN LI, HAN WANG, LILI YU, WENJING FANG, TOMAS PALACIOS, Massachusetts Institute of Technology, LAIN-JONG LI, Institute of Atomic and Molecular Sciences, Academia Sinica, JING KONG, Massachusetts Institute of Technology — Recently, monolayers of layered transition metal dichalcogenides (LTMD), such as MX2 (M=Mo, W and X=S, Se), have been reported to exhibit significant spin-valley coupling and optoelectronic performances because of the unique structural symmetry and band structures. Monolayers in this class of materials offered a burgeoning field in fundamental physics, energy harvesting, electronics and optoelectronics. However, most studies to date are hindered with great challenges on the synthesis and transfer of high quality LTMD monolayers. Hence, a feasible synthetic process to overcome the challenges is essential. Here, we demonstrate the growth of high-quality MS2 (M=Mo, W) monolayers using ambient-pressure-chemical-vapor-deposition (APCVD) with the seeding of aromatic molecules. Electronic transport and optical performances of the as-grown MS2 monolayers are comparable to those of exfoliated MS2 monolayers. The growth of MS2 monolayer is achieved on various surfaces. Growth mechanism on the novel synthetic process is investigated. Understanding and better control of seeds for the novel growth on the class of materials may stimulate the progress in the emerging filed.

3:06PM J6.00004 Oxidation of atomically thin MoS_2 on SiO_2 , MAHITO YAMAMOTO, WILLIAM CULLEN, THEODORE EINSTEIN, MICHAEL FUHRER, Materials Research Science and Engineering Center, University of Maryland, College Park, MD 20742-4111 — Surface oxidation of MoS_2 markedly affects its electronic, optical, and tribological properties. However, oxidative reactivity of atomically thin MoS_2 has yet to be addressed. Here, we investigate oxidation of atomic layers of MoS_2 using atomic force microscopy and Raman spectroscopy. MoS_2 is mechanically exfoliated onto SiO_2 and oxidized in Ar/O_2 or Ar/O_3 (ozone) at 100-450 °C. MoS_2 is much more reactive to O_2 than an analogous atomic membrane of graphene and monolayer MoS_2 is completely etched very rapidly upon O_2 treatment above 300 °C. Thicker MoS_2 (> 15 nm) transforms into MoO_3 after oxidation at 400 °C, which is confirmed by a Raman peak at 820 cm^{-1}. However, few-layer MoS_2 oxidized below 400 °C exhibits no MoO_3 Raman mode but etch pits are formed, similar to graphene. We find atomic layers of MoS_2 shows larger reactivity to O_3 than to O_2 and monolayer MoS_2 transforms chemically upon O_3 treatment even below 100 °C. Work supported by the U. of Maryland NSF-MRSEC under Grant No. DMR 05-20741.

3:18PM J6.00005 Comprehensive Studies of NbS_2 and the Affects of Nb Doping in the Layered Systems of WS_2 and MoS_2 , BRIAN COOPER, MAURICIO TERRONES, TOM MALLOUK, CAMDEN HENDERSON, NINA I. KOVTYUKHOVA, The Pennsylvania State University — Research on layered dichalcogenides (compounds of the form MX_2, with M as a metal and X as any member of group 16 in the periodic table) has picked up momentum due to a sympathetic reverberation created in response to the enormously prodigious research in graphene. Although much progress in graphene research has been made, there are still many hurdles to clear, and prudence has made requisite parallel courses in research. Layered dichalcogenides exhibit similar features to graphene; namely they are relatively easy to exfoliate, and have hexagonal symmetries, but unlike graphene, these compounds represent a spanning set of the materials under investigation in various scientific branches ($e.g.$ superconductors, semiconductors, topological insulators, *etc.*). We have taken many approaches to the synthesis, manipulation, and device design of these materials. In our attempts to better understand the role of doping Nb into the MoS_2 and WS_2 systems, we serendipitously realized the merits, which previously lay quiescent, of studying NbS_2 itself. A metallic dichalcogenide, NbS_2 exhibits both charge density wave and superconducting phase transitions below respective appropriate temperatures. Studying mono, bi, and tri-layer geometries have afforded us the opportunities to probe not only the details of quantum confinement effects in the NbS_2 system, but also how these effects percolate through and affect the various properties of other dichalcogenidal systems.

3:30PM J6.00006 Effects of strain on band structure and effective masses in MoS_2[1] , HARTWIN PEELAERS, CHRIS G. VAN DE WALLE, Materials Department, University of California, Santa Barbara, CA 93106-5050 — Molybdenum disulfide (MoS_2) is a layered semiconductor that shows great promise for devices such as field-effect transistors. It has an important advantage compared to graphene, namely that it has a band gap. However, a lot of crucial information about the band structure and electronic properties of this material is still lacking, hampering interpretation of experiments and preventing accurate device modeling. Here we use hybrid density functional theory to calculate key materials parameters such as band gaps and effective masses, as well as to investigate effects of strain. We show how strain allows engineering the nature (direct vs. indirect) and size of the band gap and the magnitude of effective masses. In addition, insight into the fundamental physics is provided by considering the transition between the bulk and the monolayer as a function of tensile uniaxial stress.

3:42PM J6.00007 Two-Dimensional Semiconductors From Theory to Experiments: MoS_2 and $MoSe_2$, CAN ATACA, JEFFREY C. GROSSMAN, Department of Materials Science and Engineering, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, United States, SEFAATTIN TONGAY, J. ZHOU, K. LO, JUNQIAO WU, Department of Material Science and Engineering, University of California, Berkeley, Berkeley, California 94720, United States — After the synthesis of graphene, single layer transition metal dichalcogenides have been shown to possess superior optical properties than those of graphene. Until now, both theorists and experimentalists have mainly focused on the properties of single-layer MoS2. In this work, the first synthesis of single and few layers of MoSe2 are shown experimentally and are complemented by stability analysis through phonon and electronic structure calculations using density functional theory (DFT). The DFT calculations include van der Waals and spin-orbit interactions which are shown to play an important role in the geometric structure, electronic, magnetic and vibrational properties. Single-layer MoSe2 is measured and calculated as a direct band gap material, having band gap values suitable for solar cells and optical devices. Dimensionality effects predicted by DFT calculations such as variation of the energy band structures and Raman active vibrational modes are confirmed by experiments. Optical and electronic properties of single and few layers MoSe2 can be tuned by varying the temperature, number of layers and applying pressure to the samples. Single layer MoS2 and MoSe2 possess a number of properties that make them highly promising materials for future nanoscale applications.

3:54PM J6.00008 ABSTRACT WITHDRAWN –

4:06PM J6.00009 Electronic Structure of Defect-Single-Layer MoS2[1] , TAKAT RAWAL, DUY LE, TALAT S. RAHMAN, University of Central Florida — We present density functional theory based investigations of the electronic structural properties of a single-layer molybdenum disulfide (MoS_2) with a sulfur vacancy row. We show that the vacancy row introduces a defect state in the band-gap of MoS_2. This state is unoccupied and localized at the vacancy row. We also present detailed analysis of the density of states and charge density of the system. The defect state reduces the band gap of the system to 0.5 eV from 1.8 eV that we obtain for the clean single-layer. In particular, we find Kohn-Sham wave functions that are confined to the defective site are responsible for this particular energy band. We discuss the possible applications of this effect on other physical properties of the system. We also extend the calculations to the case of a MoS_2 on Cu(111) for which experimental observations [1] suggest the presence of structures of the type under discussion here. [1] D. Kim, D. Sun, W. Lu, Z. Cheng, Y. Zhu, D. Le, T. S. Rahman, and L. Bartels, Langmuir 27, 11650 (2011).

4:18PM J6.00010 The Incorporation of C in the Crystal Lattice of Metals; Its Role on the Structure and Properties of these New Materials Called Covetics[1] , LOURDES SALAMANCA-RIBA, ROMAINE ISAACS, University of Maryland, DAVID FORREST, AZZAM MANSOUR, NSWC, ANDREW HERZING, NIST, MELBURNE LEMIEUX, Stanford University, JASON SHUGART, Third Millennium Metals, LLC — Nanocarbon has been successfully incorporated in molten metals and metal alloys using a new method of manufacturing in which the molten metal (or metal alloy) acts as ionizing medium causing nanocarbon structures to form in-situ. C in concentrations up to ∼10% weight was incorporated in Ag, Al and Cu. The bonding between the carbon and the metal is very strong and persists after re-melting and resolidification. These materials, called "covetics," show improved properties over those of the host metal. For example, the thermal conductivity of Cu covetic is higher than pure Cu. The electrical conductivity of Al covetic is higher than for pure Al. The yield strength of Al and Cu covetics is higher than the pure metals. We have used X-ray diffraction, X-ray photoelectron spectroscopy, and Raman spectroscopy to investigate the incorporation of C in the metal. Scanning and transmission electron microscopy (TEM) were also employed along with energy dispersive X-ray spectroscopy and electron energy loss spectroscopy (EELS). The nanocarbons in the covetics are in the form of, graphene nanoribbons, and amorphous nanocarbon, and all are bonded to the metal. The C-K edge in the EELS, and the Raman spectra from these samples show signals characteristic of graphitic sp2 bonding.

4:30PM J6.00011 Tuning Valley Magnetic Moment in Bilayer MoS2 via Symmetry Control[1] , SANFENG WU, Department of Physics, University of Washington, JASON ROSS, University of Washington, GUI-BIN LIU, The Univerity of Hong Kong, GRANT AIVAZIAN, AARON JONES, ZAIYAO FEI, University of Washington, WENGUANG ZHU, Oak Ridge National Lab, DI XIAO, Carnegie Mellon University, WANG YAO, The University of Hong Kong, DAVID COBDEN, Univeristy of Washington, XIAODONG XU, University of Washington — Monolayer MoS2 provides the opportunity to explore the coupled spin-valley physics arising from broken inversion symmetry. Although inversion symmetry is present in pristine bilayer MoS2, it can be broken by applying a perpendicular electric field. It offers the remarkable possibility of switching on/off and continuously tuning the physical properties of the Dirac valleys, such as valley magnetic moment and Berry curvature, by reversible electrical control. In this work, we employ polarization-resolved photoluminescence (PL) to investigate this effect using bilayer and monolayer MoS2 field effect transistors. We find that in bilayer MoS2 the circularly polarized PL can be continuously tuned from -15% to 15% as a function of gate voltage, whereas in structurally non-centrosymmetric monolayer MoS2 the PL polarization is gate-independent. The observations are well explained as resulting from the continuous variation of orbital magnetic moments between positive and negative values via symmetry control.

4:42PM J6.00012 Electrical tunability and optical control of valley and spin in WSe2[1] , AARON JONES, University of Washington, HONGYI YU, University of Hong Kong, NIRMAL GHIMIRE, Oak Ridge National Laboratory, BO ZHAO, SANFENG WU, GRANT AIVAZIAN, JASON ROSS, University of Washington, GUIBIN LIU, University of Hong Kong, JIAQIANG YAN, DAVID MANDRUS, Oak Ridge National Laboratory, WANG YAO, University of Hong Kong, DI XIAO, Carnegie Mellon University, XIAODONG XU, University of Washington — Monolayer group VI transition metal dichalcogenides have enormous potential for use in nano- and optoelectronic applications due to their reduced dimensionality and direct bandgap in the visible wavelength range. Their hexagonal structure is graphene-like, but with strong spin-orbit coupling effects. The interesting coupled spin-valley physics has been investigated both theoretically and experimentally based on the single particle picture. Here we investigate the physical properties of valley excitons in monolayer field effect transistor devices via photoluminescence measurements. By tuning the chemical potential to control exciton species, we are able to investigate the optical selection rules, photo-excitation energy dependence, and temperature dependence of individual excitons. These studies reveal the fine structures of valley excitons due to the electron-electron interactions, electron-phonon interactions, and coupled spin-valley degrees of freedom, which are important for the potential application of valleytronics/spintronics based on monolayer semiconductors.

4:54PM J6.00013 Electronic Properties of Few-layer Black Phosphorus , LIKAI LI, YIJUN YU, State Key Laboratory of Surface Physics and Department of Physics, Fudan University, G.J. YE, X.H. CHEN, Hefei National laboratory for Physical Science at Microscale and Department of Physics, University of Science and Technology of China, YUANBO ZHANG, State Key Laboratory of Surface Physics and Department of Physics, Fudan University — Black phosphorus is a layered allotropy of phosphorus that closely resembles graphite. In a single atomic layer, phosphorus atoms are covalently bonded into a puckered honey comb structure. All five valence electrons are localized, so unlike graphene monolayer black phosphorus is a semiconductor with a band gap of ~ 2 eV. In a bulk crystal the interlayer coupling reduces the band gap to ~ 0.3 eV. Using mechanical exfoliation method, we have successfully fabricated few layer black phosphorus field effect transistors. Our samples exhibit bipolar behavior with on-off ratio up to 10^6, and a low off-state current. Electronic mobilities up to ~ 1000 $cm^2V^{-1}s^{-1}$ are currently achieved, with possibilities for further improvement. Such characteristics make black phosphorus a potential candidate for future nanoelectronic applications.

5:06PM J6.00014 Bilayer Silicene: a first principles investigation[1] , RENATO BORGES PONTES, Federal University of Goiás, JOSÉ EDUARDO PADILHA, ALDABERTO FAZZIO, ANTÔNIO J.R. DA SILVA, University of São Paulo — By performing ab-initio total energy calculations we study the structural and electronic properties of a silicene bilayer. We show that the lowest energy configuration, contrary to the Bernal stacking of graphene, is when two silicene sheets are placed exactly one on top of the other. In this configuration, there is an energy gain if the system loses its π cloud to create extra (σ-like) chemical bonds between the two layers. To minimize the total energy and the forces that arise due to these new connections made between the layers, the system increases the lattice constant, becoming planar and, consequently, loosing its buckled structure. Moreover, the bilayer of silicene on this planar configuration is a metal and it is insensitive to the presence of an applied external electrical field, a behaviour different from the single layer. We also discuss the role played by the unoccupied 3d-orbital of the silicon in the formation of this new structure. Theoretical STM calculations show excellent agreement with experimental images of silicene bilayers.

Tuesday, March 19, 2013 2:30PM - 5:30PM –

Session J7 DMP: Focus Session: Graphene Devices VI 303 - Roman Gorbachev, University of Manchester

2:30PM J7.00001 Effects of optical and surface polar phonons on the optical conductivity of doped graphene , VASILI PEREBEINOS, IBM - Watson, BENEDIKT SCHARF, JAROSLAV FABIAN, Institute for Theoretical Physics, University of Regensburg, Germany, PHAEDON AVOURIS, IBM - Watson — During the past decade, graphene has attracted immense interest, mainly due to its excellent transport and optical properties, which make it an attractive candidate for possible applications in nanoscale electronics and optoelectronics. Using the Kubo linear response formalism, we study the effects of intrinsic graphene optical and surface polar phonons (SPPs) on the optical conductivity of doped graphene. We find that inelastic electron-phonon scattering contributes significantly to the phonon-assisted absorption in the optical gap. At room temperature, this midgap absorption can be as large as about 20-25% of the universal ac conductivity for graphene on polar substrates (such as Al_2O_3 or HfO_2) due to strong electron-SPP coupling. The midgap absorption, moreover, strongly depends on the substrates and doping levels used. We predict that with increasing temperature, the midgap absorption increases, while the Drude weight decreases. These predictions can serve as an experimental signature for the role of SPPs on transport and optical properties of graphene, which have important implications for the performance of graphene-based electronic devices and broadband modulators.

2:42PM J7.00002 Electrically detected spin resonance in epitaxial graphene[1] , RAMESH MANI, Georgia State University, JOHN HANKINSON, Georgia Institute of Technology, CLAIRE BERGER, Georgia Institute of Technology and CNRS, Institut Neel, Grenoble, WALTER DE HEER, Georgia Institute of Technology — Graphene is an appealing material for electron-spin quantum computing (QC) and spintronics, due to the expected weak spin-orbit interaction, and the scarcity of nuclear spin in natural carbon. Due to QC and spintronics, the microwave control and electrical detection of spin have become topics of interest, now in graphene nanostructures, where the small number of spins limits the utility of traditional spin resonance. Here, we report results of an experimental study examining the microwave response of epitaxial graphene.[1] The results suggest the possibility of resistive detection of spin resonance, and they provide a measurement of the g-factor and the spin relaxation time in this novel system.

2:54PM J7.00003 Growth, fabrication, and applications of graphene nanostructures , GUANGYU ZHANG, Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China — Recently, a broad category of research focused on graphene nanostructures, including graphene nanosheets and nanoribbons. These graphene nanostructures have unique properties related to their sizes, shapes, and edge configurations and might be used as building blocks for various miniaturized graphene-based devices. Large-are growth and scaled-up fabrication of high-quality graphene nanostructures are challenging. In this talk, I will introduce our recent progress on grow large area nanographene directly on substrates and scaled-up fabrication of graphene nanoribbons with controlled width and edge configurations (zigzag edges). Electronic and optical spectroscopy studies on the zigzag-edged graphene nanoribbons yield the experimentally observed metallic edge states and electron-phonon coupling effect. Nanographene-based piezoresistive strain sensors and resistive randomly accessed memories will also be introduced.

3:06PM J7.00004 Toward Graphene-Based Microwave Photon Counter , KIN CHUNG FONG, California Institute of Technology — Graphene is a material with remarkable electronic properties. However, the thermal properties of this two-dimensional Dirac Fermions, that determine the characteristics of photo detectors, plasmonic devices, and bolometers, are less explored. Here, we present our measurement of specific heat capacity, Wiedemann-Franz (WF), and electron-phonon (e-ph) thermal conductance from 0.3 to 100 K using the novel single layer graphene bolometer [1]. These measurements suggest that graphene-based devices can generate substantial advances in the areas of ultra-sensitive bolometry, calorimetry, microwave, and terahertz single photon detection for applications in areas such as observational astronomy, quantum information and measurement. The physics of the e-ph coupling and the possible violation of Wiedemann-Franz Law near the charge neutrality point in single layer graphene will be discussed.

This work is a collaboration with Emma Wollman, Harish Ravi, and K. C. Schwab of Caltech. This work has been supported by the FCRP Center on Functional Engineering Nano Architectonics (FENA) and U.S. NSF Contract No. (DMR-0804567).

3:42PM J7.00005 Photovoltaic response time in dual-gated bilayer graphene , M.-H. KIM, Center for Nanophysics and Advanced Materials(CNAM)-University of Maryland(UMD), J. YAN, Dept. of Physics, University of Massachusetts, Amherst, R.J. SUESS, T. MURPHY, Inst. for Research in Electronics and Applied Physics-UMD, M.S. FUHRER, H.D. DREW, CNAM-UMD — The intrinsic thermal response timescale of bilayer graphene is sub nanosecond, due to cooling of hot electrons mediated by acoustic phonon emission. We compare the response times of the photovoltaic and bolometric response as a function of temperature and dual-gate voltages in a gapped bilayer graphene device using a pulse coincidence technique at 1.5 μm. We find that the photovoltaic and bolometric response time are identical and vary from 100 ps to 10 ps for temperatures from 3 K to 100 K. This result shows that the near IR photovoltaic response of bilayer graphene is thermal over this temperature range. This work was supported by IARPA, the ONR MURI program, and the NSF (grants DMR-0804976 and DMR-1105224), and in part by the NSF MRSEC (grant DMR-0520471).

3:54PM J7.00006 Graphene-Superconductor hybrid device as Bolometer , HELI VORA, NAOMI MIZUNO, PIRANAVAN KUMARAVADIVEL, BENT NIELSEN, XU DU, Department of Physics and Astronomy, Stony Brook University — Low electronic heat capacity and small achievable volume has made graphene a promising candidate for a fast and sensitive bolometric detector. In our device scheme, in addition to low electron-phonon coupling we can further limit out-diffusion of hot electrons from graphene into the leads by placing tunnel-type superconducting contacts on graphene and preventing tunneling through the oxide barrier into the superconducting gap. We fabricate NbN contacts on graphene with a sandwich layer of titanium oxide tunnel barrier. Due to high dielectric constant of titanium oxide, our design allows device impedance matching with the antenna circuitry at THz frequencies, necessary to achieve practical device efficiency. We present our measurements of bolometric characteristics of thermal conductance, Noise equivalent Power (NEP) and responsivity for such a device.

4:06PM J7.00007 Temporal characterization of hot-electron thermoelectric effect in monolayer graphene devices[1] , RYAN J. SUESS, Inst. for Research in Electronics and Applied Physics (IREAP)-University of Maryland (UMD), XINGHAN CAI, Center for Nanophysics and Advanced Materials (CNAM)-UMD, ANDREI SUSHKOV, GREG JENKINS, M.-H. KIM, CNAM-UMD, JUN YAN, Dept. of Physics, University of Mass.-Amherst, H. DENNIS DREW, CNAM-UMD, THOMAS E. MURPHY, IREAP-UMD, MICHAEL S. FUHRER, CNAM-UMD — Graphene's unique electronic and optical properties have made it an attractive candidate material for photonics applications such as broadband optical detection. We report the temporal response of a monolayer graphene device with dissimilar metal electrodes in which optically induced hot-electrons are detected via a thermoelectric voltage induced between the electrodes. Measurements are carried out with a pulsed laser system (60 fs pulse width) at the telecom wavelength of 1.5 μm using an asynchronous optical sampling pulse coincidence technique. Graphene's weak electron-phonon coupling and our compact device geometry (comparable to the thermal diffusion length) result in a fast 10 - 20 ps non-linear thermal response that is nearly independent of temperature over the measured range of 15 - 150 K. Sensitivity of the devices response to optical power will also be discussed. These results are a follow-on to other talks reported by our group at this conference in which the fabrication, operating principal, and broad wavelength (THz to near IR) response of the graphene-based hot-electron bolometer are described.

[1]Supported by IARPA and ONR-MURI

4:18PM J7.00008 Sensitive bolometry using hot-electron thermoelectric effect in graphene devices[1] , XINGHAN CAI, Center for Nanophysics and Advanced Materials (CNAM)-University of Maryland (UMD), RYAN J. SUESS, Inst. for Research in Electronics and Applied Physics (IREAP)-UMD, ANDREI SUSHKOV, GREG JENKINS, M.-H. KIM, CNAM-UMD, JUN YAN, Dept. of Physics, University of Mass.-Amherst, H. DENNIS DREW, CNAM-UMD, THOMAS E. MURPHY, IREAP-UMD, MICHAEL S. FUHRER, CNAM-UMD — Due to the weak electron-phonon coupling and strong electron-electron interaction in graphene, the hot-electron thermoelectric effect provides a highly sensitive detection mechanism for heat absorbed in the electronic system, either by radiation or Joule heating. We have fabricated graphene devices using mechanically exfoliated single layer graphene contacted by two dissimilar metal electrodes (chromium and gold) in order to generate an asymmetry in the device and a net thermoelectric response to heating. We measure the thermoelectric response to Joule heating by an AC 2^{nd} harmonic method, and compare to the thermoelectric response due to optical excitation in the near infrared and at THz frequencies. We find a sensitivity exceeding 100 V/W at room temperature. We also demonstrate that the sensitivity can be significantly enhanced by patterning the graphene sheet into nanoribbon arrays. The transport measurements indicate that graphene is a promising candidate for sensitive broadband photo detectors at room temperature. Related work by our group showing that ultra-broadband detection of light can be realized in such devices will be presented in other talks at this meeting.

[1]Supported by IARPA and ONR-MURI

4:30PM J7.00009 Large-scale 2D Electronics based on Single-layer MoS2[1] , HAN WANG, LILI YU, YI-HSIEN LEE, WENJING FANG, ALLEN HSU, PATRICK HERRING, Massachusetts Institute of Technology, MATTHEW CHIN, Army Research Laboratory, MADAN DUBEY, US Army Research Laboratory, LAIN-JONG LI, Academia Sinica, Taiwan, JING KONG, TOMAS PALACIOS, Massachusetts Institute of Technology — 2D nanoelectronics based on MoS2 and other transition metal dichalcogenides (TMD) materials are attractive as high-mobility options in the emerging field of large-area low-cost electronics that is currently dominated by low-mobility amorphous silicon and organic semiconductors. Single-layer MoS2 can also complement graphene to build flexible digital and mixed-signal circuits, overcoming its lack of bandgap while still sharing many of graphene's excellent mechanical and thermal properties. This paper addresses several key challenges in the development of 2D nanoelectronics on MoS2 and TMD materials in general. First, large-area single-layer MoS2 material is grown by chemical vapor deposition (CVD) that makes the wafer-scale fabrication of MoS2 devices and circuits possible for the first time. Second, the top-gated transistors, fabricated for the first time on single-layer MoS2 grown by CVD, show multiple state-of-the-art characteristics, such as high mobility, ultra-high on/off current ratio, record current density and current saturation. Finally, key circuit building blocks for digital and analog electronics such as inverter, NAND gate, memory and ring oscillator are demonstrated for the first time.

[1]This work has been partially funded by the ONR Young Investigator Program and the Army Research Laboratory.

4:42PM J7.00010 Band-like transport in high mobility single-layer MoS_2 FETs , DEEP JARIWALA, VINOD SANGWAN, JAMES JOHNS, DATTATRAY LATE, KEN EVERAERTS, JULIAN MCMORROW, LINCOLN LAUHON, VINAYAK DRAVID, Department of Materials Science and Engineering, Northwestern University, TOBIN MARKS, Department of Chemistry and Materials Science and Engineering, Northwestern University, MARK HERSAM, Department of Materials Science and Engineering, Chemistry and Medicine, Northwestern University — The recent realization of monolayered MoS_2 as a direct band gap two-dimensional semiconductor in contrast to zero gap graphene, has attracted significant attention for digital electronic applications. In most measurements to date, single-layer MoS_2 field-effect transistors (FETs) have shown low field-effect mobility values that have been explained by Mott variable range hopping (VRH) transport. In contrast, here we report variable temperature measurements on high mobility (greater than 50 cm^2/V.s at room temperature) single-layer MoS_2 FETs that show band-like transport with monotonic increase in mobility with decreasing temperature suggesting phonon quenching at low temperatures as also observed for graphene. The magnitude of the drain current remains constant across the range of temperatures (5.7 - 298 K), while the threshold voltage displays a positive shift. In this presentation we emphasize on high quality single-layer MoS_2 FETs with band-like transport and the highest reported field-effect mobility values (120 cm^2/V.s at 5.7 K) in devices without encapsulation in a high-κ dielectric.

4:54PM J7.00011 Wafer-scalable high-performance CVD graphene devices and analog circuits , LI TAO, JONGHO LEE, HUIFENG LI, RICHARD PINER, RODNEY RUOFF, DEJI AKINWANDE, The University of Texas at Austin — Graphene field effect transistors (GFETs) will serve as an essential component for functional modules like amplifier and frequency doublers in analog circuits. The performance of these modules is directly related to the mobility of charge carriers in GFETs, which per this study has been greatly improved. Low-field electrostatic measurements show field mobility values up to 12k cm^2/Vs at ambient conditions with our newly developed scalable CVD graphene. For both hole and electron transport, fabricated GFETs offer substantial amplification for small and large signals at quasi-static frequencies limited only by external capacitances at high-frequencies. GFETs biased at the peak transconductance point featured high small-signal gain with eventual output power compression similar to conventional transistor amplifiers. GFETs operating around the Dirac voltage afforded positive conversion gain for the first time, to our knowledge, in experimental graphene frequency doublers. This work suggests a realistic prospect for high performance linear and non-linear analog circuits based on the unique electron-hole symmetry and fast transport now accessible in wafer-scalable CVD graphene. *Support from NSF CAREER award (ECCS-1150034) and the W. M. Keck Foundation are appreicated.

5:06PM J7.00012 Graphene Field-Effect Transistors with Gigahertz-Frequency Power Gain on Flexible Substrates , NICHOLAS PETRONE, INANC MERIC, KENNETH SHEPARD, JAMES HONE, Columbia University — The development of flexible electronics operating at radio-frequencies (RF) requires materials which combine excellent electronic performance and the ability to withstand high levels of strain. Graphene's unique electronic and mechanical properties make it a promising material for the fabrication of field-effect transistors (FETs) which require both high flexibility and high operating frequencies. Furthermore, large-area films of graphene which display excellent electronic properties, crucial for the commercial realization of graphene-based devices, can be synthesized facilely by chemical vapor deposition (CVD). We utilize CVD graphene to fabricate graphene FETs (GFETs) on flexible substrates. Our GFETs demonstrate unity-current-gain frequencies, f_T, and unity-power-gain frequencies, f_{max}, up to 10.7 and 3.7 GHz, respectively, with strain limits of 1.75%. These devices represent the only reported technology to achieve gigahertz-frequency power gain at strain levels above 0.5%. As such, they demonstrate the potential for CVD graphene to enable a broad range of flexible electronic technologies which require both high-flexibility and RF operation.

5:18PM J7.00013 Optimization of Ferroelectric Polymer\Graphene Films for Transparent and Flexible Electronics , ORHAN KAHYA, JING WU, GUANG-XIN NI, CHEE-TAT TOH, Department of Physics, National University of Singapore, SANG-HOON BAE, JONG-HYUN AHN, SKKU Advanced Institute of Nanotechnology (SAINT), Sungkyunkwan University, BARBAROS OEZYILMAZ, Department of Physics, National University of Singapore — Nonvolatile, electrostatic doping of graphene-based devices with ferroelectric polymers such as Poly (vinylidene fluoride-trifluoroethylene) are promising for realizing ultra-fast, flexible memory devices, nanogenerators and actuators. More recently, the same approach has been shown to provide an alternative route in enabling graphene based transparent electrodes for touch screen applications. Here, we report a systematic study of optimizing the ferroelectric polymer-graphene heterostructure as a function of thickness, various copolymer blends and coating techniques. Optimized films show outstanding mechanical properties, low sheet resistance ($\sim 100\Omega$/sq) and optical transparency levels as high as 96%.

Tuesday, March 19, 2013 2:30PM - 5:30PM –

Session J8 DMP: Focus Session: Graphene: Raman, Strain, Thermal

307 - Jun Yan , University of Massachusetts at Amhearst

2:30PM J8.00001 Identifying Few-Layer Graphene with Raman Spectroscopy , DAVID TRAN, NATHANIEL GILLGREN, KEVIN MYHRO, YONGJIN LEE, JAIRO VELASCO JR., LEI JING, MARC BOCKRATH, JEANIE LAU, University of California, Riverside — Few-layer graphene (FLG) exists in various crystallographic stacking sequences, which can strongly influence the material's electronic properties. We characterize stacking order in FLG using the distinctive features of the Raman 2D-mode's full-width at half-maximum (FWHM), relative peak size, and shape. Raman imaging allows us to visualize directly the spatial distribution of bilayer graphene, Bernal (ABA) trilayer graphene, and rhombohedral (ABC) trilayer graphene.

2:42PM J8.00002 Optical Separation of Mechanical Strain from Charge Doping in Graphene , SUNMIN RYU, JI EUN LEE, GWANGHYUN AHN, Kyung Hee University — Graphene, due to its superior stretchability, exhibits rich structural deformation behaviors and its strain-engineering has proven useful in modifying its electronic and magnetic properties. Despite the strain-sensitivity of the Raman G and 2D modes, the optical characterization of the native strain in graphene on silica substrates has been hampered by excess charges interfering with both modes. Here we show that the effects of strain and charges can be optically separated from each other by correlation analysis of the two modes, enabling simple quantification of both. Graphene with in-plane strain randomly occurring between -0.2% and 0.4% undergoes modest compression (-0.3%) and significant hole doping upon thermal treatments. This study suggests that substrate-mediated mechanical strain is a ubiquitous phenomenon in two-dimensional materials. The proposed analysis will be of great use in characterizing graphene-based materials and devices.

2:54PM J8.00003 Folded Optical Phonons in Twisted Bilayer Graphene: Raman Signature of Graphene Superlattices , YANAN WANG, ZHIHUA SU, Dept of Electrical and Computer Engineering, University of Houston, WEI WU, SIRUI XING, Center for Advanced Materials and Dept of Electrical and Computer Engineering, University of Houston, XIAOXIANG LU, Dept of Electrical and Computer Engineering, University of Houston, XINGHUA LU, Institute of Physics, Chinese Academy of Sciences, China, SHIN-SHEM PEI, Center for Advanced Materials and Dept of Electrical and Computer Engineering, University of Houston, FRANCISCO ROBLES-HERNANDEZ, College of Engineering Technology, University of Houston, VIKTOR HADJIEV, Texas Center for Superconductivity and Dept of Mechanical Engineering, University of Houston, JIMING BAO, Dept of Electrical and Computer Engineering, University of Houston — In contrast to Bernal-stacked graphene exfoliated from HOPG, twisted bilayer graphene are widely observed in the samples prepared by silicon sublimation of SiC or chemical vapor deposition (CVD). However, many of its basic properties still remain unrevealed. In this work, hexagon-shaped bilayer graphene islands synthesized by CVD method were systematically studied using Raman spectroscopy. A series of folded phonons were observed in the range from 1375 cm^{-1} to 1525 cm^{-1}. The frequency of folded phonon modes doesn't shift with laser excitation energy, but it is highly dependent on the rotational angle between two layers. In general, the frequency of folded phonon decreases with the increase of rotation angle. This rotation dependence can be qualitatively explained by the folding of phonon dispersion curve of single layer graphene into the reduced Brillouin zone of bilayer superlattice. The obseravtion of folded phonon is an important indication of superlattice band structure.

3:06PM J8.00004 Large Physisorption Strain in Graphene Grown by Chemical Vapor Deposition on Copper Substrates[1] , RUI HE[2], Department of Physics, University of Northern Iowa — Single layer graphene grown by chemical vapor deposition (CVD) on Cu substrates is subject to non-uniform physisorption strain that is dependent on the orientation of the Cu surface. The blue-shift and broadening of Raman bands of graphene on the Cu single crystal (111) surface reveal that the graphene layer is under compressive strain. This interpretation is consistent with Moire patterns seen in scanning tunneling microscopy. Graphene grown on the Cu (100) surface is subject to a highly non-uniform strain due to the mismatch between the graphene honeycomb lattice and the square lattice at this Cu surface. Molecular Dynamics simulations are in excellent agreement with experiment, predicting compressive strain on the order of 0.5 percent in graphene/Cu(111). In graphene/Cu(100) the simulated physisorption strain patterns show linear superstructures spaced about 1 nm apart and a highly non-uniform bond length distribution which leads to both compressive and tensile strains. CVD graphene grown on polycrystalline Cu foil is also studied for comparison. The strain in graphene is even more non-uniform for growth on Cu foil. However, this strain is greatly reduced after the graphene layer is removed and transferred onto a SiO2 substrate. Physisorption strain is thus revealed to be a major factor in the growth of CVD graphene on transition metals.

3:42PM J8.00005 2D line enhancement by quantum interference in graphene superlattice , ZHIHUA SU, YANAN WANG, Department of Electrical and Computer Engineering, University of Houston, Houston, TX 77204, USA, WEI WU, SIRUI XING, Department of Electrical and Computer Engineering & Center for Advanced Materials, University of Houston, Houston, TX 77204, USA, XIAOXIANG LU, Department of Electrical and Computer Engineering, University of Houston, Houston, TX 77204, USA, XINGHUA LU, Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China, SHIN-SHEM PEI, Department of Electrical and Computer Engineering & Center for Advanced Materials, University of Houston, Houston, TX 77204, USA, FRANCISCO ROBLES-HERNANDEZ, College of Engineering Technology, University of Houston, Houston, TX 77204, USA, VIKTOR G. HADJIEV, Texas Center for Superconductivity and Department of Mechanical Engineering, University of Houston, Houston, TX 77204, USA, JIMING BAO, Department of Electrical and Computer Engineering, University of Houston, Houston, TX 77204, USA — Raman scattering is used to study twisted bilayer graphene synthesized by chemical vapor deposition (CVD) method with rotation angle determined by relative edge misalignment. Degenerate Dirac band of twisted bilayer graphene is revealed by enhanced intensity of 2D line. This Raman signature is systematically studied and found to be correlated with G-line resonance and laser excitation energy. 2D enhancement only happens when the laser excitation energy is smaller than G-line resonance energy, while enhancement ratio increases as laser excitation energy decreases. The anomalous enhancement of 2D intensity is ascribed to the constructive quantum interference between two Raman paths enabled by degenerate Dirac cone.

3:54PM J8.00006 Wrinkling instability in nanoparticle-supported graphene: implications for strain engineering[1] , WILLIAM CULLEN, MAHITO YAMAMOTO, University of Maryland, OLIVIER PIERRE-LOUIS, LPMCN, Universite Claude Bernard Lyon 1, France, JIA HUANG, MICHAEL FUHRER, THEODORE EINSTEIN, University of Maryland — We have carried out a systematic study of the wrinkling instability of graphene membranes supported on SiO_2 substrates with randomly placed silica nanoparticles. At small nanoparticle density, monolayer graphene adheres to the substrate and is highly conformal over the nanoparticles. With increasing nanoparticle density, and decreasing nanoparticle separation to $\sim$100 nm, graphene's elastic response dominates substrate adhesion, and elastic stretching energy is reduced by the formation of wrinkles which connect protrusions. Above a critical nanoparticle density, the wrinkles form a percolating network through the sample. As the graphene membrane is made thicker, delamination from the substrate is observed. Since the wrinkling instability acts to remove inhomogeneous in-plane elastic strains through out-of-plane buckling, our results can be used to place limits on the possible in-plane strain magnitudes that may be created in graphene to realized strain-engineered electronic structures.[2]

4:06PM J8.00007 Graphene slides over the substrate when you pull it: Direct measurement, theory, and frictional forces , ALEXANDER KITT, ZENAN QI, HAROLD PARK, ANNA SWAN, BENNETT GOLDBERG, Boston University — Using graphene sealed cylindrical microchambers we characterize, for the first time, the sliding of graphene over a thermal oxide substrate. High spatially resolved Raman spectra recorded as external pressure is applied to the microchamber shows that as the graphene is pressed into the hole it drags some of the previously substrate-supported graphene with it. The well-understood strain response of the Raman G-band allows us to measure strains of less than .01%, corresponding to 1nm stretching over a micron, with 500 nm lateral resolution as pressure is applied to the system. Our results are compared to both atomistic and continuum models, with interesting new conclusions, of the system in order to quantify the sliding for mono, bi, and tri layer graphenes over holes of radii between 1.25 and 5 μm with applied pressures between 0 and 100 psi.

4:18PM J8.00008 Raman spectroscopy of graphene under strain[1] , HYEONSIK CHEONG, Sogang University — Raman spectroscopy is one of the most widely used characterization tools in graphene research. It has been used to estimate the number of layers, carrier concentration, edge types, thermal conductivity, etc. The effect of strain on the Raman spectrum of graphene is of particular interest, because the modification of the lattice due to strain is directly reflected on the Raman spectrum. Under uniaxial strain, the G and 2D bands of the Raman spectrum of single-layer graphene split due to the breaking of symmetry. From the polarization dependence of the split bands, one can determine the crystallographic orientation of the graphene sample. Furthermore, the splitting of the 2D band depends on the direction of the applied strain with respect to the crystallographic orientation, which provides critical information on the dominant scattering process responsible for this band. Bilayer graphene under uniaxial strain exhibits similar effects on the G and 2D bands, although the effect on the 2D band is rather complicated as each of the 4 components comprising the 2D band splits under strain. One can also estimate the thermal expansion coefficient and Young's modulus using Raman measurements under strain. Recent experimental results will be presented.

[1]Supported by the NRF grants funded by the Korean government (MEST).

4:54PM J8.00009 Experimental Measurement of Thermal Expansion Coefficient of few layer graphene , LEI JING, university of califorina, riverside, WENZHONG BAO, University of Maryland, College Park, HOON CHO, FENGLIN WANG, CHUN NING(JEANIE) LAU, university of califorina, riverside — In contrast to most materials, graphene has negative thermal expansion coefficient (TEC), which has important implications on device applications. We experimentally measure the TEC of single- and few-layer graphene by suspending them across predefined trenches, and monitoring their sagging arc lengths during cooling via in situ SEM imaging. Latest experimental data will be discussed and compared to theoretical models.

5:06PM J8.00010 Lengthy logarithms and graphene's Debye-Waller factor[1] , B.C. REGAN, BRIAN SHEVITSKI, WILLIAM A. HUBBARD, E.R. WHITE, UCLA Department of Physics and Astronomy & CNSI, BEN DAWSON, M.S. LODGE, MASA ISHIGAMI, UCF Department of Physics & NTC, MATTHEW MECKLENBURG, UCLA Department of Physics and Astronomy & CNSI — In an infinite, two-dimensional crystal, long wavelength thermal phonons create a divergence in the mean-square displacement u_p^2 of atoms from their ideal lattice positions, which has led some to infer that the existence of graphene might depend on the stabilizing influence of ripples in the third dimension. Using the Debye model to approximate graphene's phonon band structure, we calculate u_p^2 and the resulting Debye-Waller suppression of high order peaks in graphene's electron diffraction pattern. We find that at room temperature in a 10 μm sample $\sqrt{u_p^2}$ is less than 5% of the carbon-carbon bond length, well below the Lindemann melting threshold. Our TEM measurements of the Debye-Waller factor in suspended, exfoliated graphene agree with the calculation. Finite size effects are sufficient to explain graphene's evident stability at room temperature. Surprisingly, in the case of graphene even 6×10^{23} carbon atoms, representing a sheet 126 m on a side, are not enough to approximate an infinitely large crystal.

[1]Supported by NSF DMR-1206849

5:18PM J8.00011 In-Situ Thermal Mapping of Graphene via TEM Measurement of the Debye-Waller Factor[1] , WILLIAM A. HUBBARD, MATTHEW MECKLENBURG, B.C. REGAN, UCLA Department of Physics and Astronomy — Thermal motion of the constituent atoms attenuates high-order peaks in a crystal's electron diffraction pattern. Using TEM we measure this attenuation, parameterized by a Debye-Waller factor, in single-layer cleaved graphene that is Joule-heated *in situ*. We find that the Debye-Waller factor, as probed with selected area electron diffraction, provides a reliable measure of the local temperature and thus allows for quantitative thermal mapping on the nanoscale.

Session J9 DCOMP: Invited Session: Computational Physics at the Bleeding Edge: To Exascale and Beyond

308 - Timothy Germann, Los Alamos National Laboratory

2:30PM J9.00001 Intricacies of modern supercomputing illustrated with recent advances in simulations of strongly correlated electron systems , THOMAS C. SCHULTHESS, Institute for Theoretical Physics, ETH Zurich — The continued thousand-fold improvement in sustained application performance per decade on modern supercomputers keeps opening new opportunities for scientific simulations. But supercomputers have become very complex machines, built with thousands or tens of thousands of complex nodes consisting of multiple CPU cores or, most recently, a combination of CPU and GPU processors. Efficient simulations on such high-end computing systems require tailored algorithms that optimally map numerical methods to particular architectures. These intricacies will be illustrated with simulations of strongly correlated electron systems, where the development of quantum cluster methods, Monte Carlo techniques, as well as their optimal implementation by means of algorithms with improved data locality and high arithmetic density have gone hand in hand with evolving computer architectures. The present work would not have been possible without continued access to computing resources at the National Center for Computational Science of Oak Ridge National Laboratory, which is funded by the Facilities Division of the Office of Advanced Scientific Computing Research, and the Swiss National Supercomputing Center (CSCS) that is funded by ETH Zurich.

3:06PM J9.00002 Seeking a sustainable approach for computational science[1] , ROBERT HARRISON, Institute for Advanced Scientific Computing, Stony Brook University — Many are now questioning whether our current approaches to developing software for science and engineering are sustainable. In particular, can we deliver to society and the nation the full benefits expected from high-performance simulation at the peta and exascales? Or is innovative science being stifled by the increasing complexities of all aspects of our problem space (rapidly changing hardware, software, multidisciplinary physics, etc.)? Focusing on applications in chemistry and materials science, and motivated by the co-design of exascale hardware and software, I will discuss many of these issues including how chemistry has already been forced to adopt solutions that differ quite sharply to those in the mainstream, and how these solutions position us well for the technology transitions now under way. Radical changes in how we compute, going all the way back to the underlying numerical representation and algorithms used for the simulation, also promise great enhancements to both developer productivity and the accuracy of simulations.

3:42PM J9.00003 Nicholas Metropolis Award for Outstanding Doctoral Thesis Work in Computational Physics Lecture: The Janus computer, a new window into spin-glass physics , DAVID YLLANES, La Sapienza Università di Roma — Spin glasses are a longstanding model for the sluggish dynamics that appears at the glass transition. They enjoy a privileged status in this context, as they provide the simplest model system both for theoretical and experimental studies of glassy dynamics. However, in spite of forty years of intensive investigation, spin glasses still pose a formidable challenge to theoretical, computational and experimental physics. The main difficulty lies in their incredibly slow dynamics. A recent breakthrough has been made possible by our custom-built computer, Janus, designed and built in a collaboration formed by five universities in Spain and Italy. By employing a purpose-driven architecture, capable of fully exploiting the parallelization possibilities intrinsic to these simulations, Janus outperforms conventional computers by several orders of magnitude. After a brief introduction to spin glasses, the talk will focus on the new physics unearthed by Janus. In particular, we recall our numerical study of the nonequilibrium dynamics of the Edwards-Anderson Ising Spin Glass, for a time that spans eleven orders of magnitude, thus approaching the experimentally relevant scale (i.e. seconds). We have also studied the equilibrium properties of the spin-glass phase, with an emphasis on the quantitative matching between non-equilibrium and equilibrium correlation functions, through a time-length dictionary. Last but not least, we have clarified the existence of a glass transition in the presence of a magnetic field for a finite-range spin glass (the so-called de Almeida-Thouless line). We will finally mention some of the currently ongoing work of the collaboration, such as the characterization of the non-equilibrium dynamics in a magnetic field and the existence of a statics-dynamics dictionary in these conditions.

4:18PM J9.00004 Programming for 1.6 Millon cores: Early experiences with IBM's BG/Q SMP architecture[1] , JAMES GLOSLI, Lawrence Livermore National Laboratory — With the stall in clock cycle improvements a decade ago, the drive for computational performance has continues along a path of increasing core counts on a processor. The multi-core evolution has been expressed in both a symmetric multi processor (SMP) architecture and cpu/GPU architecture. Debates rage in the high performance computing (HPC) community which architecture best serves HPC. In this talk I will not attempt to resolve that debate but perhaps fuel it. I will discuss the experience of exploiting Sequoia, a 98304 node IBM Blue Gene/Q SMP at Lawrence Livermore National Laboratory. The advantages and challenges of leveraging the computational power BG/Q will be detailed through the discussion of two applications. The first application is a Molecular Dynamics code called ddcMD. This is a code developed over the last decade at LLNL and ported to BG/Q. The second application is a cardiac modeling code called Cardioid. This is a code that was recently designed and developed at LLNL to exploit the fine scale parallelism of BG/Q's SMP architecture. Through the lenses of these efforts I'll illustrate the need to rethink how we express and implement our computational approaches.

4:54PM J9.00005 Overcoming Communication Latency Barriers in Massively Parallel Molecular Dynamics Simulations on Anton , RON DROR, D. E. Shaw Research — Strong scaling of scientific applications on parallel architectures is increasingly limited by communication latency. This talk will describe the techniques used to reduce latency and mitigate its effects on performance in Anton, a massively parallel special-purpose machine that accelerates molecular dynamics (MD) simulations by orders of magnitude compared with the previous state of the art. Achieving this speedup required both specialized hardware mechanisms and a restructuring of the application software to reduce network latency, sender and receiver overhead, and synchronization costs. Key elements of Anton's approach, in addition to tightly integrated communication hardware, include formulating data transfer in terms of counted remote writes and leveraging fine-grained communication. Anton delivers end-to-end inter-node latency significantly lower than any other large-scale parallel machine, and the total critical-path communication time for an Anton MD simulation is less than 3% that of the next-fastest MD platform.

Tuesday, March 19, 2013 2:30PM - 4:54PM –

Session J10 COM: Invited Session: Fostering Collaborations in Minority-Serving Institutions

309 - Joseph Barranco, San Francisco State University

2:30PM J10.00001 Pipeline and Research Collaborations with MSIs , CHARLES WEATHERFORD, Physics Department, Florida A&M University — I am a Physics faculty member at an HBCU (Historically Black College/University). I am currently the chairperson of physics at Florida A&M University and have occupied this position for seventeen of the last twenty-three years. I am very supportive of MSIs in general but my experience has been at an HBCU and thus my statements are mostly directed at interactions with HBCUs. My remarks are directed towards facilitating pipeline and research collaborations between MSIs (minority-serving institutions) and majority research universities, government scientific laboratories and agencies, and industry (majority collaborating institutions–MCIs). I will make some generally applicable statements about what I consider are prerequisites for the MSIs and the MCIs needed to establish effective collaborations. I will then make several distinctions which are specific to HBCUs.

3:06PM J10.00002 The Center for Gravitational Wave Astronomy at UTB[1] , MARIO DIAZ, The University of Texas at Brownsville — In this talk I will succinctly describe the first ten years of research and educational activity at the Center for Gravitational Wave Astronomy at The University of Texas at Brownsville as a potential model for fostering collaborations between minority serving institutions and major research institutions in the USA.

[1]The author acknowledges support from NASA grant NNX09AV06A and from NSF grant HRD1242090.

3:42PM J10.00003 Successful strategies for building thriving undergraduate physics programs at minority serving institutions , QUINTON WILLIAMS, Jackson State University — After having been pulled back from the brink of academic program deletion, Jackson State University (Jackson, Mississippi) is now the only HBCU (Historically Black College and University) listed as a top producer of B.S. degrees earned by African Americans in both fields of physics and geoscience. Very pragmatic, strategic actions were taken to enhance the undergraduate degree program which resulted in it becoming one of the most productive academic units at the university. Successful strategies will be shared for growing the enrollment of physics majors, building productive research/educational programs, and improving the academic performance of underprepared students. Despite myriad challenges faced by programs at minority serving institutions in a highly competitive 21st century higher education system, it is still possible for undergraduate physics programs to transition from surviving to thriving.

4:18PM J10.00004 A Perspective on the Intersection of Institutional Identity and Collaborative Research: Toward More Effective Partnering With Historically Black Colleges and Universities (HBCUs) , JOHN HARKLESS, Department of Chemistry, Howard University — Science departments at historically black colleges and universities (HBCUs) play important roles in providing quality education in a distinctive environment. The presenter is an HBCU alumnus who earned his doctorate from a primarily majority institution (PMI) and has had experience as both PMI and HBCU faculty. This experience frames and informs the observations shared in this presentation about the unique challenges and opportunities across an array of HBCU departments. Resources available, demographics impacted, current challenges, and the value of the institution to students, external partners, and the community-at-large will be discussed, with a focus on development of dialogue on the cultural and collaborative competencies necessary to working across institutional types.

Tuesday, March 19, 2013 2:30PM - 5:18PM –

Session J11 DPOLY: Dillon Medal Symposium 310 - Arun Yethiraj, University of Wisconsin

2:30PM J11.00001 John H. Dillon Medal Lecture: Molecular Heterogeneity in Block Copolymer Self-Assembly , MAHESH MAHANTHAPPA, Department of Chemistry, University of Wisconsin-Madison — Narrow molecular weight dispersity in block copolymers has long been considered necessary for well-defined, periodic structure formation, by analogy to various crystallization processes. Consequently, much attention has focused on narrow dispersity copolymers derived from controlled and "living" polymerization techniques. However, these methods restrict the palette of functional monomers amenable to block copolymerization, thus constraining the physical and chemical properties of the resulting materials. New polymer syntheses enable access to a "Pandora's Box" of block copolymers with unusual chemical functionalities and useful physical properties, at the expense of introducing significant segmental dispersities into the resulting copolymers. The development and use of these functional materials requires basic understanding of the physical implications of continuous segmental dispersity on block copolymer phase behavior. Our work aims to understand the physical principles underlying polydisperse ABA-type triblock copolymer self-assembly, in order to transform segmental dispersity into a predictable and useful tool for manipulating block copolymer morphology. We have systematically demonstrated that mid-segment dispersity in ABA triblock copolymers does not preclude the formation of classical, structurally periodic, microphase separated morphologies. Mid-segment dispersity instead shifts the locations of the composition-dependent phase windows, dilates the microdomains, and unexpectedly stabilizes the microphase separated ABA triblock copolymer melts. Studies of three different polydisperse copolymer systems have provided general insights into the consequences of chain length heterogeneity on block copolymer self-assembly.

3:06PM J11.00002 Sphere Forming SISO Tetrablock Terpolymers , FRANK BATES, JINGWEN ZHANG, SANGWOO LEE, University of Minnesota — A series of poly(styrene-*b*-isoprene-*b*-styrene-*b*-ethylene oxide) (SISO) tetrablock terpolymers was synthesized using anionic polymerization methods and investigated for melt morphology by synchrotron small-angle x-ray scattering (SAXS), electron microscopy and dynamic mechanical spectroscopy. Thermodynamic incompatibility between the I and O blocks, relative to that characterizing S and I and S and O leads to the formation of spherical domains containing an O core surrounded by a S rich shell embedded in a matrix of mixed S and I. Varying the composition and relative length of the internal and terminal S blocks resulted in five distinct states of ordering, including two cubic (Im3m and Pm3n symmetry), a hexagonal (p6/mm), a tetragonal ($P4_2/mnm$) and a quasicrystalline (dodecagonal) phase. These results demonstrate the concept of decoupling domain geometry from domain packing in multiblock polymers.

3:18PM J11.00003 What do we understand about equilibrium in block polymer micelles? , TIMOTHY LODGE, University of Minnesota — The factors that dictate the choice of micellar morphology - sphere, worm, or vesicle - are generally well known. In contrast, the pathways by which micelles reach equilibrium (either in terms of morphology or aggregation number), are not. Even as simple a question as "How does the critical micelle concentration depend on chain length?" does not have a clear answer. The current situation will be summarized, in light of recent experimental results.

3:30PM J11.00004 Melt and Solid-State Structures of Polydisperse Polyolefin Block Copolymers[1] , RICHARD REGISTER, SHENG LI, Princeton University — Recent developments in coordinative chain transfer polymerization have enabled the synthesis of ethylene-co-octene block copolymers, where the blocks are either crystallizable (an ethylene-co-octene random copolymer block with low octene content) or amorphous (analogous block with high octene content). With a suitable choice of catalyst type(s) and reactor train configuration, accessible chain architectures include diblock, where each block ideally has the most-probable distribution of chain lengths, and multiblock, where both the individual blocks and the number of blocks per chain follow the most-probable distribution. With a sufficiently large interblock octene differential, block copolymers of both architectures, containing roughly equal masses of the two types of block, self-assemble in the melt into well-ordered lamellar structures, despite the large polydispersity. Interblock mixing, induced by the modest Flory interaction parameter and the broad distribution of block lengths, yields an enormous domain spacing ($>$ 100 nm) despite the relatively low average block molecular weights ($<$ 50 kg/mol). Extensive interblock mixing also allows the polyethylene crystals to grow freely and nearly isotropically across the domain interfaces, while preserving the domain structure present in the melt; in the solid state, the optical and x-ray contrasts between dissimilar domains are greatly enhanced due to their different levels of crystallinity. (Work conducted in collaboration with Jeffrey Weinhold, Philip Hustad, and Brian Landes of Dow Chemical Core R&D.)

[1]Support from the NSF Polymers Program (DMR-1003942).

3:42PM J11.00005 Effects of molecular architecture and degree of hydration on the structure and properties of electrostatically self-assembled block copolymers[1] , MATTHEW TIRRELL, University of Chicago, DANIEL KROGSTAD, NATHANIEL LYND, JASON SPRUELL, SOO-HYUNG CHOI, CRAIG HAWKER, EDWARD KRAMER, University of California, Santa Barbara — Mixtures of water-soluble block copolymers, with one neutral block and the other blocks(s) either positively or negatively charged, are known to form micelles in water with micellar cross that are formed from polyelectrolyte complexes. At sufficiently high total polymer concentrations, such micellar suspensions undergo a disorder-order transition to a bcc structure. This typically occurs between 10 to 15% polymer concentration. In this work, we present new data comparing the behavior of diblock copolymers and triblock copolymers. Initial results suggest that very similar final structures are formed in the two systems, when the diblock is just one of two symmetrical halves of the triblock. Kinetically, diblocks assemble much more rapidly and exhibit different rheological properties from triblocks. We are also investigating the structures formed and properties developed when these systems are dehydrated to less than 50% water content.

[1]Use of the Advanced Photon Source, an Office of Science User Facility operated for the U.S. Department of Energy (DOE) Office of Science by Argonne National Laboratory, was supported by the U.S. DOE under Contract No. DE-AC02-06CH11357.

3:54PM J11.00006 Probing Nanoparticle Correlations in Filled Elastomers during Tensile Deformation by SAXS , EDWARD J. KRAMER, ARTHUR K. SCHOLZ, UCSB, ALEXANDER HEXEMER, LBL, HUAN ZHANG, COSTANTINO CRETON, ESPCI-ParisTech — The 2D SAXS pattern from an unstrained 20 wt% nanosilica-filled and crosslinked siloxane elastomer is isotropic and monotonically decreasing with scattering vector q, revealing a fractal aggregate structure of primary silica particles about 10 nm in radius. Under tensile strain along z, the invariant of the SAXS pattern, corrected for the change in sample thickness, is constant, demonstrating the absence of nanovoiding but the pattern itself shows a "2 bar" enhancement of intensity along z at q* = $2\pi/\langle z\rangle$. The distance $\langle z\rangle$ and peak intensity Ip of the 2 bar pattern increase roughly linearly with extension ratio λ until $\lambda \sim 3$ with $\langle z\rangle$ saturating and Ip decreasing at higher λs. Reverse Monte Carlo simulations of particle redistribution suggest that the silica aggregates separate into short rafts with compliant polymer in between along z; the extension ratio from $\langle z\rangle$ of the nearly particle free polymer regions nearly matches λ until $\lambda \sim 3$. For $\lambda > 3$ the rafts begin to break up, providing a partial explanation for the strong Mullins effect above $\lambda = 3$ for this filled elastomer.

4:06PM J11.00007 Do thermally activated transitions influence the deformation of polymer glasses? , MARK EDIGER, University of Wisconsin-Madison, HAU-NAN LEE, DuPont, BENJAMIN BENDING, University of Wisconsin-Madison — The availability of large scale computer simulations and new experiments allows fundamental questions about the influence of temperature on polymer glass deformation to be addressed from a microscopic perspective. Some recent simulations indicate that the total mobility induced during polymer glass deformation is a function of strain but independent of the strain rate. This result suggests that thermally activated transitions are not important during deformation which would be inconsistent with many models. We find that the integrated molecular mobility in polystyrene and PMMA glasses during deformation is roughly independent of strain rate. However, the relaxation time distribution narrows with increasing strain rate, indicating that thermally activated processes do play a role.

4:18PM J11.00008 Self-Assembly of Gemini Surfactants , ARUN YETHIRAJ, University of Wisconsin, JAGANNATH MONDAL, Columbia University, MAHESH MAHANTHAPPA, University of Wisconsin — The self-assembly behavior of Gemini (dimeric or twin-tail) dicarboxylate disodium surfactants is studied using molecular dynamics simulations. This gemini architecture, in which two single tailed surfactants are joined through a flexible hydrophobic linker, has been shown to exhibit concentration-dependent aqueous self-assembly into lyotropic phases including hexagonal, gyroid, and lamellar morphologies. Our simulations reproduce the experimentally observed phases at similar amphiphile concentrations in water, including the unusual ability of these surfactants to form gyroid phases over unprecedentedly large amphiphile concentration windows. We demonstrate quanitative agreement between the predicted and experimentally observed domain spacings of these nanostructured materials. Through careful conformation analyses of the surfactant molecules, we show that the gyroid phase is electrostatically stabilized related to the lamellar phase. By starting with a lamellar phase, we show that decreasing the charge on the surfactant headgroups by carboxylate protonation or use of a bulkier tetramethyl ammonium counterion in place of sodium drives the formation of a gyroid phase.

4:30PM J11.00009 Exotic nanoparticles with block copolymer design and solution construction with kinetic control , DARRIN POCHAN, University of Delaware — Kinetic pathways and temporal stabilities of different micelles and nanoscale aggregates have been used to construct exotic nanoparticles in solution. Due to low chain exchange dynamics between block copolymeric micelles and solvent, global thermodynamic equilibrium is extremely difficult, if not impossible, to achieve in block copolymer assembly. However, by taking advantage of this slow kinetic behavior of polymeric micelles in solution, one can purposely produce multicompartment nanoparticles and mulitgeometry nanoparticles by forcing different block copolymers to reside in the same nanoscale structure through kinetic processing. While kinetically trapped in common nanostructures, local phase separation can occur producing compartments. This compartmentalization can be used within common micelle geometries to make complex spheres and cylinders or can be used to make new nanostructures such as multigeometry aggregates (e.g. hybrid cylinder-sphere aggregates, disk-cylinder nanoparticles).

4:42PM J11.00010 Polymer Solar Cell Device Characteristics Are Independent of Vertical Phase Separation in Active Layers , YUEH-LIN LOO, Princeton University — Preferential segregation of organic semiconductor constituents in multicomponent thin-film active layers has long been speculated to affect the characteristics of bulk-heterojunction polymer solar cells. Using soft-contact lamination and delamination schemes – with which we have been able to remove compositionally well characterized polymer thin films, flip them over so as to reverse their composition profiles, and then transfer them onto existing device platforms – we showed unambiguously that the device performance of P3HT:PCBM solar cells are independent of the interfacial segregation characteristics of the active layers. Temperature-dependent single-carrier diode measurements of the organic semiconductor constituents suggest that the origin of this invariance stems from the fact that P3HT comprises a high density of mid-gap states. Hole carriers in these mid-gap states can in turn recombine with electrons at the electron-collecting interface, effectively promoting electron transfer from the cathode to the active layer.

4:54PM J11.00011 Dynamics of Magnetic Field Alignment of Block Copolymers by In-Situ SAXS[1] , CHINEDUM OSUJI, MANESH GOPINADHAN, PAWEL MAJEWSKI, Department of Chemical and Environmental Engineering, Yale University — The use of external fields to direct block copolymer self-assembly is well documented. Magnetic fields offer particular promise due to their space-pervasive nature and the ability to produce arbitrary alignments over truly macroscopic length scales in appropriate systems. We present here the results of in-situ SAXS studies performed using a custom superconducting magnet integrated with lab-scale x-ray scattering instruments. We consider the case of side-chain liquid crystalline diblock copolymers ordering under high magnetic fields. Despite the coincidence of the block copolymer order-disorder transition (ODT) and the LC clearing temperature in these weakly segregated materials, there is no measurable effect of the field on the ODT of the system, up to 6 T. This is in line with estimates based simply on the magnitudes of the relevant energy scales - the free energy of field interaction and the enthalpy of the isotropic-LC transition. We show that the alignment of the system is critically limited by the viscosity of the mesophase such that alignment can only be advanced by residence in a small temperature window near the ODT. This residence produces a weakly aligned system which thereafter transitions to a strongly aligned state on cooling even in the absence of the field.

[1]This work was conducted with support from NSF under DMR-0847534

5:06PM J11.00012 Anion Transport in Hydrated Block Copolymers , NITASH BALSARA, UC Berkeley, GUILLAUME SUDRE, LBNL, SEBNEM INCEOGLU, UC Berkeley — Polystyrene-block-polychloromethylstyrene (PS-b-PCMS) copolymers, were synthesized by nitroxide-mediated controlled radical polymerization. Separate aliquots of the PS-b-PCMS samples were quarternized to transform the PCMS block. This resulted in block copolymers with ionizable blocks. We refer to ion-containing block copolymers synthesized from the same precursor as matched pairs: SAM (containing trimethylammonium chloride) and SIM (containing n-butylimidazolium chloride). Self-assembly in these copolymers resulted in the formation of lamellar phases regardless of composition, chemical formula of the bound ion, and chain length. Chloride ion conductivity and water uptake measurements on one of the matched pairs led to similar results. The chloride ions in this matched pair were replaced by hydroxide ions and the changes in conductivity due to this are reported.

Session J12 DCMP: Topological Insulators: Magnetic Transport and Weak Localization 314 - Hadar Steinberg, Massachusetts Institute of Technology

2:30PM J12.00001 ABSTRACT WITHDRAWN –

2:42PM J12.00002 Transport Signatures of the Quantum Anomalous Hall Effect in 3D Topological Insulators[1] , BRIAN DELLABETTA, TAYLOR HUGHES, MATTHEW GILBERT, University of Illinois at Urbana-Champaign — The unique physics of spin-orbit coupled topological insulators (TIs) exposed to magnetic moments leads to a quantized conductance known as the quantum anomalous Hall effect (QAHE)[2]. While magnetic disorder has been experimentally shown to open a gap in the surface states of TIs[3], no clear transport signatures of the QAHE have been observed in 3-dimensional TIs. We perform 3D real space calculations using the Non-Equilibrium Green's Function Formalism to show that topological insulators in proximity to arrays of ferromagnets offer a unique environment in which to study this phenomenon. We show that ferromagnetic domain walls on patterned surfaces manifest chiral surface modes with quantized currents that can be altered by changing the configuration of the magnetic arrays. We compare topologically trivial and nontrivial models to show a qualitative difference in the induced transport flow based on ferromagnet orientation, and propose a variety of experimental configurations which yield transport signatures of the QAHE.

2:54PM J12.00003 Singular spin response of topological insulators in ac magnetic fields[1] , HAIMING DENG, LUKAS ZHAO, INNA KORZHOVSKA, ZHIYI CHEN, LIA KRUSIN-ELBAUM, City College of New York — Orbital magnetic susceptibility in weak magnetic fields has several contributions whose physical origin is not simple in contrast to the clear Landau diamagnetism of free electrons. Experimentally, anomalous magnetism has been observed in graphite, and bismuth and Bi-Sb alloys, both of which are narrow gap semimetals. Here we report an observation of a singular response in ac magnetic susceptibility – a suppression of diamagnetism at low magnetic fields that appears ubiquitous in all topological insulators (Sb_2Te_3, Bi_2Se_3, $PbBi_2Se_4$) we have studied. We observe two distinct contributions to this effect: a broader one that typically disappears around 40-50 K and is likely related to edges, and a divergent-like one (in the $H \to 0$ limit) that is robust up to room temperature and is likely related to the bulk. The frequency dependence and the dependence on the Fermi level of these effects will be discussed in the context of separation of orbital and spin effects.

3:06PM J12.00004 Megnetoresistance in thin Bi2Te3 layers contacted by Indium (In) superconducting electrodes , ZHUO WANG, RAMESH MANI, Georgia State University — Topological Insulators (TIs) are materials that insulate in the bulk but conduct electricity on their surfaces, which topologically protected by time-reversal symmetry. Transport measurements of topological insulators in the proximity of a superconductor are theoretically predicted to be a significant method to detect Majorana Fermions. Our experiment studied the interplay between superconductivity and TI surface states below the critical temperature of a type-I superconductor. Here, we used the four terminal lock-in technique to study the transport properties of Bi2Te3 specimens contacted by Indium superconducting electrodes, while sweeping perpendicular magnetic field, at $T < 4.2$ K. The results indicate a sharp suppression of the longitudinal resistance at weak magnetic fields, below the critical temperature of Indium. What's more exciting is that the interaction between superconductivity and TI surface states induces resistance enhancement at $T \leq 2.8$K, well below the critical temperature of Indium, in the absence of a magnetic field.

3:18PM J12.00005 ABSTRACT WITHDRAWN –

3:30PM J12.00006 Magneto-optical Studies of Bi_2Te_3 Flakes , LI-CHUN TUNG, University of North Dakota, WENLONG YU, ZHIGANG JIANG, Georgia Institute of Technology, DMITRY SMIRNOV, 1National High Magnetic Field Laboratory-Tallahassee — Magneto-transmittance spectroscopy is used to probe the magnetic-field induced excitations in topological insulator-Bi_2Te_3. Bi_2Te_3 single crystals are repeatedly exfoliated on scotch tape untill the sample flakes are sufficiently thin and become permeable in the infrared frequency range. The sample with the underlying tape is placed in a 4K cryostat and the magneto-optical properties of Bi_2Te_3 are investigated by a broadband Fourier-Transform infrared spectrometer (Bruker 66) using light-pipe optics. The magneto-transmittance data of the sample on the tape and the bare tape up to 35T are collected and analyzed as a stacked multilayer. The average conductivity of the sample flakes at different magnetic fields is evaluated and several magnetic-field dependent features are revealed. These features coincide with the cyclotron resonance energy of the bulk band electrons and potentially linked to the surface state electrons. Implications of these results will be discussed in the presentation.

3:42PM J12.00007 Spin-orbit scattering in quantum diffusion of massive Dirac fermions , WENYU SHAN, Wean Hall 6424, Carnegie Mellon University, 5000 Forbes Ave, Pittsburgh — We theoretically study the effects of spin-orbit scattering on weak (anti-)localization in two-dimensional massive Dirac systems. We clarify that weak anti-localization and localization of a single massive Dirac cone come from the diffusion of a singlet Cooperon in the massless limit and one of triplet Cooperons in the large-mass limit, respectively. Spin-orbit scattering behaves like random magnetic scattering to the triplet Cooperon, and suppresses the weak localization in the large-mass regime, different from in conventional systems where spin-orbit scattering leads to a crossover from weak localization to antilocalization. This behavior suggests an experiment to detect the weak localization of bulk subbands in topological insulator thin films, in which an enhancement of "weak anti-localization" is expected after doping heavy-element impurities. Finally, we compare the conventional electron and Dirac fermion systems in the quantum diffusion transport under ordinary, spin-orbit, and magnetic scattering.

3:54PM J12.00008 Transport properties of SnPbTe topological crystalline insulator films[1] , BADIH A. ASSAF, Dept. of Physics, Northeastern University, FERHAT KATMIS, Francis Bitter Magnet Lab, Dept of Physics, MIT, PENG WEI, Francis Bitter Magnet Lab, MIT, JAGADEESH S. MOODERA, Francis Bitter Magnet Lab, Dept of Physics, MIT, DON HEIMAN, Dept. of Physics, Northeastern University — A new phase of topological insulators, the topological crystalline insulator, has been recently predicted to arise in band-inverted Sn-Pb chalcogenides, where the topological surface states are protected by crystal symmetry instead of spin-orbit coupling [1]. We grew epitaxial thin films of SnTe and $Sn_{1-x}Pb_xTe$ by MBE and sputtering on (100) and (111) surfaces of BaF_2 and Si. We report on magnetotransport measurements on SnTe films having hole densities ranging between 10^{20} and 10^{21} cm^{-3} and mobilities up to 200 cm^2/Vs. Weak antilocalization is observed in all films, allowing us to study the behavior of the phase coherence length versus temperature in an attempt to shed light on the dimensionality of the transport as a function of the Fermi level. Some evidence of 2D transport is found in low carrier density films. [1]T. H. Hsieh et al. *Nature Communication* **3,** 982 (2012).

4:06PM J12.00009 ABSTRACT WITHDRAWN –

4:18PM J12.00010 Kondo resistance minimum in topological insulators , JIE WANG, DIMITRIE CULCER, ICQD, University of Science and Technology of China — We present a theory of the Kondo resistance minimum applicable to topological insulators (TI) and spin-orbit coupled semiconductors in the high-temperature limit, defined as T >T_K, the Kondo temperature. We derive the T-matrix for a general strongly spin-orbit coupled system, including the many-body Kondo scattering terms. The physics is qualitatively different from the well-known case of metals due to the interplay of impurity degrees of freedom with the spin-orbit induced spin-momentum locking of the conduction electrons. TI have a single Fermi surface, while in spin-orbit coupled semiconductors scattering between the two spin-split Fermi surfaces must be taken into account. We determine the resistance minimum and Kondo temperature, and comment briefly on Kondo screening and Kondo singlet formation in the presence of strong spin-orbit coupling.

4:30PM J12.00011 Competing weak localization and weak antilocalization in ultrathin topological insulators[1] , MURONG LANG, LIANG HE, XUFENG KOU, PRAMEY UPADHYAYA, YABIN FAN, UCLA, HAO CHU, NAI-CHANG YEH, California Institute of Technology, KANG WANG, UCLA — We demonstrate the evidences of a surface gap opening in $(Bi_{0.57}Sb_{0.43})_2Te_3$ samples for film thickness below 6 quintuple layers, through magnetotransport and scanning tunneling spectroscopy measurements. By tuning Fermi level position relative to the gap, the striking crossover between weak antilocalization and weak localization is observed in nonmagnetic 4 and 5 QL films at low field region, a characteristic feature of quantum interferences competition, possibly owing to the change of net Berry phase. Furthermore, when the Fermi level is swept into the surface gap, the overall unitary behaviors are revealed at higher magnetic field, which are in contrast to the pure WAL signals obtained in thicker films. Besides, the surface bandgap of ultrathin film is also determined by low temperature STS measurements. Our findings show an exotic phenomenon characterizing the gapped TI surface states and point to the future realization of quantum spin Hall effect and dissipationless TI-based applications.

[1]This work was in part supported by Defense Advanced Research Projects Agency (DARPA), Focus Center Research Program-Center on Functional Engineered Nano Architectonics (FENA).

4:42PM J12.00012 Weak anti-localization in ultrathin Sb(111) films , S. CAIRNS, N. MCGLOHON, C. ROBISON, J. KEAY, C.K. GASPE, K.S. WICKRAMASINGHE, T.D. MISHIMA, M.B. SANTOS, S.Q. MURPHY, University of Oklahoma, Norman — We report the first studies of localization in ultrathin Sb films. Sb is a topological semi-metal with a negative bandgap of 180meV, however it is anticipated that in ultra-thin films, quantum confinement will open the bulk gap, such that transport is dominated by the topological surface states. We have studied the magneto-transport of nominally 4.5nm thick films of Sb(111) grown via molecular beam epitaxy at a temperature of 300C on nearly lattice matched epilayers. The longitudinal resistance shows positive magneto-resistance, well described by the standard weak anti-localization (WAL) theory of Hikami, Larkin and Nagaoka. The WAL response is consistent with that of a single conducting channel with a phase breaking length of ∼200nm at 1.8K. Scanning electron microscopy shows that the Sb growth proceeded by a Volmer-Weber (islanding) process resulting in disordered films. More recent growths performed at lower temperature have yielded significantly less resistive, smoother and thinner films for which transport measurements are ongoing.

4:54PM J12.00013 Weak-Localization-Like Magnetoresistance on a Topological Insulator - Ferromagnetic Insulator Interface[1] , QI YANG, MERAV DOLEV, LI ZHANG, Stanford University, JINFENG ZHAO, University of California, Davis, MIN LIU, Stanford University, SUBHASH RISBUD, University of California, Davis, ALEXANDER PALEVSKI, Tel Aviv University, Isreal, AHARON KAPITULNIK, Stanford University — In this talk, we will present measurements on the interface between a topological insulator (TI) and a ferromagnetic insulator (FI). The results provide a likely indication for gap opening in the TI surface states by its proximity to the FI. While above the Curie temperature (T_C) of the FI we observed weak-antilocalization-like positive magnetoresistance as ubiquitously in TIs, below T_C an unusual weak-localization-like negative magnetoresistance was seen at low magnetic fields, which has never been observed in TIs without any magnetic doping. Such proximity introduced gap-opening and resulting massive Dirac fermions will hopefully lead to realization of many intriguing phenomena such as the quantum anomalous Hall effect and the inverse spin-galvanic effect.

[1]This work is supported by DARPA

5:06PM J12.00014 Weak Localization and Antilocalization in Topological Insulator Thin Films with Coherent Bulk-Surface Coupling , ION GARATE, LEONID GLAZMAN, Yale University — We evaluate quantum corrections to conductivity in an electrically gated thin film of a three-dimensional (3D) topological insulator (TI). We derive approximate analytical expressions for the low-field magnetoresistance as a function of bulk doping and bulk-surface tunneling rate. Our results reveal parameter regimes for both weak localization and weak antilocalization, and include diffusive Weyl semimetals as a special case.

5:18PM J12.00015 Coherent Topological Transport on the Surface of Bi_2Se_3[1] , DOHUN KIM, PAUL SYERS, Department of Physics, University of Maryland, NICHOLAS P. BUTCH, Condensed Matter and Materials Division, Lawrence Livermore National Laboratory, JOHNPIERRE PAGLIONE, MICHAEL S. FUHRER, Department of Physics, University of Maryland — We report weak anti-localization (WAL) measurements in gate-tuned, bulk insulating Bi_2Se_3 thin crystals with thicknesses varying between 5 and 17 nm. The gate-voltage dependent WAL behavior shows systematic variation as a function of crystal thickness. For the thickest samples, we observe two decoupled surfaces exhibiting perfect WAL as expected for the symplectic class. As the films are made thinner, we observe a gate-voltage tuned crossover from two decoupled surfaces to a single coherently coupled 2D system exhibiting WAL. The observed crossover is governed by competition between the phase coherence time and inter-surface tunneling time associated with the hybridization gap. In contrast to classical transport in which the signature of the hybridization gap appears only in the ultrathin limit ($\leq$ 3nm), phase coherent transport is extraordinarily sensitive to sub-meV coupling between top and bottom topological surfaces, and the surfaces of a TI film may be coherently coupled even for thicknesses as large as 12 nm. On further thinning, the WAL behavior is suppressed altogether at small carrier density, which we associate with the opening of a sizable gap on order the Fermi energy and destruction of topological protection.

Tuesday, March 19, 2013 2:30PM - 5:30PM –

Session J13 DMP: Focus Session: Topological Materials - Thin Films 315 - Dennis Drew, University of Maryland

2:30PM J13.00001 Topological limit of ultrathin quasi-freestanding Bi_2Te_3 films grown on Si(111) , YANG LIU, Advanced Photon Source, Argonne National Lab, HUAN-HUA WANG, GUANG BIAN, University of Illinois, Urbana-Champaign, MARK BISSEN, Synchrotron Radiation Center, ZHAN ZHANG, Advanced Photon Source, Argonne National Lab, TOM MILLER, University of Illinois, Urbana-Champaign, HAWOONG HONG, Advanced Photon Source, Argonne National Lab, TAI-CHANG CHIANG, University of Illinois, Urbana-Champaign — A fundamental issue for ultrathin topological films is the thickness limit below which the topological surface states become impacted by interfacial interactions. We show that for Bi_2Te_3 grown on Si(111) this limit is four quintuple layers (QLs) based on angle-resolved photoemission measurements, using optimized photon energies and polarizations, of the Dirac cone warping and interaction-induced gap as a function of film thickness. The results are close to theoretical predictions for free-standing films, despite the expected strong bonding of the film with the reactive Si(111) substrate. In-situ surface X-ray scattering (SXS) study shows that a buffer layer exist on the Si(111) surface, which effectively saturates all the Si(111) dangling bonds. These interfacial properties, revealed only by diffractions from deeply penetrating X-rays, are critical in understanding the topological surface states in ultrathin films, where electronic coupling is strongly enhanced. Our SXS measurement also yields new information regarding the internal structures of these topological thin films, including layer stacking, QL-by-QL growth, relaxations, etc.

2:42PM J13.00002 Transport and Capacitance Measurements of Bi2Se3 Devices , VALLA FATEMI, HADAR STEINBERG, FERHAT KATMIS, BENJAMIN M. HUNT, LUCAS ORONA, JAGADEESH S. MOODERA, PABLO JARILLO-HERRERO, MIT — We report electronic transport and capacitance measurements on Bi2Se3 thin-film and exfoliated devices. Strong modulation of the charge carrier density is achieved via the electric field effect with a local top-gate electrode utilizing either high-k dielectric insulators or transferred hexagonal boron nitride. The understanding of ambipolarity due to the electric field effects in these systems is addressed by comparing the modulation of the quantum capacitance and resistance in different devices, accompanied by a model. Additionally, we report capacitance and resistance measurements on these devices at high magnetic fields.

2:54PM J13.00003 Photo-galvanic effect in Bi_2Se_3 thin films with ionic liquid gating[1] , YU PAN, ANTHONY RICHARDELLA, JOON SUE LEE, THOMAS FLANAGAN, NITIN SAMARTH, Department of Physics, Penn State University — A key challenge in three dimensional (3D) topological insulators (TIs) is to reveal the helical spin-polarized surface states via electrical transport measurements. A recent study [Nature Nanotech. **7**, 96 (2012)] showed that circularly polarized light can be used to generate and control photocurrents in the 3D TI Bi_2Se_3, even at photon energies that are well above the bulk band gap. Symmetry considerations suggest that this "photo-galvanic effect" arises purely from photo-currents induced in the surface Dirac states. To gain insights into this phenomenon, we have carried out systematic measurements of the photo-galvanic effect in electrically gated MBE-grown Bi_2Se_3 thin films of varying thickness. By using an ionic liquid as an optically transparent gate, we map out the behavior of the photo-galvanic effect as a function of Fermi energy over a temperature range 5 K $\leq T \leq$ 300 K.

3:06PM J13.00004 Topological insulator engineering of Bi_2Se_3 through molecular beam epitaxy[1] , SEONGSHIK OH, Rutgers University — Despite numerous reports proving the presence of the surface states on various topological insulator (TI) materials, all existing TI materials suffer from the bulk conductance problem at various levels. Therefore, achieving a truly insulating bulk state without degrading the surface state in their transport properties is one of the most important tasks of the TI materials research. In this talk, I will present how we address this problem by utilizing various molecular beam epitaxy (MBE) schemes with focus on Bi_2Se_3 family of materials. Considering that the bulk conductance problem originates mostly from the selenium vacancies in Bi_2Se_3, the typical MBE growth condition characterized by low growth temperature and high selenium vapor pressure is ideal for solving this bulk conductance problem. Moreover, thin films have another advantage of naturally reduced bulk effect due to the enhanced surface-to-bulk ratio. These intrinsic advantages of MBE-grown TI thin films recently led to a number of new findings. High quality Bi_2Se_3 thin films did show the expected dominant surface transport characters with negligible bulk conductance. However, the strong tendency toward downward band bending in undoped Bi_2Se_3 introduces trivial surface transport channels in addition to the topological surface states, leading to complications in the interpretations of transport results. Furthermore, even if reducing the thickness of TI samples helps reveal the surface transport channels by reducing the bulk contribution, it does not really solve the bulk conductance problem because regardless of how small it may be, the bulk state still remains metallic, shorting the top and bottom surfaces. According to the Mott-criterion of metal-insulator transition, in order to implement a truly insulating bulk state in the current generation TI materials, it is necessary to suppress the defect density below $\sim 10^{14}$ cm^{-3}, which might be fundamentally impossible considering the weak Van der Waals bonding character of these materials. However, we have found that it is possible to overcome this limit and achieve a bulk-insulating topological insulator with fully decoupled surface states in thin film TIs.

3:42PM J13.00005 Thin films of topological crystalline insulators in IV-VI semiconductors , JUNWEI LIU, Tsinghua University, TIMOTHY H. HSIEH, Massachusetts Institute of Technology, WENHUI DUAN, Tsinghua University, JAGADEESH MOODERA, LIANG FU, Massachusetts Institute of Technology — Topological crystalline insulators (TCI) are new topological states of matter protected by crystalline symmetry of solids. The first example of TCI has been recently predicted and subsequently observed in the SnTe class of IV-VI semiconductors. In this work, we show that thin films of TCI realize a two-dimensional Dirac fermion system with a tunable band gap and host the quantum spin Hall state in an extended thickness range. We propose a ferromagnet-TCI device to measure the spin-dependent transport through helical edge states.

3:54PM J13.00006 What Limits Mobility and Carrier Concentration in Epitaxial Topological Insulator Films? , FERHAT KATMIS, VALLA FATEMI, HADAR STEINBERG, PENG WEI, PABLO JARILLO-HERRERO, JAGADEESH MOODERA, MIT — In order to investigate the predicted exotic behavior of topological insulators (TIs) epitaxial films with near ideal electronic properties are essential. Obtaining high quality TI films requires careful control of not only growth parameters but also a good understanding of the dynamics of film formation. We have developed methods to obtain consistently high mobility and low carrier density by carefully controlling the nucleation and growth process of Bi2Se3 epitaxial films. Such MBE grown epitaxial films have been well characterized by different diffraction based techniques and electrical transport to obtain a correlation between structural and electrical properties. This has allowed us to see their systematic dependence. For example, in thin films, carrier density in low $10^{12}/cm^2$ range with bulk mobilities higher than 3000 cm^2/V-s are routinely seen which nicely compares very well with structural data. Acknowledgements: NSF grant DMR 1207469 and NSF DMR 08-19762 (CMSE – Initiative 2).

4:06PM J13.00007 Pairing of the spirals on epitaxially grown Bi2Se3 on Si(111) , YUXUAN CHEN, CHRISTOPHER MANN, CHIH-KANG SHIH, University of Texas at Austin — Bi_2Se_3 is a 3D topological insulator that exhibits backscattering suppression and helical Dirac-like Quasiparticles, making it an ideal candidate for topological physics research. Molecular beam epitaxy (MBE) can control the Se stoichiometry and vacancy density by controlling the Se overpressure during growth, thereby producing bulk insulators, allowing access to the novel physics promised by these systems. We have prepared Bi_2Se_3 thin films on Si(111) substrates by MBE. Atomic force microscopy and scanning tunneling microscopy topographies of these films often show large (100 to 500nm in diameter) triangular wedding-cake-shaped islands with spirals on top. More interestingly, the spirals often come in pairs of a clockwise and a counter-clockwise spiral. The high density of spiral pairs suggests that, such a surface structure is thermodynamically more favorable during the MBE. Our ongoing study of the very early stages of the MBE growth is unveiling more information of the spiral pairs. The knowledge of this growth mode will help us improve the sample quality.

4:18PM J13.00008 Substrate-Independent Vapor-Solid Growth of Bi2Se3 Nanostructures[1] , JEROME T. MLACK, ATIKUR RAHMAN, GARY L. JOHNS, Johns Hopkins University, KEN J.T. LIVI, JHU Integrated Imaging Center, NINA MARKOVIC, Johns Hopkins University — We describe a synthesis technique and low-temperature transport measurements of nanostructures of high-purity of topological insulator Bi2Se3. Our growth method is a catalyst-free atmospheric pressure vapor-solid growth, with the use of hydrogen as a carrier gas. It yields abundant amounts of a variety of nanostructures: nanowires, ribbons, platelets, and flakes of different sizes and shapes. Materials analysis shows highly ordered structures of bismuth selenide in all cases. The nanostructures can be used for electronic and optical applications including flexible ones: we show growth results on glass, silicon and flexible mica substrates. Low-temperature measurements of as-grown nanostructures indicate weak-antilocalization and tunable carrier density in all samples. With doping, the transport properties of the samples can be altered to exhibit superconductivity.

[1]This work was supported in part by the National Science Foundation under grants DMR-1106167 and DGE-1232825.

4:30PM J13.00009 Tunable topological electronic structures in Sb(111) bilayers: A first-principles study , FENG-CHUAN CHUANG, CHIA-HSIU HSU, CHIA-YU CHEN, ZHI-QUAN HUANG, Natl. Sun Yat-sen U., Taiwan, VIDVUDS OZOLINS, UCLA, HSIN LIN, ARUN BANSIL, Northeastern U. — Electronic structure and band topology of a single Sb(111) bilayer in the buckled honeycomb configuration are investigated using first-principles calculations with the inclusion of spin-orbit coupling. While a trivial band insulator is predicted for the free-standing thin film, a band inversion at the Brillouin zone center can be induced by tensile strain, resulting in a topological insulator with a nontrivial topological invariant $Z_2 = 1$. Our study points at the possibility of realizing the quantum spin Hall state for an Sb(111) single bilayer on a suitable substrate. Moreover, the presence of buckling provides an advantage in controlling the band gap through an out-of-plane external electric field, which breaks the inversion symmetry and lifts the spin degeneracy. A topological phase transition driven by gating is demonstrated, and six spin-polarized Dirac cones are found at the critical point. With a tunable gap and reversible spin polarization, Sb thin films are promising candidates for spintronic applications.

4:42PM J13.00010 Topological surface states of Sb thin films adsorbed with impurities[1] , CHIH-KAI YANG, CHI-HSUAN LEE, National Chengchi University, Taipei, Taiwan, ROC — An antimony film is known to exhibit topological surface states depending on the thickness of the film. If the thickness of the film is reduced to as low as four bilayers, for example, Dirac cones disappear as a result of quantum tunneling. We use density functional calculation to investigate the electronic structure of the four-bilayer Sb film and find that adsorptions of non-magnetic impurity atoms of hydrogen, copper, or zinc on the film actually facilitate the formation of Dirac cones that preserve time-reversal symmetry. But magnetic atoms such as iron and manganese do just the opposite. The results suggest the counterintuitive concept of achieving topological conduction by doping nonmagnetic foreign atoms on thin films of topological insulators.

4:54PM J13.00011 Medium Energy Ion Scattering investigation of In diffusion in In_2Se_3/Bi_2Se_3

, H.D. LEE, C. XU, S. SHUBEITA, M. BRAHLEK, N. KOIRALA, S. OH, T. GUSTAFSSON, Department of Physics and Astronomy, Rutgers University — In_2Se_3, a band insulator, and Bi_2Se_3, a three-dimensional topological insulator, have inherently good chemical and structural compatibility. This suggests possible promising applications of In_2Se_3/Bi_2Se_3 devices as tunnel barriers and gate dielectrics. Recently, it has been shown that the similar $(Bi_{1-x}In_x)_2Se_3$ thin system undergoes a transition from topological insulator to band insulator as a function of In concentration [1]. It is therefore important to understand the extent of In diffusion in In_2Se_3/Bi_2Se_3 and its consequences for the transport properties. We have grown In_2Se_3/Bi_2Se_3 thin films on sapphire by Molecular Beam Epitaxy at three different temperatures. Medium Energy Ion Scattering measurements of those films showed that the higher growth temperature resulted in more In diffusion while our transport measurements showed that the Bi_2Se_3 mobility increases as the growth temperature decreases. We found that the trend of the mobility change of In_2Se_3/Bi_2Se_3 depending on the diffusion of In is similar with the trend of the mobility of $(Bi_{1-x}In_x)_2Se_3$ as a function of In concentration [1].

5:06PM J13.00012 First-principles exploration of high-energy facets of bismuth chalcogenide nanocrystals[1]

, OLEG V. YAZYEV, NAUNIDH VIRK, Ecole Polytechnique Federale de Lausanne (EPFL), Switzerland — Binary bismuth chalcogenides Bi_2Se3, Bi_2Te_3, and derived materials are currently considered as the reference topological insulators (TIs) due to their simple surface-state band structures and relatively large bulk band gaps. Nanostructures of TIs are of particular interest as a large surface-to-volume ratio enhances the contribution of surfaces states. So far, the vast majority of research efforts have focused on the low-energy (111) surfaces which correspond to weak planes in the layered crystal structures. Low-dimensional nanostructures such as nanowires and nanoparticles will inevitably involve higher energy facets. We perform a systematic ab initio investigation of the high-energy surfaces of bismuth chalcogenide TIs characterized by different crystallographic orientations as well as surface reconstructions and stoichiometries. We find several stable surfaces which exist under varying thermodynamic equilibrium conditions. Surface orientation and stoichiometry are found to dramatically affect band dispersion and spin polarization of the topological surface-state charge carriers.

5:18PM J13.00013 Vapor-Liquid-Solid Synthesis of Bi_2Te_3 Nanowires via Metalorganic Chemical Vapor Deposition[1]

, L.D. ALEGRIA, J.R. PETTA, Princeton University — Bi_2Te_3 is a topological insulator and high figure-of-merit thermoelectric material. In the context of thermoelectrics, the synthesis of ultra-thin nanowires could enable more efficient energy conversion technologies due to quantum confinement. We describe a route for the synthesis of Bi_2Te_3 nanowires using low-pressure metalorganic chemical vapor deposition (MOCVD). The combination of metalorganic precursors trimethyl bismuth and diisopropyl telluride allow a low 350°C growth temperature that is conducive to nanowire formation. The nanowires form by VLS growth from gold nanoparticles deposited on a growth substrate. Structural and chemical characterizations of the growth products are presented, indicating that the nanowires are high quality, single crystals of Bi_2Te_3.

2:30PM J14.00001 Implications of stochastic magnetization dynamics on reliability of dipole coupled nanomagnetic logic[1]

, MOHAMMAD SALEHI FASHAMI, JAYASIMHA ATULASIMHA, SUPRIYO BANDYOPADHYAY, The Virginia Commonwealth University — Straintronic nanomagnetic logic (SML), where Boolean computation is elicited from dipole coupled multiferroic nanomagnets switched with electrically generated strain, has emerged as an extremely energy-efficient computing paradigm. We have studied the reliability of such logic circuits by computing the gate error rates in the presence of thermal noise by simulating switching trajectories with the stochastic Landau-Lifshitz-Gilbert (LLG) equation. In addition, we examine the lower bound of energy dissipation as a function of switching error and explain how the out-of-plane excursion of the magnetization vector leads to excess energy dissipation over this bound for a given switching error. This analysis is performed to understand the connection between reliability and energy dissipation for a single switch and then extended to larger nanomagnetic logic circuits to assess the viability of dipole coupled SML.

2:42PM J14.00002 Experimental realization of straintronic nanomagnetic logic using strain-induced magnetization switching in magnetostrictive nanomagnets elastically coupled to PMN-PT[1]

, NOEL D'SOUZA, MOHAMMAD SALEHI-FASHAMI, SUPRIYO BANDYOPADHYAY, JAYASIMHA ATULASIMHA, Virginia Commonwealth University — Single-domain magnetostrictive Ni nanomagnets are grown on a bulk <001> PMN-PT substrate and their domain switching is studied through Magnetic Force Microscopy (MFM) and Scanning Electron Microscopy with Polarization Analysis (SEMPA) techniques. By applying a voltage across the length of the PMN-PT substrate (d_{33} coupling), a mechanical strain is applied along the nanomagnet's easy axis of magnetization resulting in domain switching and is investigated for several scenarios. First, the magnetization switching of single, isolated nanomagnets of various sizes is observed. This is followed by studying the dipole interactions through anti-ferromagnetic (AF) and ferromagnetic (F) coupling. The accurate, unidirectional propagation of the magnetization state is also investigated through an array of three AF-coupled nanomagnets. Finally, NAND logic operation using these nanomagnets is explored. Since SEMPA analysis involves no alteration of a sample's magnetic state, unlike in MFM imaging, we also analyze these scenarios using this technique at NIST, Gaithersburg.

3:06PM J14.00004 Single Circuit Parallel Computing with Phonons through Magneto-acoustics[1] , SOPHIA SKLAN, JEFFREY GROSSMAN, Massachusetts Institute of Technology — Phononic computing – the use of (typically thermal) vibrations for information processing – is a nascent technology; its capabilities are still being discovered. We analyze an alternative form of phononic computing inspired by optical, rather than electronic, computing. Using the acoustic Faraday effect, we design a phonon gyrator and thereby a means of performing computation through the manipulation of polarization in transverse phonon currents. Moreover, we establish that our gyrators act as generalized transistors and can construct digital logic gates. Exploiting the wave nature of phonons and the similarity of our logic gates, we demonstrate parallel computation within a single circuit, an effect presently unique to phonons. Finally, a generic method of designing these parallel circuits is introduced and used to analyze the feasibility of magneto-acoustic materials in realizing these circuits.

3:18PM J14.00005 Giant magnetoimpedance effect of Co-based magnetic ribbon as a chemical sensing probe[1] , ALEJANDRO RUIZ, JAGANNATH DEVKOTA, PRITISH MUKHERJEE, HARIHARAN SRIKANTH, MANH-HUONG PHAN, University of South Florida — The giant magnetoimpedance (GMI) effect consists of a large change in the AC impedance of a soft ferromagnetic conductor subject to an external dc magnetic field that forms the basis for developing a new generation of magnetic sensors. Since the impedance of a soft ferromagnetic material is a function of the skin depth at radio frequency region, the GMI effect of the material can be modified via changes in the resistivity and permeability even at a fixed frequency. This effect arises due to the change in the magnetic anisotropy, material geometry, or electrochemical changes. In the present study, we demonstrate the GMI-based detection of various concentrations of corrosive chemicals using an amorphous Co-based ribbon. Under corrosive fluids, the magnetic permeability and hence the GMI effect of the ribbon changes due to the surface modification of the ribbon. We have found that the GMI ratio decreases with time, reaches a minimum value at a certain time, and then remains almost constant with time. The change in the GMI ratio and the time to achieve a stable value depends on the corrosive strength of the used chemical. These results show promise in developing a new class of chemical sensor using the GMI technology.

3:30PM J14.00006 All-thin-film multiferroic heterostructured cantilevers in linear and nonlinear dynamic regimes , TIBERIU-DAN ONUTA, Materials Science and Engineering Department, University of Maryland, College Park, YI WANG, Physics Department, University of Maryland, College Park, SAMUEL E. LOFLAND, Physics Department, Rowan University, NY, CHRISTIAN J. LONG, Physics Department, University of Maryland, College Park, ICHIRO TAKEUCHI, Materials Science and Engineering Department, University of Maryland, College Park — We report on fabrication and characterization of all-thin-film multiferroic magnetoelectric (ME) cantilever devices and their different modes of operation in both linear and nonlinear dynamic regimes. The devices are built on micro-electromechanical system (MEMS) platforms that involve stress-engineered designs based on *silicon oxide/nitride/oxide (ONO)* stacks. The ME layers consist of a magnetostrictive $Fe_{0.7}Ga_{0.3}$ thin film and a $Pb(Zr_{0.52}Ti_{0.48})O_3$ piezoelectric thin film. The resonant frequency was found to display DC magnetic field dependence indicative of the interplay between the anisotropy and Zeeman energies. In the magnetically-driven mode, the harvested peak power at 1 *Oe* is 0.7 mW/cm^3 (RMS) at the resonant frequency (*3.8 kHz*) and the quality factor also displays strong dependence on the DC magnetic bias. In certain conditions, the multiferroic devices show nonlinear behaviors important to logic implementation and parametric amplification.

3:42PM J14.00007 Reliability of Signal Propagation in Magnetostatically Coupled Arrays of Magnetic Nanoelements , REINIER VAN MOURIK[1], IBM Almaden Research Center; Eindhoven University of Technology; Materials Science in Mainz Graduate School of Excellence, LI GAO, BRIAN HUGHES, CHARLES RETTNER, IBM Almaden Research Center, San Jose, CA, BERT KOOPMANS, Eindhoven University of Technology, Eindhoven, the Netherlands, STUART PARKIN, IBM Almaden Research Center, San Jose, CA — Nanomagnetic logic (NML) has promise as a low-power, non-volatile, and radiation resistant alternative to CMOS-based computational devices. Lines of magnetostatically coupled magnetic nano-elements (NEs) propagate information, and the intersections between lines form logic gates. We present simulations and experiments exploring the reliability of signal propagation in NML devices composed of lines of nominally rectangular permalloy NEs, typically 90×60 nm^2 in size. An external magnetic field sets the magnetic state of an input bit and also resets each of the NEs' magnetizations along their hard axis direction. As the field is reduced to zero the input state propagates along the line of NEs as they successively relax into one of two equilibrium states. The state of the NEs is probed by (i) a magnetic tunnel junction sensing device integrated with the output NE and (ii) magnetic force microscopy imaging. We conclude that signal propagation is inherently unreliable both through variations in fabrication of the NEs and due to the innate lack of directionality of the flow of information. We demonstrate an alternative clocking method where a domain wall passing underneath an NML device clocks each NE sequentially, thereby increasing the success of signal propagation.

3:54PM J14.00008 Dynamic state switching in nonlinear multiferroic cantilevers , YI WANG, Department of Physics, University of Maryland, College Park, Maryland 20742, USA, TIBERIU-DAN ONUTA, Department of Materials Science and Engineering, University of Maryland, College Park, Maryland 20742, USA, CHRISTIAN J. LONG, Department of Physics, University of Maryland, College Park, Maryland 20742, USA, SAMUEL E. LOFLAND, Department of Physics and Astronomy, Rowan University, Glassboro, New Jersey 08028, USA, ICHIRO TAKEUCHI, Department of Materials Science and Engineering, University of Maryland, College Park, Maryland 20742, USA — We demonstrate read-write-read-erase cyclical mechanical-memory properties of all-thin-film multiferroic heterostructured $Pb(Zr_{0.52}Ti_{0.48})O_3$ / $Fe_{0.7}Ga_{0.3}$ cantilevers when a high enough voltage around the resonant frequency of the device is applied on the $Pb(Zr_{0.52}Ti_{0.48})O_3$ piezo-film. The device state switching process occurs due to the presence of a hysteresis loop in the piezo-film frequency response, which comes from the nonlinear behavior of the cantilever. The reference frequency at which the strain-mediated $Fe_{0.7}Ga_{0.3}$ based multiferroic device switches can also be tuned by applying a DC magnetic field bias that contributes to the increase of the cantilever effective stiffness. The switching dynamics is mapped in the phase space of the device measured transfer function characteristic for such high piezo-film voltage excitation, providing additional information on the dynamical stability of the devices.

4:06PM J14.00009 Verification of modified Jiles-Atherton model for determination of hysteresis behavior of materials with two ferromagnetic phases , NEELAM PRABHU GAUNKAR, Iowa State University, Ames, Iowa, CAJETAN NLEBEDIM, Ames Laboratory, US DOE, Iowa State University, Ames, Iowa, DAVID JILES, Department of Electrical and Computer Engineering, Iowa State University, Ames, Iowa — Robust theoretical models of hysteresis are important for describing the properties of ferromagnetic materials. Of the available hysteresis models, the J-A model is widely studied. Efforts have been made to modify and extend the applicability of this model and to improve its accuracy in accounting for different conditions that affect the magnetic state of ferromagnetic materials, such as stress. Recently, the J-A model has been extended to describe the ferromagnetic hysteresis in two-phase magnetic materials. Modeling hysteresis of multi-phase ferromagnetic materials is crucial especially due to the need to develop high performance composite magnetic structures. In this study, the extension of the J-A to accommodate materials with two ferromagnetic phases is experimentally verified. The approach to extracting of the J-A model parameters including saturation magnetization (M_s), domain coupling factor (α), domain density (a), reversibility (c) and pinning coefficient (k) in two-phase materials will be presented.

4:18PM J14.00010 Phase encoding technique for super-resolution NV magnetometry , KEIGO ARAI, Massachusetts Institute of Technology, CHINMAY BELTHANGADY, HUILIANG ZHANG, Harvard-Smithsonian, STEPHEN DEVIENCE, Harvard University, RONALD WALSWORTH, Harvard-Smithsonian — We report recent progress towards improving the spatial resolution of nitrogen-vacancy-center-based magnetometers by use of phase encoding techniques which are widely used in conventional magnetic resonance imaging. Since the electronic spin state of nitrogen-vacancy (NV)centers is initialized and read out optically, the resolution of current NV magnetometers is limited by optical diffraction. By applying magnetic field gradients, spatial information can be imparted to the phase of NV electron spin precession, and the resolution is inversely proportional to the magnitude of the field gradient. We will discuss methods to make magnetic field gradients of 1 T/cm which can be switched at a rate of 1 MHz in order to achieve 100 nm resolution along two spatial directions.

4:30PM J14.00011 Solid State Hanle Magnetometry , CHRISTOPHER WOLFE, VIDYA BHALLAMUDI, The Ohio State University, VIVEK AMIN, Texas A&M University, DOMINIC LABANOWSKI, ANDREW BERGER, HELENA REICHLOVA, DAVID STROUD, The Ohio State University, JAIRO SINOVA, Texas A&M University, CHRIS HAMMEL, The Ohio State University — The development of spatially resolved imaging of strongly varying vector magnetic fields is a fundamental challenge that would have scientific and technological implications in fields ranging from materials characterization to the study of magnetic particles in scanned probe techniques and tracking of biological tags. We have extended magnetometry based on the Hanle effect[1] to the characterization of vector fields in solid state systems. Local Hanle curves were measured in a GaAs membrane at various positions around a NdFeB micro-magnetic particle using spin-photoluminescence. The spatially varying vector magnetic fields from the micro-magnet cause calculable changes to the shape of the Hanle curve, and by fitting these curves we can extract information about all three components of the field of the micromagnet and infer its properties. I will also discuss the possibility of an all electrical device which could be more easily and broadly utilized.

4:42PM J14.00012 Faraday rotation echo spectroscopy of phase transitions[1] , SHAOWEN CHEN, RENBAO LIU, Department of Physics, The Chinese University of Hong Kong — Faraday rotation is widely used to study magnetic dynamics. We designed a scheme of Faraday rotation echo spectroscopy (FRES) that can be used to study spin noise dynamics in transparent materials by measuring the fluctuation of Faraday rotation angle. The FRES suppresses the static part of the noise and reveal the quantum fluctuations at relatively high temperature, which shares the same idea of the spin echo technique in nuclear magnetic resonance (NMR). We tested our theory on a rare-earth compound $LiHoF_4$. The quantum fluctuations obtained by FRES give an enhanced feature at the phase boundary. The FRES can be straightforwardly generalized to more complicated configurations that correspond to more complex dynamical decoupling sequences in NMR and electron spin resonance, which may give us more extensive information on the structural and dynamical properties of magnetic materials.

4:54PM J14.00013 Reading a Magnetic Non-Erasable Magnetic Memory , ALAN EDELSTEIN, GREG FISCHER, JONATHAN PETRIE, ROBERT BURKE, US Army Research Laboratory — Two major disadvantages of current magnetic memory are that it can be erased by inadvertently applying a magnetic field and the superparamagnetic limit is beginning to make it difficult to increase the density of magnetic recording without further limiting the already too short storage lifetime of seven years. The superparmagnetic limit can be expressed as the requirement to store information for 10 years requires that $KV/k_BT > 50$, where K is the crystalline anisotropy, V is the volume of the bit k_B is the Boltzman constant and T is the absolute temperature. Alternative methods of information storage, at present, do not have the density of magnetic memory and generally do not store information indefinitely. We have demonstrated a method for reading media in a new magnetic non-erasable memory technology based on regions of high and low magnetic permeability. We have been able to use magnetic tunnel junctions and a probe field to read 10 micron wide lines of a soft magnetic material, permalloy, with a signal to noise ratio of 45 db.

5:06PM J14.00014 Sensing RF and microwave energy with fiber Bragg grating heating via soft ferromagnetic glass-coated microwires[1] , M.H. PHAN, J. DEVKOTA, H. SRIKANTH, Department of Physics, University of South Florida, P. COLOSIMO, A. CHEN, Applied Physics Laboratory, University of Washington — The fiber Bragg grating (FBG) is the basis of numerous sensors. For the most part, strain and temperature are the primary environmental parameters that can be detected with FBGs. Other variables can be measured by using a probe design that converts the desired variable to a strain or temperature change. For example, an FBG bonded to the wall of a vacuum chamber might be used to measure pressure if the wall strain vs. pressure calibration were known. We present results from a new type of microwave energy sensor that relies on Joule heating of a soft ferromagnetic glass-coated microwire to change the temperature of an FBG. The microwire absorbs microwave energy and heats up thus raising the temperature of the FBG. Compared to a similar sensor that uses gold to absorb electromagnetic radiation, the microwire yields a sensor with greater sensitivity (10 times at f =3.25 GHz) relative to the perturbation of the microwave field. With this newly developed sensor, the best sensitivity to electromagnetic radiation corresponds to AC electric fields that have root mean square (RMS) amplitude of approximately 36 V/m. It is physically very small, can be deployed as a distributed sensor, and often only minimally perturbs the field being measured.

5:18PM J14.00015 Magnetic Field Assisted Assembly: Breaking the 50μm Barrier , VIJAY KASISOMAYAJULA, DAVID CUNNINGHAM, ANTHONY FIORY, N.M. RAVINDRA, New Jersey Institute of Technology — Magnetic Field Assisted Assembly is used to facilitate heterogeneous device assembly on various substrates. The aim of this work is to illustrate techniques that help assemble devices of dimensions less than 50μm in any direction onto Silicon/GaAs wafers. Novel methods are developed to produce highly localized magnetic fields using microfabricated solenoids and preconditioned devices whose motion is controlled with nanometer precision. The efficiency of this directed assembly is discussed and comparison is made with existing directed and self assembly techniques.

Session J15 GMAG DMP: Focus Session: Quantum Spin Liquid Theory 317 - Todari Senthil, Massachusetts Institute of Technology

2:30PM J15.00001 Z_2-vortex lattice in the ground state of the triangular Kitaev-Heisenberg model[1] , MARIA DAGHOFER, IOANNIS ROUSOCHATZAKIS, ULRICH K. ROESSLER, JEROEN VAN DEN BRINK, IFW Dresden — Investigating the classical Kitaev-Heisenberg Hamiltonian on a triangular lattice, we establish the presence of an incommensurate non-coplanar magnetic phase, which is identified as a lattice of Z_2 vortices. The vortices, topological point defects in the SO(3) order parameter of the nearby Heisenberg antiferromagnet, are not thermally excited but due to the spin-orbit coupling and arise at temperature $T \to 0$. This Z_2-vortex lattice is stable in a parameter regime relevant to iridates. We show that in the other, strongly anisotropic, limit a robust nematic phase emerges.

[1]Sponsored by the DFG (Emmy-Noether program).

2:42PM J15.00002 Dislocations in the Kitaev honeycomb model[1] , OLGA PETROVA, OLEG TCHERNYSHYOV, Johns Hopkins University — We study the effects of introducing dislocations into the Kitaev honeycomb model [1]. In the gapped phase, dislocations are Z_2 "twist defects" associated with the transmutation of electric and magnetic excitations, studied previously in the context of Z_N rotor models [2,3]. We show that each dislocation hosts one unpaired Majorana mode. As a consequence, twist defects have the statistics of Ising anyons. Because dislocations are confined, an additional phase is accumulated due to the change in system's energy during the braiding process. This means that the result of braiding can only be defined up to a phase. Therefore, twists are said to have projective non-Abelian statistics.

2:54PM J15.00003 Quantum Phase Transition in Heisenberg-Kitaev Model , ROBERT SCHAFFER, SUBHRO BHATTACHARJEE, YONG BAEK KIM, Department of Physics and Center for Quantum Materials, University of Toronto, Toronto, Canada — We explore the nature of the quantum phase transition between a magnetically ordered state with collinear spin pattern and a gapless Z_2 spin liquid in the Heisenberg-Kitaev model. We construct a slave particle mean field theory for the Heisenberg-Kitaev model in terms of complex fermionic spinons. It is shown that this theory, formulated in the appropriate basis, is capable of describing the Kitaev spin liquid as well as the transition between the gapless Z_2 spin liquid and the so-called stripy antiferromagnet. Within our mean field theory, we find a discontinuous transition from the Z_2 spin liquid to the stripy antiferromagnet. We argue that subtle spinon confinement effects, associated with the instability of gapped $U(1)$ spin liquid in two spatial dimensions, play an important role at this transition. The possibility of an exotic continuous transition is briefly addressed.

3:06PM J15.00004 Changing topology by knotting in the three-dimensional Toric Code , ANDREJ MESAROS, Department of Physics, Boston College, Chestnut Hill, MA 02467, USA, YONG BAEK KIM, Department of Physics, University of Toronto, Toronto, Ontario M5S 1A7, Canada, YING RAN, Department of Physics, Boston College, Chestnut Hill, MA 02467, USA — A novel way to study the ground state degeneracy (GSD) of topological matter is through lattice dislocations: When a second copy of a lattice model is introduced through translation by half a lattice constant ($|\vec{b}| = a/2$), then a lattice dislocation with Burgers vector $\vec{b}$ locally smoothly connects the two model copies. Such dislocations are "genon" defects, effectively changing the topology of lattice. In three dimensions (3d), dislocations are closed loops that can be linked and knotted, leading to complex three dimensional manifolds on which the topological theory is defined. We give an analytical construction, supported by exact numerical calculations, for the dependence of GSD on dislocations of such a doubled version of the exactly solvable Kitaev's Toric Code (having Z_2 topological order) in both 2d and 3d. Surprisingly, we find that GSD of the 3d model depends only on the total number of dislocation loops, no matter their linking or knotting. The analytical proof is extended to Z_n generalizations of the model. Additionally, we consider the phase in which dislocations become dynamical through proliferation of double dislocations ($2\vec{b}$) in 2d: the resulting gauge theory is non-Abelian, in the special case of Z_2 Toric Code it is D_4.

3:18PM J15.00005 Kibble-Zurek Scaling and String-Net Coarsening in Topologically Ordered Systems[1] , VEDIKA KHEMANI, ANUSHYA CHANDRAN, Princeton University, F.J. BURNELL, All Souls College, Oxford, S.L. SONDHI, Princeton University — We consider the non-equilibrium dynamics of topologically ordered systems, such as spin liquids, driven across a continuous phase transition into proximate phases with no, or reduced, topological order. This dynamics exhibits scaling in the spirit of Kibble and Zurek but now without the presence of symmetry breaking and a local order parameter. The non-equilibrium dynamics near the critical point is universal in a particular scaling limit. The late stages of the process are seen to exhibit slow, quantum coarsening dynamics for the extended string-nets characterizing the topological phase, a potentially interesting signature of topological order. Certain gapped degrees of freedom that could potentially destroy coarsening are, at worst, dangerously irrelevant in the scaling limit. We also note a time dependent amplification of the energy splitting between topologically degenerate states on closed manifolds. We illustrate these phenomena in the context of particular phase transitions out of the abelian Z_2 topologically ordered phase of the toric code, and the non-abelian $SU(2)_k$ ordered phases of the relevant Levin-Wen models.

3:30PM J15.00006 A classification of symmetry enriched topological phases with exactly solvable models , YING RAN, ANDREJ MESAROS, Department of Physics, Boston College, Chestnut Hill, MA 02467, USA — Recently a new class of quantum phases of matter: symmetry protected topological phases, such as topological insulators, attracted much attention. In presence of interactions, group cohomology provides their classification. These phases are only short-range entangled, while phases with long-range entangled topological order (having topological ground state degeneracy and/or anyons in the bulk) in presence of global symmetries are much less understood. We present a classification of bosonic gapped quantum phases with or without long-range entanglement, in the presence or absence of on-site global symmetries. In 2+1 dimensions, the quantum phases with global symmetry group SG, and with topological order described by finite gauge group GG, are classified by the cohomology group $H^3(SG \times GG, U(1))$. We present an exactly solvable local bosonic model for each class. When global symmetry is absent our models are described by Dijkgraaf-Witten discrete gauge theories. When topological order is absent, they become models for symmetry protected topological phases. When both global symmetry and topological order are present, the models describe symmetry enriched topological phases. Our classification includes, but goes beyond the projective symmetry group classification.

3:42PM J15.00007 Classifying fractionalization: symmetry classification of gapped Z2 spin liquids in two dimensions , ANDREW ESSIN, MICHAEL HERMELE, Department of Physics, University of Colorado — Quantum number fractionalization is a remarkable property of topologically ordered states of matter, such as the fractional quantum Hall liquids, and certain quantum spin liquid states. For a given type of topological order, there are generally many ways to fractionalize the quantum numbers of a given symmetry. Not all distinct fractionalizations will necessarily correspond to distinct phases of matter, however. In this work, we establish a formalism for characterizing fractionalization in gapped, two-dimensional Z2 spin liquids, which leads immediately to a classification of these topologically ordered phases.

3:54PM J15.00008 Realization of symmetry classes for gapped Z_2 spin liquids in simple models , HAO SONG, MICHAEL HERMELE, Department of Physics, University of Colorado at Boulder — Recently it has been proposed that gapped Z_2 spin liquids in two dimensions can be partially classified by the distinct types of fractional quantum numbers carried by the Z_2 charge and flux excitations. On the square lattice with space group and time reversal symmetry, there are about 2^{19} symmetry classes. It is an open question which of these classes can be realized in simple models and, more fundamentally, whether all of these classes can actually be realized. We will present results on a class of exactly solvable models addressing these issues.

4:06PM J15.00009 Chern-Simons theory for frustrated quantum magnets , KRISHNA KUMAR, EDUARDO FRADKIN, University of Illinois at Urbana-Champaign — We study the problem of frustrated quantum magnets by mapping models with Heisenberg spins, which are hard-core bosons, onto a problem of fermions coupled to a Chern-Simons gauge field [1]. Similar methods have been used successfully in the case of unfrustrated systems like the square lattice [2]. However, in the case of frustrated systems there always exists some arbitrariness in defining the problem. At the mean-field level these issues can be over looked but the effects of fluctuations, which are generally strong in these systems, are expected to alter the mean-field physics [3-4]. We discuss the difficulties involved in setting up this problem on a triangular or kagome lattice and some approaches to tackle these issues. We study the effects of fluctuations in these systems and the possibility of spin-liquid type phases.

4:18PM J15.00010 Identifying Topological Quantum Spin Liquid in Physical Realistic Models , HONG-CHEN JIANG, Kavli Institute for Theoretical Physics, University of California, Santa Barbara — Quantum spin liquids (QSLs) are elusive magnets without magnetism, resisting symmetry breaking even at zero temperature due to strong quantum fluctuations and geometric frustration. The simplest QSLs known theoretically are characterized by topological order, i.e., topological quantum spin liquid, and support fractionalized excitations. However, there is no practical way to directly determine the topological nature of states, such as QSLs. We propose a practical and extremely simple approach, i.e., cylinder construction, to numerically calculate the topological entanglement entropy (TEE), and thereby identify topological order of the state [H. C. Jiang, Z. Wang, and L. Balents, arXiv:1205.4289]. We have successfully applied this approach to a variety of lattice models and S=1/2 Kagome Heisenberg model. By extracting an accurate TEE, we identify a quantum spin liquid with topological order for the first time in physically realistic SU(2)-invariant lattice model. We emphasize that the TEE provides positive, "smoking gun" evidence for a topological quantum spin liquid, and excludes any topologically trivial states, including the valence bound solid state. Besides the Kagome Heisenberg model, based on large-scale accurate density-matrix renormalization group studies of numerous long cylinders with circumferences up to 14 lattice spacings, our results [H. C. Jiang, H. Yao, and L. Balents, Physical Review B 86, 024424(2012)], through a combination of the absence of magnetic or VBS order, nonzero spin singlet and triplet gaps, as well as a finite TEE extremely close to ln(2), provide compelling evidence that the two-dimensional ground state of the square J_1-J_2 Heisenberg model is a topological quantum spin liquid.

4:54PM J15.00011 Finite size scaling of entanglement entropy at the Anderson transition with interactions , AN ZHAO, The University of Hong Kong — We study the entanglement entropy(EE) of disordered one-dimensional spinless fermions with attractive interactions. With intensive numerical calculation of the EE using the density matrix renormalization group method, we find clear signatures of the transition between the localized and delocalized phase. In the delocalized phase, the fluctuations of the EE becomes minimum and independent of the system size. Meanwhile the EE's logarithmic scaling behavior is found to recover to that of a clean system. We present a general scheme of finite size scaling of the EE at the critical regime of the Anderson transition, from which we extract the critical parameters of the transition with good accuracy, including the critical exponent, critical point and a power-law divergent localization length.

5:06PM J15.00012 Three dimensional symmetry protected topological phase and algebraic spin liquid , CENKE XU, Department of Physics, University of California, Santa Barbara — It is well-known that one dimensional spin chains are described by O(3) nonlinear sigma models with a topological $\Theta-$term, and $\Theta = 2\pi S$. A pin-1/2 chain (described by $\Theta = \pi$) must be either gapless or degenerate, while a spin-1 chain (described by $\Theta = 2\pi$) is a symmetry protected topological phase, namely its bulk is gapped and nondegenerate, while its boundary is a free spin-1/2 with two fold degeneracy. We prove that these phenomena also occur in arbitrary odd dimensions. For example, in three dimensional space, we construct a series of SU(N) antiferromagnet models, whose low energy field theories are nonlinear sigma models with a 3+1d $\Theta-$term. We will also prove that when $\Theta = \pi$, the disordered phase of this system cannot be gapped and nondegenerate, namely it can be an algebraic liquid phase. When $\Theta = 2\pi$, the system is a three dimensional symmetry protected topological phase, whose 2+1d boundary must be either gapless or degenerate.

5:18PM J15.00013 Continuous phase transition between Néel and spin liquid states with topological order , YANG QI, Institute for Advanced Study, Tsinghua University, ZHENGCHENG GU, California Institute of Technology — It is well known that on square lattice Néel and valence bond solid states are connected by a continuous phase transition, and the critical theory consists fractionalized spinons and an emergent U(1) gauge field. Motivated by recent numerical works revealing Néel and gapped spin liquid states in J_1-J_2 model on square lattice, we study other phases that can be obtained after destroying the Néel order. We show that by condensing fields that carry both electric charge and magnetic flux of the emergent gauge field, one can obtain spin liquid phases with topological order and no lattice symmetry breaking.

Tuesday, March 19, 2013 2:30PM - 5:30PM –

Session J16 GMAG DMP: Focus Session: Molecular Nanomagnets/Devices 318 - Stefano Carretta, University of Parma

2:30PM J16.00001 Modification of Molecular Spin Crossover in Ultra-Thin Films[1] , DANIEL DOUGHERTY, ALEX PRONSCHINSKE, YIFENG CHEN, Department of Physics, North Carolina State University, ARRIGO CALZOLARI, CNR-NANO, Instituto Nanoscienze, Modena, Italy, GEOFF LEWIS, DAVID SHULTZ, Department of Chemistry, North Carolina State University, MARCO BUONGIORNO-NARDELLI, Department of Physics and Department of Chemistry, University of North Texas — Iron (II) spin crossover compounds exhibit a strong connection between molecular spin state and electronic structure that make them exciting candidates for highly tunable materials for spintronic applications. The spin crossover phenomenon is often extremely sensitive to crystal packing effects that may be modified in device environments compared to bulk materials. We report evidence for dramatic modification of spin crossover in bilayer films of Fe[$(H_2Bpz_2)_2$bpy] on Au(111) compared to bulk behavior. Scanning Tunneling Microscopy, spectroscopy, and local conductance mapping show spin-state coexistence in bilayer films of Fe[$(H_2Bpz_2)_2$bpy] on Au(111) that is independent of temperature between 130 K and 300 K due to the unique packing constraints of the bilayer film that promote deviations from bulk behavior. Local density of states measured for different spin states show that high-spin molecules have a smaller transport gap than low-spin molecules in agreement with density functional theory calculations. In addition, aggregation of spin states into "like-spin" domains is observed.

2:42PM J16.00002 Electronic and transport properties of Fe-based spin crossover complexes from first principles , YIFENG CHEN, Department of Physics, North Carolina State University, MARCO BUONGIORNO NARDELLI, Department of Physics and Department of Chemistry, University of North Texas — Using calculations from first principles, we studied the electronic and transport properties of the Fe(II) spin crossover (SCO) compound Fe$[H_2B(pz)_2]_2$(bpy). The magnetic transition has been imposed by constrained magnetization calculations and the computed electronic structure agrees with available experimental data. The unique bilayer configuration achievable by vacuum evaporation on Au(111) in experiments, is modeled by a π-stacking dimer structure that is used for the interpretation of STM and transport data. Our results explain the meandering spinodal decomposition of the spin domains of the bilayer films and the conductive properties of the system. In particular, we found the high-spin configuration to be more conductive than the low-spin case, in agreement with experimental measurements of corresponding currents through disordered thin films. The spin-switchable electronic transport properties of this kind of Fe(II) SCO compound systems provide viable proofs for future switchable molecular spintronic devices and applications.

2:54PM J16.00003 Complex Materials for Molecular Spintronics Applications: Cobalt Bis(dioxolene) Valence Tautomers, from Molecules to Polymers[1] , MARCO BUONGIORNO NARDELLI, University of North Texas, ARRIGO CALZOLARI, Istituto Nanoscienze CNR-NANO-S3, YIFENG CHEN, DANIEL DOUGHERTY, DAVID SHULTZ, North Carolina State University — Using first principles calculations we predict a complex multifunctional behavior in cobalt bis(dioxolene) valence tautomeric compounds. Molecular spin-state switching is shown to dramatically alter electronic properties and corresponding transport properties. This spin state dependence has been demonstrated for technologically-relevant coordination polymers of valence tautomers as well as for novel conjugated polymers with valence tautomeric functionalization. As a result these materials are proposed as promising candidates for spintronic devices that can couple magnetic bistability with novel electrical and spin conduction properties. Our findings pave the way to the fundamental understanding and future design of active multifunctional organic materials for spintronics applications.

3:06PM J16.00004 Electronic read-out of a single nuclear spin using a molecular spin transistor , FRANCK BALESTRO[1], Neel Institut - CNRS - UJF — Thanks to recent advances of nanofabrication techniques, molecular electronics devices can address today the ultimate probing of electronic transport flowing through a single molecule. Not only this electronic current can show signatures of the molecular quantum levels but it can also detect the magnetic state of the molecule. As a consequence, an entirely novel research field called *molecular spintronics* in which quantum magnetism of molecular systems can be interfaced to nanoelectronics is now emerging. One of the recent challenges of this field was to probe by this current, not the only spin state of an electron, but the state of a single nuclear spin. Such an achievement was experimentally unimaginable a few years ago. Indeed, the magnetic signal carried by a single nuclear spin is a thousand times less than that of a single electron spin ... Using a Single Molecular Magnet (TbPc2) as a molecular spin transistor in a three terminals configuration, the experiment consists in measuring the current changes when ones sweep the external magnetic field applied to the molecule. When the magnetic spin of the molecule changes its quantum state, a change of current is recorded. Because of the well-defined relationship that exists between the electron spin and nuclear spin carried by the nuclei of the Terbium atom, it is possible to perform the electronic read-out of the electronic spin state which, in turn give information on the state of a single nuclear spin. Application of this effect for quantum information manipulation and storage can be envisioned, as the observation of energy level lifetimes on the order of tens of seconds opens the way to coherent manipulations of a single nuclear spin.

3:42PM J16.00005 Quantum Dot Spin Valves Controlled by Single Molecule Magnets[1] , FATEMEH ROSTAMZADEH RENANI, GEORGE KIRCZENOW, Simon Fraser University — We explore theoretically for the first time the properties of a new class of spintronic nano-devices in which the electrical resistance of a non-magnetic quantum dot contacted by non-magnetic electrodes is controlled by transition metal-based single molecule nanomagnets (SMMs) bound to the dot. Although the SMMs do not lie directly in the current path in these devices, we show that the relative orientation of their magnetic moments can strongly influence on the electric current passing through the device. If the magnetic moment of one of the SMMs is reversed by the application of a magnetic field, we predict a large change in the resistance of the dot, i.e., a strong spin valve effect. The mechanism is resonant conduction via molecular orbitals extending over the entire system. The spin valve is activated by a gate that tunes the transport resonances through the Fermi energy. Detailed results will be presented for the case of Mn_{12} SMMs bound to a gold quantum dot.

3:54PM J16.00006 The effect of current-induced spin switching in the presence of quantum tunneling of magnetization , MACIEJ MISIORNY[1], Forschungszentrum Juelich, JÓZEF BARNAŚ, Adam Mickiewicz Univeristy — Knowledge of transport properties of individual large-spin ($S > 1/2$) atoms/molecules exhibiting magnetic anisotropy is of key importance from the point of view of information processing technologies [1]. The ultimate aim is to incorporate such objects as functional elements of spintronic devices, with the objective of employing spin-polarized currents to control the magnetic state of the system. In particular, for an atom/molecule with the predominant *'easy-axis' uniaxial* magnetic anisotropy this allows for switching the system's spin between two metastable states [2,3]. However, the *uniaxial* component of magnetic anisotropy, underlying the magnetic bistability, is frequently accompanied by the *transverse* one, whose presence manifests, e.g., as quantum tunneling of magnetization (QTM). Here, we show that not only does QTM induce an effective energy barrier for the spin switching, but also its effect on the transport reveals as an additional signal in transport characteristics. Furthermore, we propose how to experimentally investigate QTM by means of the STM inelastic transport spectroscopy. [1] M. Mannini et al., Nature Mater. 8, 194 (2009); [2] M. Misiorny and J. Barnaś, Phys. Rev. B 75, 134425 (2007); [3] S. Loth et al., Nature Phys. 6, 340 (2010).

4:06PM J16.00007 Vibrational properties of single-molecule magnet Fe4[1] , MICHAEL WARNOCK, KYUNG-WHA PARK, YOH YAMAMOTO, Virginia Tech — A single-molecule magnet (SMM) Fe_4 consists of four Fe ions interacting through O anions via antiferromagnetic superexchange coupling, with the total ground-state spin of $S = 5$. The SMM Fe_4 has a magnetic anisotropy energy of 16 K, and its ground-state spin multiplet is well separated from the first excited spin multiplet. A recent experimental effort demonstrated that SMMs Fe_4 can be deposited on various substrates with magnetic cores intact and that individual Fe_4 molecules can be bridged between electrodes. SMMs Fe_4 deposited on substrates or in contact with electrodes revealed interesting magnetic and transport properties. Electronic and spin degrees of freedom of SMM Fe_4 may be coupled to vibrational degrees of freedom. Such coupling can affect various properties of SMM Fe_4. Here we present our calculation of vibrational spectra (Raman and infrared) of SMM Fe_4 using density-functional theory (DFT) within simple harmonic oscillator approximation. We identify normal modes and compare our calculated result with available experimental data.

4:18PM J16.00008 Cotunneling signatures of spin-electric coupling in frustrated triangular single-molecule magnets , JAVIER NOSSA, CARLO CANALI, School of Computer Science, Physics and Mathematics, Linnaeus University, SE-39182 Kalmar, Sweden — The ground state (GS) of frustrated (antiferromagnetic) triangular single-molecule magnets is characterized by two total-spin $S = 1/2$ doublets with opposite chirality. According to a group theory analysis [M. Trif *et al.*, Phys. Rev. Lett. **101**, 217201 (2008)] an external electric field can efficiently couple these two chiral spin states, even when the spin-orbit interaction (SOI) is absent. The strength of this coupling, d, is determined by an off-diagonal matrix element of the dipole operator, which can be calculated by *ab-initio* methods [M. F. Islam *et al.*, Phys. Rev. B **82**, 155446 (2010)]. In this work we propose that Coulomb-blockade transport experiments in the cotunneling regime can provide a direct way to determine the spin-electric coupling strength. Indeed, an electric field generates a d-dependent splitting of the GS manifold, which can be detected in the inelastic cotunneling conductance. Our theoretical analysis is supported by master-equation calculations of quantum transport in the cotunneling regime. We employ a Hubbard-model approach to elucidate the relationship between the Hubbard parameters t and U, and the spin-electric coupling constant d. This allows us to predict the regime in which the coupling constant d can be extracted from experiment.

4:30PM J16.00009 ABSTRACT WITHDRAWN –

4:42PM J16.00010 Spin moment distributions in Cr-based antiferromagnetic rings Cr7M (M=Ni and Cd) studied by ^{53}Cr NMR , YUJI FURUKAWA, Department of Physics and Astronomy, Iowa State University, CECILIA CASADEI, LORENZO BORDONALI, FERDIANDO BORSA, Department of Physics "A.Volta", Università degli studi di Pavia, GRIHORE TIMCO, RICHARD WINPENNY, Department of Chemistry, University of Manchester — Recent progress in synthesizing molecular magnets offers the opportunity to investigate magnetic properties of the system composed of small number of magnetically coupled spins. In this study, we have investigated magnetic properties of Cr-based antiferromagnetic (AF) ring Cr7M (M=Ni and Cd)). The ancestor of Cr7M is a well-known AF ring Cr8 with a spin single S=0 ground state due to AF interaction (J $\sim$ 16K) between nearest neighbor Cr^{3+} (s=3/2) spins. A substitution of one of eight Cr^{3+} ions with Ni^{2+} (s=1) or Cd^{2+} (s=0) leads to destroy the coherence of spin singlet ground state in Cr8. As a result, the Cr7M has a magnetic ground state with total spin S_T =1/2 and S_T =3/2 for Cr7Ni and Cr7Cd, respectively. In the magnetic ground state, local spin moments will appear on each Cr^{3+} ion. In order to investigate the details of spin moments distributions on Cr ions in the systems, we have carried out ^{53}Cr-NMR measurements in Cr7M in its magnetic ground state at low temperature. Based on the ^{53}Cr-NMR results, we will discuss differences in distributions of the spin moments in Cr7M systems in its magnetic ground state.

4:54PM J16.00011 Spin dynamics in atomically assembled antiferromagnets , SEBASTIAN LOTH, Max Planck Research Group - Dynamics of Nanoelectronic Systems, Center for Free-Electron Laser Science, Hamburg, Germany — Antiferromagnetic materials possess ordered magnetic states that have vanishing magnetization. We used a low-temperature scanning tunneling microscope to construct few-atom antiferromagnets. Even-numbered arrays of antiferromagnetically coupled atoms were found to have no net spin. Their shapes can be defined precisely by atom manipulation avoiding uncompensated magnetic moments at the nanoparticle's edge. We use such spin-compensated atomic arrays to study the intrinsic dynamics of nanoscale antiferromagnets [1]. For chains of more than four atoms we observe two Neel-ordered ground states and frequent switching between them. The spontaneous switching rates depend strongly on the number of coupled atoms and we observed magnetic tunneling of the Neel vector for the smallest structures. In arrays with ten or more atoms the residence time in each state can exceed many hours but current-induced switching proceeds at nanosecond speed. These properties enable a model demonstration of dense magnetic data storage that uses antiferromagnets as memory elements. [1] S. Loth, S. Baumann, C. P. Lutz, D. M. Eigler and A. J. Heinrich, Science 335, 196 (2012).

5:06PM J16.00012 Spin dynamics of molecular nanomagnets unraveled at atomic scale by four-dimensional inelastic neutron scattering , PAOLO SANTINI, Dipartimento di Fisica e Scienze della Terra, University of Parma, I, MICHAEL BAKER, Institut Laue-Langevin, Grenoble, France, TATIANA GUIDI, Rutherford Appleton Laboratory, Didcot, UK, STEFANO CARRETTA, Dipartimento di Fisica e Scienze della Terra, University of Parma, I, JACQUES OLLIVIER, HANNU MUTKA, Institut Laue-Langevin, Grenoble, France, HANS GUEDEL, Department of Chemistry, University of Bern, CH, GRIGORE TIMCO, ERIC MCINNES, School of Chemistry, University of Manchester, UK, GIUSEPPE AMORETTI, Dipartimento di Fisica e Scienze della Terra, University of Parma, I, RICHARD WINPENNY, School of Chemistry, University of Manchester, UK — Molecular nanomagnets (MNMs) have been test-beds for addressing several elusive but important phenomena in quantum dynamics, but to this point it has been impossible to determine the spin dynamics directly. We show that recently-developed inelastic-neutron-scattering instrumentation, yielding the cross-section in vast portions of reciprocal space, enables two-spin dynamical correlation functions of MNMs to be directly determined without assuming an underlying model Hamiltonian. We use the Cr_8 antiferromagnetic ring as a benchmark to demonstrate the potential of this approach which allows us, for example, to examine how a quantum fluctuation propagates along the ring or to test the degree of validity of the Neel-vector-tunneling framework [1]. This result opens remarkable perspectives in the understanding of the quantum dynamics in several classes of MNMs. [1] M. Baker et al., Nature Physics in press (doi:10.1038/nphys2431)

5:18PM J16.00013 Diamagnetic Exciton Properties in Asimetrical Quantum Dot Molecules , NELSON RICARDO FINO PUERTO, HANZ RAMIREZ, ANGELA CAMACHO BELTRAN, Universidad de los Andes, GRUPO DE MATERIA CONDENSADA - UNIVERSIDAD DE LOS ANDES TEAM — The magnetic properties of nanostructures like quantum dots and rings are the subject of intense research. In particular, magnetic control of coupled quantum dots has become subject of interest. By using a first order perturbation approach, and within the effective mass approximation, we calculate magnetic field dependent electronic structures of confined excitons and trions in vertically coupled quantum dots. With these results we study the photoluminescence spectra of neutral and charged excitons in these structures that are coupled via magnetic field in the Faraday configuration (quantum dot molecules QDM). In this work study this spectra around three charge configurations: neutral exciton (X), positive trion (X^+) and negative trion (X), where the charged can be distributed over any of the dots in the basis of the optically active excitons and tunneling electron through the interdot barrier. Also we study different different ratios between the dots, that allow the appearance of crossings and anticrossings in the behavior of the energy with respect to the magnetic field.

Session J17 DMP GMAG: Focus Session: Magnetic Oxide Nano- & Hetero-Structures 319 - Yayoi Takamura, UC Davis

2:30PM J17.00001 Mesoscale spin domain formation and their correlations in quasi-1D $La_{0.67}Sr_{0.33}MnO_3$ nanowires[1] , XIAOQIAN M. CHEN, NICK BRONN, NADYA MASON, PETER ABBAMONTE, Frederick Seitz Materials Research Laboratory, University of Illinois at Urbana-Champaign, JASON HOFFMAN, ANAND BHATTACHARYA, Argonne National Laboratory — Creating materials with nano-scale dimensions can introduce finite size and boundary effects, where the scale of the system boundaries near criticality becomes comparable to the correlation of competing orders in the material. To study these effects, we have fabricated arrays of quasi-1D nanowires from epitaxially grown $La_{0.67}Sr_{0.33}MnO_3$ (LSMO) thin films on $SrTiO_3$(STO) substrates. Our studies with resonant soft x-ray scattering (RSXS) reveal a non-trivial magnetic domain formation along different momentum directions in these wires. In addition, a new magnetic order was observed below 110K, likely induced by the STO structural transition. Below the Curie temperature we also observed a series of magnetic superlattice reflections, indicating collective mesoscale ordering of the magnetic moments into a pattern with a spatial period of five wires. Our calculations using dielectric susceptibility and Ising model simulations provide us an interpretation for the mechanism of domain formation and their long-range interaction through dipole coupling.

2:42PM J17.00002 Dynamic resistive switching controlled by local lateral gating in phase separated manganite wires , HANGWEN GUO, JOO HYON NOH, SHUAI DONG, PHILIP RACK, The University of Tennessee, Knoxville, ZHENG GAI, Center for Nanophase Materials Sciences Division, Oak Ridge National Laboratory, XIAOSHAN XU, Oak Ridge National Laboratory, ELBIO DAGOTTO, The University of Tennessee, Knoxville, JIAN SHEN, Fudan University, THOMAS Z. WARD, Oak Ridge National Laboratory — Behaviors such as high T_c superconductivity, colossal magnetoresistivity, and the metal-insulator transition, have been tied to inherent electronic phases coexisting in a single crystal material. Here we demonstrate a novel approach to induce resistive electric field effect transitions based on the modification of the inherent electronic domain structures in single crystal materials. A phase separated manganite system confined to a scale which isolates a few electronic domains is controlled using laterally gated which give repeatable resistive changes of up to 50%. This technique also makes it possible to create multistate switching devices from a single confined transport channel. These findings provide an avenue to control inherent electronic phases in strongly correlated materials as a means of creating novel nano-electronic devices. Supported by the US DOE Office of Basic Energy Sciences, Materials Sciences and Engineering Division.

2:54PM J17.00003 Magnetic structure of epitaxial self-assembled $La_{0.7}Sr_{0.3}MnO_3$ nanoislands , JONE ZABALETA[1], ICMAB-CSIC, SERGIO VALENCIA, FLORIAN KRONAST, Helhmoltz-Zentrum Berlin, MIRIAM JAAFAR, ICMM-CSIC, PATRICIA ABELLAN, CESAR MORENO, JAUME GAZQUEZ, ICMAB-CSIC, OSCAR IGLESIAS-FREIRE, ICMM-CSIC, FELIP SANDIUMENGE, TERESA PUIG, ICMAB-CSIC, AGUSTINA ASENJO, ICMM-CSIC, NARCIS MESTRES, XAVIER OBRADORS, ICMAB-CSIC, ICMAB-CSIC TEAM, HELMHOLTZ-ZENTRUM BERLIN COLLABORATION, ICMM-CSIC COLLABORATION — The mixed-valence manganite $La_{0.7}Sr_{0.3}MnO_3$ (LSMO), in nanoscale configuration, is a strong candidate for magnetic logic and sensor applications because of its Curie temperature (360 K) and high degree of spin polarization. In this work we unravel the magnetic structure of self-assembled ferromagnetic LSMO epitaxial nanoislands smaller than 200 nm in lateral size and less than 40 nm in height, grown using a bottom-up solution-based methodology. Magnetic force microscopy shows that LSMO islands stabilize either single domain, multidomain, or vortex state configurations, depending on their lateral size and aspect ratio. The vortex state of islands with different morphology and two distinct crystallographic orientations is further explored using spatially-resolved x-ray magnetic circular dichroism in photoemission electron microscopy measurements. The vortex evolution of individual islands is tracked in-situ by applying in-plane magnetic field. The magnetic structure study is complemented with crystal structure, strain state, and chemical composition studies.

3:06PM J17.00004 Control with the switching behavior in exchange-coupled nanomagnets , ERIK FOLVEN, Norwegian Univ. of Science and Technology , YAYOI TAKAMURA, Univ. of California Davis , ANDREAS SCHOLL, ANDREW DORAN, ANTHONY YOUNG, Advanced Light Source, LBNL , SCOTT T. RETTERER, Oak Ridge National Laboratory , HELEN GOMONAY, National Technical Univ. of Ukraine , THOMAS TYBELL, JOSTEIN GREPSTAD, Norwegian Univ. of Science and Technology — Control with the switching behavior of monodomain nanomagnets is key to a range of magnetic device technologies. We have recently demonstrated that shape-induced stabilization of antiferromagnetic (AFM) domains can be achieved in embedded $LaFeO_3$ thin film nanostructures.[1,2] This finding offers a pathway to influence the switching behavior of nanoscale thin film ferromagnets through exchange coupling across the interface between an antiferromagnet and a ferromagnet. Here, we show how the switching field for rectangular nanomagnets may be significantly reduced in $LaFeO_3$ (AFM)/$La_{0.7}Sr_{0.3}MnO_3$ (FM) heterostructures. Mediated by the interface exchange coupling, the engineered domains in the $LaFeO_3$ layer give rise to a uniaxial bias field acting on the magnetic moments in the $La_{0.7}Sr_{0.3}MnO_3$. By tailoring the AFM domain state, we can align this bias field perpendicular to the long axis of the magnetic element, effectively lowering the potential barrier between the two stable single domain states of the rectangular nanomagnet. The experimental data obtained with element specific x-ray spectromicroscopy is compared with a simple theoretical model. 1. Folven et al., Nano Letters 10, 4578 (2010) 2. Folven et al., Nano Letters 12, 2386 (2012)

3:18PM J17.00005 Fabrication and study of CoF_2O_4 structures on Graphene substrates employing scanning probe microscopy techniques[1] , IRMA KULJANISHVILI, Saint Louis University, Dept. of Physics, MARKO SURTCHEV, NT-MDT America Inc,, JOHN CAVIN, Saint Louis University, Dept. of Physics, ALEXANDER SMETANA, SAJU NATTIKADAN, NanoInk Inc — Graphene materials are being investigated in recent years for verity of applications, including electric and optical devices and novel substrates. In this study we explore the route for assembling micro- and nanoscale architectures of magnetic complex oxide material directly on graphene surface using 'direct write' parallel patterning techniques. Ferrimagnetic oxide $CoFe_2O_4$ (CFO) was prepared by sol-gel chemical route and used as 'ink' for patterning structures. An array of CFO dots was fabricated using Dip Pen Nanolithography method at specific locations. Here we will discuss the surface properties of the formed dot structures of $CoFe_2O_4$ on graphene as compared to those formed on Si/SiO_2 substrate. Structures fabricated on each substrate with the same ambient conditions and thermal processing show different morphology and magnetic interactions when studied using AFM and MFM techniques. We will describe our findings and results acquired on individual CFO dots of different sizes. We will also show that graphene substrate is likely influencing the magnetic characteristics of CFO dots that are formed on its surface, although the role of graphene as a substrate for CFO dot formation should be further investigated.

3:30PM J17.00006 Electrical manipulation of interface conduction in BiFeO3-CoFe2O4 columnar heterostructures , YI-CHUN CHEN, Department of Physics, National Cheng Kung University, YING-HUI HSIEH, Department of Materials Science and Engineering, National Chiao Tung University, JIA-MING LIOU, Department of Physics, National Cheng Kung University, CHIA-YING SHEN, YING-HAO CHU, Department of Materials Science and Engineering, National Chiao Tung University — Complex oxide interfaces emerge as one of the most exciting subjects in the condensed-matter field due to its unique physical properties and new possibilities for next-generation electronic devices. Recently, we found local conduction at the tubular interfaces of self-assembled BiFeO3 (BFO)-CoFe2O4 (CFO) heterostructures. In this study, to further investigate the electrical properties of the tubular oxide interface, conductive atomic force microscopy (CAFM) at different temperatures was performed to examine the sample. The origin of local conduction at the BFO-CFO vertical interface is identified as a result of the accumulation of oxygen vacancies. In addition, the interface conduction can be modulated with non-volatile and reversible behaviors via an external electric field. This memritor-like phenomenon can be understood owing to the movement of oxygen vacancies driven by the applied bias. The bias causes the oxygen vacancies either accumulate or deplete to the metal contact tip, which in turn affect the resistance at the tubular interface. Our results provide the control of the conduction at complex oxide interfaces and suggest the possibility for new devices based on complex oxide interfaces.

3:42PM J17.00007 Self-Assembled Multiferroic Nanocomposites for Use in Magnetic Logic Architecture[1] , RYAN COMES, MIKHAIL KHOKHLOV, HONGXUE LIU, JIWEI LU, STUART WOLF, University of Virginia, Dept. of Materials Science and Engineering — $CoFe_2O_4$ (CFO) offers unique properties as a magnetoelectric material due to its large magnetoelastic response when strained. Previous work has shown that when CFO is co-deposited with $BiFeO_3$ (BFO) nanostructured phase segregation occurs, with CFO pillars forming in a BFO matrix. The CFO-BFO nanocomposite system has been proposed as a possible multiferroic logic or memory scheme.[1] We will discuss the patterning and growth of CFO-BFO composites using e-beam lithography and pulsed electron deposition.[2] Our results have demonstrated the ability to pattern the composites into square arrays of pillars with spacing as small as 100 nm. The magnetic properties of the patterned films have been characterized using magnetic force microscopy and are in good agreement with previous results from our group for unpatterned composites.[3] Cross-sectional TEM analysis of the films was used to quantify the strain in the CFO pillars and evaluate the elastic anisotropy. Piezoresponse force microscopy analysis and lithographic domain patterning of the BFO matrix is also presented. [1] S.A. Wolf, et al. Proc. IEEE 98 (2010). [2] R. Comes, et al. Nano Lett. 12 (2012). [3] R. Comes, et al. J. App. Phys. 111 (2012).

3:54PM J17.00008 Magnetoelectric effects in oxide magnetic tunnel junctions with ferroelectric barriers , JAVIER TORNOS, Universidad Complutense de Madrid, Y.H. LIU, S.G.E. TE VELTHUIS, Materials Science Division, Argonne National Laboratory, M.R. FITZSIMMONS, Los Alamos National Laboratory, A. RIVERA, Universidad Complutense de Madrid, R. LOPEZ ANTON, Universidad de Castilla La Mancha, G. SANCHEZ SANTOLINO, Universidad Complutense de Madrid, M. VARELA DEL ARCO, Condensed Matter Sciences Division, Oak Ridge National Laboratory, N.M. NEMES, Universidad Complutense de Madrid, S.J. PENNYCOOK, Condensed Matter Sciences Division, Oak Ridge National Laboratory, Z. SEFRIOUI, C. LEON YEBRA, J. SANTAMARIA, Universidad Complutense de Madrid — Functional properties of magnetic tunnel junction can be enhanced by employing a ferroelectric material as the barrier layer. We report on La0.7Sr0.3MnO3(LSMO)/BaTiO3(BTO)/LSMO magnetic tunnel junctions(MTJ) with BTO ferroelectric tunnel barrier. Switching BTO ferroelectric polarization influences the tunneling magnetoresistance (TMR) achieving two different r resistance states for each magnetic state (parallel or antiparallel) of the magnetization of the electrodes . The voltage dependence of the differential conductance obtained from IV curves displays oscillations whose period depends on the BTO electric polarization. This unusual behavior could be related to the presence of an induced magnetic moment in BTO ferroelectric barrier detected by XMCD measurements. These results reveal that spin polarization, and its tunneling conductance can be electrically tuned through reversal of the ferroelectric polarization of the barrier.

4:06PM J17.00009 Magnetic field effects on dielectrophoresis in manganites[1] , DANIEL GRANT, GALIN DRAGIEV, AMLAN BISWAS, Department of Physics, University of Florida, Gainesville, FL 32611 — Perovskite-type manganese oxides (manganites) are of interest for many of the different properties they possess, including colossal magnetoresistance (CMR) and ferroelectric behavior. With the application of an electric field, large resistance decreases have been noted near the insulator-to-metal transition temperature in samples of $(La_{1-y}Pr_y)_{1-x}Ca_xMnO_3$ (LPCMO). Two proposed models have emerged to explain the behavior, dielectric breakdown and dielectrophoresis, with experimental evidence showing some aspects of the dielectrophoresis model to be correct. However, neither model accounts for magnetic interactions among the ferromagnetic metallic regions and the effects of a magnetic field applied in conjunction with an electric field. We have performed measurements on LPCMO samples by varying the strength and orientation of the magnetic field and the applied voltage. Cross-shaped microstructures have been made on LPCMO samples to allow us to investigate the effects of sample size on dielectrophoresis. We will present resistance and magnetization data obtained on LPCMO samples at various magnetic field strengths, magnetic field orientations, and sample sizes to elucidate the effect of magnetic interactions on dielectrophoresis induced transport and magnetic properties.

[1]NSF DMR 0804452

4:18PM J17.00010 The observation and control of electronic nematic phase in manganites by stripy domains , CHANGCHENG JU, School of physics,Nanjing University — During the past decades, novel electronic liquid crystal phases have been revealed in strongly correlated electronic systems, especially the electronic nematic phase in strontium ruthenate and superconductors. Transport measurements show strongly transport anisotropies in these otherwise isotropic electronic systems. In this work, we report 71° striped ferroelectric domains created in BiFeO3 can also epitaxially lock the perovskite manganites leading to the emerge of an electronic nematic phase. Firstly, La1-xSrxMnO3/BiFeO3 (LSMO/BFO) bilayer samples are deposited by PLD. The 71° periodic striped ferroelectric domains and coherent growth are demonstrated by PFM and X-ray rocking curve. X-ray reciprocal space mapping have been used to confirm the epitaxial relationships of the layers and in-plane lattice constants. Transport measurements reveal a nematic phase transition without high magnetic fields. By changing the thickness of BFO and LSMO layer respectively, we observed substantial anisotropic resistivities and a shift of transition temperature for nematic phase and M-I transition. Unlike the other electronic liquid crystals, magnetic fields perpendicular to the film can suppress the appearance of nematic phase. XMCD and NEXAFS at the Mn L2, 3 edge revealed an in-plane preferential occupation of orbitals and a broken rotational symmetry for Mn-O-Mn bonds at nematic phase. At last, we also demonstrate a nonvolatile electric-field control of anisotropic resistivity switching.

4:30PM J17.00011 Characterization of interfacial charge accumulation in ferroelectric $BaTiO_3$/manganite interfaces using atomic-resolution annular bright field imaging and electron energy-loss spectroscopy[1] , ROBERT KLIE, QIAO QIAO, PATRICK PHILLIPS, University of Illinois - Chicago, HANGHUI CHEN, Columbia University, MATTHEW MARSHALL, FRED WALKER, SOHRAB ISMAIL-BEIGI, CHARLES AHN, Yale University — Interfaces in functional oxides have been the focus of many studies due to potential emergence of novel phases. In this study, we will focus on ferroelectric/manganite, more specifically the $LaSrMnO_3/BaTiO_3$ interfaces in single-crystal thin films grown on $SrTiO_3$. Using atomic-resolution annular bright field (ABF) imaging, as well as atomic-column resolved electron energy-loss spectroscopy in the aberration-corrected, cold-field emission gun JEOL ARM200CF, we will demonstrate that the interfacial accumulation/depletion of charges, depending on the orientation of the ferroelectric polarization, can be directly quantified. We find that the interfacial accumulation of electron/holes is screen within three unit-cells of $LaSrMnO_3$. Moreover, using ABF imaging, we will shows that the distortions of the oxygen sublattice can be directly quantify, in both the $BaTiO_3$ layer, as well as the interfacial $LaSrMnO_3$. Our experimental results imaging and spectroscopy results will be complemented by first-principles density functional theory calculations.

[1]This work is supported in part by the National Science Foundation (DMR-0846748). The acquisition of the JEOL ARM200CF at UIC was made possible by a NSF MRI-R^2 grant (DMR-0959470 ARRA).

4:42PM J17.00012 Magnetic properties of $La_{0.7}Sr_{0.3}MnO_3/BaTiO_3$ interfaces[1] , YAOHUA LIU, S.G.E. TE VELTHUIS, Materials Science Division, Argonne National Laboratory, Argonne, IL, USA, J.W. FREELAND, Advanced Photon Source, Argonne National Laboratory, Argonne, IL, USA, N.J. TORNOS, C. LEON, J. SANTAMARIA, GFMC. Depto. Fisica Aplicada III. U. Complutense, Madrid, Spain — Interfaces between the ferromagnetic (FM) and ferroelectric (FE) oxides may host nanoscale multiferroic phases with strong magnetoelectric coupling, which can be potentially utilized for energy-efficient spintronics. In this work, we have investigated the magnetic properties of the interface between ferromagnetic $La_{0.7}Sr_{0.3}MnO_3$ (LSMO) and ferroelectric $BaTiO_3$ (BTO) via X-ray resonant magnetic scattering (XRMS) and X-ray magnetic circular dichroism (XMCD) on a series of 10 nm LSMO / t BTO bilayers, with t = 1.2, 2.4 and 4.8 nm, respectively. Additionally, we have studied a LSMO/BTO/LSMO trilayer. Interestingly, we have observed magnetic dichroism from Ti ions between 30 K and 210 K, which closely tracks the Mn's dichroism during the magnetization reversal. In contrast, no Ti magnetization has been observed in a single-layer BTO film on a $SrTiO_3$ substrate. These results suggest that there are Ti^{3+} ions that reside at the LSMO/BTO interfaces and the interfacial Mn and Ti moments are exchange coupled.

[1]Work at ANL supported by US-DOE, Office of Science, BES, No. DE-AC02-06CH11357.

4:54PM J17.00013 Magnetoelectric coupling at the $EuO/BaTiO_3$ interface , SHI CAO, Dept. of Physics and Astronomy, Nebraska Center for Materials and Nanoscience, University of Nebraska, Lincoln, Nebraska 68588, USA, PAN LIU, JINKE TANG, Dept. of Physics & Astronomy, University of Wyoming, Laramie, Wyoming 82071 USA, CHUNG WUNG BARK, SANGWOO RYU, CHANG BEOM EOM, Dept. of Materials Science and Engineering, University of Wisconsin-Madison, Wisconsin 53706, USA, PETER DOWBEN, ALEXEI GRUVERMAN, Dept. of Physics and Astronomy, Nebraska Center for Materials and Nanoscience, University of Nebraska, Lincoln, Nebraska 68588, USA — Magnetization modulation by ferroelectric polarization pinning is reported for the ferromagnetic-ferroelectric $EuO/BaTiO_3$ (EuO/BTO) heterostructures. Away from T_c, the critical exponent β indicates that the magnetization of EuO is consistent with mean field theory despite suggestions that EuO is a typical Heisenberg ferromagnetic semiconductor. The Heisenberg model is also inconsistent with the significant band dispersion seen in EuO thin films. The possible mechanisms include extrinsic doping and/or pinning of interface states at the EuO/BTO interface. The results are discussed in the context of data also obtained for $La_{0.67}Sr_{0.33}MnO_3/BaTiO_3$ heterostructures, where the critical exponent β is also close to the predictions of mean field theory, suggesting a similarity in the importance of the magnetic interface with a ferroelectric and the possible importance of ferroelectric polarization reversal.

5:06PM J17.00014 Coupled ferromagnetism and ferroelectricity in superlattices of non-ferroelectric antiferromagnetic manganites[1] , J.D. BURTON, 1, K. ROGDAKIS, 2, J.W. SEO, 3, Z. VISKADOURAKIS, 2, Y. WANG, 1, L. AH QUNE, 3, E. CHOI, 4, E. TSYMBAL, 1, J. LEE, 4, C. PANAGOPOULOS, 2,3 — Complex oxide heterostructures present a promising avenue for the design of multifunctional properties which may find application in a variety of technological systems. In heterostructures composed of transition metal oxides the disruption introduced by an interface can affect the balance of the competing interactions among spins, charges and orbitals. This has led to the emergence of properties absent in the original building blocks of a heterostructure. We will report on the discovery of magnetically tunable ferroelectricity in artificial tri-layer superlattices consisting of non-ferroelectric and non-ferromagnetic components: $NdMnO_3/SrMnO_3/LaMnO_3$.[1] Ferroelectricity was observed below 40 K exhibiting strong tunability by superlattice periodicity. Furthermore, magnetoelectric coupling resulted in 150% magnetic modulation of the polarization. First-principles calculations indicate that broken space inversion symmetry and mixed valency give rise to the observed behavior. This discovery highlights the importance of tri-layered systems for the engineering of emergent properties in oxide heterostructures. [1] K. Rogdakis et al, Nat Commun 3, 1064 (2012)

5:18PM J17.00015 Anomalous exchange bias at collinear/noncollinear spin interface , TAO WU, Nanyang Technological Universiity — We report on the interfacial magnetic coupling in manganite bilayers of collinear ferromagnetic $La_{0.7}Sr_{0.3}MnO_3$ and noncollinear multiferroic $TbMnO_3$. Exchange bias emerges at the Neel temperature of $TbMnO_3$ (about 41 K) due to the onset of long-range antiferromagnetic ordering in the Mn spin sublattice. Interestingly, an anomalous plateau of exchange bias emerges at the ordering temperature of Tb spins (about 10 K), and we ascribe this unique feature to the strong coupling between Tb and Mn spin sublattices in $TbMnO_3$, which in turn influence the magnetic coupling across the interface. On the other hand, the enhancement of coercivity in $La_{0.7}Sr_{0.3}MnO_3$ shows monotonous temperature dependence. Our results illustrate a strong interfacial magnetic coupling at the $La_{0.7}Sr_{0.3}MnO_3/TbMnO_3$ interface, highlighting the roles of competing spin orders, magnetic frustration, and coupling between multiple spin sublattices in artificial collinear/noncollinear spin heterostructures.

Session J18 DCMP: Two Dimensional Topological Insulators: Theory 320 - Byounghak Lee, Texas State University

2:30PM J18.00001 Correlated effects in topological phase transitions , HSIANG-HSUAN HUNG, Department of Physics, The University of Texas at Austin, Austin, TX, 78712, USA, LEI WANG, Theoretische Physik, ETH Zurich, 8093 Zurich, Switzerland, ZHENG-CHENG GU, Institute for Quantum Information, California Institute of Technology, Pasadena, California 91125, USA, GREGORY A. FIETE, Department of Physics, The University of Texas at Austin, Austin, TX, 78712, USA — Correlation effects in topological phases have been a central topic of interest, yet elusive in experiment. In this talk, we present the results of a numerical study beyond mean-field theory of a phase transition between a two-dimensional Z2 topological insulator phase and a trivial insulator that is driven by correlation effects. In addition to the Z2 invariant, we find that certain features of the single-particle Green's functions (simpler to compute than the full Z2 invariant) carry important information that are strongly indicative of a non-trivial Z2 topological character. We observe that the fluctuations originating from correlations tend to move the topological phase transition boundary to larger values of interactions.

2:42PM J18.00002 Topological insulators of interacting bosons in two dimensions: Classification, effective field theory and microscopic construction , YUAN-MING LU, ASHVIN VISHWANATH, University of California, Berkeley — While topological insulators of non-interacting fermions have been extensively studied, we know very little about topological insulators of bosons, whose realization necessitates strong interaction. In this work we apply Chern-Simons effective theory to classify and characterize interacting bosonic topological insulators in two spatial dimensions. These topological phases have a unique ground state on any closed manifold and no fractional excitations: yet they feature gapless edge states which are often protected by a symmetry. Examples include a bosonic analog of chiral superconductors, bosonic integer quantum Hall states (with Hall conductance quantized to even integers) and bosonic analog of the quantum spin Hall state. We show that these topological phases can be constructed in various ways: such as in arrays of coupled one-dimensional quantum wires. Our formulation also naturally applies to topological insulators of two-dimensional interacting fermions.

2:54PM J18.00003 Topological parity invariant in interacting two-dimensional systems from quantum Monte Carlo , THOMAS C. LANG, Department of Physics, Boston University, VICTOR GURARIE, ANDREW M. ESSIN, Department of Physics, University of Colorado, STEFAN WESSEL, Institute for Theoretical Solid State Physics, RWTH Aachen University — We report results on calculating the parity invariant from Green's functions in quantum Monte Carlo simulations of strongly interacting systems. The topological invariant is used to study the trivial- to topological-insulator transitions in the Kane-Mele-Hubbard model with an explicit bond dimerization. We explore accessibility and behavior of this invariant within quantum Monte Carlo simulations.

3:06PM J18.00004 Rotating spin density wave and inverse spin pumping in quantum spin Hall edges , QINGLEI MENG, TAYLOR HUGHES, SMITHA VISHVESHWARA, University of Illinois Urbana-Champaign — We explore interaction effects in quantum spin Hall (QSH) edges in the presence of a finite bias voltage. Using bosonization techniques, we show that repulsive interactions give rise to a spin density wave phase in which the transverse magnetization shows spatial rotation. The effect of a finite bias voltage on this phase is to give the rotation a temporal variation. Using spin transfer torque methods, we show that the system can induce an inverse spin pumping effect in which the magnetic moment of a ferromagnet placed in its proximity can be made to rotate. We demonstrate that this device is equivalent to an electric inductor and in principle can also emit microwave radiation, thus providing a unique ways of probing QSH properties.

3:18PM J18.00005 Theory of correlated topological insulators with broken axial spin symmetry , STEPHAN RACHEL, Dresden University of Technology, JOHANNES REUTHER, Caltech, RONNY THOMALE, EPFL Lausanne — The two-dimensional Hubbard model defined for topological band structures exhibiting a quantum spin Hall effect poses fundamental challenges in terms of phenomenological characterization and microscopic classification. We consider weak, moderate, and strong interactions and argue that the resulting phase diagrams depend on the microscopic details of the spin orbit interactions which give rise to the non-trivial topology. In particular, it turns out that there is a crucial difference between models with broken and with conserved axial spin symmetry. These results suggest that there is a general framework for correlated 2D topological insulators with broken axial spin symmetry.

3:30PM J18.00006 ABSTRACT WITHDRAWN –

3:42PM J18.00007 Band geometry of fractional topological insulators , RAHUL ROY, University of California, Los Angeles — Recent numerical simulations of flat band models with interactions which show clear evidence of fractionalized topological phases in the absence of a net magnetic field have generated a great deal of interest. We provide an explanation for these observations by showing that the physics of these systems is the same as that of conventional fractional quantum Hall phases in the lowest Landau level under certain ideal conditions which can be specified in terms of the Berry curvature and the Fubini study metric of the topological band. In particular, we show that when these ideal conditions hold, the density operators projected to the topological band obey the celebrated W_∞ algebra. Our approach provides a quantitative way of testing the suitability of topological bands for hosting fractionalized phases.

3:54PM J18.00008 An effective theory of two-dimensional fractional topological insulators[1] , PREDRAG NIKOLIC, George Mason University — A generic spin-orbit coupling in 2D electron systems can be represented by an SU(2) gauge field with a non-trivial SU(2) flux. This makes it possible to stabilize novel non-Abelian incompressible quantum liquids by appropriate interactions (perhaps useful in quantum computing). We will discuss a generalization of the Chern-Simons Lagrangian to an arbitrary SU(N) symmetry group that describes such liquids. This effective field theory contains a Landau-Ginzburg part, which identifies the low energy fluctuations near any putative second-order quantum phase transition between conventional phases. Whenever an incompressible quantum liquid intervenes in such a phase transition, the fractional statistics of its quasiparticles is governed by the topological term of this theory and determined by the low energy dynamics. Commuting external gauge fields reduce the topological term to a Chern-Simons or BF form appropriate for fractional quantum (spin) Hall states, but the generic non-commuting gauge fields are expected to yield new classifiable topological orders without a quantum Hall analogue. We will discuss the possible non-Abelian fractional states in topological insulator quantum wells shaped by the Rashba spin-orbit coupling.

4:06PM J18.00009 Exactly soluble lattice models for abelian topological phases , CHIEN-HUNG LIN, MICHAEL LEVIN, Condensed Matter Theory Center, Department of Physics, University of Maryland, College Park, Maryland 20742, USA — We construct exactly soluble bosonic lattice models that realize a large class of abelian topological phases. These models are a generalization of the "string-net" models of Ref. [1], but unlike the original construction, we find that our models can realize phases with broken time reversal symmetry. We analyze the braiding statistics of the quasiparticle excitations and show that they are described by nonchiral $U(1) \times U(1) \times \cdots \times U(1)$ Chern-Simons theories(i.e. equal numbers of left and right moving edge modes).

[1] M. Levin and X.-G. Wen, Phys. Rev. B 71, 045110 (2005)

4:18PM J18.00010 Topological Phases in gapped edges of fractionalized systems , FRANK POLLMANN, JOHANNES MOTRUK, Max Planck Institute for the Physics of Complex Systems, 01187 Dresden, Germany, EREZ BERG, Weizmann Institute of Science, Rehovot 76100, Israel, ARI TURNER, University of Amsterdam, 1090 GL Amsterdam, The Netherlands — We present an extension of the classification scheme for topological phases in interacting one-dimensional fermionic systems to parafermionic chains. We find that the parafermions support both topological as well as symmetry broken phases in which the parafermions condense. In a series of recent works an experimental way of creating parafermions had been proposed: they can arise on the edge of a two-dimensional fractional topological insulator when coupled to superconducting and ferromagnetic domains. The low-energy edge degrees of freedom are described by a chain of coupled parafermions. As a concrete example of our classification we consider the $\nu = 1/3$ fractional topological insulator for which we calculate the phase diagram and study the entanglement spectra. We furthermore discuss a concrete physical realization which allows us to tune between the different topological phases.

4:30PM J18.00011 Quantum Geometry of the "Fuzzy-Lattice" Hubbard Model and the Fractional Chern Insulator[1] , SAGAR VIJAY, F.D.M. HALDANE, Princeton University — Recent studies of interacting particles on tight-binding lattices with broken time-reversal symmetry reveal "zero-field" fractional quantum Hall (FQH) phases (fractional Chern insulators, FCI). In a partially-filled Landau level, the non-commutative guiding-centers are the residual degrees of freedom, requiring a "quantum geometry" Hilbert-space description (a real-space Schrödinger description can only apply in the "classical geometry" of unprojected coordinates). The continuum description does not apply on a lattice, where we describe emergence of the FCI from a non-commutative quantum lattice geometry. We define a "fuzzy lattice" by projecting a one-particle bandstructure (with more than one orbital per unit cell) into a single band, and then renormalize the orbital on each site to unit weight. The resulting overcomplete basis of local states is analogous to a basis of more than one coherent state per flux quantum in a Landau level. The overlap matrix characterizes "quantum geometry" on the "fuzzy lattice", defining a "quantum distance" measure and Berry fluxes through elementary lattice triangles. We study quantum geometry at transitions between topologically-distinct instances of a fuzzy lattice, as well as N-body states with local Hubbard interactions.

4:42PM J18.00012 Series of Abelian and Non-Abelian States in C>1 Fractional Chern Insulators , ANTOINE STERDYNIAK, CÉCILE REPELLIN, Laboratoire Pierre Aigrain, ENS and CNRS, BOGDAN BERNEVIG, Department of Physics, Princeton university, NICOLAS REGNAULT, Department of Physics, Princeton university; Laboratoire Pierre Aigrain, ENS and CNRS — We report the observation of a new series of abelian and non-abelian topological states in fractional Chern insulators (FCI). The states appear at bosonic filling nu= k/(C+1) (k, C integers) in a wide variety of lattice models, in fractionally filled bands of Chern numbers C $\geq$ 1 subject to on-site Hubbard interactions. We show strong evidence that the $k = 1$ series is abelian while the k $>$ 1 series is non-abelian. The energy spectrum at both ground-state filling and upon the addition of quasiholes shows a low-lying manifold of states whose total degeneracy and counting matches, at the appropriate size, that of the Fractional Quantum Hall (FQH) SU(C) (color) singlet k-clustered states (including Halperin, non-abelian spin singlet(NASS) states and their generalizations). The ground-state momenta are correctly predicted by the FQH to FCI lattice folding. However, the counting of FCI states also matches that of a spinless FQH series, preventing a clear identification just from the energy spectrum. The entanglement spectrum lends support to the identification of our states as SU(C) color-singlets but offers new anomalies in the counting for C $>$ 1, possibly related to dislocations that call for the development of new counting rules of these topological states.

4:54PM J18.00013 Rydberg-Atom Quantum Simulation and Chern Number Characterization of a Topological Mott Insulator , ALEXANDRE DAUPHIN, Université libre de Bruxelles - Universidad Complutense, MARKUS MUELLER, MIGUEL-ANGEL MARTIN-DELGADO, Universidad Complutense — In this talk we consider a system of spinless fermions with nearest and next-to-nearest neighbor repulsive Hubbard interactions on a honeycomb lattice within the mean-field treatment, and propose and analyze a realistic scheme for analog quantum simulation of this model with cold atoms in a two-dimensional hexagonal optical lattice. Besides a semi-metallic and a charge-density-wave ordered phase, the system exhibits a quantum anomalous Hall phase, which is generated dynamically, i.e. purely as a result of the repulsive fermionic interactions and in the absence of any external gauge fields. We establish the topological nature of this dynamically created Mott insulating phase by the numerical calculation of a Chern number, and study the possibility of coexistence of this phase with the other phases characterized by local order parameters. Based on the knowledge of the mean-field phase diagram, we then discuss in detail how the interacting Hamiltonian can be engineered effective ly by state-of-the-art experimental techniques for laser-dressing of cold fermionic ground-state atoms with electronically excited Rydberg states that exhibit strong dipolar interactions.

[1] A. Dauphin, M. Mueller, and M. A. Martin-Delgado, arXiv:1207.6373. Submitted to PRA and accepted on Sep 26, 2012.

5:06PM J18.00014 Spin-orbit interactions in a helical Luttinger liquid with a Kondo impurity , ERIK ERIKSSON, University of Gothenburg — We study the transport properties of a helical Luttinger liquid with a Kondo impurity and spin-orbit interactions. Such a system, which may be realized at the edge of a quantum spin Hall insulator with a gate-induced electric field, provides a mechanism to electrically control the conductance. A Rashba spin-orbit interaction may even change the nature of the Kondo screening [Eriksson et al., Phys. Rev. B 86, 161103(R) (2012)]. Considering other types of spin-orbit interactions, together with an extended non-equilibrium analysis, we further improve the understanding of these phenomena.

5:18PM J18.00015 Manipulating Majorana Fermions in Quantum Nanowires with Broken Inversion Symmetry[1] , ALEJANDRO M. LOBOS, JQI and CMTC, Department of Physics, University of Maryland, XIONG-JUN LIU, JQI and CMTC, Department of Physics, University of Maryland, and Institute of Advanced Study, Hong Kong University of Science & Technology, Hong Kong — We study a Majorana-carrying quantum wire, driven into a trivial phase by breaking the spatial inversion symmetry with a tilted external magnetic field. Interestingly, we predict that a supercurrent applied in the proximate superconductor is able to restore the topological phase and therefore the Majorana end-states. Using Abelian bosonization, we further confirm this result in the presence of electron-electron interactions and show an insightful connection of this phenomenon to the physics of a one-dimensional doped Mott-insulator. The present results have important applications in e.g., realizing a supercurrent assisted braiding of Majorana fermions, which proves highly useful in topological quantum computation with realistic Majorana networks.

Tuesday, March 19, 2013 2:30PM - 5:18PM –

Session J19 DCMP: Quantum Criticality in Lanthanide/Actinide & Related Systems - Experiment 321 - Makariy Tanatar, Ames Laboratory

2:30PM J19.00001 Quantum criticality of YbBiPt , G.M. SCHMIEDESHOFF, Occidental College, E.D. MUN, S.L. BUD'KO, C. MARTIN, H. KIM, M.A. TANATAR, R. PROZOROV, Ames Laboratory and Iowa State University, J.-H. PARK, T. MURPHY, National High Magnetic Field Laboratory, Florida State University, N. DILLEY, Quantum Design, P.C. CANFIELD, Ames Laboratory and Iowa State University — YbBiPt is a stoichiometric heavy fermion compound with an enormous Sommerfeld coefficient and a magnetic ground state that can be suppressed by fields of about 4 kOe. We will present and discuss recent thermodynamic and transport measurements, and the evidence for field induced quantum criticality in this material. Work at Ames Laboratory was supported by the Department of Energy, Basic Energy Sciences under Contract No. DE-AC02-07CH11358. The National High Magnetic Field Laboratory was supported by the US National Science Foundation, the State of Florida and the US Department of Energy. Work at Occidental College was supported by the National Science Foundation under DMR-1006118.

2:42PM J19.00002 ABSTRACT WITHDRAWN –

2:54PM J19.00003 The High-Field Fermi Surface of $YbRh_2Si_2$, AARON SUTTON, PATRICK M.C. ROURKE, Department of Physics, University of Toronto, 60 St. George Street, Toronto, Ontario, Canada M5S 1A7, VALENTIN TAUFOUR, INAC, SPSMS, CEA Grenoble, 38054 Grenoble, France, ALIX MCCOLLAM, High Field Magnet Laboratory, Institute for Molecules and Materials, Radboud University Nijmegen, Netherlands, GERARD LAPERTOT, GEORG KNEBEL, JACQUES FLOUQUET, INAC, SPSMS, CEA Grenoble, 38054 Grenoble, France, STEPHEN R. JULIAN, Department of Physics, University of Toronto, 60 St. George Street, Toronto, Ontario, Canada M5S 1A7 — We report the culmination of our de Haas-van Alphen (dHvA) oscillation rotation studies on the heavy Fermion material $YbRh_2Si_2$. Past measurements included rotations in the a-b and a-c planes and resulted in the observation of a previously unobserved frequency attributed to the so-called J-sheet of the Fermi surface. While the purpose of these measurements was to determine whether or not the high field Fermi surface resembled a small or large Fermi surface, the measurements have highlighted the need for more advanced band structure calculations in order to determine its nature. In our latest measurements we completed our study by rotating from the (110) direction towards the c-axis. The experiment was successful in elucidating a new aspect of the Fermi surface, and though qualitative agreement with rudimentary band structure calculations was observed, the measurement has reinforced the need for a more comprehensive theoretical understanding of the material.

3:06PM J19.00004 $CePt_2In_7$: Focused Ion Beam Sample Preparation for Quantum Oscillation Measurements under High Pressure , JAKOB KANTER, P. MOLL, Laboratory for Solid State Physics, ETH Zurich, Switzerland, S. FRIEDEMANN, P. ALIREZA, M. SUTHERLAND, S. GOH, Cavendish Laboratory, University of Cambridge, Cambridge, UK, F. RONNING, E.D. BAUER, Los Alamos National Laboratory, Los Alamos, New Mexico, USA, B. BATLOGG, Laboratory for Solid State Physics, ETH Zurich, Switzerland — Electronic transport measurements under high pressures face several experimental challenges due to confined sample space and high forces acting on contacts and leads. As a result conventional preparation methods are often limited in the number of possible leads and usually do not allow for sample structuring. The Focused Ion Beam (FIB) enables sample contacting and structuring down to a sub-micrometre scale, making the measurement of several samples with complex shapes on a single anvil feasible. This talk will discuss Shubnikov-de Haas measurements of FIB prepared $CePt_2In_7$ samples under high pressures. $CePt_2In_7$ belongs to the $Ce_mM_nIn_{3m+2n}$ heavy fermion family. Compared to the $CeMIn_5$ members of this group, the structure of $CePt_2In_7$ has a more pronounced two dimensional character, but also exhibits an antiferromagnetically ordered as well as a superconducting phase. We have studied the changes of the quasiparticle masses for the various orbits as function of pressure approaching the quantum critical point.

3:18PM J19.00005 A THz spectroscopy study of the field-induced quantum phase transition in the heavy fermion antiferromagnet $CeCu_2Ge_2$[1] , GRACE BOSSE, C.M. MORRIS, Johns Hopkins University, Y. LI, J. ECKSTEIN, University of Illinois at Urbana-Champaign, N.P. ARMITAGE, Johns Hopkins University — We report time domain THz spectroscopy data of a thin film of the heavy fermion compound $CeCu_2Ge_2$ in the presence of a magnetic field. It has been shown that it is possible to tune the antiferromagnetic long-range order of $CeCu_2Ge_2$ towards a quantum critical point using magnetic field as a tuning parameter. Measurements to obtain the frequency dependent complex conductivity as a function of temperature and field were taken down to temperatures below the onset of magnetic order and fields as high as 7 T. The effects of the quantum critical fluctuations on the frequency dependent scattering rate and mass renormalization, which are obtained using an extended Drude model analysis, will be discussed.

[1]This work has been supported at JHU by the Gordon and Betty Moore Foundation. At UIUC, this work has been supported by the Center for Emergent Superconductivity, funded by the DOE award DE-AC0298CH1088.

3:30PM J19.00006 Quantum Criticality in high purity specimens of $Ce_2Rh_3Ge_5$ and $Ce_2Pt_3Si_5$, ERIC D. BAUER, RYAN E. BAUMBACH, XIN LU, Los Alamos National Laboratory, ROSS D. MCDONALD, Los Alamos National Laboratory, National High Magnetic Field Laboratory, FILIP RONNING, JOE D. THOMPSON, Los Alamos National Laboratory — We report results for high purity specimens of the heavy fermion antiferromagnets $Ce_2Rh_3Ge_5$ and $Ce_2Pt_3Si_5$, which have similar ordering temperatures: $T_N = 5.5$ K and 6.3 K, respectively, and belong to the same family of materials that includes the pressure-induced superconductor $Ce_2Ni_3Ge_5$. Our measurements show that the antiferromagnetic state is suppressed to zero temperature at similar magnetic fields ($H_c = 23$ T and 36 T, respectively), suggesting comparable magnetic energy scales in these compounds. In contrast, while the pressure needed to access a quantum critical point (QCP) in $Ce_2Rh_3Ge_5$ is extremely low ($P_c \sim 5$ kbar), the Néel temperature for $Ce_2Pt_3Si_5$ is insensitive to pressures up to 15 kbar. This result implies that although these compounds are markedly similar, the mechanism that drives the QCP in $Ce_2Rh_3Ge_5$ is not present in $Ce_2Pt_3Si_5$. We discuss possible differences between these compounds and mechanisms for their quantum criticality with an emphasis on how the shape of the Fermi surface affects their physical properties.

3:42PM J19.00007 Magnetic cluster glass formation in Ni-V close to the disordered ferromagnetic quantum phase transition[1] , RUIZHE WANG, SARA UBAID-KASSIS, ALMUT SCHROEDER, Kent State University, P.J. BAKER, F.L. PRATT, ISIS, S.J. BLUNDELL, T. LANCASTER, I. FRANKE, J.S. MOELLER, Oxford University, THOMAS VOJTA, Missouri University of Science and Technology — The d-metal alloy $Ni_{1-x}V_x$ undergoes a quantum phase transition from a ferromagnetic ground state to a paramagnetic ground state as the vanadium concentration x is increased. We present magnetization, ac-susceptibility and muon-spin relaxation data at several vanadium concentrations below and above the critical concentration $x_c \approx 11\%$ where the onset of ferromagnetic order is suppressed. Below x_c, $Ni_{1-x}V_x$ is characterized as a strongly disordered ferromagnet since the muon data reveal a broad magnetic field distribution. Above x_c, the temperature dependence of the magnetic susceptibility is best described in terms of a magnetic quantum Griffiths phase. At the lowest temperatures, we identify a magnetic cluster glass phase which masks the actual ferromagnetic quantum critical point. We study how this cluster glass is formed (i) by lowering the temperature from the quantum Griffiths phase and (ii) by increasing the vanadium concentration starting from the disordered ferromagnet. The onset of the cluster glass phase is recognized by a change of the magnetic dynamics revealed through susceptibility and muon-spin relaxation measurements.

3:54PM J19.00008 Anisotropic transport and magnetic properties, and magnetic-field tuned ground states of $CeZn_{11}$[1] , H. HODOVANETS, S.L. BUD'KO, M.G. KIM, D.K. PRATT, A. KREYSSIG, A.I. GOLDMAN, P.C. CANFIELD, Ames Laboratory and Department of Physics and Astronomy, Iowa State University, IA — We have studied the electrical, magnetic, and thermal properties of single crystals of $CeZn_{11}$ by the means of magnetization, resistivity, heat capacity, and thermoelectric power. The compound exhibits an antiferromagnetic long-range order below 2.0 K. The zero-field temperature dependent resistivity of $CeZn_{11}$ is similar to that of other strongly correlated, Kondo lattice, compounds. T_N is suppressed with the applied magnetic field and disappears for $H \sim$47.5 kOe ($H \| [110]$) and $H \sim$ 120 kOe ($H \| [011]$). Temperature-dependent resistivity for $H \| [110]$ shows sub-linear behavior up to 2.5 K for H=45 kOe, followed by Fermi liquid behavior for limited range of temperatures ($T <$1.1 K) and fields (47.5 kOe$\leq H \leq$60 kOe). The $H - T$ phase diagrams for $H \| [110]$ and $H \| [011]$ will be discussed.

4:06PM J19.00009 Electrical resistivity of $CeZn_{11}$ under pressure[1] , VALENTIN TAUFOUR, Department of Physics and Astronomy, Iowa State University, Ames, Iowa 50011, U.S.A, STELLA K. KIM, HALYNA HODOVANETS, SERGEY L. BUD'KO, PAUL C. CANFIELD, Ames Laboratory, US DOE, Iowa State University, Ames, Iowa 50011, U.S.A — In most Ce-based intermetallic compounds, the magnetic exchange is assumed to be due to the RKKY interaction. This interaction competes with the Kondo interaction, leading to the suppression of the magnetic order and the possibility of field and/or pressure induced quantum criticality. In order to study this competition in $CeZn_{11}$, a compound that orders antiferromagnetically below $T_N = 2$ K, we performed electrical resistivity measurements on a single crystal of $CeZn_{11}$ under pressure up to 5 GPa in a Bridgman pressure cell modified to use a liquid pressure transmitting medium (1:1 mixture of n-pentane: iso-pentane). $T_N(p)$ slightly increases and approaches a broad maximum in the studied pressure range. At ambient pressure, the antiferromagnetic order is suppressed by a magnetic field along the [1,1,0] direction of the tetragonal crystal structure. The temperature versus magnetic field phase diagram at 5 GPa will be compared to the one at ambient pressure.

[1]This work was supported by AFOSR-MURI grant FA9550-09-1-0603 (V. Taufour and P. C. Canfield) and by US DOE under the Contract No. DE-AC02-07CH11358 (S. K. Kim, H. Hodovanets and S. L. Bud'ko.).

4:18PM J19.00010 Magnetic structure of R_2CoGa_8 (R = Gd, Tb and Dy) and evolution of the magnetic structures along the series of intermetallic compounds with R = Gd - Tm , CARLOS GILES, JOSE RENATO MADERGAN, Argonne National Laboratory, CRIS ADRIANO, University of Illinois at Chicago, RAFAEL VESCOVI, PASCOAL PAGLIUSO, University of Campinas — In this work we have determined the magnetic structure of R_2CoGa_8 (R = Gd, Tb and Dy) intermetallic compounds using X-ray resonant magnetic scattering in order to study the evolution of the anisotropic magnetic properties along the series for R = Gd-Tm. The three compounds have a commensurate antiferromagnetic structure with a magnetic propagation vector (1/2 1/2 1/2) with Néel temperatures of 21.0, 27.5 and 15.2 K for R = Gd, Tb and Dy, respectively. The critical exponent β obtained from the temperature dependence of the integrated intensity of the resonant magnetic peaks suggest a 3D magnetism for the three compounds. The energy line shapes at the L_2 and L_3 edges of the magnetic peaks for these compounds present a purely dipolar character as demonstrated by comparison to first principle calculations. Comparing the simulated and integrated intensities corrected for absorption, we conclude that the magnetic moment direction is in the *ab*-plane for Gd_2CoGa_8 compound and parallel to the $c-$axis for the Tb_2CoGa_8 and Dy_2CoGa_8 compounds. This information is used to discuss the evolution of the magnetic structure of R_2CoGa_8 series for R = Gd-Tm where both the direction of the ordered moment and the ordering temperature evolution along the series can be explained through the competition between the indirect Ruderman-Kittel- Kasuya-Yoshida exchange interaction and crystalline electric field effects.

4:30PM J19.00011 Electronic structure and Fermi surface topology in PuIn3 and PuSn3 , CHENG-CHING WANG, Theoretical Division, Los Alamos National Laboratory, MATTHEW JONES, University at Buffalo, SUNY, JIAN-XIN ZHU, Theoretical Division, Los Alamos National Laboratory — The itinerant-to-localized crossover of the 5f electrons that occurs near plutonium in the actinide series is one of the most challenging issues in condensed matter physics, while the highest superconductivity across the whole f-electron systems emerges in PuCoGa5. These novel behaviors are indicative of strong electronic correlations effects. Electronic band structure calculations serve as the first step for better understanding of these correlation effects. The compounds PuIn3 and PuSn3 crystallize into cubic AuCu3-type structure and have an actinide-actinide distance far above the Hill limit, making the 5f-ligand hybridization the dominant mechanism for Pu 5f -electron delocalization. With their simple crystallographic structure and rich magnetic and electronic properties, these two compounds provide a particularly convenient and systematic way to study the delocalization-localization crossover of Pu 5f electrons. It is particularly encouraging that PuIn3 is the first Pu-based compound in which the de-Haas van-Alphen effect has been observed. In this talk, we present a systematic study of electronic structure calculations on PuIn3 and PuSn3 in the framework of density functional theory with the generalized gradient approximation.

4:42PM J19.00012 Quantum Criticality in the strongly correlated 3d electron system YFe_2Al_{10} , LIUSUO WU, KEESEONG PARK, Stony Brook University, MONIKA GAMZA, Brookhaven National Lab, MOOSUNG KIM, Stony Brook University, MEIGAN ARONSON, Brookhaven National Lab & Stony Brook University — A remarkable behavior in quantum critical systems is the critical scaling near the quantum critical point (QCP), where Fermi liquid (FL) physics usually breaks down. This kind of behavior has been observed in many f electron based heavy fermion (HF) systems. We have measured the magnetization and specific heat of the 3d-electron metal YFe_2Al_{10}. non-FL behavior with strong divergence in magnetic susceptibility ($\chi \sim T^{-\gamma}$, γ =1.4) and specific heat ($C_M/T \sim$ -log T) were observed, and this suggested YFe_2Al_{10} may locate close to a ferromagnetic QCP. What attracts us most is the unusual scaling of magnetic susceptibility ($d\chi/dT = B^{-\gamma}\varphi(T/B^{\beta})$) and specific heat ($\Delta C_M/T = \psi(T/B^{\beta})$), which was observed over a range more than three decades in T/B^{β}. The overall scaling behaviors mapped well with the assumption that a FL phase was resumed as the system was tuned far from the QCP, where all the critical fluctuation was suppressed. Based on the scaling analysis, a possible form of the critical free energy will also be discussed.

4:54PM J19.00013 Terahertz conductivity of MnSi thin films , J. STEVEN DODGE, LALEH MOHTASHEMI, AMIR FARAHANI, Simon Fraser University, ERIC KARHU, THEODORE MONCHESKY, Dalhousie University — We present measurements of the low-frequency optical conductivity of MnSi thin films, using time-domain terahertz spectroscopy. At low temperatures and low frequencies, we extract the DC resistivity, scattering life time and plasma frequency from a Drude fit. We obtain a value of $\omega_p \simeq 1.0$ eV, which can be used to estimate the renormalization coefficient through comparison with band theory. At higher temperatures, deviations from Drude behavior are observed, suggesting a loss of quasi-particle coherence. In the region of low temperatures and high frequencies, we see evidence for a crossover to the anomalous power law dependence observed by Mena *et al.*[1] As the temperature increases, the anomalous frequency dependence becomes more pronounced, and the plasma frequency inferred from a Drude fit decreases dramatically. Above T$\approx$ 50 K, $\sigma_2(\omega)$ develops a negative slope that is inconsistent with both a Drude model and the anomalous power law observed earlier,[1] indicating a sharp pseudogap in the conductivity spectrum.

5:06PM J19.00014 Effect of Nd Substitution on $PrOs_4Sb_{12}$ Investigated by μSR Experiments[1] , P.-C. HO, B. SOMSANUK, Physics/CSU-Fresno, D. E. MACLAUGHLIN, Physics/UC Riverside, M. B. MAPLE, UC San Diego, L. SHU, Physics/Fudan U, China, O. O. BERNAL, Physics/CSU-Los Angeles, T. YANAGISAWA, Physics/Hokkaido U, Japan — The pseudo ternary system $Pr_{1-x}Nd_xOs_4Sb_{12}$ has been used as a model system to investigate the effect of ferromagnetism (FM) on the unconventional superconductivity (SC) and quantum critical behavior of $PrOs_4Sb_{12}$ [1]. SC in this system disappears near a critical concentration $x_{cr,1} \sim 0.58$ and FM appears above $x_{cr,2} \sim 0.33$ [1,2]. The new μSR measurements have been performed on samples with $x = 0.25$, 0.75, and 1. For $x = 1$ and 0.75, the estimated frozen moments agree with the Nd^{3+} CEF ground state moment. For $x = 0.25$, neither time reversal symmetry breaking nor evidence of freezing of Nd^{3+} spins was observed in zero-field μSR measurements, the behavior of which is very different than what is observed for $x = 0.45 - 0.55$ [2]. In the SC state, an unexpected linear T dependence of the Gaussian relaxation rate was also found in the transverse field μSR data for $x = 0.25$, which is different than the plateau in $PrOs_4Sb_{12}$ below 1.3K [3]. Session J20 DMP: Focus Session: Metamaterials - Nanowires and Plasmonic Enhancement 322

- Peter Nordlander, Rice University

2:30PM J20.00001 Excited state dynamics of single metal and semiconductor nanowires studied by transient absorption microscopy[1] , SHUN S. LO, Department of Chemistry and Biochemistry, University of Notre Dame, HONG Y. SHI, Notre Dame Radiation Laboratory, University of Notre Dame; Dept. of Physics, Harbin Institute of Technology, TODD A. MAJOR, NATTASAMON PETCHSANG, Department of Chemistry and Biochemistry, University of Notre Dame, LIBAI HUANG, Notre Dame Radiation Laboratory, University of Notre Dame, MASARU K. KUNO, GREGORY V. HARTLAND, Department of Chemistry and Biochemistry, University of Notre Dame — Transient absorption microscopy (TAM) is a relatively new technique that allows the study of single nanostructures with sub-picosecond time resolution. Here, we present results for CdTe and Au Nanowires (NW). For the first material, we find an interesting power dependence of the excited dynamics, suggesting that a trap-filling mechanism is responsible for the observed behaviour. Additionally, acoustic phonons were observed, which were well described using continuum elastic models.[2] Carrier diffusion along these NWs are also reported. In the case of Au NWs, the propagation of surface plasmon polaritons was investigated. The results are in agreement with previous studies performed with fluorescence based techniques.[3,4] Unlike fluorescence techniques, multiple measurements on the same nanostructures are possible with TAM allowing one-to-one comparisons under different excitation polarizations and environments.

2:42PM J20.00002 Damping of Acoustic Vibrations of Single Suspended Gold Nanowires and Nanoplates in Air and Water Environments[1] , TODD MAJOR, University of Notre Dame, AURÉLIEN CRUT, Université Lyon 1, BO GAO, MARY DEVADAS, SHUN LO, University of Notre Dame, NATALIA DEL FATTI, FABRICE VALLÉE, Université Lyon 1, GREGORY HARTLAND[2], University of Notre Dame — The dynamics of metal nanoparticles are affected by intrinsic properties, such as crystal structure, and the viscosity and acoustic impedance of the environment. In order to separate the contribution of the environment from the dynamics of individual nanostructures, ultrafast transient absorption measurements are taken on gold nanowires suspended over trenches on the substrate in air and in water. Measurements taken in an air environment represent damping from intrinsic sources, whereas experiments in water represent a liquid environment with a well known viscosity. Quality factors of the acoustic modes from the gold nanowires were measured and match well with previous studies. The results are compared to Continuum Mechanics Calculations. The calculations show that the viscosity of water plays a minor impact on the damping of the acoustic modes. This study has been recently extended to nanoplates suspended over trenches, but the effect of viscosity has not been investigated for these materials yet.

2:54PM J20.00003 ABSTRACT WITHDRAWN –

3:06PM J20.00004 Advanced scanning transmission electron microscopy characterization of UV LED nanowires , PATRICK PHILLIPS, University of Illinois at Chicago, RAJAN KUMAR, Northwestern University, SANTINO CARNEVALE, ROBERTO MYERS, Ohio State University, ROBERT KLIE, University of Illinois at Chicago — The role of aberration-corrected scanning transmission electron microscopy (STEM) in materials characterization is examined in regards to Al(x)Ga(1-x)N nanowires. Wires were graded from x=0 to x=1 and then from x=1 to x=0 with a small active quantum disk region located between the two gradations. This configuration is the basis for previously reported UV light emitting diodes. However, to assist subsequent growth processes while striving for optimum efficiency, both structural and chemical characterization methods are necessary, which can be provided at sufficiently high resolutions by advanced STEM instruments. Specifically, structural characterization will focus on determining layer thicknesses and wire polarity, as well as visualizing any short-range ordering and/or stacking faults that may be present. STEM multislice image simulations will also be discussed. Chemically, both energy dispersive X-ray (EDX) and electron energy loss (EEL) spectroscopies will be discussed in various capacities, ranging from quantum well composition (EDX) to N K-edge fine structure of both GaN and AlN (EELS).

3:18PM J20.00005 Electrochemically Grown, Composite Au/CdS/Au Nanowires: Structural and Optical Properties , TODD BRINTLINGER, RHONDA STROUD, JAMES LONG, U.S. Naval Research Laboratory, STEFANIE SHERRILL, SANG BOK LEE, Univ. of Maryland, BLAKE SIMPKINS, U.S. Naval Research Laboratory — We present growth, characterization, and optical response of solution-synthesized nanoplasmonic structures coupled with nonlinear dielectrics. Transmission electron microscopy indicates the templated electrochemical growth of 60-300 nm diameter, 200-5000 nm long composite Au-CdS-Au cylindrical nanostructures yield wurtzite CdS spanning small gaps between Au nanowires. The electrodeposited CdS exhibits an absorption band at $\sim$ 500 nm consistent with band edge absorption of crystalline CdS and broad defect band luminescence centered $\sim$ 625 nm. CdS exhibits sufficient quality to produce second harmonic generation stimulated with a pulsed, linearly polarized pump-light from a femtosecond Ti-sapphire laser. The effect of structure geometry and environment on optical response is investigated through variations in substrates, growth parameters and focused-ion-beam (FIB) shaping of nanostructures.

3:30PM J20.00006 Synthesis and Characterization of Gold-Titanium Dioxide Nanoparticles , HAILEY CRAMER, ISMAT SHAH, University of Delaware — Nanoparticles are of recent scientific interest due to their unique size-dependent optical, electrical, and catalytic properties. Gold nanoparticles specifically, have many potential applications, especially in optoelectronic devices due to their optical properties and plasmon resonance. The specific goals of this research are to synthesize Au/TiO_2 core-shell nanoparticles for their use in improving the overall efficiency of P3HT/PCBM polymer solar cells previously prepared in our lab. The standard sodium citrate reduction method was used to synthesize gold nanoparticles with an average diameter of 15 nm. Through changing the concentration of sodium citrate in solution we were able to tune the size of the nanoparticles, and therefore change their light-absorbing properties. The goals of this research are to cap the gold nanoparticles with TiO_2 through a sol-gel method. Characterization of the Au/TiO_2 particles will be performed using high resolution tunneling electron microscopy to determine the size of the nanoparticles and the thickness of the TiO_2 shell. In addition, ultraviolet-visual spectroscopy was used to determine the absorption of the particles, and dynamic light scattering was used to confirm the size distribution of the particles. The incorporation of Au/TiO_2 nanoparticles in P3HT/PCBM devices will be discussed.

3:42PM J20.00007 New experimental evidences of Au-Cu_2S core-shell nanoparticles and atomic resolution imaging by aberration-corrected STEM[1] , SUBARNA KHANAL, GILBERTO CASILLAS, NABRAJ BHATTARAI, J. JESUS VELAZQUEZ-SALAZAR, MIGUEL JOSE YACAMAN[2], University of Texas at San Antonio — Au-Cu_2S core-shell nanoparticles present different properties than their monometallic counterparts, opening a wide range of possibilities for different applications. Au-Cu_2S core-shell nanostructures have raised interest for their many applications in photoelectronic, sensing, catalysis and so on. Au and Au-Cu_2S core-shell nanoparticles were prepared by using a modified polyol method. First Au seeds were prepared by reducing $HAuCl_4.xH_2O$ in ethylene glycol (EG) in the presence of poly(vinylpyrrolidone) (PVP) as a polymer surfactant. Then Cu_2S shells were overgrown on Au core seeds by reducing $CuSO_4$ in EG with PVP. The morphology and structural characteristics of Au and Au-Cu_2S nanostructures were studied in detail using scanning electron microcopy HITACHI S-5500 and high resolution transmission electron microscope (HRTEM), a resolution 0.19 nm. Moreover, the Cs-corrected scanning transmission electron microscopy (Cs-corrected STEM) technique allowed us to probe the structure at the atomic level of these nanoparticles revealing new structural information. We determined the structure of the four main polyhedral morphologies obtained in the synthesis: decahedral, icosahedral, triangular plates, and rods.

3:54PM J20.00008 Mechanism for resonant energy transfer in plasmonic light-harvesting materials[1] , SCOTT CUSHING, JIANGTIAN LI, NIANQIANG WU, ALAN BRISTOW, West Virginia University — Localized surface plasmon resonance (LSPR) is a promising route to extending the light-harvesting of semiconductors into the visible and near infrared. Core-shell nanostructures are studied using transient absorption spectroscopy to explore the carrier dynamics and energy harvesting mechanism [1]. The metal core@Cu_2O shell nanoparticles have a broad plasmon resonance centered at 650 nm. The amplitude of the spectral dependence of the transient absorption can be fit using three contributions: the semiconductor density of states, the LSPR, or the overlap integral between the two. The fitting procedure reveals the energy transfer mechanism in Au@Cu_2O is dominated by a plasmon induced resonant energy transfer, while the energy transfer in Ag@Cu_2O is a combination of resonant energy transfer and hot electron injection from the metal to semiconductor. The effects of core composition and shell thickness are studied with the aim of finding the best combination for a viable full solar spectrum, plasmon-enhanced photocatalyst. [1] S. K. Cushing, J. T. Li, F. K. Meng, T. R. Senty, S. Suri, M. J. Zhu, M. Li, A. D. Bristow, N. Q. Wu, J. Am. Chem. Soc. 134, 15033 (2012).

4:06PM J20.00009 Effects of plasmonic environment on electric and magnetic dipole spontaneous emission , RABIA HUSSAIN, YURI BARNAKOV, NATALIA NOGINOVA, Norfolk State University — Luminescence of Eu ions was used to study effects of plasmonic environment on spontaneous emission of magnetic and electric dipoles in several nanostructured systems, including gold nanostrips, gold and silver nanomesh and thin films. Significant changes in polarization and radiation patterns were observed in the spectral range of plasmonic resonance. The effects were different for electric and magnetic dipole related transitions. The results are discussed in terms of coupling of emitters with radiative and plasmonic modes with account for losses. We also demonstrate the possibility to map the enhancement factors for magnetic and electric dipoles separately in near field optical studies.

4:18PM J20.00010 Single particle optical investigation of gold-enhanced upconverted fluorescence emission , KORY GREEN, SHUANG FANG LIM, North Carolina State University — Near IR excited upconverting nanoparticles (UCNPs) are ideal fluorescent contrast agents, leading to background free bioimaging. However, their fluorescent brightness is hampered by low quantum efficiency due to material limitations. We investigate the plasmonic coupling of 20 nm diameter core NaYF4: Yb, Er upconverting nanoparticles (UCNPs) coupled to both gold nanoparticles and coated in a gold nanoshell. The structures of the UCNPs composites have been verified by transmission electron microscopy (TEM), UV-Vis absorption and fluorescent emission. Spectroscopic studies such as single particle spectra and time resolved decay has been performed to investigate and fine tune the luminescent enhancement. In particular, we have performed time-resolved spectroscopy between 400 nm and 1700 nm. The monitoring of all relevant energy level transitions, including intermediate levels, contribute to a complete understanding of the mechanisms at work in plasmonicly enhanced, high-efficiency, small UNCPs.

4:30PM J20.00011 Enhancement of single particle rare earth doped $NaYF_4$: Yb, Er emission with gold shell , SHUANG LIM, LING LI, HANS HALLEN, North Carolina State University — We report on the enhancement in emission of $NaYF_4$: Yb, Er upconverting nanoparticles (UCNPs) coated with a gold nanoshell. We have synthesized a doped $NaYF_4$ core of 350 nm, with a sufficiently thick undoped $NaYF_4$ shell of 65 nm thickness to minimize contact with the gold surface plasmons, and effectively minimizing luminescence quenching. Absorption and fluorescence emission measurements of single $NaYF_4$ particles show enhanced absorption in the near infrared and a 1.5 times overall enhanced emission intensity. A relative increase in green/red emission was observed for both gold seed attachment and shell growth, of approximately 1.9 and 2.3 times respectively. Both Au seed attachment and shell growth has been shown to double the green/red emission ratio. The surface plasmon resonance of the UCNP core/Au shell composite is shown to be dependent on the gold shell thickness. Our experimental results are corroborated by finite element calculations.

4:42PM J20.00012 Two-color Surface Plasmon Polariton Assisted Upconversion Luminescence in $NaYF_4$:Yb:Tm on Au Nanopillar Arrays , STEVE SMITH, ROBERT ANDERSON, AMY HOR, JON FISHER, South Dakota School of Mines and Technology, KHADIJEH BAYAT, MAHDI BAROUGHI, South Dakota State University, QUOCAHN LU, P. STANELY MAY, University of South Dakota — Spectroscopic imaging was used to study the surface plasmon polariton (SPP) enhanced upconversion luminescence of $NaYF_4$:Tm:Yb nanoparticles embedded in PMMA supported on Au nanopillar arrays. Spatially-resolved upconversion spectra show enhancement in both the visible and near-infrared region of the spectrum, clearly associated with the plasmonic resonances of an engineered periodic array of nanopillars. The array has a lattice resonance associated with the SPP near 980nm, at the peak absorption of the Yb^{3+} ion, while the local surface plasmon resonance (LSPR) of the individual pillars is seen to enhance the near-infrared emission of Tm^{3+} near 800nm. The combined effect results in a significantly higher enhancement of the near-infrared emission when compared to the visible upconversion lines of Tm^{3+}, consistent with the interpretation of sequential surface plasmon assisted absorption and emission at two separate and disparate energies. The presence of SPP and LSPR were confirmed by spectrally resolved reflectivity, and the mechanism for luminescence enhancement was investigated by time resolved measurements of the luminescence decay. Reflectivity measurements are compared to finite difference time domain simulations (FDTD).

4:54PM J20.00013 Beller Lectureship: Surface Plasmon Laser Action Near the Surface Plasmon Frequency , RUPERT F. OULTON, Imperial College London — Lasers have recently been scaled in size beyond the diffraction limit of light by using electromagnetic surface excitations of metals. In this talk, I will discuss our approach to constructing surface plasmon (SP) lasers using semiconductor materials and outline potential applications that exploit the strong interaction of nanoscale light with matter. I will also present recent results on room temperature SPs lasers operating near the SP frequency by utilizing Zinc Oxide as a gain material combined with a Silver substrate. Surface plasmon lasers could be the most efficient and compact method of delivering optical energy to the nanoscale. There are two benefits: firstly, the efficiently generated (focused) coherent laser field can be extremely intense; and secondly, vacuum fluctuations within the laser cavity are considerably stronger than in free space. Consequently, SP lasers have the unique ability to drastically enhance both coherent and incoherent light-matter interactions bringing fundamentally new capabilities to bio-sensing, data storage, photolithography and optical communications. While there is a great deal of research to do on SP laser systems, this talk highlights the feasibility of nano-scale light sources and the potential of laser science at the nanoscale.

Tuesday, March 19, 2013 2:30PM - 5:30PM –

Session J21 DMP: Focus Session: Oxide Superlattices, Interfaces and Growth 323 - Hena Das, Cornell University

2:30PM J21.00001 Oxygen Octahedral Rotations in $BaTiO_3/CaTiO_3$ Superlattices , MARGARET COSGRIFF, PICE CHEN, NATHANIEL COREY, University of Wisconsin at Madison, XIFAN WU, Temple University, APURVA MEHTA, SLAC National Accelerator Lab, HIROO TAJIRI, Japan Synchrotron Radiation Research Institute, SPring-8, HO NYUNG LEE, Oak Ridge National Laboratory, PAUL EVANS, University of Wisconsin at Madison — Complex oxide superlattices have a wide range of electronic and magnetic properties, which are affected by the structure of the interfaces between different components of the superlattice. The magnitude, coherence, and electric field response of oxygen displacements in three different $BaTiO_3/CaTiO_3$ superlattice compositions are measured using x-ray diffraction. The displacements are greater in compositions with more consecutive $CaTiO_3$ layers. The pattern of layer-by-layer alternating displacements is coherent over less than two superlattice unit cells. The net in-phase rotation of the oxygen octahedra gives rise to an x-ray reflection at (3/2 1/2 1). Density functional theory calculations for a $2(BaTiO_3)/4(CaTiO_3)$ composition predict a decrease in displacements of oxygen octahedra between barium and calcium layers when an electric field is applied, causing an intensity increase in this reflection. We found the intensity of this reflection for this composition increases by 1.6% when a 12.5 V pulse is applied, a weaker response than the 11% increase predicted. When a 20 V pulse is applied, the reflection intensity actually decreases by 3%, indicating a more complicated response.

2:42PM J21.00002 Coherent X-ray Diffraction from Striped Nanodomain in a PbTiO3/SrTiO3 Superlattice , QINGTENG ZHANG, PICE CHEN, University of Wisconsin, Madison, ZHONGHOU CAI, Argonne National Laboratory, MATTHEW DAWBER, SARA CALLORI, Stony Brook University, PAUL EVANS, University of Wisconsin, Madison — Polarization striped domains in ferroelectric/dielectric superlattices reflect the coupling between the polarization and a lattice distortion in each component layer. We have used coherent x-ray diffraction to study the variation of the striped domain pattern in a PbTiO3/SrTiO3 ferroelectric/dielectric superlattice over lateral length scales of hundreds of nanometers to microns. A coherent beam of synchrotron x-rays with a photon energy of 10 keV was focused to a spot with a diameter of approximately 200 nm. The arrangement of domains produces a speckle pattern of intensity in reciprocal space that varies according to the detailed arrangement of domains within the focal spot. When the focal spot is moved across the sample, it is found that the intensity of the total diffuse scattering remains constant while the positions of speckles vary in reciprocal space. This provides additional spatial information about the speckles which leads to better understandings of the configurations of the striped domains in ferroelectric/dielectric superlattices. This work is supported by US DOE under Grant No. DE-FG02-10ER46147.

2:54PM J21.00003 Component-Layer-Dependent Distortion of Striped Domains in PbTiO3/SrTiO3 Superlattices[1] , PICE CHEN, MARGARET COSGRIFF, QINGTENG ZHANG, University of Wisconsin-Madison, SARA CALLORI, Stony Brook University, BERNHARD ADAMS, ERIC DUFRESNE, Argonne National Laboratory, MATTHEW DAWBER, Stony Brook University, PAUL EVANS, University of Wisconsin-Madison — Weakly-coupled ferroelectric/dielectric superlattices show novel ferroelectric properties that are not accessible in compositionally uniform ferroelectrics. Nanoscale polarization striped domains are formed as a result of the minimization of the energy associated with depolarization fields. The dielectric layers are polarized, however, with a magnitude that is much smaller than in the ferroelectric layers. The unequal distribution of polarization has been predicted to induce layer-dependent dynamics of the polarization switching of striped domains. Here we experimentally test this prediction in a PbTiO3/SrTiO3 superlattice with time-resolved x-ray diffraction under electric fields up to 2.38 MV/cm. The intensities of x-ray reflections arising from striped domains decrease at a nanosecond timescale, as the polarization switching occurs. The relative magnitude of the intensity change depends on the indices of reflections. We compared the observed intensity changes of domain reflections with a kinematic x-ray simulation. The measurement agrees with a model in which the average polarization of striped domains in dielectric SrTiO3 layers is slightly increased under applied electric fields, and the ferroelectric PbTiO3 layers are unchanged.

[1]Supported by US DOE under Grant No. DE-FG02-10ER46147

3:06PM J21.00004 Static and Dynamic Properties of Ferroelectric Nanodomains , PAVLO ZUBKO, University of Geneva — The performance of ferroelectric devices is closely connected with the structure and dynamics of ferroelectric domains. In ultrathin ferroelectrics, very dense domain structures can arise naturally in response to the presence of a depolarizing field and are expected to exhibit unusual static and dynamic behavior. Superlattices composed of ultrathin ferroelectric blocks sandwiched between paraelectric layers offer an ideal system for investigating the structure and functional properties of such nanodomains. The electrostatic coupling between the ferroelectric layers can be controlled by modifying the thicknesses of the paraelectric layers and the domain structure can be tailored by exploiting Kittel's law. X-ray diffraction and transmission electron microscopy combined with electron energy loss spectroscopy were used to study the electrostatic interactions in $PbTiO_3$-$SrTiO_3$ superlattices, revealing highly inhomogeneous polarization and structural profiles that arise due to the presence of ferroelectric nanodomains. The superlattice geometry is also ideal for studying the response of the ultrathin ferroelectric layers to applied fields. Large uniform electric fields can be supported without significant leakage, while changes in the domain structure can be observed simultaneously using X-ray diffraction. The tiny, reversible displacements of the nanodomain walls were found to contribute to a large enhancement of the effective dielectric response that persists over a broad range of temperatures and exhibits low losses. The static and dynamic properties of nanodomains in $PbTiO_3$-$SrTiO_3$ superlattices will be discussed and compared with those of isolated thin films.

3:42PM J21.00005 Photo-induced stabilization and enhancement of the ferroelectric polarization in $Ba_{0.1}Sr_{0.9}TiO_3/La_{0.7}Ca(Sr)_{0.3}MnO_3$ thin film heterostructures[1] , Y.M. SHEU, S.A. TRUGMAN, L. YAN, Q.X. JIA, A.J. TAYLOR, R.P. PRASANKUMAR, Los Alamos National Laboratory, Los Alamos, New Mexico 87545, USA — We demonstrate that optically pumping carriers across the interface between ferroelectric $Ba_{0.1}Sr_{0.9}TiO_3$ and ferromagnetic $La_{0.7}Ca(Sr)_{0.3}MnO_3$ thin films can not only stabilize but also enhance ("write") the remanent polarization, which breaks crystal inversion symmetry, generating an optical second-harmonic signal that we "read." The new photo-induced ("written") ferroelectric state remains stable at low temperatures for over one day after removing the laser pulse. By optically decoupling the energy of the internal electric field from the ferroelectric double potential wells, we show that the displacement of the Ti atom increases, leading to a larger, more stable polarization state that may be suitable for applications in data storage (using similar writing and reading processes) as well as energy storage (e.g., solar nanocapacitors).

[1]This work was performed at the Center for Integrated Nanotechnologies, a U.S. Department of Energy, Office of Basic Energy Sciences user facility and also partially supported by the NNSAs Laboratory Directed Research and Development Program.

3:54PM J21.00006 Low dielectric loss in electric field-tunable $Ba_xSr_{1-x}TiO_3$ thin films grown by hybrid molecular beam epitaxy , ADAM KAJDOS, EVGENY MIKHEEV, ADAM HAUSER, SUSANNE STEMMER, Materials Department, University of California, Santa Barbara — $Ba_xSr_{1-x}TiO_3$ (BST) is an electric field-tunable dielectric that exhibits both low dielectric loss and high tunability, making it a system of particular interest for microwave device applications. In this presentation we report on the dielectric properties of paraelectric BST films (x = 0.19 - 0.46) grown by hybrid molecular beam epitaxy (MBE) on epitaxial Pt bottom electrodes. Using the hybrid MBE technique to achieve unprecedented stoichiometry control and low defect densities, we demonstrate dielectric quality factors ($Q = 1/\tan\delta$, where $\tan\delta$ is the dielectric loss tangent) exceeding 1000, an order of magnitude greater than any previously reported BST thin film. These low-loss films also exhibit high electric field tunability, with the relative tunability, $n(E) = \varepsilon(0)/\varepsilon(E)$, i.e. the ratio of the dielectric permittivity under zero and positive applied field, respectively, exceeding $n = 5$. The high quality of these BST films enables the investigation of intrinsic dielectric loss mechanisms, such as quasi-Debye loss. We will discuss the effect of point defect densities, stoichiometry and microstructure on the dielectric properties of these BST thin films.

4:06PM J21.00007 Tunable dielectric properties of Barium Magnesium Niobate (BMN) doped Barium Strontium Titanate (BST) thin films by magnetron sputtering , FIKADU ALEMA, AARON REINHOLZ, KONSTANTIN POKHODNYA, Center for Nanoscale Science and Engineering, North Dakota State University — We report on the tunable dielectric properties of Mg and Nb co-doped $Ba_{0.45}Sr_{0.55}TiO_3$ (BST) thin film prepared by the magnetron sputtering using BST target (pure and doped with $BaMg_{0.33}Nb_{0.67}O_3$ (BMN)) on $Pt/TiO_2/SiO_2/Al_2O_3$ 4" wafers at 700 °C under oxygen atmosphere. The electrical measurements are conducted on 2432 metal-ferroelectric-metal capacitors using Pt as the top and bottom electrode. The crystalline structure, microstructure, and surface morphology of the films are analyzed and correlated to the films dielectric properties. The BMN doped and undoped BST films have shown tunabilities of 48% and 52%; and leakage current densities of $2.2\text{x}10^{-6}$ A/cm^2 and $3.7\text{x}10^{-5}$ A/cm^2, respectively at 0.5 MV/cm bias field. The results indicate that the BMN doped film exhibits a lower leakage current with no significant decrease in tunability. Due to similar electronegativity and ionic radii, it was suggested that both Mg^{2+} (accepter-type) and Nb^{5+} (donor-type) dopants substitutTi^{4+} ion in BST. The improvement in the film dielectric losses and leakage current with insignificant loss of tunability is attributed to the adversary effects of Mg^{2+} and Nb^{5+} in BST.

4:18PM J21.00008 Atomic Layer-by-Layer Growth of Homo-epitaxial $SrTiO_3$ Films by Laser MBE , MARYAM GOLALIKHANI, QINGYU LEI, GUOZHEN LIU, KE CHEN, Department of Physics, Temple University, SUILIN SHI, FUQIANG HUANG, CAS Key Laboratory of Materials for Energy Conversion, Shanghai Institute of Ceramics, Chinese Academy of Sciences, XIAOXING XI, Department of Physics, Temple University — A precise customization of oxide hetero-structures at the atomic layer level became possible with layer-by-layer growth of oxide thin films by laser MBE from separate oxide targets. In situ characterization during growth helps to optimize the composition of these superlattices. In this work we focused on the reflection high energy electron diffraction (RHEED) spot analysis for in situ growth control of stoichiometric $SrTiO_3$ thin films in an atomic layer-by-layer manner from separate SrO and TiO_2 targets. We have shown that both stoichiometry and full monolayer dose can be controlled using RHEED diffraction spot intensity oscillations. Observations of a single sharp peak in x-ray diffraction spectra confirm the same composition of the films as that of the stoichiometric $SrTiO_3$ substrate. We have successfully demonstrated that this new approach of laser MBE can achieve the same precise stoichiometry control as shown by reactive MBE.

4:30PM J21.00009 In-situ x-ray diffraction studies of the epitaxial growth of $BaTiO_3$ on $SrTiO_3$, S.J. CALLORI, J. SINSHEIMER, B. BEIN, Dept. of Physics and Astronomy, Stony Brook University, P.V. CHINTA, A. ASHRAFI, R. HEADRICK, Dept. of Physics, University of Vermont, M. DAWBER, Dept. of Physics and Astronomy, Stony Brook University — When $BaTiO_3$ is grown on $SrTiO_3$ it is subject to a large epitaxial compressive strain, which means that it can actually be ferroelectric during growth. Therefore, screening provided by a bottom electrode is important in realizing fully strained $BaTiO_3$ thin films. To fully understand the role of strain, electrical boundary conditions and deposition technique in forming highly strained ferroelectric thin films, we grew thin films of $BaTiO_3$ on $SrTiO_3$, both with and without $SrRuO_3$ bottom electrodes, using both off axis RF magnetron sputtering and pulsed laser deposition, while the growth was monitored by in-situ x-ray diffraction at X21 at the National Synchrotron Light Source. Out-of-plane and in-plane lattice parameters and x-ray reflectivity were measured during growth, allowing changes in strain and tetragonality of the films to be correlated with changes in growth modes. The presence or absence of an electrode impacted the relaxation and tetragonality of the films differently for the two different growth techniques. Information gained by these synchrotron experiments provides important guidance for the growth of high quality ferroelectric thin films and superlattices.

4:42PM J21.00010 Polar structure evolution of ultrathin $BaTiO_3$ films: in-situ LEED I-V[1] , JUNSOO SHIN, Department of Physics and Astronomy, Louisiana State University, Baton Rouge, LA 70803, USA, VON BRAUN NASCIMENTO, DIOGO DUARTE DOS REIS, Departamento de Física, ICEx, Universidade Federal de Minas Gerais, Belo Horizonte, MG, Brazil, LINA CHEN, E. WARD PLUMMER, JIANDI ZHANG, Department of Physics and Astronomy, Louisiana State University, Baton Rouge, LA 70803, USA — Understanding the fundamental physics of ferroelectricity in ultrathin films is a key issue of a critical size, of which a strong debate has erupted over the existence for decades. Ferroelectricity has previously been observed experimentally down to a few unit cells, depending on a complex interplay of electrostatic depolarization energy, domain formation, and so on. Using in situ Low Energy Electron Diffraction (LEED) I-V, we have systematically examined the structure evolution of ultrathin fully strained $BaTiO_3$ films (1-12 ML) on Nb-doped $SrTiO_3$. Comparison of observed diffraction intensities for 10 ML films at 300 K with calculated intensities reveals a vertical displacement of the central Ti, corresponding to a single-domain upward polar state. To investigate the polar structure evolution of ultrathin films, we have calculated all R-factors between two sets of experimental curves from 1 ML to 12 ML with 10 ML polar structure curve as a reference. As a result, we demonstrate that 8-12 ML thick $BaTiO_3$ films have very similar polar structures, whereas thinner films (1-7 ML) have continuously evolved from uncorrelated to correlated polar structures.

4:54PM J21.00011 Epitaxial growth of $BaTiO_3$ on Ge , PATRICK PONATH, AGHAM POSADAS, KURT FREDRICKSON, University of Texas at Austin, ALEXANDER KVIT, University of Wisconsin at Madison, ALEX DEMKOV, University of Texas at Austin — Germanium with its higher hole and electron mobility than silicon, in conjunction with a ferroelectric material like barium titanate (BTO) might be a potential candidate for a Ferroelectric RAM in the future. We report the epitaxial growth of BTO directly on a germanium (100) substrate. First, 0.5 monolayer of strontium metal is deposited on the cleaned Ge surface as a passivation layer at 600C. Molecular oxygen to a pressure of $5x10^{-6}$ torr is then introduced and barium and titanium are alternately deposited on the substrate at the same temperature. The BTO film is crystalline as-deposited and remains so throughout the growth as monitored by in situ reflection high energy electron diffraction. X-ray diffraction measurements of BTO films show only substrate peaks and (h00) peaks of BTO, indicating an in-plane ferroelectric polarization. This is expected due to the thermal expansion mismatch of BTO and Ge. We will report on efforts to induce out of plane polarization of BTO films grown on Ge. We have also measured the valence band offset between BTO and Ge using x-ray photoelectron spectroscopy (XPS) and found it to be 2.6 eV, resulting in a zero conduction band offset. We compare this value to density functional calculations of the offset.

5:06PM J21.00012 Theoretical study of growth of Pt on $BaTiO_3$ slabs , KURT FREDRICKSON, AGHAM POSADAS, The University of Texas at Austin, CATHERINE DUBOURDIEU, JOHN BRULEY, IBM T.J. Watson Research Center, ALEXANDER DEMKOV, The University of Texas at Austin — $BaTiO_3$ (BTO) is a well-known ferroelectric perovskite, which is tetragonal at room temperature. As BTO has potential as a component of a ferroelectric field-effect transistor (Matthews *et al.*, Science **276**, 238 (1997)), development of metal electrodes is of crucial importance. We investigate Pt deposition on (001) BTO. The metal is deposited in ultra-high vacuum in the molecular beam epitaxy reactor and characterized using transmission electron microscopy and in situ photoemission. Using density functional theory we calculate the surface energies of Pt(001), (011), and (111), and BTO (001) and investigate the wetting conditions of Pt(001) and (011) on TiO_2-terminated BTO(001). We use transmission electron microscopy to examine the interfaces of epitaxially grown Pt on BTO and compare the sizes of the islands with the sizes predicted by theory. In addition, we examine the dependence of ferroelectricity on the sample thickness. Results of our photoemission experiments are compared with first principles spectra.

5:18PM J21.00013 Dielectric properties of perovskite oxynitride epitaxial thin films , DAICHI OKA, YASUSHI HIROSE, HIDEYUKI KAMISAKA, TOMOTERU FUKUMURA, TETSUYA HASEGAWA, Department of Chemistry, School of Science, The University of Tokyo, SEIJI ITO, AKIRA MORITA, HIROYUKI MATSUZAKI, Department of Nuclear Engineering and Management, School of Engineering, The University of Tokyo, KATSUYUKI FUKUTANI, Institute of Industrial Science, The University of Tokyo, SATOSHI ISHII, KIMIKAZU SASA, DAIICHIRO SEKIBA, Uiversity of Tsukuba Tandem Accelerator Complex (UTTAC) — Perovskite oxynitrides with the formula ABO_2N are expected to show unique electric properties hardly accessible by conventional oxides. For example, N-2p orbitals tend to form a shallow band at the top of the oxygen-nature valence band. This enables us to develop narrow-bandgap ferroelectric materials with d^0 configuration, which is applicable to ferroelectrics-based photovoltaic cells. In this study, we fabricated (001)-oriented epitaxial thin films of $SrTaO_2N$ by nitrogen-plasma assisted pulsed laser deposition on (Nb-doped) $SrTiO_3$ substrate. X-ray diffraction measurements revealed large lattice distortion (c/a of 1.015-1.03) due to compressive strain from substrate (mismatch of -3.2 %), though it is partially relaxed. The films had yellow color with a bandgap of about 600 nm. Ferroelectric behavior was observed at room temperature by piezoresponse force microscopy. As far as we know, this is the first experimental observation for ferroelectricity in perovskite oxynitrides. First principles calculations suggested that the ferroelectricity originates from *trans*-type nitrogen ordering, which can be driven by compressive strain.

Tuesday, March 19, 2013 2:30PM - 5:30PM –

Session J22 DCMP: Optical Properties and Interactions in Quantum Dots and Wells 324 - Michael Scheibner, University of California, Merced

2:30PM J22.00001 Temperature dependence of highly homogeneous excitonic spectra of site-controlled pyramidal quantum dots , VALENTINA TRONCALE[1], Ecole Polytechnique Fédérale de Lausanne (EPFL), Laboratory of Physics of Nanostructures, CH-1015 Lausanne, EMANUELE PELUCCHI, Tyndall National Institute Lee Maltings, Cork, Ireland, ALOK RUDRA, ELI KAPON, Ecole Polytechnique Fédérale de Lausanne (EPFL), Laboratory of Physics of Nanostructures, CH-1015 Lausanne, LABORATORY OF PHYSICS OF NANOSTRUCTURES, EPFL, CH-1015 LAUSANNE TEAM — Site-controlled pyramidal quantum dots grown by MOVPE on patterned GaAs substrates offer many advantages such as emission wavelength, heterostructure tailoring and higher symmetry for efficient photon entanglement. We address the temperature dependence of X, 2X, X-, X+ exciton linewidths, providing insight on exciton-phonon interaction in this system. The investigated structures consist of GaAs/AlGaAs pyramidal QDs, positioned on 5μm centers, characterized using non-resonant micro-photolumionescence at low temperatures. PL spectra of individual QDs are highly reproducible, showing transitions excitons with inhomogeneous brodening as low as 2 meV, caused by slight thickness/composition fluctuations. Interferometric T-dependent linewidth measurements of the four excitonic transitions revealed values at T=0 K smaller than previously reported but larger than the estimated exciton radiative lifetime. We conclude that even at T=0 K the exciton decoherence time in GaAs QDs is not completely governed by a radiative lifetime and discuss this effect.

[1]Present address: IBM Research GmbH, Saumerstrasse 4, CH-8803, Rueschlikon, Switzerland

2:42PM J22.00002 Carrier Dynamics in Site-Controlled InGaN/GaN Quantum Dots[1] , TYLER HILL, LEI ZHANG, HUI DENG, University of Michigan Physics, CHU-HSIANG TENG, BRANDON DEMORY, PEI-CHENG KU, University of Michigan EECS — We investigate the individual micro-photoluminescence and time resolved photoluminescence properties of several hundred site-controlled InGaN/GaN quantum dots fabricated "top down" by plasma etching. The optical properties of semiconductor quantum dots can be very inhomogeneous due to small fluctuations in dot size, compositions, growth conditions, or doping levels. Controlled variation of growth conditions combined with the knowledge of experimental uncertainties in the semiconductor properties allows for a statistical analysis to obtain quantitative correlations between the optical properties of the quantum dots and the growth conditions or structural properties. We find that, with an indium fraction of 10-15%, quantum dots with diameters smaller than 33 nm show markedly different carrier dynamics than those with a diameter larger than 60nm: 1) fluctuations in indium mole fraction or monolayer fluctuations in the InGaN layer have a more significant effect on photoluminescence than changing dot diameter; 2) non-radiative decay related to surface recombination is the dominant decay channel in the system; 3) Increasing surface to volume ratio helps suppress the internal quantum efficiency of multi-exciton states, leading to more strongly antibunched photon sources.

2:54PM J22.00003 Narrow optical line width from site-controlled InGaAs quantum dots , LILY YANG, NRC Postdoc Residing at the Naval Research Laboratory (NRL), MICHAEL YAKES, NRL, TIMOTHY SWEENEY, NRC Postdoc Residing at NRL, SAMUEL CARTER, CHULSOO KIM, NRL, MIJIN KIM, Sotera, ALLAN BRACKER, DANIEL GAMMON, NRL — The incorporation of self-assembled quantum dots (QDs) in systematically scalable quantum devices requires a method of nucleating dots with nanometer-scale spatial accuracy while preserving their narrow optical line width. We have developed a technique combining e-beam lithography, wet etching, and molecular beam epitaxial (MBE) growth to deterministically position InGaAs QDs with spectrometer limited photoluminescence line widths. Our technique takes advantage of the anisotropy in GaAs growth to evolve an etched pattern of holes and lines into faceted structures in which dots nucleate. Using this technique, we were able to grow a buffer layer of pure GaAs up to 90 nm in thickness between the processed surface and the dot nucleation surface, effectively separating the QDs from unavoidable residual defects and impurities on the patterned surface that broaden their optical line widths. Additionally, we demonstrate control over the number of dots nucleating per site, from single to a chain of several, by varying the dimensions of the original pattern. Our dots are grown in a Schottky diode structure. Their PL spectrum shows discrete charging transitions, with narrow linewidths near the spectrometer's resolution limit of 20 micro eV.

3:06PM J22.00004 Eliminating the fine structure splitting of excitons in self-assembled InAs/GaAs quantum dots via combined stresses , LIXIN HE, JIANPING WANG, University of Science and Technology of China, MING GONG, Washington State University, G.-C. GUO, University of Science and Technology of China — Eliminating the fine structure splitting (FSS) of excitons in self-assembled quantum dots (QDs) is essential to the generation of high quality entangled photon pairs. We show by a extended two-level model that the FSS of excitons in a general self-assembled InGaAs/GaAs QD can be fully suppressed via combined stresses along the [110] and [010] directions. The results of the model Hamiltonian are confirmed by atomic empirical pseudopotential calculations. For all the QDs we calculated, the FSS can be tuned to be vanishingly small (< 0.1 μeV), which is sufficient small for high quality entangled photon emission.

3:18PM J22.00005 Rabi-Kondo correlated state in a laser-driven quantum dot[1] , MOSHE GOLDSTEIN, Yale University, BJOERN SBIERSKI, ETH Zurich, MARKUS HANL, ANDREAS WEICHSELBAUM, LMU Munich, HAKAN TURECI, Princeton University, LEONID GLAZMAN, Yale University, JAN VON DELFT, LMU Munich, ATAC IMAMOGLU, ETH Zurich — Spin exchange between a single-electron charged quantum dot and itinerant electrons leads to the emergence of Kondo screening. When the quantum dot is driven resonantly by a weak laser light, the resulting emission spectrum serves as a direct probe of these correlations. In the opposite limit of vanishing exchange interaction and strong laser drive, the quantum dot exhibits coherent Rabi oscillations between the single-spin and optically excited states at the "bare" frequency Ω. Here we show that the interplay between strong exchange and non-perturbative laser coupling leads to the formation of a new non-equilibrium quantum-correlated state, featuring a second screening cloud. We elucidate the signatures of that state in the spectrum of luminescence. The spectrum consists of a delta-function peak at the laser light frequency (the peak weight scales as $\Omega^{2/3}$) and a broad peak red-shifted by the renormalized Rabi frequency $\Omega^* \propto \Omega^{4/3}$. The shape of the broad peak carries detailed information about the spin screening cloud.

[1]The work at Yale University is supported by the Simons Foundation and by NSF DMR Grant No. 1206612

3:30PM J22.00006 Adiabatic rapid passage in single InGaAs quantum dots: Towards a method of "incoherent control" , PETER BRERETON[1], MEGAN STANLEY, ALEXANDRA GRAHAM, BARBARA VAN HATTEM, PIERRE CORFDIR, AMOP Group, University of Cambridge, ISOBEL HOUGHTON, Bristol University, YANWEN WU, University of Texas Austin, MARK HOPKINSON, University of Sheffield, RICHARD PHILLIPS, AMOP Group, University of Cambridge — Adiabatic rapid passage (ARP) using frequency-swept optical pulses was shown to invert an InGaAs quantum dot from the ground state to the neutral exciton state [1,2]. As in atomic systems, ARP couples the confined electronic states of a quantum dot to a pulse that is chirped to sweep through resonance. If the sweep rate is slow with respect to the instantaneous Rabi frequency but faster than any decay rates, the dressed state of the system will adiabatically switch from one bare state to the other. Damping of the ARP inversion suggests confirmation of theoretical predictions of the effect of phonon-assisted dephasing [3]. ARP allows a train of chirped pulses to control the population state of a quantum dot without the need for locking the relative phase of the pulses. Each pulse pair will effectively drive the state vector through a 2π rotation on the Bloch sphere, regardless of the relative phase. Initial work toward this method of 'incoherent control' is presented, showing an enhancement of the photocurrent under excitation with two chirped pulses separated by greater than the electron tunneling time. [1] Y. Wu, et al, PRL 106, 067401 (2011). [2] C.-M. Simon, et al PRL, 106, 166801 (2011). [3] A. Debnath, et al PRB, 86, 161304 (2012).

[1]Now at U.S. Naval Research Laboratory

3:42PM J22.00007 Investigation of exciton states under two color optical excitation in quantum dot molecules[1] , RAMANA THOTA, ERIC STINAFF, Department of Physics and Astronomy, and Nanoscale and Quantum Phenomena Institute, Ohio University, Athens, Ohio 45701-2979, USA, ALLAN BRACKER, DAN GAMMON, Naval Research Laboratory, Washington, DC 20375, USA — It has been shown that vertically stacked InAs quantum dots may form quantum dot molecules (QDMs) where the tunneling of the carriers results in molecular wavefunction formation. These states are potentially useful for the preparation and manipulation of entangled spins, necessary components for quantum information processing. It has also been previously shown that certain charged exciton states can be created optically resulting in a straightforward method for optical spin initialization. We will present a study of optical charge state creation in vertically stacked $In_xGa_{1-x}As$ quantum dots grown by molecular beam epitaxy. This includes using a two color micro-photoluminescence experiment where we tune one laser through the states associated with the quantum dot (resonant excitation) and keep the other laser fixed with its excitation at the energy of the wetting layer (non-resonant excitation). This technique may result in a method for enhancement of various charged and neutral exciton states. In particular we have investigated the doubly charged exciton state, where the ground state is two spins in a know configuration, as well as biexciton enhancement, possibly useful for generating entangle photon pairs.

3:54PM J22.00008 Coulomb interaction signatures in self-assembled lateral quantum dot molecules , XINRAN ZHOU, University of Delaware, JIHOON LEE, Kwangwoon University, South Korea, GREGORY SALAMO, University of Arkansas, MIQUEL ROYO, JUAN CLIMENTE, Universitat Jaume I, Spain, MATTHEW DOTY, University of Delaware — Lateral quantum dot molecules (LQDMs) consist of at least two closely spaced InGaAs quantum dots arranged along axes perpendicular to the growth direction. Coherent interactions between neighboring QDs can lead to the formation of delocalized states with unique and useful properties. LQDMs provide an opportunity for independent control of both coupling and charge occupancy, and are thus of interest for prototype devices that use the QDs as bit registers. The experimental evidence for the existence of delocalized states and inter-dot tunneling in LQDMs, limited by the large center-to-center distance and weak tunneling strength, has been indirect. We use photoluminescence spectroscopy to investigate the ground state of single LQDMs. We apply a voltage along the growth direction that allows us to control the total charge occupancy of the quantum dot molecule. Using a combination of computational modeling and experimental analysis, we assign the observed discrete spectral lines to specific charge distributions. We explain the dynamic processes that lead to these charge configurations through electrical injection and optical generation. Our systemic analysis provides experimental evidence of inter-dot tunneling of electrons as predicted in previous theoretical work.

4:06PM J22.00009 Study of optical and electronic properties of self-assembled InAs/GaAs quantum rings[1] , GABRIEL LINARES, Instituto de Física "Luis Rivera Terrazas," Mexico, Puebla, SAMAR ALSOLAMY, Department of Physics and Astronomy, Ohio University, Athens, Ohio - 45701, MORGAN WARE, YURIY MAZUR, ZHIMING WANG, JIHOON LEE, GREG SALAMO, Institute for Nanoscience and Engineering, University of Arkansas, Fayetteville, Arkansas, ERIC STINAFF, Department of Physics and Astronomy, Ohio University, Athens, Ohio - 45701, LILIA MEZA-MONTES, Instituto de Física "Luis Rivera Terrazas," Mexico, Puebla — We will present a theoretical study of the properties of self assembled InAs/GaAs quantum rings. These nanostructures are grown by metal droplet epitaxy and do not follow the traditional strain driven growth model. For certain growth conditions, two quantum dots are formed on the ring structure which then, in a sense, acts as a wetting ring. A 'wetting layer' of 2D InAs is formed by migrating InAs material away from the initial In droplet. We have calculated the eigenstates of electrons and holes inside of the nanostructure using **k•p** theory, within the 1 and 4 bands approximation. We include effects such as the strain, the concentration of Indium and external electric field. The wave functions are then used to calculate optical properties and the energies of various exciton states as a function of the indium concentration and distribution. These results are compared with photoluminescence data on existing structures grown under different conditions. The energies of the various states along with the possibility of energy transfer between the dots will be explored.

4:18PM J22.00010 Luminescence studies of pairs of quantum dots formed on quantum rings by droplet epitaxy , SAMAR ALSOLAMY, Department of Physics & Astronomy, Ohio University, Athens, OH, MORGAN WARE, YURIY MAZUR, ZHIMING WANG, JIHOON LEE, GREG SALAMO, Insitute for Nanoscience and Engineering, University of Arkansas, Fayetteville, Arkansas, G. LINARES, LILIA MEZA-MONTES, Instituto de Física "Luis Rivera Terrazas", Mexico, Puebla, ERIC STINAFF, Department of Physics & Astronomy, Ohio University, Athens, OH — The use of metal droplet epitaxy may provide a novel method of growing laterally coupled nanostructures. We will present optical studies of InAs/GaAs nanostructures which result in twin quantum dots (QD) formed on a quantum ring (QR). Previous studies have investigated the coupling between vertically grown quantum dot pairs. Here we have used photoluminescence (PL) and photoluminescence excitation (PLE) to examine the possibility of energy transfer and coupling between quantum dot pairs in a single InGaAs quantum ring grown by droplet epitaxy. Power dependent photoluminescence spectra reveals a few peaks at low power, which are identified with emission from the ground state of the individual dots. As the power is increased we observe multi-exciton and excited state emission. We then perform PLE, tuning the excitation laser energy continuously from the high energy ring emission down to the individual dot states. We have observed resonant PLE emission in the QD/QR structures both at high energy and when resonant with the indentified ground states of one of the QDs which may indicate energy transfer and/or coupling between the dots.

4:30PM J22.00011 Coulomb Enhancement of Superfluorescence Bursts from the Fermi Edge in Highly-Excited Quantum Wells , JI-HEE KIM, TIM NOE, Dep. of Electrical and Computer Engineering, Rice University, STEPHEN A. MCGILL, National High Magnetic Field laboratory, Florida State University, YONGRUI WANG, ALEKSANDER K. WÓJCIK, ALEXEY A. BELYANIN, Dep. of Physics and Astronomy, Texas A&M University, JUNICHIRO KONO, Dep. of Electrical and Computer Engineering, Rice University — Superfluorescence (SF) is a many-body process in which an ensemble of excited dipoles spontaneously develops macroscopic coherence and abruptly decays by producing a burst of coherent radiation. We have recently reported the first observation of SF from semiconductor quantum wells in the presence of a strong perpendicular magnetic field [1]. Here, we report on results of our systematic magnetic field dependent studies of light emission from high-density electron-hole systems with gain. We observed SF pulses even at 0 Tesla when the excitation power is high and the temperature is low. The SF radiation at 0 Tesla shows a continuous band of emission in time-resolved photoluminescence images, i.e., the photon energy of the emitted light changes continuously with time. We interpret this phenomenon in terms of Coulomb enhancement of gain near the Fermi energy in a high-density electron-hole system. In addition, we demonstrate that the delay between the pump pulse and the SF pulses is tunable through the magnetic field and excitation pump power. Finally, the delay is longer for a lower-energy Landau level at a given magnetic field, i.e., the SF bursts proceed in a sequential manner from higher to lower Landau levels.

[1] Noe *et al.*, Nature 8, 219 (2012)

4:42PM J22.00012 Comparative Study on Intersubband Absorption in AlGaN/GaN and AlInN/GaN Heterostructures Grown on Low-Defect Substrates , COLIN EDMUNDS, LIANG TANG, JIAYI SHAO, DONGHUI LI, GEOFF GARDNER, MICHAEL MANFRA, OANA MALIS, Purdue University, ANDREW GRIER, ZORAN IKONIC, PAUL HARRISON, University of Leeds, DIMITRI ZAKHAROV, Brookhaven National Laboratory — Intersubband (ISB) devices utilizing III-nitrides have attracted attention for near- and far-infrared optoelectronic applications. However, the lattice mismatch between GaN and commonly used substrates results in a high defect density that hinders the vertical transport required for these devices. Furthermore, most devices in the literature utilize AlGaN/GaN heterostructures for which there is no lattice-matched alloy composition. Due to this lattice mismatch, AlGaN is not ideal for the development of complex devices such as quantum cascade lasers that often require active-region thicknesses on the order of microns for efficient operation. Fortunately, exact lattice matching occurs in AlInN/GaN heterostructures at roughly 18% In composition. To investigate the challenges of lattice-matched nitrides, we presents a comparative study of ISB absorption in high-quality AlGaN/GaN and near lattice-matched AlInN/GaN heterostructures grown by molecular-beam epitaxy on low-defect free-standing GaN substrates. Experimental measurements of transition energy, integrated absorbance and linewidth were compared to theoretical predictions that included many-body effects, interface roughness and calculations of the transition lifetime.

4:54PM J22.00013 Coulomb correlation effects and density dependence of radiative recombination rates in polar AlGaN quantum wells , GREG RUPPER, SERGEY RUDIN, U.S. Army Research Laboratory, FRANCESCO BERTAZZI, Politecnico di Torino, Torino, Italy, GREGORY GARRETT, MICHAEL WRABACK, U.S. Army Research Laboratory — AlGaN narrow quantum wells are important elements of deep-ultraviolet light emitting devices. The electron-hole radiative recombination rates are important characteristics of these nanostructures. In this work we evaluated their dependence on carrier density and lattice temperature and compared our theoretical results with the experimentally determined radiative lifetimes in the c-plane grown AlGaN quantum wells. The bands were determined in the k·p approximation for a strained c-plane wurtzite quantum well and polarization fields were included in the model. In order to account for Coulomb correlations at relatively high densities of photo-excited electron-hole plasma and arbitrary temperature, we employed real-time Green's function formalism with self-energies evaluated in the self-consistent T-matrix approximation. The luminescence spectrum was obtained from the susceptibility by summing over scattering in-plane directions and polarization states. The recombination coefficient was obtained from the integrated photo-luminescence. The density dependence of the radiative recombination rate shows effects of strong screening of the polarization electric field at high photo-excitation density.

5:06PM J22.00014 Second quantum state transitions in GaAs/AlGaAs Bragg MQW photonic crystal probed by Optical Reflectance and Electroreflectance , YUECHAO CHEN, Z. LIU, M.L. NAKARMI, Department of Physics, Graduate Center and Brooklyn College - CUNY, V.V. CHALDYSHEV, Ioffe Physico-Technical Institute, St. Petersburg, Russia — Electroreflectance spectroscopy measurement provides sharp and derivative-like spectral features in the energy region of excitonic transitions, while suppressing uninteresting background effects due to electro-modulation. We employed both electroreflectance and optical reflectance spectroscopies to probe excitonic transitions in a GaAs/AlGaAs multiple quantum well (MQW) structure. The sample used in this experiment consists of 60 periods of quantum well structures with GaAs well layer (13 nm) and AlGaAs barrier layer (94 nm), grown by solid source molecular beam expitaxy on a semi-insulating GaAs substrate. We performed electroreflectance and optical reflectance measurements by tuning the incident angle to coincide the second state of the heavy hole exciton (e2-hh2) transitions and the Bragg resonance. We observed a significant enhancement of excitonic features at the (e2-hh2) exciton transitions around incident angle of 23 degree in both techniques, revealing the double resonance condition. In the temperature dependent measurement of electroreflectance under the double resonance condition, we observed redshift of the excitonic features with increasing temperature. We will also discuss the effect of polarization in the electroreflectance measurements.

5:18PM J22.00015 Equispaced level in the quantum well calculated for seven semiconductor ternary alloys conduction band , ARTHUR EJERE, Department of Physics, University of Benin, Benin city, Nigeria, GODFREY AKPOJOTOR, Theoretical and Computational Condensed Matter Physics, Physics Department, Delta State University, Abraka, Nigeria — A model of equispaced-level conduction band in semiconductor quantum well (QW) nanostructures is derived. The procedure starts with the effective-mass Schrodinger equation, with the local conduction-band edge as the potential experienced by an electron in the QW. Then the effective-mass Schrodinger equation with linear harmonic potential is made to coincide with it . In this study, an attempt has been made to model some semiconductor ternary alloys ($A_xB_{1-x}C$) using this procedure, thereby adding to the varieties of QW nanostructures designs in existence. Two models are derived, one with a confining potential that may be realized by appropriate grading of the semiconductor alloy and the other with a non-confining potential where the electron effective-mass tends to zero as z tends to infinity [$m(z \to \pm\infty) \to 0$). This latter type of model is not realizable.

Session J23 DCMP: Optical Excitations, Defects and Synthesis of Dielectrics 325 - Javier Junquera, Universidad de Cantabria, Spain

2:30PM J23.00001 Unconventional Transport of Spin Bipolarons on an Antiferromagnetic buckled hexagonal lattice of half-filled d-band Mn^{2+} ions[1] , VERNER THORSMOLLE, ALEXANDER IGNATOV, MARIA PEZZOLI, KRISTJAN HAULE, DAVID KOLCHMEYER, ALEXANDER LEE, Rutgers, The State University of New Jersey, JACK SIMONSON, MEIGAN ARONSON, Stony Brook University, GIRSH BLUMBERG, Rutgers, The State University of New Jersey — $CaMn_2Sb_2$ presents a magnetic system with a buckled hexagonal lattice of half-filled d-band Mn^{2+} ions. AC resistivity and susceptibility exhibit non-monotonic temperature dependence at 85-210 K. Below 85 K it has an antiferromagnetic (AF) phase with an activation energy of 28 meV, and above 210 K a paramagnetic phase. Using Raman spectroscopy we find a mode at 32 meV which develops below the AF transition. We attribute this excitation to the activation energy associated with the motion of spin bipolarons. Here, hybridization between Sb and Mn results in extra electrons for the Mn $3d$-shells. It is energetically favorable for these extra carriers to form spin-singlets. These spin-bipolarons cover two Mn sites with a binding energy of $\sim$80 meV and conduction proceed via photo-assisted hopping with an activation energy of $\sim$32 meV. This spin bipolaron model explains the spectroscopic features providing a self-consistent picture of this conductivity mechanism that also clarifies reported unusual temperature-dependent magnetic and transport data.

2:42PM J23.00002 Infrared evidence for multiple structural transitions in single crystal $Cu_3(SeO_3)_2Cl$[1] , KEVIN H. MILLER, Department of Physics, University of Florida, HELMUTH BERGER, Institute of Physics of Complex Matter, Ecole Polytechnique Federal de Lausanne, DAVID B. TANNER, Department of Physics, University of Florida — Infrared reflection and transmission over a broad temperature range (10-300 K) have been measured on the anisotropic single-crystal $Cu_3(SeO_3)_2Cl$. Two distinct space groups have previously been reported for $Cu_3(SeO_3)_2Cl$ at 300 K (monoclinic C2/m and triclinic P1bar). Comparing the number of observed infrared active phonons with group theoretical predictions points towards the existence of the triclinic structure at 300 K; however, an impurity-rich monoclinic structure cannot be ruled out. New phonon modes are observed upon cooling below 90 K, and again upon cooling below 40 K. The latter temperature range corresponds to the onset of long range magnetic order in the material. The structural and magnetic properties of $Cu_3(SeO_3)_2Cl$ will be discussed in terms of our infrared spectra, group theoretical predictions, and comparisons to related compounds.

2:54PM J23.00003 Optical spectroscopy and Fermi Surface studies of the Rashba spin-splitting compound BiTeI[1]

, CATALIN MARTIN, K.H. MILLER, S. BUVAEV, A.F. HEBARD, University of Florida, Gainesville, Florida, 32611, USA, E.D. MUN, V. ZAPF, National High Magnetic Field Laboratory, Los Alamos, NM, 87545, USA, H. BERGER, Ecole Polytechnique Federal de Lausanne, CH-1015 Lausanne, Switzerland, D.B. TANNER, University of Florida, Gainesville, Florida, 32611, USA — We measured the temperature dependent optical reflectivity $R(\omega)$ and Shubnikov-de Haas oscillations in samples of BiTeI with different carrier concentrations. The electronic excitation spectrum, although consistent with Rashba spin-splitting of the bulk electronic bands, reveals additional features: a low energy excitation band and a larger number of phonons than expected from crystal structure. Some of the vibrational modes have strongly asymmetric line-shape. The period of quantum oscillations scales remarkably well with the component of magnetic field along the crystallographic c-axis and is rapidly suppressed when the field is tilted from this axis. We discuss our results in connection with possible charge accumulation at the surface of BiTeI.

3:06PM J23.00004 Enhancement of charge and spin orders in a photoexcited one-dimensional strongly correlated system

, HANTAO LU, Yukawa Institute for Theoretical Physics, Kyoto University, Kyoto, 606-8502, Japan, SHIGETOSHI SOTA, Computational Materials Science Research Team, RIKEN AICS, Kobe, Hyogo 650-0047, Japan, HIROAKI MATSUEDA, Sendai National College of Technology, Sendai, 989-3128, Japan, JANEZ BONCA, J. Stefan Institute, SI-1000 Ljubljana, Slovenia, TAKAMI TOHYAMA, Yukawa Institute for Theoretical Physics, Kyoto University, Kyoto, 606-8502, Japan — By using the time-dependent Lanczos method, the nonequilibrium pro- cess of the half-filled one-dimensional extended Hubbard model, driven by a transient laser pulse, is investigated. In the case of large on-site Coulomb interactions, there are two phases separated by a first order quantum phase transition, i.e., spin-density-wave (SDW) and charge-density-wave (CDW) phases, which are characterized by algebraic decay of spin cor- relations and a long-range (staggered) charge order, respectively. When the system is subjected to the irradiation of a laser pulse, from the SDW side near the phase boundary, with proper laser frequency and strength, a sustainable charge order enhancement can be realized while local spin correlations remain. Analogously, from the CDW side, the suppression of long-range charge order is accompanied with a local spin correlation enhancement. We analyze the conditions and investigate possible mecha- nisms of the emerging order enhancements. In off-resonance region, more extended recovery of spin correlations which may come from nonlinear effect is also observed.

3:18PM J23.00005 Computational study of novel half metallic compounds

, ZHIJIAN WU, JING WANG, Changchun Institute of Applied Chemistry — Half-metallic (HM) materials are metallic for one spin direction while at the same time semiconducting for the other spin direction [1]. The unique feature of HM material is that it has an integer spin magnetic moment. For a carefully selected material, the integer can be zero (compensated). Besides ferromagnetic (FM) parallel spin arrangements, ferrimagnetic or even antiferromagnetic (AFM) alignments are also possible. In particular, half-metallic antiferromagnet (HM-AFM) possesses no macroscopic magnetization, yet their carriers are fully spin-polarized. In this work, half metallic compounds have been predicted by using the first principles, such as $NiMoO_3$ [2].

3:30PM J23.00006 A non-perturbative general expression for the conductance through a leaky chiral edge mode

, KUN WOO KIM, California Institute of Technology, ALEXANDRA JUNCK, Freie Universitt Berlin, ISRAEL KLICH, University of Virginia, GIL REFAEL, California Institute of Technology — Chiral edge modes of topological insulators and Hall states exhibit non-trivial behavior of conductance in the presence of impurities or additional channels. We will present a simple formula for the conductance through a chiral edge mode coupled to a disordered bulk. For a given coupling matrix between the chiral mode and bulk modes, and a Green function matrix of bulk modes in real space, the renormalized Green function of the chiral mode is expressed in a closed form ratios of determinants. We will conclude with examples of how the formula could be applied to describe the behavior of a chiral mode coupled to different types of bulk systems.

3:42PM J23.00007 Generalization of the Peierls phase for gauge-invariant Green functions

, SYLVIA D. SWIECICKI, J.E. SIPE, University of Toronto — Solids in time-varying fields can be characterized with the non-equilibrium Green function formalism. If the interaction is described through potentials, the identification of sum rules is necessary to remove unphysical divergences that can appear in low frequency response calculations. For isolated atoms divergences are avoided by moving to a gauge-invariant Hamiltonian with the Power-Zienau-Woolley transformation.[1] For solids, a gauge-invariant Green function formalism was proposed by Levanda and Fleurov[2]; in the generalization of the Peierls phase they introduced they consider only straight lines in spacetime. We extend this work to arbitrary paths in spacetime and show that the results for isolated atoms can be derived as a special case. More general applications are considered.

3:54PM J23.00008 Evolution of the Coherent State and the Electronic Structure in the Kondo Insulator SmB_6[1]

, XIAOHANG ZHANG, Center for Nanophysics & Advanced Materials, University of Maryland, College Park and National Institute of Standards and Technology, N.P. BUTCH, Lawrence Livermore National Laboratory, P. SYERS, S. ZIEMAK, R.L. GREENE, J. PAGLIONE, Center for Nanophysics & Advanced Materials and Department of Physics, University of Maryland, College Park — As an exemplary Kondo insulator, SmB_6 has been studied for several decades; however, direct evidence for the development of the Kondo coherent state and the evolution of the electronic structure in the material has not been obtained due to the rather complicated electronic and thermal transport behavior. Recently, these open questions attracted increasing attention as the emergence of a time-reversal invariant topological surface state in the Kondo insulator has been suggested [1]. Here, we use the quasiparticle tunneling spectroscopy technique to directly investigate the temperature dependence of the electronic states in SmB_6. As a signature of the Kondo screening effect in the material, a Fano-like resonance line shape is observed in the tunneling spectroscopy at temperatures below $\sim$ 100 K. We further demonstrate that inter-ion correlation has to be taken into account [2] in order to precisely describe the observed asymmetric tunneling conductance at low temperatures. Our quasiparticle tunneling spectroscopy results also provide important implications for the predicted nontrivial topology in the Kondo insulator.

4:06PM J23.00009 Intervalley scattering and localization behaviors of group-VI transition metal dichalcoginides , HAIZHOU LU, WANG YAO, The University of Hong Kong, DI XIAO, Carnegie Mellon University, SHUN-QING SHEN, The University of Hong Kong — We study the quantum diffusive transport of multi-valley massive Dirac cones coupled by intervalley spin-orbit scattering. We show that the intervalley spin-orbit scattering and intravalley spin-conserved scattering can be distinguished from the quantum conductivity that corrects the semiclassical Drude conductivity, due to their distinct symmetries and localization trends. In immediate practice, it allows transport measurements to estimate the intervalley scattering rate in hole-doped monolayers of group-VI transition metal dichalcogenides (e.g., molybdenum dichalcogenides and tungsten dichalcogenides), an ideal class of materials for valleytronics applications. The results can be generalized to a large class of multi-valley massive Dirac systems where time-reversal symmetry demands opposite spins in opposite valleys.

4:18PM J23.00010 The structural origin of energy band gap in ultraviolet borates. , ZHESHUAI LIN, RAN HE, Technical Institute of Physics and Chemistry, Chinese Academy of Sciences — Borate crystals have been intensively studied for their broad significant application in nonlinear optics materials, fluorescent materials, and laser crystals, especially in the ultraviolet (UV) spectral region (photon energy larger than 6.2 eV). However, due to the structural complexity the mechanism determining the energy band gap in the UV borates still hides in clouds. In this work, the structural origins of the energy band gaps in UV borates are systematically studied by ab initio methods and modeling considerations. Through analyzing the electronic band structures, we find that the top of valence bands in UV borates are dominant from the orbitals on oxygen. These orbitals construct the non-bonding states which determine the energy band gaps and their magnitudes depend on the local environments around oxygen atoms. Accordingly, the UV borates are categorized into three structural types, and in each type the ideal energy band gaps by removing the non-bonding states are almost the same. Moreover, a modified Bond Valence Sum method is adopted to parameterize the local environment around oxygen atoms, and the good agreement between the calculated and experimental energy band gaps within the accuracy of 0.3 eV can be achieved in UV borates.

4:30PM J23.00011 Electron Transport in Edge Metal-Insulator-Metal Tunnel Junctions Modulated by Underlying Ferroelectric Polarization Switching[1] , KIBOG PARK, YOUNGEUN JEON, SUNGCHUL JUNG, HAN BYUL JIN, Ulsan National Institute of Science and Technology, Ulsan 689-798, South Korea, JAE-HYEON GO, Hallym University, Chuncheon Gangwondo 200-702, South Korea, SOON-YONG KWON, Ulsan National Institute of Science and Technology, Ulsan 689-798, South Korea, NAM KIM, Korea Research Institute of Standards and Science, Daejeon 305-340, South Korea — The electron energy band profile in an Edge Metal-Insulator-Metal tunnel junction (EMIM) on a Insulator/Ferroelectric thin film was calculated by performing finite-element electrostatic modeling. It is found that the energy band profile in the EMIM junction alters significantly near the underlying Insulator/Ferroelectric layer depending on the polarization direction of ferroelectric layer. The energy band profile shows pinch-off when the interface bound charge at Insulator/Ferroelectric interface is negative while it shows a valley-like shape when the interface bound charge is positive. The change of the energy band profile depending on ferroelectric polarization was confirmed to result in a significant change of electron tunneling current by using WKB method. It is believed that this switching of electron tunneling resistance in the EMIM junction opens up a way to develop non-volatile ferroelectric memory devices using non-destructive read-out.

4:42PM J23.00012 Material Designs and Combinational Growth Techniques to Enable Novel Multiferroic Devices , MELANIE COLE, ERIC NGO, MATHEW IVILL, S. GARY HIRSCH, CLIFF HUBBARD, RYAN TOONEN, WENDY SARNEY, US Army Resarch Laboratory, WMRD, INTEGRATED ELECTROMAGNETIC MATERIALS RESEARCH GROUP COLLABORATION — Voltage control of magnetism in magnetic/ferroelectric bilayers has been most recently demonstrated in ultrathin metallic magnetic films through an electric field induced spin polarized charge screening effect. Voltage-controlled magnetism in magnetic/ferroelectric multilayers would provide a unique opportunity for integrating voltage-tunable RF/microwave magnetic devices on integrated circuits. It has been theoretically predicted that the voltage-control of magnetism in ferromagnetic/ferroelectric heterostructures can be significantly enhanced by utilizing high-K dielectrics. The critical challenge is how to enhance the permittivity of the ferroelectric film while maintaining low loss and low leakage characteristics and accomplishing this in an affordable manner by employing industry standard processing methods and large area low cost substrates. In this work we demonstrate the achievement of high-k, low loss and low leakage BST films utilizing optimized sputtered SrTiO3 buffer layers combined with a MOSD grown Mg-doped Ba0.60Sr0.40TiO3 overgrowth film on affordable large area substrates. Results of this research serves to promote enhanced EM coupling to enable a new class of charge mediated integratable voltage control multiferroic devices exploiting the converse ME effect.

4:54PM J23.00013 Synchroton Soft X-ray Absorption Studies of $YbFe_{1-x}Mn_xO_3$ ($0.0 \leq x \leq 1.0$) Perovskites , P. OLALDE-VELASCO, W.L. YANG, Advanced Light Source, Lawrence Berkeley National Laboratory, Berkeley, CA 94720, USA, C. HERNANDEZ, E. CHAVIRA, Instituto de Investigaciones en Materiales, Universidad Nacional Autónoma de México, 04510 México D. F., México, I. ROSALES, Facultad de Quimica, Universidad Nacional Autónoma de México, 04510 México D. F., México, A. TEJADA, L. HUERTA, J. JIMENEZ-MIER, Instituto de Investigaciones en Materiales, Universidad Nacional Autónoma de México, 04510 México D. F., México, E.E. MARINERO, HGST San José Research Center, 3404 Yerba Buena Rd., San José, CA 95135, USA — This work aims to correlate the interplay between structure-bonding (O2p-TM3d) and magnetic properties (TM 3d) in $YbFe_{1-x}Mn_xO_3$ ($0.0 \leq x \leq 1.0$) perovskites which are synthesized by the solid state reaction method. We have investigated by XAS the O2p and the magnetic TM3d unoccupied states of $YbFe_{1-x}Mn_xO_3$ ($0 \leq x \leq 1$). We find that increasing Mn doping promotes the creation of new states at the O2p band, it also induces a shifts towards lower energies of the O K pre-edge (with reference to the O2p-TM3d hybridization) and changes the spectral distribution in the region of TM 4s, p – O 2p- Yb 5d hybridization. These changes are most marked for $x > 0.2$. A correlated effect with Mn doping is observed in the Fe $L_{2,3}$ spectra where again new electronic states and systematic changes are observed $x > 0.2$. This is in contrast with Mn $L_{2,3}$ spectra, where all the spectra are very similar except for x=0.2. Thus, we provide a comprehensive picture of the electronic structure evolution in the conduction band in these materials as a function of the Mn content.

5:06PM J23.00014 Thermodynamic stability of radiogenic Ba in $CsAlSi_2O_6$ pollucite[1] , JOHN JAFFE, Pacific Northwest National Laboratory (retired), RENÉE VAN GINHOVEN, WEILIN JIANG, Pacific Northwest National Laboratory — Pollucite, a zeolite-like nanoporous aluminosilicate structure with nominal composition $CsAlSi_2O_6$, has been suggested as a nuclear waste storage form for fission-product radioactive isotopes of cesium, especially ^{137}Cs. One factor affecting the long-term stability of this waste form is the valence change associated with the beta decay that converts Cs into barium. We have used first-principles density functional total energy calculations to evaluate the thermodynamic stability of pollucite with Ba replacing Cs at regular lattice sites with respect to the precipitation of Ba, Cs or their oxides. We included small clusters of substitutional Ba_{Cs} as well as localized complexes of Ba_{Cs} with compensating electron donor defects, specifically Cs vacancies and interstitial oxygen. We conclude that Cs-Ba pollucite is thermodynamically stable against precipitation of Cs or its oxide, but that partial precipitation of Ba or BaO may be thermodynamically favored under some conditions. Even this change may be kinetically limited, however.

5:18PM J23.00015 Metal-induced gap states in ferroelectric capacitors and its relationship with complex band structures[1] , JAVIER JUNQUERA, PABLO AGUADO-PUENTE, Universidad de Cantabria — At metal-isulator interfaces, the metallic wave functions with an energy eigenvalue within the band gap decay exponentially inside the dielectric (metal-induced gap states, MIGS). These MIGS can be actually regarded as Bloch functions with an associated complex wave vector. Usually only real values of the wave vectors are discussed in text books, since infinite periodicity is assumed and, in that situation, wave functions growing exponentially in any direction would not be physically valid. However, localized wave functions with an exponential decay are indeed perfectly valid solution of the Schrodinger equation in the presence of defects, surfaces or interfaces. For this reason, properties of MIGS have been typically discussed in terms of the complex band structure of bulk materials. The probable dependence on the interface particulars has been rarely taken into account explicitly due to the difficulties to include them into the model or simulations. We aim to characterize from first-principles simulations the MIGS in realistic ferroelectric capacitors and their connection with the complex band structure of the ferroelectric material. We emphasize the influence of the real interface beyond the complex band structure of bulk materials.

Session J24 DCOMP: Quantum Many-Body Systems and Methods I 326 - Cyrus Umrigar, Cornell University

2:30PM J24.00001 Density dependence of fixed-node errors in quantum Monte Carlo: spin-polarized systems and triplet correlations[1] , ADEM KULAHLIOGLU, KEVIN RASCH, SHUMING HU, LUBOS MITAS, North Carolina State University — We present an analysis focused on the fixed-node bias of trial wave functions for fully spin-polarized atomic systems. We benchmark the case of three electrons in the lowest state for a given symmetry which exhibits near-degeneracy effects similar to the in Be-like systems. The trial wave functions examined have been constructed at the HF level and at the pairing level in the form of a pfaffian. We find very significant fixed-node errors at the HF level, of the order of tens of percent. On the other hand, we observe that the pfaffian wave function correlated in the triplet pair channel enables us to get essentially exact results. We demonstrate that the key reason behind the large fixed-node erorr of the HF wavefunction is its artificial nodal domain topology. In addition, the fixed-node error is studied as a function of electron density by varying the atomic charge Z. We find that it scales linearly with Z what is very similar to our previous study on Be-like systems with similar dependence on density but pairing in the singlet channel.

[1]Research supported by NSF and ARO.

2:42PM J24.00002 Fixed-node errors in electronic structure quantum Monte Carlo: interplay of density and node nonlinearities[1] , LUBOS MITAS, KEVIN RASCH, SHUMING HU, North Carolina State University — We analyze valence electronic structure quantum Monte Carlo (QMC) calculations of first- and second-row atom systems. It turns out that there are significant differences (twofold or more) between the valence fixed-node errors of the first- vs second-row atom systems for single-configuration trial wave functions. The differences are illustrated on a set of atoms, molecules and Si and C solids that are valence isoelectronic, have similar correlation energies, bond patterns, geometries, same ground states and symmetries. Our analysis shows that the root cause of these differences is the increase of electron density combined with the degree of the node nonlinearity. The findings have implications for QMC fixed-node biases in systems with many elements including transition metals and others, which fall under the same electronic structure pattern. The finding has implications for both for accuracy of fixed-node energies, efficiency in elimination of the fixed-node bias and also for pseudopotential construction for very heavy elements. It has potential implications also for other correlated wave function approaches.

[1]Research supported by NSF and ARO.

2:54PM J24.00003 Diffusion quantum Monte Carlo for atomic spin-orbit interactions[1] , MINYI ZHU, SHI GUO, LUBOS MITAS, North Carolina State University — We present a generalization of the quantum Monte Carlo methods (QMC) for dealing with the spin-orbit (SO) effects in heavy atom systems. For heavy elements, the spin-orbit interaction plays an important role in electronic structure calculation and becomes comparable to the exchange, correlations and other effects. We implement relativistic lj-dependent effective core potentials for valence-only calculations. Due to the spin-dependent Hamiltonian, the antisymmetric trial wave functions are constructed from two-component spinors in jj-coupling so that the states are labeled by its total angular momentum J. A new spin representation is proposed which is based on summation over all possible spin states without generating large fluctutations and the fixed-phase approximation is used to avoid the sign problem. Our approach is different from the recent idea based on rotating (sampling) the spinors according to the action of the spin-orbit operator. We demonstrate the approach on heavy atom and small molecular systems in both variational and diffusion Monte Carlo methods and we calculate both ground and excited states. The results show very good agreement with independent methods and experimental results within the accuracy of the used effective core potentials.

[1]Research supported by NSF and ARO.

3:06PM J24.00004 Wavefunction Monte Carlo for Transport in Open Quantum Systems[1] , JAMES GUBERNATIS, Los Alamos National Laboratory — The wave function Monte Carlo method is a technique for solving the stochastic differential equation associated with the master equation (Lindblad equation) for transport in an open quantum system. For an anisotropic, spin 1/2, XXZ Heisenberg chain in an external magnetic field, whose ends interact with heat baths, we compute the heat transport through the chain as a function of chain length, temperature difference at the ends, and the anisotropy of the chain's exchange interaction from both a wavefunction Monte Carlo simulation and a deterministic solution of the master equation for the open system's density matrix. Having both solutions creates benchmarks for the more fundamental objective of studying the consequence of replacing a piecewise deterministic step, which is typically part of the wavefunction Monte Carlo method, with a stochastic step. This replacement affords the potential of simulating longer chain lengths.

[1]Supported by the US Department of Energy

3:18PM J24.00005 Prospects for efficient QMC defect calculations: the energy density applied to Ge self-interstitials[1] , JARON KROGEL, University of Illinois at Urbana-Champaign, JEONGNIM KIM, Oak Ridge National Laboratory, DAVID CEPERLEY, University of Illinois at Urbana-Champaign — Defect formation energies require expensive energy difference calculations between defective and bulk systems over a range of system sizes. At the point of convergence, subregions added to represent larger systems no longer contribute to the formation energy and therefore display similar local energetics. A recent formulation of the energy density for QMC is capable of identifying separate energetic contributions from each atom, enabling the identification of the bulk-like regions in a defect system that only add noise to the final result. The potential efficiency gains of this approach are explored in a realistic defect system, the germanium self-interstitial. Calculations involving up to 217 atoms at fixed volume show that the extent of the strain energy field depends strongly on the interstitial site. Bulk-like regions are largest for the hexagonal interstitial increasing the efficiency by a factor of 2-3. In contrast, the split structure interstitial has few bulk-like atoms and shows no speedup. Possible approaches to further improve the efficiency will be discussed.

3:30PM J24.00006 Analytic time evolution, random phase approximation, and Green functions for matrix product states , JESSE M. KINDER, Case Western Reserve University, CLAIRE C. RALPH, Cornell University, GARNET KIN-LIC CHAN, Princeton University — Drawing on similarities in Hartree-Fock theory and the theory of matrix product states (MPS), we explore extensions to time evolution, response theory, and Green functions. We derive analytic equations of motion for MPS from the least action principle, which describe optimal evolution in the small time-step limit. We further show how linearized equations of motion yield a MPS random phase approximation, from which one obtains response functions and excitations. Finally, we describe site-based Green functions associated with MPS. Using the fluctuation-dissipation theorem, we analyze the correlations introduced by the random phase approximation relative to the ground state wave function.

3:42PM J24.00007 Application of Multi-Orbital DMFT to the Dynamic Hubbard Model , CHRISTOPHER POLACHIC, FRANK MARSIGLIO, University of Alberta — Using multi-orbital dynamical mean field theory we explore the relationship between site parameters, band filling and electron-hole asymmetry arising through the electronic dynamic Hubbard model. We evaluate the emergence of hole pairing which has previously been observed through exact diagonalization and two-site DMFT studies.

3:54PM J24.00008 Thermo-Electric Transport Out-of-Equilibrium[1] , PRASENJIT DUTT, Yale University, KARYN LE HUR, Ecole Polytechnique — The manipulation of mesoscopic systems to engineer quantum circuits has become a crucial tool to test and explore novel phenomena which arise due to quantum coherence effects. Electronic transport through these systems under the combined influence of voltage biases and thermal gradients poses several open questions, the understanding of which has an immense scope for future applications. We provide an effective equilibrium description of the steady state dynamics of quantum impurity models far-from-equilibrium, which generalizes the theory presented in P.Dutt et al. (Annals of Physics, 326, 2963(2011)), to include thermal gradients. We study the interplay of strong voltage biases and large thermal gradients and its effect on the emergent Abrikosov-Suhl resonance. Taking the linear response limit, we compute the various thermo-electric coefficients of the system, such as the Peltier coefficient and thermal conductance, and verify the reciprocity relations of Onsager.

4:06PM J24.00009 Thermalization threshold in models of 1D fermions , SUBROTO MUKERJEE, RANJAN MODAK, Department of Physics, Indian Institute of Science, Bangalore, SRIRAM RAMSWAMY, TIFR Centre for Interdisciplinary Sciences, Hyderabad — The question of how isolated quantum systems thermalize is an interesting and open one. In this study we equate thermalization with non-integrability to try to answer this question. In particular, we study the effect of system size on the integrability of 1D systems of interacting fermions on a lattice. We find that for a finite-sized system, a non-zero value of an integrability breaking parameter is required to make an integrable system appear non-integrable. Using exact diagonalization and diagnostics such as energy level statistics and the Drude weight, we find that the threshold value of the integrability breaking parameter scales to zero as a power law with system size. We find the exponent to be the same for different models with its value depending on the random matrix ensemble describing the non-integrable system. We also study a simple analytical model of a non-integrable system with an integrable limit to better understand how a power law emerges.

4:18PM J24.00010 Topological Entanglement Entropy with a Twist[1] , BENJAMIN BROWN, Controlled Quantum Dynamics Theory Group, Level 12, EEE, Imperial College London, London, SW7 2AZ, United Kingdom, STEPHEN BARTLETT, ANDREW DOHERTY, Centre for Engineered Quantum Systems, School of Physics, The University of Sydney, Sydney, NSW 2006, Australia, SEAN BARRETT, Controlled Quantum Dynamics Theory Group, Level 12, EEE, Imperial College London, London, SW7 2AZ, United Kingdom — Topologically ordered phases of matter offer an attractive approach to fault tolerant quantum computation. They give rise to exotic quasi-particle excitations known as anyons. Anyons have a degenerate Hilbert space associated to them, which can be used to encode quantum information over non-local degrees of freedom. Recently, it has been shown that twists, the end points of dislocations in the toric code model, and the quasi-particles available on the toric code have some features analogous to a different anyon model; the Ising anyon model. Characteristics of topologically ordered phases can be assessed by calculating the topological entanglement entropy of regions of the ground state of its Hamiltonian. Further to this, the data of its anyonic excitations can be calculated using the von Neumann entropy. We present analytic results showing that twists have the same topological data as Ising anyons using extensions of known topological entanglement entropy formulas. This extends further the analogy between twists and Ising anyons.

4:30PM J24.00011 Nature of the Spin-Liquid Ground State of the S=1/2 Heisenberg Model on the Kagome Lattice , STEFAN DEPENBROCK, LMU Munich, IAN MCCULLOCH, The University of Queensland, ULRICH SCHOLLWOECK, LMU Munich — We perform a density-matrix renormalization group (DMRG) study of the $S = \frac{1}{2}$ Heisenberg antiferromagnet on the kagome lattice to identify the conjectured spin liquid ground state. Exploiting SU(2) spin symmetry, which allows us to keep more than 16,000 DMRG states, we consider cylinders with circumferences up to 17 lattice spacings and find a spin liquid ground state with an estimated per site energy of $-0.4386(5)$, a spin gap of $0.13(1)$, very short-range decay in spin, dimer and chiral correlation functions and finite topological entanglement γ consistent with $\gamma = \log_2 2$, ruling out gapless, chiral or non-topological spin liquids. At the same time, DMRG results provide strong evidence for a gapped topological Z_2 spin liquid.

4:42PM J24.00012 Geometrically Constructed Markov Chain Monte Carlo Study of Quantum Spin-phonon Complex Systems[1] , HIDEMARO SUWA, Department of Physics, Boston University — We have developed novel Monte Carlo methods for precisely calculating quantum spin-boson models and investigated the critical phenomena of the spin-Peierls systems. Three significant methods are presented. The first is a new optimization algorithm of the Markov chain transition kernel based on the geometric weight allocation. This algorithm, for the first time, satisfies the total balance generally without imposing the detailed balance and always minimizes the average rejection rate, being better than the Metropolis algorithm. The second is the extension of the worm (directed-loop) algorithm to non-conserved particles, which cannot be treated efficiently by the conventional methods. The third is the combination with the level spectroscopy. Proposing a new gap estimator, we are successful in eliminating the systematic error of the conventional moment method. Then we have elucidated the phase diagram and the universality class of the one-dimensional XXZ spin-Peierls system. The criticality is totally consistent with the $J_1 - J_2$ model, an effective model in the antiadiabatic limit. Through this research, we have succeeded in investigating the critical phenomena of the effectively frustrated quantum spin system by the quantum Monte Carlo method without the negative sign.

[1]JSPS Postdoctoral Fellow for Research Abroad

4:54PM J24.00013 A Study of the Uniqueness of the Density for Nonequilibrium Systems , SELMAN HERSHFIELD, University of Florida — By the Hohenberg-Kohn theorem the density in equilibrium is a unique functional of the the single particle potential. To gain an understanding of whether this is true in a nonequilibrium system with a current flowing, the density is studied for several noninteracting models. Although noninteracting models are not as realistic as interacting ones, they do have the advantage that they can be solved exactly. For sufficiently high bias or chemical potential difference we find that the density is not a unique functional of the potential for some models in the finite spatial region we study numerically. In other models the density is a unique functional of the potential even for large bias. An algorithm will be presented for finding cases where degeneracies exist and a simple physical picture will be given to understand them.

5:06PM J24.00014 Scaling of the Renyi entropy in 1D critical SU(N) spin chains[1] , JONATHAN DEMIDIO, MATTHEW S. BLOCK, RIBHU K. KAUL, University of Kentucky — Using quantum Monte Carlo techniques, we study an SU(N) antiferromagnet with each spin transforming in the fundamental representation. The spin interaction simply permutes "colors" on neighboring sites. This permutation operator is of interest to ultra-cold atomic systems, since at low energies it is the dominant effective interaction of the SU(N) symmetric Hubbard model with one atom per site. We calculate the entanglement entropy across a partition in the spin chain via the so-called "replica trick," whereby the partition function is simulated on the modified topology of an n-sheeted Riemann surface. In the thermodynamic limit, quantum critical spin chains in 1D are described by 2D conformal field theories (CFTs). Thus, the scaling form of the entanglement entropy provides information about the underlying CFT. In particular we extract the central charge of the CFT, which depends only on the symmetries of the spin model and not its microscopic details. We find that the central charge is given by $c = N - 1$, which is in agreement with previous theoretical predictions. We also find agreement in the scaling form of the entanglement entropy, which depends on the number of replicas in the Riemann surface.

5:18PM J24.00015 Measuring Entanglement at a Quantum Critical Point with Numerical Linked Cluster Expansion , ANN B. KALLIN, University of Waterloo, KATHARINE HYATT, University of California, Santa Barbara, RAJIV R. P. SINGH, University of California, Davis, ROGER G. MELKO, University of Waterloo — We develop a method to calculate the bipartite entanglement entropy of quantum lattice models in the thermodynamic limit, using a Numerical Linked Cluster Expansion (NLCE) involving only rectangular clusters. The NLCE is based on exact diagonalization of all N x M rectangular clusters at the interface between entangled subsystems A and B. We show that the method can be used to obtain the Renyi entanglement entropy of the two-dimensional transverse field Ising model, for arbitrary real Renyi index. Furthermore, extrapolating these results as a function of the order of the calculation, one can obtain subleading universal pieces of the entanglement entropy at a quantum critical point. These results are compared with series expansions, quantum Monte Carlo simulations and field theories, where available, and they demonstrate the utility of the NLCE in obtaining accurate results for the universal properties of this critical point for von Neumann and non-integer Renyi entropies.

Session J25 DCOMP: Focus Session: Explicitly correlated Methods and Quantum Few-Body Systems 327 - Ludwik Adamowicz, University of Arizona

2:30PM J25.00001 Ultracold physics with 3, 4, or 5 atoms[1] , CHRIS GREENE, Physics Department, Purdue University — Recent studies will be reviewed [1-3], which utilize hyperspherical coordinates to treat few-body systems, concentrating on processes such as recombination, in which the initial state has 3 or more free particles in the continuum. Of particular interest are ultracold species with large two-body scattering lengths, for which universal behavior has been seen experimentally [4] that goes beyond the ordinary universality associated with the Efimov effect. The so-called three-body parameter, now understood to be universal for systems having van der Waals interactions, is readily interpreted using this theoretical framework, and predictions are made concerning A+A+B collisions as well as the homonuclear case A+A+A. Various aspects of the work presented have been carried out in collaboration with Jia Wang, Yujun Wang, Jose D'Incao, Javier von Stecher, and Brett Esry.

3:06PM J25.00002 A continued fraction approach for calculating Auger electron sprectra , ANAMITRA MUKHERJEE, MONA BERCIU, GEORGE SAWATZKY, University of British Columbia — In 'core valence valence' Auger spectroscopy (AES), X-ray absorption leads to the appearance of a core hole, which then decays into two valence holes and an Auger electron. The Auger electron carries information about the spectrum of the two additional holes thus introduced in the system. This is straightforward to compute if the two holes move in an otherwise full band, but accurate results for partially filled bands are still missing. Here we present a novel approach to calculating few-body lattice Green's functions that allows us to obtain the AES spectrum for systems with both filled and open bands, such as CuO and NiO. For full bands, comparison against exact results allows us to propose efficient variational schemes, which can then be used to study partially filled bands.

3:18PM J25.00003 Progress in calculating the PES of H_3^+ , MICHELE PAVANELLO, Rutgers University, ALEXANDER ALIJAH, Université de Reims, LUDWIK ADAMOWICZ, University of Arizona — The most accurate electronic structure calculations are performed using wave-function expansions in terms of basis functions explicitly dependent on the interelectron distances. In our recent work we use such basis functions to calculate a highly accurate potential energy surface (PES) for the H_3^+ ion. The functions are explicitly correlated Gaussians which include inter-electron distances in the exponent. Key to obtaining the high accuracy in the calculations has been the use of the analytical energy gradient determined with respect to the Gaussian exponential parameters in the minimization of the Rayleigh-Ritz variational energy functional. The effective elimination of linear dependencies between the basis functions, as well as the automatic adjustment of the positions of the Gaussian centers to the changing molecular geometry of the system, are key to the success of the computational procedure. After adiabatic and relativistic corrections are added to the PES and with an effective accounting of the non-adiabatic effects in the calculation of the rotational/vibrational states, the experimental H_3^+ rovibrational spectrum is reproduced at the 0.1 cm^{-1} accuracy level up to 16,600 cm^{-1} above the ground state.

3:30PM J25.00004 Variational methods with all-particle explicitly correlated Gaussians , SERGIY BUBIN, Vanderbilt University — Accurate treatment of electron correlation in quantum systems of various nature remains an important challenge for modern theoretical and computational approaches. The variational method in conjunction with explicitly correlated Gaussian (ECG) basis sets is one of the most capable, accurate, and conceptually simple methods for calculating the ground, excited, and even scattering state properties of small quantum systems. I will review the basic theoretical foundations, recent advances, and the applications of the ECG method to Coulomb systems such as atoms, molecules, and systems containing positrons. I will also discuss some of the most important challenges that need to be overcome in order to extend the current range of applicability of the method.

4:06PM J25.00005 Hylleraas coordinates in few-body atomic and molecular systems[1] , Z.-C. YAN, L.-M. WANG, University of New Brunswick, H.-X. QIAO, Wuhan University, G. W. F. DRAKE, University of Windsor — In this talk, we will present recent progress on the calculations of few-body Coulombic systems, such as atomic lithium and hydrogen molecular ions, using variational method in Hylleraas coordinates, including relativistic and quantum electrodynamic corrections. We will also discuss the applications of these calculations in the determination of nuclear charge radii and the proton-electron mass ratio.

4:18PM J25.00006 Development of explicitly correlated congruent transformed Hamiltonian , MIKE BAYNE, Department of Chemistry, Syracuse University, JOHN DROGO, East Syracuse Minoa High School, ARINDAM CHAKRABORTY, Department of Chemistry, Syracuse University — The central idea of the explicitly correlated congruent transformed Hamiltonian (CTH) method is the treatment of the Coulomb singularity in the Hamiltonian by performing congruent transformation using an explicitly correlated wave function. However, unlike the transcorrelated methods, the CTH is Hermitian and amenable to standard variational methods. The variational solution of the CTH was obtained using FCI and the comparison between the transformed and untransformed calculation will be discussed. We found that the CTH dramatically improves the convergence of the FCI expansion. The CTH can also be represented in the occupation number (ON) space, however this representation is approximate due to the finite size of the underlying basis. Analogous to the diagrammatic summation in MBPT, we have developed partial infinite order summation (PIOS) for improving the CTH calculation in ON space and analysis of the real space, ON and ON-PIOS calculation of CTH will be discussed. The CTH has been applied to a series of 10 electron systems and comparison of the results with other methods will be presented. Preliminary results on the excited state of water will be compared with R12-MP2 and MRCI methods. The size-consistency of the CTH method was numerically analyzed and will be discussed.

4:30PM J25.00007 Stability of high and low spin states[1] , HANNES RAEBIGER, SHUHEI FUKUTOMI, Yokohama Nat'l Univ, HIROSHI YASUHARA, IMR, Tohoku Univ., Sendai — Octahedral CoL_6 complexes exhibit high or low spin states, depending on ligand L. We present an explicitly correlated first principles calculation of CoL_6 with five different ligands, and show that the total energy difference ΔE between the high and low spin states is variationally determined in an intricate interplay of the interelectron repulsion V_{ee}, internuclear repulsion V_{nn}, and electronuclear attraction V_{ne}. This is in stark contrast to "ligand field theory" [1,2], where ΔE is approximated as $\Delta E \approx \Delta V_{ee}$ in a first order perturbation theory. Moreover, we show that ΔV_{ee} exhibits the opposite trend to ΔE and is three or four orders of magnitude greater than ΔE, which demonstrates the failure of ligand field theory both quantitatively and qualitatively. Correctly, the crossover of high and low spin states is a consequence of different Co–L bondings, ionic or covalent, which is found by an accurate treatment of Coulomb correlation between ligand p and cobalt d electrons in the present calculation. 4:42PM J25.00008 Computation of Low-Energy Positronium-Hydrogen Collisions using the Kohn Variational Method[1] , DENTON WOODS, S.J. WARD, University of North Texas, P. VAN REETH, University College London — The Kohn variational method is an established method that can provide benchmark calculations for quantum few-body systems. We consider the four-body Coulomb process of positronium-hydrogen (Ps-H) scattering. We improve upon the numerics of prior accurate S- and P-wave Kohn variational calculations of Ps-H elastic scattering [1,2]. For instance, we use a procedure that removes Hylleraas-type terms that lead to linear dependence [3]. In addition to using the Kohn and inverse Kohn variational methods as previously used, we use the generalized and complex Kohn variational methods [4]. We are extending the calculations of Ps-H to include the D-wave.

4:54PM J25.00009 Influence of Angular and Spin-dependent Terms on Variational Energies of Lithium[1] , GORDON DRAKE, University of Windsor, ZONG-CHAO YAN, LIMING WANG, University of New Brunswick — Improved nonrelativistic energy bounds for the low-lying states of lithium are presented using the variational method in Hylleraas coordinates [1]. For example, the nonrelativistic energies for the infinite nuclear mass case are $-7.478\,060\,323\,910\,147(1)$ a.u. for $1s^2 2s\ ^2\mathrm{S}$, $-7.354\,098\,421\,444\,37(1)$ a.u. for $1s^2 3s\ ^2\mathrm{S}$, $-7.318\,530\,845\,998\,91(1)$ a.u. for $1s^2 4s\ ^2\mathrm{S}$, $-7.410\,156\,532\,652\,4(1)$ a.u. for $1s^2 2p\ ^2\mathrm{P}$, and $-7.335\,523\,543\,524\,688(3)$ a.u. for $1s^2 3d\ ^2\mathrm{D}$. These results represent the most accurate nonrelativistic energies in the literature. The completeness of the angular momentum and spin configurations is investigated and examples presented for the 2P and 3D states to demonstrate the effect of different coupling schemes. In particular, the so-called second spin function (i.e. coupled to form an intermediate triplet state) is shown to have no effect on the final converged results, even for the expectation values of spin-dependent operators. This resolves a long-standing controversy concerning the completeness of the spin-coupling terms.

5:06PM J25.00010 Multi-determinant electron-nuclear quantum Monte Carlo method for ground state solution of molecular Hamiltonian , ABHINANDEN SAMBASIVAM, JENNIFER ELWARD, ARINDAM CHAKRABORTY, Syracuse University — The focus of this work is to obtain the ground state energy of the non-relativistic spin-independent molecular Hamiltonian without making the Born-Oppenheimer (BO) approximation. In addition to avoiding the BO approximation, this approach avoids imposing separable-rotor and harmonic oscillator approximations. The ground state solution is obtained variationally using multi-determinant variational Monte Carlo method where all nuclei and electrons in the molecule are treated quantum mechanically. The multi-determinant VMC provides the right framework for including explicit correlation in a multi-determinant expansion. This talk will discuss the construction of the basis functions and optimization of the variational coefficient. The electron-nuclear VMC method will be applied to H_2, He_2 and H_2O and comparison of the VMC results with other methods will be presented. The results from these calculations will provide the necessary benchmark values that are needed in development of other multicomponent method such as electron-nuclear DFT and electron-nuclear FCIQMC.

5:18PM J25.00011 Low energy model estimation from detailed quantum Monte Carlo calculations for transition metal systems[1] , LUCAS WAGNER, University of Illinois at Urbana-Champaign — Systems of strongly correlated electrons have incredible potential for new devices and new quantum states. However, it is very challenging to a priori predict the quantum state of a system of correlated electrons. Detailed calculations using quantum Monte Carlo methods on the first principles Hamiltonian have in recent years shown to be quite reliable for some example transition metal oxide systems, such as FeO, ZnO, among others. These calculations, although they are accurate, have not provided much information in terms of the correct approximate low-energy model that should describe the systems in question. In this talk, I'll summarize the results of matching the two-body correlations from first principles quantum Monte Carlo on transition metal systems to models and discuss the implications for the commonly used models.

Session J26 GQI: Semiconductor Qubits - Spin Measurement and Noise 328 - Bill Coish, McGill University

2:30PM J26.00001 Taming spin decoherence in silicon[1] , STEPHEN LYON, Princeton University — Electron spins in semiconductor hosts have been candidate qubits since the early days of experimental quantum computing research, but it was generally assumed that the solid state environment would limit coherence to times much shorter than that seen in isolated atoms or ions. The longest measured electron spin coherence, measured in isotopically enriched silicon, was of order 1 ms. However, over the last 8 or 10 years the measured electron spin coherence times have steadily increased as materials and experimental techniques have improved. Much of the decoherence observed in the early ensemble Electron Spin Resonance (ESR) experiments arose from interactions amongst the spins being measured. In the most highly enriched bulk silicon measured to date, the residual silicon isotopes with nuclear magnetic moments affect the coherence of electrons bound to phosphorus donors on about a 1 second time scale. The remaining decoherence is still dominated by interactions between the donor spins, even in very lightly doped Si. Other decoherence processes have been shown to be at least an order of magnitude weaker. Recent work suggested that longer spin coherence would be obtained in bismuth doped Si, where magnetic-field insensitive "clock transitions" occur in the GHz frequency range. Recent experiments are bearing out these suggestions.

[1]This work was supported in part by the ARO and NSF.

3:06PM J26.00002 Spin-bath autocorrelation functions directly from quantum theory[1] , WAYNE WITZEL, Sandia National Laboratories, NM, KEVIN YOUNG, Sandia National Laboratories, CA, SANKAR DAS SARMA, University of Maryland, College Park — Cluster expansion techniques have enabled accurate modeling of the effects of a bath of local spins on solid state spin qubits with proven predictive power. These calculations are performed in the context of specific echo decay experiments (Hahn echo, CPMG, etc.). Classical noise, on the other hand, is described by a single autocorrelation function (or spectral density, equivalently) that is applicable to any control-specific experiment. Such a description is very useful in searching for optimal controls to produce high fidelity quantum logic gates using well-studied techniques. We demonstrate a cluster expansion method for directly computing autocorrelation functions as expectation values in the quantum spin-bath setting and show that it is a sufficient description of the noise effects for certain regimes, particularly in the high fidelity regime of interest. We use this approach to study the theoretical impact of using optimized pulse sequences tailored to individual qubits in enriched silicon.

3:18PM J26.00003 Error in a spin-SWAP gate due to hyperfine interaction in a double quantum dot[1]

, JO-TZU HUNG, Department of Physics, University at Buffalo, State University of New York, ŁUKASZ CYWIŃSKI, Institute of Physics, Polish Academy of Sciences, XUEDONG HU, Department of Physics, University at Buffalo, State University of New York — We study the SWAP gate for two exchange-coupled electron spins under the influence of hyperfine (hf) interaction in a double quantum dot. A gate error develops during such a gate because hf interaction causes dephasing between any pair of two-spin states. We find that this gate error is initial-state-dependent. For example, an initial state in the $S_z = 0$ subspace suffers only from $S - T_0$ dephasing, leading to smaller gate error than in the case of other initial states. We calculate the gate fidelity for typical initial states, and compare the resulting gate errors. We also analyze the effects of inhomogeneous broadening on the gate fidelity in the presence of a random Overhauser field.

3:30PM J26.00004 Electron Spin Relaxation and Coherence Times in Si/SiGe Quantum Dots[1]

, R.M. JOCK, JIANHUA HE, A.M. TYRYSHKIN, S.A. LYON, Princeton University, C.-H. LEE, S.-H. HUANG, C.W. LIU, National Taiwan University — Single electron spin states in Si/SiGe quantum dots have shown promise as qubits for quantum information processing. Recently, electron spins in gated Si/SiGe quantum dots have displayed relaxation (T_1) and coherence (T_2) times of 250 μs at 350mK. The experiments used conventional X-band (10 GHz) pulsed Electron Spin Resonance (pESR) on a large area (3.5 x 20 mm^2), double gated, undoped Si/SiGe heterostructure, which was patterned with 2 x 10^8 quantum dots using e-beam lithography. Dots with 150 nm radii and 700 nm period are induced in a natural Si quantum well by the gates. Smaller dots are expected to reduce the effects of nearly degenerate valley states and spin-orbit coupling on the electron spin coherence. However, the small number of spins makes signal recovery extremely challenging. We have implemented a broadband cryogenic HEMT low-noise-amplifier and a high-speed single-pole double-throw switch operating at liquid helium temperatures. The switch and preamp have improved our signal to noise by an order of magnitude, allowing for smaller samples and shorter measurement times. We will describe these improvements and the data they have enabled.

3:42PM J26.00005 Quantum theory of dynamic nuclear polarization in quantum dots

, SOPHIA ECONOMOU, Naval Research Laboratory, EDWIN BARNES, Condensed Matter Theory Center, University of Maryland — Nuclear spins play a major role in the dynamics of spin qubits in III-V semiconductor quantum dots. Although the hyperfine interaction between nuclear and electron (or hole) spins is typically viewed as the leading source of decoherence in these qubits, understanding how to experimentally control the nuclear spin polarization can not only ameliorate this problem, but in fact turn the nuclear spins into a valuable resource for quantum computing. Beyond extending decoherence times, control of this polarization can enable universal quantum computation as shown in singlet-triplet qubits and, in addition, offers the possibility of repurposing the nuclear spins into a robust quantum memory. In [1], we took a first step toward taking advantage of this resource by developing a general, fully quantum theory of non-unitary electron-nuclear spin dynamics with a periodic train of delta-function pulses as the external control driving the electron spin. Here, we extend this approach to other types of controls and further expand on the predictions and physical insights that emerge from the theory. [1] Edwin Barnes and Sophia E. Economou, Phys. Rev. Lett. 107, 047601 (2011)

3:54PM J26.00006 Enhanced spin-flip transport in a quantum dot spin-valve with uniform hyperfine coupling

, STEFANO CHESI, WILLIAM A. COISH, McGill University — We study the transport current and nuclear spin polarization dynamics in a quantum dot spin-valve, for which a strong enhancement of the spin-flip electron tunneling rates can be realized in the limit of uniform hyperfine interaction. We extend the analogy of transport to superradiance, directly applicable to a spin valve with half-metal leads and a maximally polarized nuclear system, to the more general situation of ferromagnetic contacts and a nuclear system initially fully dephased and partially polarized, as naturally realized at finite bias under stationary conditions. An analytic treatment of the dynamics in terms of simple rate equations becomes possible for very fast/slow nuclear dephasing. We recover these limiting results, as well as analyze the crossover regime, from a general master equation for the nuclear dynamics. We also present strategies to approach the limit of uniform hyperfine interaction in realistic heterostructures.

4:06PM J26.00007 Single Electron Spin Resonance in a Si-MOS Double Quantum Dot[1]

, XIAOJIE HAO, MING XIAO, HONGWEN JIANG, Department of Physics and Astronomy, University of California at Los Angeles, RUSKO RUSKOV, CHARLES TAHAN, Laboratory for Physical Sciences, USA — Pauli spin blockade is used as a means to detect the flip of spins in a silicon metal-oxide-semiconductor (MOS) based double quantum dot. Microwave driven electron spin resonance (ESR) signals, with a linewidth as narrow as 1.5 G, has been observed only in a narrow range of magnetic fields. ESR spectroscopy in the magnetic field - microwave frequency plane shows an unexpected level anti-crossing, with an energy gap of about 50 MHz. The spectral line gives an estimation of the lower bound for inhomogeneous phase decoherence time T_2^* of about a couple of hundred ns for individual spins in the nano-structured system with a Si/SiO2 interface. We explain the anti-crossing gap as due to spin-orbit mixing with higher states, which is also responsible for the narrow-window visibility of the ESR signal in Si based double quantum dots.

[1]The work is supported by the U.S. Department of Defense and by ARO (w911NF-11-1-0028).

4:18PM J26.00008 Theory of Spin Relaxation in Two-Electron Laterally Coupled GaAs and Si Quantum Dots[1]

, MARTIN RAITH, University of Regensburg, PETER STANO, University of Basel, JAROSLAV FABIAN, University of Regensburg — We present quantitative results of the phonon-induced spin relaxation in two-electron lateral double quantum dots for a wide range of tuning parameters. Both spin-orbit coupling and hyperfine coupling are taken into account. Our analysis of GaAs [1] and silicon [2] based dots includes the variation of the electric field (detuning), the exchange coupling, and the magnetic field strength and orientation. The focus is on experimentally important regimes. We find that even in strong magnetic fields, the hyperfine coupling can dominate the relaxation rate of the unpolarized triplet in a detuned double dot. Where the spin-orbit coupling dominates, the rate is strongly anisotropic and its maxima and minima are generated by an in-plane magnetic field either parallel or perpendicular to the dots' alignment dependent on specifics, such as spectral (anti-)crossings (spin hot spots), or the detuning strength. For all regimes, we give qualitative explanations of our observations. We emphasize the differences between GaAs and Si based dots. By understanding the spin lifetimes (T_1), this work marks a crucial step toward the realization of two-electron semiconductor qubits for quantum information processing.

4:30PM J26.00009 Anomalous electron spin decoherence in an optically pumped quantum dot[1] , XIAOFENG SHI, L.J. SHAM, Department of Physics, University of California San Diego, La Jolla, CA 92093-0319, USA — We study the nuclear-spin-fluctuation induced spin decoherence of an electron (SDE) in an optically pumped quantum dot. The SDE is computed in terms of the steady distribution of the nuclear field (SDNF) formed through the hyperfine interaction (HI) with two different nuclear species in the dot. A feedback loop between the optically driven electron spin and the nuclear spin ensemble determines the SDNF [W. Yang and L. J. Sham, Phy. Rev. B 85, 235319(2012)]. Different from that work and others reviewed therein, where a bilinear HI, $S_\alpha I_\beta$, between the electron (or hole) spin $\mathbf{S}$ and the nuclear spin $\mathbf{I}$ is used, we use an effective nonlinear interaction of the form $S_\alpha I_\beta I_\gamma$ derived from the Fermi-contact HI. Our feedback loop forms a multi-peak SDNF in which the SDE shows remarkable collapses and revivals in nanosecond time scale. Such an anomalous SDE results from a quantum interference effect of the electron Larmor precession in a multi-peak effective magnetic field. In the presence of a bilinear HI that suppresses the nuclear spin fluctuation, the non-Markovian SDE persists whenever there are finite Fermi contact interactions between two or more kinds of nuclei and the electron in the quantum dot.

4:42PM J26.00010 Mechanisms for Electric Field Control of Single Spin Relaxation in Double Quantum Dots[1] , V. SRINIVASA, Joint Quantum Institute, University of Maryland and NIST, K.C. NOWACK, M. SHAFIEI, L.M.K. VANDERSYPEN, Kavli Institute of Nanoscience, TU Delft, J.M. TAYLOR, Joint Quantum Institute, University of Maryland and NIST — We theoretically investigate electrically-tunable spin-flip transitions for a single electron confined within a double quantum dot. In the presence of spin-orbit and hyperfine interactions, the rate at which phonon-induced spin relaxation occurs depends non-monotonically on the detuning between the dots. We analyze this detuning dependence for both direct decay to the ground state and indirect decay via an intermediate excited state of the double dot. A description in terms of a simple toy model captures characteristic features of the relaxation rate recently measured for GaAs double quantum dots. Our results suggest that spin-orbit mediated relaxation via phonons serves as the dominant mechanism through which the electron spin-flip rate in these systems varies with detuning.

4:54PM J26.00011 Enhanced hyperfine-induced spin dephasing in a magnetic field gradient[1] , FELIX BEAUDOIN, WILLIAM A. COISH, McGill University — Magnetic field gradients are important for single-site addressability and electric-dipole spin resonance of electrons in quantum dots or in donor impurities. We show that these advantages are offset by a potential reduction in coherence time. Although the magnetic field appears uniform to the electron, it provides a non-uniform field for the nuclear-spin bath. This leads to a finite bath correlation time, preventing the full recovery of electron-spin coherence. We apply our model to single electron spins in quantum dots and single donor impurities, singlet-triplet spin qubits, and consider both free-induction decay and spin-echo. This mechanism can dominate over known dephasing sources due to nuclear dipole-dipole interactions and hyperfine flip-flops. This result is especially important for systems requiring large magnetic field gradients, including spin qubits coupled to superconducting stripline resonators.

[1]We acknowledge FRQNT, INTRIQ, NSERC and CIFAR for funding.

5:06PM J26.00012 Spin Qubit Relaxation in a Moving Quantum Dot[1] , PEIHAO HUANG, XUEDONG HU, State Univ of NY - Buffalo — Long-range quantum communication for spin qubits is a significant open problem in the scale-up of spin qubit architectures. Among the many spin information transfer proposals, directly moving the electrons themselves is attractive because of its conceptual simplicity and its similarity to the conventional charge-coupled devices. Here we focus on electron spin decoherence when the quantum dot is in motion. Specifically, we study a spin decoherence mechanism for a moving but confined electron due to the spin-orbit interaction and an environmental random electric potential. We find that at the lowest order, the magnetic fluctuations experienced by the spin have only components transverse to the total magnetic field, so that the motion induced spin decoherence is a pure longitudinal relaxation channel. Our calculated spin relaxation time ranges from as fast as sub μs in GaAs to above ms in Si. Our results also clearly indicates how to reduce the decoherence effects of electron motion.

Session J27 DAMOP: Focus Session: Nano/Optomechanics I 329 - Mohammad Hafezi, University of Maryland

2:30PM J27.00001 Nanomechanics and superconducting qubits for quantum information[1] , ANDREW CLELAND, University of California - Santa Barbara — There has been tremendous progress in the capabilities of superconducting quantum circuits, both for fundamental quantum science as well as for applications in quantum information. Superconducting qubits are based on the Josephson junction, which provides the fundamental inductive nonlinearity that affords full quantum control of otherwise quite simple electrical circuits. I will outline how a superconducting qubit can be used to measure and control the quantum state of a nanomechanical system [1], completely control multi-photon states in superconducting resonators [2,3], factor the number 15 using a von Neumann-style computing architecture [4,5], and possibly allow the transfer of a GHz-frequency quantum state to an optical signal.

3:06PM J27.00002 Observation of optical quantum measurement backaction on a mechanical resonator , THOMAS PURDY, ROBERT PETERSON, PEN-LI YU, CINDY REGAL, JILA-University of Colorado and NIST, and Department of Physics, University of Colorado, Boulder — Quantum mechanics provides an inextricable link between measurement and backaction on the subsequent dynamics of a system. Here we continuously monitor the position of a membrane microresonator in a cavity optomechanical system. We observe a fluctuating backaction force on the resonator which rises with measurement strength in accordance with the minimum allowed by the Heisenberg position-momentum uncertainty limit. For our optically-based position measurement the backaction takes the form of a fluctuating radiation pressure due to optical shot noise. We demonstrate radiation pressure shot noise that is comparable to in magnitude to thermal fluctuations at frequencies near the mechanical resonance. Additionally, we observe temporal correlations between fluctuations in the radiation force and resonator position, which we interpret as a non-demolition measurement of the intracavity photon field fluctuations. We will also discuss possible methods to lower the technical noise floor in all measurement quadratures.

3:18PM J27.00003 Quantum optics experiments with micromechanical oscillators , SIMON GROEBLACHER, AMIR SAFAVI-NAEINI, JEFF HILL, JASPER CHAN, OSKAR PAINTER, Caltech — Mechanical oscillators coupled to optical fields via the radiation pressure force have been of great interest lately as they allow for quantum experiments with macroscopic systems. Recent experiments have shown ground-state preparation and measurement of such resonators via sideband-resolved laser cooling. We will discuss our recent work that aims at achieving quantum control over nanoscale optomechanical crystal devices, both using strong coherent optical beams as well as single photons.

3:30PM J27.00004 Optomechanical Coupling Between Membrane Modes , ALEXEY B. SHKARIN, NATHAN E. FLOWERS-JACOBS, SCOTT W. HOCH, Dept of Physics, Yale University, CHRISTIAN DEUTSCH, JAKOB REICHEL, Laboratoire Kastler Brossel, ENS/UPMC, JACK G.E. HARRIS, Dept of Physics and Dept of Applied Physics, Yale University — In an optomechanical device, radiation pressure couples optical power to mechanical motion. While typical experiments couple a single optical cavity to a single mechanical resonance, there has been increasing theoretical and experimental interest in multi-mode systems where there is coupling between multiple mechanical resonances and/or multiple optical cavity modes. We report on a device consisting of a dielectric SiN membrane located inside a high finesse fiber-cavity, where two nearly-degenerate mechanical modes couple to a single cavity mode. We observe that the original mechanical modes can experience a large coupling that is mediated by intracavity field. This causes the mechanical eigenmodes of the system to depend strongly on the radiation pressure and change from the original mechanical modes to a symmetric and antisymmetric combination of the original modes. The symmetric/antisymmetric modes are also known as "dark" and "bright" modes, as they have very different coupling to the cavity. In the quantum regime, this effective interaction between mechanical modes would open up the possibility of state transfer between multiple mechanical modes.

3:42PM J27.00005 Gain-enhanced optical cooling in cavity optomechanics , LI GE, Department of Electrical Engineering, Princeton University, Princeton, New Jersey 08544, USA, SANLI FAEZ, FLORIAN MARQUARDT, Max-Planck-Institute for the Science of Light, Günther-Scharowsky-Straße 1/Bau 24, DE-91058 Erlangen, Germany, HAKAN TURECI, Department of Electrical Engineering, Princeton University, Princeton, New Jersey 08544, USA — We study the optical cooling of the mechanical motion of the resonator mirror in a cavity-optomechanical system that contains an optical gain medium. We find that the optical damping caused by radiation pressure force is vanishingly small if the active medium is pumped incoherently above its lasing threshold. In addition, we find that the spontaneous emission of the active medium always tends to increase the final effective temperature of the mechanical motion. In the presence of an additional seeding signal, i.e. a coherent drive of fixed frequency within the width of the gain curve however, we find that the cooling rate can be enhanced significantly with respect to that of a passive cavity. We attribute this effect to a reduced effective optical damping in the presence of incoherent pumping.

3:54PM J27.00006 Novel cooling mechanisms in optomechanical systems , JUAN RESTREPO, IVAN FAVERO, CRISTIANO CIUTI, Laboratoire MPQ, Université Paris Diderot and CNRS, France — We present here our theoretical work on unconventional cooling mechanisms in optomechanical systems. In particular our classical and quantum theory of photothermal cooling [1] and our more recent work on cooling of a mechanical oscillator in cavity QED systems [2].

4:06PM J27.00007 Optical measurement of the thermal motion of a micromechanical resonator and its modal interaction by sideband actuation scheme , SUNGWAN CHO, Korea Research Institue of Standards and Science, Seoul National University, MYUNG RAE CHO, SUNG UN CHO, Seoul National University, SANG GOON KIM, SEUNG BO SHIM, Korea Research Institue of Standards and Science, YUN DANIEL PARK, Seoul National University — We present measurement of the thermal motion of a micromechanical resonator and excitation of flexural mode by sideband actuation. Doubly-clamped micromechanical resonators are fabricated from high-stress silicon nitride on SiO2/Si substrate and patterned with standard e-beam lithographic techniques. Optical measurement of resonant response of micromechanical resonator reveals its fundamental flexural mode of thermal motion at approximately 3.4 MHz (f_o) with quality factor up to 180,000 and higher modes at room temperature in moderate vacuum. With fundamental and higher flexural modes of thermal motion and sideband actuation scheme, we also observe amplitude increase in flexural mode of thermal motion with blue-detuned sideband pumping.

4:18PM J27.00008 Optomechanics in a Fiber-Cavity , NATHAN E. FLOWERS-JACOBS, SCOTT W. HOCH, ALEXEY B. SHKARIN, Dept of Physics, Yale University, JACK C. SANKEY, McGill University, ANNA KASHKANOVA, ANDREW M. JAYICH, Dept of Physics, Yale University, CHRISTIAN DEUTSCH, JAKOB REICHEL, Laboratoire Kastler Brossel, ENS/UPMC, JACK G.E. HARRIS, Dept of Physics and Dept of Applied Physics, Yale University — In an optical displacement measurement, the quantum back-action is radiation pressure shot noise (RPSN), which is the Poissonian noise in the momentum transferred by reflecting photons. In an attempt to measure RPSN at room temperature, we have made an optomechanical device consisting of a fiber-based optical cavity containing a silicon nitiride membrane. In comparison with typical free-space cavities, the fiber-cavity's small mode size (10 micron waist, 60 micron length) allows the use of smaller, lighter membranes and increases the cavity-membrane linear coupling to 3 GHz/nm. This device is also intrinsically fiber-coupled and uses v-grooves for passive alignment; these improvements greatly simplify the use of optomechanical devices. Based on the parameters demonstrated by this device, we expect it to be able to detect RPSN at room temperature. The increased coupling in this system also makes it an excellent testbed for investigating optomechanical coupling between mechanical modes, and for demonstrating quadratic coupling between a single mechanical mode and the cavity.

4:30PM J27.00009 Robust entanglement via optomechanical dark mode: adiabatic scheme[1] , LIN TIAN, School of Natural Sciences, University of California, Merced, YING-DAN WANG, Department of Physics, McGill University, SUMEI HUANG, School of Natural Sciences, University of California, Merced, AASHISH CLERK, Department of Physics, McGill University — Entanglement is a powerful resource for studying quantum effects in macroscopic objects and for quantum information processing. Here, we show that robust entanglement between cavity modes with distinct frequencies can be generated via a mechanical dark mode in an optomechanical quantum interface. Due to quantum interference, the effect of the mechanical noise is cancelled in a way that is similar to the electromagnetically induced transparency. We derive the entanglement in the strong coupling regime by solving the quantum Langevin equation using a perturbation theory approach. The entanglement in the adiabatic scheme is then compared with the entanglement in the stationary state scheme. Given the robust entanglement schemes and our previous schemes on quantum wave length conversion, the optomechanical interface hence forms an effective building block for a quantum network.

4:42PM J27.00010 Development of a dispersive read-out technique for quantum measurements of nanomechanical resonators[1] , FRANCISCO ROUXINOL, MATTHEW LAHAYE, HUGO HAO, Syracuse University, SEUNG-BO SHIM, Korean Research Institute for Science and Standards — Over the last decade, there has been an active effort to prepare and measure mechanical structures in the quantum regime for the purpose of sensing weak forces and for studying fundamental topics in quantum mechanics such as quantum measurement, entanglement and decoherence in new macroscopic limits. One promsing tool for such studies is the qubit-coupled mechanical resonator. In this work we discuss some of our first results towards the development of a nanoelectromechanical system that integrates a charge-type superconducting qubit as a detector to probe the number-states of a nanomechanical mode. In our system the qubit-coupled nanoresonator is embedded in a superconducting microwave resonator (SMR); the SMR then serves to perform spectroscopic measurements of the qubit to infer the number-state statistics of the nanoresonator in a manner analogous to dispersive measurement techniques used in circuit and cavity QED to probe the number-states of electromagnetic cavities. We will discuss the design and measurement of our latest generation devices and the prospects for achieving single-phonon measurement resolution with this system.

[1]1This work is supported by NSF-DMR Career Award 1056423 and funding from the College of Arts and Sciences at Syracuse University.

4:54PM J27.00011 Fabricating Micro-Optomechanical Resonators Using High-Stress Si_3N_4 , BRIAN PEPPER, UC Santa Barbara, PETRO SONIN, University of Leiden, DIRK BOUWMEESTER, UC Santa Barbara / University of Leiden — Optomechanical systems have been highly researched as a platform for testing macroscopic quantum effects and quantum decoherence. However, the required optical and mechanical properties are difficult to achieve. Increasing the tensile stress of a device is known to correlate with higher mechanical frequency and quality factor. We discuss fabrication of monolithic optomechanical devices using dielectric mirrors and high-stress stoichiometric Si_3N_4. We also present preliminary data on their mechanical and optical properties.

5:06PM J27.00012 Coherent optical wavelength conversion via cavity-optomechanics , JEFF HILL, AMIR SAFAVI-NAEINI, JASPER CHAN, OSKAR PAINTER, California Institute of Technology — In this talk we theoretically propose and experimentally demonstrate coherent wavelength conversion of optical photons using photon-phonon translation in a cavity-optomechanical system. Our system is an engineered silicon optomechanical crystal nanocavity supporting a 4 GHz localized phonon mode, optical signals in a 1.5 MHz bandwidth are coherently converted over a 11.2 THz frequency span between one cavity mode at wavelength 1460 nm and a second cavity mode at 1545 nm with a 93% internal (2% external) peak efficiency. The thermal and quantum limiting noise involved in the conversion process is also analyzed, and in terms of an equivalent photon number signal level are found to correspond to an internal noise level of only 6 and 4×10^{-3} quanta, respectively [1].

5:18PM J27.00013 Fast readout of carbon nanotube mechanical resonators , HAROLD MEERWALDT, VIBHOR SINGH, BEN SCHNEIDER, RAYMOND SCHOUTEN, HERRE VAN DER ZANT, GARY STEELE, Delft University of Technology — We perform fast readout measurements of carbon nanotube mechanical resonators. Using an electronic mixing scheme, we can detect the amplitude of the mechanical motion with an intermediate frequency (IF) of 46 MHz and a timeconstant of 1 us, up to 5 orders of magnitude faster than before. Previous measurements suffered from a low bandwidth due to the combination of the high resistance of the carbon nanotube and a large stray capacitance. We have increased the bandwidth significantly by using a high-impedance, close-proximity HEMT amplifier. The increased bandwidth should allow us to observe the nanotube's thermal motion and its transient response, approaching the regime of real-time detection of the carbon nanotube's mechanical motion.

Tuesday, March 19, 2013 2:30PM - 5:18PM –

Session J28 DCMP: Liquid Crystals I 336 - Peter Collins, Swarthmore College

2:30PM J28.00001 2D Brownian motion of inclusions in low pressure environment on freely suspended liquid crystal film[1] , ZHIYUAN QI, CHEOL PARK, JOSEPH MACLENNAN, MATTHEW GLASER, NOEL CLARK, Department of Physics and LCMRC, University of Colorado, Boulder, Colorado, LC FILMS TEAM — The homogeneous freely suspended fluid SmA liquid crystal film of several nanometer thickness provides a very good system for studying 2D hydrodynamics. Using microscope and high-speed camera, we track the motion of inclusions of about 2-20μm in diameter that doing Brownian motion on the film. We report 2D Brownian motion experiment of drops in different air pressure environment. We found that at ambient pressure, the Hughes, Pailthorpe, and White (HPW) theory can perfectly predict the diffusion coefficient of those inclusions, while under low pressure when the mean free path of the air molecules is comparable with the size of inclusions, the HPW theory fails. We propose a model, based on freely diffused air molecules with Maxwell distribution, to explain the elevated diffusion coefficient in low pressure.

2:42PM J28.00002 Between soap bubbles and vesicles: The dynamics of freely floating smectic bubbles[1] , RALF STANNARIUS, KATHRIN MAY, KIRSTEN HARTH, TORSTEN TRITTEL, Otto von Guericke University, Magdeburg — The dynamics of droplets and bubbles, particularly on microscopic scales, are of considerable importance in biological, environmental, and technical contexts. We introduce freely floating bubbles of smectic liquid crystals and report their unique dynamic properties. Smectic bubbles can be used as simple models for dynamic studies of fluid membranes. In equilibrium, they form minimal surfaces like soap films. However, shape transformations of closed smectic membranes that change the surface area involve the formation and motion of molecular layer dislocations. These processes are slow compared to the capillary wave dynamics, therefore the effective surface tension is zero like in vesicles. Freely floating smectic bubbles are prepared from collapsing catenoid films and their dynamics is studied with optical high-speed imaging [1]. Experiments are performed under normal gravity and in microgravity during parabolic flights.

2:54PM J28.00003 Critical Behavior of A Non-polar Smectic Liquid Crystal via Optical Birefringence Measurements[1]

, MEHMET CAN CETINKAYA, SELEN ERKAN, SEVTAP YILDIZ, HALUK OZBEK, Department of Physics, Istanbul Technical University, 34469, Maslak, Istanbul, Turkey, ITU LIQUID CRYSTALS LABORATORY TEAM — We present high sensitivity and high temperature resolution experimental data on the temperature dependence of the optical birefringence in the nematic and smectic A phases of nonpolar monolayer smectogen 4-butyloxyphenyl-4'-decyloxybenzoate liquid crystal by using a rotating-analyzer technique. We have used the birefringence data to probe the temperature behavior of the nematic order parameter S(T) in the vicinity of both the nematic-isotropic (N-I) and the nematic-smectic A (N-SmA) transitions. The critical behavior of S(T) at the N-I transition has been discussed in detail by comparing our results with the latest reports in literature and we have then concluded that the isotropic internal field assumption by Vuks model is adequate to extract the critical behavior of S(T) from the birefringence data [1-3]. We have tested the validity of the scaling relation $\lambda = 1-\alpha$ between the critical exponent λ describing the limiting behavior of the nematic order parameter and the specific heat capacity exponent α. We have shown that the temperature derivative of the nematic order parameter S(T) near the N-SmA transition has the same power law behavior as the specific heat capacity [4,5].

3:06PM J28.00004 Statistical mechanics of bend flexoelectricity and the twist-bend phase in bent-core liquid crystals[1]

, SHAIKH SHAMID, SUBAS DHAKAL[2], JONATHAN SELINGER, Kent State University — We develop a Landau theory for bend flexoelectricity in a liquid crystals of bent-core molecules. In the nematic phase of the model, the bend flexoelectric coefficient increases as we reduce the temperature, and it diverges at the nematic to polar phase transition. At this critical point, there is a second order transition from high-temperature uniform nematic phase to low-temperature nonuniform polar phase composed of twist-bend or splay-bend deformations. To test the predictions of Landau theory, we perform Monte Carlo simulations to find the behavior as a function of temperature, applied electric field and interaction parameters, and to determine the orientational distribution of the mesogenic molecules.

3:18PM J28.00005 Imaging helical nano-filament and modulated smectic phases of bent shaped liquid crystals by cryo-TEM

, CUIYU ZHANG, Kent State University, HANS SAWADE, I.N. Stranski Institute, TU Berlin, WOLFGANG WEISSFLOG, Martin Luther University Halle-Wittenberg, ANTAL JAKLI, Kent State University — Recently we showed that cryo-TEM can be used to visualize smectic layers of thermotropic liquid crystals. Here we describe cryo-TEM studies of the nanofilaments (B4 phase) and the modulated smectic layers (B7 phase) of various bent shaped liquid crystal compounds. In the B4 phase a periodic array of about 15 nm wide bands of parallel stripes, separated by a distance equal to the layer spacing, appear with a periodicity of about 120 nm corresponding to the half pitch of the nanofilaments. As cryo-TEM shows only layers that are parallel to the electron beam, these results indicate grains of straight layers twisted along the filament axis compose the nano-filaments. In the B7 phase cryo-TEM not only can visualize the smectic layers, but also the periodic modulation indicating defects with less dense molecular packing. In addition we observe a labyrinth structure with curvature radii in the 150 nm ranges. These results yield information complementary to freeze fracture TEM and X-ray observations.

3:30PM J28.00006 Wide temperature range and hysteresis free blue phase liquid crystals doped with bent-core compound

, JIE XIANG, OLEG TWIEG, OLEG LAVRENTOVICH, Kent State University — We explore an approach to widen the temperature range of the liquid crystalline blue phases based on mixtures of calamitic (rod-like) and bent-core mesogens. The calamitic component has a relatively low value of the bend elastic constant that is further reduced by adding the bent-core component. The mixtures exhibit the blue phase state in a wide temperature range, about 5°C in the regime of heating and 40°C (including the room temperature) upon cooling. We present a phenomenological model to illustrate the link between the temperature range of the blue phase and the bend elastic constant that is based on Kleman's model of double twist in liquid crystals. We also study the electro-optic properties of the mixtures. The electrooptic switching is reversible in the upper temperature range of the blue phase, but once the temperature decreases below a certain level, the electrooptic switching shows a hysteresis associated with phase separation of the components. The work was supported by NSF grant DMR 11212878.

3:42PM J28.00007 Piezoelectric properties of polymers containing bent-shape liquid crystal molecules[1]

, N. DIORIO, M. VARGA, Kent State University, A. CARIF, J.E. PUSKAS, University of Akron, K. FODOR-CSORBA, Hungarian Academy of Sciences, S. SPRUNT, J.T. GLEESON, A. JAKLI, Kent State University — Recently, bent-core liquid crystal elastomers have shown to exhibit large values of flexoelectricity as many as 3 orders of magnitude larger than liquid crystal elastomers containing rod-shaped molecules. These unusual high responses are attributed to have piezoelectric origin. Motivated by this, in this study, two bent-core liquid crystals were used to make various types of materials; low molecular weight bent-core nematic fluid, side chain bent-core liquid crystal polymer, low molecular liquid crystal dispersed in a polyisobutylene-based thermoplastic elastomer, and side-chain bent-core elastomers. Liquid crystal elastomers combine elasticity and flexibility inherent to rubbers and the optical and electrical properties of liquid crystals, and are promising materials for applications such as electro-optics, flexible electronics and actuator technologies for biomedical applications. Most conventional liquid crystal elastomers have rod-shaped liquid crystal molecules chemically attached to a crosslinked polymer network. Converse piezoelectric responses were measured by a Mirau interferometer and the direct piezoelectric signals were studied by home-made device where the stress is provided by an audio speaker. The results will be analyzed in terms of ferroelectric clusters of the materials in the nematic phase and will be compared with other piezoelectric materials.

[1]Supported by Grants NSF-DMR -0964765 and NSF-DMR -0804878.

3:54PM J28.00008 SAXS studies of short-range order in the nematic phase of reduced symmetry mesogens

, S. CHAKRABORTY, Department of Physics, Kent State University, N. DIORIO, C. ZHANG, Chemical Physics Interdisciplinary Program and Liquid Crystal Institute, Kent State University, R. BRECKON, R. TWIEG, Department of Chemistry, Kent State University, J. GLEESON, Department of Physics, Kent State University, A. JAKLI, Chemical Physics Interdisciplinary Program and Liquid Crystal Institute, Kent State University, S. SPRUNT, Department of Physics, Kent State University — Recently, we proposed a model based on persistent, nano-scale smectic-C-like domains ("smectic clusters") to explain the features present in the small angle x-ray diffraction patterns from certain bent-core nematic liquid crystals (which do not possess an underlying smectic phase). We report on new results from a wider range of nematics formed by reduced-symmetry molecules – including laterally-branched ("Y"-shaped) mesogens and "H" shaped dimers – that also lack a low temperature smectic phase. We find that our model, extended to incorporate the notion of staggered molecular arrangements, is successful in reproducing the SAXS patterns and reveals variation in the temperature-dependence of cluster size among different systems. Supported by NSF DMR-0964765.

4:06PM J28.00009 Local orientation and temperature effects of a liquid crystal in contact with a nanoparticle[1] , JEFFERSON WARD TAYLOR, University of Maryland, College Park, MD, LYNN K. KURIHARA, Naval Research Laboratory, Washington, DC, LUZ J. MARTINEZ-MIRANDA, University of Maryland, College Park, MD — We have studied the effects on the orientation of the liquid crystal in the immediate vicinity of a nanoparticle. We have observed a "halo" surrounding the nanoparticle, when studying the effects of the nanoparticle on the liquid crystal with the AFM. We believe this halo has an effect on the ordering of the liquid crystal in the immediate vicinity of the nanoparticle. We have also observed a short range order peak in the X-ray scattering signal, which is also associated with the effects on the liquid crystal in the immediate vicinity of the nanoparticle. The value of the coherence length of this peak is close to the value of the molecular spacing or very close of the liquid crystal in the X-ray scattering experiment for all nanocomposites studied. This coherence length does not change as a function of temperature, when the temperature is changed and goes through the SmA-nematic transition temperature. The peak and its coherence length persist into the nematic phase.

4:18PM J28.00010 Electro-optical Characteristics of Carbon Nanotupe Doped Polar Smectic Liquid Crystal[1] , ILKNUR KOSEOGLU, Department of Physics, Istanbul Technical University, 34469, Maslak, Istanbul, Turkey, MEHMET CAN CETINKAYA, Piri Reis University, 34970, Tuzla, Istanbul, Turkey, HALUK OZBEK, SEVTAP YILDIZ, Department of Physics, Istanbul Technical University, 34469, Maslak, Istanbul, Turkey, ITU LIQUID CRYSTAL LAB TEAM — We present the results of electro-optical characteristics of the liquid crystal octyl-cyanobiphenyl (8CB) doped with well-dispersed multiwall carbon nanotubes (MWCNT) under an AC driving voltage. 8CB-MWCNT composites were prepared by following the procedures in literature [1-4]. Polarized optical microscopy (POM) has been performed to check the homogenous dispersion of 8CB-MWCNT composite. We compare threshold voltages and switching behavior of pure 8CB and 8CB doped with MWCNTs which have surfaces of untreated and treated with carboxyl functional group. Threshold voltages have been determined from optical transmittance-driving voltage curves at various temperatures. While the pure 8CB switches from a bright state through some intensity oscillations to the dark state, a drastic change has been observed in the transmittance curves for 8CB-MWCNT composites, namely hysteretic behavior has been detected. For 8CB-MWCNT composites we have observed that the first cycle for the transmittance-voltage curves shows the highest amount of loop area, which gradually decreases through the following cycles, then reaching saturation. Notice that the number cycle at which the saturation is reached depend on temperature [5].

4:30PM J28.00011 Effect of quantum dots on the isotropic to nematic and nematic to smectic-A phase transitions in nano composites , PARVATHALU KALAKONDA, GERMANO S. IANNACCHIONE, WPI — Modulated Differential Scanning Calorimetry (MDSC) is used to investigate the weakly first-order isotropic to nematic (I-N) and the continuous nemat to smectic-A (N-SmA) phase transitions of the liquid crystal octylcyanobiphenyl (8CB) doped with well-dispersed quantum dots (QdS) as a function of Qd concentrations. Thermal scans were performed for all samples having Qd (CdS) weight percent from $\phi_w = 0.3$ to 3 wt% first on cooling and then heating under near-equilibrium conditions. The I-N transitions heat capacity peak first glows then decreases in magnitude with increasing ϕ_w leaving a maximum at $\phi_w = 0.3\%$. The N-SmA heat capacity peak remains bulk-like for all samples. Both transitions temperatures shift lower monotonically by 3 K for $\phi_w = 0.3\%$. The enthalpy of both transitions evolve in a nontrival way, generally decreasing with increasing ϕ_w. These results are discussed in terms of the predominate disordering effects of the Qds.

4:42PM J28.00012 Towards an optical nano-laboratory in a liquid crystal defect , PAUL ACKERMAN, University of Colorado at Boulder, National Renewable Energy Laboratory, Renewable and Sustainable Energy Institute, IVAN SMALYUKH, University of Colorado at Boulder, JAO VAN DE LAGEMAAT, National Renewable Energy Laboratory — Probing photonic effects due to nanoscale interactions between colloids such as quantum dots and rods and anisotropic plasmonic metal nanoparticles is of great interest for applications in third-generation solar cells, optical metamaterials, and nanoantennas. Liquid crystal (LC) structures and defects stabilized by chirality, confinement, and/or presence of colloidal microparticles can enable trapping and well-defined alignment of anisotropic semiconductor, plasmonic, and other nanoparticles with respect to the far-field director and each other. Minimization of the free energy due to LC defects provides a rich environment for precisely controlled experiments with individual and small groups of nanoparticles in the LC. This presentation will discuss characterization of trapping and alignment of various nanoparticles by LC defects and also photonic experiments performed on a single-particle level for metal and semiconductor quantum nanoparticles entrapped by these defects. This work was supported by the Division of Chemical Sciences, Geosciences, and Biosciences, Office of Basic Energy Sciences of the US Department of Energy under Contract No. DE-AC36-08GO28308 with the National Renewable Energy Laboratory (J.v.d.L. and J.S.E.).

4:54PM J28.00013 Interaction of discotics and nanoparticles[1] , LUZ J. MARTINEZ-MIRANDA, University of Maryland, College Park, MD, EDUARDO A. SOTO-BUSTAMANTE, Universidad de Chile, Santiago, Chile — We mixed a discotic, and 5 nm nanoparticles of ZnO up to a percentage weight of 30 – 35%, by heating them together, past the isotropic transition temperature. At that point, we mixed them together, and allowed them to cool to room temperature. We then prepared a sample for Xray study, by taking a small amount of the crystallites formed and placing them in a glass slide. We prepared a sample of the pure discotic to compare to the mixture. We found that the addition of the nanoparticle results in an enhancement of the axis in the direction parallel to the glass slide, with an intensity approximately six times that of the discotic alone and a correlation length approximately 1.3 times better. The role of the nanoparticle isvery similar to the alignment role of a flat surface observed on discotics.

5:06PM J28.00014 High resolution synchrotron X-ray studies of lyotropic liquid crystal phases of monolayer Zirconium Phosphate nanosheet[1] , YUE SHI, YONGQIANG SHEN, NOEL CLARK, Department of Physics, Liquid Crystal Materials Research Center, University of Colorado-Boulder, CO 80309, USA, MIN SHUAI, ZHENGDONG CHENG, McFerrin Department of Chemical Engineering, Texas A&M University, College Station, TX 77843, USA — Aqueous suspensions of monolayer zirconium phosphate nanosheets (ZrP-NS) form various lyotropic liquid crystal phases. An interesting stripe pattern can be observed in a range of nanosheet concentrations when the suspensions were confined between flat surfaces. The stripe patterns were stable while slow evaporation of the solvent and were well-preserved even when the suspensions dried out. A high resolution synchrotron X-ray study gives detailed investigations of ZrPNS lyotropic phases at different concentrations.

Session J29 GSNP: Non-Equilibrium Statistical Mechanics 337 - Michel Pleimling, Virginia Polytechnic Institute and State University

2:30PM J29.00001 Three-dimensional Potts systems with magnetic friction[1]

, LINJUN LI, MICHEL PLEIMLING, Virginia Tech — Using extensive Monte Carlo simulations we study the properties of the non-equilibrium phase transition encountered in driven three-dimensional Potts systems with magnetic friction. Our system consists of two three-dimensional blocks, coupled through boundary spins, that move along their boundaries with a constant relative velocity. Changing the number of states in the system from two (Ising case) to nine states, we find different scenarios for the surface behavior depending on whether the bulk transition is continuous or discontinuous. In order to fully assess the properties of this non-equilibrium phase transition, we vary systematically the strength of the coupling between the two blocks as well as the value of the relative velocity. For strong couplings between the blocks the phase transition is found to be strongly anisotropic.

2:42PM J29.00002 Non-equilibrium steady states in two-temperature Ising models with Kawasaki dynamics[1]

, NICK BORCHERS, MICHEL PLEIMLING, Virginia Tech, R.K.P. ZIA, Virginia Tech and Iowa State University — From complex biological systems to a simple simmering pot, thermodynamic systems held out of equilibrium are exceedingly common in nature. Despite this, a general theory to describe these types of phenomena remains elusive. In this talk, we explore a simple modification of the venerable Ising model in hopes of shedding some light on these issues. In both one and two dimensions, systems attached to two distinct heat reservoirs exhibit many of the hallmarks of phase transition. When such systems settle into a non-equilibrium steady-state they exhibit numerous interesting phenomena, including an unexpected "freezing by heating." There are striking and surprising similarities between the behavior of these systems in one and two dimensions, but also intriguing differences. These phenomena will be explored and possible approaches to understanding the behavior will be suggested.

2:54PM J29.00003 Aging processes in systems with anomalous slow dynamics[1]

, NASRIN AFZAL, MICHEL PLEIMLING, Virginia Tech — Recent studies of coarsening in disordered systems show a crossover from an initial, transient, power-law domain growth to a slower logarithmic growth. Due to the anomalous slow dynamics, numerical simulations are usually not able to fully enter the asymptotic regime when investigating the relaxation of these systems toward equilibrium. In order to gain some new insights into the non-equilibrium properties of systems with logarithmic growth, we study two simple driven systems, the one-dimensional ABC-model and a related domain model with simplified dynamics, where the asymptotic regime can be accessed. Studying two-times correlation and response functions, we focus on aging processes and dynamical scaling during logarithmic growth.

3:06PM J29.00004 Random Fields at a Nonequilibrium Phase Transition[1]

, HATEM BARGHATHI, THOMAS VOJTA, Missouri University of Science and Technology — We study nonequilibrium phase transitions in the presence of disorder that locally breaks the symmetry between two equivalent macroscopic states. In low-dimensional equilibrium systems, such random-field disorder is known to have dramatic effects: it prevents spontaneous symmetry breaking and completely destroys the phase transition. In contrast, we show that the phase transition of the one-dimensional generalized contact process persists in the presence of random-field disorder. The ultraslow dynamics in the symmetry-broken phase is described by a Sinai walk of the domain walls between two different absorbing states. We discuss the generality and limitations of our theory, and we illustrate our results by large-scale Monte Carlo simulations.

[1]This work has been supported by the NSF under Grants No. DMR-0906566 and No. DMR-1205803.

3:18PM J29.00005 Monte-Carlo simulations of the clean and disordered contact process in three space dimensions

, THOMAS VOJTA, Missouri University of Science and Technology — The absorbing-state transition in the three-dimensional contact process with and without quenched randomness is investigated by means of Monte-Carlo simulations. In the clean case, a reweighting technique is combined with a careful extrapolation of the data to infinite time to determine with high accuracy the critical behavior in the three-dimensional directed percolation universality class. In the presence of quenched spatial disorder, our data demonstrate that the absorbing-state transition is governed by an unconventional infinite-randomness critical point featuring activated dynamical scaling. The critical behavior of this transition does not depend on the disorder strength, i.e., it is universal. Close to the disordered critical point, the dynamics is characterized by the nonuniversal power laws typical of a Griffiths phase. We compare our findings to the results of other numerical methods, and we relate them to a general classification of phase transitions in disordered systems based on the rare region dimensionality. This work has been supported in part by the NSF under grants no. DMR-0906566 and DMR-1205803.

3:30PM J29.00006 Fluctuation Effects in the Pair Annihilation Process with Levy Dynamics[1]

, INGO HOMRIGHAUSEN, Georg-August-Universität Göttingen, ANTON WINKLER, ERWIN FREY, Ludwig-Maximilians-Universität München — Reaction diffusion models provide a plethora of intensively studied classical nonequilibrium many body systems. One example is the diffusion limited pair annihilation process $A + A \to 0$, where the reactants diffuse in space and annihilate on contact. Inspired by the fact that many phenomena observed in nature exhibit superdiffusive behavior, we investigate the pair annihilation process in the case where the particles perform superdiffusion, realized by Levy flights. As a consequence, the critical dimension depends continuously on the control parameter of the Levy flight distribution. This instance is used to study the density decay in the pair annihilation process close to the critical dimension by means of the non-perturbative renormalization group theory. Close to the critical dimension, long-range fluctuations cause the law of mass action to break down. One crucial consequence of these fluctuations is that the law of mass action is complemented by additional non-analytic correction terms above the critical dimension. An increasing number of those corrections accumulate and give an essential contribution as the critical dimension is approached.

3:42PM J29.00007 Directed polymers in random media with short-range correlated disorder

, VIVIEN LECOMTE, LPMA, CNRS et Université Paris Diderot, France, ELISABETH AGORITSAS, THIERRY GIAMARCHI, DPMC, Université de Genève, Suisse — One-dimensional boundary interfaces between different phases are described at macroscopic scales by a rough fluctuating line, whose geometrical properties are dictated by the disorder in the underlying medium, by the temperature of the environment, and by the elastic properties of the line. A widely used and successful model is the directed polymer in a random medium, pertaining to the Kardar-Parisi-Zhang (KPZ) universality class. Much is known for this continuous model when the disorder is uncorrelated, and it has allowed to understand the static and dynamical features of experimental systems ranging from magnetic interfaces to liquid crystals. We show that short-range correlations in the disorder at a scale $\xi > 0$ modify the uncorrelated (i.e. zero ξ) picture in a non-obvious way. If the geometrical fluctuations are still described by the celebrated 2/3 KPZ exponent, characteristic amplitudes are however modified even at scales much larger than ξ, in a well-controlled and rather universal manner. Our results are also relevant to describe the slow (so called 'creep') motion of interfaces in random media, and more formally (trough replicae) one-dimensional gases of bosons interacting with softened delta potential.

3:54PM J29.00008 Novel phases in an accelerated exclusion process[1] , JIAJIA DONG, Bucknell University, STEFAN KLUMPP, Max Planck Institute of Colloids and Interfaces, ROYCE K.P. ZIA, Physics Department, Virginia Tech, Department of Physics and Astronomy, Iowa State University — We introduce a class of distance-dependent interactions in an accelerated exclusion process (AEP) inspired by the cooperative speed-up observed in transcribing RNA polymerases. In the simplest scenario, each particle hops to the neighboring site if vacant *and* when joining a cluster of particles, triggers the frontmost particle to hop. Through both simulation and theoretical work, we discover that the steady state of AEP displays a discontinuous transition with periodic boundary condition. The system transitions from being homogeneous (with augmented currents) to phase-segregated. More surprisingly, the current-density relation in the phase-segregated state is simply $J = 1 - \rho$, indicating the particles (or holes) are moving at unit velocity despite the inclusion of long-range interactions.

4:06PM J29.00009 ABSTRACT WITHDRAWN –

4:18PM J29.00010 Intrinsically Localized Modes in the three-dimensional Quantal Fermi-Pasta-Ulam Lattice , DERYA KANBUR, PETER S. RISEBOROUGH, Temple University — Intrinsically Localized Modes (ILMs) are spatially localized oscillatory modes in homogeneous lattices, that are stabilized by anharmonic interactions. ILMs are frequently found in classical low-dimensional systems, where the frequency of the oscillations is a continuous variable. By contrast, due to the internal frequencies quantized,the quantum systems support a hierarch of excitations. The hierarchy of quantal excitations can be described in terms of a hierarchy of bound states of a multiple numbers of phonons. In one-dimension, the existence of the ILMs is ensured for any strength of the repulsive interactions by the divergent van-Hove singularities in the multi-phonon density of states. Inelastic neutron scattering measurements on NaI have revealed unexpected excitations which have been interpreted in terms of ILMs. Since the energies of the observed excitations are discrete, the experiments indicate that the ILMs have quantum character. Therefore, we search for low-energy quantized ILMs in a three-dimensional generalization of the Fermi-Pasta-Ulam lattice. We find that quantized ILMs may exist for values of the interaction strengths which exceeds a critical value. We examine the polarization-dependence, dispersion and the spatial characteristics of the lowest-energy ILMs.

4:30PM J29.00011 Dynamics of Linked and Knotted Vortices , DUSTIN KLECKNER, MARTIN SCHEELER, WILLIAM T. M. IRVINE, University of Chicago — Recently developed experimental methods have allowed us to generate topologically linked fluid vortices for the first time. The intrinsically geometric nature of vortex dynamics allows us to measure physical quantities, such as energy, by reconstructing the core centerline in three-dimensions using high-speed laser scanning tomography. This novel approach offers insights into the evolution of linked and knotted vortices up to and through changes in topology.

4:42PM J29.00012 Thermally Activated Avalanches in Twinned Crystals , IDO REGEV, Los Alamos National Laboratory, XIANGDONG DING, Xi'an Jiaotong University, TURAB LOOKMAN, Los Alamos National Laboratory — In previous work it was shown that the power-spectrum of the energy release in a twinned crystal under deformation, exhibits a transition from a low-temperature power-law to a high temperature activated dynamics. In this work we provide a statistical mechanics explanation to this behavior based on the understanding that the origin of the power-law behavior stems from a pattern of vertical twins that forms at the onset of yield, and serves as pinning sites to the motion of the (horizontal) twins. The transition to activated behavior is explained by a master equation based on a "trap model."

4:54PM J29.00013 Exploring the scaling laws of crystal plasticity with a Phase Field Crystal model , GEORGIOS TSEKENIS, University of Illinois at Urbana-Champaign, THOMAS FEHM, Ludwig-Maximilians-Universität Muenchen, PAK YUEN CHAN, None, JONATHAN UHL, JONATHAN DANTZIG, Retired, NIGEL GOLDENFELD, KARIN DAHMEN, University of Illinois at Urbana-Champaign — A wealth of experiments and simulations the last years has cemented the fact that crystalline materials deform in an intermittent way with slip-avalanches that are power-law distributed. Recently we showed that zero temperature discrete dislocation dynamics simulations predict mean field scaling exponents for both static and dynamic critical exponents. To model a wider range of experimental observations and predict the dependence on experimental parameters that are not captured by discrete dislocation dynamics we work with a Phase Field Crystal (PFC) model in two dimensions. The PFC model has the advantage that it does not require any ad hoc assumptions about the dislocation interaction or their creation and annihilation. It also models the dislocation dynamics at finite temperature. We extract the avalanche distributions and show that they scale according to the Mean Field Depinning universality class even though there is no quenched disorder.

5:06PM J29.00014 Intermittency in brittle cracks: Model experiment in artificial rocks , JONATHAN BARES, DANIEL BONAMY, CEA, Saclay (CEA/DSM/IRAMIS/SPCSI/LNOCS), DAVY DALMAS, UMR CNRS-Saint Gobain, Aubervilliers, LAMINE HATTALI, CEA, Saclay (CEA/DSM/IRAMIS/SPCSI/LNOCS) — Continuum theory fails to account for disorder effect on the crack propagation in brittle heterogeneous materials: It can explain neither the crackling dynamics, nor the statistics of the macro-scale mechanical observables. In this context, some tools issued from out-of-equilibrium statistical physics that identifies crack propagation onset with a depinning transition appear promising, but lack for quantitative comparisons with experiments. We designed a model experiment set up based on a material with tunable micro-scale (ceramics of sintered polymer beads) in which tensile cracks is grown over a wide range of speeds. Crack length, mechanical energy and acoustic emission (AE) are monitored with good resolution (ms for the first two, μs for AE) during the experiments. These measures were used (i) to provide information on the nature of the acoustic energy emitted during a breaking event, (ii) to unravel the relation between material toughness and relative system size. We believe our experiment to find applications in mechanical engineering, by helping to understand the microstructural disorder effect on the toughness properties. In statistical physics, it provides a model system to study collective complex crackling dynamics. Finally, in geophysics it help to interpret AE signal used to monitor the damage in Earth crust.

Session J30 GSNP: Focus Session: Continuum Descriptions of Discrete Materials 338 - Kenneth Kamrin, Massachusetts Institute of Technology

2:30PM J30.00001 Homogenized Mechanical Behavior of Cross-Linked Fiber Networks Embedded in Matrix , CATALIN PICU, LIJUAN ZHANG, ALI SHAHSAVARI, Rensselaer Polytechnic Institute — Most biological and some biomimetic materials are made from fiber networks embedded in an elastic medium. The mechanical behavior of these composites depends in interesting ways on the elasticity of the matrix. In this work we study this issue using both 2D and 3D models, with the goal of deriving expressions linking microstructural parameters and the composite elastic properties. We show that the strong interaction between network and matrix precludes the use of linear superposition of effects and that the effective moduli are a complex function of the constituent moduli. The internal distribution of stresses is also studied and discussed in relation with failure mechanisms.

2:42PM J30.00002 Size Effects in the Mechanical Behavior of Sparsely Cross-Linked Fiber Networks , ALI SHAHSAVARI, CATALIN PICU, Rensselaer Polytechnic Institute — Random fiber networks are structural elements in many biological and man-made materials and the prediction of their mechanical properties is desirable in many applications. In this work we first address the problem of the scale of homogeneity of these discrete systems, i.e. the size of the model above which the elastic response is model size- independent. Further, using models large enough to eliminate the size effect, we determine a structure-property relation for networks with variable concentration of cross-links.

2:54PM J30.00003 Role of Inhomogeneity in Mechanochemically Active Polymers , MEREDITH SILBERSTEIN, Cornell University — Mechanically-induced reactivity is a promising means for designing self sensing and autonomous materials. Mechanically sensitive chemical groups termed mechanophores can be covalently linked into polymers in order to trigger specific chemical reactions upon mechanical loading. The mechanophore reaction kinetics, as determined by ab initio steered molecular dynamics, are exponential in force. As such the mechanochemical behavior of a solid-state polymer is highly sensitive to stress carried by that polymer, including local spatial and temporal fluctuations. Previously we developed microstructurally-based continuum models for fluorescence response in spiropyran-linked rubbery (poly methacrylate) and glassy (poly methylmethacrylate) polymers. The homogenization scheme in each relied on assigning mean effective forces acting on the mechanophores. Here we explore the theoretical influence of nanoscale spatial force distributions and fast temporal force fluctuations on the mechanochromic response of these systems. The effect of each is found to be significant and highly dependent on the intrinsic polymer mechanical behavior.

3:06PM J30.00004 Marginal Matter , MARTIN VAN HECKE, Leiden University — All around us, things are falling apart. The foam on our cappuccinos appears solid, but gentle stirring irreversibly changes its shape. Skin, a biological fiber network, is firm when you pinch it, but soft under light touch. Sand mimics a solid when we walk on the beach but a liquid when we pour it out of our shoes. Crucially, a marginal point separates the rigid or jammed state from the mechanical vacuum (freely flowing) state - at their marginal points, soft materials are neither solid nor liquid. Here I will show how the marginal point gives birth to a third sector of soft matter physics: intrinsically nonlinear mechanics. I will illustrate this with shock waves in weakly compressed granular media, the nonlinear rheology of foams, and the nonlinear mechanics of weakly connected elastic networks.

3:42PM J30.00005 Capturing nonlocal effects in 2D granular flows , KEN KAMRIN, MIT, GEORG KOVAL, INSA Strasbourgh — There is an industrial need, and a scientific desire, to produce a continuum model that can predict the flow of dense granular matter in an arbitrary geometry. A viscoplastic continuum approach, developed over recent years, has shown some ability to approximate steady flow and stress profiles in multiple inhomogeneous flow environments. However, the model incorrectly represents phenomena observed in the slow, creeping flow regime. As normalized flow-rate decreases, granular stresses are observed to become largely rate-independent and a dominating length-scale emerges in the mechanics. This talk attempts to account for these effects, in the simplified case of 2D, using the notion of nonlocal fluidity, which has proven successful in treating nonlocal effects in emulsions. The idea is to augment the local granular fluidity law with a diffusive second-order term scaled by the particle size, which spreads flowing zones accordingly. Below the yield stress, the local contribution vanishes and the fluidity becomes rate-independent, as we require. We implement the modified law in multiple geometries and validate its flow and stress predictions in multiple geometries compared against discrete particle simulations. In so doing, we demonstrate that the nonlocal relation proposed is satisfied universally in a seemingly geometry-independent fashion.

3:54PM J30.00006 Predicting dense granular flows: continuum modeling with a length-scale , DAVID HENANN, KEN KAMRIN, MIT — Dense granular materials display a complicated set of flow properties, which differentiate them from ordinary fluids. In particular, slowly-flowing granular media form clear, experimentally-robust features; most notably, shear bands, which can have a variety of possible widths and which decay non-trivially into the surrounding quasi-rigid material. Despite the ubiquity of granular flows, no model has been developed that captures or predicts these complexities, posing an obstacle in industrial and geophysical applications. We present a three-dimensional constitutive model for well-developed, dense granular flows aimed at filling this need. The key ingredient of the theory is a grain-size-dependent nonlocal rheology – inspired by efforts for emulsions – in which flow at a point is affected by both the local stress as well as the flow in neighboring material. With a single new material parameter, we show that the model is able to quantitatively describe dense granular flows in an array of different geometries. Of particular importance, it is the first model to pass the stringent test of capturing all aspects of the highly-nontrivial flows observed in split-bottom cells – a geometry that has resisted modeling efforts for nearly a decade.

4:06PM J30.00007 Changes in fluctuation patterns of a granular hopper flow near jamming , MICHAL DICHTER, Brandeis University, SHUBHA TEWARI, Western New England University, BULBUL CHAKRABORTY, Brandeis University — Jams in gravity-driven flows in a vertical hopper with rigid walls occur under extremely inhomogeneous conditions, distinct from what is observed in spatially homogeneous flows. In this work, we use event-driven simulations to study velocity fluctuations in a collisional, 2D gravity-driven flow near jamming. We find a heterogeneous spatial distribution of velocity autocorrelation relaxation times, with the spatial structure changing significantly as the flow approaches jamming. At high flow rates, the flow at the center has lower kinetic temperatures and longer autocorrelation times than at the boundary. Unexpectedly, however, this trend reverses itself as the flow rate slows, with fluctuations relaxing more slowly at the boundaries though the kinetic temperatures remain high in that region. We suggest that this behavior is an indication of the flow becoming glassy close to the boundaries as jamming is approached.

4:18PM J30.00008 Interplay between packing and flow in the shear zone at the wall of a granular hopper flow[1] , BRENDA CARBALLO-RAMIREZ, MAYA LEWIN-BERLIN, NALINI EASWAR, Smith College, Northampton, MA, NARAYANAN MENON, University of Massachusetts, Amherst, MA — A granular medium flowing through a vertical channel has a flat velocity profile in the bulk with a shear zone at the wall. The size of the shear zone and the dependence on flow parameters is poorly understood. To address this issue we image the flow of spherical steel spheres under gravity in a vertical, straight-walled 2-dimensional hopper, where the flow velocity is controlled by a taper at the outlet. Our measurements focus on the role of microstructure in controlling the shear zone. We have found that the size of this zone is larger in bidisperse, disordered flow that in monodisperse, nearly-crystalline flows. We report the effect of packing as quantified by local dilation, as a function of flow rate for systems of both bidisperse and monodisperse grains.

[1]Supported by NSF DMR 0907245 and NSF MRSEC DMR 0820506

4:30PM J30.00009 Boundary layer model for intruder drag , STEPHAN KOEHLER, JONATHAN GOLDSMITH, Physics Dept., WPI, MINGJIANG TAO, Civil and Environmental Engineering, WPI — We propose a boundary layer model for drag on vertical intruders with uniform cross-sections in granular beds. The drag is the surface integral of the stress over a monolayer of particles, where the stress has a simple dependence on depth beneath the surface and angle of the surface normal relative to the direction of flow. This model is in good experimental agreement, accounts for the scale effect and the associated force focusing observed on edges of intruders.

4:42PM J30.00010 Rheology and migration in colloidal and noncolloidal suspensions , JEFFREY MORRIS, Levich Institute, City College of New York — Suspensions of solid particles in liquids provide a useful setting for development of continuum description of particle-laden fluids. These mixtures can be made density matched, so that the volume fraction is freely variable, and the rheology can be measured in standard rheometric apparatus. This work will describe the rheology of concentrated suspensions and its implications in continuum description of the bulk flow of the mixture; the development will focus on colloidal suspensions where Brownian motion is relevant, with the limit of strong shear taken to describe noncolloidal suspensions. The normal stress response of these suspensions will be shown to be critical to description of the migration of the particles, leading to strong concentration gradients. The normal stress differences as well as the isotropic normal stress of the particle phase, or nonequilibrium osmotic pressure, will be described and related to these migration phenomena. The implications of the normal stress differences in secondary flow generation will also be described.

4:54PM J30.00011 How to predict polydisperse hard-sphere mixture behavior using maximally equivalent tridisperse systems[1] , VITALIY OGARKO, STEFAN LUDING, University of Twente — Polydisperse hard sphere mixtures have equilibrium properties which essentially depend on the number density and a reduced number K of moments of the size distribution function. Such systems are equivalent to other systems with different size distributions if the K moments are matched. In particular, a small number s of components, such that $2s-1=K$ is sufficient to mimic systems with continuous size distributions. For most of the fluid phase $K=3$ moments ($s=2$ components) are enough to define an equivalent system, while in the glassy states one needs $K=5$ moments ($s=3$ components) to achieve good agreement between the polydisperse and its maximally-equivalent tridisperse system. With $K=5$ matched moments they are also close in number- and volume-fractions of rattlers. Finally, also the jamming density of maximally-equivalent jammed packings is very close, where the tiny differences can be explained by the distribution of rattlers.

5:06PM J30.00012 Finite element modeling of the dynamic effective mass of granular media , JOHN VALENZA[1], Schlumberger-Doll Research, DAVID HENANN[2], KEN KAMRIN[3], Massachusetts Institute of Technology, DAVID JOHNSON[4], Schlumberger-Doll Research — Finite sized granular media have a frequency dependent, complex valued effective mass, characterized by several resonant features. In the vicinity of the corresponding frequencies the associated mass can be several times the static mass. This complicated behavior is due to mechanical interactions between neighboring grains. In contrast we investigate the viability of using a continuum approximation for the mechanical response to model the effective mass. We find that the granular medium is suitably represented by a linear elastic stress-strain relationship with viscous damping. The free parameters in the linear elastic model, the elastic modulus and poisson's ratio, are measured using conventional mechanical testing equipment, and a novel sensor which permits the measurement of lateral stress. Moreover, we characterize the frequency dependent displacement profile on the surface of the granular medium. In this talk we demonstrate that our continuum model is suitable for reproducing the frequency dependent effective mass, and the displacement profile at the resonant frequencies.

5:18PM J30.00013 A terradynamics of legged locomotion on granular media , CHEN LI, UC Berkeley, TINGNAN ZHANG, DANIEL GOLDMAN, Georgia Tech — The theories of aero and hydrodynamics form the bases for prediction of animal movement and device design in air and water, and allow computation of lift, drag, and thrust forces on wings and fins. While models of terrestrial legged locomotion have focused on interactions with solid ground, many legged animals (and increasingly robots) move on substrates such as sand, gravel, soil, mud, snow, grass, and leaf litter that flow in response to intrusion. However, locomotor-ground interaction models on such flowable ground are often unavailable. Here we develop a resistive force model that predicts forces on arbitrary-shaped legs and bodies moving freely in granular media in the vertical plane. Our resistive force measurements reveal a complex but generic dependence of stresses on an intruder on its depth, orientation, and movement direction in granular media of different particle size, density, friction, and compaction. Our resistive force model and a multi-body simulation predict a small legged robot's locomotion on granular media using various leg shapes and stride frequencies, and give insight into the effects of leg morphology and kinematics on movement on granular media. Our study is an initial but important step in creation of "terradynamics" of locomotion on flowable ground.

3:06PM J31.00002 Viscous Friction of Polymer Brushes , AYKUT ERBAS, MICHAEL RUBINSTEIN, University of North Carolina at Chapel Hill, UNC CHEM. POLYMER PHYSICS TEAM — Polymer brushes are unique soft structures that can exhibit solid-like behaviors, i.e., if they are deformed by an external force, they can relax and take their original conformations when the external force is removed. Despite their solid-like character, tribological behavior of polymer brushes exhibits fluid-like properties: For instance, friction force exerted on two interdigitated brushes sheared in opposite directions goes to zero linearly as the shear velocity vanishes, i.e., no static friction occurs, which is a property observed mostly for fluidic friction. In this talk, we present our simulation result and scaling arguments on the friction of planar brush-on-brush systems. Our theoretical approach and simulation regimes encompass both linear and non-linear regimes. We show that individual brush ends move on well-defined average trajectories. The dissipation in the system can be related to these average trajectories for a wide range of shear velocities.

3:18PM J31.00003 Stick-Slip Dynamics Using Velcro as Model System , LISA MARIANI, CARA ESPOSITO, PAUL ANGIOLILLO, Saint Joseph's University — Described by Galileo and further developed phenomenologically by Amontons and Coulomb, friction remains to be poorly understood especially with respect to its transition from the static to the kinetic regimes. In particular, the dynamics and control thereof of systems exhibiting stick-slip motion continues to be an area of fascination. The dry sliding behavior of the hook-and-loop system evinced by common Velcro captures many of the hallmarks of stick-slip motion typically manifested in systems at very small and very large length scales in addition to satisfying some of the classical laws as put forth by Amontons and Coulomb. Specifically, the kinetic frictional force is independent of driving velocity over nearly three orders of magnitude. In stark contrast to classical behavior, both the maximum static and the kinetic frictional forces reveal a linear dependence on the "area of contact" or more appropriately, hook number. Moreover, the frictional force (static and kinetic) exhibits a power law dependence on load with an exponent of approximately 0.25 similar to behavior seen in AFM, the implication being non-constant coefficients of static and kinetic friction. Statistical analysis shows that the fluctuations of stick-slip events follow a power law behavior with an exponent of approximately 0.5. Interestingly, this relatively simple system demonstrates evidence of precursor events prior to the onset of motion and may provide insight to the nucleation and transition from static to kinetic friction.

3:42PM J31.00005 Structure and dynamics of hyperbranched polymers in bulk and under nanoscopic confinement , S. H. ANASTASIADIS, K. CHRISSOPOULOU, Foundation for Research and Technology-Hellas and Univ. of Crete, Greece, K. KARATASOS, S. FOTIADOU, C. KARAGEORGAKI, I. TANIS, D. TRAGOUDARAS, Aristotle University of Thessaloniki, Greece, B. FRICK, Institut Laue Langevin, France — The structure and dynamics of a hyperbranched polyesteramide (Hybrane S 1200) and its nanocomposites with natural montmorillonite (Na+-MMT) are investigated. In bulk, the behavior is probed by QENS with MD simulations employed for a deeper insight into the relevant relaxation processes. The energy-resolved elastically scattered intensity from the polymer relaxes with two steps, one below and one above the polymer Tg. The QENS spectra are consistent with the elastic measurements and can be correlated to the results emerging from the detailed description afforded by the atomistic simulations, which cover a broad time range and predict the existence of three relaxation processes. The nanocomposites are investigated by XRD, DSC and QENS. XRD reveals an intercalated nanocomposite structure. The polymer chains confined within the galleries show similarities in the dynamic behavior with that of the bulk polymer for temperatures below the bulk polymer Tg, whereas they exhibit frozen dynamics under confinement at temperatures higher than that. Sponsored by the Greek GSRT (ΣΥΝΕΡΓΑΣΙΑ 09ΣΥΝ-42-580).

3:54PM J31.00006 Contact Mechanics of Nanoparticles[1] , J.-M.Y. CARRILLO, A.V. DOBRYNIN, University of Connecticut — We perform molecular dynamics simulations of the detachment of nanoparticles from a substrate. The critical detachment force, f*, is obtained as a function of the nanoparticle radius, R_p, shear modulus, G, surface energy, γ_p, and work of adhesion, W. The magnitude of the detachment force is shown to increase from πWR_p to $2.2\pi WR_p$ with increasing nanoparticle shear modulus and nanoparticle size. This variation of the detachment force is a manifestation of a neck formation upon nanoparticle detachment. Using scaling analysis, we show that the magnitude of the detachment force is controlled by the balance of the nanoparticle elastic energy, surface energy of the neck, and nanoparticle adhesion energy to a substrate. It is a function of the dimensionless parameter $\delta \propto \gamma_p (GR_p)^{-1/3} W^{-2/3}$which is proportional to the ratio of the surface energy of a neck and the elastic energy of deformed nanoparticle. In the case of small values of the parameter $\delta << 1$, the critical detachment force approaches a critical Johnson, Kendall and Roberts force, $f* \approx 1.5\pi W R_p$, as is usually the case for strongly crosslinked large nanoparticles. However, in the opposite limit, corresponding to soft small nanoparticles, for which $\delta >> 1$, the critical detachment force, f*, scales as $f* \propto \gamma_p^{3/2} R_p^{1/2} G^{-1/2}$. Simulation data are described by a scaling function $f* \propto \gamma_p^{3/2} R_p^{1/2} G^{-1/2} \delta^{-1.89}$.

4:06PM J31.00007 Probing gradient of dynamics in confined polymers with nanoparticles[1] , SIVASURENDER CHANDRAN, NAFISA BEGAM, JAYDEEP BASU, Department of Physics, Indian Institute of Science, Bangalore, India, MRINMAY MUKHOPADHYAY, Applied materials science division, Saha Institute of Nuclear Physics, Kolkota, India — We report [1] the evidence of gradient in dynamics by probing the diffusion coefficient of polymer grafted nanoparticles (PGNP) in polymer thin films of different thickness (2.5 R_g and 8R_g of the matrix). Using surface x-ray scattering, we observe a systematic vertical dispersion of PGNP from a pinned in substrate interface layer to the surface on thermal annealing. Even after annealing at high temperature ($T >> T_g$) and longer times, a fraction of PGNP pertain to stay at the substrate forming a stable interface layer. This hints about the low mobility of particles at the substrate interface and also emphasizes the presence of high viscous/gel-like interfacial layer. Real space microscopic images show the formation of lateral domains of the particles at air surface suggesting the higher surface mobility. In addition, it is also observed that the fraction of particles in the air surface is more in annealed thinner films compared to the thicker ones. Thus, we have correlated the observed lateral and vertical dispersion and its evolution with annealing, to the gradient in dynamics along the thickness of the thin films. *[1] Sivasurender Chandran, J. K. Basu and M. K. Mukhopadhyay, in communication*

4:18PM J31.00008 Confinement of conjugated polymers into soft nanoparticles: molecular dynamics simulations[1] , SIDATH WIJESINGHE, DVORA PERAHIA, Clemson University, GARY S. GREST, Sandia National Laboratories — The structure and dynamics of conjugated polymers confined into soft nanoparticles (SNPs) have been studies by molecular dynamic simulations. This new class of tunable luminescent SNPs exhibits an immense potential as bio-markers as well as targeted drug delivery agents where tethering specific groups to the surface particles offers a means to target specific applications. Of particular interest are SNPs that consist of non- crosslinked polymers, decorated with polar groups. These SNPs are potentially tunable through the dynamics of the polymer chains, whereas the polar entity serves as internal stabilizer and surface encore. Confinement of a polymer whose inherent conformation is extended impacts not only their dynamics and as a result their optical properties. Here we will present insight into the structure and dynamics of dialkyl poly *para* phenylene ethynylene (PPE), decorated by a carboxylate groups, confined into a soft particle. The conformation and dynamics of polymer within SNP will be discussed and compared with that of the linear chain in solution.

4:30PM J31.00009 Forces between nanoparticles grafted with rigid polymers: a pathway for tunable hybrids[1] , SABINA MASKEY, DVORA PERAHIA, Clemson University, J. MATTHEW D. LANE, GARY S. GREST, Sandia National Laboratories — The forces between the nanoparticles hybrids that consist of para dialkyl phenyleneethynylenes (PPEs) grafted to a silica nanoparticle have been studied using molecular dynamic simulations. PPEs are rigid polymers whose conformation determines their degree of conjugation and their assembly mode which in turn affects the electro-optical response of the nanoparticle-polymer complexes. When confined to a nanoparticle surface, the PPE chains are fully extended but cluster as the quality of the solvents is reduced. Tuning the degree of clustering by tuning the solvent-polymer interaction is expected to direct the assembly of the particles. Results for the forces between two nanoparticles functionalized with rigid polymers as a function of solvent quality, velocities and distances will be presented. These simulations will provide for the first time insight to the interactions of the nanoparticles grafted with rigid polymer, which in turn, results in formation of tunable hybrids.

[1]This work is partially carried with DOE support under grant DE-FG02-12ER46843

4:42PM J31.00010 Polymer Film Surface Fluctuation Dynamics in the Limit of Very Dense Branching , MARK FOSTER, BOXI LIU, Dept. of Polymer Science, The University of Akron, SURESH NARAYANAN, X-ray Science Division, Argonne National Laboratory, DAVID T. WU, Chemical Engr. and Chemistry Dept., Colorado School of Mines — The surface height fluctuations of melt films of densely branched comb polystyrenes of thicknesses greater than 55nm and at temperatures more than 23 C above the $T_{g,bulk}$ can be rationalized using the hydrodynamic continuum theory (HCT) known to describe melts of unentangled linear and cyclic chains. Film viscosities (η_{XPCS}) for three combs inferred from fits of the HCT to X-ray Photon Correlation Spectroscopy (XPCS) data are the same as bulk viscosities (η_{bulk}) measured with rheometry. For the comb most like a star polymer and the comb closest to showing bulk entanglement behavior, η_{XPCS} is greater than η_{bulk}. However, the values of $\eta_{XPCS} - \eta_{bulk}$ are much smaller than those seen for less densely branched polystyrenes. We conjecture that the smaller magnitude of $\eta_{XPCS} - \eta_{bulk}$ for the densely grafted combs is due to a lack of interpenetration of the side chains when branching is very dense. While data of relaxation time versus T for cyclic chains virtually collapse to a single curve when $T_{g,bulk}$ is accounted for, that is not the case for combs. $T_{g,bulk}$ and specific chain architecture both play important roles in determining the surface fluctuations. 4:54PM J31.00011 Axial and radial nanostructures in electrospun polymer fibers[1] , ISRAEL GREENFELD, Technion, Israel, ANDREA CAMPOSEO, Università del Salento, Italy, FRANCESCO TANTUSSI, Università di Pisa, Italy , STEFANO PAGLIARA, Università del Salento, Italy, FRANCESCO FUSO, MARIA ALLEGRINI, Università di Pisa, Italy, DARIO PISIGNANO, Università del Salento, Italy, EYAL ZUSSMAN, Technion, Israel — The high tensional stresses during electrospinning of semidilute polymer solutions affect the dynamic conformation of the polymer network within the liquid jet, leaving a distinctive trace in the molecular structure after solidification. We investigated such effects in electrospun nanofibers made of conjugated polymers. Modeling the polymer network evolution during electrospinning showed that as the network stretches axially, it contracts towards the jet core. The model represents the semi-flexible conjugated polymer chains as flexible freely-jointed chains, whose joints are bonding defects. Using the conjugated polymer MEH-PPV dissolved in a mixture of THF and DMF solvents, and taking advantage of its unique photophysical characteristics, we investigated optically the variations in the density and orientation of the polymer macromolecules in electrospun nanofibers. In agreement with our model, we found higher density and axial orientation at the fiber core, while lower density and radial orientation closer to the fiber surface. The non-uniformity of the resulting molecular structure can be tuned and exploited in diverse optical and structural applications.

5:06PM J31.00012 Correlation between the interfacial bond orientational order and the shift in T_g upon confinement , SIMONE NAPOLITANO, Université Libre de Bruxelles — The two-order-parameter (TOP) model rationalizes the interfacial slower dynamics in terms of enrichment in bond orientational order (BOO), near the wall [1]. Recently, we verified that the dielectric strength, $\Delta\epsilon$, is a robust parameter for measuring the BOO, as $\Delta\epsilon = g<\mu^2>/k_BT$, where μ is the dipole moment, and g accounts for the correlation among neighbor dipole moments. We obtained interfacial values of the dielectric strength, $\Delta\epsilon_{int}$, analyzing the thickness dependence of all the polymers for which $\Delta\epsilon$ was measured upon confinement in ultrathin films. Although for all the investigated systems $\Delta\epsilon$ decreases in proximity of a solid interface due to the reduction in $<\mu^2>$ upon adsorption [3], we identified a striking correlation between $\Delta\epsilon_{int}$ and the shift in T_g upon confinement. Increases in T_g were univocally correlated to nonzero positive values of $\Delta\epsilon_{int}$, implying a larger BOO near the wall, in line with the predictions of the TOP model. 5:18PM J31.00013 Conformational Relaxation of Polystyrene at Substrate Interface , HIROFUMI TSURUTA, YOSHIHISA FUJII, Dept. of Appl. Chem., Kyushu Univ., HIROSHI MORITA, AIST, KEIJI TANAKA, Dept. of Appl. Chem., Kyushu Univ., DEPT. OF APPL. CHEM., KYUSHU UNIV. TEAM, AIST TEAM — The local conformation of polymer chains in a film at a substrate interface was examined by sum-frequency generation spectroscopy. When a polystyrene (PS) film was prepared on a quartz substrate by a spin-coating method, the chains were aligned in the interfacial plane of the substrate. A dissipative particle dynamics simulation revealed that a spinning torque induced the chain orientation during the film preparation process and the extent of the orientation was a function of the distance from the interface. This interfacial orientation of chains was not observed for a PS film prepared by a solvent-casting method. Interestingly, the local conformation of chains at the substrate interface was unchanged even at a temperature that was 80 K higher than the bulk glass transition temperature. This observation means that polymer chains at the substrate interface can be only partially relaxed under conditions where the bulk chains are fully relaxed. On the other hand, interfacial chains could be easily relaxed by solvent annealing.

3:06PM J32.00002 Designing "catch and release" systems by utilizing functionalized oscillating fins , YONGTING MA, University of Pittsburgh, Pittsburgh, PA 15261, AMITABH BHATTACHARYA, Indian Institute of Technology Bombay, Mumbai, 400076, OLGA KUKSENOK, University of Pittsburgh, Pittsburgh, PA 15261, XIMIN HE, JOANNA AIZENBERG, Harvard University, Cambridge, MA 02138, ANNA C. BALAZS, University of Pittsburgh, Pittsburgh, PA 15261 — Designing a biomimetic "catch and release" device for the selective removal of target species from the surrounding solution is critical for developing many useful sensors and sorters. Via computational modeling, we simulate an array of oscillating fins that are localized on the floor of a microchannel and immersed in a two-fluid stream. The fins reach the upper fluid when they are upright and are located entirely within the lower stream when they are tilted. We introduce specific adhesive interactions between the fins and particulates in the solution and determine conditions where the oscillating fins can selectively bind ("catch") target nanoparticles within the upper fluid stream and then release these particles into the lower stream. Using our hybrid computational approach, which combines the lattice Boltzmann model for binary fluids and a Brownian dynamics model for the nanoparticles, we isolate systems parameters (e.g., frequency and amplitude of fins' oscillations) that lead to the efficient extraction of target species from the upper stream and placement into the lower fluid. Our findings provide fundamental insights into the system's complex dynamics, as well as a unique solution for detection, separation, and purification of multi-component mixtures.

3:18PM J32.00003 The Study of Lipid-Based Nanodis as a Novel Carrier for Hydrophobic Cargo

, YING LIU[1], MU-PING NIEH[2], Chemical, Materials and Biomolecular Engineering, University of Connecticut, HYUNSOOK JANG, Polymer Science, University of Connecitcut, YIKE HUANG, YONG WANG, Chemical, Materials and Biomolecular Engineering, University of Connecticut — Monodispersed nanodiscs can be self-assembled in an aqueous mixture of 1,2-dipalmitoyl-sn-glycero- 3-phosphocholine (DPPC), 1,2-dihexanoyl-sn-glycero-3-phosphocholine (DHPC) and 1,2-dipalmitoyl-sn-glycero-3-phospho- (1'-rac-glycerol) (sodium salt)(DPPG) and 1,2-distearoyl-sn-glycero- 3-phosphoethanolamine-N-[methoxy(polyethylene glycol)-2000] (ammonium salt) (PEGylated DSPE). The stability of discs and the effect of polyethylene glycol (PEG), including molecular chain length and concentration, on the disc morphology are characterized by dynamic light scattering, negative staining transmission electron microscopy and small angle neutron scattering. Fluorescent Spectroscopy is used to study the loading capacity of a hydrophobic dye, Nile red entrapped in the nanodiscs. The exchanging of Nile red between discs will be correlated with the release of hydrophobic molecule. In-vitro studies indicate that the non-specific binding of these Nile-red loaded nanodiscs to the CCRF-CEM cells is greatly reduced upon the addition of PEGylated DSPE. The system has a potential application of delivering hydrophobic molecules. The incorporation of targeting molecules with the nanodiscs is also investigated.

3:30PM J32.00004 Harnessing Fluid-Driven Vesicles to Pick Up and Drop Off Janus Particles

, XIN YONG, ISAAC SALIB, EMILY CRABB, NICHOLAS MOELLERS, GERALD MCFARLIN, OLGA KUKSENOK, ANNA BALAZS, Chemical Engineering Dept, University of Pittsburgh — Using dissipative particle dynamics (DPD) simulations, we model the interaction between nanoscopic lipid vesicles and Janus nanoparticles in the presence of an imposed flow. Both the vesicle and Janus nanoparticles are localized on a hydrophilic substrate and immersed in a hydrophilic solution. The fluid-driven vesicle successfully picks up Janus particles on the substrate and transports these particles as cargo along the surface. The vesicle can carry up to four particles as its payload. Hence, the vesicles can acts as nanoscopic "vacuum cleaners", collecting nanoscopic debris localized on the floors of the fluidic devices. Importantly, these studies reveal how an imposed flow can facilitate the incorporation of nanoparticles into nanoscale vesicles. With the introduction of a hydrophobic domain on the substrate, the vesicles can also robustly drop off and deposit the particles on the surface. The controlled pickup and delivery of nanoparticles via lipid vesicles can play an important step in the bottom-up assembly of these nanoparticles within small-scale fluidic devices.

3:42PM J32.00005 Cob-Weaving Spiders Design Attachment Discs Differently for Locomotion and Prey Capture[1]

, VASAV SAHNI, JARED HARRIS, TODD BLACKLEDGE, ALI DHINOJWALA, The University of Akron — Spiders' cobwebs ensnare both walking and flying prey. While the scaffolding silk can entangle flying insects, gumfoot silk threads pull walking prey off the ground and into the web. Therefore, scaffolding silk needs to withstand the impact of the prey, whereas gumfoot silk needs to easily detach from the substrate when contacted by prey. Here, we show that spiders accomplish these divergent demands by creating attachment discs of two distinct architectures using the same pyriform silk. A "staple-pin" architecture firmly attaches the scaffolding silk to the substrate and a previously unknown "dendritic" architecture weakly attaches the gumfoot silk to the substrate. Gumfoot discs adhere weakly, triggering a spring-loaded trap, while the strong adhesion of scaffolding discs compels the scaffolding threads to break instead of detaching. We describe the differences in adhesion for these two architectures using tape-peeling models and design synthetic attachments that reveal important design principles for controlled adhesion.

4:06PM J32.00007 Self-Tailoring of Amphiphilic Block Copolymer Assemblies by Osmotic Pressure

, JINHYE BAE, RYAN HAYWARD, Polymer Science and Engineering Department at University of Massachusetts Amherst — Compartmentalization is a crucial architectural principle employed by eukaryotic cells, and correspondingly, pathways to assemble multi-compartmental polymeric assemblies are of considerable research interest. We report a study of the self-generation of water-in-oil-in-water (w/o/w) double emulsions with inner droplet sizes of $\sim$ 2-3 micrometers due to the osmotic pressure provided by salts initially dissolved in the organic phase. We show that this process can explain previously mysterious examples of spontaneous emulsion formation, due to the presence of initiator salt impurities within copolymer samples. Further, we harness it to tailor the structures of multiple emulsions, which upon solvent evaporation can yield multi-vesicular structures or hierarchically structured porous films. Such osmotically-driven polymer assemblies may have potential applications in therapeutic, pharmaceutical, cosmetic, and separation technologies.

4:18PM J32.00008 Effect of Intrinsic Twist on Length of Crystalline and Disordered Regions in Cellulose Microfibrils[1]

, ABDOLMADJID NILI, OLEG SHKLYAEV, ZHEN ZHAO, LINGHAO ZHONG, VINCENT CRESPI, Pennsylvania State University — Cellulose is the most abundant biological material in the world. It provides mechanical reinforcement for plant cell wall, and could potentially serve as renewable energy source for biofuel. Native cellulose forms a non-centrosymmetric chiral crystal due to lack of roto-inversion symmetry of constituent glucose chains. Chirality of cellulose crystal could result in an overall twist. Competition between unwinding torsional/extensional and twisting energy terms leads to twist induced frustration along fibril's axis. The accumulated frustration could be the origin of periodic disordered regions observed in cellulose microfibrils. These regions could play significant role in properties of cellulose bundles and ribbons as well as biological implications on plant cell walls. We propose a mechanical model based on Frenkel-Kontorova mechanism to investigate effects of radius dependent twist on crystalline size in cellulose microfibrils. Parameters of the model are adjusted according to all-atom molecular simulations.

4:30PM J32.00009 The Effect of Small Molecule Additives on the Self-Assembly and Functionality of Protein-Polymer Diblock Copolymers

, CARLA THOMAS, LIZA XU, BRADLEY OLSEN, Massachusetts Institute of Technology — Self-assembly of globular protein-polymer block copolymers into well-defined nanostructures provides a route towards the manufacture of protein-based materials which maintains protein fold and function. The model material mCherry-b-poly(N-isopropyl acrylamide) forms self-assembled nanostructures from aqueous solutions via solvent evaporation. To improve retention of protein functionality when dehydrated, small molecules such as trehalose and glycerol are added in solution prior to solvent removal. With as little as 10 wt% additive, improvements in retained functionality of 20-60% are observed in the solid-state as compared to samples in which no additive is present. Higher additive levels (up to 50%) continue to show improvement until approximately 100% of the protein function is retained. These large gains are hypothesized to originate from the ability of the additives to replace hydrogen bonds normally fulfilled by water. The addition of trehalose in the bulk material also improves the thermal stability of the protein by 15-20 $^{\circ}$C, while glycerol decreases the thermal stability. Materials containing up to 50% additives remain microphase separated, and, upon incorporation of additives, nanostructure domain spacing tends to increase, accompanied by order-order transitions.

4:42PM J32.00010 Material Structure of a Graded Refractive Index Lens in Decapod Squid , JING CAI, PAUL HEINEY, ALISON SWEENEY, University of Pennsylvania — Underwater vision with a camera-type eye that is simultaneously acute and sensitive requires a spherical lens with a graded distribution of refractive index. Squids have this type of lens, and our previous work has shown that its optical properties are likely achieved with radially variable densities of a single protein with multiple isoforms. Here we measure the spatial organization of this novel protein material in concentric layers of the lens and use these data to suggest possible mechanisms of self-assembly of the proteins into a graded refractive index structure. First, we performed small angle x-ray scattering (SAXS) to study how the protein is spatially organized. Then, molecular dynamic simulation allowed us to correlate structure to the possible dynamics of the system in different regions of the lens. The combination of simulation and SAXS data in this system revealed the likely protein-protein interactions, resulting material structure and its relationship to the observed and variable optical properties of this graded index system. We believe insights into the material properties of the squid lens system will inform the invention of self-assembling graded index devices.

4:54PM J32.00011 Phase Transitions in Concentrated Solution Self-Assembly of Globular Protein-Polymer Block Copolymers , CHRISTOPHER LAM, BRADLEY OLSEN, Massachusetts Institute of Technology — The self-assembly of globular protein-polymer bioconjugate block copolymers to form biofunctional nanostructures presents potentially complex behavior due to the tertiary structures and specific interactions of protein blocks. To understand the thermodynamics of these systems, the phase behavior of the model globular protein-polymer block copolymer mCherry-*b*-PNIPAM (mChP) is investigated in concentrated aqueous solution as a function of both concentration and temperature. At low concentrations, mChP forms a homogeneous disordered phase at low temperature and macrophase separates into an ordered conjugate-rich phase and a solvent-rich phase at temperatures above the PNIPAM thermoresponsive transition temperature. mChP solutions undergo a lyotropic, low-temperature ODT and both lyotropic and thermotropic OOTs at high concentration. Similar to coil-coil block copolymers, both coil fraction and solvent selectivity have large effects on the morphologies formed—disordered micelles, hexagonally packed cylinders, lamellae, and perforated lamellae. The order-disorder transition concentration (ODTC) of mChP is minimized for symmetric conjugates, suggesting that repulsive solvent-mediated protein-polymer interactions provide a driving force for self-assembly.

5:06PM J32.00012 Interfacial curvature effects in the self-assembly and responsiveness in polypeptide-based triblock copolymers , DANIEL SAVIN, JACOB RAY, ASHLEY JOHNSON, JACK LY, CHARLES EASTERLING, The University of Southern Mississippi — The self-assembly of amphiphilic block copolymers is dictated primarily by the balance between the hydrophobic core volume and the hydrophilic corona. In these studies, ABA and BAB triblock copolymers containing poly(lysine) (PK) and poly(propylene oxide) were synthesized and their solution properties studied using dynamic light scattering, circular dichroism spectroscopy and transmission electron microscopy. This talk will present some recent studies in solution morphology transitions that occur in these materials as a result of the helix-coil transition and associated charge-charge interactions. The solution properties and responsiveness of these novel materials will be discussed in terms of their ability to encapsulate and deliver cancer therapeutics.

5:18PM J32.00013 Amphiphilic Spider Silk-Like Block Copolymers with Tunable Physical Properties and Morphology for Biomedical Applications[1] , WENWEN HUANG, SREEVIDHYA KRISHNAJI, DAVID KAPLAN, PEGGY CEBE, Tufts University — Silk-based materials are important candidates for biomedical applications because of their excellent biocompatibility and biodegradability. To generate silk amphiphilic biopolymers with potential use in guided tissue repair and drug delivery, a novel family of spider silk-like block copolymers was synthesized by recombinant DNA technology. Block copolymer thermal properties, structural conformations, protein-water interactions, and self-assembly morphologies were studied with respect to well controlled protein amino acid sequences. A theoretical model was used to predict the heat capacity of the protein and protein-water complex. Using thermal analysis, two glass transitions were observed: Tg1 is related to conformational changes caused by bound water removal, while Tg2 (>Tg1) is the glass transition of dry protein. Real-time infrared spectroscopy and X-ray diffraction confirmed that different secondary structural changes occur during the two Tg relaxations. Using scanning electron microscopy, fibrillar networks and hollow vesicles are observed, depending on protein block copolymer sequence. This study provides a deeper understanding of the relationship between protein physical properties and amino acid sequence, with implications for design of other protein-based materials.

[1]Support was provided from the NSF CBET-0828028 and the MRI Program under DMR-0520655 for thermal analysis instrumentation.

3:06PM J33.00002 Investigation of Pyrene Excimer formation in various manufacturing processes and ionic structures , HYUN-SOOK JANG[1], MU-PING NIEH[2], University of Connecticut — Electrospun pyrene (Py)/polystyrene/tetrabutylammonium hexafluorophosphate (TBAPF6) thin films can provide high-sensitivity and high-selectivity detection of nitro-aromatic explosives through fluorescence quenching of the Py excimers [1]. However, we have found that the formation of Py excimers in Py/PS/TBAPF6 thin films depends greatly on the manufacturing processes. Our results indicate that high solvent vapor pressure promotes the Py excimer fluorescence, while high temperature (around or greater than Tg of the PS) has an opposite effect in absence of solvent – reducing the Py excimer fluorescence. Moreover, we have found that salts structure such as cation chain length, anion strength can significantly affect the formation of Py excimer both in solution and solid state, presumably due to self-aggregation of the salts and electrostatic interactions between ions and pyrene excimer. 13C-NMR and steady-state fluorescence result indicate that the salt induces peak shift to the downfield in the spectra and quenches the Py excimer intensity drastically.

3:18PM J33.00003 Photoisomerization dynamics of azobenzene materials for solar thermal fuels , DAVID A. STRUBBE, JEFFREY C. GROSSMAN, Department of Materials Science and Engineering, Massachusetts Institute of Technology — A solar thermal fuel absorbs sunlight and stores the energy chemically via an induced structural change, which can later be reversed to release the energy as heat. Azobenzene molecules have a cis-trans photoisomerization with these properties, and hydrogen-bonding and packing via attachment to rigid template structures have shown promise in increasing the energy stored and the length of time it can be stored [A Kolpak et al, Nano Lett. 11, 3156-3162 (2011)]. Other important factors in determining the efficiency of a solar thermal fuel are the absorption cross-section and the quantum yield for photoisomerization, which must also be optimized for a successful material. We employ time-dependent density-functional theory (TDDFT) and the GW/Bethe-Salpeter formalism to calculate the optical absorption and dynamics in the excited-state to address these two factors. We use excited-state forces to map out potential-energy surfaces and follow the structural change after absorption for azobenzene-derived materials, to correlate the efficiency of photoisomerization with the functionalization and template.

3:30PM J33.00004 Optical absorption in fluorenone-based push-pull molecules , EDUARDO CRUZ-SILVA, PAUL J. HOMNICK, PAUL M. LAHTI, University of Massachusetts Amherst, VINCENT MEUNIER, Rensselaer Polytechnic Institute — Push-pull organic molecules include both electron donor and acceptor substituents, which upon excitation induce a charge separation with potential uses in conductive polymers and light-harvesting materials for use in solar cells. In a recent work, a new set of such molecules using fluorenone as the electron-acceptor unit have been reported [1]. Here we present a comprehensive study of their electronic structure and and optical properties using time-dependent density functional theory (TDDFT) as implemented in the NWChem software suite [2]. The remarkable agreement between experimental and computed spectra among all test systems show that TDDFT can be readily used as a predictive tool for assessing and optimizing the optical properties on these systems. 1. 3:42PM J33.00005 Exciton-Plasmon Interaction Effects in Individual Carbon Nanotubes[1] , IGOR BONDAREV, AREG MELIKSETYAN, North Carolina Central University — We have recently developed a theory for the electrostatically controlled coupling between excitons and low-energy inter-band plasmons in individual semiconducting carbon nanotubes [1]. Here, we report on our studies towards the applications of this effect of both applied and fundamental interest. One practical application is the electromagnetic absorption/photoluminescence control for individual nanotubes [2]. Another, fundamental one, comes from the fact that the coupling of the excitons to the same inter-band plasmon resonance results in their entanglement, a pre-requisite for strong quantum correlations/quantum phase transitions in many-particle systems [3]. Our coupled exciton-plasmon excitation is a quasi-1D Bose system and could possibly be Bose-condensed in an individual carbon nanotube under appropriately created external conditions — despite the mathematical statements [4] of the BEC impossibility in ideal 1D and 2D quantum systems and previously reported evidence [5] for no free-exciton BEC in carbon nanotubes.

3:54PM J33.00006 Quantitative analysis of valence photoemission spectra and quasiparticle excitations at chromophore-semiconductor interfaces[1] , CHRISTOPHER PATRICK, FELICIANO GIUSTINO, Department of Materials, University of Oxford, UK — Understanding electron energetics at interfaces between solids and molecules is a key challenge in many areas of nanotechnology research. Here we develop a quantitative theory of quasiparticle excitations at these interfaces and apply it to the prototypical dye-sensitized solar cell interface of N3 dye molecules adsorbed on the anatase TiO_2 (101) surface.[2] Our approach combines density-functional calculations on large interface models, bulk GW calculations,[3] image charge renormalization, thermal broadening and configurational disorder to obtain a quasiparticle spectrum in good agreement with experimental photoemission data. Our calculations clarify the atomistic origin of the chromophore peak at low binding energy, and illustrate the dual role played by the TiO_2 substrate in screening the quasiparticle states of the N3 molecule through both long-range image-charge effects and direct charge transfer via the covalently-bonded anchor groups.

4:06PM J33.00007 Two-dimensional Fourier transform spectroscopy of primary excitations, in conjugated polymers , KENAN GUNDOGDU, CONG MAI, ANDREW BARRETTE, ROBERT YOUNTS, TERRY MCAFEE, HARALD ADE, NC State University — Conjugated polymers have tremendous potential for use in cheap, flexible, lightweight, energy efficient opto-electronic applications, Despite years of work, critical fundamental aspects about their optical and electronic properties are still poorly understood. Photo absorption in pure semi-conducting polymer thin films eventually results in both free charges and bound excitons with varying branching ratios. However the identification of the nature of early excitations and charge generation is an unresolved problem. There has been no direct observation of initial excitons or free electron-hole pairs, and competing views persist. Here we use 2D Fourier transform spectroscopy methods to separate the spectral signatures of various processes in the photoabsorption process in a homopolymer and show that initial excitation results in an intrachain electronic coherence that persists more than 200 fs. As these coherences evolve they collapse to transient population states i.e excitons, polarons and bipolarons.

4:18PM J33.00008 Revealing photoinduced charge transfer mechanism across π-conjugated heterojunctions , YONGWOO SHIN, XI LIN, Boston University — The adapted Su-Schrieffer-Heeger (aSSH) model is extended to the π-conjugated bulk heterojunction system. The New aSSH Hamiltonian incorporated interchain π-π stacking and dynamic electron-phonon coupling effects. Excellent agreements are found between the computed photoadsorption and photoinduced adsorption spectra and their corresponding experimental measurements. It is found that excitons generated in the bulk poly-(p-phenylene vinylene) (PPV) phase must overcome an energy barrier of 0.23 eV to reach heterojunction interface. These interfacial excitons show clear charge separations, with their electron states leaning towards the interface. Therefore, electron transfers from the D_1^* state of PPV to the t_{1u}^* state of C_{60} follow non-adiabatic mechanisms, which are accelerated by the 0.97 eV energy drop, close vicinity of the D_1^* state to the C_{60} phase, and suppressed inversion symmetry that doubles the number of electron-accepting states. After non-adiabatic electron transfers, the hole D_1 states are screened by the optical phonons in PPV, forming self-localized hole polarons and moving further away from heterojunction interface.

4:30PM J33.00009 Charge transfer excitations in water-soluble sulfonated zinc-phthalocyanine (ZnPcS) donor molecules coupled to C_{60} , RAJENDRA ZOPE, LUIS BASURTO, MARCO OLGUIN, TUNNA BARUAH, University of Texas at El Paso — We present a study of charge transfer (CT) excited states for a recently synthesized group of water-soluble sulfonated zinc-phthalocyanine (ZnPcS) donor molecules coupled to C_{60}. The ZnPcS donors (ZnPcS2, ZnPcS3, and ZnPcS4) are promising materials for achieving solar cell device production with the photoactive area prepared from aqueous solution. Experimentally, decreasing the number of sulfonate substituent groups for ZnPc increased the photocurrent and lowered the open circuit voltage V_{OC}. Measurements show that the V_{OC} is largest for ZnPc-S4/C_{60} and lowest for ZnPc-S3/C_{60}. The degree of sulfonation and the measured device V_{OC} does not result in the expected pattern of values based on donor-acceptor HOMO/LUMO energy differences. Variations in film morphology may account for the unexpected pattern of V_{OC} values. Our charge transfer excited state calculations show that the lowest CT excitation energy among the group of ZnPcS/C60 donor-acceptor pairs corresponds to the disulfonated ZnPc/C60 system. The largest CT excited state energies belong to the tetrasulfonated ZnPc/C60 complex. We also examine the effect of geometrical orientation on the CT energies for the ZnPcS donor-acceptor pairs.

4:42PM J33.00010 Packing effects in charge transfer dynamics in organic molecular heterojunctions consisting of TFB and F8BT , MIKIYA FUJII, KOICHI YAMASHITA, Department of Chemical System Engineering, University of Tokyo and JST, CREST — Organic semiconductors have been widely investigated for photovoltaic and light emitting devices. Especially, further improvements for more efficient organic solar cells (OSCs) are desired. Thus, we explored computationally possibilities to make OSCs more efficient by adjusting the packing of molecular heterojunctions. We analyzed a molecular heterojunction that consists of poly(9,9-dioctylfluorene-co-N-(4-butylphenyl)diphenylenediamine) (TFB) and poly(9,9-dioctylfluorene-co-benzothiadiazole) (F8BT). Geometrical optimization of TFB(monomer)/F8BT(monomer) complex was carried out with DFT-D/B3LYP/6-31G*. Excited states were also calculated with CIS/6-31G*. To analyze packing effects, we rotated TFB around a principal axis. Then, charge transfer dynamics is analyzed with a quantum master equation (QME) approach in each packing From the excited states calculations, it is clarified that the packing strongly affects the energy level of the charge transfer state only. This packing dependency arises from a packing dependency of the exciton binding energy that is Coulomb interaction between an electron localized to F8BT and a hole localized to TFB. From the QME approach, it is confirmed that qualitative different electronic relaxation dynamics occurs in each different packing.

4:54PM J33.00011 Charge-Transfer Complexation Mechanism of Poly (4-Vinyl Pyridine)/[6,6] - Phenyl-C_{61}-Butyric Acid Methyl Ester in DMF Solution[1] , HE CHENG, GUANGMIN WEI, CHARLES HAN, Institute of Chemistry CAS — The mechanism of charge-transfer complexation in electron-donor(D)/electron-acceptor(A) active layer was studied for a pseudo-binary blend model system, poly(4-vinyl pyridine) /[6,6]-phenyl-C_{61}-butyric acid methyl ester in DMF. The time evolution of the system can be characterized by four distinct stages, i.e., induction, complexation, aggregation and precipitation, respectively. In the induction stage, the conformation of P4VP remained unchanged, while the UV-vis showed that the charge-transfer complexation had almost accomplished. In the complexation stage, each P4VP chains complexed with about 3 PCBM molecules at [4VP]/[PCBM]=57:1, and shrinked in size with almost no change in UV-vis spectrum. In the subsequent aggregation stage, P4VP/PCBM complexes aggregated with each other to form spherical aggregates with again unchanged UV-vis signals. FA model can be used to explain this mechanism. In the final precipitation stage, huge P4VP/PCBM agglomerate began to phase out. The almost unchanged UV-vis spectrum after the induction stage indicated that the electronic transition from ground to excited state is not necessarily to be influenced by any inter- or intra-polymer structural transition.

5:06PM J33.00012 Probing charge transfer complex states in organic solar cells using photocurrent spectroscopy , DHANASHREE MOGHE, DANISH ADIL, University of Missouri-Columbia, CATHERINE KANIMOZHI, GITESH DUTTA, SATISH PATIL, Indian Institute of Science, Bangalore, India, SUCHISMITA GUHA, University of Missouri-Columbia — Diketopyrrolopyrrole (DPP) containing copolymers-fullerene blends have gained a lot of interest in organic optoelectronics with a great potential in organic photovoltaics (OPVs). The interfacial charge transfer complex (CTC) states formed in donor-acceptor blended OPVs play a major role in the overall efficiency of the device. We investigate the spectral photocurrent characteristics of five DPP based copolymers; two of them being benzothiadiazole and carbazole -based statistical copolymers of DPP. These systems provide a wide range of bandgap energies ranging from $\sim$ 1.4 to 1.7 eV. We use Fourier transform photocurrent spectroscopy (FTPS) and monochromatic photocurrent (PC) to identify the CTC states in these DPP copolymer -fullerene blends. The stability of the CTC state is found to be dependent on the band gap energy difference between the donor copolymer and the acceptor. We support our inferences from theoretical results obtained using density-functional theory (DFT) and time-dependent DFT for two DPP based copolymers The theoretical calculations reveal a higher contribution of the CTC states to the lowest excited state in the phenyl-based DPP monomer, which has a larger bandgap energy compared to the thiophene-based DPP system, in the presence of a fullerene molecule.

Session J34 DPOLY DCMP DBIO: Focus Session: Charged Colloids with Short-Range Attractions II 342 - Frank Schreiber, Institut fuer Angewandte Physik, Universitaet Tuebingen

2:30PM J34.00001 DILLON MEDAL BREAK –

3:06PM J34.00002 Concentrated dispersions of therapeutic proteins , THOMAS TRUSKETT, The University of Texas at Austin — In this talk, recent experiments characterizing highly concentrated dispersions of therapeutic proteins, which are of interest for at-home treatment of disease via subcutaneous injection, are discussed. In particular, evidence for protein nanocluster formation in these systems is explored. The roles of dispersion composition, pH, and experimental pathway are elucidated for several protein systems. Observed correlations between nanocluster properties, solution viscosity, and protein stability/activity, as well as prospective theoretical explanations for these behaviors, are highlighted.

3:42PM J34.00003 Transition from monomeric phase to dynamic cluster phase in lysozyme protein solutions , YUN LIU, University of Delaware/National Institute of Standards and Technology, PETER FALUS, LIONEL PORCAR, Institut Laue-Langevin, EMILIANO FRATINI, University of Florence, WEI-REN CHEN, Oak Ridge National Laboratory, ANTONIO FARAONE, University of Maryland/National Institute of Standards and Technology, KUNLUN HONG, Oak Ridge National Laboratory, PIERO BAGLIONI, University of Florence — Intermediate range order (IRO) has been recently observed in lysozyme solution that is caused by a combination of a short-range attraction and long-range repulsion. At very high concentration, there is observed cluster formation in lysozyme solutions that is one type of IRO structures. Here, we investigate the temperature effect on the dynamic cluster formation and identify the transition concentration from a monomeric protein phase to a cluster phase. The normalized short-time self-diffusion coefficient is not affected by changing attraction strength at the concentration of about 10% mass fraction, indicating that the system is still dominated by monomeric protein phase. However, at high concentrations, the average self-diffusion coefficient is sensitive to the change of short-range attraction strength, which is interpreted due to the growth of the size of dynamic clusters in solution. The transition concentration from dominating monomeric phase to dynamic cluster phase is estimated to be around 14 % mass fraction.

3:54PM J34.00004 Langevin Dynamics Simulation of DNA Condensation Induced by Nanoparticles in Confinement , GUO-JUN LIAO, Department of Physics, National Taiwan University, Taipei, 10087, Taiwan, R.O.C, YENG-LONG CHEN, Institute of Physics, Academia Sinica, Taipei, 11529, Taiwan, R.O.C. — We study nanoparticle-induced DNA condensation in a confined suspension of dilute DNA molecules and ideal nanoparticles (NPs) with Langevin dynamics simulation. DNA condensation has been observed in a solution of dilute DNA molecules (persistence length $P \approx 50$ nm) and high concentration of electrostatically neutral NPs (diameter $d \approx 5$ to 35 nm) in recent experimental measurements. It is believed that NPs entropically induce an attraction between DNA segments. For NPs much smaller than P, a DNA molecule can be considered as a chain of connected rods, and the NP-induced depletion attraction between DNA segments can be regarded as rod-rod attraction. Thus, the strength of the depletion attraction is proportional to the number of persistence length in a DNA chain, $N = L/P$, the depletion volume NP^2d, and the NP density ρ, where L is the DNA contour length. In slit confinement, DNA conformation changes are much different from in an unconfined environment. The height of the slit relative to the NPs size (H/d) strongly influences the DNA conformation. For $H/d \approx 1$, DNA size decreases monotonically as ρ increases, while non-monotonic dependence happens for $H/d \approx 5$, due to the competition between DNA-DNA, DNA-NP, and NP-wall interactions.

4:06PM J34.00005 Small-Angle Neutron Scattering and Neutron Spin Echo Characterization of Monoclonal Antibody Self-Associations at High Concentrations , ERIC YEARLEY, MacroGenics, Inc., ISIDRO (DAN) ZARRAGA, Genentech, Inc., PAUL (DOUG) GODFRIN, University of Delaware, TATIANA PEREVOZCHIKOVA, National Institute of Standards and Technology, NORMAN WAGNER, University of Delaware, YUN LIU, University of Delaware/National Institute of Standards and Technology — Concentrated therapeutic protein formulations offer numerous delivery and stability challenges. In particular, it has been found that several therapeutic proteins exhibit a large increase in viscosity as a function of concentration that may be dependent on the protein-protein interactions. Small-Angle Neutron Scattering (SANS) and Neutron Spin Echo (NSE) investigations have been performed to probe the protein-protein interactions and diffusive properties of highly concentrated MAbs. The SANS data demonstrate that the inter-particle interactions for a highly viscous MAb at high concentrations (MAb1) are highly attractive, anisotropic and change significantly with concentration while the viscosity and interactions do not differ considerably for MAb2. The NSE results furthermore indicate that MAb1 and MAb2 have strong concentration dependencies of dynamics at high Q that are correlated to the translational motion of the proteins. Finally, it has also been revealed that the individual MAb1 proteins form small clusters at high concentrations in contrast to the MAb2 proteins, which are well-dispersed. It is proposed that the formation of these clusters is the primary cause of the dramatic increase in viscosity of MAb1 in crowded or concentrated environments.

4:18PM J34.00006 The Structural Properties and Stability of Monoclonal Antibodies at Freezing Conditions , TATIANA PEREVOZCHIKOVA, University of Delaware/NIST, ISIDRO ZARRAGA, THOMAS SCHERER, Genentech, Inc, NORMAN WAGNER, University of Delaware, YUN LIU, University of Delaware/NIST — Monoclonal Antibodies (MAb) have become a crucial therapeutic agent in a number of anti-cancer treatments. Due to the inherent unstable nature of proteins in an aqueous formulation, a freeze-drying method has been developed to maintain long-term stability of biotherapeutics. The microstructural changes in Mabs during freezing, however, remain not fully described, and it was proposed that the formed morphology of freeze drying samples could affect the final product quality after reconstitution. Furthermore, it is well known that proteins tend to aggregate during the freezing process if a careful processing procedure is not formulated. Small Angle Neutron Scattering (SANS) is a powerful tool to investigate the structural properties and interactions of Mabs during various stages of lyophilization in situ. Here we present the SANS results of freeze-thaw studies on two MAbs at several different freezing temperatures. While the chosen proteins share a significant sequence homology, their freezing properties are found to be strikingly distinctive. We also show the effect of excipients, concentration and quenching speed on the final morphology of the frozen samples. These findings provide critical information for more effective lyophilization schemes for therapeutic proteins, as well as increase our understanding on structural properties of proteins under cryogenic conditions.

4:30PM J34.00007 Shear-Dependent Interactions in Rheology Modifier (RM)-Latex Suspensions , TIRTHA CHATTERJEE, ALAN I. NAKATANI, Analytical Sciences, The Dow Chemical Company, ANTONY K. VANDYK, Dow Coatings Materials, The Dow Chemical Company — Paint viscosity, under shear is governed by its shear-induced structure which in turn controls the application properties. The micro and macroscopic structure of the RM-latex combinations under shear is central to understand paint application behavior. Using in-situ shear-small-angle neutron scattering (shear-SANS) the RM-latex structure has been studied. All studies reported here are performed on acrylic-based latex with different hydrophobically modified ethoxylated urethane (HEUR) RM varying in their hydrophobe density/chain. At a quiescent condition, latex and RM form a spherical core-shell structure, with latex particles being the core and adsorbed RMs on the surface forming the shell. The shell thickness decreases with increasing RM hydrophobe density/chain. Under shear, the solvent (D2O/H2O) is squeezed out (hydrodynamic squeezing) from the swollen RM chains and the shell structure becomes denser and *anisotropic* due to differing degrees of compression along the flow and vorticity directions. An effective shear-dependent latex-RM hydrodynamic volume fraction has been calculated using SANS structural data. High shear viscosity calculated on the basis of effective hydrodynamic volume using existing models do not match with the experimental data. This suggests the existence of RM molecule mediated interactions even at high shear rate.

4:42PM J34.00008 Multi-body effects in Charged Colloids - Polyelectrolyte systems , VICTOR PRYAMITSYN, VENKAT GANESAN, University of Texas at Austin — Multibody effects upon the electrostatic interaction between particles, polyelectrolyte molecules and monovalent ions were analyzed within Poisson-Boltzmann approximation. The numerical self-consistent field (SCF) theory for a polymer - nanoparticles systems was developed for a mixture of quenched polyelectrolytes and charged and uncharged particles and the pseudo-spectral method was used to solve polymer SCF equations in three dimensions within the Grand Canonical Ensemble for polymer and ions. A calculation of the free energies of a single particle and of two particles in polyelectrolyte solutions allowed us to calculate respectively the particle insertion free energy and particle-particle interactions as a function of the properties of solution, polymer-particle interaction and particle size. By explicitly calculating the free energy of three particles after subtraction of the contributions from two-body interaction allowed us to calculate effective contribution of 3-body particle-particle interactions in polyelectrolyte -particles systems. We have found that the polyelectrolyte mediated two body interactions are repulsive for the larger particle-particle distances and lower polymer concentrations. Interestingly, such an electrostatic repulsion exists even if particles have

4:54PM J34.00009 A density functional approach to model highly charged spherical colloids in electrolyte mixtures , BHARAT MEDASANI, ZAVEN OVANESYAN, MARCELO MARUCHO, University of Texas at San Antonio — We present a classical density functional (DFT) approach to study the effects of ion size asymmetry, ion-ion correlation and solvent excluded volume on the structural and thermodynamic properties of strongly interacting charged systems. The hard sphere correlation effects are modeled non-perturbatively with weighted density approximation, where as electrostatic correlations are modeled perturbatively within the mean spherical approximation. The present DFT approach is able to describe macro-ions in electrolytes comprising neutral hard sphere mimicking water molecules and ions with dissimilar valence and realistic sizes and densities. We applied the theory to study spherical electric double layers and obtained results in good agreement with simulations. We calculated ion profiles, integrated charge, mean electrostatic potential, ionic coordination number, zeta potential, and inverse differential capacity at different conditions. For higher surface charge on macromolecule, charge inversion is noticed and when the counter-ions are bigger than co-ions, surface charge amplification is observed. Layering and screening effects are more pronounced when water molecules are explicitly considered. This work has potential applications in bio-electrostatics and colloidal engineering.

5:06PM J34.00010 Measuring inter-nucleosome interactions and the roles of histone tails , STEVEN HOWELL, George Washington University, KURT ANDRESEN, Gettysburg College, ISABEL JIMENEZ-USECHE, CHONGLI YUAN, Purdue University, XIANGYUN QIU, George Washington University — Nucleosome is the first level of genome organization and regulation in eukaryotes, where negatively charged DNA is wrapped around positively charged histone proteins. Being a DNA-protein complex of biological origin, nucleosome is also a model multi-phasic nanoparticle with heterogeneous charge distributions and brush-like flexible tails of the histone proteins. In solutions of nucleosomes, electrostatic forces dominate inter-nucleosome interactions at long range while specific contacts, in particular the flexible histone tails, guides short range interactions. We have thus quantified how the ions from salts (KCl, MgCl2) modulate the inter-nucleosome pair potential by modeling the total small angle x-ray scattering profiles. We additionally elucidated the individual role of the charged tails of histones H3 and H4. We found that measured effective changes at low salt concentrations are about 1/5th of theoretically predicted renormalized charges and that H4 tail deletion suppresses the attraction at high salt concentrations to a larger extent than H3 tail deletion.

5:18PM J34.00011 Multivalent Colloids through DNA Patchy Particles[1] , YUFENG WANG, YU WANG, Molecular Design Institute and Department of Chemistry, New York University, DANA BREED, The Dow Chemical Company, VINOTHAN MANOHARAN, School of Engineering and Applied Sciences; Department of Physics, Harvard University, LANG FENG, ANDREW HOLLINGSWORTH, Center for Soft Matter Research and Department of Physics, New York University, MARCUS WECK, Molecular Design Institute and Department of Chemistry, New York University, DAVID PINE, Center for Soft Matter Research and Department of Physics, New York University — We demonstrate a general method for creating the colloidal analogs of atoms with multiple valences: colloidal particles with chemically functionalized patches that can form highly directional specific bonds. The valences of these "colloidal atoms" possess all the common symmetries characteristic of hybridized atomic orbitals, including sp, sp^2, sp^3, sp^3d, sp^3d^2, and sp^3d^3. The chemical functionality of the patches is programmable and specific using DNA with single-stranded sticky ends, thereby creating colloidal atoms from which different kinds of "colloidal molecules" can be assembled, including the colloidal analogs of carbon dioxide and tetrahedrally coordinated methane. The bonds between these new colloidal atoms are highly directional and fully reversible with temperature.

Tuesday, March 19, 2013 2:30PM - 5:30PM –

Session J35 DCMP: Superconductivity: Vortices II 343 -

2:30PM J35.00001 Doubling of the Critical Current Density of 2G-YBCO Coated Conductors through proton irradiation , ULRICH WELP, YING JIA, WAI-KWONG KWOK, Materials Science Division, Argonne National Laboratory, MARTY RUPICH, STEVEN FLESHLER, American Superconductor Coorporation, Devons, MA, ASFGHAR KAYANI, Western Michigan University, Kalamazoo, MI — We report on magnetization and transport measurements of the critical current density of commercial 2G YBCO coated conductors before and after proton irradiation. The samples were irradiated along the c-axis with 4 MeV protons to a fluence of 1.5×10^{16} p/cm^2. We find that at temperatures below 50 K, proton irradiation increases J_c by a factor of 2 in low fields and increases up to 2.5 in fields of 7 T. At 77 K, proton irradiation is less effective in enhancing the critical current. Doubling of J_c in fields of several Tesla and at temperatures below 50 K will be highly beneficial for applications of coated conductors in rotating machinery, generators and magnet coils. - Work supported by the US DoE-BES funded Energy Frontier Research Center (YJ), and by Department of Energy, Office of Science, Office of Basic Energy Sciences (UW, WKK), under Contract No. DE-AC02-06CH11357.

2:42PM J35.00002 Vortex dynamics in Co-doped and K-doped $BaFe_2As_2$ with point defects , TOSHIHIRO TAEN, TAKAHIRO OHORI, FUMIAKI OHTAKE, YASUYUKI NAKAJIMA, TSUYOSHI TAMEGAI, Department of Applied Physics, The University of Tokyo, KUNIHIRO KIHOU, SHIGEYUKI ISHIDA, HIROSHI EISAKI, National Institute of Advanced Industrial Science and Technology (AIST), HISASHI KITAMURA, Radiation Measurement Research Section, National Institute of Radiological Sciences — The discovery of iron-based superconductors urges scientists and engineers to study not only superconducting mechanism but also possible applications. In view of this situation, it is important to study vortex dynamics for understanding fundamental properties as well as for suggesting a suitable fabrication process in this system. In particular, the interaction between vortices and defects attract tremendous attention, which is because this interaction is responsible for finite critical current density J_c. The interaction changes with dimensionality and morphology of defects. In cuprate superconductors, vortex manifold shows vortex glass phase with point defects and Bose glass phase with columnar defects. Besides, in both cases, J_c shows pronounced enhancement compared with that in a pristine sample. We have already reported the enhancement of J_c by the introduction of point or columnar defects in the case of $Ba(Fe_{1-x}Co_x)_2As_2$ crystal. In this talk, we show the results in proton-irradiated $BaFe_2As_2$ with electron- or hole-doping. The quantitative analysis reveals the doubling of pinning potential without changing the glassy exponent in Co-doped compounds, in addition to 2.5 times enhancement of J_c. Similar effects are observed in K-doped crystals.

2:54PM J35.00003 Fundamentals of free flux flow: proposed studies[1] , J.A. ALEXANDER, O. GAFAROV, A.A. GAPUD, University of South Alabama, J.Z. WU, University of Kansas — Although much is known about free flux flow (FFF) in superconductors – in which pinning is insignificant compared to interactions between quantized vortices – there still remain questions concerning fundamental dynamics. Building on our previous work in correlating FFF with vortex core size (*PRB* **80**, 134524), we propose three new studies examining more deeply the normal state in the vortex core and interactions between vortices. A correlation between scattering inside cores and the viscosity of FFF has not been explicitly determined; this may be investigated by probing the effect of scattering centers created by proton irradiation. Using results of previous irradiation work, one could control the extent of normal state scattering while monitoring effects on FFF. Questions also exist concerning vortex motion in channels with widths approaching that of individual vortices – as determined solely by inter-vortex interactions. Studies have suggested that flux flow through constrictions could imitate "jamming" in the collective motion of *grains*: Under certain conditions, it is possible for grains to form a barrier, blocking flow. More than just qualitatively comparing flux flow and granular flow to find evidence of jamming, we propose a new experiment for quantitatively modeling flux jamming by realizing the flux flow equivalent of granular jamming in a "hopper". In the same way, we also propose a FFF equivalent of another granular-flow phenomenon, "non-Newtonian" fluids, where rapid shear causes jamming.

3:06PM J35.00004 Vortex core size due to the quasiparticle interference effect in cuprate superconductors[1] , HONG-YI CHEN, National Taiwan Normal University — We investigate the vortex core properties by solving the Bogoliubov de-Gennes equations for the t-t'-U-V Hamiltonian. The double peaks structure of the local density of states at the vortex core center characterizes the vortex core state. The local density of states maps have been numerically obtained near the slightly underdoping for the energy at the vortex core state. It is found that the field induced spin-density wave would cause the vortex core shrinking as the magnetic increases. We also found that the quasiparticle interference effect would affect the vortex core shrinking that the core size is independent the strength of the applied magnetic field.

[1]NSC 101-2112-M-003-005-MY3

3:18PM J35.00005 Field-induced Dirac fermions and Fermi-surface resonance-scattering in the vortex-lattice cores of strongly type-II superconductors , TSOFAR MANIV, VLADIMIR ZHURAVLEV, Technion-Israel Institute of Technology, Haifa 32000, Israel — A remarkable relationship between the formation of Dirac fermions in the vortex lattice of a clean 2D strongly type-II superconductor at high magnetic fields and a peculiar magneto-quantum oscillations effect is revealed. It is shown that at the magnetic fields where the low-lying BdG quasi-particle dispersion has a Dirac cone structure, dHvA oscillations amplitude is sharply modified due to Fermi-surface resonance-scatterings occurring in core regions of the vortex lattice. A Dirac cone is created at each vortex core in the reciprocal vortex lattice at magnetic fields where the effective Zeeman spin-splitting vanishes and the chemical potential is in the middle of a Landau band (M.R.Norman and A.H.MacDonald, Phys.Rev. B54 4239 (1996); Z.Tesanovic and P.Sacramento, Phys.Rev.Lett.80 1521 (1998); T.Maniv, et al., Rev.Mod.Phys.73 867 (2001)). Under these resonance conditions coherent BdG quasi-particle scatterings are singularly enhanced leading to "erratic," quasi-periodic modulation of the dHvA oscillation amplitude as a function of 1/B (V.Zhuravlev and T.Maniv, Phys.Rev. B85 104528 (2012)). For a spin-triplet superconductor in the presence of commensurate arrays of pinning centers, an "exotic" possibility of field-induced sub-lattices of bound Majorana fermions is discussed.

3:30PM J35.00006 Theory of de Haas van Alphen Oscillations in Superconductors with Preformed Pair , YAN HE, PETER SCHERPELZ, KATHRYN LEVIN, University of Chicago — We address recent observations of quantum oscillatory behavior in high temperature superconductors within a preformed pair theory of the pseudogap phase. These non condensed pairs, present in the normal and superconducting phases are shown to be reflective of a slightly distorted vortex lattice phase [1]. Importantly they contribute a separate additive ("bosonic") component to the field dependent thermodynamics in addition to that arising from fermions. In this talk we report our findings that the bosonic component appears to display the same Lifshitz-Kosevich oscillation frequencies as also found in the mixed state of conventional superconductors (associated with gapless fermionic states). We explore the different amplitude weighting factors for the bosonic and fermionic contributions and the effects of varying the pairing symmetry from s to d-wave. For the latter and for many properties, the bosonic component is most strongly associated with the anti-node, while the fermionic contribution comes from the node. Ref.1. Pseudogap Effects in Fermi Gases in the Presence of a Strong Effective Magnetic Field, P. Scherpelz, Dan Wulin, K. Levin and A. K. Rajagopal, ArXiv 1207.4826

3:42PM J35.00007 Quantum oscillations in d-wave superconductors with loop current order , LUYANG WANG, OSKAR VAFEK, National High Magnetic Field Laboratory and Department of Physics, Florida State University — Coexistence of d-wave superconductivity and Fermi pockets in underdoped high temperature cuprate superconductors has been suggested by recent quantum oscillation experiments. The origin of Fermi pockets in the superconducting state has been under debate. Here we report numerical results of quantum oscillations of the specific heat in the vortex state of a d-wave superconductor in the presence of loop current order, which gives rise to Fermi pockets coexisting with nodal d-wave superconductivity. First, we calculate the specific heat within a lattice tight-binding model, varying the loop current order and the external magnetic field. Second, we investigate the same problem in the continuum linearized limit, performing Franz-Tesanovic transformation, and find that the Bogoliubov Dirac quasiparticles also couple to a vector-like potential which corresponds to a highly nonuniform magnetic field. The results thus found are consistent with the tight-binding calculation. While the energy spectrum is qualitatively different from Landau levels, we find oscillations of the specific heat that in an intermediate temperature range approximately follow Onsager relation.

3:54PM J35.00008 Oscillations of the Magnetoresistance and the Critical Current in MoGe Thin Films with Hole-arrays in Square Vortex-ice Geometry[1] , MICHAEL LATIMER, *,***, GOLIBJON BERDIYOROV, ****, RALU DIVAN, IL WOONG JUNG, **, ZHILI XIAO, *,***, FRANCOIS PEETERS, ****, WAI-KWONG KWOK, * Matr. Sci. Div. Argonne National Lab.*, Center for Nanoscale Matr. Argonne National Lab.**, Northern Illinois Univ.***, Universiteit Antwerpen**** — Resistivity measurements on MoGe thin films containing hole-arrays in square vortex-ice configuration were carried out to study the formation of a frustrated vortex state. MoGe thin films of 20 nm thick were prepared by sputter-deposition and holes with spacings of 200 nm - 400 nm and diameters from 100 nm to 300 nm were introduced into them using focused-ion-beam milling. We observed unusual matching effects: depending on the hole-hole spacing and the experimental temperature, the pinning enhancement at the half matching field can be stronger than that at the first matching field, as divulged by the deeper dip in the magnetoresistance and the higher peak in the critical current. Computer simulations within the nonlinear time-dependant Ginzburg-Landau theory reveal an origin of vortex jamming in the square vortex-ice state, indicating the first experimental realization of a square vortex-ice.

4:06PM J35.00009 Thermal Hall effect in the underdoped cuprate superconductor $YBa_2Cu_3O_{6.5}$[1] , PHUAN ONG, MAX HIRSCHBERGER, TIAN LIANG, Princeton University, TOSHINAO LOEW, Max Planck Institute Stuttgart, WEI LI LEE, Princeton University, R. RITZ, Technische Universitaet Muenchen, BERNHARD KEIMER, Max Planck Institute Stuttgart — The thermal Hall conductivity κ_{xy} (Righi-Leduc effect) is tailor-made to probe the transport properties of Bogolyubov quasiparticles (QPs) in a superconductor because neither the phonons nor vortices contribute to the off-diagonal response. We report measurements of κ_{xy} in untwinned crystals of underdoped $YBa_2Cu_3O_{6.5}$, extending from 100 K to 15 K in fields H up to 14 T. Several key features will be described. At all temperatures T, the QPs are hole-like. However, there is a small negative contribution that appears just below T_c. Below 30 K, the curve of κ_{xy}/T vs. H approaches an apparent universal step-like profile that may reflect the behavior of long-lived Dirac excitations confined to orbits around the gap nodes in an intense magnetic field. Measurements to much lower T and higher H ($\sim$ 32 T) are planned.

4:18PM J35.00010 Zero field Hall effect in chiral p-wave superconductors near the Kosterlitz-Thouless transition , CHUN KIT CHUNG, Department of Physics, the University of Tokyo, YUSUKE KATO, Department of Basic Science, the University of Tokyo — A theory of vortex dynamics developed by Ambegaokar, Halperin, Nelson, and Siggia is employed to study two-dimensional chiral p-wave superconducting systems. Due to unequal values of drag coefficients of opposite vorticity specific to chiral p-wave cases, we find that a "convective" term, in addition to diffusivity, should enter the dynamical equations governing vortex pair unbinding process. As a consequence, we find a matrix form dielectric function and a new contribution to Hall conductance σ_{xy} automatically follows even in zero magnetic field. We predict both the Hall conductance and power dissipation show a peak across the Kosterlitz-Thouless transition temperature. Their frequency dependence is also discussed. It is found that a set of frequency-dependent length scales, which controls the truncation of renormalization process, depends on both the convective and diffusive motion of vortices.

4:30PM J35.00011 Domain Wall and Reverse Domain Superconductivity in Superconducting/Ferromagnet Hybrid Structures[1] , S. MOORE, J. FEDOR, Physics Department, Temple University, Philadelphia, PA 19122, V. NOVOSAD, Materials Science Division, Argonne National Laboratory, Argonne, IL 60439, S. CIOCYS, G. KARAPETROV, Physics Department, Drexel University, Philadelphia, PA 19104, M. IAVARONE, Physics Department, Temple University, Philadelphia, PA 19122 — We have investigated the effect of inhomogeneous stray fields of a ferromagnet on the nucleation of the superconducting order parameter in superconductor/ferromagnet (S/F) systems magnetically coupled. Low-temperature scanning tunneling microscopy and spectroscopy measurements were performed on a Pb/[Co/Pd] system, which has a nontrivial H-T phase diagram under externally applied magnetic fields. Conductance maps and tunneling spectroscopy of these systems show clear indications of domain wall and reverse domain superconductivity. Close to the transition temperature (T_c) and in zero applied field, we visualized the emergence of superconductivity in regions above the separation between adjacent magnetic domains on length scales of the order of the coherence length. We also find an increase in T_c for certain values of applied field above magnetic domains of the opposite polarity.

[1]This work was supported by US DOE Grant No. SC0004556 and UChicago Argonne, LLC, Operator of Argonne National Laboratory. Argonne, a U.S. Department of Energy Office of Science Laboratory, is operated under Contract No. DE-AC02-06CH11357.

4:42PM J35.00012 Vortex confinement by magnetic domains in superconductor-ferromagnet bilayers[1] , MARTA Z. CIEPLAK, Z. ADAMUS, Institute of Physics, Polish Acad. Sciences, Warsaw, Poland, M. KONCZYKOWSKI, Ecole Polytechnique, Palaiseau, France, L.Y. ZHU, C.L. CHIEN, Johns Hopkins University, X.M. CHENG, Bryn Mawr College — We use a line of miniature Hall sensors to study the effect of magnetic-domain-induced vortex confinement on the flux dynamics in a superconductor/ferromagnet bilayer. A single tunable bilayer is built of a ferromagnetic Co/Pt multilayer with perpendicular magnetic anisotropy and a superconducting Nb layer, with the insulating layer in between to avoid proximity effect. The magnetic domain patterns of various geometries are reversibly predefined in the Co/Pt multilayer using the appropriate magnetization procedure. The magnetic domain geometry strongly affects vortex dynamics, leading to geometry-dependent trapping of vortices at the sample edge, nonuniform flux penetration, and strongly nonuniform critical current density. With the decreasing temperature the magnetic pinning increases but this increase is substantially weaker than that of the intrinsic pinning. The analysis of the initial flux penetration suggests that vortices may form various vortex structures, including disordered Abrikosov lattice or single and double vortex chains, in which minimal vortex-vortex distance is comparable to the magnetic penetration depth.

4:54PM J35.00013 Magnetic decoration imaging of a superconductor-ferromagnet bilayer , MAXIM MARCHEVSKY, Lawrence Berkeley National Laboratory — Magnetic decoration imaging technique is used to study flux distribution and local vortex order in a superconducting Nb film deposited on a ferromagnetic yttrium-iron garnet substrate. Ambient field-cooled decoration patterns reveal concentration of vortices in the Nb along the labyrinthine magnetic domains of the garnet. Re-magnetization cycles result in a formation of the complex "vortex foam" structure due to a coupled magnetic dynamics of the superconductor-ferromagnet (S/F) bilayer system. We analyze density variations and spatial distribution of vortices in these structures. Flux exit patterns obtained upon removal of an external magnetic field show large-scale inhomogeneity of the vortex flow. Results are compared to the recent theoretical predictions and reported studies of S/F systems by other imaging methods.

5:06PM J35.00014 Vortex coalescence and type-1.5 superconductivity in Sr2RuO4[1] , EGOR BABAEV, University of Massachusetts Amherst and KTH Stockholm, JULIEN GARAUD, University of Massachusetts Amherst , DANIEL AGTERBERG, University of Wisconsin-Milwaukee — Recently vortex coalescence was reported in superconducting Sr2RuO4 by several experimental groups for fields applied along the c-axis. We argue that Sr2RuO4 is a type-1.5 superconductor with long-range attractive, short-range repulsive intervortex interaction. The type-1.5 behavior stems from an interplay of the two orbital degrees of freedom describing this chiral superconductor together with the multiband nature of the superconductivity. These multiple degrees of freedom give rise to multiple coherence lengths, some of which are larger and some smaller than the magnetic field penetration length, resulting in nonmonotonic intervortex forces. The talk is based on Phys. Rev. B 86, 060513(R) (2012)

Session J36 DCMP: Superconductivity: Properties and Phenomena 344 - Zhigang Wu, Colorado School of Mines

2:30PM J36.00001 Copper Substitution in Iron Telluride: A Phase Diagram , PATRICK VALDIVIA, THOMAS FORREST, UC Berkeley, COSTEL ROTUNDU, JINSHENG WEN, EDITH BOURRET-COURCHESNE, Lawrence Berkeley Lab, ROBERT BIRGENEAU, UC Berkeley, BIRGENEAU GROUP TEAM — Investigations of superconductivity in the FeCh family (Ch=S,Se,Te) have produced rich physics and notable materials challenges despite the ostensible simplicity of the system. We have studied the effects of copper substitution in iron-telluride. Our interests in this system are two-fold: to compare the properties of copper substitution in iron-telluride with those in the selenium-substituted compounds, and to study if there are additional controllable factors in this system such as the total excess metal content, and the distribution of iron and copper atoms over the two sites. Our initial investigations into this phase diagram involve both diffraction and transport measurements which may be used address these research goals.

2:42PM J36.00002 Kerr effect as evidence of gyrotropic order in the cuprates[1] , SRINIVAS RAGHU, PAVAN HOSUR, STEVEN KIVELSON, AHARON KAPITULNIK, Stanford University, JOSEPH ORENSTEIN, University of California, Berkeley — The Kerr effect can arise in a time-reversal invariant dissipative medium that is "gyrotropic", *i.e.* one that breaks spatial inversion and all mirror symmetries. Examples of such systems include electron analogs of cholesteric liquid crystals, and their descendants, such as systems with chiral charge ordering. We present arguments that the striking Kerr onset, *which is not invertible by application of a magnetic field*, in the pseudogap phase of a large number of cuprate high temperature superconductors is evidence of chiral charge ordering. We discuss additional experimental consequences of a phase transition to a gyrotropic system.

2:54PM J36.00003 Anomalous Hall effect in current-carrying states of matter: topology, commensuration effects, and application to Kerr measurements in the underdoped cuprates[1] , CATHERINE KALLIN, EDWARD TAYLOR, McMaster University — We calculate the anomalous Hall conductivity for states characterized by patterns of spontaneous currents. Using an exact Ward identity, we find that the DC Hall conductivity is topological provided the current pattern is commensurate and the Fermi surface is fully gapped. For incommensurate patterns, the DC Hall conductivity can be infinite, analogous to the infinite conductivity of a sliding charge density wave. We also discuss the optical Hall conductivity at high frequencies, in connection with Kerr rotation experiments performed on the underdoped cuprates.

3:06PM J36.00004 ABSTRACT HAS BEEN MOVED TO B29.00015 —

3:18PM J36.00005 Thermodynamic studies of $Cu_{0.10}TiSe_2$ via ac-calorimetry and Hall-probe magnetometry[1] , ZUZANA PRIBULOVA, JOZEF KACMARCIK, PETER SAMUELY, Institute of Experimental Physics, Slovak Academy of Sciences, Watsonova 47, 040 01 Kosice, Slovakia, ZUZANA MEDVECKA, VIKTORIA SOLTESZOVA, Faculty of Natural Sciences, University of P.J. Safarik, Park Angelinum 9, 040 01 Kosice, Slovakia, PETRA BARANCEKOVA HUSANIKOVA, VLADIMIR CAMBEL, Institute of Electrical Engineering, Slovak Academy of Sciences, Dubravska cesta 9, 84104 Bratislava, Slovakia, GORAN KARAPETROV, Department of Physics, Drexel University, 3141 Chestnut St., Philadelphia, PA 19104, USA — $TiSe_2$ is a compound with the charge density wave (CDW) transition at 200 K, the CDW state is gradually suppressed when intercalated by copper and for certain amount of Cu superconductivity occurs. We report the studies of the critical fields of an optimally doped sample with a superconducting transition at $T_c \sim 3.9$ K. Upper critical field H_{c2} has been derived from the specific heat measurements while the lower critical field H_{c1} has been extracted from local magnetization measurements using miniature Hall-probes. The temperature dependence of H_{c2} and H_{c1} and its anisotropy will be presented. Moreover, local magnetometry using array of 8 Hall-probes shows that vortices after penetration into the sample move towards the centre resulting into a dome-shape induction profile suggesting relatively low pinning.

3:30PM J36.00006 Study of Inhomogeneous Organic Superconductors , CHARLES C. AGOSTA, CHRISTOPHER CONROY, DANIEL ELLOWITZ, WILLIAM VON NOPPEN, Clark University — In many anisotropic superconductors, we have found evidence that they are inhomogeneous superconductors, such as those predicted by Fulde and Ferrell and Larkin and Ovchinnikov (FFLO), at the extremes of low temperature and high magnetic field. A FFLO superconductor has an order parameter with nonzero pair momentum that oscillates periodically as a function of distance, unlike traditional superconductors where the order parameter is uniform. During the last several years, our research group at Clark University has made careful and systematic measurements of quasi-2D organic superconductors that suggest an FFLO state can be stabilized in three different organic conductors if a magnetic field is applied precisely parallel to the conducting layers. We will compare our results with theoretical expressions that we have modified from the current literature, with the goal of extracting quantitative results from the phase diagram data such as the Maki parameter and scattering times. We will also describe improvements to our pulsed magnetic field - tunnel diode oscillator penetration depth apparatus.

3:42PM J36.00007 Superconductivity in the misfit compound of $(LaSe)_{1.14}(NbSe_2)$: STM/S, calorimetric and magnetization studies[1] , P. SAMUELY, P. SZABO, J. KACMARCIK, Z. PRIBULOVA, Slovak Academy of Sciences, T. SAMUELY, Safarik University, J.G. RODRIGO, Univesidad Autonoma de Madrid, C. MARCENAT, CEA/GrenobleINAC/SPSMS/LATEQS, T. KLEIN, Institut Neel, CNRS, L. CARIO, Institut des Matériaux Jean Rouxel — $(LaSe)_{1.14}(NbSe_2)$ is a low temperature superconductor with T_c around 1.2 K belonging to the family of the lamellar chalcogenides. Electron transfer from the LaSe to the $NbSe_2$ slab results in a natural layered system of the insulating LaSe and (super) conducting $NbSe_2$ sheets. In our previous investigations of the anisotropic transport [P. Szabó et al., Phys. Rev. Lett. 86, 5990 (2001)] indications have been found that this system behaves as a stack of Josephson-coupled superconducting $NbSe_2$ sheets separated by insulating LaSe layers. We test this hypothesis by STM/S measurements at subkelvin temperatures and in magnetic fields. Superconducting energy gap obtained by STM opens at the same temperature and field where the interlayer resistivity starts to increase before drop to zero value. Before any conclusions are made homogeneity of the superconducting parameters is to be tested. STM indicates large areas without any gap but calorimetric measurements have shown the bulk superconductivity and magnetization revealed extremely low pinning.

3:54PM J36.00008 Microwave stimulated enhancement of the upper critical field in type-II superconducting films , ANTONIO LARA, AHMAD AWAD, Universidad Autonoma de Madrid, ALEJANDRO SILHANEK, Universite de Liege, VICTOR MOSHCHALKOV, Katholieke Universiteit Leuven, FARKHAD ALIEV, Universidad Autonoma de Madrid — A few decades ago it was theoretically predicted and experimentally observed that moderate power electromagnetic fields in the GHz range could stimulate superconductivity, increasing the superconducting critical temperature and critical current. Here, on the example of Pb films without / with periodic vortex pinning centers in the form of circular Permalloy dots in the magnetic vortex state, we investigate experimentally how the microwave stimulated superconductivity phenomenon behaves in the presence of a superconducting vortex system. Namely, we present the first, to our best knowledge, experimental investigation of influence of microwave induced superconductivity on the upper critical field of type II superconducting films. An enhancement of the critical temperature of the film of up to 0.1% and of the upper critical field of up to 10% have been observed at a drive frequency of 6 GHz. A qualitative explanation for the observed difference in the dependence of the upper critical field on the temperature and microwave power, depending on the nearly parallel or perpendicular alignments of the field to the sample, is provided.

4:06PM J36.00009 New Evidences for the observation of the Higgs boson in the Superconductor 2H-$NbSe_2$, MARIE-AUDE MEASSON, BERTRAND CLAIR, YANN GALLAIS, MAXIMILIEN CAZAYOUS, Laboratory Quantum Matter and Penomena- University Paris Diderot-CNRS, PIERRE RODIÈRE, Institute Neel, CNRS-UJF, LAURENT CARIO, Institut des Materiaux Jean Rouxel (IMN), Universite de Nantes - CNRS, ALAIN SACUTO, Laboratory Quantum Matter and Penomena- University Paris Diderot-CNRS, SQUAP TEAM, SYSTÈMES À FORTES CORRÉLATIONS ÉLECTRONIQUES COLLABORATION, IMN COLLABORATION — We provide here new evidences for the observation of the amplitude mode of the superconducting order parameter, the so-called Higgs Boson, in 2H-$NbSe_2$. We report quantitatively comparative electronic Raman measurements on the dichalcogenides 2H-$NbSe_2$, whose superconductivity (SC) coexists with a charge density wave order (CDW), and 2H-NbS_2, which exhibits only the SC. A SC pair breaking peak develops below T_c in 2H-NbS_2 whose intensity is much smaller than the peak associated with the SC in 2H-$NbSe_2$. Thus, the peak observed in 2H-$NbSe_2$ below T_c certainly doesn't get its intensity only from the superconducting condensate. Moreover, we measure precisely a spectral weight transfer from the amplitude mode of the CDW to the SC peak in 2H-$NbSe_2$, versus decreasing temperature. The total spectral weight for both peaks is constant within $\pm$ 3%. This result is consistent with the theory of the observation of a Higgs mode thanks to its coupling with an amplitudon developed by Littlewood and Varma. This result complements what was firstly observed by Sooryakumar et Klein under magnetic field.

4:18PM J36.00010 Imaging the Anisotropic Nonlinear Meissner Effect in Unconventional Superconductors[1] , STEVEN ANLAGE, Physics Dept., University of Maryland, A.P. ZHURAVEL, Verkin Inst. Low Temp Physics, NAS Ukraine, Kharkov, B.G. GHAMSARI, C. KURTER, J. ABRAHAMS, Physics Dept., University of Maryland, S. REMILLARD, Hope College, P. JUNG, A.V. LUKASHENKO, ALEXEY USTINOV, CFN, Karlsruhe Inst. Tech., Germany — We have directly imaged the anisotropic nonlinear Meissner effect in an unconventional superconductor through the nonlinear electrodynamic response of both (bulk) gap nodes and (surface) Andreev bound states [1]. A superconducting thin film is patterned into a compact self-resonant spiral structure, excited near resonance in the radio-frequency range, and scanned with a focused laser beam perturbation. At low temperatures, direction-dependent nonlinearities in the reactive and resistive properties of the resonator create photoresponse that maps out the directions of nodes, or of bound states associated with these nodes, on the Fermi surface of the superconductor. The method is demonstrated on the nodal superconductor YBa_2Cu_3O_7-\delta and the results are consistent with theoretical predictions for the bulk and surface contributions. [1] A. P. Zhuravel, *et al.*, arXiv:1208.1511.

4:30PM J36.00011 X-ray edge singularity in resonant inelastic x-ray scattering (RIXS)[1] , ROBERT MARKIEWICZ, Northeastern University, JOHN REHR, University of Washington, ARUN BANSIL, Northeastern University — We develop a lattice model based on the theory of Mahan, Noziéres, and de Dominicis for x-ray absorption to explore the effect of the core hole on the RIXS cross section. The dominant part of the spectrum can be described in terms of the dynamic structure function $S(q,\omega)$ dressed by matrix element effects, but there is also a weak background associated with multi-electron-hole pair excitations. The model reproduces the decomposition of the RIXS spectrum into well- and poorly-screened components. An edge singularity arises at the threshold of both components. Fairly large lattice sizes are required to describe the continuum limit.

[1]Supported by DOE Grant DE-FG02-07ER46352 and facilitated by the DOE CMCSN, under grant number DE-SC0007091.

4:42PM J36.00012 Using photon to probe spin excitations , CHUNJING JIA, Stanford Institute for Materials and ENergy Sciences, CHENG-CHIEN CHEN CHEN, Argonne National Lab, BRIAN MORITZ, TOM DEVEREAUX, Stanford Institute for Materials and ENergy Sciences — Elementary spin excitations have attracted considerable attention in the understanding of strongly correlated materials, especially in high temperature superconductors where a full understanding of spin dynamics might reveal important information where the phase emerges in proximity of magnetic order. Photon spectroscopies, such as resonant inelastic x-ray scattering (RIXS) and optical Raman scattering, are powerful tools for the measurement of spin excitations. In this presentation, I will discuss the simulation of various spectroscopies that can reveal spin excitations, using both single- and multi-orbital models. I will show that transition metal in-direct RIXS provides information about two-magnon excitations at low energies in addition to the usual charge transfer excitations; while direct RIXS measures single spin-flip (single magnon) excitations, making it a complementary technique to inelastic neutron scattering. I also will show that Raman scattering can probe two-magnon spin excitations in correlated materials. We track the evolution of these excitations as functions of momentum and doping. These results highlight the nature of spin excitations in correlated materials and are an important step in our understanding of the corresponding experiments in real materials

4:54PM J36.00013 Investigation of 1/f flux noise in SQUIDs and Superconducting Qubits , ANTONIO PUGLIELLI, STEVEN SENDELBACH, TAYLOR KLAUS, ROBERT MCDERMOTT, University of Wisconsin-Madison, Department of Physics — Low-frequency 1/f flux noise is a dominant source of dephasing in the Josephson phase and flux qubits. Recent work has revealed the presence of a high density of unpaired spins at the surfaces of superconducting thin films; it is now believed that these spins are the source of the noise, although the microscopic noise mechanism is not understood. We have recently shown that the dielectric encapsulation of the SQUID loop substantially impacts the noise magnitude and noise exponent. Here we describe experiments on SQUIDs and Josephson phase qubits designed to shed light on the underlying noise mechanism, and we describe efforts to develop Josephson phase qubits with reduced levels of 1/f flux noise and improved dephasing times.

5:06PM J36.00014 Torque magnetization study of superconducting fluctuations in single-layer cuprates: new implications for the phase diagram[1] , GUICHUAN YU, R. FRINK, University of Minnesota, D.-D. XIA, X. ZHAO, Jilin University, China, N. BARIŠIĆ, CEA-DSM-IRAMIS, France, R.-H. HE, Boston College, N. KANEKO, AIST, Japan, T. SASAGAWA, Tokyo Institute of Technology, Japan, Y. LI, Peking University, China, A. SHEKHTER, Los Alamos National Laboratory, M. GREVEN, University of Minnesota — We have studied the superconducting fluctuations above the transition temperature by angle-dependent torque magnetization in single-layer $La_{2-x}Sr_xCuO_4$ (LSCO), $Bi_2(Sr,La)_2CuO_{6+\delta}$ (Bi2201), and $HgBa_2CuO_{4+\delta}$ (Hg1201). The latter is a more ideal compound, with a maximum T_c of 97 K, more than twice the values for LSCO and Bi2201. In all three cases, the diamagnetic signal above T_c vanishes in an unusual exponential fashion, and at a rate that is universal, despite the dramatic differences in T_c [G. Yu *et al.*, arXiv:1210.6942v1]. These observations suggest that anomalies observed at much higher temperatures in both LSCO and Bi2201 are not associated with superconducting fluctuations.

[1]Work on Hg1201 supported by DOE-BES; work on Bi2201 and LSCO supported by an NSF grant and a seed grant through the NSF MRSEC program

5:18PM J36.00015 Effect of thermal fluctuations in topological p-wave superconductors , BELA BAUER, ROMAN M. LUTCHYN, Station Q, Microsoft Research, MATTHEW B. HASTINGS, Duke University, Department of Physics, MATTHIAS TROYER, Theoretische Physik, ETH Zurich — We study the effect of thermal fluctuations on the topological stability of chiral p-wave superconductors. We consider two models of superconductors: spinless and spinful with a focus on topological properties and Majorana zero-energy modes. We show that proliferation of vortex-antivortex pairs above the Kosterlitz-Thouless temperature T_{KT} drives the transition from a thermal Quantum Hall insulator to a thermal metal/insulator, and dramatically modifies the ground-state degeneracy splitting. Therefore, in order to utilize 2D chiral p-wave superconductors for topological quantum computing, the temperature should be much smaller than T_{KT}. Within the spinful chiral p-wave model, we also investigate the interplay between half-quantum vortices carrying Majorana zero-energy modes and full-quantum vortices having trivial topological charge, and discuss topological properties of half-quantum vortices in the background of proliferating full-quantum vortices.

Session J37 DMP DCOMP: Focus Session: Fe-based Superconductors: Pressure effects 345/346

- Xiao-Jia Chen, Carnegie Institution of Washington

2:30PM J37.00001 Evolution of superconductivity in $Ca_{1-x}La_xFe_2As_2$ under pressure[1] , SHANTA SAHA, Center for Nanophysics and Advanced Materials, Department of Physics, University of Maryland, College Park, MD 20742 — The evolution of superconductivity in single crystals of the aliovalent La-doped $CaFe_2As_2$ is studied with both quasi-hydrostatic and hydrostatic applied pressures measuring transport, magnetic, and neutron scattering properties. The application of pressure to under doped samples of $Ca_{1-x}La_xFe_2As_2$ suppresses the antiferromagnetic (AFM) transition and causes an abrupt appearance of superconductivity with T_c values similar to those (about 45 K) recently been reported at ambient pressure. This superconducting phase appears under both quasi-hydrostatic and hydrostatic pressures, indicating an intrinsic property of the observed superconducting state. Unlike transition metal-doped 122 iron-superconductors where superconductivity happily coexists with AFM, the little coexistence of SC and AFM appears to mimic that found in 1111 iron-superconductors, suggesting a similar phase diagram. The unusual dichotomy between lower-T_c systems that happily coexist with AFM and tendency for the highest-T_c systems to show phase separation provides an important clue to the pairing mechanism in iron-based superconductors.

3:06PM J37.00002 c-axis transport in rare-earth doped $CaFe_2As_2$[1] , JOHNPIERRE PAGLIONE, T. DRYE, R. HU, S.R. SAHA, University of Maryland — The discovery of a low volume fraction phase of superconductivity in rare-earth doped $Ca_{1-x}R_xFe_2As_2$ with T_c= 47 K has sparked controversy over the nature of the observed superconductivity. However, an important aspect to understanding the behavior in these systems lies in understanding the role of the structural collapse wherein interlayer As atoms abruptly form a bond at sufficiently low temperatures, resulting in a ∼10% reduction of the c-axis through a first-order transition. We will present measurements of electrical transport with currents directed along the crystallographic c-axis, discussing the implications for the superconducting phase and the nature of the band structure change through the structural collapse transition.

3:18PM J37.00003 Inter-plane resistivity in single crystals $Ca(Fe_{1-x}Co_x)_2As_2$ with doping level variation[1] , MAKARIY TANATAR, S. RAN, S.L. BUD'KO, P.C. CANFIELD, RUSLAN PROZOROV, Ames Laboratory USDOE and Iowa State University — $CaFe_2As_2$ undergoes sharp first order tetragonal-to-orthorhombic phase transition on cooling below T_{SM}=175 K, accompanied by stripe type antiferromagnetic ordering. The transition temperature can be suppressed to zero by application of pressure, revealing collapsed tetragonal high pressure phase, and partial superconductivity. It can also be suppressed by Co substitution of Fe. This doping suppresses structural and magnetic instabilities and induces bulk superconductivity with T_c up to 17 K $Ca(Fe_{1-x}Co_x)_2As_2$ with x=2.8% [1]. Here we report systematics of the temperature-dependent inter-plane resistivity in this Co-doped series of compounds over complete doping phase diagram.

3:30PM J37.00004 Thermal expansion of $CaFe_2As_2$: effect of annealing and cobalt doping[1] , SERGEY L. BUD'KO, SHENG RAN, PAUL C. CANFIELD, Ames Laboratory, US DOE, and Dept. of Physics and Astronomy, Iowa State University, Ames, IA 50011, USA — Careful choice of Co concentration and annealing/quenching temperature in the $Ca(Fe_{1-x}Co_x)_2As_2$ series allows for tuning the ground state of the from orthorhombic-antiferromagnetic to superconducting to collapsed tetragonal [1].In this talk temperature-dependent, c-axis, thermal expansion measurements on several sets of Co-doped $CaFe_2As_2$ single crystals that were subjected to a variety of annealing conditions will be presented. These samples were chosen to cover all salient regions of the 3D $x - T_{anneal} - T$ phase diagram. The thermal expansion signatures of different types of phase transitions observed in these series will be discussed and comparison with the other measurements will be made.

3:42PM J37.00005 London penetration depth under pressure in Fe-based superconductors[1] , KYUIL CHO, MAKARIY A. TANATAR, CHARLES P. STREHLOW, RUSLAN PROZOROV, The Ames Laboratory and Iowa State University — Precisely measured low - temperature London penetration depth can be used as a sensitive tool to study the superconducting gap structure. Tunnel diode resonator (TDR) technique provides the ultimate sensitivity and resolution and it has been employed to study conventional and unconventional superconductors [1]. In case of Fe-based superconductors the dome - like evolution of the superconducting properties, including the gap anisotropy, has been found as a function of doping. While easier to work with, the doping also changes the scattering, especially important in Fe-based superconductors [1]. Pressure provides potentially cleaner alternative way for systematic study of the superconducting gap evolution. However, thus far no successful measurements on London penetration depth in the pressure cell were possible due to various background contributions. We have recently developed the pressure dependent London penetration depth measurement technique by combining a TDR technique with BeCu piston cell. Technical characteristics as well as the first results will be discussed.

3:54PM J37.00006 Magnetism dependent phonon anomaly in LaFeAsO observed via inelastic x-ray scattering[1]

, STEVEN HAHN, GREGORY TUCKER, The Ames Laboratory and Iowa State University, JIAQIANG YAN, Oak Ridge National Laboratory and The University of Tennessee, AYMAN SAID, BOGDAN LEU, Advanced Photon Source, Argonne National Laboratory, R.W. MCCALLUM, The Ames Laboratory, ERCAN ALP, Advanced Photon Source, Argonne National Laboratory, THOMAS LOGRASSO, ROBERT MCQUEENEY, BRUCE HARMON, The Ames Laboratory and Iowa State University — The phonon dispersion was measured at room temperature (above T_N) along (0,0,L) in the tetragonal phase of LaFeAsO using inelastic x-ray scattering. Magnetostructural effects are well documented in the AFe_2As_2-based (A=Ca,Sr,Ba,Eu) systems. Only recently have single crystals of RFeAsO (R=La,Ce,Pr,Nd,Sm,Gd)-based compounds become available. The experimentally observed splitting between two A_{1g} phonon modes at 22 and 26 meV is only produced in spin-polarized first-principles calculations imposing various types of antiferromagnetic order. Magnetostructural effects similar to those observed in the AFe_2As_2 materials are confirmed present in LaFeAsO. This is discussed in terms of the strong antiferromagnetic correlations that are known to persist above T_N and into the tetragonal phase.

4:06PM J37.00007 Ru L_2 edge X-ray resonant magnetic scattering from $Ba(Fe_{0.795}Ru_{0.205})_2As_2$ compound[1]

, MIN GYU KIM, Lawrence Berkeley National Laboratory, J. SOH, Ames Laboratory and Dept. of Physics and Astronomy, Iowa State University, J.C. LANG, Y. CHOI, Advanced Photon Source, Argonne National Laboratory, A. THALER, Ames Laboratory and Dept. of Physics and Astronomy, Iowa State University, E. BOURRET-COURCHESNE, Lawrence Berkeley National Laboratory, S.L. BUD'KO, P.C. CANFIELD, A. KREYSSIG, A.I. GOLDMAN, Ames Laboratory and Dept. of Physics and Astronomy, Iowa State University, R.J. BIRGENEAU, Lawrence Berkeley National Laboratory — We have investigated the magnetic polarization of the Ru $4d$ dopant states in $Ba(Fe_{0.795}Ru_{0.205})_2As_2$ using Ru L_2 edge x-ray resonant magnetic scattering (XRMS). We observed a XRMS signal at Q = (1/2, -1/2, 3), which is consistent with the magnetic propagation vector for the stripe AFM ordering found in the parent $BaFe_2As_2$ compound. We find that the temperature dependence of the XRMS signal follows closely the temperature dependence of the Fe order as determined by our previous neutron diffraction measurement. Our observations show evidence that the Ru $4d$ states may be spin-polarized.

[1]The work at Lawrence Berkeley National Laboratory and Ames Laboratory was supported by the Office of Basic Energy Sciences, DMSE, US DOE, under Contract No. DE-AC02-05CH11231 and DE-AC02-07CH11358, respectively.

4:18PM J37.00008 High Pressure Low Temperature Studies of the Iron-Based Superconductor $SrFe_2As_2$

, GARY CHESNUT, University of West Georgia, WALTER UHOYA, JEFFREY MONTGOMERY, University of Alabama at Birmingham, ANTONIO DOS SANTOS, JAMIE MOLAISON, Oak Ridge National Laboratory — Iron-based superconductors are a critical clue in understanding the mechanism behind high temperature superconductivity. It is well-known that superconductivity is highly influenced by magnetic fields. Recent neutron scattering experiments were performed on $SrFe_2As_2$ to examine the nuclear and magnetic structure to a temperature of 89 K and a pressure of 4.3 GPa. The structural phase transition from tetragonal to orthorhombic was observed at T_o = 196 K with an increase in orthorhombic distortion with decreasing temperature. The neutron diffraction experiments revealed subtle, but interesting results at elevated pressures.

4:30PM J37.00009 Pressure induced structural modifications in $NaFe_{1.99}Co_{0.01}As_2$ superconductor

, ELISSAIOS STAVROU, XIAO-JIA CHEN, ALEXANDER GONCHAROV, Geophysical Laboratory, Carnegie Institution of Washington, 5251 Broad Branch Road NW, Washington, DC 20015, USA, A. WANG, Y. YAN, X. LUO, X. CHEN, Hefei National Laboratory for Physical Science at Microscale, Department of Physics, University of Science and Technology, Anhui 230026, China — $NaFe_{1.99}Co_{0.01}As_2$ superconductor with the tetragonal $ThCr_2Si_2$-type structure ($I4/mmm$) has been studied using x-ray diffraction and Raman spectroscopy up to 25 GPa (at RT). Recently, it was found that, for this compound, T_c increases with pressure to a maximum of 32 K at 2.5 GPa. With further compression T_c decreases up to 6 GPa, the highest pressure superconductivity has been detected. We report that, although $NaFe_{1.99}Co_{0.01}As_2$ remains in the ambient pressure phase, the lattice parameters evolution with pressure shows distinct behavior below and above a critical pressure Pc=2.5 GPa. This is accompanied by a subtle change of Raman spectra at Pc. Below Pc, a-axis increases while both the c-axis and the c/a axial ratio decrease. In contrast above Pc, both axes show a normal decrease and c/a remains almost constant. The different behavior of c-axis, below and above Pc, can be viewed as a modification of the initial tetragonal phase (T) to a collapsed tetragonal (CT) one. This is in line with previous studies on 122 iron-based superconductors. We conclude that the high compressibility of c-axis, in the T phase, enhances superconductivity since layers are brought together. Above Pc, compression of CT phase seems to have the opposite effect.

4:42PM J37.00010 Magneto-transport properties of single crystal LaFeAsO at ambient and high pressure[1]

, COLIN MCELROY, JAMES HAMLIN, BENJAMIN WHITE, M. BRIAN MAPLE, University of California, San Diego — Electrical resistivity and magneto-transport measurements were performed on single crystals of LaFeAsO, which were grown using a NaAs flux. The magneto-transport measurements were made at ambient pressure in magnetic fields up to 9 T using the van der Pauw technique, which yielded the magnetoresistance and the Hall coefficient, from which the carrier density and mobility were inferred. The dominant charge carriers were identified as electrons, and a second anomaly was observed below the spin-density wave (SDW) transition. In order to study the evolution of these two anomalies with pressure, electrical resistivity measurements were performed under applied pressures up to 36.7 GPa.

[1]Sample synthesis was funded by the US AFOSR-MURI (Grant FA9550-09-1-0603). Measurements at ambient and high pressure were supported by the USDOE (Grant DE-FG02-04-ER46105) and NNSA under the SSAA program (Grant DE-FG52-06NA26205), respectively.

4:54PM J37.00011 Fe moments in the pressure-induced collapsed tetragonal phase of $(Ca_{0.67}Sr_{0.33})Fe_2As_2$[1]

, JASON JEFFRIES, NICHOLAS BUTCH, JOSEPH BRADLEY, Lawrence Livermore National Laboratory, YUMING XIAO, PAUL CHOW, Carnegie Institute of Washington, SHANTA SAHA, KEVIN KIRSHENBAUM, JOHNPIERRE PAGLIONE, University of Maryland — The tetragonal $AEFe_2As_2$ (AE=alkaline earth element) family of iron-based superconductors exhibits magnetic order at ambient pressure and low temperature. Under pressure, the magnetic order is suppressed, and an isostructural volume collapse is induced due to increased As-As bonding across the mirror plane of the structure. This collapsed tetragonal phase has been shown to support superconductivity under some conditions, and theoretical calculations suggest an unconventional origin. Theoretical calculations also reveal that enhanced As-As bonding and the magnitude of the Fe moments are correlated, suggesting that the Fe moments can be quenched in the collapsed tetragonal phase. Whether the Fe moments persist in the collapsed tetragonal phase has implications for the pairing mechanism of the observed, pressure-induced superconductivity in these compounds. We will present pressure-dependent x-ray emission spectroscopy (XES) measurements that probe the Fe moments through the volume collapse transition of $(Ca_{0.67}Sr_{0.33})Fe_2As_2$, and compare these measurements with the occurrence of superconductivity.

5:06PM J37.00012 Interplay of superconductivity with the SDW order and Eu^{2+} AFM order in the $Ca_{1-x}Eu_xFe_2As_2$ system at ambient and under pressures[1] , KESHAV SHRESTHA, KUI ZHAO, BEN JAWDAT, LIANGZI DENG, XIYU ZHU, YUYI XUE, BING LV, Texas Center for Superconductivity and Department of Physics, University of Houston, Houston, TX 77204-5002, PAUL CHU, Texas Center for Superconductivity and Department of Physics, University of Houston, Houston, TX 77204-5002 & Lawrence Berkeley National Laboratory — Single crystals of Eu doped $Ca_{1-x}Eu_xFe_2As_2$ ($0 \leq x \leq 1$) with size up to 5 x 5 mm size were grown from FeAs self-flux technique. Detailed magnetic and resistivity data a systematical evolution of a spin-density-wave (SDW) transition from $\sim$ 170K at x=0 to $\sim$ 190K at x =1. Moreover, the Eu^{2+} antiferromagnetic (AFM) emerged at 3.7K at a threshold doping $x \sim 0.2$, and systematically increased up to $\sim$ 20K with the increase of the Eu content. High pressure was applied to some of these compounds to explore the competition among SDW, collapsed phase and superconductivity. Superconductivity up to 18K was observed in samples without the structural "collapsed tetragonal" phase before the emergence of the superconductivity signal. The data suggest that the superconductivity in the doped Ca122 under pressure is not associated with the structural collapsed-tetragonal phase. The complex phase diagram of the SDW, Eu^{2+} AFM order and superconductivity at ambient and under pressure will be presented and its implication will be discussed.

[1]Work at Houston is supported in part by US AFOSR, the State of Texas, T. L. L. Temple Foundation and John and Rebecca Moores Endowment.

5:18PM J37.00013 Concentration dependence of magnetic characteristics in $EuFe_2(As_{1-x}P_x)_2$ single crystals[1] , TAKANARI KASHIWAGI, TAKUYA ISHIKAWA, TOMOKI GOTA, YOUHEI JONO, AKIHIKO NOZAWA, KASUMI TASHIMA, KAZUO KADOWAKI, Univ. of Tsukuba — In order to understand the structural and magnetic characteristics of $EuFe_2(As_{1-x}P_x)_2$, we have performed electron spin resonance (ESR) and magnetization measurements. The experimental results of the doping dependence of both measurements for the single crystal of $EuFe_2(As_{1-x}P_x)_2$ samples suggest the change of the exchange interaction and/or the anisotropy of Eu-site. The angular dependence of the ESR signal in the *ab*-plane clearly shows the change of the in-plane anisotropy by the doping of P. The details will be discussed in the meeting.

Session J38 GERA: Focus Session: Materials for Electrochemical Energy Storage II 347 - Shengbai Zhang, Rensselaer Polytechnic Institute

2:30PM J38.00001 Structural phase transition and Li-ion diffusion in $Li_7La_3Zr_2O_{12}$, KHANG HOANG, North Dakota State University, NOAM BERNSTEIN, MICHELLE JOHANNES, Naval Research Laboratory — Garnet-type $Li_7La_3Zr_2O_{12}$ (LLZO) is a promising candidate for solid electrolytes in Li-ion battery applications because of its high ionic conductivity and electrochemical and chemical stability. The material has a low-conductivity tetragonal phase and a high-conductivity cubic phase. It has been reported that the cubic phase can be stabilized at ambient conditions, usually with the incorporation of a certain amount of supervalent impurities. In this talk, we present results from density-functional theory and variable cell shape molecular dynamics simulations, and discuss the origin of structural phase transition, effects of extrinsic impurities, and diffusion of Li ions in LLZO. By identifying relevant mechanisms and critical concentrations of the impurities (Li vacancies) for achieving the high-conductivity phase, this work shows how controlled synthesis could be used to improve the material's electrolytic performance.

2:42PM J38.00002 ABSTRACT WITHDRAWN –

2:54PM J38.00003 Redox potential of liquid water: A first-principles theory , MICHAEL LUCKING, YIYANG SUN, DAMIEN WEST, SHENGBAI ZHANG, Rensselaer Polytechnic Institute — A first-principles molecular dynamic method is proposed to calculate the absolute redox potentials of liquid water. The key of the method is the evaluation of the difference between the vacuum level and the average electrostatic potential inside liquid water, which employs an average over both time and space. By avoiding the explicit use of the Kohn-Sham level, such as the position of the valence band maximum, as the reference energy for the excited electrons, we are able to calculate water redox potentials accurately. The results using the PBE functional are in good agreement with experiment. We attribute the success of the method to the accurate charge density given by density functional calculation under the local or semi-local approximations. This establishes the validity to apply these effective and efficient approximations to study both the energetics and dynamics of the redox processes at more complex systems such as solid/solution interfaces.

3:06PM J38.00004 Models of novel battery architectures , PAUL HANEY, DMITRY RUZMETOV, National Institute for Standards and Technology, ALEC TALIN, Sandia National Laboratories — We use a 1-dimensional model of electronic and ionic transport, coupled with experimental data, to extract the interfacial electrochemical parameters for LiCoO2-LIPON-Si thin film batteries. TEM imaging of batteries has shown that charge/discharge cycles can lead to breakdown of the interfaces, which reduces the effective area through which further Li ion transfer can occur. This is modeled phenomenologically by changing the effective cross sectional area, in order to correlate this structural change with the change in charge/discharge I-V curves. Finally, by adopting the model to radial coordinates, the geometrical effect of nanowire architectures for batteries is investigated.

3:18PM J38.00005 Paraquinone-Hydroquinone Couple for Flow Battery , SARAF NAWAR, Harvard College, BRIAN HUSKINSON, MICHAEL AZIZ, Harvard School of Engineering and Applied Sciences — At present, there is an ongoing search for the storage of energy from intermittent renewable sources like wind and solar. Flow batteries have gained attention due to their potential viability in inexpensive storage of large amounts of energy. Because of its high reversibility, low toxicity, and low component costs, the paraquinone/hydroquinone redox couple could be a viable candidate for use in a grid-scale storage device. In this report, we will present half-cell data for the 1,4-parabenzoquinone/1,4-hydroquinone redox couple and related couples in sulfuric acid. We will present results from a flow battery with maximum current density of up to 200 mA/cm2 using a mixture of 1,4-parabenzoquinone and 1,4-hydroquinone as the cathode material and hydrogen as the anode material. We report the effects of reactant concentration, reactant flow rate to the electrode, and temperature on the performance of the fuel cell.

3:30PM J38.00006 Exploring the electronic structure and dynamics of lithium compounds through first-principles interpretation of X-ray absorption spectra[1] , DAVID PRENDERGAST, TOD PASCAL, XIN LI, JINGHUA GUO, Lawrence Berkeley National Laboratory, YI LUO, KTH Royal Institute of Technology — In situ X-ray spectroscopy will reveal fundamental details of elecltrochemistry in working cells, provided that the data is interpretable. To this end, we are developing first-principles methods to simulate core-level absorption spectra of molecules, condensed phases, and interfaces with explicit inclusion of dynamics. We validate this approach by application to various lithium compounds that may be present in the solid electrolyte interphase (SEI) and to lithiation of graphite in the anode. Our calculations reveal that instantaneous broken symmetry about the x-ray excited atom may be evident in the resulting spectroscopy and highlights both dynamical and static disorder in these materials. Furthermore, we observe complex anisotropic interactions upon charge transfer between lithium and graphite that contradict a simplistic view of intercalation in terms of complete electron transfer and the rigid band approximation.

3:42PM J38.00007 Characterization of silicate based cathodes for Li Ion Batteries , AJAY KUMAR, GHOLAM-ABBAS NAZRI, Wayne State University, MARYAM NAZRI, Applied Sciences Inc., VAMAN NAIL, University of Michigan Dearborn, PREM VAISHNAVA, Kettering University, RATNA NAIK, Wayne State University, ENERGY GROUP COLLABORATION, ENERGY GROUP COLLABORATION, ENERGY GROUP COLLABORATION — The silicate compounds Li_2MSiO_4, where M= Mn, Fe, Co and Ni have gained interest as electrode materials for Lithium ion batteries due to their high theoretical capacity (>330mAh/g), high thermal stability due to strong Si-O covalent bonds, environmental friendliness, and low cost. However, these materials intrinsically have low electrical conductivity. To improve conductivity of these classes of electrode materials, we synthesized Li_2MnSiO_4 and Li_2FeSiO_4 by solid state reaction in an argon atmosphere. The lithium transition metal silicates were compounded with graphene nano-sheets and the composites were used as positive electrode in a coin cell configuration. . The materials structure-composition, morphology, conductivity and electrochemical performance were characterized by XRD, XPS, SEM, TEM and electrochemical techniques.The detail structure-composition analysis and electrochemical performance of the silicate electrodes will be reported.

3:54PM J38.00008 Solid state electrochemical studies on single crystals with hexafluoro metal centers[1] , QIFAN YUAN, YAO ZHANG, SARAH TRUE, VICTORIA SOGHOMONIAN, Virginia Tech — Electrochemical energy storage is of importance for current and future storage schemes. Our electrochemical studies on hydrothermally synthesized single crystals of metal hexafluoride, $[NH_4]_3[V_xM'_{1-x}F_6]$, probe the redox chemistry of the V center as a function of substitution, temperature, and contact configuration. The various compositions are probed by XRD and IR spectroscopy. The measured 2 and 4 point resistivity is around $10^7 \quad \Omega$ cm. Cyclic voltammograms were obtained by both 2 and 3 point geometries, and current peaks corresponding to the electrochemical reaction recorded. To understand the observed voltammograms of the various configurations measured, the potential distribution in the crystal is calculated numerically, and equipotential lines extracted. Preliminary analysis indicates the extent of the space charge for 2 versus 3 contact measurements, and the influence of the space charge region on the electrochemical reaction when performed at micron scales. For a fixed sweep rate, the amplitude of the current peak diminishes as the temperature is increased, suggesting a dissipation of the space charge.

[1]We acknowledge support from NSF DMR 0943971 and 1206338.

4:06PM J38.00009 Enhanced Lithiation of Graphitized SiC: In Situ X-ray Scattering Study at Electrolyte / Graphene / SiC(0001) Interface , SUDESHNA CHATTOPADHYAY (BANDYOPADHYAY), Mater. Sci. and Eng., Northwestern University; Physics, Indian Institute of Technology Indore, ALBERT LIPSON, HUNTER KARMEL, JONATHAN EMERY, VINAYAK DRAVID, MARK HERSAM, MICHAEL BEDZYK, Mater. Sci. and Eng., Northwestern University, PAUL FENTER, TIMOTHY FISTER, MICHAEL THACKERAY, Chem. Sci. and Eng., Argonne National Laboratory — Silicon carbide is an inert material and not traditionally viewed as a promising electrode material. However, we observed a large enhancement to the electrochemical lithiation capacity for SiC anodes that were electrically activated by the combination of surface graphitization and substrate doping. In-situ X-ray scattering studies for lithiation at the electrolyte/EG/SiC interface show that the interfacial structure of the proposed anode system is stable in the electrolyte and graphene layers remain unaltered. While a decrease in the SiC Bragg peak intensity during lithiation indicates changes to the bulk crystallinity, the emergence of a diffuse scattering feature suggests that lithiation is associated with the development of substrate defects. Characterization via multiple depth resolved spectroscopies shows that Li penetrates the activated SiC upon lithiation. These results illustrate that the electrochemical capacity of a traditionally inert material can be increased substantially by effecting the surface and bulk conductivity [1].

4:18PM J38.00010 Dynamic dimer formation between superionic fluorines in PbF_2 , NOBUTAKA NAKAMURA, KAZUO TSUMURAYA, Meiji University, Kanagawa, Japan — Recently Tsumuraya *et al.*(J. Phys. Soc. Jpn. 81,055603(2012).) have elucidated the formation of the dynamic dimers in the superionic conductor α-CuI with the first principles molecular dynamics (MD) method. They, for the first time in research, confirmed the dimer formation through the analyses the origin of the correlation peaks of the partial pair distribution functions and the partial angle distribution functions. The present study elucidates the dynamic structure of the superionc fluorines in PbF_2 crystal with the MD method through identifying the origins of the correlation peaks. The fluorines form the dynamic $32f$-$8c$ and $4b$-$8c$ dimers.

4:30PM J38.00011 First-principles study of lithium ion diffusion in crystalline β-Li_3PS_4 for solid state electrolytes , MYUNG-SOO LIM, Division of Advanced Materials Science, POSTECH, SEUNG-HOON JHI, Department of Physics and Division of Advanced materials Science, POSTECH — The safety and stability are major issues to resolve in developing high-capacity lithium secondary batteries, particularly for application to electric vehicles. Solid-state lithium-ion electrolytes have been studied as a substitute of liquid electrolytes in order to enhance the stability and increase the energy density. However, low ion-mobility and poor material integrity are limiting the use of the solid electrolytes. We study the lithium-ion diffusion in crystalline β-Li_3PS_4 using first-principles methods and the nudged elastic band method. Considering diffusion paths through both interstitials and vacancy exchanges, we calculate the migration energies of lithium ions. Our results suggest that lithium ion diffusion is likely to occur through the zigzag-shaped paths along the b-direction that comprises of two lithium ion sites with fractional occupancy factors. We discuss the implication of our calculations for understanding the lithium ion diffusion in solid electrolytes.

4:42PM J38.00012 Structural and Electrochemical Impacts of Oxygen Doped and Surfactant Coated Activated Carbon Electrodes in Li-ion Batteries , JOHN COLLINS, GERALD GOURDIN, DEYANG QU, MICHELLE FOSTER, None — Passive charge and discharge dynamics are necessary for advancing Li-ion batteries. Surfactant adsorption on activated carbon has been shown to promote advancements in the discharge capacity, time and cycle-ability of electrochemical systems—specifically by enhancing diffusion pathways for ion insertion/de-insertion and suppressing pore blockage from precipitates known to form during charge/discharge states. Enhancement of surfactant chemisorption on activated carbon is achieved through oxygen doping of the carbon surface. In addition, doping alters the degree of Faradaic processes occurring in solution, resulting in prolonged reduction at the carbon surface. The work presented describes how surface oxygen groups on a granulated activated carbon have been manipulated using nitric acid in a controlled, stepwise fashion. A nonionic surfactant was applied to oxidized and non-oxidized samples at various concentrations. The composition and structure of the activated carbon surface was characterized using DRIFTS, Raman Spectroscopy, SEM and Porosimetry. The charge/discharge Li insertion capacities along with correlating surface microstructure changes were analyzed for all treated electrodes at progressive oxidation stages.

4:54PM J38.00013 Simulation of dendrite formation in lithium-ion batteries , NING SUN, DILIP GERSAPPE, Department of Materials Science and Engineering, Stony Brook University, NY, 11794 — The design of the next generation of energy storage technologies requires both a fundamental understanding of the physical and chemical reactions taking place in a complex electrochemical environment and the factors that limit the performance of these systems. We have developed a Lattice-Boltzmann model to simulate 2-D dendrite formation during charging and discharging processes on the anode of lithium-ion batteries. Our results show that the formation of dendrites is strongly influenced by the morphology of the anode, and operating conditions, in particular the charging current density. Our simulation is able to recover the structures that form on Li anodes, including mossy and dendritic structures as a function of parameters such as the curvature of the interface and the applied current density. We also show that we can observe a linear relationship between the log current density (J) and the log dendrite formation onset time (ts) in the low current density region, which also agrees with experiment data quite well. We study additional effects such as the role of the separator and the Solid Electrolyte Interphase (SEI) layer on the formation of dendrites.

5:06PM J38.00014 Surface Structure and Stability in Li_3PS_4 and Li_3PO_4 Electrolytes from First Principles[1] , NICHOLAS LEPLEY, N.A.W. HOLZWARTH, Wake Forest University — Crystalline solid electrolyte materials continue to show considerable promise for lithium ion battery applications. Recent experiments on these materials[2] suggest that in some cases surface effects may play a significant role with regard to both stability and ionic conductivity. In this study, we extend our previous modeling work[3] to an examination of idealized surfaces of several phases of Li_3PX_4 (X=O,S). Our preliminary results suggest that energy contributions from the surface affect the relative phase stability in Li_3PS_4, although this is not observed in the phosphate analogue. Our presentation will focus on surface energies and structures, as well as examining the calculated stability of the interface between the electrolyte and lithium metal.

5:18PM J38.00015 Synthesis and Performance of $LiFe_{1-x}Mn_xPO_4$ in Lithium-ion Battery , KHADIJE BAZZI, MARYAM NAZRI, Wayne State University, PREM VAISHNAVA, Kettering University, VAMAN NAIK, University of Michigan Dearborn, GHOLAM-ABBAS NAZRI, RATNA NAIK, Wayne State University — Olivine-type lithium transition metal phosphates (i.e. $LiFePO_4$) have been intensively investigated as promising electrode materials for rechargeable lithium-ion batteries. There have been attempts to improve energy density and voltage quality of phosphate based electrode. In this study, we have partially substituted Fe^{II}/Fe^{III} redox center with Mn^{II}/Mn^{III} in $LiFePO_4$ that provides over 600 mV higher voltage. We prepared various compositions of $LiFe_{1-x}Mn_xPO_4$ (x=0, 0.2, 0.4, 0.6, 0.8 and 1) between the two end members ($LiFePO_4$ - $LiMnPO_4$). Due to intrinsic low electronic conductivity of lithium transition metal phosphates, we coat these materials with a uniform conductive carbon through a unique sol-gel process developed in our laboratory. In addition, we made a composite of the carbon coated phosphate with carbon nano-tubes to develop a highly conductive matrix electrode. We report the materials structure, morphology, electrical conductivity and electrochemical performances of $LiFe_{1-x}Mn_xPO_4$ using XRD, Raman spectroscopy, SEM, TEM, XPS, electrical conductivity and galvanostatic charge/discharge measurements.

Session J39 GSCCM DCOMP DMP: Matter at Extreme Conditions: Theory and Simulations

348 - Joseph Hooper, Naval Postgraduate School

2:30PM J39.00001 Pressure-Constrained Deformation and Superior Strength: Compressed Graphite versus Diamond[1] , YI ZHANG, CHANGFENG CHEN, Department of Physics and High Pressure Science and Engineering Center, University of Nevada, Las Vegas, WEI ZHOU, HONG SUN, Department of Physics, Shanghai Jiao Tong University, China — The discoveries of compressed carbon phases and their ability to crack diamond anvil have generated great interest in the mechanical properties of carbon allotropes under high pressure. Significant progress has been made recently in structural identification of compressed graphite; however, its surprisingly high strength approaching or exceeding that of diamond remains unexplained. Here we explore this novel phenomenon and show by first-principles calculations that high-pressure confinement suppresses usual ambient or low-pressure deformation modes toward low-density carbon allotropes, and promotes alternative mechanisms for structural evolution leading to high-density compressed graphite phases that exhibit superior strength surpassing that of diamond. This finding explains the puzzling experimental observation and suggests new principles for structural deformation under high-pressure confinement. It also imposes stringent tests on widely used empirical hardness formulas that are unable to account for changes in pressure-constrained structural evolution and their influence on material strength.

2:42PM J39.00002 Atomistic Simulation of Orientation Dependence in Shock-induced Initiation of Pentaerythritol Tetranitrate (PETN) , TZU-RAY SHAN, RYAN WIXOM, ANN MATTSSON, AIDAN THOMPSON, Sandia National Laboratories, SANDIA NATIONAL LABORATORIES TEAM — Predicting the behavior of energetic materials requires a detailed description of how chemical reactions initiate during initial stages of detonation. In this talk, the dependence of the reaction initiation mechanism of pentaerythritol tetranitrate (PETN) on shock orientation and shock strength is investigated with molecular dynamics simulations using a reactive force field and the multi-scale shock technique. In the simulations, a single crystal of PETN is shocked along [110], [001], and [100] orientations with shock velocities in the range 3-10 km/s. Major reactions occur with shock velocities of 6 km/s or stronger, and reactions initiate through the dissociation of nitro (NO_2) and nitrate (NO_3) groups from the PETN molecules. The most sensitive orientation is [110], while [100] is the most insensitive. For the [001] orientation, PETN decomposition via nitro group dissociation is the dominant reaction initiation mechanism, while for [110] and [100] orientations the decomposition is via mixed nitro and nitrate group dissociation. For shock along the [001] orientation, we find that CO-NO_2 bonds initially acquire more kinetic energy, facilitating nitro dissociation. For the other two orientations, C-ONO_2 bonds acquire more kinetic energy, facilitating nitrate group dissociation.

2:54PM J39.00003 Microstructural Evolution and Grain Growth at High Speed Frictional Interfaces[1] , J.L. MILHANS, J.E. HAMMERBERG, R. RAVELO, T.C. GERMANN, B.L. HOLIAN, Los Alamos National Laboratory — We have examined the effect of evolution of grain morphology on the frictional force at polycrystalline Al-Al interfaces as a function of grain size and sliding velocity in the velocity range 40-250 m/s for grain sizes of 13.5 and 20 nm. Sample sizes for NonEquilibrium Molecular Dynamics (NEMD) simulations ranged from 10 - 140 M atoms. For velocities below a size dependent critical velocity above which a fluid layer forms, we find enhanced grain coarsening leading to a highly strained, graded final steady state microstructure that exhibits a dynamic morphhology characterized by grain growth and breakup at time scales greater than 5-10 ns. We find that the frictional force is insensitive to the initial grain size distribution that evolves to this new nonequilibrium steady state. We discuss mechanisms for grain size and shape evolution and the emergence of a dynamic length scale and compare these results to single crystal simulations in the same sliding regime.

3:06PM J39.00004 Shock response near the elastic to plastic transition in single crystal and porous silicon , J. MATTHEW LANE, TRACY J. VOGLER, Sandia National Labs — We use molecular dynamics simulation methods to study the onset of the plastic wave transition in single crystal silicon, and characterize the altered response due to various degrees of porosity from 5 to 50 percent. Non-elastic response near onset of plasticity follows a mechanism similar to one shown previously in germanium, in which a propagating densification transition is driven by the release of shear stress in the material. This transition mechanism can be characterized as a partial transition from the ambient diamond structure to a distorted body center tetragonal (β-tin) structure. We show that this onset region is strongly influenced by porosity and large scale defects. Sandia National Laboratories is a multi program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

3:18PM J39.00005 Molecular dynamics study of the shock response in hydroxyl-terminated polybutadiene melts[1] , MARKUS G. FROEHLICH, THOMAS D. SEWELL, DONALD L. THOMPSON, Department of Chemistry, University of Missouri-Columbia — All-atom molecular dynamics (MD) simulations using the non-reactive OPLS-AA force field were performed to study the detailed structural, mechanical, and spectroscopic response of hydroxyl-terminated polybutadiene (HTPB) melts subjected to supported shock waves. A combination of Monte Carlo and MD techniques was used to generate thoroughly equilibrated initial configurations, for monodisperse systems with chain lengths ranging from 64 to 256 backbone carbons per chain. Properties characterizing the size, shape and orientation of single chains, as well as the vibrational density of states, were evaluated prior to and following shock passage for four impact velocities between 1.0 and 2.5 km/s. The structural properties and global scaling behaviors of the unshocked systems are in excellent agreement with literature data. Results for the shocked systems, obtained using a geometric binning approach that provides spatio-temporal resolution in the reference frame centered on the shock front, indicate a transition to a glass-like state with a concomitant increase by several orders of magnitude of structural relaxation times in the shocked material.

3:30PM J39.00006 ABSTRACT WITHDRAWN –

3:42PM J39.00007 The volume isotope effect in ice under high pressure[1] , STEFANO DE GIRONCOLI, Scuola Internazionale Superiore di Studi Avanzati (SISSA) and CNR-IOM DEMOCRITOS Simulation Centre, KOICHIRO UMEMOTO, Department of Earth Sciences, University of Minnesota, RENATA WENTZCOVITCH, Department of Chemical Engineering and Materials Science, University of Minnesota — The volume isotope effect (VIE) in ice has recently received considerable attention [1,2]. Ice Ih and XI, prototypical forms of low-pressure ice, have anomalous VIE, i.e., the volume of D_2O (V_{D2O}) is larger than that of H2O (V_{H2O}) [1]. In contrast, the VIE in ice VIII at 0 GPa was reported to be normal, i.e., $V_{D2O} < V_{H2O}$ [2]. Here we clarify the origin of this behavior in different forms of ice. Furthermore, we predict a reversal in the VIE in ice VIII under high pressure. [1] B. Pamuk et al., Phys. Rev. Lett. 108, 193003 (2012). [2] E. D. Murray and G. Galli, Phys. Rev. Lett. 108, 105502 (2012).

3:54PM J39.00008 New transitions of MgSiO3 post-perovskite under ultrahigh pressure[1] , KOICHIRO UMEMOTO, Department of Geophysics and Geology, University of Minnesota and Ames Laboratory, Iowa State Univand, SHUNQING WU, Ames Lab, Iowa state University and Department of Physics, Xiamen University, MIN JI, CAI-ZHUANG WANG, KAI-MING HO, Ames Lab, Iowa state University, RENATA WENTCOVITCH, Depeartment of Chem Eng Mat Sci, University of Minnesota — Understanding the behavior of $MgSiO_3$ post-perovskite (PPV) under extreme pressures is fundamental for modeling the interiors of super-Earth type exoplanets and the cores of solar giants. Previously, $MgSiO_3$ PPV was predicted to dissociate into MgO and $MgSi_2O_5$ and then into MgO and SiO_2 (Umemoto et al., Science 311, 983 (2006); Umemoto and Wentzcovitch, EPSL 311, 225 (2011)). Using the adaptive genetic algorithm, we predict new phase transitions in $MgSiO_3$. The phase diagram calculated using the quasi-harmonic approximation shows that some transitions can occur in some super-Earths type exoplanets.

4:06PM J39.00009 Elasticity of ferropericlase at lower mantle conditions , RENATA WENTZCOVITCH, Department of Chemical Engineering and Materials Science, Minnesota Supercomputer Institute, University of Minnesota, ZHONGQING WU[1], Laboratory of Seismology and Physics of Earth's Interior, School of Earth and Space Sciences, University of Science and Technology of China, Hefei, JOAO FRANCISCO JUSTO, 3 Escola Politécnica, Universidade de São Paulo, CP 61548, CEP 05424-970, São Paulo, SP, Brazil — The discovery of spin-state changes (crossovers) in ferropericlase (Fp) and in silicate perovskite (Pv) under pressure has raised new questions about Earth's mantle properties. Despite extensive experimental work on the elasticity of Fp throughout the crossover, inconsistencies reported in the literature are still not explained. We introduce here a theoretical framework for thermoelasticity across spin-state changes, apply it to Fp by combining it with predictive first principles DFT+U calculations, and contrast results with available data on samples with various iron concentrations. We explain why the shear modulus of Fp should not soften throughout the spin crossover under hydrostatic conditions and show the importance of constraining well the elastic properties of minerals at lower mantle conditions and likely compositions without extrapolations.

4:18PM J39.00010 Dielectric properties of water and their impact on the Earth's deep carbon cycle[1] , DING PAN, Department of Chemistry and Department of Physics, University of California Davis, Davis, CA 95616, LEONARDO SPANU, Department of Chemistry, University of California Davis, Davis, CA 95616, BRANDON HARRISON, DIMITRI SVERJENSKY, Department of Earth & Planetary Sciences, Johns Hopkins University, Baltimore, MD 21218, GIULIA GALLI, Department of Chemistry, University of California Davis, Davis, CA 95616; Department of Physics, University of California Davis, Davis, CA 95616 — Knowledge of the dielectric constant of water as a function of pressure (P) and temperature (T) plays a critical role in understanding the chemistry of aqueous systems, and in particular of fluids in the Earth's mantle. By using *ab initio* molecular dynamics, we computed the dielectric constant of water at T = 1000 and 2000 K, between 1 and 12 GPa, under conditions of the Earth's upper mantle. By comparing our results with available experimental data and empirical models, we discuss how the changes in the molecular dipole moments and hydrogen-bond network upon compression affect the dielectric constant of the liquid. Based on the calculated dielectric constants, the solubility products of carbonate minerals were predicted. At P $\sim$ 10 GPa and T = 1000 K, we found that $MgCO_3$ (magnesite) is slightly soluble in water at the millimolal level, which suggests that water in the Earth's mantle has the capacity to store and transport significant quantities of oxidized carbon.

4:30PM J39.00011 Structure change, layer sliding, and metallization in high-pressure MoS2[1] , ERIO TOSATTI, SISSA, ICTP, CNR-IOM Democritos, LILIANA HROMADOVA, ROMAN MARTONAK, Comenius University Bratislava — Based on ab initio calculations and metadynamics simulations, we predict that 2H-MoS_2, a layered insulator, will metallize under pressures in excess of 20-30 GPa. In the same pressure range, simulations and enthalpy optimization predict a structural transition. Reminiscent of this material's frictional properties, free mutual sliding of layers takes place at this transition, where the original $2H_c$ stacking changes to a $2H_a$ stacking typical of 2H-$NbSe_2$, a transformation which explains for the first time previously mysterious X-ray diffraction data. Phonon and electron phonon calculations suggest that metallic pristine MoS_2 will require ultrahigh pressures in order to develop superconductivity.

4:42PM J39.00012 Electronic structure and topological transition of SnTe at high pressure[1] , QUAN LI, DAN ZHOU, Department of Physics and High Pressure Science and Engineering Center, University of Nevada, Las Vegas, Nevada 89154, USA, YANMING MA, State key Laboratory of Superhard Materials, Jilin University, Changchun 130012, China, CHANGFENG CHEN, Department of Physics and High Pressure Science and Engineering Center, University of Nevada, Las Vegas, Nevada 89154, USA — Recent x-ray diffraction measurements and first-principles calculations have revealed intriguing structural evolution of tin telluride (SnTe) under high pressure. Here we report on a systematic study of the electronic band structure, density of states, Fermi surface and charge density of SnTe at high pressure using first-principles density functional theory calculations. Our results unveil an electronic topological transition in the cubic Fm-3m phase of SnTe with its Fermi surface changing from disconnected pockets to inter-connected quasicubic tubes near the L points of the Brillouin zone under high pressure. The pressure-induced quasicubic tubular Fermi surface is similar to that previously obtained via carrier doping. The induced change in electronic charge distribution stabilizes the Fm-3m structure and thus suppresses the transition to the rhombohedral structure, which explains experimental observations. Furthermore, our calculations show that pressure-induced electronic topological transition is also present in the orthorhombic Cmcm and Pnma phases of SnTe in the pressure range of 5 to 18 GPa, but this transition is absent in the high-pressure (above 18 GPa) Pm-3m phase.

4:54PM J39.00013 Achieving unusual oxidation state of matter under high pressure , XIAOLI WANG, Beijing Computational Science Research Center Beijing, 100084, P. R. China Institute of Condensed Matter Physics, Linyi University Linyi 276005, P. R., HAIQING LIN, Beijing Computational Science Research Center Beijing, 100084, P. R. China, YANMING MA, State Key Lab of Superhard Materials, Jilin University Changchun 130012, P. R. China, MAOSHENG MIAO, Materials Research Lab, University of California Santa Barbara, CA 93110, USA — Pressure has many effects to matter including the reduction of the volume, the increase of the coordination number and the broadening of the band-widths. In the past, most of the high-pressure studies focused on structural and electronic state phase transitions. Using first principles calculations and a bias-free structural search method, we will demonstrate that high pressure can lead to high oxidation state of elements that can never be achieved under ambient condition, making high pressure technique a nice tool to explore many traditional topics in solid state and molecular chemistry. As an example, we will show that Hg can transfer the electrons in its outmost d shell to F atoms and form HgF_4 molecular crystals under pressure, thereby acting as a true transition metal. Group IIB elements, including Zn, Cd, and Hg are usually defined as post-transition metals because they are commonly oxidized only to the +2 state. Their d shells are completely filled and do not participate in the formation of chemical bonds. Although the synthesis of HgF_4 molecules in gas phase was reported before, the molecules show strong instabilities and dissociate. Therefore, the transition metal propensity of Hg remains an open question.

5:06PM J39.00014 Dynamic structure of superionic protons in hydrogen fluoride crystal , YOSHIYUKI OHDE, KAZUO TSUMURAYA, Meiji University, Kanagawa, Japan — Hydrogen fluoride crystal forms zig-zag chains of hydrogen fluoride molecules forming covalent bond between them. Goldman et al.(J. Chem. Phys.125,044501(2006).) have found the superionic state of the protons in the hydrogen fluoride crystal at 900 K and beyond the pressures at 33 GPa. The present study elucidates the dynamic structure of the protons in the superionic state of the crystal at the extreme conditions with the first principles molecular dynamics method. The strong covalent bond between the proton and the fluorine in the conductor has shown a different dynamic structure from that in the α-CuI; The protons in the conductor are bonded with the nearest fluorine and the other protons are located at incommensurate sites of the bcc fluorine lattice. This is a different dynamic structure from the formation of the incommensurate dynamic copper dimers in the α-CuI.(Tsumuraya *et al.* J. Phys. Soc. Jpn. 81,055603(2012).)

Session J40 DAMOP: Quantum Simulation II 349 - Khan W. Mahmud, University of Maryland

2:30PM J40.00001 Simulation of a Non-Equilibrium Localization Transition of Photons in a Superconducting Circuit-QED Dimer , DARIUS SADRI, JAMES RAFTERY, ANDREW HOUCK, HAKAN TURECI, Princeton University, SEBASTIAN SCHMIDT, ETH Zurich, DEVIN UNDERWOOD, WILL SHANKS, SRIKANTH SRINIVASAN, MIKOLA BORDYUH, Princeton University — The exponential scaling of Hilbert space dimension with number of quantum degrees of freedom, while serving as a resource for quantum computation, makes simulation of large quantum systems on classical computers prohibitive, particularly when interactions with an environment are included. Quantum simulation promises to make possible the investigation of rich quantum behavior on a controlled quantum mechanical device (effectively a specialized quantum computer), deepening our understanding of fascinating physics such as quantum phase transitions, non-equilibrium quantum dynamics, and quantum chaos. Superconducting circuit Quantum Electrodynamics (cQED) is a promising framework for the realization of such simulators. As a first step, we have constructed a quantum simulator for a conjectured dissipation-driven localization transition of light in a dimer using cQED techniques. A proper understanding of the physics and signature of this transition has been made possible by our development of a new classical simulator based on the stochastic quantum jump method, taking advantage of a fractal structure in our Hamiltonian to enable a study of the very large Hilbert spaces demanded by this problem. We present results of these simulations, and discuss possible future directions.

2:42PM J40.00002 Quantum simulations of cooper pairing and driven nonlinear Schrödinger equation with stationary light , PRIYAM DAS, MINGXIA HUO, CHANGSUK NOH, Center for Quantum Technologies, National University of Singapore, B. M. RODRIGUEZ-LARA, Instituto Nacional de Astrofisica, Optica y Electronica, Mexico, DIMITRIS G. ANGELAKIS, Center for Quantum Technologies, National University of Singapore and Science Department, Technical University of Crete — Strongly correlated states of photons generated in strongly coupled light-matter interfaces, such optical waveguides interacting with ensembles of cold atoms, have recently emerged as promising routes for a new kind of quantum simulators. In this work, we present two of our most recent results along this line, motivated by earlier proposals on strongly interacting stationary polaritons and a proposal to create an effective polaritonic lattice potential. In the first part, we show how to realize an optically tunable two-component Bose-Hubbard model and discuss the feasibility of generating an effective Fermi-Hubbard model of polaritons. This allows one to simulate and detect the 1D analog of the BEC-BCS crossover through correlation measurements. In the second part, we show how a similar setup allows one to study nonlinear transport properties. In the semi-classical regime, the system is formally analogous to a Bose-Einstein condensates in optical lattices or propagation of EM fields in photonic Kerr media, allowing for simulations of similar effects with distinct advantages due to the photonic nature of the proposed system. We conclude by proposing how one of the signature effects of nonlinear dynamics, bistablity, can be experimentally observed in our set up.

2:54PM J40.00003 Experimental investigation of a nonequilibrium delocalization-localization crossover of photons in circuit quantum electrodynamics , JAMES RAFTERY, DARIUS SADRI, MYKOLA BORDYUH, DEVIN UNDERWOOD, WILLIAM SHANKS, SRIKANTH SRINIVASAN, Princeton University, SEBASTIAN SCHMIDT, ETH Zurich, HAKAN TURECI, ANDREW HOUCK, Princeton University — We report measurements of the time-dynamics of a Jaynes-Cummings dimer. The dimer is fabricated in the circuit quantum electrodynamics (cQED) architecture, with two coupled resonators each coupled to a single transmon qubit. Such a system is predicted to exhibit three distinct behavioral regimes: delocalized, in which photons can oscillate between the two cavities; localized, in which photons are locked into a single cavity; and exiguous, in which extremely low photon numbers lead to the disappearance of locking. Dissipation in the system drives crossovers between the regimes. The experimental measurements of the on and off-site correlation functions will be presented.

3:06PM J40.00004 On the phase transition of light in cavity QED lattices , MARCO SCHIRO, Princeton Center for Theoretical Science and Department of Physics, Joseph Henry Laboratories, Princeton University, Princeton, NJ 08544, USA, MYKOLA BORDYUH, BARIS OZTOP, HAKAN TURECI, Department of Electrical Engineering, Princeton University, Princeton, NJ 08544, USA — Systems of strongly interacting atoms and photons, that can be realized wiring up individual cavity QED systems into lattices, are perceived as a new platform for quantum simulation. While sharing important properties with other systems of interacting quantum particles here we argue that the nature of light-matter interaction gives rise to unique features with no analogs in condensed matter or atomic physics setups. By discussing the physics of a lattice model of delocalized photons coupled locally with two-level systems through the elementary light-matter interaction described by the Rabi model, we argue that the inclusion of counter rotating terms, so far neglected, is crucial to stabilize finite-density quantum phases of correlated photons out of the vacuum, with no need for an artificially engineered chemical potential. We show that the competition between photon delocalization and Rabi non-linearity drives the system across a novel Z_2 parity symmetry-breaking quantum criticality between two gapped phases which shares similarities with the Dicke transition of quantum optics and the Ising critical point of quantum magnetism. We discuss the phase diagram as well as the low-energy excitation spectrum and present analytic estimates for critical quantities.

3:18PM J40.00005 Phonon mediated quantum spin simulator made from a two-dimensional Wigner crystal in Penning traps[1] , JOSEPH WANG, Theoretical Division, Los Alamos National Lab, ADAM KEITH, University of Cororado at Boulder, J. K. FREERICKS, Georgetown University — Motivated by recent advances in quantum simulations in a Penning trap, we give a theoretical description for the use of two-dimensional cold ions in a rotating trap as a quantum emulator. The collective axial phonon modes and planar modes are studied in detail, including all effects of the rotating frame. We show the character of the phonon modes and spectrum, which is crucial for engineering exotic spin interactions. In the presence of laser-ion coupling with these coherent phonon excitations, we show theoretically how the spin-spin Hamiltonian can be generated. Specifically, we notice certain parameter regimes in which the level of frustration between spins can be engineered by the coupling to the planar modes. This may be relevant to the quantum simulation of spin-glass physics or other disordered problems.

[1]This work was supported under ARO grant number W911NF0710576 with funds from the DARPA OLE Program. J. K. F. also acknowledges the McDevitt bequest at Georgetown University. A. C. K. also acknowledges support of the National Science Foundation under grant

3:30PM J40.00006 Goldstone and Higgs modes of photons inside an cavity and their detections[1] , YU YIXIANG, Department of Physics and Astronomy, Mississippi State University, Mississippi State, 39762, YU CHEN, Department of Physics, Peking University, Beijing 100871, China, JINWU YE, Department of Physics and Astronomy, Mississippi State University, Mississippi State, 39762, WUMING LIU, Beijing National Laboratory for Condensed Matter Physics, Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China — It was well known that a broken global continuous symmetry leads to two associated collective modes: a massless Goldstone mode and a massive Anderson-Higgs amplitude mode. The two modes have been detected in various condensed matter systems and recently also in cold atom systems. The Higgs mode in particle physics was finally detected in two recent LHC experiments. In this work, we show that the two modes can also be detected in optical systems inside a cavity with only a few (artificial) atoms. We demonstrate this connection by studying the $U(1)$ Dicke (Tavis-Cummings) model where N qubits (atoms) coupled to a single photon mode. We perform both $1/J = 2/N$ expansion and exact diagonization (ED) study on the model. We determine the Goldstone and Higgs modes and theirs corresponding spectral weights from the system's energy spectrum and also from various photon and atom correlation functions. We find nearly perfect agreements between the results achieved from the $1/J$ calculations with those from the ED studies in all these physical quantities even when N gets down even to $N = 2$. The experimental detections of both modes are also discussed.

3:42PM J40.00007 Coherent radiation from a collection of molecules interacting with surface plasmons[1] , MICHAEL STOPA, SEMION SAIKIN, ALAN ASPURU-GUZIK, Harvard University — A collection of molecules interacting coherently with a radiation field has dramatically different absorption and emission properties than the same collection of molecules interacting incoherently with the field. In the former case, the collective states of the molecules become important and these consist of states which radiate super-classically (Dicke superradiance) as well as states which are dark. Treated as two-level systems such a collection of molecules can be thought of as a set of spins. The product state of those spins can be transformed to a basis of states of good total "angular momentum" J, and good J_z (z-component of total angular momentum). Here, we construct a numerical, invertible transformation between the direct product basis and the total J basis for N total molecules. For an arbitrary product state we calculate the rate of transition via radiation out of an arbitrary state in first order perturbation theory. For an ensemble of initial states we calculate the statistical distribution of the radiance (as a function of the J_z quantum number and disorder in the couplings) of the initial state. We show that the average radiance is approximately equal to the classical value but that the distributions have an asymmetric tail toward superradiance.

[1]Supported by DTRA.

3:54PM J40.00008 Exciton-Polaritons condensates with flat bands in a two-dimensional kagome lattice , NA YOUNG KIM, Stanford University, NAOYUKI MASUMOTO, National Institute of Informatics, YOSHIHISA YAMAMOTO, Stanford University, SVEN HOEFLING, ALFRED FORCHEL, University of Wuerzburg — Microcavity exciton-polariton condensates have provided immense opportunity to investigating hydrodynamic vortex properties, superfluidity, and low energy quantum state dynamics. Recently, exciton-condensates have been trapped in various artificial periodic potential geometries: one-dimensional, two-dimensional (2D) square, triangular, and hexagonal lattices. A 2D kagome lattice has been of interest for many decades, which exhibits spin frustration, giving rise to magnetic phase order in real materials. In particular, flat bands in the 2D kagome lattice are physically interesting in that localized states in the real space are formed. Here, we realize exciton-polariton condensates in a 2D kagome lattice potential and examine their photoluminescence properties. Above quantum degeneracy threshold values, we observe meta-stable condensation in high-energy bands; the third band exhibits a signature of weaker dispersive band structures, flat band. We perform single-particle band structure calculation to compare measured band structures.

4:06PM J40.00009 Spinor condensates of ortho- and para-positronium , YI-HSIEH WANG, Chemical Physics Program and Joint Quantum Institute, University of Maryland, CHARLES W. CLARK, Joint Quantum Institute — In 1994, Platzman and Mills [1] considered the possibility of making a Bose-Einstein condensate (BEC) of positronium atoms (Ps). There are four low-lying states of Ps: a singlet, often called parapositronium (p-Ps); and three triplet states, often referred to as orthopositronium (o-Ps). The lifetime against electron- positron annihilation for o-Ps is a thousand times longer than that of p-Ps. By converting a long-lived triplet o-Ps BEC to a p-Ps condensate with a magnetic field, strong γ-ray emission can be generated as the outcome of the annihilation of coherent p-Ps atoms. However, inelastic scattering processes which convert p-Ps atoms to o-Ps may deplete the p-Ps population and further quench the γ emission. We investigate this possibility by treating the system as a spinor condensate, and use the coupled time dependent Gross-Pitaevskii (GP) equations to take into account possible population-exchanging scatterings and annihilation processes in the p-Ps/o-Ps BEC mixture. This GP simulation is used to predict the γ-ray yield in realistic experimental scenarios.

4:18PM J40.00010 Quantum simulation of non-equilibrium dynamical maps with trapped ions , PHILIPP SCHINDLER, Institut für Experimentalphysik, Universität Innsbruck, 6020 Innsbruck, Austria, MARCUS MÜLLER, Departamento de Física Teórica I, Universidad Complutense, 28040 Madrid, Spain , DANIEL NIGG, THOMAS MONZ, Institut für Experimentalphysik, Universität Innsbruck, 6020 Innsbruck, Austria, JULIO T. BARREIRO, LMU München, 80799 München, Germany, ESTEBAN A. MARTINEZ, MARKUS HENNRICH, Institut für Experimentalphysik, Universität Innsbruck, 6020 Innsbruck, Austria, SEBASTIAN DIEHL, PETER ZOLLER, Institut für Theoretische Physik, Universität Innsbruck, und IQOQI, 6020 Innsbruck, Austria, RAINER BLATT, Institut für Experimentalphysik, Universität Innsbruck, und IQOQI, 6020 Innsbruck, Austria — Dynamical maps are central for the understanding of general state transformations of physical systems. Prime examples include classical nonlinear systems undergoing transitions to chaos, or single particle quantum mechanical counterparts showing intriguing phenomena such as dynamical localization. Here, we extend the concept of dynamical maps to an open-system, many-particle context and experimentally explore the stroboscopic dynamics of a complex many-body spin model in a universal quantum simulator using up to five ions. We generate quantum mechanical long range order by an iteration of purely dissipative maps, reveal the characteristic features of a combined coherent and dissipative non-equilibrium evolution, and develop and implement various error detection and reduction techniques that will facilitate the faithful quantum simulation of larger systems.

4:30PM J40.00011 Quantum simulations of neutrino oscillations and the Majorana equation[1] , CHANGSUK NOH, Center for Quantum Technologies, NUS, BLAS RODRIGUEZ-LARA, Instituto Nacional de Astrofisica, Optica y Electronica, Coordinación de Óptica, DIMITRIS ANGELAKIS, Science Department, Technical University of Crete and Center for Quantum Technologies, NUS — Two recent works on quantum simulations of relativistic equations are presented. The first is on neutrino oscillations with trapped ions as a generalization of Dirac equation simulation in 1 spatial dimension. It is shown that with two or more ion qubits it is possible to mimic the flavour oscillations of neutrinos. The second part is on quantum simulations of the Majorana equation based on the earlier work by Casanova et al. (PRX 1, 021018). We show that by decoupling the equation, it is possible to simulate with a smaller number of qubits given that one can perform complete tomography, including the spatial degrees of freedom.

4:42PM J40.00012 Phase Diagram of a driven-dissipative Bose-Hubbard model , ALEXANDRE LE BOITÉ, GIULIANO ORSO, CRISTIANO CIUTI, Laboratoire MPQ, Université Paris Diderot-Paris 7 and CNRS — In recent years, quantum fluids of light in nonlinear optical systems have attracted a lot of interest [1]. In particular, a considerable activity is presently devoted to non-equilibrium many-body phenomena with light, such as superfluid propagation and generation of topological excitations. We present here recent theoretical results on strongly correlated photons in arrays of nonlinear cavities, described by a driven-dissipative Bose-Hubbard model. We have determined the mean-field phase diagram, studied the collective excitations and quantum correlations [2], finding interesting properties which are absent in the equilibrium case.

Session J41 DAMOP: Interacting Bosons in Optical Lattices 350 - Tigran Sedrakyan, University of Minnesota

2:30PM J41.00001 Characterizing boson density wave and valence bond orders in a lattice by its dual vortex degree of freedoms , YAN CHEN, Fudan University, China, JINWU YE, Mississippi State University — A duality transformation in quantum field theory is usually established first through partition functions. It is always important to explore the dual relations between various correlation functions in the transformation. Here, we explore such a dual relation to study quantum phases and phase transitions in an extended boson Hubbard model at $1/3$ $(2/3)$ filling on a triangular lattice. We develop systematically a simple and effective way to use the vortex degree of freedoms on dual lattices to characterize both the density wave and valence bond symmetry breaking patterns of the boson insulating states in the direct lattices. In addition to a checkerboard charge density wave (X-CDW) and a stripe CDW, we find a novel CDW-VBS phase which has both local CDW and local valence bond solid (VBS) orders. Implications on QMC simulations are addressed. The possible experimental realizations of cold atoms loaded on optical lattices are discussed.

2:42PM J41.00002 Expansion dynamics of interacting bosons in homogeneous lattices , STEPHAN LANGER, University of Pittsburgh, LMU Munich, JENS P. RONZHEIMER, MICHAEL SCHREIBER, SIMON BRAUN, SEAN HODGMAN, LMU and MPQ Munich, IAN P. MCCULLOCH, University of Queensland, FABIAN HEIDRICH-MEISNER, FAU Erlangen and LMU Munich, IMMANUEL BLOCH, ULRICH SCHNEIDER, LMU and MPQ Munich — Due to independent real-time control of Hamiltonian parameters in optical lattices, the non-equilibrium transport properties of interacting bosons and fermions can be studied in experiments with ultra-cold atomic gases (see [1] for a sudden expansion experiment with fermions). In this work, we experimentally and numerically investigate the expansion of initially localized bosons in homogeneous one- and two-dimensional optical lattices. Dimensionality has a crucial influence, since one-dimensional systems expand ballistically both in the non-interacting and the strongly interacting limit, separated by a pronounced minimum in the expansion velocity at intermediate interaction strengths. For two-dimensional and sufficiently strongly coupled one-dimensional systems, even weak interactions lead to a dramatic suppression of the expansion, indicative of diffusive dynamics. In the case of one dimension, we find an excellent agreement between the experimental results and time-dependent density-matrix renormalization group simulations. [1] Schneider et al. Nature Phys. 8, 213 (2012)

2:54PM J41.00003 Phase diagram of two-species hard-core bosons in a two-dimensional optical lattice[1] , KALANI HETTIARACHCHILAGE, VALÉRY ROUSSEAU, KA-MING TAM, MARK JARRELL, JUANA MORENO, Louisiana State University, Baton Rouge, LA — We study the finite temperature phase diagram as a function of doping for strongly correlated two-species hard-core bosons in a two-dimensional optical lattice by using Quantum Monte Carlo simulations. This model contains a repulsive interspecies interaction and different hopping terms between nearest neighbors of the two species. The phase diagram shows several competing phases such as an anti-ferromagnetically ordered Mott insulator, a coexistent, a phase separated, a superfluid and a normal liquid phases. Among them, coexistence of anti-ferromagnetic and superfluid phases near half filling and a phase separated region inside superfluid region away from half filling are of main interests. Mott behaviors of heavy species and Mott and superfluid behaviors of light species at low temperatures create this novel phase separation region. At high temperatures only a normal liquid phase appears.

3:06PM J41.00004 Fractional charge separation in the hard-core Bose Hubbard Model on the Kagome Lattice , XUE FENG ZHANG, SEBASTIAN EGGERT, University of Kaiserslautern — We consider the hard core Bose Hubbard Model on a Kagome lattice with fixed (open) boundary conditions on two edges. We find that the fixed boundary conditions lift the degeneracy and freeze the system at 1/3 and 2/3 filling at small hopping. At larger hopping strengths, fractional charges spontaneously separate and are free to move to the edges of the system, which leads to a novel compressible phase with solid order. The compressibility is due to excitations on the edge which display a chrial symmetry breaking that is reminiscent of the quantum Hall effect. Large scale Monte Carlo simulations confirm the analytical calculations.

3:18PM J41.00005 Thermodynamics of the Two-Dimensional Hubbard Model , JAMES LEBLANC, Max-Planck Institute for the Physics of Complex Systems, EMANUEL GULL, University of Michigan — The application of a numerically exact continuous time impurity solver with the DCA dynamical mean field theory has allowed us to study the thermodynamics of the two-dimensional Hubbard model for finite, but large cluster sizes. Variation in cluster size, upwards of 50-sites, allows for extrapolation to the thermodynamic limit. We present results relevant to cold gas systems, such as entropy, double occupancy and nearest-neighbour spin correlations as well as discuss the implications of these calculations on pseudogap physics of the High-Tc Cuprate superconductors away from half filling.

3:30PM J41.00006 Bosonic Mott Insulator with Pseudo-spin Meissner Currents , KARYN LE HUR, Center For Theoretical Physics (CPHT), Ecole Polytechnique and CNRS, 91128 Palaiseau France, ALEXANDRU PETRESCU, Yale University, Physics Department USA and CPHT Ecole Polytechnique France — We introduce a two-component bosonic Mott insulator that can support chiral Meissner edge currents as a result of time-reversal symmetry breaking due to the application of a uniform magnetic field. The key ingredient is the presence of two layers exhibiting both charge (total density) and pseudo-spin (relative density) degrees of freedom. This then allows for a Mott phase characterized by pseudospin edge currents of Meissner type [1]. A simple example can be built from a ladder system [2]. We determine the temperature scale for the existence of such a phase as a function of the interlayer Josephson coupling and interaction. We show that it is possible to probe this phase by introducing gauge fields parallel to the layers, and that in the low-field limit the system exhibits a Meissner effect, in which interlayer currents are suppressed, and the overall current circulation in the layers opposes the applied field. For higher field values the currents organize themselves in vortices, as a result of a commensurate-incommensurate transition.

3:42PM J41.00007 Experimental predictions based on LOAF theory in dilute Bose atomic gases , BOGDAN MIHAILA, Los Alamos National Laboratory — We discuss possible new experimental signatures of correlations in dilute Bose gases with tunable interactions within the framework of LOAF theory. The leading-order auxiliary field (LOAF) theoretical framework is a non-perturbative approximation treating the contributions of the normal and anomalous densities on equal footing [Cooper et al. Phys. Rev. Lett. 105, 240402 (2012)]. LOAF is a conserving and gapless approximation, satisfies Goldstone's theorem, yields a Bose-Einstein transition that is second order, and can be applied outside the regime of weakly-interacting particles.

3:54PM J41.00008 Quadrature interferometry for nonequilbrium ultracold atoms in optical lattices[1] , PHILIP JOHNSON, American University, EITE TIESINGA, Joint Quantum Institute, NIST and University of Maryland — We propose an interaction-based interferometric technique for making time-resolved measurements of quadrature operators of nonequilibrium ultracold atoms in optical lattices. The technique creates two subsystems of magnetic atoms in different spin states and lattice sites–the arms of the interferometer. A Feshbach resonance turns off atom-atom interactions in one spin subsystem, making it a well-characterized reference state, while atoms in the other subsystem undergo nonequilibrium many-body dynamics for a variable hold time. The nonequilibrium evolution can involve a variety of Hamiltonians, including systems with tunneling and spin-orbit couplings using artificial gauge fields. Interfering the subsystems via a second beam-splitting operation, time-resolved quadrature measurements are directly obtained by detecting relative spin populations. Analyzing a simple application of the interferometer, we obtain analytic predictions for quadratures for deep optical lattices with negligible tunneling. As a second, distinct application, we show that atom-atom interaction strengths can in principle be determined with super-Heisenberg scaling $n^{-3/2}$ in the mean number of atoms per lattice site n, making it possible to test the physics of interaction-based quantum metrology.

4:06PM J41.00009 Utilizing nonequilibrium effects to probe the Mott-insulator-superfluid transition of a trapped gas of interacting bosons[1] , LEV VIDMAR, LMU Munich, S. LANGER, University of Pittsburgh, I. MCCULLOCH, University of Queensland, St Lucia, U. SCHOLLWOECK, LMU Munich, U. SCHNEIDER, LMU Munich and MPQ Garching, F. HEIDRICH-MEISNER, FAU Erlangen-Nuremberg and LMU Munich — An increased effort has been lately devoted to explore and establish the possible links between equilibrium and nonequilibrium properties of interacting quantum many-body systems. Recent experiments on optical lattices have shown the possibility of measuring the expansion velocity of an initially trapped system, which after the sudden release of the trap expands in an empty lattice [1]. Recent theoretical studies of interacting fermions indicated that the measurement of expansion velocity may provide information about the initial state [2]. In our work, we show that measuring the expansion velocity of an initially trapped gas of interacting bosons allows one to distinguish between a superfluid and a Mott insulating state in the initial ground state in 1D. We perform time-dependent DMRG calculations of the Bose-Hubbard model in a harmonic trap and a box trap. We derive a state diagram of a trapped system as a function of Coulomb repulsion and density from the expansion velocity. The resulting diagram is consistent with the state diagram obtained by measuring equilibrium properties such as local density fluctuations and on-site compressibility [3]. [1] Schneider et al. Nature Physics 8, 213 (2012) [2] Langer et al., PRA 85, 043618 (2012) [3] Rigol et al, PRA 79, 053605 (2009)

4:18PM J41.00010 Effects of Dissipation in a BEC Dimer , T. PUDLIK, Boston University, H. HENNIG, Harvard University, D. WITTHAUT, MPI-DS, Goettinger, D.K. CAMPBELL, Boston University — Recently[1] we have shown that a "global phase space" (GPS) approach provides valuable understanding of the long-time coherence and Einstein-Podolsky-Rosen entanglement of a Bose-Einstein Condensate trapped in a two-well optical lattice ("BEC dimer"). In particular, the GPS approach allows one to distinguish purely quantum effects from those which are captured by semi-classical methods. The GPS approach in Ref. (1) was applied in the limit of zero dissipation. In the present contribution, we extend the approach to allow for dissipation and again compare the results with relevant experiments. We also report preliminary results on a BEC trimer, for which the semi-classical phase space is no longer completely integrable, in contrast to the the dimer.

4:30PM J41.00011 Higgs boson in two dimensional superfluid and Mott insulator states[1] , KUN CHEN, YUAN HUANG, University of Science and Technology of China and University of Massachusetts, Amherst, LONGXIANG LIU, University of Science and Technology of China, YOUJIN DENG, University of Science and Technology of China and University of Massachusetts, Amherst, LODE POLLET, Ludwig-Maximilians-Universität München, NIKOLAY PROKOF'EV, University of Massachusetts, Amherst and Russian Research Center "Kurchatov Institute" — We find that despite strong decay into Goldstone modes the Higgs boson survives as a well-defined resonance in the two-dimensional relativistic field theory realized in the cold atomic system near the quantum critical point between the superfluid (SF) and Mott insulator(MI) states. Using scaling analysis of analytically continued results from quantum Monte Carlo simulations we construct universal spectral functions for scalar response both for SF and MI phases and reveal that they share similar properties: a resonant peak followed by a broader secondary peak before saturating to a near plateau behavior at higher frequencies, i.e. the Higgs amplitude mode is present in the MI phase under the correlation length scale. Our simulations of a trapped system of ultra-cold ^{87}Rb atoms explain recent experimental data and how the signal is modified by tight confinement.

4:42PM J41.00012 How the scaling behavior changes near the quantum phase transition point? , HAO LEE, SHIANG FANG, DAW-WEI WANG, Physics Department and Frontier Research Center on Fundamental and Applied Sciences of Matter, National Tsing-Hua University, Hsinchu, Taiwan — With unbiased quantum Monte Carlo simulation (worm algorithm), we investigate off-diagonal long-ranged correlation and density-density correlation in two-dimensional Bose-Hubbard model. For a finite size system, we show how the Bose-Einstein condensate and the off-diagonal long-range order can appear before the presence of superfluidity in higher temperature, and demonstrate the difference of the definition of Tc for various model independent methods. Furthermore, we systematically explore the critical behaviors such as the decaying behavior of the single-particle correlation function near the classical (BKT) and quantum phase transition point. We define the regime when the critical behavior works and observe how this regime changes when the critical temperature approaches zero near the quantum critical point (SF-Mott). Our results show the higher order behavior beyond the universal scaling regime, and provides a lot of insight to future experiments on critical behavior near various quantum phase transition.

4:54PM J41.00013 Real space renormalization of the Mott-insulator to Bose-glass transition in the disordered Bose-Hubbard model , ANTHONY HEGG, University of Illinois, Urbana-Champaign, FRANK KRUGER, University of St. Andrews, PHILIP PHILLIPS, University of Illinois, Urbana-Champaign — We show the explicit breakdown of self-averaging, due to rare region Griffiths physics, in the disordered Bose-Hubbard model . The real space renormalization flow of the disorder is toward a Gaussian distribution with vanishing relative variance in the Mott insulator, whereas the Bose glass distribution becomes distinctly non-Gaussian with diverging relative variance. We explore distributions which correspond to a non-trivial fixed point in the renormalization group equations.

5:06PM J41.00014 Anomalous hall phases in a bosonic Mott insulator , CLEMENT WONG, REMBERT DUINE, Utrecht University — Spin-orbit coupled systems that break time-reversal symmetry can exhibit the anomalous hall phase, which support a hall conductivity in the absence of a magnetic field. These topological phases are in a sense the building blocks of topological insulators and bears similarities to chiral topological superconductors. Recently, it has become possible to engineer spin-orbit couplings in cold atomic systems, making it possible to study these systems in the strongly interacting regime, for bosons and fermions. With these motivations, we study spin-orbit coupled bosons in an optical lattice in the Mott-insulating phase using a strong-coupling perturbation theory. We show that quite generally, strong interactions can induce an anomalous Hall phase even for a topologically trivial spin-orbit coupling. For the spin orbit coupling in experiment Lin et. al. [Nature (London) 471, 83 (2011)], we compute the quasiparticle dispersions, spectral weights, renormalized momentum space texture and the associated interaction-generated Berry curvature. Our results have implications for the Mott-insulating phases with textured magnetic order.

5:18PM J41.00015 Superfluid-insulator transition in a disordered two-dimensional quantum rotor model with random on-site interactions , TAEYANG AN, MIN-CHUL CHA, Department of Applied Physics, Hanyang University, Ansan, 426-791, Korea — We study the superfluid-insulator quantum phase transition in a disordered two-dimensional quantum rotor model with random on-site interactions in the presence of particle-hole symmetry. Via worm-algorithm Monte Carlo calculations of superfluid density and compressibility, we find the dynamical critical exponent $z \approx 1.13(2)$ and the correlation length critical exponent $1/\nu \approx 1.1(1)$. These exponents suggest that the insulating phase is a incompressible Mott glass rather than a Bose glass.

Session J42 DCP: Focus Session: Physics of Glasses and Viscous Liquids II Hilton Baltimore Holiday Ballroom 3 - Mark Ediger, University of Wisconsin

2:30PM J42.00001 Theoretical and Computational Studies of Dynamical Heterogeneity and Growing Length Scales in Supercooled Liquids , DAVID REICHMAN, Columbia University — In this talk I review recent progress made by our group and collaborators in elucidating quantitative aspects connected to growing length and time scales in supercooled liquids. In particular, I focus on extraction of static length scales and the relationship between soft modes and dynamical heterogeneity. Connections to jamming are discussed. If time permits, I will discuss recent work on the mean-field theory of growing dynamical length scales in supercooled liquids with respect to critical fluctuations and the putative upper critical dimension.

3:06PM J42.00002 Equilibrium study of a liquid-glass transition , LUDOVIC BERTHIER, CNRS — The liquid-glass transition in dense fluids is characterized by several crossover temperatures, but glasses are obtained without crossing any sharp singularity. The existence of an underlying phase transition, predicted theoretically in some limiting cases, is therefore only supported by uncontrolled extrapolations of macroscopic observables. Here we use a specific random pinning field to induce a liquid-glass transition in a simulated fluid. We discover a range of control parameters for which the transition can be crossed at thermal equilibrium, which allows us to probe for the first time the microscopic nature of an equilibrium glass. Our results, obtained for a range of modest system sizes, suggest that the glass transition is of the random first order type.

3:42PM J42.00003 Static and dynamic length scales in glass-forming liquids , GILLES TARJUS, LPTMC (CNRS/UPMC) — A recurring question about glass formation concerns the collective nature of the dynamics as one cools or compresses a liquid. If the phenomenon is indeed collective, it should be characterized by the development of nontrivial correlations to which one or several typical length scales might be associated. One source of growing correlations has been clearly identified in connection with the increasingly heterogeneous character of the dynamics as one approaches the glass transition. An associated length, commonly referred to as "dynamic", can be extracted from multi-point space-time correlation functions. In addition, several theories of the glass transition posit the existence of a growing "static" length accompanying a liquid's dynamical slowdown. This length is not detectable through standard measurements on pair density correlations, which have been shown to display only unremarkable behavior as the relaxation slows down. However, a number of proposals have been put forward for unveiling such a nontrivial static length. Through computer simulation of model glass-forming liquids, we address the two following central questions: (i) Are the variations with temperature or pressure of these various lengths correlated? (ii) Is the increase of the relaxation time due to the growth of any of the above lengths, or, with less compelling consequences, is it at least correlated to it? While our results rule out the existence of a general principle tying together the evolutions of dynamic and static lengths in glass-forming systems, we discuss how the answer to the above questions depends on the dynamic regime under consideration as well as on the type of material.

4:18PM J42.00004 Correlations between Elementary Relaxation Steps in a Model Glass Former , DIETER BINGEMANN, NAI CHIEN YEAT, Williams College — Despite decades of research the dramatic slowdown of the dynamics in glasses upon cooling remains a mystery. We identify individual, sudden, local, structural relaxation events in a deeply supercooled binary Lennard-Jones system through statistical analysis of the particle trajectories. Correlations between these events in space and time show that (a) relaxation events often occur in clusters (cooperatively rearranging regions), (b) events follow each other in space and time (facilitation), (c) regions with the longest waiting times between events are encapsulated in layers with increasingly shorter waiting times (dynamic heterogeneity), (d) the length scales of these fast and slow regions show very little temperature dependence. Focusing on individual relaxation events we find that large-amplitude vibrations of atoms surrounding each event open a gateway for structural relaxation, hinting at a potential molecular mechanism for the dramatic slowdown of glass dynamics.

4:30PM J42.00005 Diffusion in Crowded Environments: Monte Carlo and Molecular Dynamics Studies[1] , ROBIN SELINGER, PRITHVIRAJ NANDIGRAMI, ANDREW KONYA, Kent State University, JENNIFER TOTH, Grove City College — Anomalous diffusion is sometimes, but not always, observed in dense multicomponent mixtures, e.g. in diffusion of proteins in a lipid membrane [1]. To investigate this phenomenon, we carry out 2-d simulation studies using both on-lattice Monte Carlo and off-lattice Molecular Dynamics. "Tracer" particles are emitted from a source along one side of the simulation cell and absorbed by a sink along the other side, diffusing through a chamber containing "crowder" particles whose number remains constant. On-lattice Monte Carlo studies show that equilibrium tracer flux drops linearly with crowder density, showing non-Fickian behavior well below the percolation threshold. Molecular dynamics studies in the same geometry also show non-Fickian behavior, but tracer flux is a nonlinear function of crowder density. We compare our results with analytical calculations and experimental studies, and discuss implications for understanding diffusion-mediated processes in cell membranes.

4:42PM J42.00006 Crystallization and glass formation in multi-component liquids[1] , KAI ZHANG, MINGLEI WANG, STEFANOS PAPANIKOLAOU, JAN SCHROERS, COREY O'HERN, Yale University — When a liquid is cooled faster than the critical cooling rate, crystallization is avoided, and amorphous solids are formed. What sets the critical cooling rate? We perform molecular dynamics simulations of model metallic alloys—polydisperse spheres with hard-sphere and modified Lennard-Jones interactions—to study the critical cooling rate as a function of the particle size ratio, stoichiometry, and strength of the attractive interactions. We also characterize the structural properties of glassy and crystalline states that form at rapid and slow cooling/compression rates, respectively, using local order parameters, position correlation functions, and Voronoi and other tessellations.

[1]NSF MRSEC DMR-1119826

4:54PM J42.00007 What controls the relaxation time? Lessons learnt from simple liquids' quasiuniversality , JEPPE DYRE, Roskilde University — The relaxation time of a supercooled liquid is extremely temperature and density dependent, approaching hours upon cooling or compression. Is this quantity controlled by the entropy, is it controlled by high-frequency elastic properties as assumed in the shoving and related elastic models, or by another physical property? It is far from certain that there is a simple and generally valid answer to this question for glass-forming liquids with quite different chemistry, but as physicists we like to think that this is the case. The talk summarizes recent results [1] on the quasiuniversality of simple liquids, where a simple liquid is defined as a system with strong virial / potential-energy correlations in the equilibrium NVT fluctuations. Such systems, which include e.g. the Lennard-Jones liquid, have good isomorphs. An isomorph is a curve in the phase diagram along which structure, dynamics, and some thermodynamic properties in reduced units are invariant to a good approximation [2-5]. It was recently conjectured [1] that simple liquids have almost the same isomorphs in the sense that these systems are characterized by a quasiuniversal one-parameter family of reduced-coordinate constant-potential-energy manifolds encoding all isomorph invariants. The entropy is the logarithm of the area of this manifold and the high-frequency elastic properties are basically the surface's curvature. Since the relaxation time is also encoded in the manifold, both quantities will appear to "control" the relaxation time, as will any isomorph invariant.

Session J43 DCP DBIO: Focus Session: Protein Misfolding and Aggregation I Hilton Baltimore Holiday Ballroom 2 - Elsa Yan, Yale University

2:30PM J43.00001 Role of sequence and membrane composition in structure of transmembrane domain of Amyloid Precursor Protein , JOHN STRAUB, Boston University — Aggregation of proteins of known sequence is linked to a variety of neurodegenerative disorders. The amyloid β (Aβ) protein associated with Alzheimer's Disease (AD) is derived from cleavage of the 99 amino acid C-terminal fragment of Amyloid Precursor Protein (APP-C99) by γ-secretase. Certain familial mutations of APP-C99 have been shown to lead to altered production of Aβ protein and the early onset of AD. We describe simulation studies exploring the structure of APP-C99 in micelle and membrane environments. Our studies explore how changes in sequence and membrane composition influence (1) the structure of monomeric APP-C99 and (2) APP-C99 homodimer structure and stability. Comparison of simulation results with recent NMR studies of APP-C99 monomers and dimers in micelle and bicelle environments provide insight into how critical aspects of APP-C99 structure and dimerization correlate with secretase processing, an essential component of the Aβ protein aggregation pathway and AD.

3:06PM J43.00002 Spontaneous Formation of Oligomers and Fibrils in Large-Scale Molecular Dynamics Simulations of A-beta Peptides[1] , CAROL HALL, North Carolina State University — Protein aggregation is associated with serious and eventually-fatal neurodegenerative diseases including Alzheimer's and Parkinson's. While atomic resolution molecular dynamics simulations have been useful in this regard, they are limited to examination of either oligomer formation by a small number of peptides or analysis of the stability of a moderate number of peptides placed in trial or known experimental structures. We describe large scale intermediate-resolution molecular dynamics simulations of the spontaneous formation of fibrils by systems containing large numbers (48) of peptides including A-beta (16-22), and A-beta (17-42) peptides. We trace out the aggregation process from an initial configuration of random coils to proto-filaments with cross-β structures and demonstrate how kinetics dictates the structural details of the fully formed fibril. Fibrillization kinetics depends strongly on the temperature. Nucleation and templated growth via monomer addition occur at and near a transition temperature above which fibrils are unlikely to form. Oligomeric merging and structural rearrangement are observed at lower temperatures.

[1]In collaboration with Mookyung Cheon, Iksoo Chang, Pusan University; and David Latshaw, North Carolina State University.

3:42PM J43.00003 Exploring the Free Energy and Conformational Landscape of Peptides Upon Aggregation and Amyloid Formation , ROLAND WINTER, TU Dortmund University — Using various physical-chemical tools and perturbation parameters, the effects of temperature, pressure as well as lipid interfaces and confining geometries on the various stages of the aggregation and fibrillation reaction of amyloidogenic peptides have been studied. First we show data on the experimentally derived static structure factor obtained for the protein insulin which has been analyzed with a statistical mechanical model based on the DLVO potential. The data reveal that the protein self-assembles into equilibrium clusters already at low concentrations in the pre-nucleation phase. Then, mechanistic details about the nucleation process and concurrent aggregation pathways of insulin and more disease related amyloidogenic peptides, such as IAPP and PrP, and the differential stability of the aggregate structures formed are discussed. Also solvational perturbations, accomplished by the addition of various salts and cosolvents have been explored. They exert pronounced and diversified effects on the unfolding, non-native assembly and fibril formation, which ultimately manifest in morphological variations of mature aggregates and fibrils. Finally, the presence of lipid interfaces and soft-matter confinement will be discussed, which drastically change the aggregation pathway as well as the kinetics of peptide aggregation. Using various model membrane systems, the influence of different membrane characteristics on the lipid-protein interaction has been revealed.

4:18PM J43.00004 Chaotic ("Non-Pathway") Aggregation of β-Amyloid Congener Peptides , STEPHEN C. MEREDITH, The University of Chicago — We compared Aβ_{21-30} and Aβ_{16-34}, with or without N-terminal Cys or cyclization. All Aβ_{21-30} variants were monomeric and unstructured. In contrast, Aβ_{16-34} and Cys-Aβ_{16-34} formed fibrils – the latter more rapidly, due to disulfide bond formation. NMR showed no long-range nOes. In serial NOESYs, after changing pH (3 to 7.4) to initiate aggregation, some chemical shifts did not change, while others changed dramatically. In addition, although signals diminished globally with aggregation, the decay rates for individual peaks varied over $\sim$ 4-fold range. We attribute selective signal loss to conformational constraints restricting local tumbling and/or static structural heterogeneity. Signal decays for Aβ_{16-34} and Cys-Aβ_{16-34} differed in three ways: 1) Decay rates for Cys-Aβ_{16-34} > Aβ_{16-34}; 2) variances for rate constants of Cys-Aβ_{16-34} < Aβ_{16-34} across replicate experiments; 3) smaller variances of rate constants within single experiments for Cys-Aβ_{16-34} than Aβ_{16-34}. These results indicate both acceleration and ordering of aggregation by the disulfide bond in Cys-Aβ_{16-34} compared to which aggregation of Aβ_{16-34} was chaotic and disordered. Our results highlight several essential differences between protein folding and unfolded protein aggregation.

In collaboration with Laura M. Luther, Joshua T.B. Williams, Andrew J. Hawk, and Joseph R. Sachleben, The University of Chicago.

4:54PM J43.00005 Challenges for understanding protein aggregation through computer simulations[1] , NORMAND MOUSSEAU, Université de Montréal — The first computer simulations of protein aggregation were performed a little more than decade ago. Over the years, the community of computer biochemists, chemists and physicists has grown considerably and the simulations becoming more realistic and often closer to experiments, due both to a better understanding of the onset of aggregation and to ever more powerful computers. In view of this expansion both in terms of papers and system size, what have been the real contribution of these simulations to our understanding of amyloid diseases? In this talk, I will present a personal view of the progress that has been accomplished over the last decade. I will aslo discuss some of the challenges that must still be overcome for computer simulations to move to the next level of contributions to this fundamental problem.

Tuesday, March 19, 2013 2:30PM - 5:30PM –

Session J44 DBIO: Biological Networks Hilton Baltimore Holiday Ballroom 1 -

2:30PM J44.00001 Network complexity: when interaction strengths matter more than topology[1] , MIKHAIL TIKHONOV, Joseph Henry Laboratories of Physics, Princeton University, WILLIAM BIALEK, Joseph Henry Laboratories of Physics, Lewis-Sigler Institute for Integrative Genomics, Princeton University — A typical cellular network has thousands of microscopic parameters that cannot all be equally relevant to the network function; yet discarding them and considering only the topology of interactions is unacceptably coarse. How much do quantitative details matter? We present a toy model where the appropriately mesoscopic level of description can be found exactly. We define a measure of network complexity and find that both the choice of topology and strength of interactions can affect the complexity dramatically, but optimizing interaction strengths typically has a stronger effect. We further show that a larger network is not automatically more complex; constructing a high-complexity network always requires a careful adjustment of the strengths of interactions. This suggests that the challenge of "evolving a complex network" does not reduce to making new connections and constructing a dense topology of interactions. Evolution acting on "numbers on arrows" (interaction strengths), even within the confines of a fixed topology, is a much more effective way of increasing complexity than adding new components and connections of some typical strength.

[1]NSF Center for Science of Information

2:42PM J44.00002 Ising models of strongly coupled biological networks with multivariate interactions[1] , LINA MERCHAN, Department of Physics, Emory University, Atlanta, GA 30322, USA, ILYA NEMENMAN, Departments of Physics and Biology, Computational and Life Sciences Initiative, Emory University, Atlanta, GA 30322, USA — Biological networks consist of a large number of variables that can be coupled by complex multivariate interactions. However, several neuroscience and cell biology experiments have reported that observed statistics of network states can be approximated surprisingly well by maximum entropy models that constrain correlations only within pairs of variables. We would like to verify if this reduction in complexity results from intricacies of biological organization, or if it is a more general attribute of these networks. We generate random networks with p-spin ($p > 2$) interactions, with N spins and M interaction terms. The probability distribution of the network states is then calculated and approximated with a maximum entropy model based on constraining pairwise spin correlations. Depending on the M/N ratio and the strength of the interaction terms, we observe a transition where the pairwise approximation is very good to a region where it fails. This resembles the sat-unsat transition in constraint satisfaction problems. We argue that the pairwise model works when the number of highly probable states is small. We argue that many biological systems must operate in a strongly constrained regime, and hence we expect the pairwise approximation to be accurate for a wide class of problems.

2:54PM J44.00003 Add HOC?: dendritic nonlinearities shape higher-than-pairwise correlations and improve coding in noisy (spiking) neural populations[1] , JOEL ZYLBERBERG, ERIC SHEA-BROWN, University of Washington — Recent experiments with relatively large neural populations show significant higher-order correlations (HOC): the data are poorly fit by pair-wise maximum entropy models, but well-fit by higher-order models. We seek to understand how HOC are shaped by the properties of networks and of the neurons therein, and how these HOC affect population coding. In our presentation, we will demonstrate that dendritic non-linearities similar to those observed in physiology experiments are equivalent to beyond-pairwise interactions in a spin-glass-type statistical model: they can either increase, or decrease, the magnitude of the HOC relative to the pair-wise correlations. We will then discuss a population coding model with parameterized pairwise- and higher-order interactions, revealing the conditions under which the beyond-pairwise interactions (dendritic nonlinearities) can increase the mutual information between a given set of stimuli, and the population responses. For jointly Gaussian stimuli, coding performance can be slightly improved by shaping the output HOC via dendritic nonlinearities, if the neural firing rates are low. For skewed stimulus distributions, like the distribution of luminance values in natural images, the performance gains are much larger.

3:06PM J44.00004 Automated adaptive model inference to predict biological network dynamics[1] , BRYAN DANIELS, University of Wisconsin-Madison, ILYA NEMENMAN, Emory University — Dynamical models of cellular regulation often consist of large and intricate networks of interactions at the molecular scale. Since individual interaction parameters are usually difficult to measure, these parameters are often estimated implicitly, using statistical fits. This can lead to overfitting and degradation in the quality of models' predictions. Here we study phenomenological models that adapt their level of detail to the amount of available data, leading to accurate predictions even when microscopic details are not well understood. The model search is made computationally efficient by testing an ordered, nested set of models and by using a model class that can be solved using linear regression in log-space. We test the method on synthetic data and find that phenomenological models inferred this way often outperform detailed, "correct" molecular models in making predictions about responses of the system to signals yet unseen.

[1]This research has been partially supported by Los Alamos LDRD Program and by the James S McDonnell Foundation grant No. 220020321.

3:18PM J44.00005 Using dynamics to identify network topology , SAHAND JAMAL RAHI, The Rockefeller University, KRASIMIRA TSANEVA-ATANASOVA, University of Bristol — To elucidate the topology of a signaling pathway, generally, experimentalists manipulate a cell's molecular architecture, for example, by knocking out genes. Molecular biology techniques, though, are not only invasive and labor-intensive, they have also often been eluded by the complexity of biological networks, e.g., in the case of the gonadotropin-releasing hormone (GnRH) system. Inspired by the rapidly accumulating examples of oscillatory signaling in biology, we explored whether such dynamical stimuli can be used to discriminate different topologies of adaptive pathways, which are ubiquitous in biology. Responses to static inputs are nearly indistinguishable given strong measurement noise. Sine function stimuli, widely used in physics, are difficult to implement in standard microfluidics or optogenetics set-ups and do not simplify the mathematical analysis because of the nonlinearities in these systems. With periodic on-off pulses, which can be easily produced, however, simple adaptive circuit motifs and detailed models from the literature robustly reveal distinct output characteristics, which manifest in how the period of maximal output varies with pulse width. Our calculations provide a framework for using existing methods to discover difficult to reveal mechanisms. Furthermore, our results constrain the possible design principles of the presumed frequency decoders in biological systems where pulsatile signaling has recently been discovered.

3:30PM J44.00006 Characterization of genotype-phenotype mapping of biological networks reconciles robustness-evolvability paradox[1] , CHENGHANG DU, HAO CHEN, CHEN ZENG, Department of Physics, The George Washington University — Typical biological system is both highly robust and highly evolvable. Yet robustness appears against changes whereas evolvability for changes. The concurrence of these two seemingly incompatible features is a central paradox for contemporary evolutionary biology. Using a Boolean model of yeast cell cycle networks, we quantitatively determine (1) the genotype-phenotype mapping. Here genotype stands for the network structure and phenotype for its dynamics; (2) the precise topology of neutral network, i.e. the interconnecting network of networks of different structures but the same dynamics; and (3) the number of new phenotypes in the vicinity of a neutral network. Our results demonstrate that both biological genotype and phenotype are atypical. We next show via sampling that all neutral networks exhibit a similar topology that is simply connected, fractal and sloppy (stiff in certain dimensions but diffusive otherwise). This percolating nature of neutral network leads to a positive correlation between robustness and evolvability and hence resolves the paradox. A likely explanation for such a correlation is that higher robustness results in a larger neutral network, measured by its designability and radius of gyration, which in turn accesses more new phenotypes.

3:42PM J44.00007 Robustness of Network Measures to Link Errors , JOHN PLATIG, MICHELLE GIRVAN, ED OTT, University of Maryland, College Park — Researchers studying biological networks use a variety of measures to identify "important" nodes in their networks. However, the robustness of these measures in the presence of link inaccuracies stemming from noisy data has not been well characterized. Here we present two simple models of false and missing links and their effect on different commonly used centrality measures, focusing particularly on degree centrality, betweenness centrality, and dynamical importance. We show that, compared to degree centrality, betweenness centrality and dynamical importance are much more robust in the face of noise if the false positives are randomly distributed. When the noise has more structure, the differences in the robustness levels of the various metrics can change dramatically.

3:54PM J44.00008 Cascade-likeness is an intrinsic property of biological processes[1] , HAO CHEN, GUANYU WANG, CHENGHANG DU, Department of Physics, George Washington University, RAHUL SIMHA, Department of Computer Science, George Washington University, CHEN ZENG, Department of Physics, George Washington University — A central theme in systems biology is to reveal the intricate relationship between structure, dynamics, and function of biological networks. The biological function is usually realized by the transformation of the relevant molecules through their interacting network. We name this trajectory of transformation as a biological process. In contrast to the structure-centric approach, we take a process-centric view to address such questions as what a biological process looks like and how it differs from an arbitrary process. As an example, we studied a simple Boolean model for the cell cycle process of budding yeast to characterize a large number of putative processes. This computational task was made possible by some highly efficient algorithms we developed. Our results demonstrated that the biological process is very robust and highly designable. Moreover, we uncovered two dynamical rules that dramatically enhance the robustness and designability. Finally, all processes in a system of small size were enumerated and highly designable processes are cascade-like. This implies that cascade-likeness is an intrinsic property of biological processes.

4:06PM J44.00009 Autonomous Boolean Models of Regulatory Networks , MENGYANG SUN, XIANRUI CHENG, JOSHUA SOCOLAR, Duke physics — Autonomous Boolean network (ABN) models have been developed to represent directly the connectivity, logic, and timing of updates in regulatory networks. [1] An ABN is a Boolean network in which the sequence of updates of nodes is determined internally by time delay parameters associated with each link. We propose a method to convert a given ODE model into an ABN that is applicable when the ODE dynamics produces clearly separated high and low values at each node. The ODE parameters are mapped into ABN logic and delay parameters using only local information about each link. Using the example of Ingolia's ODE model of the regulatory network that maintains segment boundaries in the *Drosophila* embryo [2], we show that the resulting ABN model captures both the biologically relevant outcomes and the transient dynamics of the ODE model, and that the ABN framework provides direct insights into the mechanism supporting the biological function. [1] X. Cheng, M. Sun, and J. E. S. Socolar, 2012, J. R. Soc. Interface, (DOI: 10.1098/rsif.2012.0574) [2] Ingolia NT., 2004, PLoS Biol. 2, 805-815. (DOI:10.1371/journal.pbio.0020123)

4:18PM J44.00010 Epigenetic landscapes explain partially reprogrammed cells and identify key reprogramming gene , ALEX LANG, HU LI, JAMES COLLINS, PANKAJ MEHTA, Boston University — A common metaphor for describing development is a rugged epigenetic landscape where cell fates are represented as attracting valleys resulting from a complex regulatory network. Here, we introduce a framework for explicitly constructing epigenetic landscapes that combines genomic data with techniques from physics, specifically Hopfield neural networks. Each cell fate is a dynamic attractor, yet cells can change fate in response to external signals. Our model suggests that partially reprogrammed cells (cells found in reprogramming experiments but not in vivo) are a natural consequence of high-dimensional landscapes and predicts that partially reprogrammed cells should be hybrids that coexpress genes from multiple cell fates. We verify this prediction by reanalyzing existing data sets. Our model reproduces known reprogramming protocols and identifies candidate transcription factors for reprogramming to novel cell fates, suggesting epigenetic landscapes are a powerful paradigm for understanding cellular identity.

4:30PM J44.00011 Phage-bacteria infection networks: From nestedness to modularity[1] , CESAR O. FLORES, Georgia Institute of Techonology, SERGI VALVERDE, University Pompeu Fabra, JOSHUA S. WEITZ, Georgia Institute of Techonology — Bacteriophages (viruses that infect bacteria) are the most abundant biological life-forms on Earth. However, very little is known regarding the structure of phage-bacteria infections. In a recent study we re-evaluated 38 prior studies and demonstrated that phage-bacteria infection networks tend to be statistically nested in small scale communities (Flores et al 2011). Nestedness is consistent with a hierarchy of infection and resistance within phages and bacteria, respectively. However, we predicted that at large scales, phage-bacteria infection networks should be typified by a modular structure. We evaluate and confirm this hypothesis using the most extensive study of phage-bacteria infections (Moebus and Nattkemper 1981). In this study, cross-infections were evaluated between 215 marine phages and 286 marine bacteria. We develop a novel multi-scale network analysis and find that the Moebus and Nattkemper (1981) study, is highly modular (at the whole network scale), yet also exhibits nestedness and modularity at the within-module scale. We examine the role of geography in driving these modular patterns and find evidence that phage-bacteria interactions can exhibit strong similarity despite large distances between sites.

4:42PM J44.00012 Continuum neural dynamics models for visual object identification[1] , VIJAY SINGH, MARTIN TCHERNOOKOV, Dept. of Physics, Emory University, ILYA NEMENMAN, Dept. of Physics & Dept. Of Biology, Emory University — Visual object identification has remained one of the most challenging problems even after decades of research. Most of the current models of the visual cortex represent neurons as discrete elements in a largely feedforward network arrangement. They are generally very specific in the objects they can identify. We develop a continuum model of recurrent, nonlinear neural dynamics in the primary visual cortex, incorporating connectivity patterns and other experimentally observed features of the cortex. The model has an interesting correspondence to the Landau-DeGennes theory of a nematic liquid crystal in two dimensions. We use collective spatiotemporal excitations of the model cortex as a signal for segmentation of contiguous objects from the background clutter. The model is capable of suppressing clutter in images and filling in occluded elements of object contours, resulting in high-precision, high-recall identification of large objects from cluttered scenes.

4:54PM J44.00013 The parameter landscape of a mammalian circadian clock model , CRAIG JOLLEY, HIROKI UEDA, RIKEN Center for Dev. Bio., Laboratory for Systems Biology — In mammals, an intricate system of feedback loops enables autonomous, robust oscillations synchronized with the daily light/dark cycle. Based on recent experimental evidence, we have developed a simplified dynamical model and parameterized it by compiling experimental data on the amplitude, phase, and average baseline of clock gene oscillations. Rather than identifying a single "optimal" parameter set, we used Monte Carlo sampling to explore the fitting landscape. The resulting ensemble of model parameter sets is highly anisotropic, with very large variances along some (non-trivial) linear combinations of parameters and very small variances along others. This suggests that our model exhibits "sloppy" features that have previously been identified in various multi-parameter fitting problems. We will discuss the implications of this model fitting behavior for the reliability of both individual parameter estimates and systems-level predictions of oscillator characteristics, as well as the impact of experimental constraints. The results of this study are likely to be important both for improved understanding of the mammalian circadian oscillator and as a test case for more general questions about the features of systems biology models.

5:06PM J44.00014 Effect of Transcranial Magnetic Stimulation on Neuronal Networks , AHMET UNSAL, RAVI HADIMANI, DAVID JILES, Iowa State University — The human brain contains around 100 billion nerve cells controlling our day to day activities. Consequently, brain disorders often result in impairments such as paralysis, loss of coordination and seizure. It has been said that 1 in 5 Americans suffer some diagnosable mental disorder. There is an urgent need to understand the disorders, prevent them and if possible, develop permanent cure for them. As a result, a significant amount of research activities is being directed towards brain research. Transcranial Magnetic Stimulation (TMS) is a promising tool for diagnosing and treating brain disorders. It is a non-invasive treatment method that produces a current flow in the brain which excites the neurons. Even though TMS has been verified to have advantageous effects on various brain related disorders, there have not been enough studies on the impact of TMS on cells. In this study, we are investigating the electrophysiological effects of TMS on one dimensional neuronal culture grown in a circular pathway. Electrical currents are produced on the neuronal networks depending on the directionality of the applied field. This aids in understanding how neuronal networks react under TMS treatment.

5:18PM J44.00015 Biochemical response and the effects of bariatric surgeries on type 2 diabetes[1] , ROLAND ALLEN, TYLER HUGHES, JIA LERD NG, ROBERTO ORTIZ, Texas A&M University, MICHEL ABOU GHANTOUS, OTHMANE BOUHALI, Texas A&M University at Qatar, ABDELILAH ARREDOUANI, Qatar Biomedical Research Institute — A general method is introduced for calculating the biochemical response to pharmaceuticals, surgeries, or other medical interventions. This method is then applied in a simple model of the response to Roux-en-Y gastric bypass (RYGB) surgery in obese diabetic patients. We specifically address the amazing fact that glycemia correction is usually achieved immediately after RYGB surgery, long before there is any appreciable weight loss. Many studies indicate that this result is not due merely to caloric restriction, and it is usually attributed to an increase in glucagon-like peptide 1 (GLP-1) levels observed after the surgery. However, our model indicates that this mechanism alone is not sufficient to explain either the largest declines in glucose levels or the measured declines in the homeostatic model assessment insulin resistance (HOMA-IR). The most robust additional mechanism would be production of a factor which opens an insulin-independent pathway for glucose transport into cells, perhaps related to the well-established insulin-independent pathway associated with exercise. Potential candidates include bradykinin, a 9 amino acid peptide. If such a substance were found to exist, it would offer hope for medications which mimic the immediate beneficial effect of RYGB surgery.

Tuesday, March 19, 2013 2:30PM - 5:18PM –

Session J45 DBIO: Focus Session: Physics of Proteins II Hilton Baltimore Holiday Ballroom 4 - Wouter Hoff, Oklahoma State University

2:30PM J45.00001 Probing Single-Molecule Protein Conformational Folding-Unfolding Dynamics: The multiple-State and Multiple-Channel Energy Landscape , H. PETER LU, ZHIJIANG WANG, YUFAN HE, Bowling Green State University — The folding-unfolding dynamics of protein provides an important understanding of the protein conformational dynamics and functions. We have used single-molecule fluorescence resonance energy transfer combined with statistical data analysis to characterize enzyme and signaling protein fundamental conformational dynamics of Calmodulin (CaM) and kinase (6-Hydroxymethyl-7,8-dihydropterin pyrophosphokinase, HPPK). The concentration dependence of FRET efficiency of GdmCl indicates the unfolding conformational transition of the proteins. At 2M of denaturant solvent, the majority of the HPPK and CaM protein molecules are under fluctuating folding-unfolding conformational changes, spending about half time in their native state and half time in their unfolded state. We obtained the fluctuation rates from the autocorrelation function analyses of the protein conformational fluctuation trajectories, and we have identified multiple intermediate states involving in bunched time dynamics and the related energy landscape. We had also analyzed the protein folding-unfolding pathways using detailed balance theoretical model analysis in order to understand the complex multiple-state and multiple-channel protein dynamics.

2:42PM J45.00002 Thermodynamics and kinetics of apoazurin folding under macromolecular crowding effect and chemical interference[1]

FABIO ZEGARRA, MARGARET CHEUNG, University of Houston — Proteins fold in a cellular milieu crowded by different kinds of macromolecules. They exert volume exclusion impacting protein folding processes in vivo. Folding processes, however, has been studied by chemical denaturation under in vitro conditions. The impact of the two factors as an attempt to advance the understanding of folding mechanism in vivo is not understood. Here, we investigate the folding mechanisms of apoazurin affected by the macromolecular crowding and chemical interference by using coarse-grained molecular simulations. Crowding agents are modeled as hard-spheres and the chemical denaturation effects are implemented into an energy function of the side chain and backbone interactions. Protein folding stability, mechanism, and kinetics rates of apoazurin under chemical interference and macromolecular crowding conditions are being investigated.

2:54PM J45.00003 Using Electronic Properties of Adamantane Derivatives to Analyze their Ion Channel Interactions: Implications for Alzheimer's Disease[1]

JASON BONACUM, Indiana State University — The derivatives of adamantane, which is a cage-like diamondoid structure, can be used as pharmaceuticals for the treatment of various diseases and disorders such as Alzheimer's disease. These drugs interact with ion channels, and they act by electronically and physically hindering the ion transport. The electronic properties of each compound influence the location and level of ion channel hindrance, and the specific use of each compound depends on the functional groups that are attached to the adamantane base chain. Computational analysis and molecular simulations of these different derivatives and the ion channels can provide useful insight into the effect that the functional groups have on the properties of the compounds. Using this information, conclusions can be made about the pharmaceutical mechanisms, as well as how to improve them or create new beneficial compounds. Focusing on the electronic properties, such as the dipole moments of the derivatives and amino acids in the ion channels, can provide more efficient predictions of how these drugs work and how they can be enhanced.

3:06PM J45.00004 A scoring framework for predicting protein structures

XIAOQIN ZOU, Department of Physics and Astronomy, Department of Biochemistry, Dalton Research Center, and Informatics Institute, University of Missouri-Columbia — We have developed a statistical mechanics-based iterative method to extract statistical atomic interaction potentials from known, non-redundant protein structures. Our method circumvents the long-standing reference state problem in deriving traditional knowledge-based scoring functions, by using rapid iterations through a physical, global convergence function. The rapid convergence of this physics-based method, unlike other parameter optimization methods, warrants the feasibility of deriving distance-dependent, all-atom statistical potentials to keep the scoring accuracy. The derived potentials, referred to as ITScore/Pro, have been validated using three diverse benchmarks: the high-resolution decoy set, the AMBER benchmark decoy set, and the CASP8 decoy set. Significant improvement in performance has been achieved. Finally, comparisons between the potentials of our model and potentials of a knowledge-based scoring function with a randomized reference state have revealed the reason for the better performance of our scoring function, which could provide useful insight into the development of other physical scoring functions. The potentials developed in the present study are generally applicable for structural selection in protein structure prediction.

3:42PM J45.00005 Structure of a protein (H2AX): a comparative study with knowledge-based interactions[1]

MIRIAM FRITSCHE, DIETER HEERMANN, University of Heidelberg, BARRY FARMER, Air Force Research Laboratory, RAS PANDEY, University of Southern Mississippi — The structural and conformational properties of the histone protein H2AX (with143 residues) is studied by a coarse-grained model as a function of temperature (T). Three knowledge-based phenomenological interactions (MJ [1], BT [2], and BFKV [3]) are used as input to a generalized Lennard-Jones potential for residue-residue interactions. Large-scale Monte Carlo simulations are performed to identify similarity and differences in the equilibrium structures with these potentials. Multi-scale structures of the protein are examined by a detailed analysis of their structure functions. We find that the radius of gyration (R_g) of H2AX depends non-monotonically on temperature with a maximum at a characteristic value T_c, a common feature to each interaction. The characteristic temperature and the range of non-monotonic thermal response and decay pattern are, however, sensitive to interactions. A comparison of the structural properties emerging from three potentials will be presented in this talk.

3:54PM J45.00006 Investigation of phonon-like excitation in hydrated protein powders by neutron scattering[1]

XIANG-QIANG (ROSIE) CHU, Wayne State University, EUGENE MAMONTOV, HUGH O'NEILL, QIU ZHANG, ALEXANDER KOLESNIKOV, Oak Ridge National Laboratory — Detecting the phonon dispersion relations in proteins is essential for understanding the intra-protein dynamical behavior. Such study has been attempted by X-ray in recent years [1,2]. However, for such detections, neutrons have significant advantages in resolution and time-efficiency compare to X-rays. Traditionally the collective motions of atoms in protein molecules are hard to detect using neutrons, because of high incoherent scattering background from intrinsic hydrogen atoms in the protein molecules. The recent availability of a fully deuterated green fluorescent protein (GFP) synthesized by the Bio-deuteration Lab at ORNL opens new possibilities to probe collective excitations in proteins using inelastic neutron scattering. Using a direct time-of-flight Fermi chopper neutron spectrometer, we obtained a full map of the meV phonon-like excitations in the fully deuterated protein. The Q range of the observed excitations corresponds to the length scale close to the size of the secondary structures of proteins and reflects the collective intra-protein motions. Our results show that hydration of GFP seems to harden, not soften, the collective motions. This result is counterintuitive but in agreement with the observations by previous neutron scattering experiments [3].

4:06PM J45.00007 Biological Signaling: the Role of "Electrostatic Epicenter" in "Protein Quake" and Receptor Activation , AIHUA XIE, SANDIP KALEDHONKAR, ZHOUYANG KANG, Department of Physics, Oklahoma State University, USA, JOHNNY HENDRIKS, KLAAS HELLINGWERF, Swammerdam Institute for Life Sciences, University of Amsterdam, NL — Activation of a receptor protein during biological signaling is often characterized by a two state model: a receptor state (also called "off state") for detection of a stimuli, and a signaling state ("on state") for signal relay. Receptor activation is a process that a receptor protein is structurally transformed from its receptor state to its signaling state through substantial conformational changes that are recognizable by its downstream signal relay partner. What are the structural and energetic origins for receptor activation in biological signaling? We report extensive evidence that further support the role of "electrostatic epicenter" in driving "protein quake" and receptor activation. Photoactive yellow protein (PYP), a bacterial blue light photoreceptor protein for the negative phototaxis of a salt loving *Halorhodospira halophia*, is employed as a model system in this study. We will discuss potential applications of this receptor activation mechanism to other receptor proteins, including B-RAF receptor protein that is associated with many cancers.

4:18PM J45.00008 Fluctuation-allosteric regulation of protein function: Continuum elastic model and its geometrical implications , MICHAEL S. DIMITRIYEV, PAUL M. GOLDBART, Georgia Institute of Technology, T.C.B. MCLEISH, Durham University — In many proteins, function is strongly modified by the binding of some small ligand to the protein surface. We address the issue of *fluctuation* allostery, in which thermal motion of the protein medium far from the binding site is a key factor in determining the activity of the protein (i.e., the strength with which it functions). We develop a simple, coarse-grained model in which the protein is viewed as a homogeneous, isotropic, elastic continuum of specified shape, and the binding of the ligand is regarded as a small alteration of this shape. We construct a perturbative approach to the response of the thermal fluctuations to a shape-alteration as a diagnostic of the impact on protein activity that ligand binding causes. At leading order in the size of the ligand, we show how this response is determined via familiar geometrical properties of the ligand shape. Thus, we find that there are "sweet spots" for ligand binding—determined by the overall shape of the protein and location of its active site—for which the effects of ligand binding are qualitatively enhanced. To simplify the analysis whilst retaining the essential geometrical ideas, we present results for the case of a scalar field rather than the true vector displacement field of elasticity.

4:30PM J45.00009 Predicting Allostery Wiring Diagrams within Motor Proteins , RIINA TEHVER, Denison University — Motor proteins are intricate molecular machines that make use of allostery as a basis of their function. Fundamental questions in trying to understand the operational mechanism of the motors is, therefore, how allostery communicated is within the proteins, what are the pathways that transmit allosteric signals, how to model and predict them. We have proposed a normal-mode analysis based perturbation model that predicts the pathways based on the structure and chemical composition of the molecules. We use the model to investigate allosteric pathways (allostery wiring diagrams) within motor proteins myosin V and VI.

4:42PM J45.00010 Direct evidence on the force-stabilized calcium binding of the gelsolin G6 domain , YI CAO, CHUNMEI LV, XIANG GAO, MENG QIN, WEI WANG, Department of Physics, Nanjing University — Many proteins are subjected to forces in vivo. However, how force controls the structure, ligand binding and function has only been studied recently with the invention of single molecule force spectroscopy techniques. Generally, force will destabilize the native conformation of a protein and decrease its affinity to ligands. Here we show, for the first time, that force can also increase the ligand binding affinity. We used single molecule force spectroscopy by atomic force microscopy (AFM) to study the effect of calcium binding on the unfolding of the G6 domain of gelsolin. We found that at saturated calcium concentration, the unfolding forces of G6 are $\sim$ 40 pN, which are significantly higher than those of apo G6 of $\sim$ 20 pN. At intermediate calcium concentrations, the unfolding forces show a unimodal distribution, indicating fast inter-conversion rate between apo and holo G6. More strikingly, we found that if the binding constant of G6 is independent of force, the predicted unfolding forces based on the kinetic parameters obtained from apo and holo G6 are significantly lower than the experimentally obtained ones. To reconcile such discrepancy, we proposed a new model, in which we considered that the binding affinity of calcium to G6 is also force dependent. Fitting this model to experimental data clearly indicates that G6 has much higher calcium binding affinity at higher forces. We proposed that such a special force stabilized calcium binding may be important for the function of gelsolin in vivo.

4:54PM J45.00011 THz Microscopy of Anisotropy and Correlated Motions in Protein Crystals[1] , KATHERINE NIESSEN, GHEORGHE ACBAS, Department of Physics, SUNY at Buffalo, Buffalo, New York, EDWARD SNELL, Hauptman-Woodward Medical Research Institute and SUNY at Buffalo, Buffalo, New York, ANDREA MARKELZ, Department of Physics, SUNY at Buffalo, Buffalo, New York — We introduce a new technique, Crystal Anisotropy Terahertz Microscopy (CATM) which can directly measure correlated intra-molecular protein vibrations. The terahertz (THz) frequency range (5-100 cm^{-1}) corresponds to global correlated protein motions, proposed to be essential to protein function [1, 2]. CATM accesses these motions by removal of the relaxational background of the solvent and residue side chain librational motions. We demonstrate narrowband features in the anisotropic absorbance for hen egg-white lysozyme (HEWL) single crystals as well as HEWL with triacetylglucosamine (HEWL-3NAG) inhibitor single crystals. The most prominent features for the HEWL crystals appear at 45 cm^{-1}, 69 cm^{-1}, and 78 cm^{-1} and the strength of the absorption varies with crystal orientation relative to the THz polarization. Calculations show similar anisotropic features, suggesting specific correlated mode identification is possible. 1. Hammes-Schiffer, S. and S.J. Benkovic, Relating Protein Motion to Catalysis. Annu. 5:06PM J45.00012 Intrinsic Mean Square Displacement in Lysozyme , DERYA VURAL, HENRY R. GLYDE, Department of Physics and Astronomy, University of Delaware, LIANG HONG, Oak Ridge National Laboratory — The internal dynamics of proteins is the essential interest of biophysics. The mean square displacement (MSD) of hydrogen in proteins and its associated hydration water is obtained by molecular dynamic (MD) simulation. The MSD as currently determined depends on the time of the MD simulation. A method is proposed in this paper to obtain the intrinsic MSD $\langle r^2 \rangle$ of hydrogen in the proteins. The intrinsic MSD is independent of the simulation time and defined as the infinite time value of calculated MSD that appears in the Debye-Waller factor. The method consists of fitting a model to the incoherent intermediate scattering function. The model contains the intrinsic MSD and a rate constant characterizing the motions of H in the protein. The method is illustrated by obtaining the intrinsic MSD $\langle r^2 \rangle$ of lysozyme in 100 ns and 1 μs MD simulations.

Tuesday, March 19, 2013 2:30PM - 5:42PM –

Session J46 GIMS: Focus Session: X-ray and Neutron Instruments and Measurement Science

Hilton Baltimore Holiday Ballroom 5 - Albert Migliori, Los Alamos National Laboratory

2:30PM J46.00001 Coherent Imaging , STEFANO MARCHESINI, Lawrence Berkeley National Laboratory — No abstract available.

3:06PM J46.00002 Coherent Diffraction Imaging of Device Nanostructures , EDWIN FOHTUNG, JONG WOO, Physics Department University of California, San Diego USA, MARTIN HOLT, Center for Nanoscale Materials, Advanced Photon Source, Argonne, USA, STEPHAN HRUSZKEWYCZ, Materials Science Division, Advanced Photon Source, Argonne, USA, NA LEI, DAFINE RAVELOSONA, Institut d' Electronique Fondamentale, UMR CNRS, and Universite Paris-Sud, 91405 Orsay, France, ROSS HARDER, Advanced Photon Source, Argonne, Illinois 60439, USA, ERIC FULLERTON, Center for Magnetic Recording Research, University of California-San Diego, USA, IAN MCNULTY, Center for Nanoscale Materials, Advanced Photon Source, Argonne, USA, OLEG SHPYRKO, Physics Department University of California, San Diego USA — We employ x-ray coherent diffraction imaging to map the lattice strain distribution, elastic properties and device responses to external stimuli such as magnetic and electric field in a host of device nanostructures. For the case isolated Ni (001) nanowire grown vertically on an amorphous SiO2 /Si substrate we utilize the retrieved projection of lattice distortion to predict the Young's Modulus of the wire based on the elasticity theory [1]. We also image for the first time, the evolution of magnetostriction in these wires in the presence of an external magnetic field. For extended ferroelectric thin films, we utilized the recently developed Bragg Ptychography [2] to image the evolution of ferroelectricity [3].

3:18PM J46.00003 Development of a 10 nm spatial resolution Hard X-ray Microscope for the Nanoprobe beamline at NSLS-II , EVGENY NAZARETSKI, HANFEI YAN, JUNGDAE KIM[1], KENNETH LAUER, KAZIMIERZ GOFRON, Brookhaven National Laboratory, DEMING SHU, Argonne National Laboratory, YONG CHU, Brookhaven National Laboratory — We present recent progress on the development of an x-ray microscope for the Hard X-ray Nanoprobe (HXN) beamline at NSLS-II. We discuss design approach suitable for achieving sub-10 nm spatial resolution x-ray fluorescence and diffraction measurements. Different types of focusing optics e.g. Multilayer Laue Lenses (MLL) and Zone Plates (ZP) will be implemented in the microscope yielding diverse scientific applications for the targeted spatial resolutions of 10 nm and 30 nm respectively. We discuss modular design of the microscope that enables multi-functionality and includes the possibility to regulate temperature at the sample location. The design of the microscope is greatly based on our in-depth evaluation of numerous commercially available components; detailed studies of their performance in terms of mechanical stability, resolution, and thermal characteristics. Also, our design approach greatly relies on extensive experience acquired during construction and subsequent using of a prototype scanning MLL-based microscope.

3:30PM J46.00004 Application of ultra-small-angle X-ray scattering / X-ray photon correlation spectroscopy to relate equilibrium or non-equilibrium dynamics to microstructure[1] , ANDREW ALLEN, FAN ZHANG, LYLE LEVINE, NIST, JAN ILAVSKY, Argonne National Laboratory — Ultra-small-angle X-ray scattering (USAXS) can probe microstructures over the nanometer-to-micrometer scale range. Through use of a small instrument entrance slit, X-ray photon correlation spectroscopy (XPCS) exploits the partial coherence of an X-ray synchrotron undulator beam to provide unprecedented sensitivity to the dynamics of microstructural change. In USAXS/XPCS studies, the dynamics of local structures in a scale range of 100 nm to 1000 nm can be related to an overall hierarchical microstructure extending from 1 nm to more than 1000 nm. Using a point-detection scintillator mode, the equilibrium dynamics at ambient temperature of small particles (which move more slowly than nanoparticles) in aqueous suspension have been quantified directly for the first time. Using a USAXS-XPCS scanning mode for non-equilibrium dynamics incipient processes within dental composites have been elucidated, prior to effects becoming detectable using any other technique.

[1]Use of the Advanced Photon Source, an Office of Science User Facility operated for the United States Department of Energy (U.S. DOE) Office of Science by Argonne National Laboratory, was supported by the U.S. DOE under Contract No. DE-AC02-06CH11357.

3:42PM J46.00005 Solution measurements yield atomic scale resolution , DEREK MENDEZ, JONGMIN SUNG, Stanford Applied Physics, DANIEL RATNER[1], Stanford Linear Accelerator Center, CLEMENT LEVARD, MARC MICHEL, GORDON BROWN, Stanford Geology, SEBASTIAN DONIACH[2], Stanford Applied Physics — A conventional measure on a solution of identical non-interacting particles (e.g. a dilute solution of proteins) is the scattering averaged over all particle orientations. Such scattering results in a 1-D profile, e.g. the standard powder diffraction rings. Here, we aim to recover information that is averaged out in such a measurement. By recording many short, bright X-ray pulses one can obtain the scattering fluctuation, i.e. the 2-photon correlation function. Intensity correlations arise from double scattering events in which two photons from an incoming beam scatter off the same particle, belonging to an ensemble of randomly oriented particles. The double scattering must occur during a single exposure, and before the scatterer has undergone significant diffusion. At wide angles, such correlations have the potential to yield Å-scale single-particle structural information. The problem is to extract correlated events from a background of uncorrelated single-photon scattering events. This is done by forming statistics over an ensemble of correlation measurements and comparing to correlations between uncorrelated pairs of exposures. Samples range from naturally occurring nano-minerals measured using focused synchrotron X-rays, to biomolecules measured using a free electron laser.

3:54PM J46.00006 Interpreting SAXS spectra of non-spherical nonane-water nanodroplets using a new particle form factor[1] , ABDALLA OBEIDAT, FAWAZ HRAHSHEH, GERALD WILEMSKI, Missouri University of Science and Technology, HARSHAD PATHAK, BARBARA WYSLOUZIL, The Ohio State University — The structure of nanodroplets plays a critical role in many natural phenomena involving atmospheric nucleation and aerosol formation. Here, we review our theoretical efforts to interpret experimental measurements of small angle x-ray scattering (SAXS) from nonane/water nanodroplets formed in supersonic nozzles. We simulated nonane/water nanodroplets using classical molecular dynamics (MD) and found that they have a nonspherical Russian-Doll (RD) structure consisting of a roughly spherical water droplet partially wetted by a large nonane lens. We have developed an exact analytical expression for the particle form factor P(q) of a lens-on-sphere droplet with sharp interfaces and uniform lens and sphere densities for use in fitting the experimental data. The model was validated by comparing it with exact results for P(q) based on the MD simulations. Excellent agreement was found. The fits of the measured SAXS spectra generated with this model are good and generally better than those based on simpler structural models, but the resulting particle size distributions do not produce mass balance for either water or nonane. Further work is needed to resolve this discrepancy.

4:06PM J46.00007 Radiation Induced Defect Clusters in Fe and Fe-alloys Investigated by X-Ray Diffuse Scattering Measurements and Molecular Dynamics and Monte Carlo Simulations[1]

, BEN LARSON, Oak Ridge National Laboratory, JON TISCHLER, Argonne National Laboratory, HONGBIN BEI, ROGER STOLLER, HAIXUAN XU, Oak Ridge National Laboratory, YANWEN ZHANG, Oak Ridge National Laboratory/ Univ. TN-K — We have initiated fundamental investigations of 15 MeV Ni-ion induced defect clusters in single crystal Fe and Fe-Cr using diffuse scattering measurements near Bragg reflections combined with molecular dynamics (MD) and self-evolving atomistic kinetic Monte Carlo (SEAK-MC) simulations. Synchrotron x-ray diffuse scattering measurements performed near the (002) reflection of <001>oriented Fe and Fe(30%)Cr single crystals are analyzed within the so-called asymptotic regime using scattering cross-sections based on MD simulated local lattice distortions and SEAK-MC generated interstitial and vacancy cluster configurations. Measurements for Ni-ion irradiations of Fe and Fe-Ni with doses corresponding to 0.2 and 1 displacements per atom (DPA) at ambient temperature will be presented and discussed in connection with the local Bragg scattering interpretation of defect cluster diffuse scattering in ion-irradiated Cu. Methods for calculating diffuse scattering cross sections directly from MD simulations of atomic displacements around vacancy and interstitial loops within the single defect approximation will be considered and the importance of such approaches for complex defect clusters will be addressed.

4:18PM J46.00008 Investigation of the experimental effects on the quality of the rapid acquisition pair distribution function (RA-PDF) data[1]

, AHMAD S. MASADEH, Department of Physics, University of Jordan, Amman 11945, Jordan — Series of experiments have been carried out to investigate the quality of the recently developed rapid acquisition atomic pair distribution function (RA-PDF) method, which combines the uses of high energy X-rays and an image plate area detector. Image plate data for simple elements (C, Mg, Al, Si, Ni, Cu, Zn, Ag, and Pb) have been analyzed, using (RA-PDF) technique. The affect of undiscriminated Compton and fluorescence is investigated for a wide range of materials with atomic Z numbers ranging from 6(Carbon) and 82 (Pb). We find the RA-PDF method is capable of obtaining high quality PDFs where quantitatively reliable structure information can be extracted.

[1]We would also like to acknowledge Dr. Simon Billinge group at NSLS and The University of Jordan for the support.This work was supported in part by (NSF) grant DMR-0304391.Use of the APS is supported by the U.S. DOE, Contract No. W-31-109-Eng-38.

4:30PM J46.00009 Test of the Cross Correlation Method for Efficient Single Crystal Diffuse Neutron Scattering with Elastic Discrimination[1]

, STEPHAN ROSENKRANZ, JOHN PAUL CASTELLAN, RICH VITT, RAYMOND OSBORN, Argonne National Laboratory, RICK RIEDEL, MARIANO RUIZ-RODRIGUEZ, LOREN FUNK, Oak Ridge National Laboratory — Single crystal diffuse scattering provides a powerful probe of the complex disorder associated with many emergent phenomena of great interest. It provides a determination not only of the local distortions around a point defect but also of the length scale and morphology of short-range order on the nanoscale. However, obtaining accurate models of the local structure usually demands measurements over large volumes of reciprocal space with sufficiently high momentum and energy resolution. In order to overcome limitations of current instrumentation, we propose to utilize the cross-correlation method at pulsed neutron sources. This concept that combines the high efficiency of white-beam Laue diffraction for measuring large volumes of reciprocal space with energy discrimination produced by the use of a statistical chopper is currently being implemented in a dedicated instrument, *Corelli* , under construction at the Spallation Neutron Source. Here, we present our detailed investigation of the effectiveness of this method for measuring weak diffuse signals, based on full experiment simulations as well as actual measurements of the diffuse scattering from powder and single crystal samples obtained utilizing the cross correlation method on a prototype instrument.

4:42PM J46.00010 Design of Ultra Small Angle Neutron Scattering (KIST-USANS) at HANARO Cold Neutron Guide, CG4B[1]

, MAN-HO KIM, Korea Institute of Science and Technology — The ultra small angle neutron scattering instrument can measure the lower limit of scattering vector to near Q $\sim$ 2.0x10^{-5} Å^{-1} while the upper limit can reach to an intermediate scattering vector Q $\sim$ 10^{-2} Å^{-1} of a typical small angle neutron scattering (SANS) depending on the contrast of sample. USANS is useful when measuring objects that are micron to submicron in size while SANS is useful when measuring objects that are micron to nano in size. When both USANS and SANS were used together, we could measure sizes from micron to nano scale, which is useful when studying the hierarchical structures in the wide scale of Q and total cross-section, dΣ/dΩ(Q). Recently, KIST has developed the USANS (so called KIST-USANS) at HANARO cold neutron guide hall of KAERI. We will present the instrument design, performance, future plan, and some examples of measurements that cover approximately 11 orders of magnitude in the dΣ/dΩ(Q) and 4 orders in the Q.

4:54PM J46.00011 Photon Source Capabilities of the Jefferson Lab THz to VUV FEL[1]

, G.P. WILLIAMS, S.V. BENSON, D. DOUGLAS, P. EVTUSHENKO, F.E. HANNON, C. HERNANDEZ-GARCIA, J.M. KLOPF, R.A. LEGG, G.R. NEIL, M.D. SHINN, C.D. TENNANT, S. ZHANG, Jefferson Lab — Jefferson Lab operates a sub-picosecond photon science R&D facility with peak and average brightness values that are many orders of magnitude higher than storage rings in the THz - VUV range. It also has multiphoton capabilities that provide unique opportunities for out of equilibrium dynamical studies at time-scales down to $\sim$ 100 fs FWHM. The facility is based on a superconducting energy recovered linac which is operated with CW RF that powers oscillator-based IR and UV Free Electron Lasers (FELs) with diffraction limited sub-picosecond pulses with $> 10^{13}$ photons per pulse (1.0% BW) at pulse repetition frequencies up to 75 MHz. Details of the facility and its present performance will be presented along with some example science applications. In addition we will discuss on-going upgrades to the facility that will allow 10 eV lasing in the fundamental. Finally we will present two potential upgrades including the design of an oscillator-based VUV-FEL that would produce 6 $\times$ 10^{12} coherent (0.5% BW) 100 eV photons per pulse at multi-MHz repetition rates in the fundamental, and a dual FEL configuration that would allow simultaneous lasing at THz and UV wavelengths.

[1]We acknowledge support from the Commonwealth of Virginia. Jefferson Lab is supported by the U.S. DOE under Contract No. DE-AC05-84-ER40150.

5:06PM J46.00012 Picosecond Time-Resolved Strain Rosette at Atomic Length Scale , MARIA I. CAMPANA, G. JACKSON WILLIAMS[1], DePaul University, SOO HEYONG LEE, Korean Research Institute of Standards and Science, DONALD WALKO, Argonne National Laboratory, ERIC LANDAHL[2], DePaul University — Ultrafast optical absorption in a crystalline solid generates coherent motions of strain, which propagate through the bulk at the speed of sound. Energy relaxation dynamics of the excited lattice system and the subsequent transport properties of the strains have been actively studied. Recently, these high-speed transient dynamics have been studied using laser based pump-probe techniques and time resolved x-ray diffraction (TRXD). However, the interpretation of these studies always assumes a uniaxial spatial profile for the strain (i.e. strain is exerted only along the direction of surface normal of the sample). This assumption comes from a symmetry argument originally given by Thomsen: if the illuminated area of the pump laser beam on the sample surface is much larger than the optical penetration depth, strain gradient along surface normal is expected to be much steeper than along lateral direction, and therefore, the strain generated is usually assumed to be one dimensional. While this assumption simplifies the analysis of the data, (and makes possible such applications as picosecond ultrasonics for the in-situ measurement of semiconductor heterostructure thickness), it overlooks any physical processes that take place along transverse direction. Here we report the experimental generation and detection of the transverse component of the impulsively generated strain in a single GaAs crystal using TRXD. Our analysis is based on a strain rosette applied to three non-collinear Bragg reflections.

5:18PM J46.00013 A high-energy x-ray precession camera at the Advanced Photon Source , A. KREYSSIG, D.K. PRATT, M. RAMAZANOGLU, G. TUCKER, Ames Laboratory, Dept. of Physics and Astronomy, Iowa State University, Ames, IA, D.S. ROBINSON, L.C. LANG, Advanced Photon Source, ANL, Argonne, IL, R.J. MCQUEENEY, A.I. GOLDMAN, Ames Laboratory, Dept. of Physics and Astronomy, Iowa State University, Ames, IA — A key distinguishing feature of the APS is the capability for high-energy x-ray scattering, which has been exploited for numerous powder sample applications. The instrumentation for high-energy single-crystal diffraction measurements at the APS, however, remains underdeveloped. High-energy x-rays offer several advantages: (1) absorption effects are minimized and the entire bulk of the sample is probed and; (2) a large range of reciprocal space can be imaged when used together with even a modestly sized area detector. We have developed a high-energy x-ray precession camera (HEXPC) for imaging of reciprocal-space planes. This technique is highly suited to studies of Bragg and diffuse scattering with its flexibility in dynamic range, resolution and scattering vector range. These capabilities have been demonstrated by studies of single crystals and quasicrystals.

The work at the Ames Laboratory was supported by US DOE, Office of Basic Energy Sciences, DMSE, contract DE-AC02-07CH11358.

5:30PM J46.00014 SESAME as a Model Project for Other Regions[1] , HERMAN WINICK[2], SLAC National Accelerator Laboratory — UNESCO became the umbrella organization for SESAME at its Executive Board 164th session, May 2002. The following comments about SESAME were made by this board: "a quintessential UNESCO project combining capacity building with vital peace-building through science" and "a model project for other regions." Now that SESAME is well underway, other regions (e.g.; Africa and Central Asia) should be made aware of this progress, and they should be welcomed to join SESAME as a first step in developing similar projects in their region. Students and scientists from other regions should be encouraged to attend SESAME Users' meeting, schools, workshops, etc. where they can learn about synchrotron radiation sources, beamlines, and science. They should be invited to join SESAME scientists in designing and commissioning accelerators and beamlines, gaining relevant experience for their own projects and helping SESAME in the process.

Session M1 DCMP: Invited Session: Tunable, Intense, Coherent THz Emission From a High Temperature Superconductor Ballroom I - Ulrich Welp, Argonne National Laboratory

8:00AM M1.00001 Hot Spot and THz Wave Generation in $Bi_2Sr_2CaCu_2O_8$ Intrinsic Josephson Junction Stacks , REINHOLD KLEINER, University of Tuebingen — Stacks of intrinsic Josephson junctions made of the high temperature superconductor $Bi_2Sr_2CaCu_2O_8$ have been shown to emit coherent radiation at THz frequencies [1]. Emission is observed both in a low bias regime and a high bias regime. While at low bias the temperature of the stack is close to the bath temperature, at high bias a hot spot and a standing wave, formed in the "cold" part of the stack, coexist [2-5]. THz radiation is very stable in this regime, exhibiting a linewidth which is much smaller than expected from a purely cavity-induced synchronization mechanism [6]. We investigate the interaction of hot spots and THz waves using a combination of transport measurement, direct electromagnetic wave detection and low temperature scanning laser microscopy (LTSLM). In this talk recent developments will be presented, with a focus on the mechanism of hot spot formation.

In collaboration with B. Gross, S. Guénon, M. Y. Li, J. Yuan, N. Kinev, J. Li, A. Ishii, K. Hirata, T. Hatano, R. G. Mints, D. Koelle, V. P. Koshelets, H. B. Wang and P. H. Wu.

8:36AM M1.00002 Towards practical applications of powerful and widely-tunable THz sources made of layered superconductors[1] , HUABING WANG, National Institute for Materials Science (NIMS) — Terahertz (THz) emission from intrinsic Josephson junction stacks made of high temperature superconductor $Bi_2Sr_2CaCu_2O_{8+\delta}$ have been obtained both in a low bias and a high bias regime [1, 2]. While at low bias the temperature distribution in the stack is almost homogeneous, at high bias an over-heated part (hot spot area) and a cold part of the sample coexist [2, 3]. Previous resolution-limited measurements indicated that the linewidth Δf of THz emission may be below 1 GHz, showing no difference between two regimes. In this talk, we report on measurements of the linewidth of THz radiation using a Nb/AlN/NbN integrated receiver for detection [4]. While at low bias we found Δf to be not smaller than ∼500 MHz, at high bias Δf turned out to be as narrow as a few MHz. We attribute this to the hot spot acting as a synchronizing element. Also thanks to the variable size of the hot spot and the temperature rise due to the self-heating, the emission frequency can be tuned over a wide range of up to 500 GHz. Last but not least, the emission power was measured to be above 25 μW. All these properties imply that THz sources made of layered cuprate superconductors can be employed for practical applications.

9:12AM M1.00003 THz Radiation from Mesas of Intrinsic Josephson Junction of $Bi_2Sr_2CaCu_2O_{8+\delta}$ under Extreme Thermal Inhomogeneity[1] , KAZUO KADOWAKI, Graduate School of Pure & Applied Sciences, University of Tsukuba — After the discovery of intense, coherent and continuous electromagnetic waves at terahertz frequencies (THz waves) in 2007,[2] a number of experimental and theoretical works have been carried out to understand the THz radiation phenomena from mesa structure of layered high temperature superconductor $Bi_2Sr_2CaCu_2O_{8+\delta}$ (hereafter abbreviated as Bi2212). At present after five year intensive studies, the basic mechanism of the THz wave emission can be understood by two principles: one is the ac-Josephson effect working in-between individual intrinsic Josephson junctions in the mesa of Bi2212 and the other is the cavity resonance effect associated with both the geometrical shape and the electromagnetic properties of the mesa structures of Bi2212. However, the precise conditions to obtain strong THz radiation are not yet established well at the stage of mesa fabrication.[3] Moreover, it appears that our recent results of measurement of the inhomogeneous temperature distribution due to the hot-spot formation producing gigantic Joule heat in the mesa may give us much more complicated situations to understand physics of the THz radiation.[4] In this talk based on the experimental results we will provide a unified picture of the THz radiation phenomena in spite of highly nonequilibrium thermal condition, which hopefully will give us a hint to improve the performance and the efficiency of the emission power exceeding 1 mW from a single mesa structure. This will be also useful for various applications.

9:48AM M1.00004 Modelling the coherent THz radiation from $Bi_2Sr_2CaCu_2O_{8+\delta}$ mesas of various geometries , RICHARD KLEMM, University of Central Florida — Mesa structures of the high-temperature superconductor $Bi_2Sr_2CaCu_2O_{8+\delta}$ have been prepared in a variety of ways. Groove mesas have so far been made in rectangular, square, circular, triangular, and pentagonal shapes. There are distinct differences in the properties of the radiation that depend strongly on the type and shape of the mesas. Two types of experiments have provided information regarding the mechanism of the coherent radiation: Angular distribution studies and frequency spectrum measurements. In analyzing the angular distribution measurements, we used the Love equivalence principles to model the radiation as arising from two effective sources: the uniform ac Josephson current source, and the radiation from the excitation of an EM cavity mode, and modelled the substrate by a simple image model. We generally found the fractions of the output from these two sources to be comparable in magnitude, implying that the quality factor Q of the EM cavity is very low, allowing for a high degree of output frequency tunability. The largest tunability observed to date from the outer current-voltage characteristic branch was found for an acute isosceles triangular mesa shape. In several geometries, radiation was observed at frequencies far from EM cavity mode frequencies.

10:24AM M1.00005 Intrinsic line shape of electromagnetic radiation from a stack of intrinsic Josephson junctions synchronized by an internal cavity resonance[1] , ALEXEI KOSHELEV[2], Materials Science Division, Argonne National Laboratory — Stacks of intrinsic Josephson-junctions are realized in mesas fabricated out of layered superconducting single crystals, such as $Bi_2Sr_2CaCu_2O_8$ (BSCCO). Synchronization of phase oscillations in different junctions can be facilitated by the coupling to the internal cavity mode leading to powerful and coherent electromagnetic radiation in the terahertz frequency range. An important characteristic of this radiation is the shape of the emission line. A finite line width appears due to different noise sources leading to phase diffusion. We investigated the intrinsic line shape caused by the thermal noise for a mesa fabricated on the top of a BSCCO single crystal. In the ideal case of fully synchronized stack the finite line width is coming from two main contributions, the quasiparticle-current noise inside the mesa and the fluctuating radiation in the base crystal. We compute both contributions and conclude that for realistic mesa's parameters the second mechanism typically dominates. The role of the cavity quality factor in the emission line spectrum is clarified. Analytical results were verified by numerical simulations. In real mesa structures part of the stack may not be synchronized and chaotic dynamics of unsynchronized junctions may determine the real line width.

Session M2 DCMP: Invited Session: Interaction-Driven Quantum Hall States in Graphene

Ballroom II - Pablo Jarillo-Herrero, Massachusetts Institute of Technology

8:00AM M2.00001 Unconventional Sequence of Fractional Quantum Hall States in Graphene , BENJAMIN FELDMAN, Harvard University, Department of Physics — Electronic compressibility is a powerful tool for the study of correlated electron phases in two-dimensional electron systems. Using a scanning single-electron transistor, we have measured the local electronic compressibility of suspended graphene in the quantum Hall regime. The local nature of the measurement technique allows us to probe exceptionally clean regions of graphene, revealing delicate many-body effects that are obscured by disorder in global transport studies. In this talk, I will review recent measurements of the fractional quantum Hall effect (FQHE) in graphene. We observe a multitude of FQH states that follow the standard composite fermion sequence between $\nu = 0$ and 1, but only occur at even-numerator fractions between $\nu = 1$ and 2, suggesting that an underlying symmetry remains. Moreover, we observe a series of phase transitions in the FQH states between $\nu = 0$ and 1 that are marked by a decreased energy gap and a narrow region of negative compressibility that cuts across the FQH state. We use a simple model based on crossing composite fermion Landau levels with different internal degrees of freedom to reproduce much of the experimental behavior. Our results provide insight into the interplay between electron-electron interactions and the spin and valley symmetries of graphene.

8:36AM M2.00002 Phase diagram and edge excitations of the $\nu = 0$ quantum Hall state in graphene[1] , MAXIM KHARITONOV, Center for Materials Theory, Rutgers University — The interaction-induced broken-symmetry incompressible quantum Hall states in graphene at integer and fractional filling factors have by now been firmly established in transport and compressibility measurements. However, identifying their precise nature (e.g., how the symmetry is broken) still remains a tough challenge: on the experimental side, transport and compressibility probes do not provide direct information about the physical order; on the theoretical side, the presence of additional to spin discrete degrees of freedom, valleys, results in a variety of competing phases in this multicomponent system. As the prime example of this rich behavior, I will present a generic phase diagram for the intriguing $\nu = 0$ state, obtained within the framework of quantum Hall "ferromagnetism." The diagram consists of the canted antiferromagnetic, ferromagnetic, charge-density-wave (charge-layer-polarized), and Kekulé (interlayer-coherent) phases in monolayer (bilayer). I will then discuss the edge excitations of the $\nu = 0$ state. Remarkably, the edge excitations are nonuniversal (e.g., can be gapped or gapless) and crucially depend on which phase is realized in the bulk of the system. Besides being of considerable theoretical interest, these unprecedented properties simultaneously allow one to infer about the nature of the phases from the transport experiments. I will present arguments based on this analysis and existing data why the insulating $\nu = 0$ state realized in real bilayer (and possibly, monolayer) graphene is likely to be canted antiferromagnetic. Finally, I will mention how this theoretical framework can be generalized to fractional quantum Hall states in graphene, which could shed light on some of the puzzling features of the recent experiments.

9:12AM M2.00003 Spin and Valley Quantum Hall Ferromagnetism and Quantum Phase Transitions in Graphene , CORY DEAN, Columbia University — No abstract available.

9:48AM M2.00004 Tunable electron interactions and robust non-Abelian quantum Hall states in graphene and other Dirac materials[1] , DMITRY ABANIN, Perimeter Institute for Theoretical Physics — Discovery of the fractional quantum Hall effect inspired a concept of quasiparticles with non-Abelian exchange statistics. However, a major limitation for experimental studies of non-Abelian quasiparticles in traditional GaAs-based 2d systems is their lack of tunability: the effective electron interactions in such systems are fixed at values which make non-Abelian states either absent of very fragile. Therefore it is desirable to find alternative, tunable 2d systems that host robust non-Abelian quantum Hall states. In this talk, we will discuss the phase diagram of fractional quantum Hall states in recently discovered 2d Dirac materials (graphene, bilayer graphene, topological insulators). We will show that the effective interactions in these materials can be naturally tuned in a broad range, in contrast to GaAs. This tunability is achieved by external fields that control the mass gap of Dirac fermions. Alternatively, the effective interactions can be controlled by engineering the dielectric environment of the 2d Dirac electron gas. We will demonstrate that the tunability of interactions in Dirac materials allows one to stabilize non-Abelian states, as well as to drive phase transitions between various correlated phases (quantum Hall states, Fermi-liquid-like states, and states with broken translational symmetry) in a controlled manner. Connecting to experiments, we will argue that a very promising candidate material for tuning interactions and stabilizing non-Abelian states is bilayer graphene, where the gap can be naturally controlled by perpendicular electric field. Our study provides a realistic route towards engineering robust fractional and non-Abelian quantum Hall states in graphene and other Dirac materials.

10:24AM M2.00005 Superconducting states in graphene , BRUNO UCHOA, University of Oklahoma — In spite of the remarkable electronic properties of graphene, which include the existence of massless Dirac quasiparticles, the low density of states near the Dirac points seems to conspire against the formation of new many body ground states. In this context, the search for intriscic superconductivity in graphene has involved either combining graphene with other materials [1], or else exploring ways to modify the electronic density of states at the Fermi level. In this talk, after discussing the classification of symmetry states in the honeycomb lattice and analysing the general thermodynamic properties for Dirac fermion superconductors [2], I will describe a few promissing mechanisms to induce superconductivity in graphene. In particular, I will show that in the situation where strain effects lead to a reconstruction of the vacuum into a discrete spectrum of Landau levels due to pseudo magnetic fields, which preserve overall time reversal symmetry, superconductivity is quantum critical at integer filling of the Landau levels, when the system is incompressible. At partial filling, the quenching of the kinetic energy due to the Landau levels leads to a crossover to a non-Fermi liquid regime, where the critical temperature scales linearly with the coupling in the weak coupling limit. I will show that the critical temperature can be orders of magnitude larger than in conventional weak coupling superconductors, and may be triggered by phonons.

Session M3 DCMP: Invited Session: Novel Quantum Phases in Artificial Lattices and Networks

Ballroom III - Steven Louie, University of California, Berkeley

8:00AM M3.00001 Mott-Hubbard Physics in a Patterned GaAs Heterostructure with Honeycomb Topology[1] , VITTORIO PELLEGRINI, NEST CNR-NANO and Scuola Normale Superiore, Pisa (Italy) — This talk considers efforts directed towards the design and exploration of novel collective electron states in artificial lattice structures that are realized in semiconductor heterostructures by nanofabrication methods. These studies reveal striking interplays between electron interactions and geometrical constraints (topology). We focus on the honeycomb topology, or "artificial graphene" (AG) [1,2], that supports Dirac fermions. Dirac fermions and the emergence of quantum phases, such as spin liquids and topologically protected states, can be studied by highly demanding inelastic light scattering methods and by electrical transport at low temperatures [3,4]. In particular, we probed the excitation spectrum of electrons in the honeycomb lattice in a magnetic field identifying collective modes that emerged from the Coulomb interaction [4], as predicted by the Mott-Hubbard model [5]. These observations allow us to determine the Hubbard gap and suggest the existence of a Coulomb-driven ground state [4]. Studies of electrons confined to artificial lattices should provide key perspectives on strong electron correlation in condensed matter science.

8:36AM M3.00002 Dirac Fermions in a Nanopatterned Two-Dimensional Electron Gas[1] , CHEOL-HWAN PARK, Department of Physics and Astronomy and Center for Theoretical Physics, Seoul National University — If a lateral periodic potential with triangular (or honeycomb) lattice symmetry is applied to a conventional two-dimensional electron gas (2DEG), the charge carriers behave like massless Dirac ferions [1,2]. A very interesting and useful point of these newly-generated massless Dirac fermions is that, unlike the case of graphene, their properties can be tuned through the external periodic potential. In this presentation, I will review the electronic properties of those newly-generated massless Dirac fermions in an artificial 2DEG superlattice system and will discuss how the elecctronic structure of those massless Dirac fermions changes depending on the external periodic potential [3].

9:12AM M3.00003 Designer Dirac Fermions, Topological Phases, and Gauge Fields in Molecular Graphene , HARI C. MANOHARAN, Department of Physics, Stanford University / Stanford Institute for Materials and Energy Sciences — The observation of massless Dirac fermions in monolayer graphene has propelled a new area of science and technology seeking to harness charge carriers that behave relativistically within solid-state materials. Using low-temperature scanning tunneling microscopy and spectroscopy, we show the emergence of Dirac fermions in a fully tunable condensed-matter system—molecular graphene—assembled via atomic manipulation of a conventional two-dimensional electron system in a surface state. We embed, image, and tune the symmetries underlying the two-dimensional Dirac equation into these electrons by sculpting the surface potential with manipulated molecules. By distorting the effective electron hopping parameters into a Kekulé pattern, we find that these natively massless Dirac particles can be endowed with a tunable mass engendered by the associated scalar gauge field, in analogy to the Higgs field. With altered symmetry and texturing of the assembled lattices, the Dirac fermions can be dressed with gauge electric or magnetic fields such that the carriers believe they are in real fields and condense into the corresponding ground state, as confirmed by tunneling spectroscopy. Using these techniques we ultimately fabricate a quantum Hall state without breaking time-reversal symmetry, in which electrons quantize in a gauge magnetic field ramped to 60 Tesla with zero applied laboratory field. We show that these and other chiral states now possible to realize have direct analogues in topological insulators, and can be used to guide or confine charge in nontrivial ways [1].

9:48AM M3.00004 Electron-electron interactions in artificial graphene , ESA RASANEN, Department of Physics, Tampere University of Technology — Recent advances in the creation and modulation of graphenelike systems are introducing a science of "designer Dirac materials." In its original definition, artificial graphene is a man-made nanostructure that consists of identical potential wells (quantum dots) arranged in an adjustable honeycomb lattice in the two-dimensional electron gas. As our ability to control the quality of artificial graphene samples improves, so grows the need for an accurate theory of its electronic properties, including the effects of electron-electron interactions. Here we determine those effects on the band structure and on the emergence of Dirac points, and discuss future investigations and challenges in this field.

10:24AM M3.00005 Quantum Simulation with Circuit QED , ANDREW HOUCK, Princeton University — Superconducting circuits and circuit quantum electrodynamics provide an excellent toolbox for non-equilibrium quantum simulation. In circuit QED, the strong interaction of light with a single qubit can lead to strong qubit-mediated photon-photon interactions. Recent theoretical proposals have predicted phase transitions in arrays of these cavities, demonstrating that complex matter-like phenomena can emerge with such interacting photons. Due to inevitable photon dissipation and the ease of adding photons through driving, these systems are fundamentally open and a useful tool for studying non-equilibrium physics. I will discuss recent experimental and theoretical progress towards realization of these non-equilibrium quantum simulators. I will focus on a localization-delocalization crossover in a pair of coupled cavities, and discuss preliminary measurements of large cavity arrays. I will discuss a variety of available measurements in these systems, including transport, photon number statistics, and a scanned local quantum probe.

Wednesday, March 20, 2013 8:00AM - 11:00AM –

Session M4 DAMOP: Invited Session: Quantum Simulation with Photons Ballroom IV - Ivan Deutsch, University of New Mexico

8:00AM M4.00001 High Orbital Exciton-Polariton Condensates in Two-Dimensional Lattices , NA YOUNG KIM, Stanford University — Microcavity exciton-polaritons are hybrid quantum quasi-particles as admixtures of cavity photons and quantum-well excitons. The inherent light-matter duality provides experimental advantages to undergo a phase change to condensation at high temperatures (e.g. 4-10 K in GaAs and room temperatures in GaN materials) due to the extremely light effective mass and stimulated scattering processes, and the dynamical nature in the open-dissipative condition allows us to control orbital symmetries of condensates. We have engineered two-dimensional polariton-lattice systems for the investigation of exotic quantum phase order arising from high orbital bands. Via photoluminescence signals in both real and momentum coordinates, we have observed d-orbital meta-stable condensation, vortex-antivortex phase order, linear Dirac dispersion, and flattened band structures in square, honeycomb, triangular and kagome lattices respectively. We envision that the polariton-lattice systems will be promising solid-state quantum emulators in the quest for understanding strongly correlated materials and in the development of novel optoelectronic devices.

8:36AM M4.00002 Quantum Hall physics with light , JACOB TAYLOR, Joint Quantum Institute/National Institute of Standards and Technology — Quantum Hall physics provides a variety of novel phenomena in both the integer and fractional domain, with applications in metrology, technology, and quantum computation. I will discuss implementing quantum Hall physics with optical systems by means of synthetic gauge fields and photon-photon interactions. First, in the integer quantum Hall regime, I consider our theoretical and experimental efforts using established photonics technology to see expected phenomena, such as edge states of light. I will then consider the nonlinear regime, where photon-photon interactions via optical or microwave nonlinearities enable the potential realization of fractional quantum Hall states, and indicate challenges and solutions for examining pumped, non-equilibrium systems that do not admit a mean-field description. Finally, potential applications of these ideas in passive and active photonics will be examined.

9:12AM M4.00003 Many body physics with light[1] , HAKAN E. TURECI, Princeton University — Systems of strongly interacting atoms and photons, which can be realized wiring up individual Cavity QED (CQED) systems into lattices, are perceived as a new platform for quantum simulation [1-3]. While sharing important properties with other systems of interacting quantum particles, the nature of light-matter interaction gives rise to unique features with no analogs in condensed matter or atomic physics setups. Such Lattice CQED systems operate on polaritonic quasi-particles that are hybrids of light and matter in a controllable proportion, combining long-range coherence of photons and strong interactions typically displayed by massive particles. In this talk, I will discuss our recent efforts [4-6] on the possibility of observing quantum many body physics and quantum phase transitions in Lattice CQED systems. Unavoidable photon loss coupled with the ease of feeding in additional photons through continuous external driving renders such lattices open quantum systems [5]. Another key aspect of many body physics with light that I will focus on is the particle number non-conserving nature of the fundamental light-matter interaction [6] and the question of what quantity, if not the chemical potential, can stabilize finite density quantum phases of correlated photons.

9:48AM M4.00004 Bose-Einstein condensation of photons , JAN KLAERS, Institut fur Angewandte Physik, Universitat Bonn, Wegelerstr. 8, 53111 Bonn, Germany — In recent work, we have observed Bose-Einstein condensation (BEC) of a two-dimensional photon gas in an optical microcavity [1]. Here, the transversal motional degrees of freedom of the photons are thermally coupled to the cavity environment by multiple absorption-fluorescence cycles in a dye medium, with the latter serving both as a heat bath and a particle reservoir. The photon energies in this system are found to follow a Bose-Einstein distribution at room temperature. Upon reaching a critical total photon number, a condensation into the transversal ground state of the resonator sets in, while the population of the transversally excited modes roughly saturates. The critical photon number is experimentally verified to agree well with theoretical predictions. Owing to particle exchange between the photon gas and the dye molecules, grandcanonical experimental conditions can approximately be realized in this system. Under these conditions, two markedly different condensate regimes are theoretically expected [2]. On the one hand, this includes a condensate with Poissonian photon number statistics, being the analog to present atomic Bose condensates. Additionally, we predict a second regime with anomalously large condensate fluctuations accompanied by a Bose-Einstein-like photon number distribution that is not observed in present atomic BEC experiments. The crossover between these two regimes, corresponding to the emergence of second-order coherence, depends on the size of the molecular reservoir (e.g. the dye concentration) and is expected to occur at a temperature below the BEC phase transition. In my talk, I will give an update on our experimental work.

10:24AM M4.00005 From Mott transitions to interacting relativistic theories with light: A brief history of photonic quantum simulators , DIMITRIS G. ANGELAKIS, Centre for Quantum Technologies Singapore/Technical University of Crete — I will start by reviewing our early works for observing photon-blockade induced Mott transitions in coupled cavity QED systems [1]. After briefly touching on the idea of simulating spin-models and the Fractional Hall effect [2], I will analyze more recent developments in realizing continuous 1D models in nonlinear optical fibers exhibiting electromagnetically induced transparency nonlinearities. Here the concept of the "photonic Luttinger liquid" will be introduced, along with a proposal to observe spin-charge separation with polarized photons in a nonlinear slow light set up [3]. I will continue by presenting our recent efforts in simulating 1D lattice models in the non-relativistic regime, such as the sine-Gordon and Bose-Hubbard [4], and the efforts for simulations of out of equilibrium phenomena using driven systems [5,6]. I will conclude by presenting ongoing work on interacting relativistic models (Thirring)[7]. Possible experimental implementations in quantum optical systems such as photonic crystals, optical fibers coupled to cold atoms, and Circuit QED will be discussed.

Session M5 DMP DCOMP: Focus Session: Computational Discovery and Design of New Materials: Semiconductors, Molecular Systems and Interfaces 301 - Joerg Neugebaur, Max-Planck Institute fuer Eisenforschung

8:00AM M5.00001 ReaxFF-based molecular dynamics studies on reactions at complex material surfaces , ADRI VAN DUIN, Penn State — The ReaxFF method provides a highly transferable simulation method for atomistic scale simulations on chemical reactions at the nanosecond and nanometer scale. It combines concepts of bond-order based potentials with a polarizable charge distribution. Since it initial development for hydrocarbons in 2001, we have found this concept to be highly transferable, leading to applications to elements all across the periodic table, including all first row elements, metals, ceramics and ionic materials. In this presentation we will provide an overview of recent developments of the ReaxFF method for reactions at the complex material interfaces, in particular TiO_2/water, silica/water and graphite/oxygen interfaces. We will describe the ReaxFF parameter development process and show how, by employing parallel molecular dynamics methods, ReaxFF can assist in bridging the gap between atomistic-scale simulations and experiment. We will also discuss new developments in metadynamics and Monte Carlo based implementations of ReaxFF, which enable us to extend molecular dynamics simulation times to beyond hundreds of nanoseconds.

8:36AM M5.00002 Reliable Modeling of Complex Organic/Metal Interfaces , WEI LIU, SERGEY FILIMONOV, VICTOR G. RUIZ, MATTHIAS SCHEFFLER, ALEXANDRE TKATCHENKO, Fritz-Haber-Institut der MPG, Berlin, Germany — The understanding of electronic properties of complex organic/metal interfaces requires a reliable method for the prediction of their structure and stability. The bonding at complex interfaces arises from delicate balance between covalent bonds, van der Waals (vdW) forces, charge transfer, and Pauli repulsion. We developed a method based on density-functional theory with vdW interactions (PBE+vdW$^{\rm surf}$ [1]) to accurately model adsorbates on surfaces, by a synergetic linkage of the PBE+vdW [2] for intermolecular interactions with the Lifshitz-Zaremba-Kohn theory [3] for the dielectric screening within the substrate surface. This method is demonstrated to reliably model a multitude of molecules on metal surfaces [1,4], leading to an accuracy of 0.1 Å in adsorption heights and 0.1 eV in binding energies wrt experiments. To demonstrate the predictive power of the PBE+vdW$^{\rm surf}$, we design a novel type of single-molecule push button switch, by carefully controlling the stability and activation barrier between a chemically bound state and a physically bound state for benzene derivatives adsorbed on metal surfaces.

8:48AM M5.00003 A High-Throughput Computational Search for New Transparent Conducting Oxides , GEOFFROY HAUTIER, ANNA MIGLIO, Universite Catholique de Louvain, GERBRAND CEDER, Massachusetts Institute of Technology, GIAN-MARCO RIGNANESE, XAVIER GONZE, Universite Catholique de Louvain — Transparent conducting oxides (TCOs) are critical to many technologies from solar cells to electronics. However, finding materials that combine the two antagonistic properties of large conductivity and transparency to the visible light can be extremely challenging. In this talk, we will present a high-throughput screening approach aimed at discovering new high-performance TCOs. Combining different *ab initio* techniques from density functional theory to GW, we evaluated thousands of oxides in terms of essential TCO properties (e.g., band gap and carrier transport). From these results, we will present new interesting compounds as well as discuss the chemistries likely to form high performance TCOs.

9:00AM M5.00004 Generation and analysis of the largest ab initio database for metal borides , ABRAM VAN DER GEEST, ALEKSEY KOLMOGOROV, Binghamton University - SUNY — Boron-based materials have been observed in a remarkable variety of crystal structures with outstanding superconducting, mechanical, and refractory properties. Aiming to provide a systematic description of known compounds and to identify new synthesizable candidate materials, we have generated an extensive ab initio database spanning over 40 binary and ternary metal boride systems at ambient and gigapascal pressures. The considered crystal structures include known prototypes listed in the ICSD as well as brand-new prototypes found with an evolutionary search implemented in MAISE [1]. Having examined over 15,000 entries of calculated formation enthalpies, we find a number of surprising disagreements between theory and experiment regarding the ground state crystal structures and identify over a dozen systems in which novel compounds are expected to form under high pressures. Data mining of the ab initio information has revealed trends in the electronic, magnetic, vibrational, and elastic properties which can help fine-tune the metal boride materials for specific applications. [1] Module for Ab Initio Structure Evolution, http://maise-guide.org

9:12AM M5.00005 Mechanistic Design of New Materials and Processes through Multifunctional Atomic-Scale Simulations , SUSAN SINNOTT, University of Florida — Multifunctional systems that contain heterogeneous interfaces are ubiquitous in numerous applications, including catalysis, electronic devices, friction, and coatings. Traditionally, computational studies of these complex interfacial systems have relied on methods such as first-principles density functional theory (DFT), because of the difficulty in describing the changes in bonding environment with empirical approaches. Here, empirical, charge optimized many-body (COMB) potentials are used in classical, atomic-scale simulations to examine several model systems that involve heterogeneous material interfaces or surface reactions at size scales that are much larger than are currently tractable with traditional DFT methods. . The COMB potentials allow for dynamic charge transfer between atoms and across interfaces, and are demonstrated to describe metallic, covalent, and ionic bonding across interfaces and at surfaces. The simulations yield mechanistic insights that allow for the design of materials and optimization of process conditions for several applications, including catalysis, thin-film growth, and supported two-dimensional materials with well-defined interfacial interactions.

9:48AM M5.00006 Towards Reliable Predictions of Molecular Materials , ANTHONY REILLY, ALEXANDRE TKATCHENKO, Fritz-Haber-Institut der MPG, Berlin, Germany — While dispersion interactions are known to be essential to the stability and accurate prediction of molecular-crystal structures, the vast majority of computational methods use simple pairwise approximations to model these interactions, ignoring the non-additive, many-body nature of long-range electron correlation. Here we use the recently developed many-body dispersion (MBD) method (PRL 108, 236402; PNAS 109, 14791) together with a representative database of molecular crystals, to illustrate how important electrodynamic screening and many-body contributions are to crystal stability. Crucially, these MBD contributions allow DFT calculations to reach the highly coveted "chemical accuracy" with respect to high-level calculations and experiments in both the crystalline and gaseous phases. This ability to treat molecular solids and their components on such an accurate and equal footing is essential for controled and informed design of complex materials.

10:00AM M5.00007 Property optimization in isovalent and aliovalent semiconductor alloys based on MnO[1] , HAOWEI PENG, STEPHAN LANY, National Renewable Energy Laboratory — Materials for solar energy conversion need to fulfill specific targets in regard of the band-structure, optical properties, carrier transport, and doping. In order to design or discover novel materials that satisfy multiple requirements, we employ design principles to select a range of material compositions where those properties are likely to occur, and then evaluate them computationally. Here we are addressing the design of semiconductor alloys based on the d^5 oxide MnO, which was recently identified as an interesting base material for semiconducting transition metal oxides [PRB 85, 201202(R)]. To calculate the properties for different alloy compositions with the many-body GW method, we modeled the alloy systems by searching for special quasi-random structures (SQS). In isovalent alloys, the SQS was chosen such that the correlation functions were as close as possible to the ideal random alloy. For aliovalent alloys where strong short-range-ordering is expected, the target correlation functions for the SQS search were determined by a Monte-Carlo simulation based on a cluster expansion of the total energy for the alloy. The optical properties determined from GW calculations for such SQS alloy structures are compared with available experimental data.

10:12AM M5.00008 Abundant defects and defect clusters in kesterite Cu_2ZnSnS_4 and $Cu_2ZnSnSe_4$[1] , SHIYOU CHEN, East China Normal University, and Lawrence Berkeley National Lab, LIN-WANG WANG, Lawrence Berkeley National Lab, ARON WALSH, University of Bath, XIN-GAO GONG, Fudan Univerisity, SU-HUAI WEI, National Renewable Energy Lab — Cu_2ZnSnS_4 and $Cu_2ZnSnSe_4$ are drawing intensive attention as the light-absorber materials in thin-film solar cells. A large variety of intrinsic defects can be formed in these quaternary semiconductors, which have important influence on their optical and electrical properties, and hence their photovoltaic performance. We will present our first-principles calculation study on a series of intrinsic defects and defect clusters in Cu_2ZnSnS_4 and $Cu_2ZnSnSe_4$, and discuss: (i) strong phase-competition between the kesterites and the coexisting secondary compounds; (ii) the dominant Cu_{Zn} antisites and Cu vacancies which determine the intrinsic p-type conductivity, and their dependence on the elemental ratios; (iii) the high population of charge-compensated defect clusters (like V_{Cu}+Zn_{Cu} and $2Cu_{Zn}$+Sn_{Zn}) and their contribution to non-stoichiometry ; (iv) the deep-level defects which act as recombination centers. Based on the calculation, we will explain the experimental observation that Cu poor and Zn rich conditions give the highest solar cell efficiency, as well as suggesting an efficiency limitation in $Cu_2ZnSn(S,Se)_4$ cells with high S composition.

10:24AM M5.00009 Strain Induced Photoabsorption of $CuGa_{1-x}Fe_xO_2$, M. KYLEE UNDERWOOD, BARRY HAYCOCK, JAMES LEWIS, West Virginia University, JONATHAN LEKSE, CHRISTOPHER MATRANGA, DOE NETL Pittsburgh — Delafossite oxides are a family of materials that hold promise for photocatalytic, thermoelectric, and other cutting edge applications. These materials are of interest because they exhibit a disparity between their optical and electronic band gaps due to inversion symmetry according to the Laporte selection rule. Though they appear transparent, their electronic structure suggests that they should absorb visible light, aside from conduction and valence band parity. We use B-site substitution to break inversion symmetry and allow the absorption of visible light. Here we present computational and experimental electronic and optical results of B-site substitution of the delafossite $CuGaO_2$ with Fe which supports the inversion symmetry theory of the band gap disparity. Included are experimental and computational absorption spectra for $CuGa_{1-x}Fe_xO_2$. We find and explain an interesting increase optical absorption in the visible range at the 5% Fe substitution level. To the best of our knowledge computational results to this degree of percentage accurate substitution or alloying have not been performed on this or similarly complicated systems.

10:36AM M5.00010 Massive computational search for n-type organic semiconductors[1] , ANDRE LEITAO BOTELHO, TIM MUELLER, Department of Materials Science and Engineering, Johns Hopkins University — In a search for n-type organic materials, which are rare compared to p-type, we calculate the optimized geometries and electronic structures for millions of conjugated oligomers. A good n-type material (electron conductor) must have a low-lying LUMO level (high electron affinity) in order to avoid chemical reactions that create electron traps. For high conductivity, it must have a low barrier to electron hopping, indicated by an internal reorganization energy in the meV range. The calculations use the adapted Su-Schrieffer-Heeger tight-binding Hamiltonian and include both neutral and singly charged structures. The group of structures with a combination of low-lying LUMO levels and small internal reorganization energies is presented as candidates for n-type organic semiconductor materials. The data are also used to directly compute the optical band gaps and exciton binding energies, while the HOMO and LUMO levels are used to estimate cyclic voltammetry oxidation and reduction potentials. Application of the methodology to other organic materials searches is discussed.

10:48AM M5.00011 Theoretical study of LaOXS {X=Cu, Ag} layered oxide sulphides[1] , KANBER LAM, GIANCARLO TRIMARCHI, ARTHUR J. FREEMAN, Northwestern University — The ternary oxides, owing to the mismatch between the energy levels of the transition metal *d*-orbitals and the deep oxygen *p*-orbitals, typically show a limited dispersivity of the valence band maxima (VBM) and relatively heavy masses that make them not favorable in applications as p-type transparent conducting oxides (TCOs). In a hope to increase the *p-d* hybridization and preserve large band gaps in oxides with the addition of sulphur atoms, we studied the reported layered quarternary oxysulphides (LaCuOS, LaAgOS) using density functional theory with G0W0 self energy corrections. We confirmed that the VBM is mainly contributed by the antibonding state of Cu/Ag-*d* and S-*p* and the hole effective mass increases upon Cu substitution by Ag, which has a deeper *d* level than the Cu *d* one.

Session M6 DCMP: Graphene: Multilayer and Tunneling 302 - Chun Ning (Jeanie) Lau, University of California, Riverside

8:00AM M6.00001 Quantumn Hall Effect in single-, bi- and tri-layer graphene , ZENG ZHAO, KEVIN MYHRO, DAVID TRAN, HANG ZHANG, JHAO-WUN HUANG, JAIRO VELASCO, YANMENG SHI, FENGLIN WANG, YONGJIN LEE, CHUN NING LAU, University of California, Riverside — Quantum Hall Effect has been extensively studied in single layer, bilayer and trilayer graphene. Our recent studies showed intrinsic gapped state at the charge neutrality point in bilayer and trilayer graphene. Here we describe the fabrication of high-quality single-bilayer and bi-trilayer hybrid graphene devices, and present results from magneto-transport measurements.

8:12AM M6.00002 ABSTRACT WITHDRAWN –

8:24AM M6.00003 Velocity renormalization in multilayer graphene , HONGKI MIN, Department of Physics and Astronomy, Seoul National University, Seoul 151-747, Korea — Multilayer graphene has recently attracted considerable attention because of its chiral electronic structure which is sensitive to stacking sequences, and its possible use as the basis of new electronic devices. Furthermore, as sample quality improves, it is expected that electron-electron interactions play a significant role which was hidden by disorder. In this talk, we study velocity renormalization in multilayer graphene due to electron-electron interactions. After analyzing velocity renormalization in the chiral two-dimensional electron gas which is a low-energy effective model of graphene systems, we discuss its implication for multilayer graphene.

8:36AM M6.00004 Emergent Electromagnetism in Bilayer Graphene[1] , ROLAND WINKLER, Dept. of Physics, Northern Illinois University and Materials Science Division, Argonne National Laboratory, ULRICH ZÜLICKE, School of Chemical and Physical Sciences and MacDiarmid Institute, Victoria University of Wellington, New Zealand — Recently atomically flat layers of carbon known as graphene have become the rising star in spintronics as their electrons carry not only the ordinary spin degree of freedom, but they also have a pseudospin degree of freedom tied to the electrons' orbital motion which could enable new routes for spintronics. Here we focus on bilayer graphene (BLG). Using group theory we have established a complete description of how electrons in BLG interact with electric and magnetic fields. We show that electrons in BLG experience an unusual type of matter-field interactions where magnetic and electric fields are virtually equivalent: every coupling of an electron's degrees of freedom to a magnetic field is matched by an analogous coupling of the same degrees of freedom to an electric field. This counter-intuitive duality of matter-field interactions allows novel ways to create and manipulate spin and pseudo-spin polarizations via external fields that are not available in other materials. See arXiv:1206.4761.

8:48AM M6.00005 Coexisting massive and massless Dirac fermions in quasi-freestanding bilayer graphene , KEUN SU KIM, ANDREW L. WALTER, LUCA MORESCHINI, Lawrence Berkeley National Laboratory, THOMAS SEYLLER, University of Erlangen-Nurnberg, KARSTEN HORN, Fritz-Haber-Institut der Max-Planck-Gesellschaft, ELI ROTENBERG, AARON BOSTWICK, Lawrence Berkeley National Laboratory — The most widely accepted theoretical model to describe charge carriers in bilayer graphene is "massive Dirac fermions", characterized by a nearly parabolic band pair touching each other at the Dirac energy. This electronic structure of bilayer graphene is widely believed to be unstable towards symmetry breaking either by structural distortions, such as twist and strain, or electronic interactions. In this work, we investigate quasi-freestanding bilayer graphene by angle-resolved photoemission spectroscopy, which shows an unexpected electronic spectrum, consisting of both massive and massless Dirac fermions. The latter has a unique band topology with a chiral pseudospin texture, and its origin will be discussed in terms of symmetry breaking induced by a native imperfection of bilayer graphene.

9:00AM M6.00006 Quasiparticle Energy and Excitonic Effects of Gated Bilayer Graphene , LI YANG, Department of Physics, Washington University in St Louis — By employing the first-principles GW-Bethe-Salpeter Equation simulation, we obtain the accurate quasiparticle (QP) band gap and optical absorption spectra of gated bilayer graphene (GBLG). Many-electron effects are shown to be extremely important for understanding these excited-state properties; enhanced electron-electron interactions dramatically enlarge the QP band gap; infrared optical absorption spectra are dictated by bright bound excitons. In particular, these QP band gaps, exciton binding energies, and even the exciton spectra can be tuned in a wide range by the gate field. Our results satisfactorily explain recent experiments. Moreover, our calculation predicts exotic excitonic effects that have not been observed yet, which can be of interest for optoelectronics applications based on GBLG.

9:12AM M6.00007 A theoretical study of symmetry-breaking organic overlayers on single- and bi-layer graphene[1] , JOSUE MORALES-CIFUENTES, T.L. EINSTEIN, Physics & CMTC, Univ. Maryland, College Park — An "overlayer" of molecules that breaks the AB symmetry of graphene can produce (modify) a band gap in single- (bi-) layer graphene.[2] Since the triangular shaped trimesic acid (TMA) molecule forms two familiar symmetry breaking configurations, we are motivated to model TMA physisorption on graphene surfaces in conjunction with experiments by Groce et al. at UMD. Using VASP, with ab initio van der Waals density functionals (vdW-DF), we simulate adsorption of TMA onto a graphene surface in several symmetry-breaking arrangements in order to predict/understand the effect of TMA adsorption on experimental observables.

9:24AM M6.00008 Vortex zero mode and charge of mass skyrmion in graphene[1] , CHI-KEN LU, IGOR HERBUT, Physics Department, Simon Fraser University, Burnaby, British Columbia, Canada V5A 1S6 — We investigate the skyrmion formed by the mass order parameters in graphene and bilayer graphene. The skyrmion out of the three quantum anomalous spin Hall order parameters carries charge of 2e and 4e, respectively, in graphene and BA-stacking bilayer graphene. The origin of the above is related to the counting of vortex zero-mode and the representation of Clifford algebra imposed on the mass order parameters. The doubling of charge in bilayer case is due to the Kramers's degeneracy implied by the pseudo time-reversal symmetry, which is a result of the quadratic band touching at low-energy.

9:36AM M6.00009 Broken Symmetry Phases in ABC Trilayer Graphene[1] , VLADIMIR CVETKOVIC, OSKAR VAFEK, National High Magnetic Field Laboratory, Florida State University — We study the effects of electron-electron interaction in ABC-stacked trilayer graphene (TLG) within the framework of weak coupling renormalization group (RG). We find that, when the interaction is mainly in the forward scattering channel, the system orders into a gapless phase characterized by breaking of the TLG lattice mirror symmetries. A presence of small but finite back scattering changes the nature of the leading instability and results in gapped phases. The repulsive back scattering favors layered anti-ferromagnetic order, while the attractive back scattering yields the quantum spin Hall phase (gapped in bulk only). By classifying order parameters in TLG according to irreducible representations of the TLG space group, we conclude that any orders that break the rotational symmetry (e.g., the nematic state) in TLG are disfavored compared to the orders that do not break the lattice trifold rotational symmetry. The results are discussed in the context of present experiments on TLG.

9:48AM M6.00010 Unravelling the intrinsic and robust nature of van Hove singularities in twisted bilayer graphene , FELIX YNDURAIN, IVAN BRIHUEGA, Dept. Física de la Materia Condensada, Universidad Autónoma de Madrid, E-28049 Madrid, Spain, PIERRE MALLET, Institut Néel, CNRS-UJF, BP 166, F-38042 Grenoble, France, HECTOR GONZALEZ-HERRERO, Dept. Física de la Materia Condensada, Universidad Autónoma de Madrid, E-28049 Madrid, Spain, GUY TRAMBLY DE LAISSARDIÈRE, Laboratoire de Physique Théorique et Modélisation, Université de Cergy-Pontoise-CNRS, F-95302 Cergy-Pontoise, France, MIGUEL UGEDA, JOSE MARIA GÓMEZ-RODRÍGUEZ, Dept. Física de la Materia Condensada, Universidad Autónoma de Madrid, E-28049 Madrid, Spain, LAURENCE MAGAUD, JEAN YVES VEUILLEN, Institut Néel, CNRS-UJF, BP 166, F-38042 Grenoble, France — Extensive scanning microscopy and spectroscopy experiments completed by first principles and parameterized tight binding calculations provide a clear answer to the existence, origin and robustness of van Hove singularities in twisted grapheme layers. Our results are conclusive: vHs due to interlayer coupling are present in abroad range of rotation angles. From the variation of the energy separation of the vHs with rotation angle we recover the Fermi velocity of the grapheme monolayer as well as the strength of the interlayer interaction. The robustness of the vHs is assessed both by experiments and calculations which test the role of the periodic modulation and absolute value of the interlayer distance. We clarify the origin of the moiré corrugation observed in the STM images.

10:00AM M6.00011 Study on Metal/Metal oxide/Graphene Tunnel Junctions , KE CHEN, YING FENG, RAJA KHALID ZAHIR, Department of Physics, Temple University, Philadelphia, Pennsylvania 19122, USA — Metal/metal-oxide/graphene (Metal = Al, Ti, Hf, Zr) tunnel junctions were fabricated by transferring single-layer graphene grown by chemical vapor deposition on Cu onto metal strips by either a wet or dry approach. The metal strips were prepared by dc magnetron sputtering through a shadow mask and were exposed to air for about 10 minutes for native oxides to grow prior to the transfer. Good tunneling properties were observed for all the junctions fabricated by either means of graphene transfer. The zero-bias resistance of these junctions all increases with time to a final value, indicating continuing oxidation of the metals with a self-limited oxidation rate. Some junctions show the final area-normalized zero-bias resistances and self-limited oxidation time scales for Al, Ti, Hf, Zr are about 0.15, 0.2, 6000, 1000 kΩcm^2 and 25, 90, 6, 9 hour, respectively. The tunneling spectra were studied at various temperature down to 4.2 K and analyzed by the Brinkman-Dynes-Rowell model to get the height and width of the tunnel barriers, taking into account the electron structure of graphene. The junctions are good candidates for chemical sensing applications.

10:12AM M6.00012 Tunneling Spectroscopy of Graphene using Planar Pb Probes[1] , YANJING LI, NADYA MASON, University of Illinois at Urbana-Champaign — We show that evaporating lead directly on graphene can create high-quality tunnel probes. By monitoring and comparing the resistances of probes made from Pb, Al and Ti/Au, we have found unique and robust behavior of the Pb probes: the contact resistance between the Pb and graphene first increases and then saturates over a time period of approximately one week. Characterization via transport measurements at low temperature shows that after oxidation a well-formed tunnel barrier is created between the Pb and the graphene. Tunneling spectroscopy using the Pb probes manifests energy-dependent features such as scattering resonances and localization behavior, and can thus be used to probe the microscopic electronics of graphene.

[1]This work was supported by the NSF DMR-0906521.

10:24AM M6.00013 Mg/MgO/Graphene Tunnel Junctions Made by Dry Transfer of Graphene in Vacuum , YING FENG, KE CHEN, Department of Physics, Temple University, Philadelphia, Pennsylvania 19122, USA — Mg/MgO/Graphene junctions were fabricated by dry transfer of single layer graphene film grown by chemical vapor deposition on Cu Mg strips were deposited onto Si/SiO_2 or glass substrates by thermal evaporation through a shadow mask. The tunnel barrier MgO was formed by exposing deposited Mg for about 10 minutes in air prior to the graphene transfer. To prevent degradation of MgO by liquids, a dry transfer technique is used. First a graphene film was transfer onto a free-standing 4μm-thick Cu film using the traditional wet method, then pressed onto a transparent and flexible PDMS stamp followed by etching away the Cu film in $FeCl_3$ solution, and finally stamped onto the Mg strips in vacuum to prevent any gas bubbles that may form between graphene and Mg strips. The dry-transferrd graphene has similar properties to traditional wet-transferred graphene, characterized by scanning electron microscopy, atomic force microscopy, Raman spectroscopy, and transport measurements. It has a sheet resistance of 1.6 $\sim$ 3.4 k$\Omega/\Box$, charge carrier density of 4.1 $\sim$ 5.3 $\times$ 10^{12} /cm^2 and mobility of 460 $\sim$ 760 cm^2/Vs without doping at room temperature. Mg/MgO/graphene junctions show good tunneling characteristics at temperatures down to 4.2 K. The barrier height and width were obtained by fitting with the Brinkman-Dynes-Rowell trapezoid-shaped barrier model with consideration of graphene electron structure.

10:36AM M6.00014 Intrinsic Dirac Point Energy Level and Band Offset of Graphene/SiO_2 interface , KUN XU, Purdue University, National Institute of Standard and Technology, CAIFU ZENG, KANG WANG, University of California, Los Angeles, QIN ZHANG, National Institute of Standard and Technology, PEIDE YE, Purdue University, RUSEN YAN, ALAN SEABAUGH, HUILI XING, University of Notre Dame, JOHN SUEHLE, CURT RICHTER, DAVID GUNDLACH, NHAN NGUYEN, National Institute of Standard and Technology — Advancing toward the rational design, fabrication, and implementation of graphene(GR)-based electronic and optical devices, the intrinsic barrier height of undoped GR (the Dirac point of GR to the conduction band(CB) edge of an insulator), as well as the intrinsic work function(WF) of GR must be accurately determined. We present an internal photoemission (IPE) investigation of a unique semi-transparent metal/high-k/GR/SiO_2/Si structure, and focus our study on the photoemission phenomena at the GR/SiO_2 interface. By taking advantage of the optical interference of the SiO_2 cavity, the enhanced photoemission from GR was observed. As a result, a complete electronic band alignment at the GR/SiO_2/Si interfaces is established. The intrinsic positions of the undoped GR Dirac point with respect to the CB of SiO_2, 3.58 eV (Al_2O_3 TG) and 3.60 eV (HfO_2 TG), are obtained. The intrinsic WF of graphene is found to be 4.50 eV. The determination of the WF of GR is of significant importance to the engineering of GR-base devices and the IPE spectroscopy, combined with specific interference cavity structures, would be a valuable measurement technique for other GR-like2-D material systems.

10:48AM M6.00015 Point Contacts to Graphene for Corbino Disk Geometry Devices , BIN CHENG, PENG WANG, LEI JING, CHUN NING LAU, MARC BOCKRATH, University of California, Riverside — A Corbino disk geometry raises new possibilities for observing novel phenomena for Dirac electrons in graphene [1]. For example, Recent theoretical work has suggested the possibility of observing a quantum relativistic Corbino effect in which the conductance of a graphene layer measured in a Corbino disk geometry shows magneto-oscillations related to to the number of flux quanta threading the area of the disk [2]. We will discuss a technique we have developed for making air-bridge contacts to graphene layers based on a multi-layer resist technique [3]. The air bridge enables a Corbino disk geometry in the absence of topside dielectric layers, potentially facilitating annealing techniques in conjunction with placement on, for example, BN substrates to enable high mobility devices. The latest transport results will be discussed.

8:00AM M7.00001 Negative refractive index electron 'optics', pseudospintronics and chiral tunneling in graphene pn junction – beating the Landauer switching limit?[1] , REDWAN SAJJAD, University of Virginia, CHENYUN PAN, AZAD NAEEMI, Georgia Institute of Technology, AVIK GHOSH, University of Virginia — We use atomistic quantum kinetic calculations to demonstrate how graphene PN junctions can switch with high ON currents, low OFF currents, steep gate transfer characteristics and unipolar rectification. The physics of such unconventional switching relies on (a) field-engineering with patterned gates to create a *transmission gap,* by sequential filtering of all propagating modes, and (b) using tilted junctions to suppress Klein tunneling under appropriate gate biasing, making that transmission gap *gate tunable*. The doping ratio of the junction dictates the energy range over which the tilt angle exceeds the critical angle for transmission, generating thereby a gate tunable transmission gap that enables switching at voltages less than the Landauer-Shannon thermal limit. The underlying physics involves a combination of 'electron optics' driven by Snell's law, negative index metamaterial with a PN junction, and pseudospin driven chiral tunneling, for which we also present experimental verification. [Sajjad et al, APL 99, 123101 (2011); Sajjad et al, PRB 86, 155412 (2012)].

8:12AM M7.00002 All-carbon optical diode , BENOY ANAND, SSSIHL, Puttaparthi, India, RAMAKRISHNA PODILA, KIRAN LINGAM, Department of Physics, Clemson University, Clemson, SC 29634, REJI PHILIP, Raman Research Institute, Bangalore, India, APPARAO RAO, Department of Physics, Clemson University, Clemson, SC 29634, CLEMSON PHYSICS TEAM, SSSIHL, INDIA TEAM — Optical diodes that allow unidirectional transport of light, similar to an electronic p-n junction diode, are vital to manipulate and control light for information processing. These "optical diodes" have already been realized using photonic crystals (PC) with engineered periodicity. However, an important criterion for the functioning of a PC-based optical diode is that the periodicity of the PC should be on the same length scale as half the wavelength of the electromagnetic waves used. For the visible region of the electromagnetic spectrum, this periodicity must be $\sim$ 200-350 nm making the fabrication of PCs expensive, cumbersome and complicated. An optical diode based on the transmission of optical pulses through structures with an abrupt variation in the longitudinal nonlinear absorption coefficient, as opposed to periodic variation of refractive index or dielectric constant is demonstrated. In particular, we present the studies performed on an all carbon optical diode with C60 and graphene coated on quartz cover slips. We find that the reverse saturable absorption of C60 and the saturable absorption of graphene can be combined to obtain modest reciprocity factors for a solid-state all-carbon optical diode.

8:24AM M7.00003 Photoconductivity of biased graphene , MARCUS FREITAG, IBM TJ Watson Research Center — The origin of photosensitivity of graphene devices has been attributed to either thermoelectric, photovoltaic, or bolometric effects. Here we report on the intrinsic photoresponse of electrically biased, but otherwise homogeneous single-layer graphene. In this simple, yet unstudied experimental condition, the photocurrent shows polarity reversal, as it alternates between two of these effects while sweeping the electronic potential. Near the Dirac point, the photovoltaic effect dominates, and the photocurrent adds to the transport current. Away from the Dirac point, the bolometric effect dominates, and reduces the transport current. Magnitude and polarity of the photocurrent allow us to infer the hot carrier and phonon temperatures under light illumination. The electron temperature is found to be an order of magnitude higher than the phonon temperature, shedding light on energy loss pathways other than via intrinsic graphene phonons. (M. Freitag et al., Nature Photonics, accepted for publication (2012).)

8:36AM M7.00004 Far-IR Spectroscopy and FDTD Simulations of Graphene Plasmonic Structures , JARED STRAIT, PARINITA NENE, WEIMIN CHAN, CHRISTINA MANOLATOU, JOSHUA KEVEK, PAUL MCEUEN, FARHAN RANA, Cornell University — Plasmonics, the field of manipulating charge density waves, is uniquely suited to graphene due to graphene's high mobility and tunable plasma frequency in the THz range. Graphene microstructures, such as strips, discs, and rings confine plasmon modes, leading to plasma resonances with THz frequencies. These micro- and nanostructures form the building blocks of graphene plasmonic devices for tunable terahertz generation, detection, filtering, and switching. We present experimental results on the spectroscopy of plasmon resonances in the far-IR wavelength range in various graphene microstructures. Analytical methods of modeling even the simplest graphene plasmonic structures are not quantitatively accurate, and as such, we developed a 3D finite-difference time-domain (FDTD) tool for simulating the plasmon modes. By fitting simulations to the measured data, we have quantitatively extracted the parameters characterizing graphene's intraband conductivity and carrier scattering time with good accuracy. We have also investigated the interaction between plasmon modes of nearby structures and found them to be strong when the distance between structures is less than the dimension of the structures. FDTD simulations enable a quantitative characterization of such interactions.

8:48AM M7.00005 Ultra-Amplification of Surface Plasmon Coupled Emission in Graphene-Silver Hybrid Films , PRADYUMNA MULPUR, Sri Sathya Sai Institute of Higher Learning, India, KIRAN LINGAM, Dept. of Physics and Astronomy, Clemson University, S.K. VEMULA, S.S. RAMAMURTHY, V. SRINIVASAN, V. KAMISETTY, Sri Sathya Sai Institute of Higher Learning, India, APPARAO RAO, Dept. of Physics and Astronomy, Clemson University, CLEMSON UNIVERSITY TEAM, SRI SATHYA SAI INSTITUTE OF HIGHER LEARNING TEAM — Surface Plasmon Coupled Emission (SPCE) stems from an interaction between fluorophores and thin metallic films and leads to strongly directional p-polarized emission with signal intensities that are 10-1000 times greater than isotropic fluorescence emission. Conventional SPCE methods use silver thin films with a SiO_2 spacer layer to prevent oxidation of silver, and the latter has no role in the signal generation. Here we employ single- and bi-layer graphene (SLG-BLG) as the spacer layer and demonstrate a 10 fold enhancement in comparison to the isotropic fluorescence intensity for rhodamine B fluorophore doped in PVA matrix. A fiber optic spectrometer was used to record the emission which was strongly directional (at 50° relative to the incident excitation) and 97% p-polarized. Base on our preliminary simulations, we attribute the synergistic interaction between the π-plasmons of graphene and the surface plasmons of silver as the most important factor in the amplification of the SPCE.

9:00AM M7.00006 Single layer graphene plasmonic detector for broadband THz spectroscopy[1] , DENNIS DREW, XINGHAN CAI, ANDREI SUSHKOV, GREGORY JENKINS, MICHAEL FUHRER, CNAM and MRSEC, Department of Physics, University of Maryland, L. NYAKITI, V.D. WHEELER, R.L. MYERS-WARD, N.Y. GARCES, C.R. EDDY, JR., D.K. GASKILL, U.S. Naval Research Laboratory, Washington, DC 20375 — Among many possible applications of graphene, THz detection is one of the most promising. The Drude-type absorption of THz radiation by free carriers is much stronger than the frequency-independent 2.3% absorption for interband transitions. By patterning the graphene sheet strips the Drude-type response is transformed into a Lorentzian peak corresponding to a THz plasmon resonance on the width w of each strip. The plasmon resonance frequency $\omega_0 \propto n^{1/4} w^{1/2}$, where n is carrier concentration which is tunable by gate(s) as was reported in Ref. 1 for graphene grown by chemical vapor deposition. We have reproduced results of Ref. 1 on our single layer graphene on Si-face SiC with electrolyte top gate. The next step to a detector is extraction of DC photocurrent without destroying plasmons. We will present our solution to this problem and compare the performance of our room-temperature detector to existing THz detector technologies. Other aspects of our graphene photodetectors such as device fabrication, response time, and response mechanism will be presented in other talks at this meeting. [1] L. Ju et al, Nature Nanotechnology, 6 (2011) 630-634.

9:12AM M7.00007 Graphene electrically reconfigurable patterns for THz imaging applications , BERARDI SENSALE-RODRIGUEZ, SUBRINA RAFIQUE, RUSEN YAN, MINGDA ZHU, VLADIMIR PROTASENKO, DEBDEEP JENA, LEI LIU, HUILI GRACE XING, Department of Electrical Engineering, University of Notre Dame — THz waves are attractive for several imaging applications, since they can propagate through non metallic media such as paper, cloth, plastics, and ceramics, and do not scatter over nano-scale defects or ionize the material under imaging -as might shorter wavelengths do- while offering an image resolution similar to that of the human eye. In this work we propose and experimentally demonstrate electrically reconfigurable patterns for single-pixel terahertz imaging based on arrays of graphene THz electro-absorption modulators. In an optical setup, in conjunction with mirrors, the modulator array can transform the output radiation from a CW THz source into a pixelated and collimated beam of illumination. Single-atom-thick graphene is employed as the active element of these modulators, achieving a modulation of the THz wave reflectance >50% with a potential modulation depth approaching 100% (i.e. each region of the pixelated collimated beam can be potentially completely turned-off). Although the proof-of-concept device here discussed only consists of 4x4 elements, we foresee that this technology can enable low-cost video rate THz imaging systems.

9:24AM M7.00008 Graphene Based Tunable SPR Sensors , ERGUN SIMSEK, George Washington University — Today's highly mobile world requires widely deployable disease detection and monitoring systems. We need compact, sensitive, and cost-effective biosensors, which can also tolerate a wide range of operating conditions to be field-deployable. Especially for point-of-care diagnostics, where the testing environment can be highly variable, it would be advantageous to have sensors with tunable operating ranges. To address this need, we propose tunable, localized surface plasmon resonance (SPR) based biosensors using graphene layers and metal nanoparticle arrays. Tuning capability is achieved by bias voltage applied to the thin layers of the substrate, where on metal nanoparticle arrays are fabricated. The key component of the design is graphene. The applied voltage changes not only optical properties of graphene but also the induced dipole moment of each nanoparticle and hence the resonance wavelength of the sensor. For the modeling of proposed tunable biosensors, we use both a frequency domain approximate solver (layer medium coupled dipole approximation) and a full wave time-domain electromagnetic solver (Wavenology). Numerical results obtained with these two independent solvers reveal the tuning capability of the proposed structures.

9:36AM M7.00009 Ferroelectric-Gated Terahertz Plasmonics on Graphene[1] , DAFEI JIN, ANSHUMAN KUMAR, KIN HUNG FUNG, JUN XU, NICHOLAS FANG, Massachusetts Institute of Technology — Inspired by recent advancement of low-power ferroelectic-gated memories and transistors, we propose a design of ferroelectic-gated nanoplasmonic devices based on graphene sheets clamped in ferroelectric crystals. We show that the two-dimensional plasmons in graphene strongly couple with the phonon-polaritons in ferroelectrics at terahertz frequencies, leading to characteristic modal wavelength of the order of 100–200 nm at only 3–4 THz. By patterning the ferroelectrics into different domains, one can produce compact on-chip plasmonic waveguides, which exhibit negligible crosstalk even at 50 nm separation distance. Harnessing the memory effect of ferroelectrics, low-power electro-optical switching can be achieved on these plasmonic waveguides.

9:48AM M7.00010 Graphene nano-photonics and carrier dynamics , FRANK KOPPENS, ICFO - The Institute of Photonic Sciences — Graphene, a two-dimensional sheet of carbon atoms, has recently emerged as a novel material with unique electrical and optical properties, with great potential for novel opto-electronic applications, such as ultrafast photo-detection, optical switches, strong light-matter interactons etc. In the first part of this talk, I will review recent experimental work on exploiting graphene as a host for guiding, switching and manipulating light and electrons at the nanoscale [1]. This is achieved by exploiting surface plasmons: surface waves coupled to the charge carrier excitations of the conducting sheet. Due to the unique characteristics of graphene, light can be squeezed into extremely small volumes and thus facilitate strongly enhanced light-matter interactions. Additionally, I will discuss novel types of hybrid graphene photodetectors [2] and recent findings on carrier dynamics and hot carrier multiplication in graphene. By studying the ultrafast energy relaxation of photo-excited carriers after excitation with light of varying photon energy, we find that electron-electron scattering dominates the energy relaxation cascade rather than electron-phonon interaction [3]. This solves a long- standing debate on the relative contribution of electron-electron scattering versus optical phonon emission.

10:24AM M7.00011 High-performance Photoconductive devices based on Graphene-Nanowire Hybrid Structures , HYUNGWOO LEE, Department of Physics and Astronomy, Seoul National University, Seoul, Korea, KWANG HEO, Seoul National University, JAESUNG PARK, Pohang University of Science and Technology, YONGJU PARK, SEUNGUK NOH, Seoul National University, KWANG S. KIM, Pohang University of Science and Technology, CHANGHEE LEE, BYUNG HEE HONG, Seoul National University, JIKANG JIAN, Xinjiang University, SEUNGHUN HONG, Department of Biophysics and Chemical Biology, Seoul National University — The photoconductivity effect in various semiconducting materials has been extensively utilized for optoelectronic applications. However, conventional photoconductive channels exhibited rather slow responses to external light pulses because the photogenerated electrons and holes survive for a rather long time even after the lights are turned off. On the other hand, single-layer graphene (SLG) was reported to exhibit quite a fast photoconductivity, while its rather small photocurrent levels may limit the practical applications. Herein, we developed graphene-CdS nanowire (NW) hybrid structures for high-speed photoconductivity and large photoresponse. The hybrid structure consists of CdS NWs which were selectively grown in specific regions on a SLG sheet. The photosensor based on graphene-CdS NW hybrid structures exhibited rather large photocurrents as well as much faster operation speed than those based only on CdS NW networks. This simple but efficient strategy takes advantages of both graphene and NWs, and it should enable the fabrication of high performance optoelectronic devices for practical applications.

10:36AM M7.00012 Liquid-Gated Epitaxial Graphene: How Leakage Currents Affect Ionic Strength Sensing[1] , MAURICIO D. BEDOYA, School of Physics, Georgia Tech, PETER J. METAXAS, School of Physics, UWA, Australia, JAN SCRIMGEOUR, YIKE HU, RUI DONG, CLAIRE BERGER, WALT A. DE HEER, JENNIFER E. CURTIS, School of Physics, Georgia Tech — Graphene is a promising material for the fabrication of miniaturized biological and chemical sensors. Epitaxial graphene is an exciting candidate due to its compatibility with standard processing techniques and its intrinsic robustness. We have fabricated liquid-gated FET-like devices based upon sub-millimeter wide epitaxial graphene strips defined using optical lithography methods. The devices exhibit a bipolar conductance versus gate voltage behavior with the minimum conductance point being dependent upon the ionic strength of a KCl solution. Measurements of the graphene conductance and gate-leakage currents during the stepping of the gate voltage demonstrate the presence of time dependent nA-scale leakage currents which limit signal stability at short times. Notably, these currents depend upon the gate voltage and the composition of the gate electrode. These and other electrode dependent effects have ramifications for graphene sensor design and implementation such as the need to limit gate voltage operating windows as and carefully design electrodes. With high transconductance and controlled doping, such devices should be able to function at low gate voltages if a full understanding of charge and charge transport at the graphene interface is obtained.

10:48AM M7.00013 Graphene as a Platform for Hybrid Optomechanical Devices , VINCENT BOUCHIAT, ANTOINE RESERBAT-PLANTEY, DIPANKAR KALITA, LAETITIA MARTY, OLIVIER ARCIZET, NEDJMA BENDIAB, Neel institute, CNRS-Grenoble — Graphene is known for providing a flat 2D material with outstanding optical, electrical and mechanical properties. We propose to take advantage of all three features by developing an optomechanical platform based on cantilevers made of freestanding multilayer graphene connected to an electrode. In this talk I will present several examples of a simple optomechanical systems involving a multilayer graphene suspended cantilevers that can act as a mirror closing an optical cavity. By varying the gate voltage applied on the mirror, its angle can be adjusted on a wide range (exceeding the wavelength of the incoming light) and its motion can be actuated and followed in real time from DC up to the tens of MHz range. Detection of elastic and inelastic scattered light can be performed. It allows simultaneous detection of motion, local stress and temperature of the membrane. A fully spectral detection of NEMS resonance is presented (1) and allows a novel optomechanical scheme based on coupling between motion and light through the dynamic mechanical stress. Further applications are presented as well such as a gate tunable enhancement of the Raman signal of molecular species adsorbed on the graphene platform. Session M8 DMP: Focus Session: Graphene - Twisted Layers, Stacking 307 - Taisuke Ohta, Sandia National Laboratories

8:00AM M8.00001 Single-layer behavior and its breakdown in twisted graphene layers[1] , ADINA LUICAN-MAYER, Argonne National Laboratory — Stacking order plays a major role in the electronic properties of graphene layers because hopping between carbon atoms in neighboring layers is a key ingredient in their band structure. Twisting the layers away from the equilibrium Bernal stacking, which produces the superstructures known as Moiré patterns in scanning tunneling microscopy, decreases the overlap between atoms in adjacent layers and therefore significantly alters their electronic properties. Using scanning tunneling microscopy and spectroscopy, we obtained direct evidence for the electronic structure of twisted graphene layers.[2] The samples were membranes of CVD grown graphene and graphite crystals which contain areas with various twist angles. In topographic images the regions where layers are twisted away from Bernal stacking exhibit Moiré patterns with periods which depend on the twist angle. We find that the density of states on the twisted layers develops two Van Hove singularities that symmetrically flank the Dirac point at an energy that depends on the twist angle. High magnetic field scanning tunneling microscopy and Landau level spectroscopy of twisted graphene layers reveal that for twist angles exceeding $\sim$3 degrees the low energy carriers exhibit Landau level spectra characteristic of massless Dirac fermions. Above 20 degrees the layers effectively decouple and the electronic properties are indistinguishable from those in single-layer graphene, while for smaller angles we observe a slowdown of the carrier velocity which is strongly angle dependent.[3] These results are compared with theoretical predictions.

8:36AM M8.00002 Interacting Dirac Fermions and Neutrino-Like Oscillation in Twisted Bilayer Graphene , LEDE XIAN, ZHENGFEI WANG, M.Y. CHOU, School of Physics, Georgia Tech — The low-energy quasiparticles in graphene can be described by a Dirac Hamiltonian for massless fermions, hence graphene has been proposed to be an effective medium to study exotic phenomena originally predicted for particle physics, such as Klein tunneling and Zitterbewegung. In this work, we show that another important particle-physics phenomenon – the neutrino oscillation can be studied and observed in a particular graphene system, namely, twisted bilayer graphene. It has been found that graphene layers grown epitaxially on SiC or by the chemical vapor deposition (CVD) method on metal substrates display a stacking pattern with adjacent layers rotated by an angle with respect to each other. The quasiparticle states in two distinct graphene layers act as neutrinos with two flavors, and the interlayer interaction between them induces an appreciable coupling between these two "flavors" of massless fermions, leading to neutrino-like oscillations. In addition, anisotropic transport properties manifest in this specific energy window, which is accessible in experiment for twisted bilayer graphene. We demonstrate that combining two graphene layers enables us to probe the rich physics involving multiple interacting Dirac fermions.

8:48AM M8.00003 Landau level splitting in rotationally faulted multilayer graphene , HRIDIS PAL, MARKUS KINDERMANN, Georgia Institute of Technology — In this work we explore theoretically whether the interlayer motion of electrons in rotationally faulted multilayer graphene can break the valley degeneracy. We show that in the presence of a magnetic field and interlayer commensurations this is indeed possible. It leads to the splitting of Landau levels linear in the field. Our theoretical work is motivated by a recent experiment [1] on epitaxially grown multilayer graphene where a splitting of Landau levels was observed. This Landau level splitting was found to be linear in the field at moderate fields. We consider both bilayer and trilayer configurations and find that in both cases a linear splitting can occur. The predicted lack of valley degeneracy is due to a simultaneous breaking of time-reversal symmetry and inversion symmetry by the magnetic field and interlayer commensurations, respectively. [1] Y. J. Song, et al., Nature 467, 185 (2010).

9:00AM M8.00004 Simultaneous investigation of magnetoresistance (MR) and twisted angle of twisted bilayer graphene , SUNG JU HONG, Department of Physics and Astronomy, Seoul National University, JULIO MANZO, Department of Physics and Astronomy, University of Pennsylvania, KYUNG HO KIM, MIN PARK, SEUNG JAE BAEK, Department of Physics and Astronomy, Seoul National University, DMITRY KHOLIN, P.L. Kapitza Institute for Physical Problems, Russian Academy of Sciences, MIN WOO LEE, Department of Chemistry Education, Seoul National University, EUN SANG CHOI, National High Magnetic Field Laboratory, Florida State University, DAE HONG JEONG, Department of Chemistry Education, Seoul National University, AUGUST YURGENS, Department of Microtechnology and Nanoscience, Chalmers University of Technology, MARIA DRNDIC, ALAN JOHNSON, Department of Physics and Astronomy, University of Pennsylvania, YUNG WOO PARK, Department of Physics and Astronomy, Seoul National University — We have measured magnetoresistance (MR) and twisted angle of twisted bilayer graphene, simultaneously. Twisted angle was measured by transmission electron microscopy (TEM) diffraction experiment on SiN_x substrate. We performed Raman spectroscopy experiment and observed enhanced G mode which results from double resonance scattering process near van Hove singularity (vHs). MR shows superposition of two Shubnikov de Haas (SdH) oscillations and is analyzed by Landau fan diagram.

9:12AM M8.00005 Probing electronic and vibrational interactions in few-layer graphene by optical spectroscopy , CHUN HUNG LUI[1], Columbia University — Graphene possesses remarkable physical properties and great potential for novel applications. As more than one graphene layers are stacked on one another, the properties of the few-layer system can be strongly modified by the interactions between electrons and lattice vibrations in different graphene layers. We have investigated, by means of infrared and Raman spectroscopy, the electronic and vibrational properties of few-layer graphene with different layer thickness and stacking sequence. Our results reveal the critical roles of these degrees of freedom in defining the properties of few-layer graphene. We show how optical spectroscopy offers important routes to characterizing the thickness and stacking order of the graphene samples as well as probing the material's response to external perturbations. In particular, we will describe the use of Raman spectroscopy to identify the interlayer breathing modes in few-layer graphene of up to 20 layers in thickness, and the use of Infrared spectroscopy to probe the modulation of electronic structure and electron-phonon interactions in few-layer graphene with varying thickness, stacking order and doping level. This work was performed at Columbia University in collaboration with L. Brus, E. Cappelluti, G. L. Carr, Z.Y. Chen, Z.Q. Li, K.F. Mak, L.M. Malard and R. Saito.

[1]Current Address: Physics Department, Massachusetts Institute of Technology, Cambridge, MA, USA.

9:48AM M8.00006 Resonance profile of Moire-pattern Raman peaks in twisted graphene layers , MARCOS PIMENTA, ARIETE RIGHI, SARA COSTA, CRISTIANO FANTINI, HELIO CHACHAM, Departamento de Fisica, UFMG, CARL MAGNUSON, ROD RUOFF, Department of Mechanical Engineering and the Texas Materials Institute, The University of Texas at Austin, 1 University Station C2200, Austin, Texas, WOLFGANG BACSA, CEMES/CNRS, University of Toulouse, 29 rue Jeanne Marvig, 31055 Toulouse, France, LUIGI COLOMBO, Texas Instruments Incorporated 13121 TI Blvd, MS-365 Dallas, TX 75243., PEDRO VENEZUELA, Instituto to de F?sica, Universidade Federal Fluminense, Niteroi, Brazil — In this work, we study the Raman spectra of graphene samples grown by CVD on a Cu foil, with different laser excitation lines. The spectra exhibit a number of extra sharp Raman peaks, classified in different families, each one associated with Moire patterns of graphene layers twisted with different angles. The presence of these extra peaks is theoretically analyzed considering the interlayer potential perturbation, that gives rise to a set of wavevectors within the interior of the Brillouin zone of graphene, activating special selective double-resonance (DR) Raman modes, in a so-called umklapp DR (u-DR) process. The resonance Raman profile of the Moire peaks obtained experimentally by changing the laser energy is compared with the calculations of the u-DR process, showing that Raman spectroscopy is useful to characterize Moire patterns in graphene systems.

10:00AM M8.00007 Interaction Induced Symmetry Breaking in ABA Trilayer Graphene , ROHIT HEGDE, ALLAN H. MACDONALD, University of Texas at Austin — We present a mean-field phase diagram of dual-gated ABA trilayer graphene which is obtained by numerically solving the self-consistent Hartree-Fock equations. A metal-insulator phase transition occurs in neutral ABA trilayers at interaction strength $\alpha = 0.18$ which is not associated with broken lattice symmetries. ABA trilayers do not possess the inversion symmetry present in bilayers, but do possess a mirror-plane symmetry which remains unbroken for realistic values of alpha for the case of spinless, valley-less fermions. The manner in which SU(4) spin-valley symmetry breaks depends on doping, interlayer bias, and the surrounding dielectric medium. We compare interaction effects in ABA graphene with those in the more familiar chirally-stacked multilayers.

10:12AM M8.00008 Quantized Strain Channels in Bilayer Graphene , ADAM TSEN, ROBERT HOVDEN, JONATHAN ALDEN, PINSHANE HUANG, LOLA BROWN, DAVID MULLER, PAUL MCEUEN, JIWOONG PARK, Cornell University — For bilayer graphene, Bernal stacking presents the lowest energy configuration. However, when the two layers are free to translate, there are two mirrored Bernal stacking orders with degenerate energies [1]. In large-area bilayer systems grown by chemical vapor deposition domains of both stacking configurations have been observed [2], although the precise structure of their boundaries was not understood. Here, we image such structures with atomic resolution using scanning transmission electron microscopy (STEM). We find that domain boundaries are formed by continuous strain of one layer with respect to the other, while the direction and magnitude of their displacements are quantized by the energy landscape. Finally, we extend their characterization over many microns with standard dark-field TEM imaging and discover that the strain regions form long channels that can perhaps be exploited for their electronic properties in the future. 1. Lebedeva et al., J. Chem. Phys. 134, 104505 (2011) 2. Brown et al., Nano Lett. 12, 1609 (2012)

10:24AM M8.00009 Electronic structure of multilayer graphene with a mixture of Bernal and rhombohedral stacking , MIKITO KOSHINO, Department of Physics, Tohoku University, EDWARD MCCANN, Department of Physics, Lancaster University, Lancaster — We propose a general scheme to describe the electronic band structure of multilayer graphene with an arbitrary mixture of Bernal and rhombohedral stacking. The system can be viewed as a series of finite Bernal graphite sections connected by rhombohedral-type stacking faults. We find that the low-energy eigenstates are mostly localized in each Bernal section, and the whole spectrum is well approximated by a collection of the spectra of independent sections. In the ensemble-averaged electronic structure, there are frequently-appearing linear bands and quadratic bands with particular band velocities or curvatures, corresponding to finite Bernal sections and their combinations.

10:36AM M8.00010 Electronic dispersion from long-range atomic ordering and periodic potentials in two overlapping graphene sheets[1] , TAISUKE OHTA, Sandia National Laboratories, JEREMY ROBINSON, Naval Research Laboratory, PETER FEIBELMAN, THOMAS BEECHEM, BOGDAN DIACONESCU, Sandia National Laboratories, AARON BOSTWICK, ELI ROTENBERG, Advanced Light Source, Lawrence Berkeley National Laboratory, GARY KELLOGG, Sandia National Laboratories — A worldwide effort is underway to learn how to build devices that take advantage of the remarkable electronic properties of graphene and other two-dimensional crystals. An outstanding question is how stacking two or a few such crystals affects their joint electronic behavior. Our talk concerns "twisted bilayer graphene (TBG)," that is, two graphene layers azimuthally misoriented. Applying angle-resolved photoemission spectroscopy and density functional theory, we have found van Hove singularities (vHs) and associated mini-gaps in the TBG electronic spectrum, which represent unambiguous proof that the layers interact. Of particular interest is that the measured and calculated electronic dispersion manifests the periodicity of the moiré superlattice formed by the twist. Thus, there are vHs not just where the Dirac cones of the two layers overlap, but also at the boundaries of the moiré superlattice Brillouin zone. Moirés, ubiquitous in hybrid solids based on two-dimensional crystals, accordingly present themselves as tools for manipulating the electronic behavior.

[1]Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. DOE's National Nuclear Security Administration under contract DE-AC04-94AL85000.

Wednesday, March 20, 2013 8:00AM - 11:00AM –

Session M9 FHP: Invited Session: A History of Physics in Industry followed by Panel Discussion

308 - Joseph Martin, University of MinnesotaTwin Cities

8:00AM M9.00001 Commercial Scholarship: Spinning Physics Research into a Business Enterprise , ORVILLE BUTLER, Center for History of Physics, American Institute of Physics — The American Institute of Physics' Center for History of Physics has conducted a three year NSF funded study of physicist entrepreneurs during which we interviewed 140 physicists who have founded ninety-one startups. Forty of those companies have spun research out of twenty-some universities. Startups spun out of university research tend to be technology push companies, creating new potentially disruptive technologies for which markets do not yet clearly exist, in contrast to market pull companies founded to address innovations responding to market demands. This paper addresses the unique issues found in university spinout companies and their responses to them. While technology push companies are generally considered to be higher risk compared to market pull companies, the university spinouts in our study had a higher rate of both SBIR and venture capital funding than did the market pull companies in our study.

8:24AM M9.00002 A Place for Materials Science: University of Pennsylvania's Laboratory for Research on the Structure of Matter , BRITTANY SHIELDS, University of Pennsylvania — The University of Pennsylvania's Laboratory for Research on the Structure of Matter (LRSM) opened its doors in 1965. Constructed to house cutting-edge research on Materials Science, the LRSM building was designed to foster interdisciplinary research among physicists, chemists and metallurgical engineers. Each of the five floors of the new building included a central facility, including a high magnetic field center, an analytical chemistry research center and an electron microscopy center. While primarily funded by the Department of Defense's Advanced Research Projects Agency, the LRSM also was also partly sponsored by industry. The LRSM received funding from Philadelphia Electric Company, General Electric Company, and IBM, among others. In this paper, I will study how the building was designed to encourage interdisciplinary collaboration, while also becoming a place of intersection among academic, private, and governmental interests. This project is a collaboration with Hyungsub Choi.

8:48AM M9.00003 Dad's in the Garage: Santa Barbara Physicists in the Long 1970s , CYRUS MODY, Rice University — American physicists faced many challenges in the 1970s: declining research budgets; public skepticism of scientific authority; declining student enrollments; and pressure to shift to topics such as biomedicine, environmental remediation, alternative energy, public housing and transport, and disability technologies. This paper examines the responses to these challenges of a small group of Santa Barbara physicists. While this group is not representative of the American physics profession, the success and failure of their responses to changed conditions tells us something about how American physicists got through the 1970s, and about the origins of some features of American physics today. The three physicists examined here are Philip Wyatt, David Phillips, and Virgil Elings. In the late '60s, Wyatt left a defense think tank to found an instrumentation firm. The Santa Barbara oil spill and other factors pushed that firm toward civilian markets in biomedicine and pollution measurement. Phillips joined Wyatt's firm from UCSB, while also founding his own company, largely to sell electronic devices for parapsychology. Phillips was also the junior partner in a master's of scientific instrumentation degree curriculum founded by Elings in order to save UCSB Physics' graduate program. Through the MSI program, Elings moved into biomedical research and became a serial entrepreneur. By the 1990s, Wyatt, Phillips, and Elings' turn toward academic entrepreneurship, dual military-civilian markets for physics start-ups, and interdisciplinary collaborations between physicists and life scientists were no longer unusual. Together, their journey through the '70s shows how varied the physics' profession's response to crisis was, and how much it pivoted on new interactions between university and industry.

9:12AM M9.00004 Industrial Physics—Southern California Style , STUART LESLIE, The Johns Hopkins University — Only in Southern California did space-age style really come into its own as a unique expression of Cold War scientific culture. The corporate campuses of General Atomic in San Diego and North American Aviation in Los Angeles perfectly expressed the exhilarating spirit of Southern California's aerospace era, scaling up the residential version of California modernism to industrial proportion. Architects William Pereira and A.C. Martin Jr., in collaboration with their scientific counterparts, fashioned military-industrial 'dream factories' for industrial physics that embodied the secret side of the space-age zeitgeist, one the public could only glimpse of in photographs, advertisements, and carefully staged open houses. These laboratories served up archetypes of the California dream for a select audience of scientists, engineers, and military officers, live-action commercials for a lifestyle intended to lure the best and brightest to Southern California. Paradoxically, they hid in plain sight, in the midst of aerospace suburbs, an open secret, at once visible and opaque, the public face of an otherwise invisible empire. Now, at the end of the aerospace era, these places have become an endangered species, difficult to repurpose, on valuable if sometimes highly polluted land. Yet they offer an important reminder of a more confident time when many physicists set their sights on the stars.

9:36AM M9.00005 Panel Discussion - Perspectives on the History of Industrial Physics , JOSEPH MARTIN, University of Minnesota-Twin Cities — This panel discussion provides the speakers and the audience an opportunity to explore the common themes these papers exhibit in greater detail.

10:00AM M9.00006 PANEL DISCUSSION –

Wednesday, March 20, 2013 8:00AM - 11:00AM –

Session M10 FGSA: Invited Session: Physics Jobs in Government and Science Policy followed by Panel Discussion

309 - Laura Boon, Purdue University

8:00AM M10.00001 Off the Beaten Path: A Journey to a Career Beyond the Laboratory , AMY FLATTEN[1], American Physical Society — This presentation will provide insights on how a scientific graduate degree can lead to opportunities that combine scientific expertise with diverse interests such as business, international affairs, and science policy. The speaker will talk about potential challenges for PhD scientists working outside of a traditional research environment and the professional skills that help ensure success in careers beyond the laboratory.

[1]Director of International Affairs

8:36AM M10.00002 "Political" Science , LAURA BERZAK HOPKINS, Lawrence Livermore National Laboratory, APS/AAAS Congressional Fellow 2010-2011 — Politics and policy affect all of us, both as scientists and as citizens, and issues ranging from laboratory budgets to arms control treaties clearly require research problem-solving skills and technical expertise. There is a critical role for scientists in each aspect of the political system, and in fact, we as a society need more scientists to take part in politics. Furthermore, the research we pursue has important societal applications and is fascinating! We have a right and a responsibility to share our scientific knowledge not only with each other, but with the general public as well. So, why are we as a community of scientists reticent in the public arena, hesitant to enter politics, and even at times unsupportive of our peers who transition into governmental roles? In this time of fiscal constraint, when difficult research funding (and de-funding) choices are regularly being made, we as scientists must step up to the plate, reach across the aisle, and explain why what we do is fascinating, inspiring, and important, not just to us, but to society as a whole. A range of policy-relevant roles exists inside and outside the laboratory, such as Congressional Fellowships. Each year the Congressional Fellowships program brings together approximately thirty scientists at all stages of their careers to serve as scientific advisors in a variety of offices in the U.S. Senate and House of Representatives. Although the jump from lab to lobbying meetings can be frustrating, the transition can also be intriguing. Firsthand experience with the "how" and "why" (or lack thereof) of politics and policy is invaluable and provides a unique opportunity to expand and broaden one's background. The opportunity to work on Capitol Hill is unparalleled, particularly because our nation has a definite need for scientists with the inclination and interest to inform and develop policy. But, whatever role you decide to take, from contributing scientific news to local publications to running for Congress, it's high time to show that we as scientists have important contributions to make both inside and outside the laboratory. We as scientists can and should contribute to ongoing political discussions, and there is no better time than now to speak up and apply our expertise to the policy issues at hand.

9:12AM M10.00003 A Career Path in Science, Policy, and Politics , JOHN LOONEY, Brookhaven National Laboratory — No abstract available.

9:48AM M10.00004 PANEL DISCUSSION –
Panelists: Tyler Glembo and Hugh Van Horn

Wednesday, March 20, 2013 8:00AM - 11:00AM –

Session M11 DPOLY: Invited Session: Polymer Electrolytes for Energy Storage 310 - Enrique Gomez, Pennsylvania State University

8:00AM M11.00001 Effect of Ion Clusters on Transport in Hydrated Block Copolymers , NITASH BALSARA, UC Berkeley — Transport through hydrated membranes is important for a wide variety of applications including desalination, artificial photosynthesis, and hydrogen fuel cells. Model membranes for these applications can be created by self-assembly of block copolymers containing an ion-containing hydrophilic block and a nonionic hydrophobic block that provides the membrane with structural integrity in the hydrated state. The formation of ordered microdomains such as lamellae and cylinders in block copolymers is well-established. The ion-containing microdomains also contain nanoscale ionic aggregates. The talk will focus on the effect of morphology on transport of protons and hydroxide ions. We pay particular attention to the effect of clusters on ion transport.

8:36AM M11.00002 New Approaches to Conjugated Polymer Electrodes for Organic Energy Storage , JODIE LUTKENHAUS, Texas A&M University — Conjugated polymers have been explored as electrodes in batteries and pseudocapacitors for over 30 years. Yet, their widespread implementation has been hindered for several reasons such as oxidative stability, low capacity, and rate limitations associated with ionic mobility relative to current state-of-the-art. On the other hand, conjugated polymers have much to offer because of their good electronic conductivity, high Coulombic efficiency, and theoretical capacities comparable to those of metal oxides. Our lab's current goal is to overcome the aforementioned challenges, so that conjugated polymeric electrodes can be suitable used in energy storage for applications such as mechanically flexible energy storage and structural power system. This talk will present several approaches towards synthesis and processing of polyaniline that achieve oxidatively stable, high capacity, ionically mobile electrodes. These approaches include template polymerization, synthesis of nanofibers, and layer-by-layer assembly.

9:12AM M11.00003 Ionomer Design, Synthesis and Characterization for Ion-Conducting Energy Materials[1] , RALPH H. COLBY, Materials Science and Engineering, Penn State University, University Park, PA 16802 USA — For ionic actuators and battery separators, it is vital to utilize single-ion conductors that avoid the detrimental polarization of other ions; the commonly studied dual-ion conductors simply will not be used in the next generation of materials for these applications. *Ab initio* quantum chemistry calculations at 0 K in vacuum characterize ion interactions and ion solvation by various functional groups, allowing identification of constituents with weak interactions to be incorporated in ionomers for facile ion transport. Simple ideas for estimating the ion interactions and solvation at practical temperatures and dielectric constants are presented that indicate the rank ordering observed at 0 K in vacuum should be preserved. Hence, such *ab initio* calculations are useful for screening the plethora of combinations of polymer-ion, counterion and polar functional groups, to decide which are worthy of synthesis for new ionomers. Single-ion conducting ionomers are synthesized based on these calculations, with low glass transition temperatures (facile dynamics) to prepare ion-conducting membranes for ionic actuators and battery separators. Characterization by X-ray scattering, dielectric spectroscopy, NMR and linear viscoelasticity collectively develop a coherent picture of ionic aggregation and both counterion and polymer dynamics. Examples are shown of how *ab initio* calculations can be used to understand experimental observations of dielectric constant, glass transition temperature and conductivity of polymerized ionic liquids with counterions being either lithium, sodium, fluoride, hydroxide (for batteries) or bulky ionic liquids (for ionic actuators).

9:48AM M11.00004 Thermodynamics of salt-doped polymers , ZHEN-GANG WANG, California Institute of Technology — There is much current interest in salt-doped polymers as materials for energy applications. For example, a promising system for rechargeable battery applications consists of diblock copolymers of an ion-dissolving block, such as polyethylene oxide (PEO) and a nonconducting block such as polystyrene. Experimentally, it has been shown that the addition of lithium salts significantly alters the order-order and order-disorder transition (ODT) temperatures. In particular, the ODT temperature can increase substantially upon adding even a small amount of lithium salt, and the domain spacing in the ordered phases also increases significantly. Both changes are found to depend on the anion type. In this talk, I describe a simple theory for explaining these phenomena. A key effect is the solvation energy of the anions by the polymers, which we approximate using the Born solvation model. The difference in the Born energy between different polymers provides a driving force towards phase separation. By studying the shift in the mean-field spinodal of the disordered phase, we can identify an effective χ parameter, with a systematic dependence on the anion radius, in agreement with available experimental data. Furthermore, by studying the behavior of the domain spacing with salt concentration, we clarify the relationship between different definitions of the effective χ parameter. We propose that the effective χ parameter determined from the structure factor of the disordered phase is a more robust measure of the change in miscibility between the two blocks. Finally, we demonstrate that salt doping induces a strongly first-order transition from the disordered phase to the lamellar phase, with different salt concentrations in the two phases.

Session M12 DCMP: Topological Insulators: Topological States in Superconductors 314 - Andrew Wray, Lawrence Berkeley National Laboratory

8:00AM M12.00001 Engineering Majorana modes in MBE grown III-V semiconductor heterostructures , PEDRAM ROUSHAN, PETER O'MALLEY, YU CHEN, BROOKS CAMPBELL, Department of Physics, UCSB, BORZOYEH SHOJAEI, JAVAD SHABANI, BRIAN SCHULTZ, CHRIS PALMSTROM, Materials department, UCSB, JOHN MARTINIS, Department of Physics, UCSB — Several theoretical proposals for realizing Majorana fermions in condensed matter systems have created much excitement and are being intensely followed by experimental groups. A common feature of all these proposals is the large size of the parameter space. We are pursuing a proposal based on coupling a semiconductor nanowire with strong spin-orbit coupling to an s-wave superconductor. Considering only the energy landscape, the size of the induced quasiparticle gap depends on the spin-orbit coupling, Zeeman energy, mobility, coupling between the two materials, and the s-wave superconducting gap. We find that Majorana modes can only be realized through carefully engineered materials. We explore this parameter space and discuss the feasibility of realizing Majorana modes based on measured parameters in our MBE grown semiconductor heterostructures.

8:12AM M12.00002 Tunneling spectroscopy of topological superconducting states – toward detection of Majorana fermions[1] , WAN KYU PARK, K. COUGHLIN, C. WAN, M. LIU, L.H. GREENE, University of Illinois at Urbana-Champaign, J. SCHNEELOCH, R.D. ZHONG, Z.J. XU, G. GU, Brookhaven National Laboratory — Topological insulators and superconductors have attracted much research interest recently. These materials are known to possess exotic electronic structures that cannot be adiabatically transformed to topologically trivial ones. The spin-momentum locked (helical) Dirac fermions form surface conduction bands while the bulk is insulating. When they become superconducting, charge-neutral zero-energy modes, the so-called Majorana fermion modes, are predicted to emerge due to the unique quasiparticle properties in such a superconducting state. Aiming at detect them, we investigate two novel superconducting systems using tunneling spectroscopy: i) thin film Nb which is proximity-coupled to the helical Dirac fermions in $(Bi,Sb)_2Se_3$; ii) (Sn,In)Te, a potential topological superconductor. Our measurements reveal unusual conductance features in the background and near zero bias. We will report results on their temperature and magnetic field dependences and discuss their implications.

8:24AM M12.00003 Transport properties of topological superconductor-Luttinger liquid junctions , ROMAN LUTCHYN, Microsoft Station Q, JACOB SKRABACZ, University of California Santa Barbara — Devices involving topological superconductor-Luttinger liquid junctions have been fabricated recently [1,2] to detect Majorana zero-energy modes. One of the signatures of Majoranas in such systems is the so-called "zero-bias anomaly" - a quantization of the tunneling conductance at zero temperature. We have developed a framework based on Keldysh formalism to study the corrections to the tunneling conductance due to finite temperature and voltage. Our results are important for understanding the experimental data.

8:36AM M12.00004 Interface currents in topological superconductor-ferromagnet junctions , PHILIP BRYDON, CARSTEN TIMM, Technische Universität Dresden, ANDREAS SCHNYDER, Max-Planck-Institut für Festkörperforschung — Both fully gapped and nodal pairing states of noncentrosymmetric superconductors (NCS) display non-trivial topological properties, manifested by topologically protected dispersing and flat-band surface states [1,2]. Using a 2D model of an NCS, we show that the surface states typically have strong spin-polarization $s_{\mu=x,z}(k_y)$, which is odd in the surface-Brillouin-zone momentum k_y. Upon placing the NCS in proximity contact with a ferromagnet, the coupling to the exchange field gives a perturbative correction to the energy of these states $\propto s_\mu(k_y)$, thus generating an interface charge current $\propto \partial_{k_y} s_\mu(k_y)$ in the NCS. This is most clearly realized in a nodal NCS, where the weak dispersion acquired by the singly degenerate zero-energy flat bands leads to a strong enhancement of the interface current at low temperatures. We argue that this effect is a "smoking-gun" signature of the singly degenerate flat bands.

8:48AM M12.00005 Majorana fermions in spin-singlet nodal superconductors with coexisting non-collinear magnetic order , ZIQIANG WANG, Boston College, YUAN-MING LU, University of California, Berkeley — Realizations of Majorana fermions in solid state materials have attracted great interests recently in connection to topological order and quantum information processing. We propose a novel way to create Majorana fermions in superconductors. We show that an incipient non-collinear magnetic order turns a spin-singlet superconductor with nodes into a topological superconductor with a stable Majorana bound state (MBS) in the vortex core or on the edge. Moreover the topologically-stable point defect of non-collinear magnetic order also hosts a zero-energy MBS. We argue that such an exotic non-Abelian phase can be realized in extended t-J models on the triangular and square lattices. Our proposal suggests a new avenue for the search of Majorana fermions in correlated electron materials where nodal superconductivity and magnetism are two common caricatures.

9:00AM M12.00006 Tuning between s-wave and p-wave superconductors as well as emerging Majorana fermions in extended Hubbard lattices , KUEI SUN, University of Cincinnati, CHING-KAI CHIU, University of Illinois at Urbana-Champaign, JIANSHENG WU, Hong Kong University of Science and Technology — We study spin-half fermions in one dimensional extended Hubbard lattices in which the superconducting pairing orders are induced by the tuning of nearest-neighbor charge and spin interactions. We derive gap equations for three p-wave (triplet) as well as one s-wave (singlet) pairing orders and obtain a phase diagram characterizing these orders as a function of interaction couplings. We find that the system can evolve between s-wave and p-wave pairing states, accompanied with the emergence of Majorana fermions in the p-wave regime, identified as a time-reversal invariant Kitaev Majorana chain. Finally we discuss the effects on the topological non-trivial states when time-reversal or SU(2) symmetry breaks.

9:12AM M12.00007 Robustness of Majorana modes in multiband topological superconductors , SHUSA DENG, Dartmouth College, GERARDO ORTIZ, University of Indiana, Bloomington, LORENZA VIOLA, Dartmouth College — We investigate the robustness of Majorana modes in a multiband topological superconductor model belonging to symmetry class DIII, against various perturbations. In the three dimensional case, we find that in topological phases where an even number of Kramer pairs of Majorana modes exist on each boundary, these modes may become gapped under a boundary perturbation, despite time-reversal invariance being preserved. Conversely, in two dimensions, the gapless Majorana modes may remain gapless in the presence of certain time-reversal breaking fields or impurities. However, upon changing the strength of an applied longitudinal Zeeman field, a transformation from helical Majorana modes to chiral Majorana modes may be induced, accompanied by a quantum phase transition in the bulk.

9:24AM M12.00008 Majorana end modes in STM Fabricated Atomic Chains on the Surface of a Superconductor: Theory & Experiment , STEVAN NADJ-PERGE, ILYA DROZDOV, JUNGPIL SEO, ANDREI BERNEVIG, ALI YAZDANI, Princeton University — The search for Majorana fermions (MF) in solid state devices has been hampered by the possible affects of disorder which may induce signatures similar to those expected by novel MF boundary states. Therefore it is important to identify clean solid state systems in which MF modes can be easily distinguished from disorder related effects. In this talk, we will present theoretical calculations and preliminary experimental results on chains of magnetic atoms on the surface of an s-wave superconductors. The theoretical efforts show that surprisingly short magnetic chains (20 atoms long or more) support MF under specific conditions depending on spins of the magnetic atoms and their coupling. We will describe these theoretical results along with experiments in which a scanning tunneling microscopy (STM) has been used to assemble chains of magnetic atoms (3d transition metals) on Nb and Pb single crystals. Presence of Majorana boundary modes in these structures can be probed using spatially-resolved STM spectroscopy.

9:36AM M12.00009 Topological defects and subgap excitations in two-band superconductors[1] , KIRILL SAMOKHIN, MICHELLE PRZEDBORSKI, Brock University — Phase solitons are topological defects peculiar to two-band superconductors, which are associated with a 2π winding of the relative phase of the two superconducting condensates. The order parameter phase variation in each of the bands leads to the quasiparticle bound states whose energies are below the bulk gap. We calculate the single soliton energy as well as the interaction energy of two solitons, at arbitrary temperature. Applications to a similar system – one or more domain walls in a chiral p-wave superconductor – are discussed.

9:48AM M12.00010 Symmetry Protected Majorana fermions in topological superconductors , MASATOSHI SATO, Department of Applied Physics, Nagoya University — Recently, there are considerable interests in Majorana fermions in topological superconductors. It has been found that promising schemes to realize Majorana fermions is to break some of symmetries of the system. Indeed, by inducing the spin-orbit interaction and the Zeeman coupling which break inversion and time-reversal symmetries, conventional s-wave superconductors may support Majorana fermions on the boundaries. Moreover, by breaking the spin-rotation symmetry, spin-triplet superconductors may support Majorana fermions. Therefore, one might expect that symmetry is an obstruction to detect Majroana fermions. In this talk, however, we will show that this is not always the case. We show that symmetry may protect Majorana fermions in topological superconductors. As an example, we will show that Majorana Ising charater , which gives a detectable signal of Majorana fermion , is stabilized by symmetry of the system. We will also discuss some other roles of symmetry for Majorana fermions in topological crystalline superconductors.

10:00AM M12.00011 Majorana fermions in 3DTI with superconductivity , PEDRO LOPES, Unicamp/UIUC, POUYAN GHAEMI, SHINSEI RYU, UIUC — We study the problem of a strong 3D topological insulator (TI) with intrinsic superconductivity (SC). Particularly we present microscopic calculations using a low energy model of bulk massive Dirac fermions with mean field s-wave SC pairing. Introducing a kink in the mass in one spatial direction we can verify the appearance of localized (around the kink) states which correspond to the TI surface states and, with the further introduction of a vortex in the SC pairing, we are able to bind Majorana zero-modes (MZM's). The MZM's are known to be elusive particles in the sense that they are hard to detect. We then introduce a Majorana representation to the system Hamiltonian described above and propose an artificial doubling of this system which gives rise to a O(2) symmetry and allows us to define a conserved charge that can be used to probe for the presence of the MZM's. This doubled Majorana system then becomes an interesting playground, allowing us to search for masses which mix the different Hilbert spaces and study the behavior of this charge. We finish with a path-integral formulation of the problem through which we can integrate out the fermions and find an effective action for both, the electromagnetic as well as the corresponding to the O(2) conserved charge, gauge fields.

10:12AM M12.00012 Josephson-Majorana cycle in topological single-electron hybrid transistors[1] , NICOLAS DIDIER, Universite de Sherbrooke and McGill University, MARCO GIBERTINI, Scuola Normale Superiore, ALI G. MOGHADDAM, University of Duisburg-Essen and IASBS Zanjan, JUERGEN KOENIG, University of Duisburg-Essen, ROSARIO FAZIO, Scuola Normale Superiore — Charge transport through a small topological superconducting island in contact with a normal and a superconducting electrode occurs through a cycle which involves coherent oscillations of Cooper pairs and tunneling in/out the normal electrode through a Majorana bound state, the Josephson-Majorana cycle. We illustrate this mechanism by studying the current-voltage characteristics of a superconductor - topological superconductor - normal metal single-electron transistor. At low bias and temperature the Josephson-Majorana cycle is the dominant mechanism for transport. We discuss a three-terminal configuration that constitutes a direct probe of the non-local character of the Majorana bound states. Non-local cotunneling dominates over the local contributions and the current noise is maximally correlated independently of the length of the wire. Preprint: arXiv:1202.6357

10:24AM M12.00013 Superconducting Klein tunneling and AC Josephson effect in superconductor/topological insulator/superconductor junctions[1] , EWELINA HANKIEWICZ, GRIGORY TKACHOV, Wuerzburg University — We consider superconductor(S)/surface state of topological insulator(TI)/superconductor junctions (S) where the S regime describes the surface state of the TI with the proximity with the s-wave superconductor. The novelty of such S/TI/S junctions originates from the electron spin helicity (locking of the mometum and the spin for a surface of TIs) which leads to both the s-wave singlet and the p-wave triplet pairing on the surface underneath the superconductor. Existence of these two superconducting channels lead to interesting features in transport through these junctions. In particular we show that superconducting Klein tunneling and topological Andreev bound state (ABS) (state of hybridized two Majorana fermions)) occur for the normal incidence where ABS is protected against backscattering. For transport channels different than for the normal incidence, the scattering from the junction barrier generates an energy gap in the spectrum supporting non-topological ABSs. Due to mixed order parameter, the AC Josephson effect is fractional showing higher odd harmonics. We conclude that favorable conditions for the observation of the topological ABS exist in narrow TI links with a small number of open channels close to one.

10:36AM M12.00014 Josephson currents through topological insulator surfaces , JENS H. BARDARSON, RONI ILAN, UC Berkeley, HEUNG-SUN SIM, KAIST, JOEL E. MOORE, UC Berkeley — Motivated by recent experiments carried out on superconductor – 3D topological insulator – superconductor junctions, we study the transport properties of these junctions. Transport is believed to be dominated by the surface states of the topological insulator, and we discuss the effects of the junctions geometry on the Josephson supercurrent in the presence of a magnetic field.

10:48AM M12.00015 X-ray absorption spectroscopy of doped Bi2Se3 and Bi2Te3 , JESSICA MCCHESNEY, RICHARD ROSENBERG, DUCK YOUNG CHUNG, Argonne National Laboratory, MERCOURI KANATZIDIS, Argonne National Laboratory; Northwestern University — Topological insulators are a prototypical system to investigate correlated electron physics. Analogous to quantum hall states, these remarkable materials have conducting surface/edge states surrounding an insulating in the bulk state. Unlike quantum hall systems the conducting states of topological insulators do no arise from an applied magnetic field but instead emerge as a result of spin-orbit interactions. Furthermore, doping with different 3d-metals can significantly alter the electronic structure, inducing superconductivity in the case of CuxBi2-xSe3, and ferromagnetism in Bi2-xMnxTe3. In an effort to elucidate the role of the local bonding environment on the electronic structure in the chalchogenide topological insulators, Bi2Te3 and Bi2Se3 with various transition metal as dopants, we have preformed a series of soft x-ray absorption spectroscopy measurements.

Wednesday, March 20, 2013 8:00AM - 10:48AM –

Session M13 DMP: Focus Session: Topological Materials - Surface Effects 315 - Arun Bansil, Northeastern University

8:00AM M13.00001 Photoelectron spin-flipping and texture manipulation in a topological insulator , CHRIS JOZWIAK, Advanced Light Source, Lawrence Berkeley National Lab, CHEOL-HWAN PARK, Department of Physics and Astronomy, Seoul National University, KENNETH GOTLIEB, Graduate Group in Applied Science and Technology, University of California, Berkeley, CHOONGYU HWANG, Materials Sceinces Division, Lawrence Berkeley National Lab, DUNG-HAI LEE, STEVEN G. LOUIE, Department of Physics, University of California, Berkeley, JONATHAN D. DENLINGER, Advanced Light Source, Lawrence Berkeley National Lab, COSTEL R. ROTUNDU, Materials Sciences Division, Lawrence Berkeley National Lab, ROBERT J. BIRGENEAU, Department of Physics, University of California, Berkeley, ZAHID HUSSAIN, Advanced Light Source, Lawrence Berkeley National Lab, ALESSANDRA LANZARA, Department of Physics, University of California, Berkeley — A hallmark characteristic of the recently discovered topological insulators is their protected metallic surface states. Electrons in these surface states are spin polarized with their spins governed by their momentum, resulting in a helical spin texture in momentum space. Spin- and angle-resolved photoemission spectroscopy has been the only tool capable of directly observing this central feature with simultaneous energy, momentum, and spin sensitivity. By using an innovative photoelectron spectrometer with a high-flux laser, we found that the spin polarization of the resulting photoelectrons exhibits rich phenomena previously unobserved. These surprising results provide insight into the physics of these fascinating materials and the use of spin-resolved photoemission in general.

8:12AM M13.00002 Interaction between Dirac fermions and phonons on the (001) surface of the strong 3D topological insulator Bi_2Te_3 , COLIN HOWARD, MICHAEL EL-BATANOUNY, Boston University, FANG-CHENG CHOU, R. SHANKAR, National Taiwan University — We report on studies of the interaction of Dirac fermion quasiparticles with phonons on the (001) surface of the strong 3D topological insulator Bi_2Te_3. Studying this coupling is essential for determining the technological viability of this new class of materials. We employed inelastic helium atom scattering to determine surface phonon dispersions along the ΓM and ΓKM directions. In contrast to our previous studies on Bi_2Se_3,[1] which exhibited a strong Kohn anomaly at $2k_F \approx 0.2\text{Å}^{-1}$ in a low-lying optical phonon branch, the current results show a weaker Kohn anomaly at $2k_F \approx 0.1\text{Å}^{-1}$ in a similarly low-lying branch. The lower value of k_F is consistent with the smaller carrier concentration in Bi_2Te_3 as evidenced by Hall conductivity measurements. Our results are further substantiated by lattice dynamical calculations performed within the pseudo-charge model. We also report on a detailed analysis of the electron-phonon coupling as a function of phonon branch index and wave vector utilizing the methods we recently developed.[2]

8:24AM M13.00003 Polarization-Dependent Scanning Photocurrent Microscopy of Bi2Se3[1] , BEHNOOD GHAMSARI, DOHUN KIM, MICHAEL FUHRER, STEVEN ANLAGE, Center for Nanophysics and Advanced Materials, Department of Physics, University of Maryland, College Park, MD, 20742, USA — We measured the spatially-resolved response of Bi2Se3 topological insulator to polarized light by means of scanning photocurrent microscopy. A polarized laser spot of 1 um diameter is raster scanned over a gate-controlled Bi2Se3 two-contact device oriented at 45 degrees to the plane of incidence, and the photo-generated current is measured at each point for varying light polarization states from linearly polarized to right-handed circularly polarized to left-handed circularly polarized. The data is, in turn, used to differentiate the contributions from helicity-dependent spin-orbit coupling effects and helicity-independent photovoltaic and photothermoelectric effects, as well as map their spatial distributions over the device. The experiment is repeated for different carrier densities, through varying the voltage of the back gate, to investigate the dependence of the photoresponse on the carrier density.

8:36AM M13.00004 Investigation of Positron Sticking to the Surfaces of Topological Insulators[1] , K. SHASTRY, P.V. JOGLEKAR, A.Y. OLENGA, N.G. FAZLEEV, A.H. WEISS, University of Texas at Arlington, B. BARNIELLINI, Northeastern University — We describe experiments aimed at probing the sticking of positrons to the surfaces of topological insulators. In these experiments, a magnetically beam will be used to deposit positrons at the surface of Bi_2Te_2Se. The energy spectra and intensities of electrons emitted as a result of Positron Annihilation induced Auger electron Spectroscopy (PAES) provides a distinct element specific signal which can be used to determine if positrons can be trapped efficiently into a surface localized bound state. The experiments are aimed at determining the practicality of using positron annihilation to selectively probe the critically important top most layer of topological insulator system.

[1]Welch Y1100, NSF DMR 0907679

8:48AM M13.00005 Emergent quantum size effects at topological insulator surfaces , PHIL D.C. KING, Kavli Institute at Cornell for Nanoscale Science, USA & University of St Andrews, UK, M.S. BAHRAMY, RIKEN-ASI, Japan, G. BALAKRISHNAN, University of Warwick, UK, R. ARITA, N. NAGAOSA, RIKEN-ASI & University of Tokyo, Japan, F. BAUMBERGER, University of Geneva, Switzerland — Bismuth-chalchogenides are model examples of three-dimensional topological insulators. Their ideal bulk-truncated surface hosts a single spin-helical surface state, which is the simplest possible surface electronic structure allowed by their non-trivial Z_2 topology. However, real surfaces of such compounds, even if kept in ultra-high vacuum, rapidly develop a much more complex electronic structure[1] whose origin and properties have proved controversial. Here we demonstrate that a conceptually simple model, implementing a semiconductor-like band bending in a parameter-free tight-binding supercell calculation, can quantitatively explain the entire measured hierarchy of electronic states.[2] In combination with circular dichroism in angle-resolved photoemission experiments, we further uncover a rich three-dimensional spin texture of this surface electronic system, resulting from the non-trivial topology of the bulk band structure. Moreover, our study sheds new light on the surface-bulk connectivity in topological insulators, and reveals how this is modified by quantum confinement.

9:00AM M13.00006 Surface metal doping of topological insulator Bi_2Se_3 thin films[1] , Y.Y. LI, Y. LIU, M. WEINERT, L. LI, University of Wisconsin, Milwaukee — Three-dimensional topological insulators have attracted much attention due to their spin-momentum locked surface Dirac states, which have been proposed as the basis for spintronics and quantum computing. In the case of Bi_2Se_3, thin films grown by molecular beam epitaxy are typically heavily doped n-type, which places the Fermi level outside its band gap, making it challenging to develop devices that rely on the behavior of surface Dirac fermions. In this work, we grow high quality Bi_2Se_3 films and tune the topological surface state by metal doping on the surface. The atomic structure and morphology of the metal/Bi_2Se_3 are investigated by *in situ* scanning tunneling microcopy. Furthermore, scanning tunneling spectroscopy reveals that the position of Dirac energy can be shifted by as much as 150 meV. These results and comparison with first-principles calculations will be discussed at the meeting.

[1]Supported by NSF (DMR-1105839).

9:12AM M13.00007 Carrier control via charge transfer at the topological-insulator/organic-molecule interface , KATSUMI TANIGAKI, AIMR, Tohoku University, YOICHI TANABE, KHUONG KUYNH, TAKAHIRO URATA, Department of Physics, Graduate School of Science, Tohoku University, RYO NOUCHI, Center of Nano Science and Technology, Osaka Prefecture University, SATOSHI HEGURI, HIDEKAZU SHIMOTANI, Department of Physics, Graduate School of Science, Tohoku University, AIMR, TOHOKU UNIVERSITY COLLABORATION, DEPARTMENT OF PYSICS, GRADUATE SCHOOL OF SCIENCE, TOHOKU UNIVERSITY COLLABORATION[1], OSAKA PREFECTURE UNIVERSITY COLLABORATION — A topological insulator is a material that behaves as an insulator as a bulk state, while permitting metallicity on its Dirac cone surface state. One of the most serious issues of recent researches in this field, however, has been the fact that the Fermi levels in many TIs actually fall in either the conduction or valence band due to the naturally occurring defects and must be controlled by further doping. We report here that the major electron carriers on the SS of a $Bi_{2-x}Sb_xTe_{3-y}Se_y$(BSTS) single crystal can be converted to the hole carriers via interface control using 2,3,5,6-tetrafluoro-7,7,8,8-tetracyanoquinodimethane(F4-TCNQ), with strong electron affinity. The evidence can be elucidated using a detailed three-carrier model. The results apparently demonstrate that the charge transfer at the TI/organic-molecule interface is very efficient in order to control the carrier density of TIs, particularly on the SS. Our present results will be very important for studying the fundamental aspects of TIs as well as their future device applications.

9:24AM M13.00008 The Effects of Different Ambient Environments on the Electrical Properties of Bi_2Se_3 Thin Films over Time , JOSEPH BROM, The Pennsylvania State University, MALIA KAWAMURA, Colby College, JOAN REDWING, The Pennsylvania State University — It has been recognized recently that the Bi_2Se_3 surface is highly susceptible to environmental doping at room temperature when exposed to ambient air. The change in conductivity is correlated to oxidation of the surface; however, the roles of O_2 and residual H_2O in the process are not fully understood. In this study, we investigated the effects of different ambient environments (air, O_2, N_2, H_2O) on the electrical properties of Bi_2Se_3 thin films grown by hybrid physical-chemical vapor deposition. Hall measurements were performed on samples exposed to each of the gases over a period of several hours to days. The electron concentration of the Bi_2Se_3 films initially decreased upon exposure to air but began to rapidly increase and continued to do so over the next several hours. The use of an O_2 purge resulted in a large initial decrease in electron concentration suggesting that O_2 rapidly diffuses into Bi_2Se_3 and partially compensates the native donors. Over time, however, the electron concentration began to rise rapidly in a similar manner to that observed in air. Exposure of the surface to water vapor resulted in nearly identical behavior to that obtained in air. In contrast, measurements carried out under a N_2 purge demonstrate a small initial decrease in electron concentration but do not exhibit an appreciable increase in electron concentration even after 24 hours. The mechanism of surface oxidation and conductivity change will be discussed.

9:36AM M13.00009 Modeling electron dynamics at the topological insulator-metal interface , SUSMITA BASAK, HSIN LIN, Northeastern University, SU-YANG XU, M. Z. HASAN, Princeton University, ARUN BANSIL, Northeastern University — The surface environment of the topological insulators possesses ideal properties such as spin-polarized conductivity and suppressed scattering for advanced electronics applications. A major key missing ingredient in this connection is lack of understanding of how topologically ordered electrons respond to the presence of interfaces and various surface terminations that constitute device components at the nanometer scale. To explore these issues we have developed a Green's function implementation of the $k \cdot p$ model to numerically simulate junctions and surfaces of topological insulator Bi_2Se_3 based on experimentally measured bulk electron kinetics. Our model explains a number of interesting features observed in ARPES experiments for surface deposition in Bi_2Se_3.

9:48AM M13.00010 Interaction of Dirac fermions with surface lattice excitations and electron-phonon coupling on topological insulator surfaces , MICHAEL EL-BATANOUNY, Boston University — Surface Dirac fermions are robust against backscattering, but other scattering events can affect their anticipated ballistic behavior. Technical improvements may minimize or eventually eliminate surface defects, but phonons are always present. Consequently, coupling to phonons should be the dominant scattering mechanism for Dirac fermions on these surfaces at finite temperatures. Recent measurements of phonon dispersion curves on the (001) surfaces of several binary and ternary topological insulators were carried out using coherent inelastic helium beam surface scattering techniques. The dispersion curves reveal similar features among these materials: first, the absence of long-wavelength Rayleigh waves. Second, the appearance of a low-lying optical phonon branch with isotropic convex dispersive character in the vicinity of the Γ-point. Lattice dynamics calculations based on the pseudo-charge model show that the optical phonon branch appears with a concave shape when Dirac fermions are absent, but its dispersion changes to a convex shape when Dirac fermions are present. Theoretical analysis attributes this dispersive profile to the renormalization of the surface phonon excitations by the surface Dirac fermions. The contribution of the Dirac fermions to this renormalization is derived in terms of a Coulomb-type perturbation model. Moreover, this optical branch displays a V-shaped minimum at approximately $2\mathbf{k}_F$ that defines a Kohn anomaly. Using a Hilbert transform, we are able to obtain the imaginary part of the phonon self-energy from the real part fitted to the dispersion curve of the surface optical phonon branch. From this imaginary part of the self-energy we obtain a branch-specific electron-phonon coupling constant as a function of wave-vector. The average electron phonon coupling associated with this branch is found to be strong, especially for Bi_2Se_3, reflecting the pronounced renormalization described above.

10:24AM M13.00011 Direct Real Space Imaging of Quantum Spin Hall Edge States in HgTe Quantum Well[1] , YUE MA, WORASOM KUNDHIKANJANA, JING WANG, REYES CALVO, YONGLIANG YANG, KEJI LAI, MATTHIAS BAENNINGER, MARKUS KÖNIG, Stanford University, CHRISTOPHER AMES, CHRISTOPH BRÜNE, HARTMUT BUHMANN, PHILIP LEUBNER, Universität Würzburg, QIAOCHU TANG, KUN ZHANG, XINXIN LI, Shanghai Institute of Microsystem and Information Technology, LAURENS MOLENKAMP, Universität Würzburg, SHOU-CHENG ZHANG, DAVID GOLDHABER-GORDON, MICHAEL KELLY, ZHI-XUN SHEN, Stanford University — Microscopic real space imaging of the helical edge states is an important milestone to fully elucidate quantum spin Hall effect as a new state of quantum matter. By employing a unique cryogenic microwave impedance microscope, we directly imaged quantum spin Hall edges in a gapped HgTe quantum well. The edge state size increases monotonically as the Fermi level is tuned from p-type across the Dirac point into n-type. Whereas this result is counter-intuitive within any particle-hole symmetric model, it actually agrees well with the 8-band model of real material. Real space evolution of the edge states shows surprising dependence on the magnetic field which could not be explained by Landau level physics assuming a clean system. Alternative scenarios will be discussed.

10:36AM M13.00012 Layer-by-layer entangled spin-orbital texture of the topological surface state in Bi_2Se_3 , ZHIHUAI ZHU, C.N. VEENSTRA, G. LEVY, I.S. ELFIMOV, A. DAMASCELLI, Quantum Matter Institute, UBC, Canada, M.W. HAVERKORT, MPI, Stuttgart, Germany, A. UBALDINI, Univ. of Geneve, Switzerland, P. SYERS, N.P. BUTCH, J. PAGLIONE, CNAM, Univ. of Maryland, USA — With their spin-helical metallic surface state, topological insulators (TI) define a new class of materials with a strong application potential in quantum electronic devices. Technological exploitation depends on the degree of spin polarization of the topological surface state (TSS) - assumed to be 100% in phenomenological models. Yet in real materials, spin- and angle-resolved photoemission spectroscopy (ARPES) showed that the TSS spin polarization varies over a wide range: 20-85%. This striking variation in TSS spin polarization has remained unexplored, leaving an undefined application prospect of TIs. Here we present a light-polarization study of ARPES momentum maps to unveil the entangled spin-orbital texture of the TSS in Bi_2Se_3. By determining the layer-by-layer evolution of this spin-orbital entanglement, we solve the puzzle of the observed TSS spin polarization and also provide means to manipulate the spin polarization of photoelectrons and photocurrents in TI devices.

Session M14 GMAG DMP: Focus Session: Patterned Magnetic Nanostructures 316 - Frances Hellman, University of California, Berkeley

8:00AM M14.00001 Magnetic ToF GISANS on self-assembled nanoparticles[1] , ARTUR GLAVIC, Oak Ridge Natl Lab, Quantum Condensed Matter Div, Oak Ridge, TN 37831 USA, ELISABETH JOSTEN, OLEG PETRACIC, Juelich Centre for Neutron Science JCNS-2 and PGI-4, Juelich, Germany, VALERIA LAUTER, Oak Ridge Natl Lab, Quantum Condensed Matter Div, Oak Ridge, TN 37831 USA — Nanoparticle superlattices can be considered as novel type of materials with controllable electronic, optical and magnetic properties. Their building blocks are nanoparticles (or "nanocrystals") from a metallic, metal-oxide, or semiconducting material or hybrid between different materials. Using self-assembling techniques it is possible to create a large amount of highly ordered 3D structures, which we have investigated for their structural and magnetic properties. The lateral ordering is quantified using electron microscopy and grazing incidence small angle X-ray scattering (GISAXS) [1,2,4]. The macroscopic magnetic behavior and correlations are investigated by superconducting quantum interference device (SQUID) magnetometry [1,3]. Utilizing the time of flight (ToF) magnetism reflectometer at SNS the magnetic correlations have been studied with polarized GISANS and PNR.

8:12AM M14.00002 Anomalous Magnetoresistance Effect in Topographical Nanoengineered Material[1] , DEEPAK SINGH, University of Maryland, College Park / NIST, Gaithersburg, STEFAN DICKERT, RUKSHAN THANTIRIGE, MARK TUOMINEN, University of Massachusetts, Amherst — Recent developments in nanofabrication allow for the engineering of a broad range of topographical materials with strong implications in spin caloritronics of condensed matter physics. We have applied the top down approach to create a series of nanoengineered materials, which consists of locally hexagonal periodic array of Co dots (12 nm in diameter and 3 nm in thickness, with a periodicity of 28 nm) in direct multidirectional contact with encapsulating thin layer of polycrystalline Cu film (15-30 nm). The electrical transport measurements on the nanoengineered materials unveiled a host of interesting properties that includes the giant thermal hysteresis, which is onset above the room temperature, and anomalous magnetoresistance (MR) behavior. The thermal hysteresis exhibits strong magnetic field dependence, applied perpendicular to the substrate. The most unusual behavior, perhaps, is manifested by MR oscillations, which occur only in the initial field scan in a very unusual temperature range of 100 K $<$T $<$200 K. The qualitative interpretation of the experimental results suggests that the spin-orbit-type coupling between giant localized moments in periodic sites and the surrounding conduction electrons play important role in the anomalous MR oscillation.

8:24AM M14.00003 Magnetic Dipole Interaction on a Square Lattice[1] , HARTMUT ZABEL, MELANIE EWERLIN, DERYA DEMIRBAS, FRANK BRUESSING, Ruhr-Universitaet Bochum, FLORIAN KRONAST, Helmholtz-Zentrum Berlin — We have studied interactions and phase transitions of circular magnetic islands with dipole character on a square lattice. By lithographic means we have prepared square patterns of periodicity 300 nm decorated with circular islands of 150 nm diameter using Pd0.87Fe0.13 as magnetic alloy. Below the Curie temperature of 260 K each island is in a ferromagnetic, single domain state with dipolar character and zero in-plane anisotropy. Below a second transition temperature the dipoles start to interact. MOKE measurements show a characteristic change in the magnetic hysteresis for temperatures below 160 K with increasing coercivity for decreasing temperatures. Furthermore, below the second transition the in-plane hysteresis becomes anisotropic, having an easy axis along [10] direction and a hard axis along [11] direction. SPEEM experiments at BESSY II of the HZB with circularly polarized incident photons tuned to the Fe L3 - edge show clearly the development of dipolar chains below the second phase transition that increase in length with decreasing temperature. Neighbouring chains are found to be oriented parallel as well as antiparallel.

8:36AM M14.00004 Real-time imaging of magnetic-field gradient directed self-assembly of magnetic nanoparticles into patterns using magnetic recording media[1] , THOMAS CRAWFORD, MATTHEW CHAPMAN, LONGFEI YE, University of South Carolina, O. T. MEFFORD, Clemson University — We employ enormous magnetic field gradients at the surface of disk drive media to self-assemble ferrite nanoparticles from a colloidal fluid onto the medium surface. Thus we "nanomanufacture" a user-programmed and magnetically-recorded pattern with demonstrated 25 nm precision. Using a low-noise CCD camera for bright-field microscopy with a 40x water dipping lens, we demonstrate real-time optical imaging of the pattern formation. By introducing concentrated ferrofluid to a water solution covering the recording medium, we observe both diffusion of the ferrofluid as well as self-assembly of nanoaprticles onto the magnetic field pattern recorded on the disk. The average intensity of the nanoparticle pattern increases exponentially and then saturates, while the overall brightness of the image decreases exponentially, over both patterned and unpatterned regions. These results hint at interesting nanoparticle dynamics during the initial ferrofluid diffusion and after the nanoparticle assembly process occurs on the disk medium surface. We suggest real-time optical microscopy can help explain the dynamics of colloidal magnetic nanoparticles in the presence of extreme magnetic field gradients which are not employed in typical magnetophoretic assembly.

8:48AM M14.00005 Self-assembly of magnetic nanoparticles in a liquid-crystalline media[1] , JOSE AMARAL, R. ANDOSCA, A.L. RODARTE, C.G.L. FERRI, S. GHOSH, University of California, Merced — We investigate the self-assembly of magnetic Fe_3O_4 nanoparticles (NPs) dispersed in a liquid crystal (LC) matrix. The NP assembly is driven by the temperature-induced transition of the LC from the isotropic to the nematic phase. Using magneto-optical Kerr effect (MOKE) and polarized optical miscroscopy, we observe that the NPs are mostly expelled into the isotropic regions, finally ending up clustered around LC defect points when the transition is complete. We use NPs with diameters between 10-30 nm and the concentration of NPs in the LC media range from 0.02% to 0.2% by weight. We find that the resulting NP assemblies exhibit superparamagnetic and ferrimagnetic behavior, depending on their sizes.

9:00AM M14.00006 Toward Dynamic Control over Ordered Nanoparticle Monolayer Fabrication by Electrophoretic Deposition[1] , JAMES DICKERSON, ISABEL GONZALO-JUAN, ALEX KREJCI, Vanderbilt University — A primary challenges to the implementation of nanoparticles into device applications is the rapid production of densely packed, ordered films of these materials. The ordered arrangement of the nanomaterials is required for applications that rely on the collective interactions of the constituents or on the high density of the materials for information storage or surface protection. Rapid fabrication is a manufacturing demand to reduce operation costs and to streamline production. We have achieved a substantial milestone toward the mass production of macroscopic monolayers and thin films of colloidal nanocrystals on various substrates, including conducting metals and doped-semiconducting substrates. Our approach combines the advantages of liquid-phase, colloidal suspension approaches with the superior deposition rate, size scalability, and cost effective features of electrophoretic deposition (EPD) to achieve monolayer-by-monolayer deposition control over nanocrystal films with various degrees of internal order. Such work has the potential for the fabrication of industrial scale quantities and surface areas of these colloidal solids. Our recent research activities have demonstrated film formation with titanium dioxide nanoparticles and core/shell iron oxide nanoparticles.

9:12AM M14.00007 Magnetic Nanostructures by Templated Self Assembly , CAROLINE ROSS, Massachusetts Institute of Technology — Self assembly techniques provide a route to the rapid synthesis of nanostructures whose long range order and registration can be controlled by pre-patterning the substrate lithographically. This presentation will focus on two processes. First, masks made from templated block copolymer films are used for patterning of metallic magnetic films and multilayers into arrays of lines or dots with feature sizes of 10 nm and above. Second, codeposition of spinel and perovskite oxide phases leads to epitaxial thin film nanocomposites in which ferrimagnetic cobalt ferrite pillars are embedded in a ferroelectric bismuth orthoferrite matrix. The pillars form a regular array when templated by pits of pitch 60 nm and above, and have a strong magnetoelastic anisotropy. Magnetic properties of the resulting nanostructured materials are described.

9:48AM M14.00008 Assembly and manipulation of planar ordered magnetic micro-bead clusters , M. PRIKOCKIS, A. CHEN, T. BYVANK, G. VIEIRA, R. SOORYAKUMAR, The Ohio State University — The driving forces for many complex systems in nature often rely on the competition and cooperation between interacting simple components. These natural systems yield a framework to develop artificial phenomena and devices. In this vein we have investigated interacting micrometer sized beads containing superparamagnetic particles where competing deterministic and stochastic forces are tuned to create ordered clusters that are then maneuvered in a cooperative manner. Ferromagnetic microwires patterned on a silicon surface are utilized to regulate the magnetic interactions by confining the fluid-borne beads to a planar surface. Oriented weak external magnetic fields yield repulsive inter-particle forces that compete with local forces directed toward trap sites whose locations are determined by the underlying magnetic microwire pattern. The self-assembled ordered "clusters" of interacting dipolar beads are also subject to observable Brownian fluctuations. The geometrical order and inter-bead spacing within individual clusters are magnetically tuned, while entire clusters can be transported to nearby traps and reform into predictable shapes upon arrival. These features offer the potential for interesting engineering and biophysics studies.

10:00AM M14.00009 Characterization of barium hexaferrite thick films deposited by aerosol deposition method[1] , SCOOTER JOHNSON, SHU-FAN CHENG, MING-JEN PAN, FRITZ KUB, CHARLES EDDY, U.S. Naval Research Laboratory — We present results on the first deposition of nano-crystalline barium hexaferrite ($BaFe_{12}O_{19}$) (BaM) powder onto copper, silicon, and sapphire substrates using the aerosol deposition method (ADM). BaM is an important magnetic compound with many applications, including, permanent magnets, magnetic recording, and components in electronic circuits. Advantages of the ADM include the ability to form up to hundreds of microns thick, dense ceramic films at room temperature at high deposition rate on a variety of substrates. Deposition is achieved by creating a pressure gradient that accelerates particles in the aerosol to high velocity. Upon impact with the target the particles fracture and embed. Continual deposition forms the thick compacted film. Scanning electron microscopy and profilometry suggest that the film is compact and well adhered to the substrate surface. We compare magnetization curves of the raw nano-crystalline powder, pressed sintered powder, and deposited film. Our typical values of magnetic saturation are about 60 emu/g, coercive field 2 kOe, remnant magnetization 30 emu/g, and squareness 0.5. The similarity between the deposited films suggests comparable deposition quality across this range of substrate hardness. The reduction in remnance and saturation compared with the powder may suggest a more random orientation of moments and an increase in fracturing of the particles. We conclude with preliminary attempts to magnetically align particles during deposition.

10:12AM M14.00010 FMR Study of Quasicrystalline Arrays of Antidots in Permalloy Films[1] , VINAYAK BHAT, JUSTIN WOODS, BARRY FARMER, LANCE DE LONG, Department of Physics and Astronomy, University of Kentucky, TODD HASTINGS, Department of Electrical and Computer Engineering, University of Kentucky, JOSEPH SKLENAR, JOHN KETTERSON, Department of Physics and Astronomy, Northwestern University — We have used electron beam lithography to pattern permalloy films of thickness 25 nm with **quasiperiodic,** five-fold rotationally symmetric Penrose tilings of antidots (AD). Two samples were fabricated with AD kites and darts having long (d_1) and short edges (d_2) equal to 1620 nm or 810 nm, and 1000 nm or 500 nm, respectively, with fixed Py line width of 100 nm. We have studied broad-band (RF frequencies 10 MHz $<$f $<$15 GHz, DC applied fields -3.5 kOe $<$H $<$3.5 kOe) and narrow-band FMR (f = 9.7 GHz, 0 $<$H $<$8 kOe) for various angles between the in-plane DC field and the array edge. BBFMR spectra for f $<$4 GHz exhibit rich, highly reproducible structure, in spite of low-field (|H|$<$500 Oe) hysteresis, including a **frequency-independent** (implying localized) mode near H = 0 Oe. Both low-field FMR data and dynamic simulations exhibit two-fold rotational symmetry instead of the expected five-fold symmetry, which we attribute to an unsaturated state. Higher-field (|H|$<$12 kOe) simulations exhibit ten-fold rotational symmetry, which we attribute to the symmetry of the demagnetization fields.

10:24AM M14.00011 Magnetization Reversal Study of Geometrically Frustrated, Quasiperiodic Antidot Arrays[1] , JUSTIN WOODS, VINAYAK BHAT, BARRY FARMER, LANCE DE LONG, Department of Physics and Astronomy, University of Kentucky, TODD HASTINGS, Department of Electrical and Computer Engineering, University of Kentucky, JOSEPH SKLENAR, JOHN KETTERSON, Department of Physics and Astronomy, Northwestern University — We have used electron beam lithography to pattern quasiperiodic AD arrays in permalloy films of thickness 25 nm. Two five-fold rotationally symmetric Penrose tilings were fabricated with AD kites and darts having long (d1) and short edges (d2) equal to 1620 nm or 810 nm, and 1000 nm or 500 nm, respectively, with fixed Py line width of 100 nm. Two eight-fold Ammann tilings were patterned with square and rhomboid AD of edge lengths of 1000 nm or 2000 nm, resp. Magnetization reversal was studied at various angles between the in-plane, applied DC magnetic field H and the quasiperiodic array. We observed very reproducible hysteresis curves with low-field anomalies not present in our previous studies of periodic, square arrays of square-, circular- and diamond-shaped AD; e.g., for the Penrose tilings, we observed four reproducible knee anomalies (both for 81 <H <331 Oe, and for -19 >H >-71 Oe). Micromagnetic simulations exhibit systematic evolution of domain walls (DW) in the hysteretic regime due to DW pinning by edges of the quasicrystalline pattern, which correlates DW evolution with observed features in magnetic hysteresis.

[1]Research at Kentucky is supported by U.S. DoE Grant DE-FG02-97ER45653 and NSF Grant EPS-0814194.

10:36AM M14.00012 Observation of Novel Low-Field FMR modes in Permalloy Antidot Arrays[1] , LANCE DE LONG, VINAYAK BHAT, BARRY FARMER, JUSTIN WOODS, Department of Physics and Astronomy, University of Kentucky, TODD HASTINGS, Department of Electrical and Computer Engineering, University of Kentucky, JOSEPH SKLENAR, JOHN KETTERSON, Department of Physics and Astronomy, Northwestern University — Permalloy films of thickness 23 nm were patterned with square arrays of square antidots (AD) with feature size D = 120 nm, and lattice constants d = 200, 300, 500 and 700 nm (total sample area = 2 mm x 2mm), using electron beam lithography. Our broad-band (frequencies f = 10 MHz-15 GHz) and narrow-band (9.7 GHz) FMR measurements of even dilute (D/d <<1) AD lattices (ADL) reveal remarkably reproducible absorption spectra in the low-frequency, hysteretic regime in which disordered domain wall (DW) patterns and unsaturated magnetization textures are expected for unpatterned films, but in the present case are strongly affected by the periodic ADL. Other modes in the saturated regime exhibit strong dependence on the angle between the applied DC field H and the ADL axes, as confirmed by our micromagnetic simulations. Novel modes are observed at DC fields above that of the uniform mode, which simulations indicate are localized at AD edges. Other novel modes are observed for DC fields below that of the uniform mode, which simulated power and phase maps indicate are confined to ADL interstices oriented parallel to H. These results show even dilute AD concentrations can effect strong control of DW evolution.

[1]Research at Kentucky is supported by U.S. DoE Grant DE-FG02-97ER45653 and NSF Grant EPS-0814194.

10:48AM M14.00013 Micromagnetic Simulations of Quasiperiodic (Penrose Tiling) Antidot Arrays[1] , BARRY FARMER, VINAYAK BHAT, JUSTIN WOODS, LANCE DE LONG, Department of Physics and Astronomy, University of Kentucky, TODD HASTINGS, Department of Electrical and Computer Engineering, University of Kentucky, JOSEPH SKLENAR, JOHN KETTERSON, Department of Physics and Astronomy, Northwestern University — We have performed static and dynamic micromagnetic simulations of permalloy antidots (AD) patterned on quasiperiodic arrays of 25 nm film thickness. Two Penrose tilings (five-fold rotationally symmetric) were simulated with AD kites and darts with long (d_1) and short edges (d_2) equal to 1620 nm or 810 nm, and 1000 nm or 500 nm, respectively, and fixed Py line width of 100 nm. Two Ammann tilings were patterned with square and rhomboid AD of edge lengths 1000 nm or 2000 nm, and line width of 100 nm. Our simulations exhibit FMR modes not previously predicted; for example, power and phase maps for Penrose tilings exhibit three bulk modes (at angles $\varphi = 0^o$, 72^o and 144^o with respect to in-plane applied DC field H) and two edge modes ($\varphi = 72^o$ and 144^o) for H = 1.2 kOe. Static micromagnetic simulations exhibit highly repeatable evolution of domain walls (DW) with apparent long-range order in the **hysteretic regime**. We attribute this remarkable reproducibility in a **geometrically frustrated, aperiodic system** to magnetic reversal controlled by DW pinning by AD edges.

Session M15 GMAG DMP: Focus Session: Spin/orbital Frustration and Short-range Order 317 - Collin Broholm, Johns Hopkins University

8:00AM M15.00001 Spin-orbital quantum liquid on the honeycomb lattice[1] , PHILIPPE CORBOZ, Theoretische Physik, ETH Zurich, Switzerland — The symmetric Kugel-Khomskii can be seen as a minimal model describing the interactions between spin and orbital degrees of freedom in transition-metal oxides with orbital degeneracy, and it is equivalent to the SU(4) Heisenberg model of four-color fermionic atoms. We present simulation results for this model on various two-dimensional lattices obtained with infinite projected-entangled pair states (iPEPS), an efficient variational tensor-network ansatz for two dimensional wave functions in the thermodynamic limit. This approach can be seen as a two-dimensional generalization of matrix product states - the underlying ansatz of the density matrix renormalization group method. We find a rich variety of exotic phases: while on the square and checkerboard lattices the ground state exhibits dimer-Néel order and plaquette order, respectively, quantum fluctuations on the honeycomb lattice destroy any order, giving rise to a spin-orbital liquid. Our results are supported from flavor-wave theory and exact diagonalization. Furthermore, the properties of the spin-orbital liquid state on the honeycomb lattice are accurately accounted for by a projected variational wave-function based on the pi-flux state of fermions on the honeycomb lattice at 1/4-filling. In that state, correlations are algebraic because of the presence of a Dirac point at the Fermi level, suggesting that the ground state is an algebraic spin-orbital liquid. This model provides a good starting point to understand the recently discovered spin-orbital liquid behavior of $Ba_3CuSb_2O_9$. The present results also suggest to choose optical lattices with honeycomb geometry in the search for quantum liquids in ultra-cold four-color fermionic atoms.

[1]We acknowledge the financial support from the Swiss National Science Foundation.

8:36AM M15.00002 Spin-orbital short-range order in the honeycomb-based quantum magnet $Ba_3CuSb_2O_9$[1]

, SATORU NAKATSUJI, Institute for Solid State Physics, University of Tokyo — The realization of quantum correlated matter beyond one dimension has been vigorously pursued in geometrically frustrated spin systems for decades. In frustrated magnetic materials, however, symmetry breaking of orbital and chemical origin is usually found to induce semi-classical spin freezing. In this talk, I present a contrast case where spins and possibly orbitals remain in a liquid state down to low temperature even in a highly disordered structure of 6H-perovskite $Ba_3CuSb_2O_9$. Our comprehensive experimental analysis indicates that the geometrical frustration of Wannier's Ising antiferromagnet on a triangular lattice can be exploited to build a nano-structured bipartite honeycomb lattice from electric dipolar spin-1/2 molecules. Despite a strong local Jahn-Teller distortion about the Cu^{2+} ion, the resulting spin-orbital random bond lattice not only retains hexagonal symmetry averaged over time and space, but it supports a gapless excitation spectrum without spin freezing down to ultralow temperatures. This is the work based on the collaboration with K. Kuga, K. Kimura, R. Satake, N. Katayama, E. Nishibori, H. Sawa, R. Ishii, M. Hagiwara, F. Bridges, T. U. Ito, W. Higemoto, Y. Karaki, M. Halim, A. A. Nugroho, J. A. Rodriguez-Rivera, M. A. Green, C. Broholm.

9:12AM M15.00003 Spin-orbital entanglement due to dynamical Jahn-Teller effect

, JOJI NASU, SUMIO ISHIHARA, Department of Physics, Tohoku University — Quantum spin liquid (QSL) state is one of the fascinating themes in correlated electron systems. Recently, a new candidate of the QSL state is experimentally reported in a layered copper oxide $Ba_3CuSb_2O_9$. In this material, a Cu^{2+} has the e_g orbital degree of freedom and the dynamical Jahn-Teller effect (DJTE) is suggested to play a key role for the emergence of the QSL state. Motivated from the recent experiments in $Ba_3CuSb_2O_9$, we study the DJTE in the spin-orbital coupled system and examine a possibility of the QSL state in a spin-orbital system with lattice vibrations. In particular, we focus on the competitive or cooperative phenomena between the superexchange (SE) interaction and the DJTE. A SE interaction Hamiltonian is derived from the d-p type Hamiltonian and the DJTE Hamiltonian for the low-lying vibronic states is represented by the orbital pseudo-spin and the lattice vibration. We analyze the model, where these two interactions are taken into account on a honeycomb lattice, by using the cluster mean-field approximation with the exact diagonalization (ED) method and the combined method of the quantum Monte-Carlo method and ED method. We find that magnetic orders are unstable in a wide parameter region and a spin-singlet dimer state associated with an orbital order is realized. With increasing the DJTE, the orbital order is strongly suppressed and a resonance state of the spin-orbital dimers appears. We confirm that the spin and orbital degrees of freedom are strongly entangled with each other in this resonance state.

9:24AM M15.00004 Raman phonon study of Jahn-Teller distortion in $Ba_3CuSb_2O_9$[1]

, NATALIA DRICHKO, COLLIN BROHOLM, Department of Physics and Astronomy, Johns Hopkins University, Baltimore 21218 MD USA, KENTA KIMURA, RIEKO ISHII, SATORU NAKATSUJU, Institute for Solid State Physics, University of Tokyo, Kashiwa, Chiba 277-8581, Japan — The frustrated magnet $Ba_3CuSb_2O_9$ does not exhibit either structural or magnetic ordering down to the lowest measured temperatures and is of great current interest as a spin-liquid candidate. It has been proposed recently that the lack of ordering is due to a static or dynamic Jahn-Teller distortion that leads to orbital disorder [1]. We use phonon Raman scattering at temperatures between 20 and 380 K to investigate Jahn-Teller distortion in crystals with different Sb:Cu stoichiometry. We focus on phonons in the range of 500-800 cm^{-1} attributable to oxygen vibrations. In addition to signatures of the strong disorder due to Cu-Sb site mixing present in these materials, we observe mode-splitting due to a static Jahn-Teller distortion below 200 K in samples that undergo a transition to an orthorhombic phase. In contrast, samples that remain hexagonal to the lowest temperatures do not show such mode splitting. References: [1] S. Nakatsuji et al. Science 336, 559 (2012)

9:36AM M15.00005 Orbital short range correlation in $Ba_3CuSb_2O_9$

, YUSUKE WAKABAYASHI, YUKI ISHIGURO, Division of Materials Physics, Graduate School of Engineering Science, Osaka University, Japan, KENTA KIMURA, SATORU NAKATSUJI, Institute for Solid State Physics, University of Tokyo, Japan, SATOSHI TSUTSUI, Japan Synchrotron Radiation Research Institute, SPring-8, Japan, ALFRED Q.R. BARON, Japan Synchrotron Radiation Research Institute, SPring-8/Materials Dynamics Laboratory, RIKEN, Japan, TSUYOSHI KIMURA, Division of Materials Physics, Graduate School of Engineering Science, Osaka University, Japan — $Ba_3CuSb_2O_9$ is consist of short range honeycomb lattice of $S = 1/2$ Cu^{2+} with the Weiss temperature -55 K[1]. Because of the similar energy scale of the spin and orbital degrees of freedom, the interaction between them is important in this system. We have studied the behavior of the orbital degree of freedom, which can fluctuate under an effect of frustrated spin system, by means of x-ray diffuse scattering method. Measurements were performed with a four-circle diffractometer at BL-3A of the Photon Factory, KEK, Japan. Clear Huang scattering that reflects lattice strain induced by the Jahn-Teller distortion was observed. The orbital correlation provides additional scattering intensity around the Γ point in low temperatures. The lifetime of the strain field was examined by inelastic x-ray experiments performed at BL-35XU of the SPring-8, Japan. Quasielastic intensity corresponding to the Huang scattering had slightly broader energy width than the instrumental resolution, and the lifetime was estimated as 3 picoseconds.

9:48AM M15.00006 Local Probe Studies of the Quantum Honeycomb Antiferromagnet $Ba_3CuSb_2O_9$[1]

, JEFFREY QUILLIAM, Laboratoire de Physique des Solides, Université Paris-Sud; Université de Sherbrooke, FABRICE BERT, EDWIN KERMARREC, Laboratoire de Physique des Solides, Université Paris-Sud, CHRISTOPHE PAYEN, CATHÉRINE GUILLOT-DEUDON, Institut des Matériaux Jean Rouxel, Université de Nantes, PIERRE BONVILLE, Service de Physique de l'État Condensé, CEA-CNRS, CE-Saclay, PHILIPPE MENDELS, Laboratoire de Physique des Solides, Université Paris-Sud — The 6H-perovskites, $Ba_3MSb_2O_9$, have generated an enormous amount of interest in the last two years following the possible discovery of quantum spin liquid physics in two such materials. We present local probe studies (muon spin rotation and nuclear magnetic resonance) on the spin-1/2 honeycomb antiferromagnet $Ba_3CuSb_2O_9$. We show that the system presents no spin freezing down to temperatures as low as 20 mK. NMR measurements show evidence of a spin gap and suggest that the material has a random singlet ground state rather than the alternative spin-orbital liquid state.

[1]We acknowledge support from ANR, EC FP6 and NSERC.

10:00AM M15.00007 Electronic structure and the suppression of the Jahn-Teller distortion in the quantum antiferromagnet $Ba_3CuSb_2O_9$

, K.V. SHANAVAS, Z. POPOVIC, S. SATPATHY, Department of Physics & Astronomy, University of Missouri — In recent years, the field of geometrically frustrated materials have regained interest by the dicsovery of several candidates for quantum spin liquids. The antiferromagnet $Ba_3CuSb_2O_9$ is one such material where the $S = \frac{1}{2}$ on a triangular (more recently hexagonal) lattice leads to frustration. Using density functional methods, we study the electronic structure of the material, both in the triangular lattice as well as the honeycomb structure. For both structures, a simple tight-binding description involving the Cu (e_g) orbitals describes the band structure rather well, confirming the central role of these orbitals in the physics of the problem. It has been suggested that the Jahn-Teller effect could play an important role in the properties of the system. We find that in spite of the presence of the Cu (d^9) ion, the Jahn-Teller coupling is surprisingly weak in the material, which suppresses any Jahn-Teller distortion of the CuO_9 octahedra in the compound.

10:12AM M15.00008 Ba NMR studies of the triangular lattice antiferromagnets $Ba_3MSb_2O_9$ (M=Co, Ni) , T. ZHOU, UCLA, G. KOUTROULAKIS, Los Alamos National Laboratory, S.E. BROWN, UCLA, H.D. ZHOU, University of Tennessee, J.G. CHENG, Texas Materials Institute, University of Texas at Austin, J.S. BROOKS, National High Magnetic Field Laboratory — $Ba_3MSb_2O_9$, with M=Co, Ni are triangular lattice magnetic systems with near-neighbor antiferromagnetic exchange. For M=Co (S=1/2), the ground state is ordered and there are field-induced changes to the symmetry, whereas for the Ni (S=1) system there is no evidence for a phase transition to a lower-symmetry phase. Here we report on Ba nuclear magnetic resonance (NMR) spectroscopy and spin-lattice relaxation measurements for both systems. For example, the temperature dependence of the relaxation rate is independent of temperature for the Ni-based compound, and is similar to what is observed for the high-symmetry phase of the Co compound. The spin structures for the ordered phases of the Co material are also explored.

10:24AM M15.00009 Physical Properties of new A_2TO_3 (A = Na, Li, T = Ru, Rh, Ir) materials , YOGESH SINGH, Indian Institute of Science Education and Research (IISER) Mohali, Knowledge city, Sector 81, Mohali 140306, India, SOHAM MANNI, PHILIPP GEGENWART, I. Physikalisches Institut, Georg-August-Universität Göttingen, D-37077 Göttingen, Germany — The layered iridates A_2IrO_3 (A = Na, Li) have recently been suggested to be spin-orbit driven Mott insulators with their magnetism being consistent with an extended Kitaev-Heisenberg model [1-6]. While Na_2IrO_3 was found to lie deep in a magnetically ordered region, Li_2IrO_3 was suggested to lie close to the spin-liquid state expected in the strong Kitaev limit [6]. To explore the effect of chemical pressure and the effect of varying the spin-orbit coupling we have synthesized the new materials Li_2RhO_3, Na_2RuO_3, and $Na_2Ir_{1-x}Ru_xO_3$. We will present magnetic, electrical transport, and heat capacity measurements on these materials.

10:36AM M15.00010 Neutron Scattering Study on the Spin-Orbital Coupling in $Mn_{1-x}Co_xV_2O_4$(x=0.2, 0.4, and 0.6)[1] , JIE MA, MASAAKI MATSUDA, HUIBO CAO, Quantum Condensed Matter Division, Oak Ridge National Laboratory, Oak Ridge, TN 37831, USA, HAIDONG ZHOU, Department of Physics and Astronomy, University of Tennessee, Knoxville, TN 37996, USA, QUANTUM CONDENSED MATTER DIVISION, OAK RIDGE NATIONAL LABORATORY, OAK RIDGE, TN 37831, USA TEAM, DEPARTMENT OF PHYSICS AND ASTRONOMY, UNIVERSITY OF TENNESSEE, KNOXVILLE, TN 37996, USA COLLABORATION — Two consecutive magnetic transitions have been reported in MnV_2O_4 compounds: the first transition is collinear and is from paramagnetic to ferrimagnetic state; The second transition, which is noncollinear, is accompanied by a tetragonal distortion, which produces an excitation gap in the magnetic spectrum [1]. However, the V-V distance is interfered with Co doping, and there is no structural phase transition observed in CoV_2O_4 down to 10 K [2]. In order to study the Co-doping effects on the structural and magnetic properties of $Mn_{1-x}Co_xV_2O_4$, elastic and inelastic neutron scattering is applied in our experiments and the interaction between magnetism and orbital will be discussed.

10:48AM M15.00011 Vibronic excitations in the orbitally active A-site spinels $FeSc_2S_4$, $FeCr_2O_4$, and $FeCr_2S_4$, J. DEISENHOFER, M. SCHMIDT, Z. WANG, Center for Electronic Correlations and Magnetism, Augsburg University, D-86135 Augsburg, Germany, YU. GONCHAROV, General Physics Institute of the Russian Academy of Sciences, 119991 Moscow, Russia, D.V. QUACH, J.R. GROZA, Department of Chemical Engineering and Materials Science, University of California, Davis, CA 95616, USA, A. LOIDL, Center for Electronic Correlations and Magnetism, Augsburg University, D-86135 Augsburg, Germany, V. TSURKAN, Institute of Applied Physics, Academy of Sciences of Moldova, MD-2028 Chisinau, Republic of Moldova — We investigated the low-lying excitations of the spinels $FeSc_2S_4$, $FeCr_2O_4$, and $FeCr_2S_4$ by THz spectroscopy. $FeSc_2S_4$ reportedly is in a spin-orbital singlet ground state [1,2], while the other two compounds exhibit complex magnetically ordered ground states and orbital ordering transitions [3]. In all compounds we observed excitations which we assign to transitions between vibronic levels of the Fe2+ ions in tetrahedral environment. We will discuss the evolution of these excitations in the case of orbital ordering transition and the competition of spin-orbit coupling and electron-phonon interaction as a source for (spin-)orbital frustration in these systems.

Session M16 GMAG DMP: Focus Session: Ferromagnetic Chains/Nanostructures 318 - Christopher Landee, Clark University

8:00AM M16.00001 Terahertz excitations near the quantum critical point in the 1D Ising chain quantum magnet $CoNb_2O_6$[1] , CHRISTOPHER M. MORRIS, R. VALDÉS AGUILAR, S. KOOPAYEH, T.M. MCQUEEN, N.P. ARMITAGE, The Institute for Quantum Matter, Department of Physics and Astronomy, The Johns Hopkins Unversity, Baltimore, MD 21218 — The one-dimensional magnet $CoNb_2O_6$ was recently demonstrated to be an excellent realization of a one-dimensional quantum Ising spin chain. It has been shown to undergo a quantum phase transition in a magnetic field oriented transverse to its ferromagnetically aligned spin chains. Low energy spin-flip excitations in the chains were recently observed via inelastic neutron scattering.[2] The energy spectrum of these excitations was shown to have a interesting energy scaling governed by symmetries of the E8 exceptional Lie group. Here, time-domain terahertz spectroscopy (TDTS) is used to investigate these optically active spin flip excitations in $CoNb_2O_6$ in an external magnetic field. For static magnetic fields oriented transverse to the spin chains, the terahertz excitations show evidence of the phase transitions that occur near the quantum critical magnetic field. Additional spin flip excitations are also observed for longitudinally oriented magnetic fields.

8:12AM M16.00002 Low Temperature 1D-Ising-like Behaviour of Cobalt Niobate , TIMOTHY MUNSIE, ALISON KINROSS, McMaster University, PAUL DUBE, Brockhouse Institute for Materials Research, DAVID POMARANSKI, JAN KYCIA, University of Waterloo, GRAEME LUKE, McMaster University, Brockhouse Institute for Materials Research — Cobalt niobate, $CoNb_2O_6$, is a material that exhibits 1D-Ising-like behaviour at low temperatures, based primarily on chains of spins of the Co^{2+} atoms. Specific heat and magnetic susceptibility measurements on cobalt niobate have found magnetic transitions at 1.9 K and 2.9 K, in agreement with previous work. Specifically, we have performed specific heat measurements in zero field down to 330 mK and have mapped some of the field dependence of the specific heat above 2 K. The low temperature specific heat measurements show an increasingly long relaxation time, implying that the spins become increasingly decoupled from the lattice with decreasing temperature. We have also been the first group to examine the magnetic properties of this material with muon spin rotation (μSR). This work found that the cobalt moments remain largely dynamic on the microsecond timescale for temperatures well below 1.9 K, indicating that the ground state of $CoNb_2O_6$ is more complex than previously thought.

8:24AM M16.00003 Dispersion relations near quantum criticality in the quasi one-dimensional Ising chain $CoNb_2O_6$ in transverse magnetic field , IVELISSE CABRERA, JORDAN THOMPSON, RADU COLDEA, Clarendon Laboratory, Department of Physics, University of Oxford, Oxford OX1 3PU, United Kingdom, NEIL ROBINSON, FABIAN ESSLER, The Rudolf Peierls Centre for Theoretical Physics, Oxford University, Oxford OX1 3NP, United Kingdom, DHARMALINGAM PRABHAKARAN, Clarendon Laboratory, Department of Physics, University of Oxford, Oxford OX1 3PU, United Kingdom, ROBERT BEWLEY, TATIANA GUIDI, ISIS Facility, Rutherford Appleton Laboratory, Chilton, Didcot, Oxon OX11 0QX, United Kingdom — The Ising chain in a transverse magnetic field is one of the canonical examples of a quantum phase transition. We have recently realized this model experimentally in the quasi-one-dimensional (1D) Ising-like ferromagnet $CoNb_2O_6$ [1]. Here, we present single-crystal inelastic neutron scattering measurements of the magnetic dispersion relations in the full three-dimensional (3D) Brillouin zone for magnetic fields near the critical point and in the high field paramagnetic phase. We explore the gap dependence as a function of field and quantify the cross-over to 3D physics at the lowest energies due to the finite interchain couplings. We parametrize the dispersion relations in the high-field paramagnetic phase to a spin wave model to quantify the sub-leading terms in the spin Hamiltonian beyond the dominant 1D Ising exchange. [1] R. Coldea, D.A. Tennant, E.M. Wheeler et al, Science 327 177-180 (2010).

8:36AM M16.00004 Electron-phonon and magnetoelastic interactions in ferromagnetic $Co[N(CN)_2]_2$[1] , TATIANA BRINZARI, University of Tennessee, JASON HARALDSEN, Los Alamos National Laboratory, PENG CHEN, QI SUN, University of Tennessee, YOUNGHEE KIM, LI-CHUN TUNG[2], National High Magnetic Field Laboratory, ALEXANDER LITVINCHUK, University of Houston, JOHN SCHLUETER, Argonne National Laboratory, DMITRY SMIRNOV, National High Magnetic Field Laboratory, JAMIE MANSON, Eastern Washington University, JOHN SINGLETON, Los Alamos National Laboratory, JANICE MUSFELDT, University of Tennessee — Many of the most attractive properties of multifunctional materials can be traced to the competition between charge, structure, and magnetism. The discovery that these interactions can be tuned with various physical stimuli has accelerated investigation of their behavior under extreme conditions. In this work, we combined Raman and infrared vibrational spectroscopies with complementary lattice dynamics calculations and magnetization measurements to highlight the signatures of two different coupling processes in the molecule-based magnet $Co[N(CN)_2]_2$. In addition to a large anisotropy, our work reveals electron-phonon coupling as a field-driven avoided crossings of the low-lying Co^{2+} electronic excitation with the ligand phonons and a magnetoelastic effect that signals a flexible local CoN_6 environment. These findings broaden our understanding of charge-lattice-spin interactions under extreme conditions and demonstrate rich new aspects of multifunctionality in tunable molecular materials.

8:48AM M16.00005 Colossal reduction in Curie temperature due to finite-size effects in CoFe2O4 nanoparticles , JAVIER TEJADA, VICTOR LOPEZ-DOMINGUEZ, JOAN MANEL HERNANDEZ, Dept. de Fisica Fonamental, Universitat de Barcelona, C. Marti i Franques 1, Barcelona 08028, Spain, RONALD F. ZIOLO, Centro de Investigación en Química Aplicada, Boulevard Enrique Reyna 140, Saltillo, 25253 México, GMAG TEAM, CIQA TEAM — In this talk I will show the tremendous size effect on the ordering transition temperature, T_O, in samples of $CoFe_2O_4$ nanoparticles with diameters ranging from 1 to 9 nm. Samples were characterized by HRTEM and XRD analyses and show a bimodal particle size distribution centered at 3 nm and around 6 nm for "small" and "large" particles, respectively. The results and their interpretation are derived from studies of the magnetization dependence of the samples on temperature at low and high magnetic fields and relaxation times using both DC and AC fields. The large particles show a typical superparamagnetic behavior with blocking temperatures, T_B, arround 100K and a Curie temperature, T_C, above room temperature. The small particles, however, show a colossal reduction of their magnetic ordering temperature and display paramagnetic behavior down to about 10K. At lower temperatures these small particles are blocked and show both exchange and anisotropy field values above 5T. The order of magnitude reduction in T_O demonstrates a heretofore unreported magnetic behavior for ultrasmall nanoparticles of $CoFe_2O_4$, suggesting its further study as an advanced material.

9:00AM M16.00006 The effect of shape, spin, and grain boundary on the vibrational properties of iron nanoparticles , GIRIDHAR NANDIPATI, SAMPYO HONG, TALAT RAHMAN, University of Central Florida — We have performed both spin-polarized and nonspin-polarized density functional theory (DFT) calculations of vibrational modes for Fe113 of either rectangular or spherical shape. We also have calculated them for a spherical nanoparticle with a single grain boundary ($\sum$3(111)) to understand the effect of grain boundary. We used both classical molecular dynamics and DFT to optimize the geometry of the Fe113 nanoparticles. Regarding the vibrational density of states (VDOS) of the nonspin-polarized Fe nanoparticles, the spherical shape exhibits a slightly enhanced VDOS in high frequency modes as compared to rectangular shape. The grain boundary brings about remarkable changes in the VDOS in all frequency ranges (as compared to the VDOS of Fe nanoparticles without a grain boundary: (1) enhanced VDOS in low frequency range (10-15 meV) (2) peak shift to higher frequency in middle range (20 – 35 meV) (3) new peaks in high frequency range (40 - 55 meV). Most remarkable changes occur when spin is taken into account for Fe113 nanoparticle. The average magnetic moment (per atom) of the spherical Fe113 nanoparticle calculated by DFT is 2.7 Bohr magneton, which is already close to that of iron bulk (2.2 Bohr magneton). The spin-induced features in VDOS (as compared to non-spin cases) are: remarkable (1) increase in the low and middle frequency regions (7-30 meV) and (2) decrease in the high frequency regions. These spin effects are possibly correlated to spin-induced Fe-Fe bond softening (Fe-Fe bond length expansion). Work supported by DOE Grant No. DE-FG02-07ER46354.

9:12AM M16.00007 Controlling Magnetism by Light in Nanoscaled Heterostructures of Cyanometallate Coordination Networks: the role of increased complexity[1]

, MARK W. MEISEL, Physics and NHMFL, University of Florida, Gainesville, FL USA, and Institute of Physics, P. J. Šafárik, University, Košice, Slovakia — Nanometer-sized heterostructures of the Prussian blue analogues $A_jCo_k[Fe(CN)_6]_\ell \cdot nH_2O$ (Co-Fe PBA, with A = K, Rb) and $Rb_aNi_b[Cr(CN)_6]_c \cdot mH_2O$ (Ni-Cr PBA) have been investigated, and new phenomena, not observed for the constituent bulk phases, have been observed.[2,3,4,5] A crucial aspect of the ability to photocontrol the persistent magnetism up to 70 K is the role of the strain coupling present at the interfaces between the nanoscaled regions of the constituents. Increasing the morphological complexity of the samples has the potential to provide materials possessing novel combinations of properties. In parallel, the interplay between long-range magnetic order and structural coherence is an important consideration in our attempts to design new systems. Open, unresolved issues will be discussed, and potential future paths will be sketched.

9:48AM M16.00008 Effects of Pressure on the Magnetic Properties of Prussian Blue Analogue Heterostuctures[1]

, MARCUS K. PEPRAH, MARK W. MEISEL, Dept. Physics and NHMFL, Univ. Florida, CARISSA H. LI, DANIEL R. TALHAM, Dept. Chemistry, Univ. Florida — Magnetic studies on the Prussian blue analogues (PBAs), $Li_xCu[Fe(CN)_6]_y \cdot mH_2O$ (CuFe-PBA) and $Li_kNi[Cr(CN)_6]_l \cdot nH_2O$ (NiCr-PBA), as well as CuFe@NiCr-PBA core-shell heterostructures, have been conducted under pressures ranging from ambient to $\approx$ 1.4 GPa and at temperatures of 2 - 90 K. Our results for the single phase CuFe-PBA indicate robust magnetic properties under the range of pressures studied: a T_c of 20 K was observed at all pressures.[2] However, our pressure studies of single phase NiCr-PBA are consistent with the results of Zentková *et al.* up to 1 GPa.[3] At pressures above 1.0 GPa, the decrease in magnetization is accompanied by a decrease in the T_c, an indication of changes in the superexchange value, an effect not reported by Zentková *et al.* Lastly, our results on the effects of pressure on the magnetic properties of heterostructed PBAs, specifically CuFe@NiCr-PBA, will be presented.

10:00AM M16.00009 Strain-Mediated Photocontrol in Core-Shell Prussian Blue Analogue Particles[1]

, ELISABETH S. KNOWLES, MARCUS K. PEPRAH, MARK W. MEISEL, Dept. Phys. and NHMFL, Univ. Florida, CARISSA H. LI, OLIVIA N. RISSET, MATTHEW J. ANDRUS, DANIEL R. TALHAM, Dept. Chem., Univ. Florida — The Prussian blue analogue (PBA), $A_iNi[Cr(CN)_6]_j \cdot nH_2O$ (**A**), has been shown to exhibit a pressure-induced decrease in magnetization under both external isotropic pressure[2] and internal photoinduced structural strain when layered with $Rb_iCo[Fe(CN)_6]_j \cdot nH_2O$ (**B**).[3] Current investigations of a series of core-shell PBAs, consisting of the photoactive ferrimagnetic **B** surrounded by ferromagnetic **A**, quantitatively model this photoinduced phenomenon, which is shown to affect both the magnetic moment and superexchange of roughly half the volume of the **A** shells. An accurate understanding of the mechanism of strain-mediated photocontrol in these heterostructures will allow the pursuit of rationally designed room temperature photocontrol systems by incorporating pressure-sensitive materials with higher magnetic ordering temperatures.

[3]M. F. Dumont *et al.*, Inorg. Chem. **50** (2011) 4295; D. M. Pajerowski *et al.*, J. Am. Chem. Soc. **132** (2010) 4058.

10:12AM M16.00010 First-Principles Modeling of Bonding and Magnetic Exchange in the Metal-TCNE Magnet Family[1]

, CHRISTOPHER OLSON, The Center for Nanoscale Science and Engineering, North Dakota State University, SHRUBA GANGOPADHYAY, SVETLANA KILINA, The Department of Chemistry and Biochemistry, North Dakota State University, KONSTANTIN POKHODNYA, The Center for Nanoscale Science and Engineering, North Dakota State University — The chemical bond and its role as a mediator of magnetic exchange interaction remains a crucial aspect in the study of molecular magnetism. Within the M-TCNE (M=3d metal; TCNE=tetracyanoethylene) class of organic-based magnets, only $V[TCNE]_x$ (x$\sim$2) orders magnetically above room-temperature (T_c $\sim$400 K), while structural factors underlying this exceptional behavior remain elusive. Conversely, Mn-TCNE complexes of diverse crystal structure, e.g., 1D-chain MnTPP[TCNE] (T_c $\sim$10 K), 2D-layer $[Mn(TCNE)(NCMe)_2]SbF_6$ (T_c $\sim$75 K), and 3D-network $[Mn(TCNE)_{1.5}](I_3)_{0.5}$($T_c$ $\sim$170 K) have recently become available. Using this structural data, hybrid DFT simulations has been performed and the spin-polarized electronic structures resolved. The nature of bonding and non-bonding orbital interactions crucial for understanding magnetic behavior was revealed. Orbital ordering, hybridization, and trends in spin-density transfer (bonding/backbonding) as well as the formation of exchange/superexchange pathways have been identified and interpreted in terms of the dimensionality of magnetic interaction. The role of these and additional factors in establishing high-T_c magnetism in the broader M-TCNE class will be discussed.

[1]Support from NSF DMR-CMP-1005882 is acknowledged.

10:24AM M16.00011 Neutron-Scattering Evidence for the Spin State of a Molecule-Based Magnet with Interpenetrating Sublattices[1]

, RANDY FISHMAN, Oak Ridge National Laboratory, Oak Ridge, TN 37831 USA, JAVIER CAMPO, Materials Science Institute of Aragon (CSIC-University of Zaragoza), E-50009, Zaragoza, Spain, THOMAS VOS, JOEL MILLER, Department of Chemistry, University of Utah, Salt Lake, UT 84112, USA — The molecule-based magnet $[Ru_2(O_2CMe)_4]_3[Cr(CN)_6]$ contains two interpenetrating cubic sublattices. Each sublattice is magnetically frustrated by the easy-plane anisotropy of the spin-3/2 diruthenium (II/III) paddlewheel complexes, which lie at the middle of each cube edge and are antiferromagnetically coupled by the exchange interaction $J_c \sim 1.7$ meV to two spin-3/2 Cr(III) ions at the cube corners. Symmetry considerations suggest that each cubic sublattice has a non-collinear spin state with net moment along one of the cubic diagonals. The moments of the two interpenetrating sublattices are antiferromagnetically coupled at small magnetic fields and become aligned above a critical field of about 1000 Oe $\sim K_c/\mu_B$, where $K_c \sim 2 \times 10^{-3}$ meV is the weak dipolar coupling between sublattices. Powder neutron-diffraction measurements on a deuterated sample confirm that the sublattice moments lie along the cubic diagonals and provide indications for substantial quantum corrections to the spin state of each sublattice.

10:36AM M16.00012 Approach to criticality in disorder-tuned antiferromagnetic manganese thin films[1] , SIDDHARTHA GHOSH, SANAL BUVAEV, ARTHUR HEBARD, University of Florida — Using a specialized high vacuum deposition/characterization chamber, we study the *in situ* temperature-dependent conductivity $\sigma(T,R_0)$ of thin magnetic films (Gd, Cr & Mn) prepared at different stages of disorder where disorder is characterized by the sheet resistance R_0 measured at $T = 5$ K. The temperature dependence of normalized conductivity in these thin-films follows power-law dependence of the form, $\sigma(T,R_0) = A + BT^P$. The fitting parameters A, B and P vary systematically with increasing disorder. For Mn the parameter A asymptotically approaches zero but always remains positive on the metallic side of a possible metal-insulator transition (MIT) for this material. In contrast, for Gd the parameter A crosses from positive (metal) to negative (insulator) values at critical disorder ($A = 0$) with a critical disorder strength $R_0 = R_C = 22.67$ kΩ at the MIT. The behavior of Mn is strikingly different when compared with Gd, where the MIT occurs before granularity emerges. Most likely this difference of behavior occurs because the inelastic phase breaking length L_ϕ is not sufficiently high in antiferromagnet Mn to reach the 3D limit where L_ϕ is less than the film thickness b.

[1]National Science Foundation

10:48AM M16.00013 Determination of ground state in potassium intercalated polyacenes , QUYNH PHAN, SATOSHI HEGURI, YOICHI TANABE, HIDEKAZU SHIMOTANI, KATSUMI TANIGAKI, Department of Physics, Graduate School of Science, Tohoku University, 6-3 Aoba, Aramaki, Aoba-ku, Sendai, Japan, TAKEHITO NAKANO, YASUO NOZUE, Department of Physics, Graduate School of Science, Osaka University, 1-1 Machikaneyama, Toyonaka, Osaka, Japan — Intercalated compounds of polycyclic aromatic hydrocarbons have been drawing much attention from the view point of new type of organic superconductors. The mechanism of superconductivity in these materials is still unclear, and therefore the true ground states with various carrier concentrations must be understood. The antiferromagnetic ground states were reported particularly on K-doped pentacene, a typical polyacene. In the present study, we focus on the synthesis and the magnetic properties of K-intercalated polyacenes, such as anthracene, tetracene, and pentacene. The improved synthetic method based on the conventional solid state reaction was employed to obtain high quality bulk samples. The X-ray powder diffraction profiles of doped samples showed new stable phases. Interestingly, a pronounced hump at 150 K was observed in the temperature dependence of magnetic susceptibility of K_1anthracene. In ESR measurements the linewidth of the signals decreased significantly with a decrease in temperature below 150 K and no Pauli magnetic contribution was detected. These results clearly indicate that charge transfer occurs but the most stable ground state is still insulating via antiferromagnetic interactions. Further discussion will be made among these K-intercalated polyacenes.

Wednesday, March 20, 2013 8:00AM - 11:00AM –

Session M17 DMP GMAG: Focus Session: Frustrated Multiferroics 319 - Jaime Fermandez-Baca, Oak Ridge National Laboratory

8:00AM M17.00001 Magnetic Order and Spin Correlations in the Multiferroic $Sr_{0.56}Ba_{0.44}MnO_3$, JEFFREY LYNN, NIST Center for Neutron Research, Gaithersburg, MD 20899-6102, JAMES MAIS, OMAR CHMAISSEM, BOGDAN DABROWSKI, Department of Physics, Northern Illinois University, De Kalb, IL 60115 — Neutron diffraction and inelastic scattering measurements have been carried out on a polycrystalline sample of Ferroelectric $Sr_{0.56}Ba_{0.44}MnO_3$ (T_F =400 K) using the BT-7 and SPINS triple-axis spectrometers. The system orders antiferromagnetically at 190 K with an order parameter that varies smoothly with temperature. Inelastic measurements at base temperature reveal an energy gap of 1.7 meV, with a continuous distribution of magnetic scattering above the gap that exhibits a weak peak at 7.5 meV. The inelastic scattering is strongly peaked at the magnetic reciprocal lattice position up to the highest energy of 15 meV measured so far, indicating strong spin correlations. With increasing temperature the magnetic scattering increases in intensity as expected according to the Bose-Einstein thermal population factor for spin waves. Above Tn strong correlations persist, but the scattering does noticeably broaden.

8:12AM M17.00002 Magnetic field effects on the multiferroic phases and the ferroelectric polarization of $Mn_{1-x}Co_xWO_4$, B. LORENZ, K.-C. LIANG, Y.Q. WANG, Y.Y. SUN, TCSUH, University of Houston, F. YE, J.A. FERNANDEZ-BACA, Neutron Scattering Science Division, ORNL, Oak Ridge, C.W. CHU, TCSUH, University of Houston — $MnWO_4$ is a classical multiferroic where ferroelectricity is induced by an inversion symmetry breaking helical spin order. The origin of the helical order is found in competing magnetic exchange interactions with strong uniaxial anisotropy, resulting in magnetic frustration. The extreme sensitivity of the multiferroic state with respect to chemical substitution of Fe, Zn, or Co for Mn was recently shown and $Mn_{1-x}Co_xWO_4$ ($0 < x < 0.3$) has the most complex phase diagram with multiple polarization flops upon increasing Co content. We report the effects of external magnetic fields on the multiferroic phases in $Mn_{1-x}Co_xWO_4$ and show that, depending on the Co content, magnitude and orientation of the ferroelectric polarization can be continuously controlled and even complete reversals of the polarization as function of temperature or field are observed. The experimental results are discussed in terms of the external field tuning of the helical or conical spin structures giving rise to the multiferroic state.

8:24AM M17.00003 Magnetic properties of multiferroic hexagonal $LuFeO_3$ thin film , WENBIN WANG, University of Tennessee & Oak Ridge National Laboratory, XIAOSHAN XU, Oak Ridge National Laboratory, JUN ZHAO, University of California, Berkeley, ZHENG GAI, WEI TIAN, Oak Ridge National Laboratory, JIAN SHEN, Fudan University — We present magnetic properties of multiferroic hexagonal $LuFeO_3$ single crystalline thin films grown on Al_2O_3(0001) substrates using pulsed laser deposition(PLD) technique. Neutron diffraction and superconducting quantum interference device (SQUID) measurements suggest that the hexagonal $LuFeO_3$ thin film displays an antiferromagnetic order above room temperature and a second magnetic phase transition at lower temperature. The possible magnetic structures of this system are discussed.

8:36AM M17.00004 Origin of ferroelectricity and exotic magnetism in frustrated $LiCuVO_4$[1] , MARTIN MOURIGAL, Johns Hopkins — The spin-1/2 Heisenberg chain with competing ferromagnetic nearest-neighbor (J_1) and antiferromagnetic next-nearest neighbor (J_2) interactions is probably one the simplest, yet richest model in frustrated magnetism. It is experimentally realized in a diversity of Mott insulators, in particular in copper-oxide materials built-up from edge-sharing CuO_6 octahedra. The quasi-1D compound $LiCuVO_4$ stands out for the diverse emergent magnetic and multiferroic phenomena it displays, its simple crystal structure and its availability as high-quality single crystals. I will review recent elastic neutron scattering works [1,2] on $LiCuVO_4$ which elucidate the nature of its ground-state as a function of applied electric field and magnetic field up to 14 T. Below 3.5 T [1], a model long-range ordered ferroelectric spin-cycloid is unveiled, its chirality fully controlled by an applied electric field, and the corresponding magnetoelectric coupling in excellent agreement with the predictions of a purely electronic mechanism based on spin currents. Above 8 T [2], a transition to a new quantum state is observed. This new phase resembles the longitudinal density-wave of magnon-pairs (p=2 SDW) predicted in the purely 1D case but is characterized by the intriguing absence of long-ranged dipolar correlations.

[1]Work performed at the Institut Laue-Langevin in Grenoble and in collaboration with M. Enderle, B. Fåk, R. K. Kremer and J. Law.

9:12AM M17.00005 Magnetism and Ferroelectricity in the frustrated spin chain compound Ca_3CoMnO_6 , EUNDEOK MUN, J. KIM, M. JAIME, N. HARRISON, V. ZAPF, NHMFL, LANL, Los Alamos, NM 87545, Y. KAMIYA, C. BATISTA, T-division, LANL, Los Alamos, NM 87545, H. YI, Y. OH, S. CHEONG, RCEM and Dept. of Physics and Astronomy, Rutgers University, Piscataway, NJ 08854 — In many multiferroics, there is little or no net magnetism coupled to electric polarization. Ca_3CoMnO_6 is unusual among multiferroics since it has a net, hysteretic magnetization coupled to electric polarization, which is important for many applications. Thus, understanding the origin of the magnetic behavior and its coupling to the electric polarization is important. Up to now the arrangement of magnetic exchange interactions, the size of the Co spin, and the origin of magnetic hysteresis were not completely understood. We show magnetization, magnetostriction, electric polarization, and magnetocaloric effect data up to 100 T, including notably a 1/2 and a 2/3 plateau in the magnetization and non-monotonic magnetostriction behavior. We determine that the spin state of Co is definitely $\mathbf{S} = 3/2$ at both high fields and low fields. We show that this behavior is consistent with an ANNNI-like model with antiferromagnetic interactions in the hexagonal **ab**-plane, and ferromagnetic interactions along **c**-axis. The model takes into account Ising-like Co spins and Heisenberg-like anisotropic Mn spins. The evolution of the Ising-like Co spins accounts for the hysteresis and steps in the physical properties up to 20 T, and also produces a positive magnetostriction, whereas alignment of the Heisenberg-like Mn spins produce non-hysteretic behavior up to saturation at $\sim$85 T, as well as negative magnetostriction.

9:24AM M17.00006 Magnetic field switching of ferroelectricity in spiral magnet $CuCrO_2$, E.-D. MUN, V. ZAPF, NHMFL, LANL, Los Alamos, NM 87545, A. PODLESNYAK, G. EHLERS, R. FISHMAN, Neutron Scattering Science Division, ORNL, Oak Ridge, TN 37831, S. SHIRYAEV, S. BARILO, Institute of Solid State and Semiconductor Physics, Minsk 220 072, Belarus, M. FRONTZEK, LNS, Paul Scherrer Institute, 5232 Villigen-PSI, Switzerland — The triangular lattice antiferromagnet $CuCrO_2$ show ferroelectricity induced by a proper-screw spiral magnetic structure, where spins in form 120° angles with neighboring spins due to frustration. $CuCrO_2$ is thought to be a rare example of the Arima mechanism for multiferroic behavior. In addition, it has been shown that the magnetoelectric coupling can be tuned by both an electric and a magnetic field along **ab**-plane. We test a prediction for the magnetic field-evolution of the physical properties of $CuCrO_2$ via magnetization and electric polarization measurements up to 65 T. We explore the complicated $H-T$ phase diagram along different crystalline directions. In zero field, a spontaneous electric polarization in $CuCrO_2$ is coupled to antiferromagnetic ordering below 24 K without an accompanying structural phase transition. In high fields, we observe electric polarization flops for magnetic fields applied along both the **ab**-plane and the **c**-axis, although at different magnetic fields than predicted. By contrast no noticeable anomaly is detected in magnetization isotherms, which are linear in fields up to 65 T. The electric polarization reversal is highly sensitive to the external magnetic field for both the **ab**-plane and **c**-axis due to a 3-dimensional proper-screw structure. We find that additional interactions may be necessary to explain our observed results.

9:36AM M17.00007 The Effect of Electric Field on Multiferroic $Ba_{0.5}Sr_{1.5}Zn_2(Fe_{0.92}Al_{0.08})_{12}O_{22}$ Investigated by NMR , SANGIL KWON, SOONCHIL LEE, Department of Physics, KAIST, Daejeon 305-701, Republic of Korea, YI SHENG CHAI, SAE HWAN CHUN, KEE HOON KIM, CENSCMR, Department of Physics and Astronomy, Seoul National University, Seoul 151-747, Republic of Korea, BYEONGKI KANG, CHANGSOO KIM, EUNA JO, Department of Physics, KAIST, Daejeon 305-701, Republic of Korea — Multiferroic helimagnet $Ba_{0.5}Sr_{1.5}Zn_2(Fe_{0.92}Al_{0.08})_{12}O_{22}$ (Al-BSZFO) shows extremely high magnetoelectric susceptibility so that the critical field for switching electric polarization is less than 1 mT below 90 K [1]. Recently, a large macroscopic magnetization was successfully induced by the electric field (± 2 μ_B/f.u. by ± 2 MV/m) in properly annealed Al-BSZFO [2]. To reveal the microscopic origin, a study on the magnetic domain structure is needed. In the magnetic material, NMR intensity is enhanced by the coupling between the electron magnetic susceptibility and the nuclear magnetic susceptibility. Hence if we trace out the amount of NMR intensity enhancement, we would get the information of the magnetic domain configuration. By measuring both the magnetic field and the electric field dependence of NMR intensity enhancement, we found the area of the magnetic domains is actually tuned by the electric field. [1] S. H. Chun et al., Phys. Rev. Lett. 104, 037204 (2010). [2] K. H. Kim, The 19th International Conference on Magnetism (2012); Y. S. Chai et al., unpublished.

9:48AM M17.00008 Gigantic ferroelectric polarization and magnetoelectric coupling in a ferrimagnetic oxide $CaBaCo_4O_7$, JOHN MITCHELL, Argonne National Laboratory, VINCENT CAIGNERT, ANTOINE MAIGNAN, KIRAN SINGH, CHARLES SIMON, BERNARD RAVEAU, VALERIE PRALONG, Laboratoire CRISMAT, UMR 6508 CNRS/ENSICAEN, LAURENT CHAPON, Institut Laue-Langevin — From both fundamental and applications points of view, improper ferroelectrics that exhibiting a strong coupling between polarization and magnetic structure are challenging the scientific community. Several multiferroics belonging to that category have been reported; however, they exhibit rather small values of electric polarization combined with low magnetic ordering temperatures. Only the CuO (tenorite), the ordered perovskites $LBaCuFeO_5$ and the Z-type hexaferrites display magnetic ordering temperatures near room temperature, but they all suffer from polarization much smaller than that of proper ferroelectrics. Here, we report a ferrimagnetic cobaltite, $CaBaCo_4O_7$, crystallizing in a polar space group, which enters an improper ferroelectric phase below $T_C = 64$ K. Single crystals of $CaBaCo_4O_7$ demonstrate the highest polarization value reported among improper ferroelectrics to date, reaching 10 mC/m^2 at T_C and approaching 16 mC/m^2 at 8 K. Moreover a large magnetoelectric coupling coefficient is also evidenced near T_C. This result points to routes for exploring new multiferroics among ferrimagnetic phases.

10:00AM M17.00009 Spin Wave Excitations in the Multiferroic $Ba_2CoGe_2O_7$, TOOMAS ROOM, National Institute of Chemical Physics and Biophysics, Tallinn, Estonia, KARLO PENC, JUDIT ROMHANYI, Institute for Solid State Physics and Optics, Hungarian Academy of Sciences, Budapest, URMAS NAGEL, National Institute of Chemical Physics and Biophysics, Tallinn, Estonia, AGNES ANTAL, TITUS FEHER, ANDRAS JANOSSY, Department of Physics, Budapest University of Technology, Hungary, HANS ENGELKAMP, High Field Magnet Laboratory, Institute for Molecules and Materials, Radboud University, Nijmegen, The Netherlands, H. MURAKAWA, YOSHI TOKURA, Quantum-Phase Electronics Center, Department of Applied Physics, The University of Tokyo, Japan, DAVID SZALLER, SANDOR BORDACS, ISTVAN KEZSMARKI, Department of Physics, Budapest University of Technology, Hungary — $Ba_2CoGe_2O_7$ is a multiferroic material where spin waves exhibit giant directional dichroism and natural optical activity at THz frequencies due to the large ac magnetoelectric effect [S. Bordacs et al., Nature Physics **8**, 734 (2012)]. We studied spin excitations in the magnetically ordered phase of the noncentrosymmetric $Ba_2CoGe_2O_7$ in high magnetic fields up to 33 T [Penc et al., Phys. Rev. Lett. **108**, 257203 (2012)]. In the ESR and THz absorption spectra we found several spin excitations beyond the two conventional magnon modes expected for such a two-sublattice antiferromagnet. A multiboson spin-wave theory describes these unconventional modes, including spin-stretching modes, characterized by an oscillating magnetic dipole and quadrupole moment. The lack of inversion symmetry allows each mode to become electric dipole active.

10:12AM M17.00010 Muller matrix ellipsometry of dynamic magnetoelectric effects in multiferroics[1] , T.N. STANISLAVCHUK, R. BASISTYY, T.D. KANG, Department of Physics, NJIT, Newark, NJ, USA, M. KOTELYANSKII, Rudolph Technologies Inc., NJ, USA, G.L. CARR, National Synchrotron Light Source, Brookhaven National Lab, Upton, NY, USA, S-W. CHEONG, Rutgers Center for Emergent Materials and Department of Physics and Astronomy, Rutgers U., NJ, USA, A.A. SIRENKO, Department of Physics, NJIT, Newark, NJ, USA — Far-IR spectra of magneto-electric (ME) and multiferroic materials are in the focus of modern experimental and theoretical studies. Bi-anisotropic optical properties of these materials require consideration of not only dielectric susceptibility tensor $\hat{\varepsilon}(\omega)$ but also magnetic permeability $\hat{\mu}(\omega)$ and ME $\hat{\alpha}(\omega)$ tensors that cannot be distinguished from a single transmission or reflection spectrum. We report on the application of Mueller matrix spectroscopic ellipsometry (MM-SE) for studies of elementary excitations in multiferroic materials such as $TbMnO_3$, $TbMn_2O_5$, and $TbFe_3(BO_3)_4$ single crystals. We show that magnetic, electric, and ME dipole excitations, such as magnons, phonons, and electromagnons can be distinguished from each other using a single MM measurement without introducing any modeling arguments. The fit of MM spectra based on the Berreman's 4×4 propagation matrix formalism allowed us to determine parameters of electromagnon excitations separating the electric $\hat{\varepsilon}(\omega)$ and ME $\hat{\alpha}(\omega)$ tensors components.

10:24AM M17.00011 Reinvestigation of the linear magnetoelectric effect in Cr_2O_3 single crystals , AYATO IYAMA, TSUYOSHI KIMURA, Division of Materials Physics, Graduate School of Engineering Science, Osaka University — Cr_2O_3 is not only the first experimentally confirmed magnetoelectric compound but also a rare example compound in which the magnetoelectric effect occurs at room temperature. It is worthwhile to revisit this compound from the standpoint of recently developed "multiferroic" where electric and magnetic orders coexist. Thus, we grew single crystals of Cr_2O_3 and measured their magnetodielectric and magnetoelectric effects. We found that the temperature dependence of the dielectric constant measured in a magnetic field shows a sharp peak around Neel temperature 307 K. Furthermore, we observed that the electric polarization induced by a magnetic field is reversed by sweeping an electric field at room temperature. In this talk, we present our experimental results on electric and magnetic properties in Cr_2O_3, and discuss the origins from current point of view.

10:36AM M17.00012 Temperature-dependent electrical and electro-optical properties of $LuFe_2O_4$ thin films , RAM RAI, B.S. FRANKS, Department of Physics, SUNY College at Buffalo, NY 14222, B. CAI, M.L. NAKARMI, Department of Physics, Brooklyn College of the CUNY, Brooklyn, NY 11210 — We present temperature-dependent electrical properties of $LuFe_2O_4$ (LFO) thin films deposited on (001) sapphire substrates. The Hall-effect measurements of LFO thin films showed the p-type conductivity at temperatures above 440 K, which is the 2D charge-ordered (CO) state of LFO. In the 3D CO stated below 340 K, we observed complex electrical properties of LFO thin films: dc voltage-current measurements displayed a hysteresis behavior and transient response of voltage-under-current pulses showed a nonlinear voltage-current relationship. We also present the electro-optical effects of LFO in the photon energy range of 0.5 - 6 eV. At 170 K, LFO thin films show the electro-optical effects of size up to 8% near Fe^{2+} d to d on-site electronic transitions. The electrical and electro-optical properties of LFO thin films could be associated with the changes of the ferroelectric polarization in applied electric fields through the interplay of the spin, charge, and lattice degrees of freedom in the multiferroic state of LFO. We will discuss the measured data in the view of the Maxwell-Wagner effects at the contacts, and demonstrate that LFO does show the ferroelectric state below 330 K.

10:48AM M17.00013 Crystal field splitting and optical band gap of hexagonal $LuFeO_3$ films[1] , XIAOSHAN XU, Oak Ridge National Lab, WENBIN WANG, University of Tennessee, Oak Ridge National Lab, HONGWEI WANG, Temple University, University of Science and Technology of China, XIAOYING XU, Oak Ridge National Lab, LEYI ZHU, Argonne National Lab, LIXIN HE, University of Science and Technology of China, ELIZABETH WILLS, XUEMEI CHENG, Bryn Mawr College, DAVID KEAVNEY, Argonne National Lab, JIAN SHEN, Fudan University, University of Tennessee, XIFAN WU, Temple University — In order to study the electronic structures, we have characterized the hexagonal $LuFeO_3$ films (grown by pulsed laser deposition) using x-ray absorption and optical spectroscopy. The crystal splitting of Fe^{3+} is extracted as $E_{e'} - E_{e''}$=0.7 eV and $E_{a_1'} - E_{e'}$=0.9 eV and a 2.0 eV optical band gap is determined assuming a direct gap. First-principles calculations confirm the experiments that the relative energies of crystal field splitting states do follow $E_{a_1'} > E_{e'} > E_{e''}$ with slightly underestimated values and a band gap of 1.35 eV.

Wednesday, March 20, 2013 8:00AM - 11:00AM –

Session M18 GMAG DMP FIAP: Focus Session: Spin-Dependent Phenomena in Semiconductors - Diamond 320 - Olaf van't Erve, Naval Research Laboratory

8:00AM M18.00001 Nitrogen-vacancy centers in diamond: a local probe to study magnetic oxides , LAETITIA PASCAL, CLAIRE MCLELLAN, GINO GRAZIANO, PREETI OVARTCHAIYAPONG, BRYAN MYERS, ANIA JAYICH, University of California Santa Barbara, JAYICH GROUP TEAM — We report on the development of a diamond-based scanning probe magnetometer (SPM) that operates over a wide range of temperature from 300 K to 4 K. The magnetic sensor is a nitrogen-vacancy (NV) center in diamond, which is read out via optically detected magnetic resonance. This sensor promises non-invasive imaging with single spin sensitivity and spatial resolution down to $\sim$ 10 nm. We have fabricated single-crystal diamond scanning probes with an embedded RF antenna for coherent manipulation of the NV electronic spin. The SPM is integrated into a variable temperature transport set-up in order to study interface magnetism in complex oxide heterostructures.

8:12AM M18.00002 Probing dynamics of a spin ensemble of P1 centers in diamond using a superconducting resonator[1] , GIJS DE LANGE, VISHAL RANJAN, RON SCHUTJENS, Kavli Institute of Nanoscience, Delft University of Technology, THIBAULT DEBELHOIR, ICFP, Departement de Physique de l'ENS, JOOST GROEN, DANIEL SZOMBATI, DAVID THOEN, TEUN KLAPWIJK, RONALD HANSON, LEONARDO DICARLO, Kavli Institute of Nanoscience, Delft University of Technology — Solid-state spin ensembles are promising candidates for realizing a quantum memory for superconducting circuits. Understanding the dynamics of such ensembles is a necessary step towards achieving this goal. Here, we investigate the dynamics of an ensemble of nitrogen impurities (P1 centers) in diamond using magnetic-field controlled coupling to the first two modes of a superconducting (NbTiN) coplanar waveguide resonator. Three hyperfine-split spin sub-ensembles are clearly resolved in the 0.25-1.2 K temperature range, with a collective coupling strength extrapolating to 23 MHz at full polarization. The coupling to multiple modes allows us to distinguish the contributions of dipolar broadening and magnetic field inhomogeneity to the spin linewidth. We find the spin polarization recovery rate to be temperature independent below 1 K and conclude that spin out-diffusion across the resonator mode volume provides the mechanism for spin relaxation of the ensemble. Furthermore, by pumping spins in one sub-ensemble and probing the spins in the other sub-ensembles, we observe fast steady-state cross-relaxation (compared to spin repolarization) across the hyperfine transitions. These observations have important implications for using the three sub-ensembles as independent quantum memories.

8:24AM M18.00003 High-Resolution Correlation Spectroscopy of ^{13}C Spins Near a Nitrogen-Vacancy Center in Diamond[1] , CARLOS MERILES, ABDELGHANI LARAOUI, City College of New York - CUNY, FLORIAN DOLDE, JOERG WRACTHRUP, FRIEDEMANN REINHARD, CHRISTIAN BURK, 3rd Physics Institute, University of Stuttgart — We use a pulse protocol to monitor the time evolution of the 13C ensemble in the vicinity of a NV center. We observe time correlations in the nuclear spin dynamics that extend over several milliseconds exceeding the color center coherence lifetime by more than an order of magnitude. Upon Fourier transform, we separate 13C spins exhibiting differing coupling constants with a frequency resolution inversely proportional to the NV spin-lattice relaxation time. Further, we use the nuclear spin of the host nitrogen as a quantum register during the correlation interval and demonstrate that hyperfine-shifted resonances in this spectrum can be separated from the bare carbon peak upon proper initialization of the NV. Intriguingly, we find that the amplitude of the correlation signal exhibits a sharp dependence on the applied magnetic field, virtually disappearing below a critical field common to all centers. The value of this transition field can be 'tuned' by properly adjusting the timing within our correlation scheme. We discuss these observations in the context of the 'quantum-to-classical' transition proposed recently to explain the combined dynamics of the NV spin and the 13C bath at variable magnetic field.

8:36AM M18.00004 Measurement and control of single spins in diamond above 600 K[1] , DAVID M. TOYLI[2], Center for Spintronics and Quantum Computation, University of California, Santa Barbara, CA 93106 — The nitrogen vacancy (NV) center in diamond stands out among spin qubit systems in large part because its spin can be controlled under ambient conditions whereas most other solid state qubits operate only at cryogenic temperatures. However, despite the intense interest in the NV center's room temperature properties for nanoscale sensing and quantum information applications, the ultimate thermal limits to its measurement and control have been largely unknown. We demonstrate that the NV center's spin can be optically addressed and coherently controlled at temperatures exceeding 600 K and show that its addressability is eventually limited by thermal quenching of the optical spin readout [1]. These measurements, in combination with computational studies, provide important information about the electronic states that facilitate the optical spin measurement and, moreover, suggest that the coherence of the NV center's spin states could be utilized for thermometry. We infer that single spins in diamond offer temperature sensitivities better than 100 mK/$\sqrt{\text{Hz}}$ up to 600 K using conventional sensing techniques and show that advanced measurement schemes provide a pathway to reach 10 mK/$\sqrt{\text{Hz}}$ sensitivities. Together with diamond's ideal thermal and mechanical properties, these results suggest that NV center thermometers could be applied in cellular thermometry and scanning thermal microscopy.

9:12AM M18.00005 Approach to Dark Spins Initialization in Nanodiamond , ABDELGHANI LARAOUI, CAROS MERILES, Department of Physics, City College of New York, CUNY — Diamond nanoparticles host a number of paramagnetic point defects and impurities–many of them adjacent to the surface–whose response to external stimuli could help probe the complex dynamics of the particle and its local, nanoscale environment. Here we use a Hartman-Hahn protocol to demonstrate spin polarization transfer from a single, optically-polarized nitrogen-vacancy (NV) center to the ensemble of paramagnetic defects hosted by an individual diamond nanocrystal (30 nm in diameter). Owing to the strong NV-bath coupling, the transfer takes place on a short, microsecond time scale. Upon fast repetition of the pulse sequence we observe strong polarization transfer blockade, which we interpret as an indication of spin bath cooling. Numerical simulations indicate that the spin bath polarization is non-uniform throughout the nanoparticle averaging approximately 2% over the crystal volume, but reaching up to 20% in the immediate vicinity of the NV. These observations may prove relevant to the planning of future bath-assisted magnetometry tests.

9:24AM M18.00006 Engineering shallow spins in diamond with nitrogen delta-doping[1] , K. OHNO, F.J. HEREMANS, L.C. BASSETT, B.A. MYERS, D.M. TOYLI, A.C. BLESZYNSKI JAYICH, C.J. PALMSTROM, D.D. AWSCHALOM, Center for Spintronics and Quantum Computation, University of California, Santa Barbara, CA, 93106 — The excellent spin properties of diamond nitrogen-vacancy (NV) centers motivate applications from sensing to quantum information processing. Still, external electron and nuclear spin sensing are limited by weak magnetic dipole interactions, requiring NVs be within a few nm of the surface and retain long spin coherence times (T_2). We report a nitrogen delta-doping technique to create artificial NVs meeting these requirements. Isotopically pure $^{15}N_2$ gas is introduced to form a thin N-doped layer (1–2 nm thick) during chemical vapor deposition of a diamond film. Post growth electron irradiation creates vacancies and subsequent annealing forms NVs while mitigating crystal damage. We identified doped NVs through the hyperfine signature of the rare ^{15}N isotope in electron spin resonance measurements. We confirm the doped NV depth dispersion is less than 4 nm by doping NVs in the ^{12}C layer of an isotopically engineered ^{13}C/^{12}C/^{13}C structure and probing the coupling between the doped NVs and the ^{13}C nuclear spins. Furthermore, despite their surface proximity, doped NVs embedded in ^{12}C films 5 (52) nm below the surface show T_2 greater than 100 (600) μs [1].

9:36AM M18.00007 Optically trapped nanodiamonds with nitrogen-vacancy center spins for scanning magnetometry and thermometry[1] , BENJAMIN J. ALEMAN, VIVA R. HOROWITZ, PAOLO ANDRICH, DAVID J. CHRISTLE, DAVID M. TOYLI, ANDREW N. CLELAND, DAVID D. AWSCHALOM, Center for Spintronics and Quantum Computation, University of California, Santa Barbara, CA 93106 — Nanodiamonds with nitrogen-vacancy (NV) centers are a versatile sensing platform that combines the optically addressable atom-like properties of embedded NV centers, which are sensitive to electromagnetic fields and temperature, with the physical size and mobility necessary for nanometer-scale spatial resolution. We constructed an optical tweezers apparatus that accomplishes position control of nanodiamonds in solution within a microfluidic circuit and enables simultaneous optical measurement and microwave manipulation of the NV centers' ground-state spins [1]. We observe nanodiamond fluorescence and trapping stability over many hours, and infer high d.c. magnetic field and temperature sensitivities from measured spin resonance spectra. Scanning the position of the trapped nanodiamonds enables us to map the magnetic field of current-carrying wires and magnetic nanostructures, and perform thermometry in liquid. This work provides an approach to three-dimensional spin-based scanning probe magnetometry and thermometry in fluids for applications in the biological and physical sciences.

9:48AM M18.00008 Exchange Interaction of Transition Metal Dopants in Diamond[1] , VICTORIA KORTAN, CUNEYT SAHIN, MICHAEL E. FLATTÉ, University of Iowa — Advances in single-ion implantation and spectroscopy have permitted direct observation of the exchange interaction between two dopant spins in a semiconductor[1], which is accurately described by tight-binding models of the semiconducting host[1,2]. These advances suggest controllable fabrication and utilization of few-dopant structures to explore fundamental properties and for applications[3]. Transition metal substitutional dopants in tetrahedrally-bonded semiconductors are good candidates for controllable spin manipulation and spin-spin interaction because they offer both highly-localized and much more extended spin-polarized states. For example, both the Ni and Cr dopant have spin-1 ground states in diamond, but with differing spatial extent[4]. We calculate the exchange interaction between pairs of Ni and Cr dopants in diamond using the technique of Ref. 2, but with an spds* tight-binding model. We find strong exchange interactions between pairs of Ni, and pairs of Cr, which are influenced by the differing symmetry of the dopants' ground state. [1] D. Kitchen et al., Nature 442, 436 (2006). 10:00AM M18.00009 Detection and Manipulation of Single NV Centers in Diamond[1] , S. SANGTAWESIN, T.O. BRUNDAGE, S.A. PERLMAN, J.R. PETTA, Department of Physics, Princeton University — We use a scanning confocal microscope to investigate the fluorescence emission from nitrogen vacancy (NV) centers in diamond, a promising building block for quantum computing due to its long coherence time at room temperature. We demonstrate detection and coherent manipulation of a single NV center spin in synthetic diamond. Rabi oscillation data shows a modulation in the amplitude that is accounted for by simulating NV center spin dynamics in the presence of a proximal ^{14}N nuclear spin. The hyperfine interaction opens up the possibility of coupling the electronic spin of an NV center to nearby nuclear spins, forming multi-qubit systems for quantum computation. For applications where a long coherence time is necessary, decoherence caused by the hyperfine interaction can be suppressed using a spin-echo pulse sequence, resulting in electron spin coherence times of over 1 μs at room temperature in type Ib diamond of high impurity content.

10:12AM M18.00010 Improving the Collection Efficiency of Bulk Diamond NV Center Fluorescence with Solid Immersion Lenses[1] , T.O. BRUNDAGE, S. SANGTAWESIN, J.R. PETTA, Department of Physics, Princeton University — The spin-dependent fluorescence of nitrogen vacancy (NV) centers in diamond makes them promising systems for a variety of applications ranging from magnetic field sensing to quantum information processing. The fidelity of optical detection of NV center spin states is therefore dependent on the collection efficiency of the NV fluorescence. While the crystal structure of diamond is useful in allowing for stable, room temperature measurements, its high index of refraction leads to a shallow critical angle of total internal reflection ($\sim 24^\circ$) significantly limiting the optical collection efficiency. Here we develop a method for fabricating a solid immersion lens (SIL) on the surface of bulk diamonds. The hemispherical SILs, milled with high-energy gallium ions, are positioned such that the NV center of interest is at the origin of the sphere, thereby utilizing the full numerical aperture of the objective lens in the confocal microscope. Our lenses have already improved the collection efficiency by a factor of 2-3. With simple first order corrections to the milling process, higher collection efficiencies should be attainable. Further improvements in the lenses will allow single-shot readout of the spin states of NV centers.

10:24AM M18.00011 Towards Nuclear Polarization of Nanodiamond[1] , EWA REJ, DAVID WADDINGTON, TORSTEN GAEBEL, DAVID REILLY, ARC Centre of Excellence for Engineered Quantum Systems, School of Physics, The University of Sydney, Sydney, NSW 2006, Australia — Nanoparticles with long nuclear spin relaxation times [1] are candidates for use in targeted therapeutic delivery [2] and magnetic resonance imaging [3]. We report progress towards the development of contrast agents based on 13C in nanodiamond. Nuclear relaxation and electron spin resonance data is presented. We describe the development of a DNP setup at X band frequencies based on an ENDOR cavity, together with a novel brute force setup that combines milli-Kelvin temperatures of a dilution refrigerator, high magnetic fields and fast sample exchange. [1] J. Aptekar, *et al.*, ACS Nano, 3, 4003-4008 (2009). [2] H. Huang , E. Pierstorff, E. Osawa, and D. Ho, Nano Lett, 7, 3305-3314 (2007). [3] L Manus T. J. Meade, Nano Lett, 10, 484-489 (2010).

10:36AM M18.00012 Effective spin-orbit Hamiltonians and spin lifetimes for diamond and strontium titanate , CUNEYT SAHIN, Optical Science and Technology Center and Department of Physics and Astronomy, University of Iowa, Iowa City, Iowa 52242, USA, GIOVANNI VIGNALE, Department of Physics and Astronomy, University of Missouri, Columbia, Missouri 65211, USA, MICHAEL E. FLATTÉ, Optical Science and Technology Center and Department of Physics and Astronomy, University of Iowa, Iowa City, Iowa 52242, USA — The long spin coherence times of spin centers in diamond and the large Rashba coefficients and spin injection efficiencies in strontium titanate-based two-dimensional systems makes these wide band-gap semiconductors strong candidates for spintronics applications. To calculate the spin properties of these inversion-symmetric materials we have constructed a low-energy Hamiltonian, making use of a tight-binding model with atomic spin-orbit interactions. Furthermore we have derived and calculated the tensor that controls the form of the effective spin-orbit interaction in the non-spherical conduction bands of these materials. Finally we have computed the spin relaxation rates via the Elliott-Yafet mechanism through impurity scattering for diamond and uniaxially strained strontium titanate as a function of temperature and carrier density. Long spin lifetimes suggest the potential for novel spintronic applications of these wide bandgap semiconductors. This work was supported by an ARO MURI and an AFOSR MURI.

10:48AM M18.00013 Dynamic nuclear polarization of single nitrogen isoelectronic centers in GaAs , GABRIEL ETHIER-MAJCHER, PHILIPPE ST-JEAN, SEBASTIEN FRANCOEUR, Ecole Polytechnique de Montreal — Due to their very long coherence time, nuclear spins of atomic systems represent good candidates for spin-based qubits in semiconductors. In this work, the dynamic nuclear polarization of isoelectronic centers formed from two nitrogen impurities in GaAs is investigated as a function of the external magnetic field and the polarization ellipticity of the exciting light. The nuclear spins of a single center are probed by the Overhauser shift of the neutral exciton and negatively charged exciton bound states. A nuclear magnetic field of 25 mT is measured at low external magnetic field and it decreases with this external field, indicating an efficiency loss in the exciton-nucleus spin-flip process. A peculiar Overhauser shift, scaling as the square of the ellipticity, is found for the exciton. A strong hysteretic behavior is also observed for both the neutral and charged excitons. These effects are believed to originate from the complex dynamic of the hyperfine interaction between the different excitonic spin states and nuclei. Our results show that dynamic nuclear polarization, much studied in quantum dots, is scalable to a single atomic-sized system. These results represent a first step towards the optical control of single nuclear spins in semiconductors.

Session M19 DCMP: Strongly Correlated Electron Systems and Phase Transitions 321 - Andriy Nevidomskyy, Rice University

8:00AM M19.00001 Quantum criticality in the pseudogap two-channel Anderson and Kondo models , TATHAGATA CHOWDHURY, KEVIN INGERSENT, University of Florida, FARZANEH ZAMANI, PEDRO RIBEIRO, MPI-PKS, Dresden, Germany, STEFAN KIRCHNER, MPI-PKS, MPI-CPFS, Dresden, Germany — The two-channel Anderson and Kondo impurity models with a density of states $\rho(E) \propto |E|^r$ that vanishes at the Fermi energy ($E = 0$) is of current interest in connection with impurities in graphene and in unconventional superconductors. The phase diagram of these models has been established previously [1,2]. We study the low-temperature static and dynamical properties of the models using the numerical renormalization-group method, and compare our results against exact and perturbative analytical theories [2], and against calculations performed within the non-crossing approximation. In the vicinity of the quantum critical points separating local-moment and non-Fermi liquid phases, the static local spin susceptibility is characterized by a set of critical exponents that satisfy the hyperscaling relations expected of an interacting system below its upper critical dimension. The dynamical local susceptibility and the impurity spectral function exhibit forms consistent with frequency-over-temperature scaling, another feature associated with interacting quantum critical points. [1] C. Gonzalez-Buxton and K. Ingersent, Phys. Rev. B 57, 14254 (1998). [2] I. Schneider et al., Phys. Rev. B, 84, 125139 (2011).

8:12AM M19.00002 Phase Diagram of a Correlated Band Insulator , GEORGE BATROUNI, AXEL EUVERTE, Institut Non-Linéaire de Nice, RICHARD SCALETTAR, Physics Department, UC Davis, SIMONE CHIESA, College William & Mary — The effect of on-site electron-electron repulsion U in a band insulator is explored for a bilayer Hubbard Hamiltonian with opposite sign hopping on the two sheets. Unlike the case of the ionic Hubbard model, which has a closely related noninteracting dispersion relation, no evidence is found for a metallic phase intervening between the Mott and band insulators: The gap in the spectral function monotonically increases with U from its initial band insulating value. The origin of such difference can be traced to the fact that the local interaction in a bilayer favors the formation of independent singlets whereas in the ionic model is responsible for a homogenization of the density and a consequent reduction of band structure effects. We found that the formation of singlets between the planes, and the resulting destruction of antiferromagnetic order occurs much more rapidly than in the case of a symmetric Hubbard bilayer, which has the same sign of hopping in the two sheets.

8:24AM M19.00003 Quantum Griffiths singularities in ferromagnetic metals , DAVID NOZADZE, THOMAS VOJTA, Missouri University of Science and Technology — We present a theory of the quantum Griffiths phases associated with the ferromagnetic quantum phase transition in disordered metals. For Ising spin symmetry, we study the dynamics of a single rare region within the variational instanton approach. For Heisenberg symmetry, the dynamics of the rare region is studied using a renormalization group approach. In both cases, the rare region dynamics is even slower than in the usual quantum Griffiths case because the order parameter conservation of an itinerant ferromagnet hampers the relaxation of large magnetic clusters. The resulting quantum Griffiths singularities in ferromagnetic metals are stronger than power laws. For example, the low-energy density of states $\rho(\epsilon)$ takes the asymptotic form $\exp[\{-\tilde{\lambda}\log(\epsilon_0/\epsilon)\}^{3/5}]/\epsilon$ with $\tilde{\lambda}$ being non-universal. We contrast these results with the antiferromagnetic case in which the systems show power-law quantum Griffiths singularities in the vicinity of the quantum critical point. We also compare our result with existing experimental data of ferromagnetic alloy $\mathrm{Ni}_x\mathrm{V}_{1-x}$.

8:36AM M19.00004 Quantum Criticality of Charged Particles in Polar Liquids , SHAHRIAR SHADKHOO, ROBIJN BRUINSMA, University of California, Los Angeles, Department of Physics and Astronomy — We propose a general theory for the interaction of electrons with polarizable media for which the dynamical structure factor for charge fluctuations is known. The theory is based on a generalization of Leggett's method for the construction of path integral functionals for electrons in dissipative media. We apply the method to the case of electrons in polar liquids using a dynamical structure factor obtained by numerical simulations. The functional integrals are approximated using Feynman's variational method. At low temperatures, a dynamical structure factor with local spatial structure along with a Debye-like decaying frequency dependence, as suggested by the simulations, produces a first-order transition at a critical coupling constant. This is in contrast with the Feynman polaron theory, which does not have local structure formation, where no transition takes place. We also find a line of continuous quantum criticality.

8:48AM M19.00005 Unbinding of giant vortices in states of competing order[1] , CHRIS HOOLEY, Scottish Universities Physics Alliance, University of St Andrews, UK, JON FELLOWS, University of Birmingham, UK and University of Warwick, UK, SAM CARR, JÖRG SCHMALIAN, Institut für Theorie der Kondensierten Materie and DFG Center for Functional Nanostructures, Karlsruher Institut für Technologie, Germany — We consider a two-dimensional system with two order parameters, one with O(2) symmetry and one with O(M), near a point in parameter space where they couple to become a single O($2+M$) order. While the O(2) sector supports vortex excitations, these vortices must somehow disappear as the high symmetry point is approached. We develop a variational argument which shows that the size of the vortex cores diverges as $1/\sqrt{\Delta}$ and the Berezinskii-Kosterlitz-Thouless transition temperature of the O(2) order vanishes as $1/\ln(1/\Delta)$, where Δ denotes the distance from the high-symmetry point. Our physical picture is confirmed by a renormalization group analysis which gives further logarithmic corrections, and demonstrates full symmetry restoration within the cores.

9:00AM M19.00006 Numerical study of a mobile magnetic impurity in a one-dimensional quantum liquid , JULIAN RINCON, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, Oak Ridge, Tennessee, DANIEL GARCIA, KAREN HALLBERG, Centro Atomico Bariloche and Instituto Balseiro, CNEA, CONICET, Bariloche, Argentina, MATTHIAS VOJTA, Institut fuer Theoretische Physik, Technische Universitaet Dresden, 01062 Dresden, Germany — We study a mobile spin-1/2 impurity, coupled antiferromagnetically to a one-dimensional gas of fermions. Combining perturbative ideas and extensive density matrix renormalization group calculations, we study the interplay between the screening of the impurity by the electrons and the kinetic and magnetic properties of the impurity. We show that this problem displays a quantum phase transition between one- and two-channel Kondo physics. Using finite-size scaling, we construct a ground-state phase diagram and discuss various non-trivial regimes.

9:12AM M19.00007 Critical fluctuations in N-component superconductor models , LORENZ BARTOSCH, Frankfurt University — Inspired by recent conflicting views on the order of the phase transition from an antiferromagnetic Néel state to a spin liquid or valence bond solid, we use the functional renormalization group to reconsider the N-component superconductor models, in which a dynamic gauge field is minimally coupled to N bosonic complex fields. In contrast to previous work, we only expand in covariant derivatives and use a truncation in which the full field dependence of all wave-function renormalization functions is kept. As a consequence, we find non-trivial RG fixed points for all positive integer N.

9:24AM M19.00008 Zigzag Quantum Phase Transition in Quantum Wires[1] , ABHIJIT C. MEHTA, Duke University, CYRUS J. UMRIGAR, Cornell University, HAROLD U. BARANGER, Duke University — We use Quantum Monte Carlo (QMC) techniques to study the quantum phase transition of interacting electrons in a quantum wire to a quasi-one-dimensional zigzag phase. Interacting electrons confined to a wire by a transverse harmonic potential form a linear Wigner crystal at low densities; as density increases, symmetry about the axis of the wire is broken and the electrons undergo a transition to a quasi-one-dimensional zigzag phase. The phase diagram of particles with Coulomb interaction that undergo a linear to zigzag transition is relevant to electrons in quantum wires and ions in linear traps. We characterize this phase transition by using QMC to study the order parameter, correlation functions, pair density, power spectrum, and addition energies.

9:36AM M19.00009 Construction of local order parameters from non-vanishing mutual information , WING CHI YU, SHI-JIAN GU, Department of Physics, The Chinese University of Hong Kong, HAI-QING LIN, Department of Physics, The Chinese University of Hong Kong; Beijing Computational Science Research Center — In the recent decades, raising attention has been paid in the study of quantum phase transitions (QPTs) from quantum information perspectives. In this talk, we will present a scheme in constructing the local order parameters by investigating the spectra of the reduced density matrices that are used to calculate the mutual information. We will briefly review the relation between non-vanishing mutual information and the presence of long-range correlation in a system. In particular, we will illustrate our scheme using the numerical exact diagonalization result of the one-dimensional Hubbard model.

9:48AM M19.00010 Columnar and superfluid order in an extended Shastry-Sutherland model , KEOLA WIERSCHEM, PINAKI SENGUPTA, Nanyang Technological University — The low temperature magnetic properties of several rare-earth tetraborides have been shown to be well-characterized by an extension of the Shastry-Sutherland model (SSM). This extension includes additional next-nearest-neighbor bonds, and the exchange interaction along all bonds is anisotropic with strictly ferromagnetic transverse exchange. The extended SSM is thus equivalent to a system of hard-core bosons and is free of the quantum Monte Carlo (QMC) sign problem. Using large scale QMC simulations, we study the phase diagram of the extended SSM in a new parameter regime that stabilizes a zero-field columnar antiferromagnetic state. We show how application of an external magnetic field can induce a phase transition to a spin supersolid phase. We compare the overall magnetization process to experimental observations of ErB_4, a rare-earth tetraboride with ground state columnar antiferromagnetic ordering. Finally, we speculate that if the zero-field columnar order present in ErB_4 is driven by similar interactions it may also possess a field-induced supersolid phase.

10:00AM M19.00011 Resummation of divergent fluctuations near to metallic ferromagnetic quantum criticality[1] , CHRIS PEDDER, ANDREW GREEN, London Centre for Nanotechnology & University College, London — Fluctuations near to the metallic ferromagnetic quantum critical point can have profound effects. They lead to new quantum critical scaling at high temperatures, which gives way to reconstruction of the phase diagram at lower temperatures. In the vicinity of the quantum critical point, new spatially modulated magnetic or spin nematic phases appear. These new phases may be revealed by means of non-analytic corrections to Hertz-Millis theory [1], or in the recently-developed quantum order-by-disorder approach [2]. Here we demonstrate a re-summation of all the leading divergences in the latter approach to extend the analysis from the finite-temperature tricritical point down to zero temperature.

10:12AM M19.00012 ABSTRACT WITHDRAWN –

10:24AM M19.00013 Tractable Crossing-symmteric Equations Formalism and Applications in Two Dimensions , KELLY REIDY, KHANDKER QUADER, Kent State University, KEVIN BEDELL, Boston Collge — The tractable crossing symmetric formalism is developed for the 2D case. We first consider circular Fermi surfaces and then extend this to 2D square lattice systems. Limiting cases, such as small (q, ω), vanishing momentum-energy transfer $(q \to 0, \omega \to 0)$, vanishing q but non-zero ω are considered. This is applied to the study of various properties of 2D Fermi systems. Of particular interest is the physics near Pomeranchuk instabilities: in Fermi systems, interactions can cause symmetry-breaking deformations of the Fermi surface, called Pomeranchuk instabilities. In Fermi liquid theory language, this occurs when one of the Landau harmonics $F_\ell^{s,a} \to -(2\ell+1)$; e.g. $F_0^{s,a} \to -1$ are related to ferromagnetic transition (a), and density instabilities(s). The corresponding points in parameter space may be viewed as quantum critical points. Using graphical and numerical methods to solve coupled non-linear integral equations that arise in the crossing symmetric equation scheme, we obtain results in the 2D case close to Pomeranchuk instabilities. We compare our 2D results for various response functions and instabilities with the results of recent calculations in the 3D case, which will also be discussed.

10:36AM M19.00014 Strongly-correlated phases in a flatband with incommensurate filling , EVELYN TANG, XIAO-GANG WEN, Perimeter Institute/MIT — We explore strongly-correlated electronic phases in flatband systems (such as on the kagome lattice) with incommensurate filling, in the presence of spin-orbit interactions and ferromagnetism. The competition between Fermi-liquid, charge-density wave and superconducting phases in this system is examined.

Wednesday, March 20, 2013 8:00AM - 11:00AM –

Session M20 DCMP: Focus Session: Metamaterials - Plasmonics 322 - David Smith, Duke University

8:00AM M20.00001 Quantum Plasmonics: Electron transfer processes , PETER NORDLANDER, Rice University — Plasmon energies can be tuned across the spectrum by simply changing the geometrical shape of a nanostructure. Plasmons can efficiently capture incident light and focus it to nanometer sized hotspots which can enhance electronic and vibrational excitations in nearby structures.[1] Another important but still relatively unexplored property of plasmons, is that they can be efficient sources of hot energetic electrons which can transfer into nearby structures and induce a variety of processes. This process is a quantum mechanical effect: the decay of plasmon quanta into electron-hole pairs. I will discuss how plasmon induced hot electrons can be used in various applications: such as to induce chemical reactions in molecules physisorbed on a nanoparticle surface;[2] to inject electrons directly into the conduction band of a nearby substrate;[3] and to induce local doping of a nearby graphene sheet.[4] References [1] N.J. Halas *et al.*, Adv. Mat. 24(2012)4842 [2] R. Huschka *et al.*, JACS 133(2011)12247; S. Mukherjee *et al.* TBP 2012 [3] M. W. Knight *et al.*, Science 332(2011)702, Z.Y. 8:12AM M20.00002 Plasmonic electron injection drives ultrafast phase transition by catastrophic phonon collapse I: experiment[1] , KANNATASSEN APPAVOO, Vanderbilt University, NATHANIEL F. BRADY, University of Alabama-Birmingham, BIN WANG, Vanderbilt University, MINAH SEO, Los Alamos National Lab, JOYEETA NAG, Vanderbilt University, ROHIT P. PRASANKUMAR, Los Alamos National Lab, SOKRATES T. PANTELIDES, Vanderbilt University, DAVID J. HILTON, University of Alabama-Birmingham, RICHARD F. HAGLUND, Vanderbilt University — Phase transitions in quantum materials such as vanadium dioxide (VO_2) can provide functionality in nanophotonic devices. Here we report on a novel all-optical mechanism to trigger phase transformation (PT) of VO_2 faster than its intrinsic single phonon period. By optically exciting a spectrally resonant sparse mesh of plasmonic gold nanoparticles, hot electrons created are ballistically injected across the Au/VO_2 interface to assist the sub-picosecond PT, lowering the switching threshold by a factor of five. As confirmed by density functional calculations, the injected electrons cause a catastrophic collapse of the 6 THz phonon mode in VO_2, essential for triggering its PT (next abstract). This demonstration of plasmon-induced hot-electron-driven PT controlled by this ultrafast technique represents a critical step towards developing hybrid nanomaterials with optimal switching thresholds.

[1](1)DOE:DE-FG02-01ER45916 (2)HDTRA1-10-1-0047 (3)NSF:ARI-R2 DMR-0963361 and DMR-1207241 (5)McMinn Endowment (6)LANL:DE-AC52-06NA25396 (7)SNL:DE-AC04-94AL85000 (8)GAANN:P200A0901

8:24AM M20.00003 Plasmonic electron injection drives ultrafast phase transition by catastrophic phonon collapse II: theory[1] , BIN WANG, KANNATASSEN APPAVOO, Vanderbilt University, NATHANIEL BRADY, University of Alabama, Birmingham, MINAH SEO, LANL, JOYEETA NAG, Vanderbilt University, ROHIT PRASANKUMAR, LANL, DAVID HILTON, University of Alabama, Birmingham, RICHARD HAGLUND, Vanderbilt University, SOKRATES PANTELIDES, Vanderbilt University, ORNL — The ultrafast photo-induced phase transition in VO_2 is promising for data storage and sensing applications. Our experimental work (the previous talk) shows that in a Au/VO_2 hybrid nanostructure, electrons excited in the Au photocathode by an ultrafast laser trigger the insulator-to-metal transition in VO_2. Here we report first-principles density-functional calculations showing that the collapse of a 6 THz optical phonon, corresponding to a twisting motion of V atoms, is responsible for the ultrafast phase transition. Above a concentration threshold, we find that injected electrons from Au induce collapse of the VO_2 phonon, which stimulates the monoclinic-to-rutile structural phase transition. We also show that hole-doping can induce the same effect. The abrupt change of the critical phonon results from the weakening of the V-V bonds induced by the combined flux of injected electrons and holes. Thus, our results explain the experimental finding of plasmonic-electron-driven ultrafast phase transition and represent a step towards manipulating the photo-induced phase transition by surface modification.

8:36AM M20.00004 Optical circulation and power flow rotation with nonreciprocal plasmonic structure[1] , ARTUR DAVOYAN, NADER ENGHETA, Department of Electrical and Systems Engeenering, University of Pennsylvania — In this work we propose a concept for tailoring the near-zone optical field with the plasmonic nanostructures mixed with MO materials, and demonstrate a novel effect of a subwavelength power flow circulation. We study both analytically and numerically plasmonic nanostructures embedded into magneto-active media, and analyze their resonances and corresponding eigenmode spectra. We show that when the structure is degenerate the magneto-optical activity, when introduced, causes strong interaction between these modes. Such intermodal interaction leads to a formation of a novel set of rotating states and to a frequency splitting between them. We study the plane wave excitation of such nanostructures and reveal a strong power flux circulation around such structures in the presence of magneto-optical activity. We will discuss a possible application of the observed effect and propose a subwavelength optical circulator. In particular, we study numerically a plasmonic nanostructure embedded into the core of the Y-junction formed by single mode optical waveguides. We show that mixing the plamonic nanostructures with magneto-optical materials it is possible to break significantly the symmetry between the output arms of the junction and almost completely isolate one of them.

[1]This work is supported in part by the US Air Force Office of Scientific Research (AFOSR) grant number FA9550-10-1-0408.

8:48AM M20.00005 Mode matching for optimal plasmonic nonlinear generation , KEVIN O'BRIEN, HAIM SUCHOWSKI, JUN SUK RHO, BOUBACAR KANTE, XIAOBO YIN, XIANG ZHANG, NSF Nano-scale Science and Engineering Center (NSEC), University of California, Berkeley, California — Nanostructures and metamaterials have attracted interest in the nonlinear optics community due to the possibility of engineering their nonlinear responses; however, the underlying physics to describe nonlinear light generation in nanostructures and the design rules to maximize the emission are still under debate. We study the geometry dependence of the second harmonic and third harmonic emission from gold nanostructures, by designing arrays of nanostructures whose geometry varies from bars to split ring resonators. We fix the length (and volume) of the nanostructure on one axis, and change the morphology from a split ring resonator on the other axis. We observed that the optimal second harmonic generation does not occur at the morphology indicated by a nonlinear oscillator model with parameters derived from the far field transmission and is not maximized by a spectral overlap of the plasmonic modes; however, we find a near field overlap integral and mode matching considerations accurately predict the optimal geometry.

9:00AM M20.00006 Theory of plasmon-enhanced metal photoluminescence , TIGRAN V. SHAHBAZYAN, Jackson State University — Metal photoluminescence (MPL) originates from radiative recombination of photoexcited core holes and conduction band electrons. In metal nanostructures, MPL is enhanced due to surface plasmon local field effect. We identify another essential process in plasmon-assisted MPL - excitation of Auger plasmons by core holes - that hinders MPL from small nanostructures. We develop a microscopic theory of plasmon-enhanced MPL that incorporates both plasmonic enhancement and suppression mechanisms and derive enhancement factor for MPL quantum efficiency. Our numerical calculations of MPL from Au nanoparticles are in excellent agreement with experiment.

9:12AM M20.00007 Probing light-matter interactions in plasmonic nanostructures with a single quantum dot , CHAD ROPP, ZACHARY CUMMINS, SANGHEE NAH, JOHN T. FOURKAS, BENJAMIN SHAPIRO, EDO WAKS, University of Maryland — Understanding and controlling the interactions between single quantum emitters and plasmonic nanostructures is important for a wide variety of applications in quantum optics and nanophotonics. Metal nanostructures provide subwavelength confinement of electromagnetic fields in the form of surface plasmon polaritons, which can enhance optical nonlinearities for improved light-matter interactions. In this talk we will present recent results on nano-manipulation of single colloidal quantum dots (QDs) for deterministic probing of light-matter interactions in plasmonic nanostructures. Single QDs are manipulated using a combination of microfluidics and engineered fluid chemistry. We achieve deterministic positioning with 50 nm accuracy and demonstrate probing of the surface plasmon mode of a silver nanowire. Spatially variant interactions are quantified by measuring the coupling rate of the QD into the wire mode as well as changes to the QD emission lifetime. The resulting interactions are resolved with nanoscale resolution and reveal features such as the evanescent field decay away from the wire surface and interference along the wire length.

9:24AM M20.00008 Giant circular dichroism of a molecule in a plasmonic nanoparticle dimer[1] , HUI ZHANG, A.O. GOVOROV, Ohio University — We report on giant circular dichroism (CD) of a molecule inserted into a plasmonic hot spot. Naturally occurring molecules and biomolecules have typically CD signals in the UV range, whereas plasmonic nanocrystals exhibit strong plasmon resonances in the visible spectral interval. Therefore, excitations of chiral molecules and plasmon resonances are typically off-resonant. Nevertheless, we demonstrate theoretically that it is possible to create strongly-enhanced molecular CD utilizing the plasmons. Specifically, by employing a nanoparticle dimer, we gain simultaneously a strong plasmonic enhancement and a shift of optical CD from the UV range to the visible. The associated mechanism of giant CD comes from the Coulomb interaction which is greatly amplified in a plasmonic hot spot. Two key factors play a role in the described effect: One is the Coulomb interaction within the molecule-dimer complex giving rise to the plasmon peak in the CD spectrum, whereas the other one is the plasmonic enhancement of the absorption process in a chiral molecule. We propose that, by using the hot spot effect and plasmon-induced CD signals, one can design optical sensors to study chirality of biomolecules.

9:36AM M20.00009 Exciton-plasmon coupling in monolayer molybdenum disulfide[1] , JED ZIEGLER, A.K.M. NEWAZ, KIRILL BOLOTIN, RICHARD HAGLUND, Vanderbilt University — Two-dimensional materials such as monolayer molybdenum disulfide (MoS_2) represent a unique platform for investigating the dynamics of exciton-plasmon coupling. We report on the generation and modulation of coherent and incoherent coupled states between excitons in monolayer MoS_2 and plasmons in an array of gold nanoparticle deposited onto the surface of MoS_2. We study the behavior of these coherent states, termed plexcitons using a combination of photoluminescence, extinction and ultrafast spectroscopies. The close proximity of the two characteristic exciton bands of MoS_2 presents multiple coherent coupling configurations, including A-or-B exciton-plasmon, and A-and-B exciton-plasmon interactions. These configurations of plexciton formation that are shown to modulate both the extinction and photoluminescence spectra of the hybrid system. This includes broadband photoluminescence and Fano-type resonances. This behavior is distinct from the spectral response of the MoS_2 and plasmonic components of the system. Incoherent exciton-plasmon coupling, achieved by detuning from the plasmon extinction peaks, enhances the interaction of MoS_2 with light by focusing the plasmon energy. Depending on which coupling configuration is chosen, our results show that the MoS_2/plasmon hybrid systems can act as high efficiency light harvesters, broadband emitters and as tunable visible and NIR photodetectors.

9:48AM M20.00010 Optical Properties of Graphene Plasmons in Periodic Gate Structures , STEFAN C. BADESCU, ROBERT C. FITCH, Air Force Research Laboratory, WPAFB, Dayton OH — Plasmons in graphene have been shown to be tunable in a wide frequency range including the THz regime. Room temperature, narrow plasmon modes have been demonstrated in graphene ribbons arranged periodically on surfaces. Here we present computational results of localized modes in continuous graphene layers with periodic arrangements of gates that modulate spatially the charge density. These induce boundary conditions different from those in graphene ribbons and open the possibility of electrical injection. We discuss the optical absorption and reflection spectra for different gate voltages and for a range of gate widths and spacing. We also discuss different regimes of electrical injection and the role of substrates in coupling to plasmons and in heat dissipation.

10:00AM M20.00011 Optical Properties of Epitaxially Grown Silver Films , YANWEN WU[1], CHENDONG ZHANG[2], MATT ZHANG, CHIH-KANG SHIH, XIAOQIN LI, Department of Physics, The University of Texas at Austin, Austin, TX 78712, USA — One major obstacle in the advancing field of plasmonics is the loss in metals. A sizable contribution of this loss comes from grain boundaries and surface roughness introduced during thin film growth using conventional deposition methods. A novel epitaxial growth technique is used to produce silver (Ag) thin films free of such flaws. We investigate the optical properties–namely the dielectric optical constants–of these new epitaxial films in the bulk region and in the ultrathin film limit where quantum mechanical behaviors emerge due to energy quantization in the growth direction. The values for the dielectric optical constants are extracted from the spectral ellipsometry (SE) measurements over a wide range of optical frequencies. By using an adequate model of the sample structure and initial values of the fitting parameters (i.e. the real and imaginary parts of the optical constants), we can extract these measured values for the new Ag films. We have confirmed that in the bulk region, the optical constants converge with the well-known Johnson and Christy measurements [1]. In the ultrathin film limit, however, we observed significant changes near the D-band transition likely due to a quantum well-like density of states.

10:12AM M20.00012 Hamiltonian Optics Approach for Hybridized Surface Plasmon Polariton in Graded Metal-Dielectric-Metal Waveguide with Periodically Varying Index , SZE FUNG LEE, KING CHUN LAI, KIN WAH YU, The Chinese University of Hong Kong — In a complex plasmonic nanostucture, it is possible to support several elementary modes of surface plasmon polariton due to the multi-surface configuration. Hybridized surface plasmon polariton (HSPP) is formed when those modes interact with each others. The dispersion curves of these complex plasmon modes will be shifted from the original ones. As the shifting depends strongly on the geometry of the structure, it allows one to manage the properties of light inside the structure with much higher flexibility and complexity. We have studied the properties of HSPP in a graded metal-dielectric-metal (MDM) waveguide with the refractive index of the dielectric varying periodically, using the Hamiltonian optics approach, to investigate the feasibility of light manipulation inside this structure. We have extracted the allowed phase orbits using the quantization condition. The time series of position and wavevector of HSPP were also simulated by solving the Hamiltonian equations of motion. The results revealed two possible orbits of the HSPP inside the waveguide: confinement and propagation. The range of angular frequency such that the phase orbits become singular is also determined. In this regime, the photon energy is efficiently converted into surface plasmon energy.

10:24AM M20.00013 Self-Complementary Plasmonic Structures for High Efficiency Broadband Absorber in the Visible Range , TIANYI SUN, Boston College, YANG WANG, South China Normal University, ZHIFENG REN, KRZYSZTOF KEMPA, Boston College — We demonstrate, by simulation, that a planar 3-layer structure on a metal substrate can highly absorb electromagnetic radiation in the entire visible range, which can become a potential platform for high-efficiency broadband absorber. Such a structure consists of an ultrathin semiconducting layer topped with a solid nanoscopically perforated metallic film and then a dielectric interference layer. It is shown that the perforated metallic film and the ultrathin absorber form an effective metamaterial film, which negatively refracts light in this broad frequency range. Our quantitative simulation confirms that the absorption bandwidth is maximized at the self-complementary pattern of the percolation threshold. If amorphous silicon (a-Si) is selected as the ultrathin semiconducting material, the absorbance of the structure with a checkerboard-patterned perforated metallic film is about 90% in the visible range (from 400 nm to 700 nm), where 80% goes into the a-Si layer and the other 10% being absorbed by other layers. Further simulation shows that for a single p-i-n a-Si junction, the energy conversion efficiency of an optimized structure can exceed 12%.

10:36AM M20.00014 Plasmonic halos: optical surface plasmon drumhead modes , FAN YE, MICHAEL J. BURNS, MICHAEL J. NAUGHTON, Boston College, Department of Physics, 140 Commonwealth Avenue, Chestnut Hill, MA, 02467 — We present the discovery and systematic study of a novel optical phenomenon, wherein optically-pumped surface plasmons on circular silver microcavities form confined drumhead modes that, under off-resonant conditions, transform to colorful far field radiation at their circumferential boundaries. We call this phenomenon the "plasmonic halo." We demonstrate both experimentally and theoretically that such circular microcavities integrated with perimeter step gaps can generate surface plasmon cavity modes, and modulate optical transmission/emission through/from the device, yielding the plasmonic halo effect. Via the tuning of geometric and/or material parameters, optical properties of this device can be manipulated in the visible range, leading to promising applications in biomedical plasmonics, dielectric constant sensing and discrete optical filtering, among others.

10:48AM M20.00015 Tunable Fano resonance due to interaction between molecular vibrational modes and a double-continuum of a plasmonic metamolecule[1] , EDWARD OSLEY, CLAUDIU BIRIS, PAUL THOMPSON, RAHAM JAHROMI, NICOLAE PANOIU, PAUL WARBURTON, University College London — We have fabricated and characterized a plasmonic system comprised of an array of asymmetric cross-shaped apertures in a metallic film coated with poly(methyl methacrylate) (PMMA). The apertures (called plasmonic metamolecules) produce localized surface plasmon (LSP) resonances that can be tuned by varying the polarization of incident light. Arrays of these nano-scale apertures, designed to have resonances at infrared wavelengths, were fabricated using electron beam lithography and argon ion milling of a gold film. Filling the apertures with PMMA allowed its C=O bond resonance to interact with tunable LSP modes. The transmission, reflection and absorption spectra of the system were measured using FTIR. Coupling between the LSPs and the C=O bond is shown to produce a Fano resonance that can be tuned in situ. The system was investigated theoretically using (a) rigorous electromagnetic calculations and (b) a quantum mechanical model that describes the interaction between a discrete state (the C=O bond) and multiple continua (the LSPs of the plasmonic metamolecule). We demonstrate that the predictions of the quantum model are in good agreement with the experimental data and show that the model allows an intuitive interpretation, at the quantum level, of the plasmon-molecule coupling.

Session M21 DMP: Focus Session: Relaxors, Nanostructures and Morphotropic Phase Boundaries 323 - Patrycja Paruch, Universite de Geneve

8:00AM M21.00001 Spontaneous ferroelectric-ferroelectric phase transitions and giant electro-mechanical energy conversion in [011] cut relaxor ferroelectric crystals , PETER FINKEL, AHMED AMIN, Naval Undersea Warfare Center, WEN DONG, UCLA — We report on giant electro-mechanical energy conversion is demonstrated under a ferroelectric/ferroelectric phase transformation in [011] cut and poled lead titanate-based relaxor perovskite morphotropic $Pb(In_{1/2}Nb_{1/2})O_3$-$Pb(Mg_{1/3}Nb_{2/3})O_3$-$PbTiO_3$ (PIN-PMN-PT). single crystals. It is found that under mechanical pre-stress, a relatively small oscillatory stress drives the material reversibly between rhombohedral and orthorhombic phases with a remarkably high polarization and strain jumps induced at zero bias electric field and room temperature. The measured electrical output per cycle is more than an order of magnitude larger than that reported for linear piezoelectric materials. Ideal thermodynamic cycles are presented for this electro-mechanical energy conversion followed by a presentation and discussion of the experimental data. The stress dependence of thermally driven polarization change is reported for a ferroelectric rhombohedral to ferroelectric orthorhombic phase transformation in [011] cut and poled. A giant jump in polarization and strain is associated with the phase transformation of the ferroelectric material. The phase transition temperature can be tuned, over a broad temperature range, through the application of bias stress. This phenomenon results in a new approach to applications in the field of energy harvesting

8:12AM M21.00002 ABSTRACT WITHDRAWN –

8:24AM M21.00003 Successive pressure-induced structural transitions in relaxor $Pb(In_{1/2}Nb_{1/2})O_3$[1] , MUHETAER AIHAITI, Carnegie Institution of Washington, Washington DC 20015, USA, SEIJI KOJIMA, University of Tsukuba, Ibaraki 305-8573, Japan, NAOHIKO YASUDA, Gifu University, Gifu 501-1193, Japan, RUSSELL HEMLEY, Carnegie Institution of Washington, Washington DC 20015, USA — We employed Raman scattering and x-ray diffraction to investigate the behavior of disordered $Pb(In_{1/2}Nb_{1/2})O_3$ (PIN) under pressure up to 50 GPa at 300 K. The sharp peak centered at 370 cm^{-1} increases its intensity with pressure. Two Raman peaks around 550 cm^{-1} merge at 16 GPa and their linewidths increase with pressure. The structural phase transition is associated with a splitting of the 50 cm^{-1} peak above 16 GPa. In most Pb-based relaxors, in contrast to PIN, the 50 cm^{-1} peak shows a slight hardening with pressure and no splitting is observed. The pressure evolution of the diffraction patterns for PIN shows obvious splittings above 16 GPa, particularly for the pseudo-cubic [110], [111] and [220] diffraction peaks, indicative of a symmetry-lowering transition. Our results demonstrate that PIN undergoes successive structural phase transitions. The transition at 6 GPa is similar to that observed in other Pb-based relaxors and related to the octahedra tilting; the transition at 16 GPa could be a rhombohedral to orthorhombic transition, and the transition at 38 GPa is assigned to an orthorhombic to a monoclinic transition.

8:36AM M21.00004 Strain, composition tuning and size effect in $Pb_xSr_{1-x}TiO_3$ piezoelectric thin films and nanostructures , SYLVIA MATZEN, OLEKSIY NESTEROV, JEROEN HEUVER, Zernike Institute for Advanced Materials, University of Groningen, The Netherlands, GIJSBERT RISPENS, DPMC, University of Geneva, Switzerland, MICHAEL BIEGALSKI, HANS M. CHRISTEN, CNMS, Oak Ridge Nat. Lab, Tennessee -USA, BEATRIZ NOHEDA, Zernike Institute for Advanced Materials, University of Groningen, The Netherlands — Optimizing the piezoelectric performance at the nanoscale is one of the main challenges for future piezoelectric applications, especially in the field of vibrational energy harvesting. In this work, we have investigated the combined influence of epitaxial strain, compositional variation and size reduction on the crystallographic structure, ferroelectric domain configuration and piezoelectric properties of $Pb_xSr_{1-x}TiO_3$ thin films and nanostructures epitaxially grown by Pulsed Laser Deposition on $SrRuO_3$-buffered (110)-$DyScO_3$ substrates. Theoretical predictions on the $PbTiO_3$-$SrTiO_3$ solid solution show an interesting phase transition, expected to give rise to enhanced piezoelectric properties, as a function of composition when the films are grown under strain on (110)-$DyScO_3$. A series of high quality epitaxial thin films has been grown with various Pb/Sr ratios. We have experimentally confirmed the predicted phase transition. Highly periodic domains with purely in-plane polarization have been observed by both X-ray diffraction and piezoresponse force microscopy. The piezoelectric properties have then been studied as a function of composition and of the lateral dimensions of nano-objects defined by Electron Beam Lithography.

8:48AM M21.00005 Direct observation of intrinsic localized modes as precursors to polar nanoregions in a relaxor ferroelectric , MICHAEL MANLEY, OLIVIER DELAIRE, Oak Ridge National Laboratory, JEFFREY LYNN, National Institute of Standards and Technology, ALAN BISHOP, Los Alamos National Laboratory, RAFFI SAHUL, TRS Technologies Inc., JOHN BUDAI, Oak Ridge National Laboratory — Displacive ferroelectric phase transitions can be understood in terms of a soft zone center phonon tending towards zero frequency as the material is cooled towards the transition. Relaxor ferroelectrics are less well understood but there is a growing consensus that dispersed polar nanoregions (PNRs), pinned by chemical inhomogeneities, are responsible for the behavior. Furthermore, it has been argued that PNRs form via soft localized phonon modes, modeled as intrinsic localized modes (ILMs), tending towards zero frequency as the material is cooled into the relaxor region, but these modes have never been observed directly. In this talk, neutron scattering measurements will be presented that reveal the existence of a dispersionless (localized) mode appearing near the Burns temperature in PMN-PT. The local mode softens and diminishes in intensity on cooling towards the relaxor region, ultimately vanishing as the PNRs form.

9:00AM M21.00006 Structure and dynamics analyses of $Pb(Mg_{1/3},Nb_{2/3})O_3$-$PbTiO_3$[1]

HIROYUKI TAKENAKA, DIOMEDES SALDANA-GRECO, ILYA GRINBERG, ANDREW M. RAPPE, University of Pennsylvania — Relaxor ferroelectric materials are of importance in applications due to their giant piezoelectricity, anomalous dielectric response, and diffuse phase transitions. However, mechanisms of the anomalous physical properties are still ambiguous, especially local structure and dynamics. According to our recent molecular dynamics simulations using a rock salt random site B-cation arrangement, the relax local structure is analogous to the hydrogen bonded network in water. In this work, we present structure and dynamics obtained from Bond-Valence model atomistic molecular dynamics simulations with the random site model and fully disordered 0.75PMN-0.25PT using diffuse scattering and dynamic pair distribution function techniques and compare our results with the available experimental data.

9:12AM M21.00007 Debye Relaxations, Fano Resonances and Heterophase Oscillations in the Relaxor $K_{1-x}Li_xTaO_3$[1]

JEAN TOULOUSE, LING CAI, Lehigh University, RADHA PATTNAIK, Lafayette College, LYNN BOATNER, Oak Ridge National Laboratory — Besides characteristic dielectric relaxations, relaxor ferroelectrics have also been shown to exhibit strong resonances. These resonances are related to the ubiquitous presence of polar nanodomains in relaxors in their "paraelectric" phase below a certain temperature T*. In the relaxor $K_{1-x}Li_xTaO_3$ (KLT), the dielectric spectrum reveals pairs of coupled resonances with a Fano-type line shape that evolves dramatically with temperature. At higher temperature, the line shape reflects the close interplay between relaxations and resonances. Near the phase transition, it reveals the existence of coherent heterophase fluctuations. KLT provides a good example of the multiscale dynamics (from nano to macro) that is intrinsic to relaxors.

9:24AM M21.00008 Finite-Temperature Properties of Ba(ZrTi)O3 Relaxors from First Principles[1]

SERGEY PROSANDEEV, University of Arkansas, ALI AKBARZADEH, Rice University, ERIC WALTER, College of William and Mary, ABDULLAH AL-BARAKATY, Umm Al-Qura University, LAURENT BELLAICHE, University of Arkansas — A first-principles-based technique is developed to investigate the properties of Ba(ZrTi)O3 relaxor ferroelectrics as a function of temperature. The use of this scheme provides answers to important, unresolved and/or controversial questions such as the following. What do the different critical temperatures usually found in relaxors correspond to? Do polar nanoregions really exist in relaxors? If yes, do they only form inside chemically ordered regions? Is it necessary that antiferroelectricity develop in order for the relaxor behavior to occur? Are random fields and random strains really the mechanisms responsible for relaxor behavior? If not, what are these mechanisms? These ab initio based calculations also lead to deep microscopic insight into relaxors.

9:36AM M21.00009 Resonant Ultrasonic Spectroscopy of O-18 and O-16 Strontium Titanate

, JAMES F. SCOTT, Cavendish Lab., Dept. Physics, Cambridge University — We have carried out [J. F. Scott, M. A. Carpenter, E. K. H. Salje et al., Phys. Rev. Lett. 106, 105502 (2011); 108, xxxxxx (2012)] resonant ultrasonic studies of bulk strontium titanate. Below 50K both O-18 and O-16 isotope studies reveal asymmetric Fano-lineshapes due to interaction between acoustic phonon branches related to C44 near 400 kHz and a continuum background due to Sr disorder along [111] directions, originally determined by the NMR studies of Blinc et al. The inference is that the ferroelectric phase of O-18 SrTiO3 has a disordered triclinic ground-state structure; this is compatible with the neutron studies by Bartkowiak et al. at ANSTO and helps reconcile paradoxes in the Brillouin studies of Shigenari et al. and Takesada, Yagi et al. For O-16 isotopic SrTiO3 the data show that the Brillouin splitting below ca. 50K previously misinterpreted as second sound by Courtens et al. and Tagantsev et al. is simply the required splitting of modes that would be degenerate in the tetragonal phase. The new studies show that the ferroelastic domains in O-16 SrTiO3 are polar and compatible with the 2012 flexoelectric model of Morozovska et al.

10:12AM M21.00010 Neutron Diffuse Scattering in Pure and Ba-Doped Single Crystals of the Relaxor NBT[1]

, WENWEI GE, CHRISTOPHER DEVREUGD, Virginia Tech, DANIEL PHELAN[2], PETER GEHRING, National Institute of Standards and Technology, QINHUI ZHANG, Chinese Academy of Sciences, Shanghai Institute of Ceramics, MUHTAR AHART, Carnegie Institution of Washington, JIEFANG LI, HAOSU LUO, DWIGHT VIEHLAND, Virginia Tech — We report neutron diffuse scattering measurements on the lead-free relaxors $Na_{1/2}Bi_{1/2}TiO_3$ (NBT) and NBT doped with 5.6% $BaTiO_3$, a composition that is located close to the morphotropic phase boundary. The diffuse scattering in NBT appears on cooling near 700 K, which coincides with the temperature at which the dielectric constant deviates from Curie-Weiss behavior. Strong, anisotropic diffuse scattering intensity is observed near the (100), (110), (200), (220), and (210) Bragg peaks. The reciprocal space distribution of the diffuse scattering is consistent with the presence of competing rhombohedral and tetragonal short-range structural correlations. Doping NBT with 5.6% $BaTiO_3$ reduces the correlation length associated with the tetragonal order by a factor of 10 while simultaneously enhancing the piezoelectric properties.

10:24AM M21.00011 Effects of electric field on acoustic properties of $0.83Pb(Mg_{1/3}Nb_{2/3})$-$0.17PbTiO_3$ single crystals studied by Brillouin light scattering[1]

, TAE HYUN KIM, University of Tsukuba, JAE-HYEON KO, Hallym University, SEIJI KOJIMA, University of Tsukuba — Relaxor-based ferroelectric $Pb[(Mg_{1/3}Nb_{2/3})_{1-x}Ti_x]O_3$ (PMN-xPT) single crystals have attracted great attention because of their exceptionally strong piezoelectric properties. This peculiar characteristic was attributed to the rotation of polarization directions and structural complexity. In this study, the phase transition behaviors of PMN-17PT single crystals have been investigated under an electric field applied along [001] by micro-Brillouin scattering. PMN-17PT single crystals were grown by the modified Bridgeman method. The two (001) surfaces were Au-coated to apply the electric field, and the coating was thin enough to allow the incident beam to transmit without much loss. The electric field of different values was applied to the sample along the [001] direction, and the Brillouin scattering spectrum was measured under both field-heating (FH) and field-cooling (FC) conditions. The electric field of 1kV/cm induced a new longitudinal acoustic (LA) mode component along with a broad Brillouin peak evolving continuously from the paraelectric phase during both FC and FH processes. This was attributed to the remnant polar nanoregions that were not aligned under the electric field due to quenched random fields. However, the splitting of the LA mode did not appear when the electric field was over 2kV/cm indicating a clear structural phase transition.

10:36AM M21.00012 Polarization Reversal in Ferroelectric Nanowires using Terahertz Pulses[1] , RYAN HERCHIG, KEVIN MCCASH, INNA PONOMAREVA, University of South Florida — Ferroelectric nanowires are very attractive for potential applications in nanodevices, nanosensors or ferroelectric computer memory, since they posses reversible polarization at the nanoscale. Here we report the possibility to remotely control the polarization direction in ferroelectric nanowires by the application of a small biased field in combination with a terahertz Gaussian-shaped pulse. Our study is carried out on $Pb(Zr_{0.4}Ti_{0.6})O_3$ nanowires using classical molecular dynamics with first-principle-based effective Hamiltonian[1]. The conditions for which the polarization reversal in the nanowire can be achieved by the coupled effect of a biased field with the application of a terahertz pulse are investigated. In particular, we will report computational data on the polarization reversal by application of THz pulses of different amplitude, frequency and width. Furthermore the dependence of the polarization reversal on the temperature is considered.

Session M22 DMP: Strongly Correlated Electron Theory II 324 - Srinivas Raghu, Stanford University

8:00AM M22.00001 Bond Disorder Induced Criticality of the Three-Color Ashkin-Teller Model[1] , ARASH BELLAFARD, UCLA, HELMUT KATZGRABER, ETHZ, TAMU, MATTHIAS TROYER, ETHZ, SUDIP CHAKRAVARTY, UCLA — An intriguing result of statistical mechanics is that a first-order phase transition can be rounded by disorder coupled to energylike variables. In fact, even more intriguing is that the rounding may manifest itself as a critical point, quantum or classical. In general, it is not known, however, what universality classes, if any, such criticalities belong to. In order to shed light on this question we examine in detail the disordered three-color Ashkin-Teller model by Monte Carlo methods. Extensive analyses indicate that the critical exponents define a new universality class. We show that the rounding of the first-order transition of the pure model due to the impurities is manifested as criticality. However, the magnetization critical exponent, β, and the correlation length critical exponent, ν, are found to vary with disorder and the four-spin coupling strength, and we conclusively rule out that the model belongs to the universality class of the two-dimensional Ising model.

8:12AM M22.00002 A multi-critical point of strongly interacting itinerant fermions with supersymmetry , LIZA HUIJSE, Harvard University, BELA BAUER, Station Q Microsoft Research , EREZ BERG, Weizmann Institute, MATTHIAS TROYER, ETH Zürich, KARELJAN SCHOUTENS, University of Amsterdam — A key challenge in theoretical condensed matter physics is the study of strongly interacting fermions, for which perturbative techniques do not work. In recent years a specific model has been put forward where exact results at intermediate densities can be obtained by incorporating supersymmetry. For 2D lattices the supersymmetric model exhibits superfrustration, a strong form of quantum charge frustration, characterized by an extensive ground state entropy. In 1D the model also shows a rich structure. In particular, we discuss the supersymmetric model on the square ladder and show that it describes a multi-critical point where an Ising and a KT transition coincide. The RG equations for the continuum theory reveal an intricate flow diagram with a marginal direction that preserves supersymmetry. We will argue that these results imply that there is a whole class of models with a U(1) and a Z2 symmetry, for which the multi-critical point has emergent supersymmetry.

8:24AM M22.00003 Two-dimensional Hubbard model on a honeycomb lattice , KUN FANG, University of University, GAYANA FERNANDO, University of Connectcut, ALEXANDER BALATSKY, Los Alamos National Lab, ARMEN KOCHARIAN, California State University, KALUM PALANDAGE, Trinity College — In the honeycomb lattice, a combination of nontrivial topology and electronic correlations drives a great variety of phenomena. We study the 2-dimensional fermionic Hubbard model on a honeycomb lattice using exact diagonalization method at various onsite interaction strength U values. By introducing holes in the model at different filling levels, we analyze the charge gap instability of the lattice which indicates the possibility the system going into a paired state. We further monitor the one-particle excitation spectrum and density of states at various k-points. We find that the electronic interaction introduces quasiparticle states around the Fermi level and the system can undergo a metal-insulator transition. /newline /newline The authors acknowledge the computing facilities provided by the Center for Integrated Nanotechnologies, a U.S. Department of Energy, Office of Basic Energy Sciences user facility at Los Alamos National Laboratory (Contract DE-AC52-06NA25396) and Sandia National Laboratories (Contract DE-AC04-94AL85000) and the Center for Functional Nanomaterials, Brookhaven National Laboratory supported by the U.S. Department of Energy, Office of Basic Energy Sciences, under Contract No.DE-AC02-98CH10886.

8:36AM M22.00004 Order and supersymmetry at high filling zero-energy states on the triangular lattice , DIMITRIOS GALANAKIS, Nanyang Technological University, Singapore, CHRIS HENLEY, Cornell University, STEFANOS PAPANIKOLAOU, Yale University — We perform exact diagonalization studies in $d = 2$ dimensions for the Fendley and Schoutens model of hard-core and nearest-neighbor excluding fermions that displays an exact non-relativistic supersymmetry. Using clusters of all possible shapes up to 46 sites, we systematically study the behavior of the ground state phase diagram as a function of filling. We focus on the highly degenerate zero-energy states found at fillings between $1/7$ and $\sim 1/5$. At the lower end of that interval, at filling $1/7$, we explicitly show that the ground states are gapped crystals. Consistent with previous suggestions, we find that the extensive entropy of zero states peaks at a filling of ~ 0.178. At the higher end of the interval, we find zero energy ground states at fillings above $1/5$, contrary to previous expectations; which display non-trivial amplitude degeneracies.

8:48AM M22.00005 Toward a unified description of spin incoherent behavior at zero and finite temperatures , MOHAMMAD SOLTANIEH-HA, ADRIAN FEIGUIN, Northeastern Univ. — While the basic theoretical understanding of spin-charge separation in one-dimension, known as "Luttinger liquid theory", has existed for some time, recently a previously unidentified regime of strongly interacting one-dimensional systems at finite temperature came to light: The "spin-incoherent Luttinger liquid" (SILL). This occurs when the temperature is larger than the characteristic spin energy scale. I will show that the spin-incoherent state can be written exactly as a generalization of Ogata and Shiba's factorized wave function in an enlarged Hilbert space, using the so-called "thermo-field formalism." Interestingly, this wave-function can also describe the *ground-state* of other model Hamiltonians, such as t-J ladders, and the Kondo lattice. This allows us to develop a unified formalism to describe SILL physics both at zero, and finite temperatures.

9:00AM M22.00006 Duality of Weak and Strong Scatterer in Luttinger Liquid Coupled to Massless Bosons[1]

, ALEXEY GALDA, Materials Science Division, Argonne National Laboratory, Argonne, IL, IGOR YURKEVICH, Nonlinearity and Complexity Research Group, Aston University, Birmingham, United Kingdom, OLEG YEVTUSHENKO, Ludwig Maximilians University, Arnold Sommerfeld Center and Center for Nano-Science, Munich, Germany, IGOR LERNER, School of Physics and Astronomy, University of Birmingham, Birmingham, United Kingdom — We study electronic transport in a Luttinger liquid (LL) with an embedded impurity, which is either a weak scatterer (WS) or a weak link (WL), when interacting electrons are coupled to one-dimensional massless bosons (e.g., acoustic phonons). The additional coupling competes with Coulomb interaction changing scaling exponents of various correlation functions. The impurity strength λ and the tunneling amplitude t in the WS and WL limits scale at low energies ε as: $\lambda(\varepsilon) \sim \lambda_0\, \varepsilon^{\Delta_{\rm ws}-1}$ and $t(\varepsilon) \sim t_0\, \varepsilon^{\Delta_{\rm wl}-1}$, correspondingly. We find that the duality relation between the scaling dimensions established for the standard LL, $\Delta_{\rm ws}\Delta_{\rm wl} = 1$, holds in the presence of the additional coupling for an arbitrary fixed strength of boson scattering from the impurity. As a result, at low temperatures the system remains either an ideal insulator or an ideal metal, regardless of the scattering strength. However, in the case when electron and boson scattering from the impurity are correlated, the system has a rich phase diagram that includes a metal-insulator transition at some intermediate values of the scattering.

9:12AM M22.00007 Absence of Luttinger's Theorem

, KIARAN DAVE, Dept. of Physics, MIT, Cambridge, MA. 02139, PHILIP PHILLIPS, Loomis Laboratory of Physics, Univ. of Illinois, Urbana, Il. 61801-3080, CHARLES KANE, Dept. of Physics, Univ. Penn., Philadelphia, PA. 19104 — We show exactly with an $SU(N)$ interacting model that even if the ambiguity associated with the placement of the chemical potential, μ, for a $T = 0$ gapped system is removed by using the unique value $\mu(T \to 0)$, Luttinger's sum rule is violated. The failure stems from the non-existence of the Luttinger-Ward functional for a system in which the self-energy diverges. Since it is the existence of the Luttinger-Ward functional that is the basis for Luttinger's theorem which relates the charge density to sign changes of the single-particle Green function, no such theorem exists. Experimental data on the cuprates are presented which show a systematic deviation from the Luttinger count, implying a breakdown of the electron quasiparticle picture in strongly correlated electron matter.

9:24AM M22.00008 Non-Fermi Liquid behavior at the Orbital Ordering Quantum Critical Point in the Two-Orbital Model[1]

, KA WAI LO, WEI-CHENG LEE, PHILIP PHILLIPS, University of Illinois at Urbana-Champaign — The critical behavior of a two-orbital model with degenerate d_{xz} and d_{yz} orbitals is investigated by multidimensional bosonization. We find that the corresponding bosonic theory has an overdamped collective mode with dynamical exponent $z = 3$, which appears to be a general feature of a two-orbital model and becomes the dominant fluctuation in the vicinity of the orbital-ordering quantum critical point. Since the very existence of this $z = 3$ overdamped collective mode induces non-Fermi liquid behavior near the quantum critical point, we conclude that a two-orbital model generally has a sizable area in the phase diagram showing non-Fermi liquid behavior. Furthermore, we show that the bosonic theory resembles the continuous model near the d-wave Pomeranchuk instability, suggesting that orbital order in a two-orbital model is identical to nematic order in a continuous model. Our results can be applied to systems with degenerate d_{xz} and d_{yz} orbitals such as iron-based superconductors and bilayer strontium ruthenates $Sr_3Ru_2O_7$.

9:36AM M22.00009 Time-reversal symmetry breaking Pomeranchuk instabilities in hexagonal systems: emergence of the β phase[1]

, AKASH MAHARAJ, RONNY THOMALE, SRINIVAS RAGHU, Stanford University — We show how nematic order that breaks time reversal symmetry can be stabilized by longer-range repulsive interactions in a variety of hexagonal systems. For the triangular, honeycomb and Kagome lattices at the van Hove filling, we show how spinful fermions can enter the so called β phase, in analogy to the B phase in superfluid ^{3}He. This Pomeranchuk instability in the spin channel involves a splitting of the Fermi surface into two parts, with the spin direction winding in momentum space. This is possible for angular momentum $l = 2$ nematics, since these form a doubly degenerate irreducible representation of the C_{6v} point group symmetry of the lattices in question. We demonstrate how our results are exact in the weak coupling limit, although separate numerical studies have shown that these phases can persist at stronger coupling.

9:48AM M22.00010 Self consistent solution of the tJ model in the overdoped regime[1]

, B. SRIRAM SHASTRY, DANIEL HANSEN, University of California Santa Cruz — Detailed results from a recent microscopic theory of extremely correlated Fermi liquids, applied to the t-J model in two dimensions, are presented. The theory is to second order in a parameter λ, and is valid in the overdoped regime of the tJ model. The solution reported here is from Ref [1], where relevant equations given in Ref [2] are self consistently solved for the square lattice. Thermodynamic variables and the resistivity are displayed at various densities and T for two sets of band parameters. The momentum distribution function and the renormalized electronic dispersion, its width and asymmetry are reported along principal directions of the zone. The optical conductivity is calculated. The electronic spectral function $A(k, \omega)$ probed in ARPES, is detailed with different elastic scattering parameters to account for the distinction between LASER and synchrotron ARPES. A high (binding) energy waterfall feature, sensitively dependent on the band hopping parameter t' is noted.

10:00AM M22.00011 ECFL in the limit of infinite dimensions

, EDWARD PEREPELITSKY, DANIEL HANSEN, Physics Department, University of California, Santa Cruz, California 95064,USA, ANTOINE GEORGES, Centre de Physique Théorique (CPHT) École Polytechnique 91128 Palaiseau Cedex France, SRIRAM SHASTRY, Physics Department, University of California, Santa Cruz, California 95064, USA — Novel techniques for strongly correlated matter are of great importance. Here we compare two recent and independent methods that show considerable promise, and have overlapping regimes of applicability. We evaluate in infinite dimensions the leading order (i.e. $O(\lambda^2)$) equations from the theory of Extremely Correlated Fermi Liquids of the tJ model and compare the resulting Greens functions with recent results from the dynamical mean field theory of the Hubbard model, valid at large U/t that are broadly in the same parameter range where the tJ model is valid. Using the Schwinger equations of motion of the tJ model, we also show exactly that in infinite dimensions a suitably defined Dysonian self energy for the tJ model is independent of the wave vector, while the two self energies of the ECFL theory $\Phi(\vec{k}, i\omega_n)$ and $\Psi(\vec{k}, i\omega_n)$ are respectively linear in $\varepsilon_{\vec{k}}$ and independent of $\vec{k}$ in a minimal description. In particular, we prove that in the minimal theory $\Psi(\vec{k}, i\omega_n) = \Psi(i\omega_n)$ and $\Phi(\vec{k}, i\omega_n) = \chi(i\omega_n) + \varepsilon_{\vec{k}}\Psi(i\omega_n)$.

10:12AM M22.00012 Chiral Non-Fermi Liquids , SHOUVIK SUR, McMaster University, SUNG-SIK LEE, McMaster University and Perimeter Institute for Theoretical Physics — We propose a renormalization group scheme which is suitable for theories with Fermi surface. Low energy modes near the Fermi surface are viewed as a collection of one dimensional fermions with a continuous flavor labelling the momentum along the Fermi surface. Based on this approach, we study a class of chiral metals where one patch of Fermi surface is coupled with a gapless boson in two dimensions. Depending on the dispersion of the boson, one obtains either non-Fermi liquid or Fermi liquid state. We provide a non-perturbative argument for the stability of the states, and compute the exact critical exponents. Finally, we propose a possible experimental realization of a chiral non-Fermi liquid state.

10:24AM M22.00013 Non-Fermi liquids in three dimensions , SUBHRO BHATTACHARJEE[1], Department of Physics and Centre for Quantum Materials, University of Toronto, Toronto, Canada, SUNG-SIK LEE[2], Department of Physics and Astronomy, McMaster University, Hamilton, Canada, YONG BAEK KIM[3], Department of Physics and Centre for Quantum Materials, University of Toronto, Toronto, Canada — The shape of the fermi surface may have important effects in determining the relevance (in Renormalization group sense) of interactions for the underlying fermions. In our work, we show that for certain physically realizable fermi surfaces in three dimensions, the coupling of the fermions to critical bosons is relevant at the Gaussian fixed point. We find that such interactions may lead to a three dimensional non-Fermi liquid state. We calculate one-loop corrections to the electron self energy within a scheme of (3-ϵ) perturbation in the spatial dimensions to understand the features of such a non-Fermi liquid state.

10:36AM M22.00014 Broken time-reversal symmetry phase in a 2D electron fluid by using higher dimensional bosonization[1] , WATHID ASSAWASUNTHONNET, EDUARDO FRADKIN, University of Illinois at Urbana-Champaign — We explore a phase in two-dimensional electron fluids in which the time-reversal symmetry is broken spontaneously by using the method of higher dimensional bosonization. This phase breaks time-reversal and chiral symmetries but does not break space inversion and the combination of chiral and time-reversal symmetries. This phase exhibits non-quantized anomalous Hall effect in the absence of external magnetic fields which corresponds to the Berry curvature on the Fermi surface. In the mean-field limit we show that the fluid spontaneously transforms into the the time-reversal broken phase [1]. The properties deep within the phase is also studied by solving the semi-classical equation of the bosonized fields. [1] Kai Sun and Eduardo Fradkin, Phys. Rev. B **78**, 245122 (2008).

10:48AM M22.00015 There is more to d-electrons than Hubbard U and Hund's rule J , HUGO U. R. STRAND, University of Gothenburg, SE-41296 Gothenburg, Sweden, NICOLA LANATÀ, Rutgers University, Piscataway, New Jersey 08856-8019, USA, MATS GRANATH, BO HELLSING, University of Gothenburg, SE-41296 Gothenburg, Sweden — Multi-band Hubbard models including all d-bands are central for the description of many interesting correlated materials, e.g., the Iron based High-T_c materials. In this work we compare two prevailing spin and angular momentum rotationally invariant models for the local dd-interaction, the generalized Kanamori interaction, and the Slater-Condon atomic Coulomb interaction, and establish how the first can be mapped to a very special case of the former. Using the recently developed multi-band Gutzwiller approximation solver, we show that the partial localization of orbital moments in the intermediately correlated regime of the paramagnetic state, is poorly described by the Kanamori model containing only Hubbard and Hund's rule interactions. In fact, for some integer fillings it differs qualitatively compared to the Slater-Condon interaction.

Session M23 DCMP: Optical and Dielectric Properties 325 - Qingteng Zhang, University of Wisconsin

8:00AM M23.00001 Temperature-Dependent Cathodoluminescence of Disordered SiO2 Layers[1] , AMBERLY E. JENSEN, JR DENNISON, GREGORY WILSON, JUSTIN DEKANY, USU Materials Physics Group — Optical coatings of disordered thin film SiO2/SiOx dielectric samples on reflective metal substrates exhibited electron-induced luminescence (cathodoluminescence) under electron beam irradiation. These experiments provided measurements of the absolute radiance and emission spectra as functions of incident electron energy, flux and power over a range of sample temperatures (<40 K to >300 K). The overall luminescent intensity increased linearly with increasing power, plateaued, then fell off approximately exponentially. Spectrometer data revealed four spectral bands. The structural defects associated with three of the four bands have been identified. Temperature dependence of the peak intensity and central position differs for the lower and higher energy bands. These results are interpreted with a model of the band structure of highly disordered trapped states within the band gap of SiO2, used to describe the excitation of electrons from the valence band to the conduction band and subsequent relaxation into trapped states. The cathodoluminescence model describes these experimental observations, providing a fundamental basis for understanding the dependence of cathodoluminescence on irradiation time and accumulated charge, incident flux and energy, and sample thickness and temperature.

8:12AM M23.00002 Mechanical properties of highly porous low-k dielectric nano-films: A Brillouin light scattering study , J. ZIZKA, S. BAILEY, Department of Physics, The Ohio State University, E. MAYS, D.J. MICHALAK, R. CHEBIAM, S. KING, Intel Corporation, Logic Technology Department, R. SOORYAKUMAR, Department of Physics, The Ohio State University, DEPARTMENT OF PHYSICS, THE OHIO STATE UNIVERSITY COLLABORATION, INTEL CORPORATION, LOGIC TECHNOLOGY DEPARTMENT COLLABORATION — To reduce RC time delays in micro-electronic devices, the semiconductor industry has pursued low dielectric constant (k) hybrid organic-inorganic interconnect layers with controlled levels of porosity. However, increased porosity as well as reduced film thicknesses (< 100nm) could reduce mechanical and thermal stability thereby degrading device functionality. Such structural characteristics present limitations with traditional measurement techniques as nanoindentation to characterize the mechanical properties of these highly compact and porous structures. We report on Brillouin light scattering measurements to determine the independent elastic constants, and thus the mechanical properties, of dielectric films with thicknesses as low as 25 nm and porosity levels up to 45%, the highest in the industry. The frequency dispersion and associated light scattering intensities of longitudinal and transverse acoustic standing mode type excitations were utilized to determine Poisson's Ratio (ν) and Young's Modulus (E). Significant modifications were found in ν and E of these highly porous carbon-doped SiO_2(Si-O-C-H) and amorphous carbon(a-C:H) materials compared to traditional SiO_2 and non-porous low-k materials.

8:24AM M23.00003 Power and Charge Deposition and Electron Transport in Disordered SiO2 Layers Under Electron Bombardment[1] , GREGORY WILSON, JR DENNISON, AMBERLY E. JENSEN, JUSTIN DEKANY, USU Materials Physics Group — Power and charge deposition in multilayer dielectrics from electron bombardment is dependent on the flux and energy-dependent electron penetration depth of the electron beam. Using the Continuous Slow Down Approximation (CSDA), a composite analytical formula has been developed to approximate the electron range which can be related to the dose rate, deposited power and Radiation Induced Conductivity (RIC). Based on the constituent layer geometry and material, the deposited charge can also be inferred. Three separate pulsed electron beam experiments were conducted to measure charge deposition, power dependent cathodoluminescence and RIC. The power and charge deposition experiments measured the net surface potential, electrode currents and electron induced luminescence of disordered SiO2 multilayer dielectrics with a grounded or floating conductive middle layer, using beam energies from 200 eV to 25 keV at <40 K to room temperature. These results showed that the power and charge deposition's dependence on electron beam flux and incident energy compare favorably with the model predictions. The RIC experiments measured electrode currents using disordered SiO2 layers from <40 K to >320 K with dose rates from 10-5 Gy/s to 10-1 Gy/s. The onset of RIC in the energy-dependant depth of the RIC region provides an explanation for observed retrograde charging.

8:36AM M23.00004 Structural evolution of nanoporous ultra-low k dielectrics under voltage stress[1] , ARCHANA RAJA, Columbia University, THOMAS SHAW, ALFRED GRILL, IBM Yorktown Heights, ROBERT LAIBOWITZ, TONY HEINZ, Columbia University — High speed interconnects in advanced integrated circuits require ultra-low-k dielectrics. Reduction of the dielectric constant is achieved via incorporation of nanopores in structures containing silicon, carbon, oxygen and hydrogen (SiCOH). We study nanoporous SiCOH films of k=2.5 and thicknesses of 40 - 400 nm. Leakage currents develop in the films under long-term voltage stress, eventually leading to breakdown and chip failure. Previous work* has shown the build-up of trap states as dielectric breakdown progresses. Using FTIR spectroscopy we have tracked the reorganization of the bonds in the SiCOH networks induced by voltage stress. Our results indicate that the cleavage of the Si-C and SiC-O bonds contribute toward increase in the density of bulk trapping states as breakdown is approached. AC conductance and capacitance measurements have also been carried out to describe interfacial and bulk traps and mechanisms. Comparison of breakdown properties of films with differing carbon content will also be presented to further delineate the role of carbon. *Atkin, J.M.; Shaw, T.M.; Liniger, E.; Laibowitz, R.B.; Heinz, T.F. Reliability Physics Symposium (IRPS), 2012 IEEE International

8:48AM M23.00005 Spectroscopic analysis of erbium doped laser-induced crystals for fiber-laser applications , BRIAN KNORR, ADAM STONE, HIMANSHU JAIN, VOLKMAR DIEROLF, Lehigh University — Laser induced crystallization of glasses is a highly spatially selective process which could be used to produce crystalline-core optical fibers for fiber-laser applications. Toward this goal, single crystal lines were "written" in Er:$LaBGeO_5$ glass using a femtosecond pulsed laser. These structures were analyzed using micro-Raman and luminescence spectroscopy in order to determine their viability as waveguiding laser gain media. Two-dimensional scans reveal that the erbium fluorescence is inhomogeneous over the cross-section of the crystal and lacks spatial coordination with the Raman emission, implying a physical ion accumulation in addition to enhancement due to the crystal field. Additionally, erbium fluorescence spectra taken at low temperatures from polycrystals with varying concentrations of erbium were compared to those from the laser-induced crystal lines. Significant differences in the emission energies and intensity ratios of the erbium peaks were observed. These differences may be due to the presence of strain, grain boundaries, or charge resulting from the different crystallization processes used.

9:00AM M23.00006 Luminescence and Local Structure Correlation of Er-doped Glasses and Composites , MATTHEW OTTEN, CARLO SEGRE, JEFF CECIL, MYCHALO CHAVARA, Illinois Institute of Technology, KRIS LIPINSKA, Harry Reid Center for Environmental Studies, University of Nevada Las Vegas, YOSHIMICHI OHKI, Kagami Memorial Research Institute for Materials Science and Technology, Waseda University, Tokyo, Japan, PATRICIA KALITA, Dept. of Physics and Astronomy, University of Nevada Las Vegas — Er-doped (0.05% to 3%) Ga2O3 containing silicate glasses and composites have been prepared by rapid coolong from the melt (glasses), followed by annealing at various temperatures from 800C to 1100C (composites). The Er luminescence has been measures and will be correlated to the llcal structural properties of the Er atoms as measured by x-ray absorption spectroscopy (XAS) at the MRCAT (Sector 10) beamline at the Advanced Photon Source. Preliminary analysis of the XAS data indicates that the Er is in an octahedral environment in both the glasses and composites. The glasses show no clustering of Er atoms which would lead to quenched lumineacence.

9:12AM M23.00007 Large change in dielectric constant of $CaCu_3Ti_4O_{12}$ under violet laser , C. MASINGBOON, Suranaree University of Techology, Nakhon Ratchasima, 30000, Thailand, P. THONGBAI, Khon Kaen University, Khon Kaen, 40000, Thailand, P.D.C. KING, University of St. Andrews, St. Andrews, Fife KY16 9SS, United Kingdom, S. MAENSIRI, W. MEEVASANA, Suranaree University of Techology, Nakhon Ratchasima, 30000, Thailand — This work reports the influence of light illumination on the dielectric constant of $CaCu_3Ti_4O_{12}$ (CCTO) polycrystals which exhibit giant dielectric constant. When the CCTO samples were exposed to 405-nm laser light, the enhancement in capacitance as high as 22% was observed for the first time, suggesting application of light-sensitive capacitance devices. To understand this change better microscopically, we also performed electronic-structure measurements using photoemission spectroscopy, and measured the electrical conductivity of the CCTO samples under different conditions of light exposure and oxygen partial pressure. All these measurements suggest that this large change is driven by oxygen vacancy induced by the irradiation.

9:24AM M23.00008 Giant dielectric constant in $CaCu_3Ti_4O_{12}$-MgB_2 composites near the percolation threshold , RUPAM MUKHERJEE, Wayne State University, LUCIA FERNANDEZ, CINN Research Center on Nanomaterials and Nanotechnology, GAVIN LAWES, BORIS NADGORNY, Wayne State University — We have investigated the enhancement of the dielectric constant K in $CaCu_3Ti_4O_{12}$ (CCTO)-MgB_2 composite near the percolation threshold. To optimize the dielectric properties of pure CCTO we have sintered the samples at variuos temperatures. We will present the results of the measurements of K in a broad frequency for pure CCTO for the samples sintered at 1100°C and 500°C. Commercially available MgB_2 powder was mixed with different weight fractions of CCTO and the pressure of 1GPa was applied to form composite pellets. Near the percolation threshold P_C, CCTO/MgB_2 composite system exhibit a dramatic increase of the dielectric constant K by several orders of magnitude, compared to pure CCTO. We will also discuss the magnetic field dependence of the capacitance of CCTO composite powders.

9:36AM M23.00009 Coupling of photonic, plasmonic and electric effects in metal nanostructures , NATALIA NOGINOVA, VINCENT RONO, Norfolk State University — Strong photon drag was observed in thin metal films and nanostructures, with the maximum of the effect at plasmon resonance conditions. To better understand mechanism of the effect and explore the possibility to control it with nanoscale geometry, we studied photoinduced currents in gold films and nanomesh structures in the dependence on the wavelength and period of nanostructure. We showed that nanostructuring of the surface lead to significant (50-fold) increase in the magnitude of the effect. Results are discussed in terms of coupling of optical, plasmonic and electric effects

9:48AM M23.00010 Plasmons for Coulomb Coupled Spherical Shells , ANTONIOS BALASSIS, Fordham University, ANDRII IUROV, GODFREY GUMBS, Hunter College of the CUNY — We report calculations of the collective plasmon excitations for an electron gas confined to the surface of a spherical shell. The energy spectra of the plasmons and particle-hole modes are presented as functions of the radius of the shell as well as the angular momentum quantum number L. We compare results for the plasma excitations for a single shell, a pair of concentric shells as well as when two shells have their centers separated by a distance which exceeds the sum of the radii of the two shells. For the single shell and pair of concentric shells, the plasma modes are labelled by the angular momentum quantum number L only. However, for the pair of non-concentric shells, the plasma modes are labelled by both L and M, the projection of angular momentum on the z axis. These results have been obtained in the random phase approximation (RPA).

10:00AM M23.00011 High Optical Performance and Practicality of Active Plasmonic devices based on Rhombohedral $BiFeO_3$[1] , PHUONG-KHUONG ONG, HONG-SON CHU, Institute of High Performance Computing, A-STAR, DAVID SINGH, Materials Science and Engineering Division Oak Ridge National Laboratory, JOHN WANG, Department of Materials Science and Engineering National University of Singapore — $BiFeO_3$ is a multiferroic oxide with perovskite type structure, which has been studied extensively for its ferroelectric and magnetic behavior. The magnetoelectric coupling could potentially provide new functionalities. We have studied the electronic and optical properties of Rhombohedral $BiFeO_3$, which we show to be a very promising candidate material to build active nanophotonic devices, in particular nanoplasmonic devices. It has a strong switching modulated optical properties and a large optical birefringence Δn arising from the combination of octahedral tilts, ferroelectricity and G-type antiferromagnetism in $BiFeO_3$. A prototype of a plasmonic resonator with a Rhombohedral $BiFeO_3$ thin film layer is used as an example and shows excellent switch and modulation responses. The proposed approach provides potential opportunities to develop high performance nanophotonic devices for optical communication. We find excellent switching and modulation responses. The use of Rhombohedral $BiFeO_3$ provides an effective way to actively control optical performance of plasmonic nanostructures.

10:12AM M23.00012 Taming the flow of light via active magneto-optical impurities[1] , SAMUEL KALISH, HAMIDREZA RAMEZANI, ZIN LIN, TSAMPIKOS KOTTOS, Department of Physics, Wesleyan University, Middletown, CT-06459, USA, VASSILIOS KOVANIS, ILYA VITEBSKIY, Air Force Research Laboratory, Sensors Directorate, Wright Patterson AFB, OH 45433 USA — We demonstrate that the interplay of a magneto-optical layer sandwiched between two judiciously balanced gain and loss layers which are both birefringent with misaligned in-plane anisotropy, induces unidirectional electromagnetic modes. Embedding one such optically active non-reciprocal unit between a pair of birefringent Bragg reflectors, results in an exceptionally strong asymmetry in light transmission. Remarkably, such asymmetry persists regardless of the incident light polarization. This photonic architecture may be used as the building block for chip-scale non-reciprocal devices such as optical isolators and circulators.

[1]This research was supported by an AFOSR No. FA 9550-10-1-0433 grant and LRIR 09RY04COR grant, and by an NSF ECCS-1128571 grant.

10:24AM M23.00013 Gyro-active structures: Unidirectional Reflectionless Isolators and Perfect Absorbers[1] , JUNSIK LEE, Wesleyan University, ZIN LIN, Harvard University, HAMIDREZA RAMEZANI, TSAMPIKOS KOTTOS, Wesleyan University — We propose a novel circuit architecture that consists of gyrotropic elements sandwiched between two judiciously balanced gain and loss constituents. These structures exhibit unique transport characteristics stemming from a generalized parity-time ($\mathcal{P}\overset{\circlearrowleft}{\mathcal{T}}$)-symmetry. Some of these features include unidirectional reflection-less isolation and perfect absorption as well as asymmetric Anderson localization when disorder is introduced. Realizations as well as applications within the framework of electronic and photonic circuitry are discussed.

[1]This research was partially supported by the AFOSR and NSF.

10:36AM M23.00014 Local heating of ZnO due to the surface plasmon excitation of Au nanoparticles[1] , OSHADHA RANASINGHA, NETL, Pittsburgh / WVU, Morgantown, CONGJUN WANG, NETL, Pittsburgh / URS, Pittsburgh, JAMES P. LEWIS, NETL, Pittsburgh / WVU, Morgantown, CHRISTOPHER MATRANGA, NETL, Pittsburgh — Temperature dependent E_2*(high)* Raman active optical phonon mode was investigated to identify the local heating of the ZnO, due to the surface plasmon excitation of the Au nanoparticles. The variation of the linewidth (FWHM) of E_2*(high)* mode for ZnO was investigated from room temperature to 450 °C with 25 °C steps under constant 532 nm laser excitation intensity of 2.6*10^5 W/m^2. Linewidth (FWHM) was increased with the temperature and it was fitted into the theoretical model originally developed by Menendez *et al*, which contains both cubic and quadratic anharmonicities. After optimizing the cubic and quadratic anharmonic coupling constants, the fit was used to estimate the local temperatures of Au/ZnO, which were irradiated with different laser intensities. The estimated local temperature for Au/ZnO was 613 °C at the laser intensity of 8.1*10^5 W/m^2. ZnO without Au nanoparticles didn't show any large temperature variation under the different laser intensities. This is a clear evidence for the heat generation of Au nanoparticles due to the surface plasmon excitation.

Wednesday, March 20, 2013 8:00AM - 11:00AM –

Session M24 DCOMP: Electronic Structure Methods I 326 - Wenguang Zhu, University of Tennessee

8:00AM M24.00001 Role of electronic localization in the phosphorescence of iridium sensitizing dyes , BURAK HIMMETOGLU, ALEX MARCHENKO, University of Minnesota, ISMAILA DABO, CERMICS, Universite Paris-Est, MATTEO COCOCCIONI, University of Minnesota — In this talk we present a recent systematic study[1] of three representative iridium dyes, namely, Ir(ppy)$_3$, FIrpic and PQIr, which are commonly used as sensitizers in organic optoelectronic devices. We show that electronic correlations play a crucial role in determining the excited state energies in these systems, due to localization of electrons on Ir d orbitals in the ground state. Electronic localization is treated by employing hybrid functionals within time-dependent density functional theory (TDDFT) and with Hubbard model based corrections within the Δ-SCF approach. The performance of both methods are studied in a comparative fashion and shown to be in good agreement with experiments (within a few tenths of an electron-volt in predicting singlet-triplet splittings and optical resonances). The Hubbard corrected functionals provide further insights on the charge-transfer character of the excited states. The gained insight allows us to comment on envisioned functionalization strategies to improve the performance of these systems.

8:12AM M24.00002 A Strategy for Finding a Reliable Starting Point for G_0W_0 Demonstrated for Molecules

, THOMAS KORZDORFER, University of Potsdam, NOA MAROM, University of Texas at Austin — Many-body perturbation theory in the G_0W_0 approximation is an increasingly popular tool for calculating electron removal energies and fundamental gaps for molecules and solids. However, the predictive power of G_0W_0 for molecules is limited by its sensitivity to the density functional theory (DFT) starting point. In this contribution, the starting point dependence of G_0W_0 is demonstrated for several small organic molecules. Analysis of the starting point dependence leads to the development of a non-empirical scheme that allows to find a consistent and reliable DFT starting point for G_0W_0 calculations by adapting the amount of Hartree-Fock-exchange in a hybrid DFT functional. The G_0W_0 spectra resulting from this *consistent starting point (CSP) scheme* reliably predict experimental photoelectron spectra over the full energy range. This is demonstrated for a test set of various typical organic semiconductor molecules.

[1] T. Korzdorfer and Noa Marom, Phys. Rev. B Rapid Communications **86**, 041110 (2012).

8:24AM M24.00003 A Benchmark of GW Methods for Azabenzenes: Is the GW Approximation Good Enough?

, NOA MAROM, The University of Texas at Austin, FABIO CARUSO, XINGUO REN, OLIVER HOFMANN, Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin, THOMAS KÖRZDÖRFER, University of Potsdam, Germany, JAMES CHELIKOWSKY, The University of Texas at Austin, ANGEL RUBIO, MATTHIAS SCHEFFLER, PATRICK RINKE, Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin — Many-body perturbation theory in the *GW* approximation is a useful method for describing electronic properties associated with charged excitations. A hierarchy of *GW* methods exists, starting from non-self-consistent G_0W_0, through partial self-consistency in the eigenvalues (ev-scGW) and in the Green's function (scGW_0), to fully self-consistent GW (sc*GW*). Here, we assess the performance of these methods for benzene, pyridine, and the diazines. The quasiparticle spectra are compared to photoemission spectroscopy (PES) experiments with respect to all measured particle removal energies and the ordering of the frontier orbitals. We find that the accuracy of the calculated spectra does not match the expectations based on their level of self-consistency. In particular, for certain starting points G_0W_0 and scGW_0 provide spectra in better agreement with the PES than sc*GW*.

8:36AM M24.00004 Local atomic energies from optimal atomic orbitals

, BJÖRN LANGE, CHRISTOPH FREYSOLDT, JÖRG NEUGEBAUER, Max Planck Institute for Iron Research GmbH — Decomposing the energy of a condensed matter system into atomic contributions is of great use e.g. for understanding the physical origin of defect and surface energetics or for identifying chemically reactive regions in disordered systems. However, commonly employed energy calculations in the framework of density-functional theory (DFT) do not in general provide a natural decomposition into atoms. Here we propose a novel scheme to achieve this based on the recently introduced concept of atom-centered Quamols [1] that are variationally optimized to represent the electronic structure with a minimal basis set, which largely avoids local overcompleteness issues. The spillage resulting from the remaining small incompleteness is segmented according to a space separation derived from the Quamol atomic densities, maintaining the accuracy of the underlying DFT calculation. The total energy is then decomposed by combining this basis set with a local energy density treatment based on the ideas of Chetty and Martin [2]. We demonstrate the performance of our scheme by visualizing and analyzing the energy distribution at surfaces and in amorphous silicon.

8:48AM M24.00005 Fast response function for finite and bulk systems

, PETER KOVAL, FEDERICO MARCHESIN, DANIEL SANCHEZ PORTAL, Centro de Fisica de Materiales, Donostia-San Sebastian, Spain (Donostia International Physics Center, Spain), DIETRICH FOERSTER, Laboratiore Ondes et Matiere d'Aquitaine, Bordeaux, France — Many-body perturbation theory of bulk systems is often realized within reciprocal space, using plane-wave (PW) basis sets. PW basis is advantageous because of its elementary basis functions and simple convergence control. However, the number of functions in PW basis grows with third power of unit cell size, irrespective of actual number of atoms present in the unit cell. Moreover, PW basis gives rise to full matrices in tensor algebra due to space-filling nature of PW. An alternative to PW would be usage of localized basis functions. In this contribution, we show how a basis of *dominant products* (DP) can be used to describe excitations in finite and bulk systems. We present calculations of absorption spectra and electron-energy loss spectra within time-dependent density functional theory, realized within DP basis. The usage of localized functions and iterative techniques allow to keep the complexity of the calculations rather low: the overall number of operations grows with third power of number of atoms in the unit cell.Moreover, we have recently shown that Hedin's GW calculations can also be performed using DP basis with an order-N^3 scaling for finite systems. We are currently extending this GW methodology to bulk systems.

9:00AM M24.00006 Density-Functional Theory Applied to Rare Earth Metals: Approaches Based on the Random-Phase Approximation

, MARCO CASADEI, XINGUO REN, PATRICK RINKE, MATTHIAS SCHEFFLER, Fritz-Haber-Institut der MPG, Berlin, Germany, ANGEL RUBIO, University of the Basque Country UPV/EHU, Donostia, Spain — The description of the volume collapse exhibited by some *rare earth* metals poses a great challenge to density-functional theory (DFT) since local/semilocal functionals (LDA/GGA) fail to produce the associated phase transitions. We approach this problem by treating all electrons at the same quantum mechanical level, using both hybrid functionals (e.g. PBE0 and HSE06) and exact-exchange plus correlation in the random-phase approximation (EX+cRPA). We also assess the performance of recently developed beyond RPA schemes (e.g. rPT2 [1]). The calculations are performed for cerium and praseodymium, that display a volume collapse, and neodymium, in which the volume collapse is absent. The isostructural α-γ phase transition in cerium is the most studied. The exact exchange contribution in PBE0 and HSE06 is crucial to produce two distinct solutions that can be associated with the α and γ phases, but quantitative agreement with the extrapolated phase diagram requires EX+cRPA [2].

9:12AM M24.00007 Vibrational spectroscopy of liquid water from first principles simulations: Raman Spectra[1]

, QUAN WAN, LEONARDO SPANU, Department of Chemistry, University of California, Davis, GIULIA GALLI, Department of Chemistry and Department of Physics, University of California, Davis, FRANCOIS GYGI, Department of Applied Science and Department of Computer Science, University of California, Davis — Raman spectroscopy is an important probe of the structural and vibrational properties of aqueous solutions and of water at interfaces. While many experimental data are available for various systems, no results of ab initio computations have yet been reported for the Raman spectra of liquid water or solutions. We computed the Raman spectrum of water at ambient conditions using first principles molecular dynamics simulations, coupled to the calculation of polarizability within density functional perturbation theory. We used semi-local functionals, 64 molecule cells and the Qbox code. Our results are in satisfactory agreement with experiment. We provided an interpretation of the spectral features oberved at low frequency and within the stretching band by defining a polarizability of water molecules in the fluid. Coupling the calculation of Raman and IR spectra is in progress: such coupling will open the way to interpret advanced vibrational spectroscopy measurements, e.g. Sum Frequency Generation spectroscopy.

9:24AM M24.00008 The bond-breaking and bond-making puzzle: many-body perturbation versus density-functional theory , FABIO CARUSO, Fritz Haber Institute, Berlin, Germany, DANIEL ROHR, Rice University, Houston, United States, MARIA HELLGREN, Sissa, Trieste, Italy, XINGUO REN, PATRICK RINKE, Fritz Haber Institute, Berlin, Germany, ANGEL RUBIO, Universidad del Pais Vasco, Donostia, Spain, MATTHIAS SCHEFFLER, Fritz Haber Institute, Berlin, Germany — Diatomic molecules at dissociation provide a prototypical situation in which the ground-state cannot be described by a single Slater determinant. For the paradigmatic case of H_2-dissociation we compare state-of-the-art many-body perturbation theory in the GW approximation and density-functional theory (DFT) in the exact-exchange plus random-phase approximation for the correlation energy (RPA). Results from the recently developed renormalized second-order perturbation theory (rPT2) are also reported. For an unbiased comparison and to prevent spurious starting point effects both RPA and GW are iterated to *full* self-consistency (i.e. sc-RPA and sc-GW). Both include topologically identical diagrams for the exchange and correlation energy but are evaluated with a non-interacting Kohn-Sham and an interacting GW Green function, respectively. This has profound consequences for the kinetic and the correlation energy. GW and rPT2 are both accurate at equilibrium, but fail at dissociation, in contrast to sc-RPA. This failure demonstrates the need of including higher order correlation diagrams in sc-GW. Our results indicate that RPA-based DFT is a strong contender for a universally applicable electronic-structure theory. F. Caruso *et al.* arxiv.org/abs/1210.8300.

9:36AM M24.00009 Structural and Electronic Properties of the Solvated Chloride Ion from First Principles Simulations , FRANCOIS GYGI, Department of Computer Science, University of California, Davis, CUI ZHANG, TUAN ANH PHAM, Department of Chemistry, University of California, Davis, GIULIA GALLI, Department of Chemistry, Department of Physics, University of California, Davis — First principles simulations of anions in aqueous solutions represent a challenging task both from a theoretical and computational standpoint, and only sporadic ab initio studies of their electronic properties have appeared in the literature. We carried out first principles molecular dynamics (MD) simulations of the chloride anion in liquid water with semi-local (PBE) and hybrid (PBE0) functionals, using the Qbox code. We found substantial differences in the orientation of the water molecules in the first anion solvation shell when using the two different levels of theory. Most importantly, the relative energies of the highest occupied level (HOMO) of the anion was found to be lower than the top of the valence band of water with PBE and the HOMO state is fairly delocalized, while it is higher with PBE0 and the corresponding state is localized on the anion. Although qualitative correct, the result obtained with PBE0 is only in fair agreement with experiment. It is only when using many body perturbation theory at the GW level and PBE0 trajectories that we could find qualitative and quantitative agreement with experiment [1]. Work supported by DOE-CMSN DE-SC0005180 and DOE-BES DE-SC0008938.

9:48AM M24.00010 Ab initio calculations of quasiparticle energies of solids, liquids and molecules using a spectral decomposition of the dielectric matrix[1] , TUAN ANH PHAM, Department of Chemistry UC Davis and Lawrence Livermore National Laboratory, HUY-VIET NGUYEN, Institute of Physics, Hanoi, Vietnam, DARIO ROCCA, Department of Chemistry, UC Davis, GIULIA GALLI, Department of Chemistry and Department of Physics, UC Davis — We recently developed a method for the calculation of quasiparticle energies within many body perturbation theory, at the GW level, which avoids costly summations over empty electronic states and does not require the use of plasmon-pole models [1]. We present a comprehensive validation of this method, encompassing calculations of i) the vertical ionization energies of a set of over 80 molecules (containing from 14 to 424 valence electrons); ii) the relative position of energy levels of anions and water in hydrated sulfate and chloride clusters; iii) the band structure of a variety of semiconductors and (iv) the electronic properties of amorphous and liquid systems. The efficiency of our approach allowed us to compute quasiparticle energies of multiple configurations of liquid water, using samples with 64 molecules, selected over trajectories generated by ab initio molecular dynamics simulations.

10:00AM M24.00011 Structural Stability Driven by the Spin-Orbit Coupling and the Superconductivity in simple-cubic Polonium , CHANG-JONG KANG, KYOO KIM, B.I. MIN, POSTECH — Polonium is the only element which has the simple-cubic (SC) structure in the periodic table. We have studied its structural stability based on the phonon dispersion calculations using the first-principles all-electron full-potential band method. We have demonstrated that the strong spin-orbit coupling (SOC) in SC-Po suppresses the Peierls instability and makes the SC structure stable. We have also discussed the structural chirality realized in beta-Po, as a consequence of the phonon instability. Further, we have investigated the possible superconductivity in SC-Po, and predicted that it becomes a superconductor with Tc $\sim$ 4 K at ambient pressure. The transverse soft phonon mode at q $\sim$ 2/3 R, which is greatly affected by the SOC, plays an important role both in the structural stability and the superconductivity in SC-Po. We have explored effects of the SOC and the volume variation on the phonon dispersions and superconducting properties of SC-Po.

10:12AM M24.00012 Parallelized electronic transport calculations in real space , BARUCH FELDMAN, Weizmann Institute of Science, Israel, ODED HOD, Tel Aviv University, Israel, TAMAR SEIDEMAN, Northwestern University, LEEOR KRONIK, Weizmann Institute of Science, Israel — We present a real-space method for first-principles nano-scale electronic transport calculations, using the non-equilibrium Green's function (NEGF) method and complex absorbing potentials (CAPs) to represent the effects of the semi-infinite leads. In real space, the electronic Hamiltonian from Density Functional Theory (DFT) is very sparse. As a result, the transport problem parallelizes naturally and can scale favorably with system size. We illustrate our method with calculations on several realistic test systems and find good agreement with a reference calculation.

10:24AM M24.00013 Surface chemistry in a full-potential QM/MM approach: making hybrids affordable , DANIEL BERGER, Technical University Munich, VOLKER BLUM, Fritz-Haber-Institut der MPG, Berlin, KARSTEN REUTER, Technical University Munich — Nanostructured oxide surfaces are promising candidates for a wide range of energy and catalysis applications. When addressing corresponding functionalities through quantitative first-principles calculations, exploitation of the localized character of the chemical processes yields numerically most efficient approaches. To this end we augment the FHI-aims[1] package with a QM/MM[2] functionality, in which the nanostructure and immediate oxide surrounding is described quantum mechanically, the long-range electrostatic interactions with the support are accounted for through a polarizable monopole field, and a shell of norm-conserving pseudopotentials correctly connects the two regions. We illustrate the accuracy and efficiency of the implementation with examples from the photo-catalytic water splitting context and specifically discuss the use of charged system states to address charge transfer processes.

10:36AM M24.00014 Spin-Orbit Coupling within the GW Approximation[1] , BRAD BARKER, University of California-Berkeley, Lawrence Berkeley National Laboratory, JACK DESLIPPE, National Energy Research Scientific Computing Center, MANISH JAIN, JOHANNES LISCHNER, University of California-Berkeley, Lawrence Berkeley National Laboratory, OLEG YAZYEV, Ecole Polytechnique Federale de Lausanne (EPFL), Switzerland, STEVEN G. LOUIE, University of California-Berkeley, Lawrence Berkeley National Laboratory — We have developed and implemented an approach in which the effects of spin-orbit interactions to the quasiparticle band structure are incorporated within the GW approach, employing spinor wavefunctions computed at the density functional theory (DFT) level with fully relativistic pseudopotentials. Special consideration is given to the significance of the spin-dependent exchange-correlation potential. We compare these results to separate calculations where spin-orbit coupling is applied as a perturbation. We apply these methods to the properties of materials with heavy ion cores to determine the possible differences from the different treatments of spin-orbit coupling.

10:48AM M24.00015 Cumulant expansion treatment of phonon contributions to the electron spectral function[1] , S.M. STORY, J.J. KAS, University of Washington, M.J. VERSTRAETE, Université de Liège, J.J. REHR, University of Washington — We present an approach for calculations of phonon contributions to the electron spectral function at finite temerature based on cumulant expansion techniques. Our approach is based on a many–pole representation of the Eliashberg function for the electron–phonon interaction, calculations of the dynamical matrix using ABINIT [1], and an Einstein self–energy model [2]. The code has been implemented as part of a plug–in to ABINIT for calculations of various phonon properties, and is applicable to complex structures with several atoms per unit cell. Results are given for a number of systems and compared to those obtained with the GW approximation.

Session M25 DCOMP: Focus Session: Modeling of Rare Events I 327 - Amit Samanta, Princeton University

8:00AM M25.00001 Local Hyperdynamics[1] , ARTHUR VOTER, Los Alamos National Laboratory — We present a new formulation of the hyperdynamics method in which the biasing effect is local, making it suitable for large systems. In standard hyperdynamics, the requirement that the bias potential be zero everywhere on the dividing surface bounding the state has the consequence that for large systems the boost factor decays to unity, regardless of the form of the bias potential. In the new method, the bias force on each atom is obtained by differentiating a local bias energy that depends only on the coordinates of atoms within a finite range D of this atom. This bias force is thus independent of the bias force in distant parts of the system, providing a method that gives a constant boost factor, independent of the system size. Although the resulting dynamics are no longer conservative, we show that for a homogeneous system (all atoms equivalent) using a simplifed bond-boost bias potential, the bias forces in any local region are equivalent to those in a system accelerated by a specific boost factor, except for additional error forces that balance in a time average. We also argue that even for inhomogeneous systems, the errors relative to an exactly accelerated dynamics should should decay roughly as 1/D. We demonstrate for some realistic atomistic systems that the method gives escape rates in excellent agreement with direct molecular dynamics simulations.

8:36AM M25.00002 A Local Superbasin Kinetic Monte Carlo Method[1] , KRISTEN FICHTHORN, YANGZHENG LIN, Penn State University — A ubiquitous problem in atomic-scale simulation of materials is the small-barrier problem, in which the free-energy landscape presents "superbasins" with low intra-basin energy barriers relative to the inter-basin barriers. Rare-event simulation methods, such as kinetic Monte Carlo (KMC) and accelerated molecular dynamics, are inefficient for such systems because considerable effort is spent simulating short-time, intra-basin motion without evolving the system significantly. We developed an adaptive local-superbasin KMC algorithm (LSKMC) for treating fast, intra-basin motion using a Master-equation / Markov-chain approach and long-time evolution using KMC. Our algorithm is designed to identify local superbasins in an on-the-fly search during conventional KMC, construct the rate matrix, compute the mean exit time and its distribution, obtain the probability to exit to each of the superbasin border (absorbing) states, and integrate superbasin exits with non-superbasin moves. We demonstrate various aspects of the method in several examples, which also highlight the efficiency of the method.

8:48AM M25.00003 Free energy calculation from umbrella sampling using Bayesian inference , NOAM BERNSTEIN, Naval Research Laboratory, THOMAS STECHER, GÁBOR CSÁNYI, Department of Engineering, University of Cambridge — Using simulations to obtain information about the free energy of a system far from its free energy minima requires biased sampling, for example using a series of harmonic umbrella confining potentials to scan over a range of collective variable values. One fundamental distinction between existing methods that use this approach is in what quantities are measured and how they are used: histograms of the system's probability distribution in WHAM, or gradients of the potential of mean force for umbrella integration (UI) and the single-sweep radial basis function (RBF) approach. Here we present a method that reconstructs the free energy from umbrella sampling data using Bayesian inference that effectively uses all available information from multiple umbrella windows. We show that for a single collective variable, our method can use histograms, gradients, or both, to match or outperform WHAM and UI in the accuracy of free energy for a given amount of total simulation time. In higher dimensions, our method can effectively use gradient information to reconstruct the multidimensional free energy surface. We test our method for the alanine polypeptide model system, and show that it is more accurate than a RBF reconstruction for sparse data, and more stable for abundant data.

9:00AM M25.00004 Characterization of the relation between energy landscape and the time evolution of complex materials using kinetic ART , KOKOU GAWONOU N'TSOUAGLO, JEAN-FRANCOIS JOLY, LAURENT KARIM BELAND, Departement de Physique, Universite de Montreal, PETER BROMMER, Department of Physics and Centre for Scientific Computing, University of Warwick, NORMAND MOUSSEAU, Departement de Physique, Universite de Montreal — In the last two decades, there has been a considerable interest in the development of accelerated numerical methods for sampling the energy landscape of complex materials. Many of these methods are based on the kinetic Monte Carlo (KMC) algorithm introduced 40 years ago. This is the case of kinetic ART, for example, which uses a very efficient transition-state searching method, ART nouveau, coupled with a topological tool, NAUTY, to offer an off-lattice KMC method with on-the-fly catalog building to study complex systems, such as ion-bombarded and amorphous materials, on timescales of a second or more. Looking at two systems, vacancy aggregation in Fe and energy relaxation in ion-bombarded c-Si, we characterize the changes in the energy landscape and the relation to its time evolution with kinetic ART and its correspondence with the well-known Bell-Evans-Polanyi principle used in chemistry.

9:12AM M25.00005 Atomistic simulations of melting and solidification using temperature accelerated molecular dynamics , TANG-QING YU, Courant Institute of Mathematical Sciences, New York University, AMIT SAMANTA, Program in Applied and Computational Mathematics, Princeton University, WEINAN E, Department of Mathematics and Program in Applied and Computational Mathematics, Princeton University, MARK TUCKERMAN, Department of Chemistry and Courant Institute of Mathematical Sciences, New York University, ERIC VANDEN-EIJNDEN, Courant Institute of Mathematical Sciences, New York University — A detailed understanding of melting/solidification mechanisms in metals remains obscure, though over the years many simulations and experiments have been performed for clarifying it. We have applied the enhanced-sampling method, Temperature-Accelerated Molecular Dynamics, to study the melting/solidification of FCC metals like copper, nickel under the constant temperature and pressure conditions. Free energy surfaces along Steinhardt order parameters and local density are obtained and minimum free energy path (MFEP) between the metastable states are calculated. An analysis of the atomic structure along the MFEP, reveals that an interplay between orientation ordering and positional ordering governs this phase transition.

9:24AM M25.00006 An Algorithm to Compute Statistics of Stochastic Paths on Complex Landscapes , MICHAEL MANHART, ALEXANDRE V. MOROZOV, Rutgers University — Many systems in physics, chemistry, and biology can be modeled as a random walk on a network subject to a potential landscape. There is great interest in understanding the statistical properties of pathways on these landscapes, especially their times, lengths, and distributions in space. The complexity of the networks and landscapes arising in many models makes them difficult to solve by traditional analytical and computational tools. Moreover, standard methods do not always provide the most relevant information for characterizing these pathways. We develop an explicitly path-based formalism for studying these problems, which we implement using a numerical dynamic programming algorithm. It is especially well-suited to studying first-passage problems and rare transitions between metastable states. This method is valid for arbitrary networks and landscapes, as well as semi-Markovian processes with non-exponential waiting-time distributions. We explore this method on a variety of simple models including regular lattices, fractals, and protein sequence evolution.

9:36AM M25.00007 ABSTRACT WITHDRAWN –

9:48AM M25.00008 An Efficient Kernel Polynomial Method for Calculating Transition Rates in Large-Scale Materials[1] , CHEN HUANG, ARTHUR VOTER, DANNY PEREZ, Los Alamos National Laboratory — We present an efficient method for calculating transition rates in large-scale materials using harmonic transition state theory. In this method, we first reformulate the prefactor of the transition rates in terms of the density of states (DOS) of Hessian matrices. The DOS are then efficiently calculated with the kernel polynomial method. The scaling of our method is discussed in detail. We demonstrate our approach by calculating the prefactors for vacancy hopping and Frenkel pair formation in silver. Very good agreement between the KPM approach and exact diagonalization is observed.

[1]DOE/BES and DOE/ASCR

10:00AM M25.00009 Reaching extended length-scales with temperature-accelerated dynamics[1] , JACQUES G. AMAR, YUNSIC SHIM, University of Toledo — In temperature-accelerated dynamics (TAD) a high-temperature molecular dynamics (MD) simulation is used to accelerate the search for the next low-temperature activated event. While TAD has been quite successful in extending the time-scales of simulations of non-equilibrium processes, due to the fact that the computational work scales approximately as the cube of the number of atoms, until recently only simulations of relatively small systems have been carried out. Recently, we have shown that by combining spatial decomposition with our synchronous sublattice algorithm, significantly improved scaling is possible. However, in this approach the size of activated events is limited by the processor size while the dynamics is not exact. Here we discuss progress in developing an alternate approach in which high-temperature parallel MD along with localized saddle-point (LSAD) calculations, are used to carry out TAD simulations without restricting the size of activated events while keeping the dynamics "exact" within the context of harmonic transition-state theory. In tests of our LSAD method applied to Ag/Ag(100) annealing and Cu/Cu(100) growth simulations we find significantly improved scaling of TAD, while maintaining a negligibly small error in the energy barriers.

10:12AM M25.00010 Switching time distributions and scaling behavior in a bistable tunnel diode circuit with adjustable noise intensity[1] , STEVEN J. JONES, YU BOMZE, S.W. TEITSWORTH, Duke University — We report the measurement of first-passage time distributions associated with electrical current switching in a tunnel diode circuit that is driven by a noise generator with adjustable noise intensity D. The tunnel diode circuit is biased with a voltage $V_{\rm f}$ that is set in a range of bistability which terminates at the upper end in a saddle-node bifurcation at voltage $V_{\rm th}$. We employ a high bandwidth technique that permits measurement of stochastically-varying switching times over a very large dynamic range [1], with measured times ranging from 1 μs to several seconds. The dependence of both the form of the distribution and extracted mean switching time τ are also studied as a function of reduced voltage $V_{\rm th} - V_{\rm f}$ and D. Switching time distributions are generally found to possess exponential tails at long times, consistent with a picture of noise-induced escape via a single saddle point. Also, parameter regimes are identified in which the mean switching time scales as reduced voltage to the 3/2 power and linearly with inverse noise intensity. [1] Yu. Bomze, R. Hey, H. T. Grahn, and S. W. Teitsworth, Phys. Rev. Lett. **109**, 026801 (2012).

10:24AM M25.00011 Dependence of switching path distributions on relative noise intensities for a two-dimensional model of electrical conduction in a tunnel diode circuit[1] , PAUL H. DANNENBERG, J.C. NEU, S.W. TEITSWORTH, Duke University — The incorporation of negative differential resistance elements such as tunnel diodes into electronic circuits often leads to bistability, i.e., distinct co-existing states of current for a given applied voltage. Such systems are generally far-from-equilibrium and non-gradient. We discuss a model of electrical conduction in a tunnel diode circuit in the form of a two-dimensional dynamical system, and use a geometric minimum action method (gMAM) [1] to study the dependence of the most probable escape paths (MPEPs) and associated actions on the ratio of the noise amplitudes associated with the two variables. We find that the MPEP follows the time-reversed path (i.e., a saddle-node trajectory) for a unique value of noise amplitude ratio; however, in general, MPEPs follow distinct paths that vary significantly as the noise amplitude ratio is varied. Additionally, we find good agreement between the computed MPEPs and actions and numerically generated switching path distributions and mean first-passage times, respectively.

10:36AM M25.00012 Kinetics of droplet wetting-mode transitions on grooved surfaces: Forward flux sampling , AZAR SHAHRAZ, ALI BORHAN, KRISTEN FICHTHORN, Pennsylvania State University — Liquid droplets on rough surfaces typically exhibit either the Cassie wetting mode, in which the droplet resides on top of the roughness, or the Wenzel mode, in which the droplet penetrates into the roughness. For a fixed surface topology and droplet size, one of these modes is the global free-energy minimum. However, the other state is often metastable and long-lived due a free-energy barrier that hinders the transition between the two wetting states. Metastable wetting states have been observed experimentally and we also observe them in molecular dynamics (MD) simulations of a droplet on a grooved surface. Using forward flux sampling, we study the kinetics of the Cassie-Wenzel transition. The global-minimum wetting states that emerge from our nanoscale MD approach are consistent with those predicted by a macroscopic model for the free energy. We find that the free-energy barrier for this transition depends on the droplet size and surface topology. A committor analysis indicates that the transition-state ensemble consists of droplets that are on the verge of initiating/breaking contact with the substrate below the grooves.

10:48AM M25.00013 Diffusion of small Ni and Cu clusters on Ni (111): Application of SLKMC-II*[1] , SYED ISLAMUDDIN SHAH, Department Of Physics, University Of Central Florida, GIRIDHAR NANDIPATI, Pacific Northwest National Laboratory, TALAT S. RAHMAN, Department Of Physics, University Of Central Florida — We have examined the diffusion of small Ni and Cu islands (consisting of up to 10 atoms) on the Ni(111) surface using a self-learning kinetic Monte Carlo (SLKMC-II) [1] method with an improved pattern-recognition scheme that allows inclusion of both fcc and hcp sites in the simulations. In an SLKMC simulation [2] a database holds information about the local neighborhood of an atom and associated processes that is accumulated on-the-fly, as the simulation proceeds. The activation energy barriers for the identified diffusion processes were calculated using semi-empirical interaction potential based on the embedded-atom method. Although a variety of concerted, multi-atom and single-atom processes were automatically revealed in our simulations, we found that these small islands diffuse primarily via concerted motion. We report diffusion coefficients for each island size at several temperatures, and from the Arrhenius plot extract the size-dependent effective diffusion barrier for these islands. Our evaluation of the occurrence frequency of processes most responsible for the diffusion of island of a specific size reveal several that are not accessible in SLKMC-I [2] or in short time-scale MD simulations. We also provide results of extending SLKMC-II to examine epitaxial growth in these systems. [1] S. Islamuddin Shah, et al., J. Phys.: Condens. Matter 24, 354004 (2012). [2] O. Trushin, et al., Phys. Rev. B 72, 115401 (2005).

Session M26 GQI: Semiconductor Qubits - RF Measurement and Hybridization 328 - David Reilly, The University of Sydney

8:00AM M26.00001 Circuit quantum electrodynamics with a spin qubit[1] , KARL PETERSSON, Princeton University — Electron spins in quantum dots have been proposed as the building blocks of a quantum information processor. While both fast one and two qubit operations have been demonstrated, coupling distant spins remains a daunting challenge. In contrast, circuit quantum electrodynamics (cQED) has enabled superconducting qubits to be readily coupled over large distances via a superconducting microwave cavity. I will present our recent work aimed at integrating spin qubits with the cQED architecture.[2] Our approach is to use spin qubits formed in strong spin-orbit materials such as InAs nanowires to enable a large effective coupling of the spin to the microwave cavity field. For an InAs nanowire double quantum dot coupled to the superconducting microwave cavity we achieve a charge-cavity coupling rate of ~ 30 MHz. Combining this large charge-cavity coupling rate with electrically driven spin qubit rotations we demonstrate that the cQED architecture can be used a sensitive probe of single spin dynamics. In another experiment, we can apply a source-drain bias to drive current through the double quantum dot and observe gain in the cavity transmission. We additionally measure photon emission from the cavity without any input field applied. Our results suggest that long-range spin coupling via superconducting microwave cavities is feasible and present new avenues for exploring quantum optics on a chip.

8:36AM M26.00002 Measuring the Charge Parity of an InAs Double Quantum Dot[1] , M.D. SCHROER, M. JUNG, K.D. PETERSSON, J.R. PETTA, Princeton University — We have fabricated tunable, few electron InAs nanowire double quantum dots (DQDs) which support rapid electrically driven single spin rotations.[2] However, the measurement of nanowire DQDs presents an outstanding problem, typically relying on transport through the sample due to the lack of a local quantum point contact charge detector. We demonstrate a non-invasive charge sensing method based on a radio frequency measurement of the sample's complex admittance, which yields a fast and sensitive determination of the charge state.[3] We show that this measurement is also sensitive to the spin state of the DQD, allowing a simple determination of the total charge parity in the sample.[4] Radio frequency charge parity measurement may prove useful in high effective mass systems, such as Si/SiGe quantum dots, where the determination of the absolute charge number is not always feasible.

8:48AM M26.00003 Photon emission from a cavity-coupled double quantum dot[1] , Y.-Y. LIU, K.D. PETERSSON, J.R. PETTA, Princeton University, J.M. TAYLOR, Joint Quantum Institute and NIST — Circuit quantum electrodynamics (cQED) allows strong coupling between a microwave photon and a superconducting qubit. We recently demonstrated coupling of a double quantum dot (DQD) spin qubit to a high quality factor cavity in the cQED architecture, with a charge-cavity coupling rate of 30 MHz. Here we explore the same system, but with a finite source-drain bias applied across the DQD, which forces electrons to tunnel through the device. For specific experimental conditions, we observe gain in the cavity transmission. Moreover, in the absence of an input field, we directly measure photon emission from the cavity-coupled DQD. Our results are inconsistent with existing theoretical models, suggesting that contributions from phonons or cotunneling may be necessary to quantitatively describe the gain mechanism.

9:00AM M26.00004 Superconducting coplanar waveguide resonators for electron spin resonance applications[1] , A.J. SIGILLITO, R.M. JOCK, A.M. TYRYSHKIN, Princeton University, H. MALISSA, The University of Utah, S.A. LYON, Princeton University — Superconducting coplanar waveguide (CPW) resonators are a promising alternative to conventional volume resonators for electron spin resonance (ESR) experiments where the sample volume and thus the number of spins is small. However, the magnetic fields required for ESR could present a problem for Nb superconducting resonators, which can be driven normal. Very thin Nb films (50 nm) and careful alignment of the resonators parallel to the magnetic field avoid driving the Nb normal, but flux trapping can still be an issue. Trapped flux reduces the resonator Q-factor, can lead to resonant frequency instability, and can lead to magnetic field inhomogeneities. At temperatures of 1.9 K and in a magnetic field 0.32 T, we have tested X-band resonators fabricated directly on the surface of a silicon sample. Q-factors in excess of 15,000 have been obtained. A thin layer of GE varnish applied directly to the resonator has been used to glue a sapphire wafer to its surface, and we still find Q-factors of 16,000 or more in the 0.32 T field. ESR applications of these resonators will be discussed.

[1]Supported in part by the ARO.

9:12AM M26.00005 Microwave Measurements Electrons on Helium with Superconducting Coplanar Waveguide Resonators , GE YANG, Department of Physics, University of Chicago, ANDREAS FRAGNER, Applied Physics Department, Yale University, BING LI, Department of Physics, University of Chicago, ROB SCHOELKOPF, Applied Physics Department, Yale University, DAVID I. SCHUSTER, Department of Physics, University of Chicago, ELECTRONS ON HELIUM COLLABORATION — Electrons on helium is a unique two-dimensional electron gas system formed at the interface of a quantum liquid (superfluid helium) and vacuum. The motional and spin states of single-electron quantum dots defined on such systems have been proposed for hybrid quantum computing [1,2]. Traditional AC transport experiments of electrons on helium are conducted at kilohertz frequencies. Here, we will present microwave measurements of electrons trapped in a 5GHz superconducting coplanar waveguide resonator with 1 MHz bandwidth. The effect of trapping parameters on the resonance, and experimental progress towards a single trapped electron regime will also be discussed.

9:24AM M26.00006 Photon mediated interaction between distant quantum dot circuits , TAKIS KONTOS, MATTHIEU DELBECQ, LAURE BRUHAT, JÉRÉMIE VIENNOT, SUBHADEEP DATTA, AUDREY COTTET, CNRS/ENS — Cavity QED allows one to study the interaction between light and matter at the most elementary level, by using for instance Rydberg atoms coupled to cavity photons. Recently, it has become possible to perform similar experiments on-chip, by using artificial two-level systems made from superconducting circuits instead of atoms. This circuit-QED offers unexplored potentialities, since other degrees of freedom than those of superconducting circuits could be used, and in particular, those of quantum dots. Such a hybrid circuit QED would allow one to study a large variety of situations not accessible with standard cavity QED, owing to the versatility of nanofabricated circuits. Here, we couple two quantum dot circuits to a single mode of the electromagnetic field in a microwave cavity. Our quantum dots are separated by 200 times their own size, with no direct tunnel and electrostatic couplings between them. We demonstrate their interaction mediated by the cavity photons. This could be used to scale up quantum bit architectures based on quantum dot circuits, and simulate on-chip phonon-mediated interactions between strongly correlated electrons.

9:36AM M26.00007 Phonon-Mediated Population Inversion in a Driven Double Quantum Dot[1] , XANTHE CROOT, JAMES COLLESS, ANDREW DOHERTY, ARC Centre of Excellence for Engineered Quantum Systems, School of Physics, The University of Sydney, Sydney, NSW 2006, Australia, TOM STACE, ARC Centre of Excellence for Engineered Quantum Systems, School of Mathematics and Physics, University of Queensland, Brisbane, QLD 4072, Australia., SEAN BARRETT, Blackett Laboratory and Institute for Mathematical Sciences, Imperial College London, London SW7 2PG, United Kingdom, HONG LU, ART GOSSARD, Materials Department, University of California, Santa Barbara, California 93106, USA., DAVID REILLY, ARC Centre of Excellence for Engineered Quantum Systems, School of Physics, The University of Sydney, Sydney, NSW 2006, Australia — We examine phonon emission processes in a double quantum dot, configured as either a single or two-electron charge qubit and driven with resonant microwave excitation. Fast readout using a proximal rf quantum point contact (rf-QPC) enables charge sensing with high resolution and allows fine phonon-related features to be observed in microwave spectroscopy data. Spontaneous phonon emission is observed to produce level broadening and population inversion of a two-level system, a phenomena predicted theoretically but previously unreported. For the two-electron configuration, microwave transitions are shown to be spin-dependent, consistent with the well-understood mechanism of Pauli-blockade in double quantum dots.

9:48AM M26.00008 Dispersive Readout of a Few-Electron Double Quantum Dot with Fast rf Gate-Sensors[1] , ALICE MAHONEY, JAMES COLLESS, JOHN HORNIBROOK, ANDREW DOHERTY, DAVID REILLY, ARC Centre of Excellence for Engineered Quantum Systems, School of Physics, The University of Sydney, Sydney, NSW 2006, Australia., HONG LU, ART GOSSARD, Materials Department, University of California, Santa Barbara, California 93106, USA. — We report the dispersive charge-state readout of a double quantum dot in the few-electron regime using the *in situ* gate electrodes as sensitive detectors. We benchmark this gate-sensing technique against the well established quantum point contact (QPC) charge detector and find comparable performance with a bandwidth of $\sim$ 10 MHz and an equivalent charge sensitivity of $\sim 6.3 \times 10^{-3}$ e/$\sqrt{\text{Hz}}$. Dispersive gate-sensing alleviates the burden of separate charge detectors for quantum dot systems and promises to enable readout of qubits in scaled-up arrays.

[1]We acknowledge funding from the U.S. Intelligence Advanced Research Projects Activity (IARPA), through the U.S. Army Research Office and the Australian Research Council Centre of Excellence Scheme (Grant No. EQuS CE110001013)

10:00AM M26.00009 Spectroscopy of a GaAs Double Dot Qubit with Dispersive Readout[1]

JAMES COLLESS, ALICE MAHONEY, XANTHE CROOT, JOHN HORNIBROOK, ANDREW DOHERTY, ARC Centre of Excellence for Engineered Quantum Systems, School of Physics, The University of Sydney, Sydney, NSW 2006, Australia, TOM STACE, ARC Centre of Excellence for Engineered Quantum Systems, School of Mathematics and Physics, University of Queensland, Brisbane, QLD 4072, Australia, HONG LU, ART GOSSARD, Materials Department, University of California, Santa Barbara, California 93106, USA, DAVID REILLY, ARC Centre of Excellence for Engineered Quantum Systems, School of Physics, The University of Sydney, Sydney, NSW 2006, Australia — We report microwave spectroscopy of a GaAs double dot qubit device using the dispersive gate sensor (DGS) readout technique. In contrast to charge sensing methods based on quantum point contacts (QPCs) or single electron transistors (SETs), the DGS detection method senses the tunneling of charge between states that are near degenerate in energy. Microwave excitation applied to the surface gates enables this readout approach to resolve low energy spectroscopic features not apparent in transport or standard charge sensing measurements. We discuss the origin of these features and the use of this technique for characterizing semiconductor qubit systems.

[1]We acknowledge funding from the U.S. Intelligence Advanced Research Projects Activity (IARPA), through the U.S. Army Research Office and the Australian Research Council Centre of Excellence Scheme (Grant No. EQuS CE110001013).

10:12AM M26.00010 Radio frequency charge sensing in a Si double quantum dot device[1]

C. PAYETTE, K. WANG, Y. DOVZHENKO, J.R. PETTA, Department of Physics, Princeton University — Coherent spin manipulation has recently been demonstrated in a variety of silicon based devices.[2,3] We fabricate accumulation mode double quantum dot devices and use radio frequency reflectometry to perform fast charge sensing in the few-electron regime. Our devices employ a nearby single quantum dot as a charge sensor. Charge transitions in the double dot result in a $\sim$60% relative change in the charge sensor conductance when the sensor is operated in the Coulomb blockade regime, compared to a $\sim$1% conductance change when the sensor is operated as a traditional quantum point contact. Further development of these techniques may enable us to perform single shot spin readout in a silicon quantum dot.

10:24AM M26.00011 Transport and Charge Manipulation in a Single Electron Silicon Double Quantum Dot[1]

K. WANG, C. PAYETTE, Y. DOVZHENKO, J.R. PETTA, Princeton University — Silicon is one of the most promising candidates for ultra-coherent qubits due to its relatively early position in periodical table and the absence of nuclear spin in its naturally abundant isotope. Here we demonstrate a reliable recipe that enables us to reproducibly fabricate an accumulation mode few electron double quantum dot (DQD). We demonstrate tunable interdot tunnel coupling at single electron occupancy in the device. The charge state of the qubit is monitored by measuring the amplitude of the radio frequency signal that is reflected from a resonant circuit coupled to a charge sensor. By applying microwave radiation to the depletion gates, we probe the energy level structure of the DQD using photon assisted tunneling (PAT). We apply bursts of microwave radiation and monitor the dependence of the PAT peak height on the burst period to extract the charge relaxation time, T_1. By experimentally tuning the charge qubit Hamiltonian, we measure the tunnel coupling and detuning dependence of T_1.

10:48AM M26.00013 Fabrication and measurement of an RF-QPC in an undoped Si/SiGe heterostructure

ROBERT MOHR, DANIEL ENDERICH , JONATHAN PRANCE, LEON MAURER, DANIEL WARD, DONALD SAVAGE, MAX LAGALLY, ROBERT MCDERMOTT, SUSAN COPPERSMITH, MARK ERIKSSON, University of Wisconsin - Madison — We perform radio-frequency reflectometry measurements on a quantum point contact fabricated in an undoped accumulation-mode Si/SiGe heterostructure. This device is a promising candidate for high-bandwidth charge sensing in Si/SiGe, and it provides the capability for fast qubit readout in this material. We show operation of the device with a well-defined resonance that can be modulated by a nearby gate. We will discuss design challenges that are particular to accumulation-mode structures and how they can be resolved.

Wednesday, March 20, 2013 8:00AM - 11:00AM –

Session M27 GQI: Focus Session: Quantum Error Correction and Decoherence Control I 329 - Kenneth Brown, Georgia Institute of Technology

8:00AM M27.00001 Dynamical quantum error correction: recent achievements and prospects[1]

LORENZA VIOLA, Dartmouth College — Precisely controlling the dynamics of real-world open quantum systems is a central challenge across quantum science and technology, with implications ranging from quantum physics and chemistry to fault-tolerant quantum computation. Dynamical quantum error correction strategies based on open-loop time-dependent modulation of the system dynamics provide a general perturbative framework for boosting physical-layer fidelities in the non-Markovian regime. I will describe recent progress in designing dynamical error correction schemes able to incorporate various system and control constraints encountered in realistic scenarios. In particular, I will show how to employ dynamical decoupling methods to achieve high-fidelity quantum storage for long times, while minimizing access latency and sequencing complexity, and how to synthesize dynamically corrected quantum gates for simultaneously canceling non-Markovian decoherence and control errors, while accommodating internal always-on dynamics and limited control. In the process, I will make contact with current qubit devices to the extent possible and point to remaining challenges and directions for further explorations.

8:36AM M27.00002 Quantum Control and Fault-tolerance , GERARDO PAZ SILVA, JASON DOMINY, DANIEL LIDAR, University of Southern California — Quantum control (QC) and the methods of fault-tolerant quantum computing (FTQC) are two of the cornerstones on which the hope for a quantum computer rests. However QC methods do not generally scale well with the size of the system, and it is not known how their performance is hindered when integration with FTQC methods, especially considering these demand a large system size overhead, is attempted under realistic noise models. Here we study this problem using dynamical decoupling in the bang-bang limit as a toy model, with a non-Markovian noise where interactions decay with distance, and show that there exists a regime of the norms of the relevant Hamiltonians, in which dynamical decoupling protected gates provide an advantage over the bare gate implementation. This is a first step towards showing that QC protocols designed for a small set of qubits can be extended to larger sets without a significant loss of performance, as long as the noise model behaves reasonably well.

8:48AM M27.00003 Preserving electron spin coherence by dynamical decoupling based on Nitrogen-Vacancy center in diamond , JIANGFENG DU, University of Science and Technology of China — To exploit the quantum coherence of electron spins in solids in future technologies such as quantum manipulating, it's first vital to overcome the problem of spin decoherence due to their coupling the noisy environment. Dynamical decoupling is a particularly promising strategy for combating decoherence. I will briefly introduce the roadmap for dynamical decoupling and show our experimental research on the field in detail. We first applied the optimal dynamical decoupling scheme [1] on electron spins of ensemble sample [2]. Based on the technology, the dynamical decoupling sequence was used to observe the anomalous coherence effect and of single electron spin based on nitrogen-vacancy defect center in diamond [3]. For application, combined the dynamical decoupling together with quantum metrology protocol, the phase estimation was enhanced [4]. Instead of pulsed model, continuous dynamical decoupling was realized in our experiment and applied to protect quantum gate [5]. The next step, we will apply multi flip pulses to enhance the magnetic field sensitivity of NV center towards to the micro-scale magnetic resonance and single molecular imaging. [1] G. S. Uhrig, Phys. Rev. Lett. 98, 100504 (2007) [2] J. Du, et al., Nature 461, 1265 (2009) [3] P. Huang, et al., Nature Communications, 2, 570 (2011) [4] X. Rong, et al., Europhys. Lett. 95, 60005 (2011) [5] X. Xu, et al., Phys. Rev. Lett. 109, 070502 (2012)

9:00AM M27.00004 Improving quantum gate fidelities by using a qubit to measure microwave pulse distortions , SIMON GUSTAVSSON, OLGER ZWIER, JONAS BYLANDER, FEI YAN, Massachusetts Institute of Technology, Cambridge, MA 02139, FUMIKI YOSHIHARA, The Institute of Physical and Chemical Research (RIKEN), Wako, Saitama 351-0198, Japan, YASUNOBU NAKAMURA, Research Center for Advanced Science and Technology (RCAST), The University of Tokyo, Komaba, Meguro-ku, Tokyo 153-8904, Japan, TERRY ORLANDO, Massachusetts Institute of Technology, Cambridge, MA 02139, WILLIAM OLIVER, MIT Lincoln Laboratory, 244 Wood Street, Lexington, MA 02420, USA — We present a new method for determining pulse imperfections and improving the single-gate fidelity in a superconducting qubit. By applying consecutive positive and negative π pulses, we amplify the qubit evolution due to microwave pulse distortions, which causes the qubit state to rotate around an axis perpendicular to the intended rotation axis. Measuring these rotations as a function of pulse period allows us to reconstruct the shape of the microwave pulse arriving at the sample. Using the extracted response to predistort the input signal, we are able to improve the pulse shapes and to reach an average single-qubit gate fidelity higher than 99.8%.

9:12AM M27.00005 ABSTRACT WITHDRAWN –

9:24AM M27.00006 Accurate quantum Z rotations with less magic , ANDREW LANDAHL, Sandia National Laboratories, CHRIS CESARE, University of New Mexico — We present quantum protocols for executing arbitrarily accurate $\pi/2^k$ rotations of a qubit about its Z axis. Unlike reduced instruction set computing (RISC) protocols which use a two-step process of synthesizing high-fidelity "magic" states from which $T = Z(\pi/4)$ gates can be teleported and then compiling a sequence of adaptive stabilizer operations and T gates to approximate $Z(\pi/2^k)$, our complex instruction set computing (CISC) protocol distills magic states for the $Z(\pi/2^k)$ gates directly. Replacing this two-step process with a single step results in substantial reductions in the number of gates needed. The key to our construction is a family of shortened quantum Reed-Muller codes of length $2^{k+2} - 1$, whose distillation threshold shrinks with k but is greater than 0.85% for $k \leq 6$. AJL and CC were supported in part by the Laboratory Directed Research and Development program at Sandia National Laboratories. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

9:36AM M27.00007 Fault-tolerant, nondestructive measurement of logical operators and quantum teleportation in large stabilizer codes , TODD BRUN, University of Southern California — Fault-tolerant quantum computation seeks to perform large calculations by protecting quantum information against decoherence using quantum error-correcting codes. Such schemes have been widely studied, but the resources needed to actually perform a fault-tolerant computation are daunting. In principle, it may be possible to reduce this overhead by using large block codes with significantly higher rates. Logical gates can be done in such a scheme by teleporting the logical qubits between code blocks. Logical teleportation can be done fault-tolerantly by measuring a particular set of logical operators. This measurement involves preparing an entangled ancillary state and doing a transversal circuit between the codeword and the ancilla. We study this procedure, and show that a wide range of such measurement protocols exist. There is a trade-off between the size of of the ancilla and the robustness against errors; for a large codeword, it may be fruitful to use a larger ancilla that has greater error-correcting power.

10:12AM M27.00008 Quantum "hyperbicycle" low-stabilizer-weight finite-rate error correction codes[1] , LEONID P. PRYADKO, ALEXEY A. KOVALEV, University of California, Riverside — We construct a large family of finite-rate quantum error correcting codes (QECCs) which interpolate between the hypergraph-product [1] and generalized bicycle codes [2]. The construction allows for the lower and upper bounds on the distance which generally scale as a square root of the block size; in several important cases the two bounds coincide. The constructed QECCs include several new classes of codes with low stabilizer weights; they can offer an advantage compared to the toric codes.

10:24AM M27.00009 Error correction with quantum low-density parity check codes[1] , ALEXEY KOVALEV, LEONID PRYADKO, University of California, Riverside — We study quantum low-density parity check (LDPC) codes and their fault tolerance. We show that any family of quantum LDPC codes where each syndrome measurement involves a limited number of qubits, and each qubit is involved in a limited number of measurements (as well as any similarly-limited family of classical LDPC codes), where distance scales as a positive power of the number of physical qubits, has a finite error probability threshold. We conclude that for sufficiently large quantum computers, finite-rate quantum LDPC codes can offer an advantage over the toric codes. Error correction in the presence of errors in syndrome measurements is also addressed. We discuss possible realizations of decoders and their error thresholds, e.g. in relation to LDPC versions of the quantum hypergraph-product codes [1] and their generalizations [2].

10:36AM M27.00010 Relative performance of ancilla verification and decoding in the [[7,1,3]] Steane code[1] , ALI ABU-NADA, BENJAMIN FORTESCUE, MARK BYRD, Southern Illinois University at Carbondale, SOUTHERN ILLINOIS UNIVERSITY AT CARBONDALE TEAM — We present numerical simulation results comparing the logical error rates for the fault-tolerant [[7,1,3]] Steane code using standard ancilla verifications techniques vs. the newer method of ancilla decoding, as described in [1]. We simulate a realistic QEC procedure in which failed ancilla creation requires storing the data until a new ancilla can be created; we expect the decoding method, which avoids the need for such storage, to be advantageous when the failure probability is sufficiently high. For the [[7,1,3]] code, we analyze the effect of both different syndrome extraction techniques and of different classes of physical error (initialization, measurement, hold etc.) on the relative performance of these two methods.

[1]Authors gratefully acknowledge support from the Intelligence Advanced Research Projects Activity (IARPA) via Department of Interior National Business Center contract number D11PC20168.

10:48AM M27.00011 Quantum Error Correction with Mixed State Ancilla Qubits[1] , MIKIO NAKAHARA, YASUSHI KONDO, CHIARA BAGNASCO, Department of Physics, Kinki University — It is commonly assumed that ancilla qubits must be in a pure state for successful quantum error correction. We show in our talk that they can initially be in any mixed state if the error operator acts simultaneously on all the physical qubits (fully correlated noise). In particular, they can be in the uniformly mixed state, which makes implementation of our scheme extremely cheap. We also note that 1-qubit gate operations can be implemented easily within the codeword. We experimentally demonstrated our scheme by using a liquid state NMR quantum computer. The encoded state has an interesting nature in terms of quantum discord, which is purely quantum correlations between the data qubit and the ancilla qubits.

Wednesday, March 20, 2013 8:00AM - 10:36AM –

Session M28 DCMP: Liquid Crystals II 336 - Luz Martinez-Miranda, University of Maryland

8:00AM M28.00001 Stable nematic droplets with handles , JAYALAKSHMI VALLAMKONDU, EKAPOP PAIRAM, Georgia Institute of Technology, VINZENZ KONING, Instituut-Lorentz Universiteit Leiden, BATES MARTIN, York University, VINCENZO VITELLI, Instituut-Lorentz Universiteit Leiden, ALBERTO FERNANDEZ-NIEVES, Georgia Institute of Technology — We use a simple method to generate nematic liquid crystal droplets with handles. The method relies on the viscous forces exerted by a flowing continuous phase above its yield stress over a liquid crystal which is extruded from an injection needle; the resultant jet is forced to close into a torus, due to the imposed rotation, and is stable against surface tension instabilities, due to the elasticity of the outer phase. We find that the ground state of these nematic liquid crystal toroidal droplets is defect free and exhibits twist, irrespective of the aspect ratio of the torus. By including the saddle-splay contribution to the elastic free energy density, we find that this state indeed corresponds to the lowest energy state. For droplets with additional handles, we find there are two surface defects or boojums per additional handle.

8:12AM M28.00002 Nanosecond electrooptics of nematic liquid crystals: induced orientational order and quenching of director fluctuations[1] , VOLODYMYR BORSHCH, SERGIJ V. SHIYANOVSKII, OLEG D. LAVRENTOVICH, Liquid Crystal Institute and Chemical Physics Interdisciplinary Program, Kent State University, Kent, 44240, OH — We demonstrate a fast (1-100 ns) electrooptic response of a thermotropic nematic liquid crystal in a geometry when a strong electric field ($> 10^8$ V/m) does not realign the director and influences only the orientational order and the spectrum of director fluctuations.

[1]The work was supported by DOE Grant #DE-FG02-06ER 46331.

8:24AM M28.00003 Impact of Photo-Induced Surface Adsorption of Azo-Dyes on the Liquid Crystal Anchoring Conditions , DAVID STATMAN, Allegheny College — Using optical techniques, we measured the anchoring conditions of azo-dye doped nematic liquid crystals on rubbed polyimide surfaces. Linearly polarized light induces the formation of a second easy axis on the polymer surface oriented toward the polarization direction of the pump laser beam. This additional easy axis is the result of photo-induced adsorption of the *cis* isomer of the azo dye. An effective easy axis is the weighted average of the original easy axis and this new easy axis.

8:36AM M28.00004 Surface Nano pattering for aligning Chromonic liquid crystals , JEONG YEON, Korea Advanced Institute of Science and Technology, MOHAN SRINIVASARAO, Georgia Institute of Technology, HEE TAE JUNG, Korea Advanced Institute of Science and Technology — We present results on planar alignment of several Chromonic Liquid Crystals. We use a high aspect ratio nano pattern of electrically conductive ITO, which was fabricated by employing a new patterning technique that relies on a secondary sputtering phenomenon (SSP). This method is particularly useful in the case of aligning Chromonics which are considerably harder to align in comparison with conventional thermotropics. Berreman's theory was employed to study the alignment of the Liquid Crystals as a function of the anchoring energy which depend on the dimension of the ITO patterns.

8:48AM M28.00005 Differential Dynamic Microscopy for measuring viscoelastic ratios of Chromonic Liquid Crystals , KARTHIK NAYANI, JUNG OK PARK, MOHAN SRINIVASARAO, Georgia Institute of Technology — Differential Dynamic Microscopy(DDM) enables one to access the scattering information from a sample by Fourier analyzing the real space images obtained from a light microscope. Thermal fluctuations of the director about the mean position allows one to study the viscoelastic properties of the nematic. Normally such measurements of the viscoelastic constants require time consuming and sensitive light scattering experiments. DDM enables us to extract the same data just by analyzing a real space movie a few seconds long using a high speed camera. We present results of viscoelastic measurements of Chromonic liquid crystal Sunset yellow using DDM measurements.

9:00AM M28.00006 Phase and Topological Behavior of Lyotropic Chromonic Liquid Crystals in Double Emulsions[1] , ZOEY S. DAVIDSON, JOONWOO JEONG, Department of Physics, University of Pennsylvania, FUQUAN TU, Department of Chemical and Biomolecular Engineering, University of Pennsylvania, MATT LOHR, Department of Physics, University of Pennsylvania, DAEYEON LEE, Department of Chemical and Biomolecular Engineering, University of Pennsylvania, PETER J. COLLINGS, Department of Physics and Astronomy, Swarthmore College and Department of Physics, University of Pennsylvania, TOM C. LUBENSKY, A.G. YODH, Department of Physics, University of Pennsylvania — Lyotropic chromonic liquid crystals, assembled by non-covalent interactions, have fascinating temperature- and concentration-dependent phase behavior. Using water-oil-water double emulsions, we are able control the inner droplet chromonic phase concentration by osmosis through the oil phase. We then study the configurations of the chromonic liquid crystal phases in droplets by varying the oil types, oil soluble surfactants, and inner droplet diameter. We employ polarization microscopy to observe resulting nematic and columnar phases of Sunset Yellow FCF, and we deduce the liquid crystal configuration of both phases within the droplets. Simulations based on Jones matrices confirm droplet appearance, and preliminary observations of chromonic liquid crystal shells in oil-water-oil double emulsions are reported.

9:12AM M28.00007 Homeotropic alignment of the lyotropic chromonic liquid crystal Sunset Yellow FCF using pi-pi stacking chemical interactions[1] , JOONWOO JEONG, GANGHEE HAN, A.T. CHARLIE JOHNSON, TOM C. LUBENSKY, PETER J. COLLINGS[2], A.G. YODH, Department of Physics & Astronomy, University of Pennsylvania, Philadelphia, PA 19104, USA — We report on the homeotropic alignment of the lyotropic chromonic liquid crystal, Sunset Yellow FCF (SSY), using pi-pi stacking interactions between the SSY molecules and (1) thin parylene films or (2) a graphene monolayer. The nematic and columnar phases of SSY molecules arise via self-assembly in water into stacks through non-covalent attractions between the SSY molecules. Interestingly, we find that the same non-covalent interactions between SSY molecules and a parylene or graphene alignment layer lead to homeotropic anchoring of these stacks. The nematic phase of SSY is introduced between two glass substrates coated with parylene films or graphene monolayers, and homeotropic alignment of SSY is confirmed by polarized optical microscopy and conoscopy. Additionally, we observe and can explain the stripe domains that occur during cooling of the sample in this cell, and we consider possible novel applications for homeotropically aligned chromonic liquid crystals.

9:24AM M28.00008 Kinetics of Assembly and Dis-assembly of Structures Forming a Chromonic Liquid Crystal at Low Concentrations[1] , KENNETH NIESER, PETER COLLINGS, Department of Physics & Astronomy, Swarthmore College, Swarthmore, PA 19081 — The molecules of the near-IR absorbing dye IR-806 spontaneously assemble in water at very low concentrations, forming a chromonic liquid crystal phase at room temperature when the concentration is above 0.5 wt%. The assembly process proceeds in two steps and results in a complex structure that orientationally orders in a liquid crystal phase. The kinetics of the assembly and dis-assembly of these complex structures can be followed through absorption measurements by rapidly mixing the initial sample with either a small fraction of salt solution (assembly) or a large fraction of water (dis-assembly). The kinetics of dis-assembly is exponential while the kinetics of assembly is non-exponential, both with rate constants depending on the starting and ending conditions, but falling in the 0.1-1.0 s^{-1} range. While past equilibrium absorption measurements on IR-806 offer evidence for a threshold concentration for the assembly of these complex structures, the kinetics experiments show with certainty the existence of such a threshold. Similar experiments on Benzopurpurin 4B, another dye that forms a chromonic liquid crystal at low concentrations, reveal kinetics that are slower by two orders of magnitude and a threshold concentration for the assembly of complex structures.

9:36AM M28.00009 Free energy power expansion for orientationally ordered phases: energy and entropy[1] , SERGIJ SHIYANOVSKII, Liquid Crystal Institute, Kent State University — We propose a new approach for description of orientational phase transitions that utilizes the following specific features of the orientational energy E and entropy S: (a) S possesses an additional symmetry in comparison with E, being invariant under rotation of the molecular frame; and (b) E contributes only to the second order terms because the pair molecular interaction is dominant. The approach is based on minimization of the scaled orientational free energy $\bar{F} = F/T = E/T - S$ instead of F because $\bar{F}$ obeys the standard assumption of the Landau theory that only the second order terms are temperature dependent. We apply the approach to build a model for nematic phases in materials with non-polar parallelepiped-type molecules with symmetry D_{2h}. The presented model introduces complex OPs, generalizes the Landau-de Gennes (LdeG) theory and predicts the existence of a biaxial nematic phase for the forth order expansion of $\bar{F}$.

9:48AM M28.00010 Surface topography and rotational symmetry breaking , RAJRATAN BASU, The US Naval Academy, IAN NEMITZ, Case Western Reserve University, QINGXIANG SONG, ROBERT LEMIEUX, Queen's University, CHARLES ROSENBLATT, Case Western Reserve University — The surface electroclinic effect, which is a rotation of the molecular director in the substrate plane proportional to an electric field applied normal to the substrate, requires both a chiral environment and C_2 (or lower) rotational symmetry about the field. The two symmetries typically are created in tandem by manipulating the surface topography, a process that conflates their effects. Here we use a pair of rubbed polymer-coated substrates in a twist geometry to obtain our main result, viz., that the strengths of two symmetries, in this case the rub-induced breaking of C_∞ rotational symmetry and chiral symmetry, can be separated and quantified. Experimentally we observe that the strength of the reduced rotational symmetry arising from the rub-induced scratches, which is proportional to the electroclinic response, scales linearly with the induced topographical rms roughness and increases with increasing rubbing strength of the polymer. Our results also suggest that the azimuthal anchoring strength coefficient is relatively insensitive to the strength of the rubbing.

10:12AM M28.00012 Probing Viscoelasticity of Cholesteric Liquid Crystals in a Twisting Cell[1] , JOSEPH ANGELO, ALIREZA MOHEGHI, NICK DIORIO, ANTAL JAKLI, Liquid Crystal Institute — Viscoelastic properties of liquid crystals are typically studied either using Poiseuille flow, which can be produced by a pressure gradient in a capillary tube,[2] or Couette flow, which can be generated by a shear between concentric cylinders.[3] We use a different method in which we twist the liquid crystal sandwiched between two cylindrical glass plates, one of which can rotate about its center, the other of which is fixed. When the cell is twisted, there is a force proportional to the twist angle and the twist elastic constant, and inversely proportional to the pitch and sample thickness, normal to the substrates due to the change in pitch in the cholesteric liquid crystal (CLC). Measuring this force on various CLCs with known pitch we could obtain the twist elastic constants. In addition to the equilibrium force, we observed a transient force during the rotation, which is related to the flow of the material, thus allowing us to determine the Leslie viscosity component α_1, which typically cannot be assessed by other methods. We expect this apparatus to be a useful tool to study the visco-elastic properties of liquid crystals.

10:24AM M28.00013 Chiral hierarchal self-assembly in Langmuir monolayers of diacetylenic lipids[1] , ELIZABETH MANN, PRITAM MANDAL, PREM BASNET[2], DOMINIC MALCOLLM[3], Deptartment of Physics, Kent State University, SAHRAOUI CHAIEB, Physical Science and Engineering, KAUST, Thuwal, KSA — A Langmuir monolayer made of chiral lipid molecules forms a hierarchal structure when compressed in the intermediate temperature range below the chain melting temperature. These structures are captured via Brewster angle microscopy. When the liquid monolayer is compressed, an optically anisotropic condensed phase nucleates in the form of long, thin claws. These claws pack closely to form stripes. This appears to be a new mechanism for forming stripes within Langmuir monolayers. In the lower temperature range these stripes arrange into spirals within overall circular domains, while near the chain melting transition the stripes arrange into target-structure. We attributed this transition to a change in boundary conditions at the core of the largest-scale circular domains.

Session M29 GSNP: Focus Session: Wet Granular Material: Capillary Aggregation to Shaping of Landscapes 337 - Arshad Kudrolli, Clark University

8:00AM M29.00001 Dynamics of failure in 2d granular packings , JENNIFER RIESER, YUKA TAKEHARA, University of Pennsylvania, WENBIN LI, JU LI, Massachusetts Institute of Technology, JERRY GOLLUB, Haverford College, DOUGLAS DURIAN, University of Pennsylvania — We explore the grain-scale interactions that precede large-scale deformations and mark the onset of mechanical failure in two-dimensional granular packings. The two-dimensionality of the system allows for direct observation of all particle dynamics during the compression of a pillar. The grains are cohesive, with an attraction governed by tunable capillary forces that are induced through an interstitial fluid. We are particularly interested in the initial deformation of the pillar. Here we characterize local structure and dynamics leading up to the first large-scale event. For our analysis, we focus on how local structure within the packing relates to local dynamics and eventually to large-scale deformation. Local structure and rearrangements are characterized by information from a Delaunay triangulation, and are compared with larger-scale deformations identified by spatial variations in the velocities of the particles. We explore the the effects of pillar size and cohesion strength on the dynamics in both ordered and disordered packings.

8:12AM M29.00002 Compaction dynamics of wet granular packings , NICOLAS VANDEWALLE, FRANCOIS LUDEWIG, GRASP, Universite de Liege, B-4000 Liege, Belgium., JORGE E. FISCINA, Experimental Physics, Saarland University, D-66123, Saarbrücken, Germany., GEOFFROY LUMAY, GRASP, Universite de Liege, B-4000 Liege, Belgium. — The extremely slow compaction dynamics of wet granular assemblies has been studied experimentally. The cohesion, due to capillary bridges between neighboring grains, has been tuned using different liquids having specific surface tension values. The characteristic relaxation time for compaction τ grows strongly with cohesion. A kinetic model [1], based on a free volume kinetic equations and the presence of a capillary energy barrier (due to liquid bridges), is able to reproduce quantitatively the experimental curves. This model allows one to describe the cohesion in wet granular packing [2]. The influence of relative humidity (RH) on the extremely slow compaction dynamics of a granular assembly has also been investigated in the range $20\% - 80\%$. Triboelectric and capillary condensation effects have been introduced in the kinetic model. Results confirm the existence of an optimal condition at $\mathrm{RH} \approx 45\%$ for minimizing cohesive interactions between glass beads [3]. Lett. 105, 048001 (2010) [3] N.Vandewalle, G.Lumay, F.Ludewig, J.E.Fiscina, Phys. Rev. E 85, 031309 (2012)

8:24AM M29.00003 Self-assembled granular towers[1] , FELIPE PACHECO-VAZQUEZ, FLORIAN MOREAU, NICOLAS VANDEWALLE, STEPHAN DORBOLO, GRASP, Physics Department B5, Universite de Liege, B4000-Liege, Belgium, GROUP FOR RESEARCH AND APPLICATIONS IN STATISTICAL PHYSICS TEAM — When some water is added to sand, cohesion among the grains is induced. In fact, only 1% of liquid volume respect to the total pore space of the sand is necessary to built impressive sandcastles. Inspired on this experience, the mechanical properties of wet piles and sand columns have been widely studied during the last years. However, most of these studies only consider wet materials with less than 35% of liquid volume. Here we report the spontaneous formation of granular towers produced when dry sand is poured on a highly wet sand bed: The impacting grains stick on the wet grains due to instantaneous liquid bridges created during the impact. The grains become wet by the capillary ascension of water and the process continues, giving rise to stable narrow sand towers. Actually, the towers can reach the maximum theoretical limit of stability predicted by previous models, only expected for low liquid volumes.

8:36AM M29.00004 Building towers, domes, and arches by self-organized solidifying flows , JULIEN CHOPIN, Clark University — We demonstrate that a wide variety of delicate solid structures from slender towers to arches, and chiral pagodas can be created by simply pouring a mixture of grains and water on a liquid absorbing substrate [Phys. Rev. Lett. 107, 208304 (2011)]. The same suspension poured on a solid substrate would form a featureless puddle or a pile with an angle of repose. However, an absorbing substrate can quickly drain the liquid from the suspension, rapidly causing the solidification of the fluid into a mechanically stable structure. In a dripping regime, successive drops are observed to jam rapidly upon impact literally stacking on top of each other forming slender granular towers. In a jetting regime and using a moving substrate, the jet is found to bounce on and off the substrate forming regular arches. We will discuss the subtle interplay of the incoming flux of the granular suspension, the drainage efficiency of the substrate, and the mechanical properties of the solid structure. The drainage driven jamming of granular suspensions gives a new route to shape cohesive granular materials and, from a broader perspective, demonstrates the potential a solidifying fluid spreading on a substrate to create new morphologies harder to achieve by other techniques. Applications to surface patterning, rheology of dense suspension and mechanics of wet granular materials will be discussed.

9:12AM M29.00005 Capillary fracturing in granular media , MICHAEL SZULCZEWSKI, Massachusetts Institute of Technology, RAN HOLTZMAN, The Hebrew University of Jerusalem, MATHIAS TROJER, University of Leoben, RUBEN JUANES, Massachusetts Institute of Technology — The invasion of gas into liquid-saturated, deformable porous media occurs in many processes including gas venting, hydrocarbon recovery, and geologic CO_2 sequestration. While fracturing during gas invasion has been observed in several studies, the underlying mechanisms and macroscopic patterns remain poorly understood. Here, we experimentally investigate the fracturing mechanism and resulting patterns during the invasion of air into a thin bed of water-saturated glass beads. The control parameters are the air injection rate, the bead size, and the vertical confining stress applied to the top of the bed. We identify three invasion regimes: capillary fingering, viscous fingering, and "capillary fracturing," where capillary forces overcome frictional resistance and induce the opening of fracture-like conduits. We show that the transitions between the regimes are governed by a modified capillary number and a fracturing number. We then extend the experiments to investigate the effect of wettability. Our analysis predicts the emergence of fracturing in fine-grained media under low confining stress, a phenomenon that likely plays a fundamental role in many natural systems.

9:24AM M29.00006 Diffusive evolution of experimental river channel networks , MEREDITH REITZ, Columbia University, DOUGLAS JEROLMACK, University of Pennsylvania, ERIC LAJEUNESSE, ANGELA LIMARE, OLIVIER DEVAUCHELLE, FRANCOIS METIVIER, Institut de Physique du Globe de Paris — Braided rivers are complex systems in which a network of ephemeral, interacting channels continually migrate to create a rapidly changing landscape. We present results of a set of $\sim$ 1m-scale experiments of braided rivers forming over a bed of monodisperse glass beads. The experiments evolve from an initial flat bed, allowing us to study the approach to a steady state, with data in the form of repeat high-resolution topography scans. We find that, although channels migrate rapidly, they have stable, self-similar geometries organized to a critical Shields stress criterion. Above the individual channel scale, we find that we can directly describe many aspects of the system with a diffusional framework. The timescale to equilibrium slope, the timescale of decorrelation of the channel network, the rate at which downstream correlation lengthscales increase, and the dependence of the equilibrium slope on sediment flux can all be described with diffusivities that are consistent with a theoretical prediction. The emergent picture of our braided river system is one in which sediment transport drives the interaction of dynamic but equilibrium channels, which in turn act as elements of randomness that create diffusive behavior at the system scale.

9:36AM M29.00007 A converging granular flow driven by fluid drag , STEVEN MEIER, ExxonMobil Research and Engineering Company, DAVID YALE, ExxonMobil Upstream Research Company, ARNOLD KUSHNICK, ExxonMobil Research and Engineering Company, PAUL CHAIKIN, New York University, ERIC HERBOLZHEIMER, ExxonMobil Research and Engineering Company — The dynamics of granular flows are known to depend on applied confining stresses and the need for the material to dilate when subjected to a shearing motion, as has been shown by studies on free-surface flows driven by gravity and confined flows driven by a moving boundary. Here, we present an experimental study at the 2 meter scale of a granular flow subject to a confining stress driven by fluid drag as is encountered in some petroleum recovery and geologic processes. Before the particles start to flow, a Darcy's law pressure gradient is generated by fluid flow. The onset of flow, or failure, is history dependent. That is, it depends on both the stress state and the particle concentration as a result of the history of deformation applied to the material. The particles begin to flow when the pressure gradient exceeds the friction due to the confining stress and the gradient of stress along the flow direction. The flow also depends on the ability of the granular material to dilate. We will show that converging flow conditions allow for this required dilation. Once the particles are flowing, the pressure gradient is proportional to the confining stress on the moving sand rather than on the fluid flow rate.

9:48AM M29.00008 Rainwater Channelization and Infiltration in Granular Media , CESARE MIKHAIL CEJAS, CNRS-Rhodia-UPenn Complex Assemblies of Soft Matter COMPASS UMI3254, Bristol, PA 19007, YULI WEI, Department of Physics and Astronomy, University of Pennsylvania, Philadelphia, PA 19014, REMI BARROIS, CNRS-Rhodia-UPenn Complex Assemblies of Soft Matter COMPASS, Bristol, PA 19007, DOUGLAS J. DURIAN, Department of Physics and Astronomy, University of Pennsylvania, Philadelphia, PA 19014, REMI DREYFUS, CNRS-Rhodia-UPenn Complex Assemblies of Soft Matter COMPASS, Bristol, PA 19007, COMPASS TEAM — We investigate the formation of fingered flow in dry granular media under simulated rainfall using a quasi-2D experimental set-up composed of a random close packing of mono-disperse glass beads. We determine effects of grain diameter and surface wetting properties on the formation and infiltration of water channels. For hydrophilic granular media, rainwater initially infiltrates a shallow top layer of soil creating a uniform horizontal wetting front before instabilities occur and grow to form water channels. For hydrophobic media, rainwater ponds on the soil surface rather than infiltrates and water channels may still occur at a later time when the hydraulic pressure of the ponding water exceeds the capillary repellency of the soil. We probe the kinetics of the fingering instabilities that serve as precursors for the growth and drainage of water channels. We also examine the effects of several different methods on improving rainwater channelization such as varying the level of pre-saturation, modifying the soil surface flatness, and adding superabsorbent hydrogel particles.

10:00AM M29.00009 Characterizing shear-flow-driven erosion of granular beds , JULIA SALEVAN, Yale University, MARK SHATTUCK, City College of New York, COREY O'HERN, NICHOLAS OUELLETTE, Yale University — The complex interactions between granular media and flowing fluid play a principal role in shaping landscapes via erosion. Despite a large body of work in granular materials and large scale topographical changes in granular beds due to fluid flow, the detailed physical mechanisms that underlie particle entrainment into a fluid flow from an erodible bed and the coupling between hydrodynamic shear and internal rearrangement remain poorly understood. To address these questions, we perform experimental studies of pulsed shear flow across granular beds. We characterize the fluid flow using particle tracking techniques and monitor changes in the structural properties of the granular packing and contour of the granular bed.

10:12AM M29.00010 River deltas: channelizing sandpiles with memory , DOUGLAS JEROLMACK, University of Pennsylvania, MEREDITH REITZ, Columbia University — River deltas are wedges of sediment that are built via the lateral migration of self-channelizing rivers, but the timescale of this process is prohibitively long to observe in nature. Here we present laboratory results that allow us to examine how channels form and fill space to create a delta. Flow collapses into a single channel whose dimensions adjust to threshold transport conditions for the imposed sediment load. This channelization causes localized shoreline growth until the slope drops below a threshold value for sediment transport. This leads to deposition within the channel, with an upstream-migrating step akin to a stopping front in granular flows, which causes widespread flooding and the selection of a new (steeper) channel path. This cycle is remarkably periodic; delta slope oscillates between two thresholds - entrainment and distrainment - analogous to static and dynamic angles of repose. Selection of a new flow path is inherently stochastic, but previously abandoned channels act as significant attractors for the flow. Once a critical density of flow paths has been established, the flow oscillates among the same 3-5 channels indefinitely. These dynamics result in self-similar (quasi-)radial growth of delta lobes, which can be described using a simple geometric model. Despite its simplicity, the experimental system agrees well with what can be measured from natural deltas Thus, temporal and spatial patterns of deltas appear to be a robust result of mass conservation and transport thresholds.

10:24AM M29.00011 Effect of moisture content on nest construction activity of fire ants[1] , DARIA MONAENKOVA, NICKOLAS GRAVISH, DANIEL GOLDMAN, MICHAEL GOODISMAN, Georgia Institute of Technology — Large underground nests protect ants from severe weather and predators. Field observations have revealed that the soil wetness affects the nest building activity. In this work we use x-ray computed tomography to study the growth of fire ants nests as a function of soil moisture content. Because capillary cohesion in wet soils leads to the competition between tunnel stability and the labor-intensity of the excavation, we expect to find an optimal soil wetness, which allows the most effective nest construction. We prepared digging containers (3.8 cm diameter by 14.5 cm deep aluminum tubes) with 2 types of simulated soil (50 and 210 um glass particles). The prepared moisture content W varied from 0.01 to 0.18 by mass. Hundred ants were allowed to dig in the containers for 20 hours. Although, the ants were able to construct tunnels in all moisture levels, the maximum tunnel depth, H, was significantly affected by W. At moderate moisture content (W=0.1) H was at least twice greater than at the lowest moisture content (W=0.01) for all tested colonies (n=9) for both particle sizes. The increase in H mirrors the dependence of the soil cohesion on W and we therefore conclude that the tunnel stability is a key factor influencing the digging strategy of fire ants.

[1]We acknowledge the support of NSF, grant 0957659

10:36AM M29.00012 Role of Surface Tension in Magnetorheological Adhesion , CARLOS ORELLANA, HEINRICH JAEGER, The University of Chicago — Magnetorheological (MR) fluids are colloidal suspensions of magnetizable particles that show an increment the yield stress and in the apparent viscosity in the presence of a magnetic field. It has been shown previously that MR fluids can be used for field-controlled static adhesion to non magnetic surfaces. Here we demonstrate the important role the surface tension plays in this adhesion effect (for a low viscosity carrier fluid) and that the adhesive property is not related to the field-dependent yield stress.

10:48AM M29.00013 Shear thickening oscillation in a dilatant fluid , SHIN-ICHIRO NAGAHIRO, Sendai National College of Technology, HIIZU NAKANISHI, Department of Physics, Kyushu University, NAMIKO MITARAI, Niesl Bohr Institute, University of Copenhagen — We report experimental observations of the shear thickening oscillation; spontaneous macroscopic oscillation in the shear flow of severe shear thickening fluids. Using a phenomenological fluid dynamics model for dilatant fluids, we have been predicted theoretically that a dilatant fluid under constant shear stress oscillates due to the shear thickening property coupled with the fluid dynamics. However, such a macroscopic oscillation has never been reported in the literature. In this presentation, we report that strong vibrations of the frequency around 20 Hz is observed using a density-matched starch-water mixture, in the cylindrical shear flow of a few centimeters flow width. The oscillation behavior is consistent with the theoretical prediction.

Wednesday, March 20, 2013 8:00AM - 11:00AM –

Session M30 DCMP: Self-Assembly: Janus and other Colloids 338 - Stefano Sacana, New York University

8:00AM M30.00001 Directed Self-Assembly of Colloidal Janus Matchsticks , KUNDAN CHAUDHARY, Harvard University, QIAN CHEN, JAIME JUAREZ, STEVE GRANICK, University of Illinois at Urbana-Champaign, JENNIFER LEWIS, Harvard University — The ability to assemble anisotropic colloidal building blocks into ordered configurations is scientifically and technologically important for developing new classes of soft materials. We are studying the fabrication and electric field driven assembly of end- and side-coated Janus rods. Specifically, we fabricate silica rods (L/D = 2-4) functionalized with hydrophobic gold (Au) patches using a multistep process involving electric field alignment and crystallization, microcontact printing, and selective metallization. In the absence of an applied electric filed, the Janus matchsticks (end-coated rods) self-assemble into multi pods (e.g., bi-, tri- and tetrapods) of varying coordination number and patch angle in aqueous solution. By contrast, both Janus matchsticks and side-coated Janus rods form complex chains in applied AC electric fields of varying magnitude and frequency, whose configurations vary significantly from those formed by pure silica rods.

8:12AM M30.00002 Theory of crystallization and orientational ordering of spherical Janus colloids , HOMIN SHIN, KENNETH SCHWEIZER, University of Illinois at Urbana-Champaign — Amphiphilic Janus particles have two chemically distinct surfaces, one hydrophobic (attractive) and the other hydrophilic (repulsive), resulting in orientationally anisotropic interparticle interactions. In contrast to homogeneous spherical particles, broken rotational symmetry can result in more exotic crystals that possess distinct orientational patterns, and also plastic crystals. We study the rich phase behavior of Janus colloids using a self-consistent phonon theory that includes coupled translational and rotational entropic and enthalpic contributions to the free energy. Ground states are identified based on the compatibility between the patch geometry of particles (e.g., patch coverage, number, shape) and the lattice symmetry. The coupled self-consistent equations for translational and rotational localization parameters are then solved for a given crystal symmetry, thermodynamic state, and patch orientational order, and their stability determined. For two-dimensional diblock AB Janus crystals, we predict the phase sequence of stripes, modulated stripes (zig-zag), and plastic crystals (rotator phases), which depends sensitively on particle chemical composition and pressure. We also study triblock Janus colloids, including the possibility a Kagome lattice.

8:24AM M30.00003 Modeling of tunable structural re-configuration of Janus colloidal particles[1] , DANIEL BELTRAN, RONALD LARSON, Chemical Engineering, University of Michigan, Ann Arbor — Colloidal particles can assemble into a myriad of structures by virtue of the many interaction forces available to them. Variable range attraction and repulsion and the recently explored non-isotropic character, exemplified by Janus particles, are examples of the versatility of colloidal particles as building blocks. A systematic approach to understand the assembly of Janus colloids, as a function of Janus balance and particle concentration is not yet available. In this work we study the phase behavior of Janus particles as a function of the strength of interaction, Janus balance and volume fraction of spherical particles. A secondary goal of this work is the assessment of re-configurability of the structures found. Our results show the range of stability of several structures, including a fluid phase of small clusters, bilayers and worm-like aggregates. We find the bilayer structures are very stable over a range of phase space and provide a good pre-cursor to hexagonally close-packed structures. These findings enable the understanding of the assembly process of Janus building blocks and provide a framework with which to study the kinetics of structure change.

[1]Work supported by U.S. Army Research Office under Grant Award No. W911NF-10-1-0518

8:36AM M30.00004 Janus Magnetic Rods, Ribbons, and Rings , JING YAN, KUNDAN CHAUDHARY, SUNG CHUL BAE, JENNIFER LEWIS, STEVE GRANICK, Department of Materials Science and Engineering, University of Illinois at Urbana-Champaign — Dipolar particles are fundamental building blocks in nature and technology but the roles of anisotropy are seldom explored in their assembly. Here, we fabricate colloidal silica rods coated on one hemicylinder with a thin magnetic layer to satisfy multiple criteria: nearly monodisperse, easily imaged, and magnetic interaction dominant over gravity. We confirm long-predicted features of dipolar assembly and stress the microstructural variety brought about by shape and chemical anisotropy, especially by borrowing knowledge learned from molecules. We describe analogies to liquid crystalline deformations with bend, splay and twist; an analogy to cis/trans isomerism in organic molecules, which in this system can be controllably and reversibly switched; and a field-switching methodology to direct single ribbons into not only single but also multiple rings that can subsequently undergo hierarchical self-assembly. Going beyond earlier investigations of phase behavior, we show that dynamic reconfigurability presents subtle materials issues and possibilities.

8:48AM M30.00005 Study of Aggregation of Janus Ellipsoids , DONOVAN RUTH, Lehigh University, WEI LI, University of California Santa Barbara, SHREEYA KHADKA, Colgate University, JEFFREY RICKMAN, JAMES GUNTON, Lehigh University — We perform numerical simulations of a quasi-square well potential model of one-patch colloidal particles to investigate the collective structure of a system of Janus ellipsoids. We show that for Janus ellipsoids such that one half is an attractive patch, while the entire ellipsoid has a hardcore repulsion, the system organizes into a distribution of orientationally ordered micelles and vesicles. We analyze the cluster distribution at several temperatures and low densities and show that below certain temperatures the system is populated by stable clusters and depending on temperature and density the system is populated by either vesicles or micelle structures.

9:00AM M30.00006 Amphiphilic Janus cylinders at fluid-fluid interfaces , DAEYEON LEE, BUM JUN PARK, University of Pennsylvania, CHANG-HYUNG CHOI, CHANG-SOO LEE, Chungnam National University — We study the configuration and assembly of amphiphilic Janus cylinders at fluid-fluid interfaces at the single- and two-particle levels using experimental and theoretical approaches. We observe that high aspect ratio Janus cylinders have two configurations – upright and tilted orientation, whereas Janus cylinders with small aspect ratios adopt only the upright orientation. These configurations are confirmed by numerically calculating and minimizing the attachment energy of each Janus cylinder as a function of the orientation angle as well as the vertical displacement with respect to the interface. Unlike homogenous cylinders which show deterministic assembly behaviours at fluid-fluid interfaces, Janus cylinders exhibit a variety of assembly behaviours. We show the origin of such a diversity stems from the attractive capillary interactions between tilted Janus cylinders, which could be explained by the quasi-quadrupolar interface deformation that is caused by the wetting of the fluids on the particle surface. We will also describe our recent results involving the configuration and interactions of asymmetrically hydrophilic cylinders at an air-water interface.

9:12AM M30.00007 Thermodynamically Stable Pickering Emulsions Stabilized by Janus Dumbbells , FUQUAN TU, BUM JUN PARK, DAEYEON LEE, University of Pennsylvania — Janus particles have two sides with different, often opposite, surface properties. Janus dumbbell is one type of Janus particles that consists of two partially fused spherical lobes. It is possible to independently control the geometry and surface wettability of Janus dumbbells. Janus dumbbells can also be produced in a large quantity, making them useful for practical applications such as emulsion stabilization. In this work, we calculate the free energy of emulsion formation using amphiphilic Janus dumbbells as solid surfactants. In contrast to kinetically stable emulsions stabilized by homogeneous particles, emulsion stabilized by Janus dumbbells can be thermodynamically stable. There also exists an optimal radius of droplets that can be stabilized by infinite or limited number of amphiphilic dumbbells in the continuous phase. We demonstrate that the optimal radius of dumbbell-stabilized droplets can be predicted based on the volume of the dispersed phase and the volume fraction of dumbbells in the continuous phase. We believe our calculation will provide guidelines for using Janus dumbbells as colloid surfactants to generate stable emulsions.

9:24AM M30.00008 Analytic Solutions and Numerical Simulation of Self-Assemble Magnetic Colloidal Structures[1] , DAVID PIET, Northwesten University/Argonne National Laboratory, IGOR ARONSON, ALEX SNEZHKO, Argonne National Laboratory, ATHUR STRAUBE, Humboldt University of Berlin — Self-assembled magnetic colloidal structures that lie at a fluid-air interface can have a wide range of behavior, from localized axisymmetric star-like objects to linear, snake-like ones. Modeling these structures requires both the extensive use of the Navier-Stokes Equations from an analytic standpoint as well as the ability to numerically solve and simulate them alongside Newton's Equations. Analytically, these equations are approximated by an asymptotic expansion with a small viscosity. Using those expressions, simulations are run on GPU's to utilize their parallel capability. The result is a remarkable, qualitative recapturing of the experimentally observed behavior, namely, the formation of both snakes and stars from a randomized initial condition.

9:36AM M30.00009 Dynamic phases in non-equilibrium magnetic colloids at liquid interfaces under in-plane magnetic field driving[1] , ALEXEY SNEZHKO, Argonne National Laboratory, USA, GASPER KOKOT, Josef Stefan Institute, Ljubliana, Slovenia, DAVID PIET, Argonne National Laboratory, IGOR ARANSON, Argonne National Laboratory, USA — Ensembles of interacting colloidal particles subject to an external periodic forcing often develop nontrivial collective behavior. We study emergent phenomena in magnetic colloidal ensembles suspended at a liquid-air interface and driven out of equilibrium by alternating magnetic fields. We use ferromagnetic colloidal micro-particles (so the magnetic moment is fixed in each particle and interactions between colloids is highly anisotropic and directional) suspended over a water-air interface and energized by alternating magnetic fields applied in-pane of the interface. Experiments reveal new types of dynamic self-assembled phases (in particular, "wires," "rotators") emerging in such systems in a certain range of excitation parameters. Transition between different self-assembled phases with parameters of external driving magnetic field is observed. Molecular dynamic simulations captures some of the non-equilibrium self-assembled phases in our system.

[1]The research was supported by the U.S. DOE, Office of Basic Energy Sciences, Division of Materials Science and Engineering, under the Contract No. DE AC02-06CH11357

9:48AM M30.00010 Strictly Polyhedral Colloids Challenged by Electric Field , NOBUHIRO YANAI, MELINDA SINDORO, JING YAN, STEVE GRANICK, University of Illinois, Urbana-Champaign — We have succeeded in fabricating monodisperse polyhedral metal-organic framework (MOF) crystals. Here, the micron-sized rhombic dodecahedra are suspended in liquid as candidates for directed self-assembly. The application of AC electric field is found to produce assembly at various facets truncations, probably owing to induced dipole attraction, with linear chaining that we observe and analyze based on direct in-situ imaging. The facet-to-facet preference during assembly produces striking selectivity for these1D chains.

10:00AM M30.00011 Crystalline aggregates of magnetic colloidal particles[1] , JOSHUA E.S. SOCOLAR, CATHERINE C. MARCOUX, Physics Department, Duke University, Durham, NC, LIN FU, PATRICK CHARBONNEAU, Duke Chemistry, YE YANG, BENJAMIN B. YELLEN, Duke Mechanical Engineering and Materials Science — A colloidal system of magnetic and non-magnetic spheres confined to a 2D monolayer has been found to form a variety of structures, including Kagome, honeycomb, and square lattices, as well as various chain and ring configurations [1]. In these experiments, the layer of beads is immersed in a ferrofluid and placed in an external magnetic field and the different structures are obtained for different values of the relative concentrations of the bead types, the susceptibility of the ferrofluid, and the angle of the field with respect to the assembly plane. We study an approximate model for the potential energy of the system based on self-consistent solutions for the magnetic moments of point dipoles. We find that the model accounts well for the stability of the observed phases and we identify additional possible phases via a genetic algorithm that searches for crystal structures with up to ten atoms per unit cell. Further calculations suggest the possibility of creating materials with strong elastic responses to applied magnetic fields.

10:12AM M30.00012 Using chaotic Faraday waves to create a two-dimensional pseudo-thermal bath for floating particles with tunable interaction potentials

, KYLE WELCH, ISAAC HASTINGS-HAUSS, RAGHUVEER PARTHASARATHY, ERIC CORWIN, Materials Science Institute and Department of Physics, University of Oregon — Whether chaos in actively driven systems can be described by an effective temperature is an unresolved question in the study of nonlinear physics. We use chaotic Faraday waves to create a two-dimensional pseudo-thermal bath to investigate tunable interactions between floating particles. By vertically oscillating a liquid with an acceleration greater than g we excite the Faraday instability and create surface waves. Increasing this acceleration above some critical value causes this instability to become chaotic with fluctuations over a broad range of length scales. Particles placed on the surface are buffeted by random excitations in analogy to Brownian motion. We can change the "temperature" of the pseudo-thermal bath by manipulating the driving frequency and amplitude, a feature of the system we verify using real-time tracking to follow the diffusive movement of a single particle. With an eye toward creating complex self-assembling systems we use this system to measure the tunable interaction potential in two-, three-, and many-particle systems and to probe the effects of particle size, shape, symmetry, and wetting properties.

10:24AM M30.00013 Twisted results on interior packing and surface energy for filament bundles

, ISAAC BRUSS, GREGORY GRASON, University of Massachusetts - Amherst — Twisted filament bundles are a common structural motif found in both natural and synthetic systems. Examples range from protein assemblies such as collagen and fibrin, to artificial structures such as carbon nanotube ropes and microfabricated materials. They are oftentimes found to self-assemble from fibers via various adhesive interactions, be they depletion, capillary, or other such forces. In these assemblies, twist frustrates the perfect crystalline order of the fibers, requiring the presence of defects in the packing. Through numerical simulations, we discover defect organizations ranging from dislocations and grain boundaries for low twist, to multi-five-fold disclination clusters for high twist. And furthermore, by developing and employing an analytical continuum model, we find that for sufficiently long fibers, twist reduces the surface energy of the assembly. Together, this suggests that the equilibrium lowest energy state of a filament bundle may be twisted regardless of any intrinsic chirality present in the system.

10:36AM M30.00014 Kinetics of Phase Separation in Binary Mixtures

, SHAISTA AHMAD, Department of Chemical Engineering, Pennsylvania State University, University Park, PA - 16802, SUBIR K. DAS, Theoretical Sciences Unit, Jawaharlal Nehru Center for Advanced Scientific Research, Jakkur, Bangalore - 560064, India, SANJAY PURI, School of Physical Sciences, Jawaharlal Nehru University, New Delhi - 110067, India — We present numerical simulation results of the phase separation kinetics in three-dimensional symmetric binary fluid mixtures and binary solid mixtures. In the former system, our extensive molecular dynamics simulation is able to probe an extended period where the domain size grows linearly with time, leading to an unambiguous confirmation of the viscous hydrodynamic regime. On the other hand, for the binary solid mixture, we use Monte Carlo simulation with spin-exchange dynamics to verify the Lifshitz-Slyzov growth law. In spite of the differences in the growth mechanisms, the pair correlation functions and structure factors of the two systems overlap, indicating similarity in the morphologies during phase separation.

10:48AM M30.00015 Cooperative Symmetry Breaking from One to Three Dimensions in Multi-Component Double Emulsions

, LAURA ADAMS, Physics Department and SEAS Harvard University, JACY BIRD, Mechanical Engineering Department, Boston University, JAIWEI YANG, SEAS Harvard University, THOMAS FRANKE, Microfluidic Group, EPI, Universtat Augsburg, Universitatsstr 1, Augsburg, Germany and Harvard University, VINOTHAN MANOHARAN, DAVID WEITZ, Physics Department and SEAS Harvard University — We follow the evolution of aqueous inner drops confined in a thin sheath of oil in the dimensional crossover from one to three dimensions using a fast camera and microfluidics. Surprisingly, inner drops interact cooperatively to pair with their next nearest neighbor to transform their linear configuration into a three dimensional composite sphere. The measured time scales of transforming these multi-component double emulsions are investigated as a function of number, size, and composition of inner drops. We model the dynamics to understand and predict how both folding and buckling occur in these complex microfluidic systems.

Session M31 DPOLY: Polymer Melts and Solutions

339 - Megan Robertson, University of Houston

8:00AM M31.00001 Uniaxial Extension of Entangled Polymer Melts close to T_g[1]

, HAO SUN, SHI-QING WANG, The University of Akron — Transient (nonlinear) responses of entangled polymers to startup deformation indicate a transition from the initial elastic deformation to irreversible deformation (flow) [1-3]. This yielding behavior varies with the applied rate: at a higher rate the entanglement network can be strained to a higher degree before its breakdown. In this work, we subject entangled melts such as polystyrene to startup uniaxial extension to show how yielding takes place as a function of temperature. The objective is to explore whether there would be any mechanical signature of emergence of any secondary structure as the glass transition temperature T_g is approached from above.

8:12AM M31.00002 Non-Gaussian chain stretching in simple shear of branched polystyrene solutions[1]

, GENGXIN LIU, Department of Polymer Science, The University of Akron, HYOJOON LEE, Department of Chemistry, Pohang University of Science and Technology, HONGWEI MA, SHIWANG CHENG, RODERIC QUIRK, Department of Polymer Science, The University of Akron, TAIHYUN CHANG, Department of Chemistry, Pohang University of Science and Technology, SHI-QING WANG, Department of Polymer Science, The University of Akron, DEPARTMENT OF POLYMER SCIENCE THE UNIVERSITY OF AKRON TEAM, DEPARTMENT OF CHEMISTRY, POHANG UNIVERSITY OF SCIENCE AND TECHNOLOGY TEAM — Entangled polymers with long chain branching (LCB) exhibit a higher apparent viscosity than the zero-rate viscosity upon startup uniaxial extension whereas polymers either of linear chains or with LCB only show a lower transient viscosity than the zero-rate viscosity envelope. We report for the first time that simple shear of well-entangled polystyrene solutions with LCB produces a higher transient viscosity than the zero-shear envelope. In presence of sufficient LCB, non-Gaussian stretching can even show up in simple shear, which was previously observed only in uniaxial extension. Moreover, LCB resists against a structural breakdown of the entanglement network, postponing the stress overshoot to an unprecedented high shear strain of 30 units when the backbone of the PS would be nearly straightened without retraction and resulting elastic recovery as high as 20 strain units.

[1]This work is supported by NSF under DMR 1105135.

8:24AM M31.00003 Tube diameter of oriented polymer melts , JIAN QIN, University of Chicago, SCOTT MILNER, Pennsylvania State University — The tube diameter is a key material parameter controlling the flow behavior of polymer melts. The Lin-Noolandi ansatz successfully accounts for the dependence of the tube diameter on polymer density, chain stiffness and diluent concentration. We extend the Lin-Noolandi ansatz to polymer melts under uniform tension. We find that the tube diameter a decreases as $F^{-1/2}$ when the pulling force F exceeds the thermal tension k_BT/a, and approaches a limiting value for typical flexible polymers near full extension of about half the unperturbed value. Our prediction is compatible with assumptions made in the GLaMM model [1] for polymer rheology. We have directly verified the predicted force-dependence of tube diameter by using isoconfigurational ensemble averaging [2] to measure the tube diameter in simulations of oriented polymer melts. In the simulations, the chains are oriented by pulling on the ends of the chains, and topologically equilibrated by allowing the chains to occasionally cross.

8:36AM M31.00004 An Intriguing Empirical Rule for Estimating the First Normal Stress Difference from Steady Shear Viscosity Data for Concentrated Polymer Solutions and Melts , VIVEK SHARMA, University of Illinois at Chicago, GARETH MČKINLEY, Mechanical Engineering, Massachusetts Institute of Technology, Cambridge, MA — The Cox-Merz rule and Laun's rule are two empirical relations that allow the estimation of steady shear viscosity and first normal stress difference, respectively, using small amplitude oscillatory shear measurements. The validity of the Cox-Merz rule and Laun's rule imply an agreement between the linear viscoelastic response measured in small amplitude oscillatory shear and the nonlinear response measured in steady shear flow measurements. We show that by using a lesser known relationship also proposed by Cox and Merz, in conjunction with Laun's rule, a relationship between the rate-dependent steady shear viscosity and the first normal stress difference can be deduced. The new empirical relation enables *a priori* estimation of the first normal stress difference using only the steady shear viscosity vs shear rate data. Comparison of the estimated first normal stress difference with the measured values for six different polymer solutions and melts show that the empirical rule provides values that are in reasonable agreement with measurements over a wide range of shear rates; thus deepening the intriguing connection between linear and nonlinear viscoelastic response of entangled polymeric materials.

8:48AM M31.00005 Assumptions in Entanglement models and Their Effect on Non-Linear Rheology Predictions , MARAT ANDREEV, RUDI STEENBAKKERS, JAY SCHIEBER, Illinois institute of Technology — While tube and slip-link theories are able to describe shear flow stresses qualitatively, and in some cases quantitatively, elongational flow prediction remains elusive. Both the GLaMM tube theory and primitive chain network simulations overpredict the magnitude of stress. As a result, several groups have suggested making the friction chain-conformation dependent, giving an enhancement to stress relaxation in elongational deformations when chains are highly oriented. Here we take a different tack, and examine the effect of typical assumptions and approximations made in these theories by use of the discrete slip-link model. Since the model exists on a relatively detailed level of description, it allows examination of assumptions without resorting to crude approximations. We find that while some of these approximations indeed fail in elongational flows at high strains, the theory is still unable to predict data. What's more, unlike other predictions, this model underpredicts the stress, and would therefore not be in agreement with the assumption of conformation-dependent friction as currently hypothesized.

9:00AM M31.00006 Microscopic Theory of Entangled Polymer Melt Dynamics: Flexible Chains as Primitive-Path Random Walks and Super Coarse-Grained Needles , KEN SCHWEIZER, University of Illinois at Urbana-Champaign, DANIEL SUSSMAN, University of Pennsylvania — We qualitatively extend our recent microscopic dynamical theory for the transverse confinement potential and diffusion of infinitely thin rigid rods (PRL, 107, 078102 (2011)) to construct a first-principles theory of topologically entangled melts of flexible polymer chains (PRL, 109, 168306 (2012)). Polymer coils are treated as ideal random walks of self-consistently determined primitive-path (PP) steps, and chain uncrossability is included exactly at the binary collision level. A strongly anharmonic (tube) confinement potential for a primitive path segment is derived and favorably compared with recent simulations. A fundamental basis is derived for the Lin-Noolandi conjecture that relates the tube diameter to the invariant packing length, along with the reptation scaling laws for the diffusion constant and terminal relaxation time, including numerical prefactors. The relationship of the PP-level theory to two simpler models, the melt as a disconnected fluid of primitive-path steps, and a super coarse-graining that replaces the entire chain by a needle corresponding to its end-to-end vector, is examined. Remarkable connections between the different levels of coarse graining are discovered.

9:12AM M31.00007 Entanglement elasticity in polymer chain melts: microscopic calculation of the rubbery plateau modulus via intermolecular correlations , DANIEL SUSSMAN, University of Pennsylvania, KEN SCHWEIZER, University of Illinois at Urbana-Champaign — Textbook models of stress relaxation in melts of entangled polymer chains are built on the assumption that intra-molecular or backbone stresses are the dominant contribution to the system's total stress. Numerous simulations over the last two decades have challenged this assumption, but calculating the intermolecular or non-bonded contribution to the stress has proven a daunting theoretical task. Building on our recent progress in microscopically constructing the transverse confinement field of entangled rods (PRL 107, 078102 (2011)) and ideal coils (PRL 109, 168306 (2012)), we explicitly separate stress correlations into intra- and inter-molecular terms, and calculate the contribution of intermolecular stress correlations in the "plateau" region of stress relaxation. We derive, with no adjustable parameters, the characteristic relation $G_e \sim k_BT/p^3$ (where p is the packing length) with a prefactor that agrees within a factor of two with experiment and simulation. This theoretical advance has major implications for the effect of nonlinear deformation, confinement, and chain orientational ordering on entanglement elasticity.

9:24AM M31.00008 Influence of Reversibly Associating Side Group Bond Strength on Viscoelastic Properties of Polymer Melts[1] , CHRISTOPHER LEWIS, KATHLEEN STEWART, MITCHELL ANTHAMATTEN, University of Rochester — Reversible hydrogen-bonding between side-groups of linear polymers can sharply influence a material's dynamic mechanical behavior, giving rise to valuable shape memory and self-healing properties. Here, we investigate how bond-strength affects the bulk rheological behavior of functional poly(n-butyl acrylate) (PBA) melts. A series of random copolymers containing three different reversibly bonding groups (aminopyridine, carboxylic acid, and ureidopyrimidinone) were synthesized to systematically vary the side-group hydrogen bond strength (∼26, 40, 70 kJ/mol). The materials' volumetric hydrogen-bond energy densities can be tuned by adjusting the side-group composition. By comparing the viscoelastic behavior of materials containing an equivalent bond energy density, with different bonding groups, the efficacy and cooperativity of reversible binding can be directly examined. Melt rheology results are interpreted using a state-of-ease model that assumes continuous mechanical equilibrium between applied stress and resistive stresses of entropic origin arising from a network of reversible bonds.

9:36AM M31.00009 Correction of Doi-Edwards' Green function in harmonic potential and its implication for stress-optical rule[1]

, TSUTOMU INDEI, JAY SCHIEBER, Illinois Institute of Technology, Department of Chemical and Biological Engineering, and Center for Molecular Study of Condensed Soft Matter — We derive a corrected Green's function for a polymer chain trapped in a two-dimensional anisotropic harmonic potential with a fixed boundary condition. This Green's function is a modified version of what Doi and Edwards first derived to describe the polymer chain trapped in the tube-like domain of surrounding entangled polymers [J. Chem. Soc. Farad. Trans. II 74 (1978) 1802]. In contradiction to the results found by Ianniruberto and Marrucci using the incorrect Green's function [J. Non-Newtonian Fluid Mech. 79 (1998) 225], we find that the stress-optical rule is violated for any tube potential either circular or elliptic. The violation is due to the presence of the virtual springs to trap the chain in the tube rather than the anisotropy of the confinement potential.

9:48AM M31.00010 Explaining the absence of high-frequency relaxation modes of polymers in dilute solutions

, INDRANIL SAHA DALAL, RONALD LARSON, University of Michigan — Using multi-scale modeling, including Molecular Dynamics and Brownian dynamics (BD) simulations, we explain the long-mysterious absence of high frequency modes in the dynamics of isolated polymer chains in good solvents, reported years ago by Schrag and coworkers. The relaxation spectrum we obtain for a chain of 30 monomers at atomistic resolution is, remarkably, a single exponential while that of a chain of 100 monomers is fit by only two modes. This result is surprising in view of the many relaxation modes present in melts of such chains, but agrees perfectly with experimental observations (Peterson et al. J. Polym. Sci.: Part B 2001). We also performed BD simulations in which the explicit solvent molecules are replaced by a viscous continuum. Although the local dynamics is suppressed with the addition of bending, torsion, side groups and excluded volume interactions (as suggested in Jain and Larson, Macromolecules 2008), none of the BD simulations predict a single exponential relaxation for a short chain. Our results indicate that the chain dynamics at small length scales (down to a few Kuhn steps) is significantly different from the predictions of models based on a continuum solvent, and finally help explain the experimental results of Schrag and coworkers.

10:00AM M31.00011 Simultaneous determination of the interaction parameter and topological scaling features of polymers in dilute solutions

, DURGESH RAI, GREGORY BEAUCAGE, University of Cincinnati, RATKANTHWAR KEDAR, NIKOS HADJICHRISTIDIS, University of Athens, HONG KUNLUN, DAVID UHRIG, Oak Ridge National Laboratory, ANDY TSOU, ExxonMobil Research & Engineering Company — The RPA equation using the Debye polymer chain scattering function has been widely used to model polymer blends of linear chains in the melt where it is safe to assume a Gaussian conformation. When chains display more complicated topologies or when chains are in dilute solution Gaussian scaling no longer applies. In some cases the Zimm double extrapolation has been used to determine the second virial coefficient and the interaction parameter under the assumption that the deviation of chain scaling from a random walk is acceptable in the low qRg region such as when light scattering is used. If it is of interest to explicitly determine the nature of chain scaling, related to topology or solvent quality, as well as to quantify the thermodynamic interaction, such as in studies of cyclic and branched chains, networks, or polymers in good solvents, there is no analytically valid scattering model for data analysis. We propose the coupling of the unified scattering function with the RPA equation to analytically model these effects. Nevertheless, some issues remain to be resolved with star polymers in particular, such as scattering from highly branched high molecular weight symmetric stars in good solvents where it appears that the Daoud-Cotton model may be appropriate but a colloidal scattering model may be more appropriate.

10:12AM M31.00012 Anisotropic Thermal Conduction in Polymers and its Molecular Origins[1]

, JAY SCHIEBER, DAVID VENERUS, SAHIL GUPTA[2], Illinois Institute of Technology — The strong coupling of mechanical and thermal effects in polymer flows have a significant impact on both the processing and final properties of the material. Simple molecular arguments suggest that Fourier's law must be generalized to allow for anisotropic thermal conductivity in polymers subjected to deformation. In our laboratory we have developed a novel application of the optical technique known as Forced Rayleigh Scattering to obtain quantitative measurements of components of the thermal diffusivity (conductivity) tensor in polymers subjected to deformations. We report measurements of anisotropic thermal diffusivity and stress in molten, cross-linked and solid polymers subjected to several types of flows. The deformed samples have significant anisotropy in polymer chain orientation that results in significant anisotropy in thermal conductivity. Stress and thermal conductivity data support the validity of the stress-thermal rule, which is analogous to the well-known stress-optic rule. We also report measurements on solid polymers with isotropic polymer chain orientation that are under stress, which display rather unexpected behavior. These measurements are used to develop an understanding of the molecular origins of anisotropic thermal conduction in polymeric material

[1]NSF-DMR-706582

10:24AM M31.00013 Molecular modeling simulations in phase stability of polyethylene solutions at elevated pressures

, MOEED SHAHAMAT, McGill University, ALEJANDRO D. REY, Professor-McGill University — Molecular dynamics (MD) simulations using the OPLS-AA force field are conducted to compute pressure, molecular weight dependence of Hildebrand's solubility parameters (SP) and density of hexane and high-density polyethylene (HDPE) at high pressures from 100 to 3000 bar. The electrostatic energy contribution to the cohesive energy and density leads to increases in the SP with pressure for molecular mechanical models (MMM) with and without electrostatic terms. The Flory-Huggins interaction parameter (IP) predicted from the pressure dependence of SPs and molar volumes decreases upon increasing pressure, indicating that miscibility improves by raising pressure. This is consistent with the solution polymerization process for producing PE, where pressure-induced phase separation (PIPS) is used to separate the polymer from solution. Exclusion of electrostatic potentials in the MMM results in larger IPs while the decreasing trend remains intact with and without electrostatic forces. There is a pressure limit beyond which the IP has less sensitivity to pressure indicating that PE miscibility is not further affected. It is shown that pressure increases the chemical potential factor of the phase stability condition, stabilizing the solution. These results contribute to the fundamental understanding of PIPS, an important demixing process poorly understood when compared to thermally-induced phase separation.

10:36AM M31.00014 Miscibility of Polymers in Supercritical Solvents[1]

, JEFFREY DEFELICE, JANE LIPSON, Dartmouth College — In this work we make use of our ability to correlate underlying thermodynamic behavior with trends in miscibility to study mixtures of polymers and supercritical carbon dioxide ($scCO_2$). $scCO_2$ has garnered significant interest as a "green" solvent, and supercritical solvent in general, for its highly accessible critical point. Experimental cloud point investigations have determined the miscibility for a range of polymers in $scCO_2$. We have used a simple equation of state (EOS) to study a series of poly-(acrylates) in $scCO_2$ solvent. Although polymer/$scCO_2$ mixtures have been modeled with some success in the past, the ability of an EOS to make accurate predictions has yet to be demonstrated. Our mixture modeling procedure yields parameters from pure component experimental data. Then, by pinning the mixed interaction parameter to the experimental critical temperature (T_c) for one mixture from the series, we predict the T_c shifts for the remaining members. In addition to discussing miscibility we draw insight via the trends revealed from the parameterization of the pure component data, alone.

10:48AM M31.00015 The effect of topology on the conformations of cyclic polymers in melts , MICHAEL LANG, JAKOB FISCHER, JENS-UWE SOMMER, Leibniz Institut für Polymerforschung Dresden, Hohe Straße 6, 01069 Dresden, Germany, THEORIE DER POLYMERE TEAM — The bond fluctuation method is used to simulate both non-concatenated entangled and interpenetrating melts of cyclic polymers. We find that the swelling of interpenetrating rings upon dilution follows the same laws as for linear chains. The knotting probability of cyclic polymers decays exponentially as function of the number of blobs per chain. A power law dependence $f_n \sim \phi R^2 \sim \phi^{0.77} N$ for the average number f_n of linked rings per cyclic polymer at concentrations larger than the overlap volume fraction of rings ϕ^* is determined from the simulation data. The fraction of non-concatenated cyclic polymers displays an exponential decay $P_{OO} \sim \exp(-f_n)$, which indicates f_n to provide the entropic effort for not forming concatenated conformations. These results lead to four different regimes for the conformations of cyclic polymers in melts separated by critical lengths N_{OO}, N_C and N^* that describe the onset of concatenation, the cross-over between weak and strong compression, and the cross-over to an overlap dominated concatenation contribution. The four characteristic exponents describing ring size in these regimes are 1/2, 2/5, 3/8, and 4/9 as confirmed by simulation data for the first three regimes.

Wednesday, March 20, 2013 8:00AM - 11:00AM –

Session M32 DPOLY: Focus Session: Polymer Nanocomposites: Dynamics 340 - Laura Clarke, North Carolina State University

8:00AM M32.00001 Polymer Dynamics in Nanocomposites and under Confinement , DIETER RICHTER, Juelich Centre for Neutron Science, Forschungszentrum Juelich, 52425 Juelich Germany — In this talk I will present neutron spin echo investigations on polymers interacting attractively with nanoparticles or confining surfaces. Polyethylene-oxide (PEO) was filled with neat SiO_2 nanoparticles up to 15 vol%. Investigating a short chain matrix we realised that a fraction of chains is adsorbed at the nanoparticle surface suppressing completely its translational diffusion. Nevertheless these adsorbed chains undergo an unchanged segmental dynamics seemingly forming a micelle like corona of chains connected with their OH-end groups. Changing to methylene terminated chains the picture changes drastically now showing a tightly adsorbed layer that however is not glassy as often assumed but undergoes pico second local dynamics. These results are corrobated and extended in studying the dynamics of Polydimethylsiloxane (PDMS) confined in nanoporous Alumina. There a partly anchored chain fraction is found that undergoes restricted Rouse motions with segmental mobilities as in the bulk phase. The size of this layer exceeds significantly the length scale of the directly adsorbed polymer, presenting a first direct microscopic evidence for the hypothetical interphase.

8:36AM M32.00002 Universal Scaling of Polymer Diffusion in Nanocomposites , JIHOON CHOI, MICHAEL J.A. HORE, Department of Materials Science and Engineering, University of Pennsylvania, JEFFREY S. METH, DuPont Nanocomposite Technologies, Central Research & Development, NIGEL CLARKE, Department of Physics and Astronomy, The University of Sheffield, KAREN I. WINEY, RUSSELL J. COMPOSTO, Department of Materials Science and Engineering, University of Pennsylvania — The tracer diffusion of deuterated polystyrene (dPS) is measured in a polystyrene (PS) nanocomposite containing hard and soft silica nanoparticles (NPs). The soft NPs are grafted with a PS brush (87 kg/mol). The matrix for both NPs is PS (160 kg/mol). The diffusion coefficients for dPS (23 - 1,866 kg/mol) decrease as the hard and soft NP volume fractions increase. To accurately determine the interparticle distances (ID) relevant to each dPS (M) diffusing through the PS(160k):soft NP matrix, self consistent field theory and small angle neutron scattering studies were performed; both theory and experiment show that short dPS chains can deeply penetrate the brush, whereas longer dPS chains only penetrate the periphery and mainly remain in the matrix. The reduced diffusion coefficient (D/D_0), plotted against the confinement parameter, namely ID relative to tracer size ($2R_g$), collapses onto a master curve independent of NP type. These experiments demonstrate that polymer diffusion in nanocomposites is captured by the confinement parameter over an extremely wide range of $ID/2R_g$ and, hopefully, motivate new models to capture the dynamics in confined ($ID/2R_g < 10$) regimes.

8:48AM M32.00003 Hopping Diffusion of Nanoparticles Subjected to Topological Constraints[1] , LI-HENG CAI, Department of Chemistry, University of North Carolina at Chapel Hill, SERGEY PANYUKOV, P. N. Lebedev Physics Institute, Russian Academy of Sciences, MICHAEL RUBINSTEIN, Department of Chemistry, University of North Carolina at Chapel Hill — We describe a novel hopping mechanism for diffusion of large non-sticky nanoparticles subjected to topological constraints in polymer solids (networks and gels) and entangled polymer liquids (melts and solutions). Probe particles with size larger than the mesh size of unentangled polymer networks (tube diameter of entangled polymer liquids) are trapped by the network (entanglement) cages at time scales longer than the relaxation time of the network (entanglement) strand. At long time scales, however, these particles can move further by hopping between neighboring confinement cages. This hopping is controlled by fluctuations of surrounding confinement cages, which could be large enough to allow particles to slip through. The terminal particle diffusion coefficient dominated by this hopping diffusion is appreciable for particles with size slightly larger than the network mesh size (tube diameter). Very large particles in polymer solids will be permanently trapped by local network cages, whereas they can still move in polymer liquids by waiting for entanglement cages to rearrange on the relaxation time scale of the liquids.

9:00AM M32.00004 The Role of Excluded Volume on the Reduction of Polymer Diffusion into Nanocomposites , JEFF METH, DuPont Co, SANGAH GAM, RUSSELL COMPOSTO, KAREN WINEY, University of Pennsylvania — An analytic model for the reduction of polymer chain diffusion in nanocomposites attributable to excluded volume effects is presented. The nanocomposite is modeled as an ensemble of cylinders through which the polymer chain diffuses. The distribution of cylinder diameters in the ensemble is predicted from statistical mechanical theories based on the packing of spheres. The reduction in polymer diffusion is accounted for by the truncation of the partition function for a random walk in a cylinder. For low loadings of spherical particles in nanocomposites, we show that this theory results in a master curve for the reduced diffusion coefficient. The theory, with no adjustable parameters, is in agreement with recent data for tracer diffusion measurements in polymer nanocomposites at low loading.

9:12AM M32.00005 Diffusivity and Transient Localization of Filler Particles in Polymer Melts and Crosslinked Systems , ZACHARY E. DELL, KENNETH S. SCHWEIZER, University of Illinois at Urbana-Champaign — Building on recent progress in describing the microscopic equilibrium structure of polymer nanocomposites (PRISM theory), as well as the naïve mode coupling and nonlinear Langevin equation approaches for predicting localization and activated barrier hopping, we have initiated the study of dynamical phenomena in nanocomposites at finite filler loading. A colloidal suspension perspective is adopted whereby the polymer dynamics are assumed to remain unperturbed by fillers. Both entangled polymer melts and crosslinked systems are studied. The long time behavior of a tagged nanoparticle (localization and diffusivity) is calculated for various melt (tube diameter, polymer radius of gyration) and nanoparticle (filler size and volume fraction, polymer-filler attraction strength) parameters. For transiently localized particles, a dynamic free energy is constructed and employed to compute the nanoparticle localization length, mean barrier hopping time, and self-diffusion constant. The influence of filler-filler interactions on the Stokes-Einstein violation phenomenon in entangled melts is established. In addition, the influence of nanocomposite statistical structure (e.g., in the depletion, steric stabilization, or bridging regimes) on slow dynamics and localization is investigated.

9:24AM M32.00006 Nanoparticle diffusion in dense polymer melts , JAGANNATHAN T. KALATHI, SANAT K. KUMAR, Columbia University, GARY S. GREST, Sandia National Laboratories — The diffusion of nanoparticles in melts and solutions of polymers facilitates understanding of the viscoelastic behavior of the respective polymers and their composites. It also plays a vital role in determining the equilibrium structure and morphology of polymer nanocomposites and hence, their mechanical properties. In this work, we present the diffusion coefficients of non-sticky smooth spherical particles of different sizes (1-10 σ) in an athermal mixture of particles and polymers of different chain lengths (N = 20 to 400) using molecular dynamics simulations. The diffusion of nanoparticles of size comparable to the polymer segment size (σ) is independent of chain length and hence, nanoparticles apparently feel only the local viscosity, as predicted by scaling theories. When the nanoparticle becomes larger than a segment (or alternately the correlation length in the melt), then, the diffusion coefficient decreases. This is due to the fact that the mobility of the particles is retarded either by a chain section of size equivalent to the particle size or by entanglement mesh size depending on the nanoparticle size. We also elucidate the role of chain entanglements on diffusion of nanoparticles.

9:36AM M32.00007 Entanglement-Controlled Subdiffusion of Nanoparticles within Concentrated Polymer Solutions , R.L. LEHENY, JHU, H. GUO, UCSD, G. BOURRET, R.B. LENNOX, M. SUTTON, McGill U., J.L. HARDEN, U. Ottawa — Microrheology techniques, in which colloids suspended in a complex fluid probe their mechanical environment, can provide unique information on the microscopic length scales characterizing the fluid's hierarchical structure. We describe x-ray photon correlation spectroscopy (XPCS) experiments tracking the motion of colloidal gold nanoparticles in solutions of high-molecular-weight polystyrene. The particle radius is tuned to be comparable to the length scales characterizing the entangled polymer mesh. Over displacements of nanometers to tens of nanometers, the particles undergo subdiffusive motion in which the particle mean-squared displacement grows as a power law in time, with power-law exponent, $\alpha < 1$, that depends on solution conditions. Scaling behavior of the nanoparticle mobility with respect to temperature and to polymer concentration and molecular weight indicates the subdiffusion results from the temporal evolution of the entanglement mesh in the immediate vicinity of the particles. The results thus provide a novel microscopic dynamical characterization of a key structural property of polymers and more broadly demonstrate the capability of XPCS-based microrheology to interrogate heterogeneous mechanical environments in nanostructured soft materials.

9:48AM M32.00008 Segmental Dynamics of Polymer Nanocomposites by Dielectric Relaxation Spectroscopy , SHUSHAN GONG, QUAN CHEN, RALPH COLBY, JOSEPH MOLL, SANAT KUMAR, None — The addition of nanoparticles dramatically affects the physical properties of polymer melts. The general agreement on this interaction mechanism is that the polymer-filler interface is the key region for the changes of properties. Previous studies have suggested the existence of a bound polymer layer in this interfacial region by various techniques. Here, we use Dielectric Relaxation Spectroscopy (DRS) to study the segmental relaxation of poly-2-vinylpyridine (P2VP) nanocomposites by the presence of silica nanoparticles (NPs), with sizes ranging from 14nm to 100nm. For nanocomposites with large amounts of surface area per unit volume (i.e., 14 nm NPs at high loadings) the segmental relaxation dispersion is broadened significantly, suggesting that the bound layer of P2VP is slower than the bulk P2VP, which is attributable to a restriction from solid surface of NPs. Additionally, the thickness of the bound polymer layer is estimated from the reduction in the magnitude of the segmental relaxation.

10:00AM M32.00009 Dissipative Particle Dynamics Simulations of Polymer Nanocomposites , NIGEL CLARKE, ARGYRIOS KARATRANTOS, University of Sheffield, RUSSELL COMPOSTO, KAREN WINEY, University of Pennsylvania — We investigate the topological constraints (entanglements) in polymer - nanorod nanocomposites in comparison to polymer melts using dissipative particle dynamics (DPD) simulations. The nanorods have a radius smaller than the polymer radius of gyration. We observe an increase in the number of entanglements, corresponding to a 50% decrease of the entanglement degree of polymerization in the case of 0.11 volume fraction of nanorods dispersed in the polymer matrix, in the nanocomposites as evidenced by larger contour lengths of the primitive paths. The end-to-end distance is essentially unchanged with the nanorod volume fraction for the range of concentrations that we have studied. An increase of the nanorod radius reduces the polymer - nanorod entanglements while the polymer – polymer entanglements remain unaffected. Interaction between polymers and nanorods affects the dispersion of nanorods in the nanocomposites and also alters the primitive path.

10:12AM M32.00010 Polymer Chain Conformation in CNT/Polystyrene Nanocomposites by SANS , WEI-SHAO TUNG, University of Pennsylvania, VIKKI J. BIRD, University of Durham, NIGEL CLARKE, University of Sheffield, RUSSELL J. COMPOSTO, KAREN I. WINEY, University of Pennsylvania — Polymer conformations are a critical factor that affects the performance of polymer nanocomposites. Using small angle neutron scattering, we probed chain conformations and confinement of polymers in both SWCNT/polystyrene ($R_{SWCNT} < R_g$) and MWCNT/polystyrene ($R_{MWCNT} \sim R_g$) nanocomposites. Through contrast matching experiments, we optimize the dPS:hPS ratio (0.725:0.275) to minimize the scattering from CNTs. To fit the scattering data, we developed a fitting model that includes scattering from polymer chains, rod networks, and defects. We found that the rod network scattering increases as the CNT concentration increases (0.3wt% - 10wt%) in both SWCNT and MWCNT composites, and the rod network scattering is much higher for SWCNT due to the smaller mesh size. When the CNTs concentration is below 2wt%, there is no significant change in R_g for both SWCNT and MWCNT nanocomposites. Above 2wt%, the R_g for SWCNT nanocomposites increases monotonically as a function of CNT concentration ($\sim$ 30% increase for 10wt% SWCNT loading), while the R_g for MWCNT is not affected.

10:24AM M32.00011 Microscopic theory for tube confinement and self-diffusivity of entangled needle liquids in presence of hard spherical obstacles , UMI YAMAMOTO, KENNETH SCHWEIZER, University of Illinois, Urbana-Champaign — A microscopic theory for the motion of topologically entangled, non-rotating needles in presence of spatially fixed, hard sphere inclusions has been formulated. Exact two-body dynamical uncrossability constraints are imposed, and an effective Brownian evolution equation at two-needle level is self-consistently constructed. The needle transverse localization length (effective tube diameter) and long-time diffusivity are determined as a function of its length and concentration, the sphere diameter and volume fraction, and needle-sphere liquid pair structure. In contrast to single-component entangled needle liquids, the transverse and longitudinal diffusivity become coupled, and reptation is increasingly suppressed with sphere volume fraction in a manner that depends on the relative sphere-needle size. The slow dynamics also depends on needle concentration, reflecting a competition between inter-needle topological uncrossability constraints and needle-sphere excluded volume interactions. The effective tube diameter is a monotonically decreasing function of the sphere density, consistent with the suppression of polymer translational diffusion. Extension to treat entangled flexible chains, and comparison with recent simulations and experiments, are under study.

10:36AM M32.00012 Dynamics of nanoparticles in non-Newtonian aqueous dispersions , JACINTA CONRAD, FIROOZEH BABAYE KHORASANI, RAMANAN KRISHNAMOORTI, University of Houston — The transport properties of nanoparticles in soft complex media are relevant for polymer and hydrogel nanocomposites but are still poorly understood. We use single-particle tracking to measure the diffusional dynamics of nanoparticles in non-Newtonian aqueous polymer solutions, which also serve as models of viscoelastic porous media. We track the motion of polystyrene nanoparticles of diameter 400 nm in aqueous solutions of hydrolyzed polyacrylamide whose radii of gyration are comparable to the diameter of the nanoparticles over a wide range of dilute and semi-dilute concentrations. At all concentrations, the mean-square displacement (MSD) of nanoparticles at long times is linearly proportional to time, indicating diffusive motion. The viscosity extracted from the MSD systematically varies with polymer concentration but is smaller than the zero shear rate viscosity measured at each polymer concentration using bulk rheometry, indicating that the dynamics cannot be explained in the context of microrheology of viscous solutions.

10:48AM M32.00013 The impact of fragility on the properties of the glass formation of polymer nanoparticle composites[1] , BEATRIZ A. PAZMINO BETANCOURT, Physics Dept., Wesleyan University, Middletown, CT, JACK F. DOUGLAS, Polymer Division, NIST, Gaithersburg, MD, FRANCIS W. STARR, Physics Dept., Wesleyan University, Middletown, CT — We investigate the effects of nanoparticles on glass formation in a model polymer melt by molecular dynamics simulations. The addition of nanoparticles allows us to change the relaxation time, glass transition temperature T_g, the fragility of glass formation in a controlled fashion. We show that the structural relaxation for different temperatures, concentrations, and polymer-NP concentrations can be expressed in terms of a simple universal function of the short-time Debye-Waller factor. We further examine how the stretching exponent β and the degree of the breakdown of the Stokes-Einstein relation depend upon fragility, which we relate to the extent of cooperative motion.

Session M33 DMP: Focus Session: Organic Electronics and Photonics - Excited State Dynamics for Photovoltaics 341 - Mike Arnold, University of Wisconsin-Madison

8:00AM M33.00001 Time resolved energy transfer in polymers doped with heavy atom molecule[1] , ELLA OLEJNIK, YAXIN ZHAI, ZEEV VARDENY, Department of Physics and Astronomy, University of Utah — We used the technique of pump/probe transient photomodulation (PM) spectroscopy with high intensity and low repetition rate in the spectral range of 1.2 – 2.5 eV and 100 fs time resolution for studying the excitons dynamics properties of solid state mixtures of few % (X) heavy metal organic molecules in a pi-conjugated polymer host up to 2 ns. We found that the photobleaching (PB) spectrum contains two components; an instantaneous component due to the direct excitation of the heavy metal molecule guests, and a slower component due to energy transfer from the host polymer chains to the guest molecules. The PM spectrum also contains a built-up of a photoinduced absorption band at ∼1.5 eV that we assigned as due to excitons in the guest molecules, that has the same dynamics as that of the PB.

8:12AM M33.00002 Femtosecond optical study of chemically induced polaron states in polythiophene films , HIDEO KISHIDA, TAKAKI FUJII, TOMOYA UCHIDA, TAKESHI KOYAMA, ARAO NAKAMURA, Department of Applied Physics, Nagoya University — We performed femtosecond pump-probe measurements in poly(3-hexylthiophenes) (P3HT) doped with ionic liquid (OMIM/BF_4). We fabricated an electrochemical cell with glass/ITO/P3HT (regioregular oriented film)/ionic liquid/ITO/glass structure. By applying the voltage between the electrodes, we electrochemically control the doping level. By increase of the applied voltage, the two polarized absorption peaks due to polaron states appear within the optical gap. The dynamics of the photoexcited states were studied by two-color femtosecond pump-probe measurements, in which the photon energies of the pump and probe pulses correspond to the π-π* transition and the polaron absorption band, respectively. At lower voltage, the increase of the near infrared absorption is observed, which is assigned to the photoinduced polaron absorption. On the other hand, at higher voltage, photoinduced bleaching is observed. The increase of the applied voltage reduces the lifetime of the excited states. These facts suggest that the photoexcitation in the chemically induced polaron states changes the electronic states and induces the new photoexcited species. The detailed origins of the new states are discussed by comparison with the femtosecond pump-probe spectra in PEDOT/PSS.

8:24AM M33.00003 Transient picosecond studies of pristine and DIO doped PTB7/PC71BM blend for photovoltaic applications[1] , UYEN HUYNH, TEK BASEL, VALY VARDENY, Department of Physics & Astronomy, University of Utah, YONGYE LIANG, LUPING YU COLLABORATION[2] — Recently there have been reports of a significant increase of power conversion efficiency in organic solar cells upon mixing the donor-acceptor blend with various additives. We studied the photoexcitation dynamics in thin films of pristine PTB7 (a low band-gap polymer), and pristine and doped PTB7/PCBM blend with DIO additives, using the pump/probe photoinduced absorption technique with probe in the mid-IR spectral range. We found that the photogenerated charges in DIO doped blend is more efficient than in the pristine blend. Specifically we found that the charge polarons in the DIO doped blend are photogenerated instantaneously, simultaneously with photogenerated singlet excitons. The excitons decay into charge-transfer (CT) excitons at the D-A boundaries within ∼1ps.The CT excitons may geminately recombine or dissociate into free charge polarons; where the dissociation time constant was found to be ∼450 ps.

8:36AM M33.00004 ABSTRACT WITHDRAWN –

8:48AM M33.00005 Managing thermal effects in z-scan measurements on PTCDA films , NIRANJALA WICKREMASINGHE, XIAOSHENG WANG, Department of Physics, University of Cincinnati, Cincinnati, OH 45221, HEIDRUN SCHMITZER, Department of Physics, Xavier University, Cincinnati, OH 45207, HANS PETER WAGNER, Department of Physics, University of Cincinnati, Cincinnati, OH 45221 — We study the two-photon absorption in micrometer thick polycrystalline PTCDA (perylene-3,4,9,10-tetracarboxylic-3,4,9,10-dianhydride) films using the open aperture z-scan technique. The films were grown by organic molecular beam deposition on Pyrex substrate and have been excited with 150 fs high repetition rate laser pulses at a wavelength of 820 nm. The pulses are focused onto the sample with a 10 x or a 20 x long distance microscope objective lens. The excitation intensities have been kept the same in both cases. To study the influence of sample heating the laser repetition rate has been varied from 4 MHz to 50 kHz by an acousto-optic pulse selector. At laser repetition rates larger than 200 kHz and 1 MHz for the 10 x and 20 x microscope lenses, respectively, we observe a reduction of the z-scan transmission dip. This reduction is attributed to a counteracting thermal effect due to film heating in the focus area. The reduced thermal effect using a 20 x microscope lens is attributed to faster thermal diffusion from the smaller focus area into the unexcited film. At lower repetition rates the z-scan dip is independent of the repetition rate and the two-photon absorption coefficient in PTCDA films was determined to be approximately 4 cm/GW.

9:00AM M33.00006 Excitonic Properties of Novel π-conjugated Polymers for Organic Electronics , EVAN LAFALCE, XIAOMEI JIANG, University of South Florida, CHENG ZHANG, South Dakota State University — We compare the photophysics of different derivatives of the π-conjugated polymer Poly(thienylenevinylene) (PTV) by photoluminescence (PL) and electro-absorption (EA) spectroscopy. The binding energy of the primary excitonic excited state is obtained from EA and is found to be related to the quantum efficiency for PL. In particular, both quantities are determined by the energies of the first optically allowed state and the first optically forbidden state above the ground state. In most PTV derivatives, the optically forbidden state lies below the optically allowed state and the PL is efficiently quenched by internal conversion. When the order of excited states is reversed, PL is observable with an efficiency that scales with the binding energy of the exciton as determined by EA. Thus, the chemical structure governs the interplay between π-conjugation delocalization and electron correlation that determines the ordering of excitonic states. This ordering then in turn dictates the effectiveness of a π-conjugated polymer for both emission and exciton dissociation and therefore dictates a material's suitability for either Organic Light-emitting Diodes or Organic Photovoltaic devices. This information then may be useful in the design of novel materials for application in these devices.

9:12AM M33.00007 External quantum efficiency exceeding 100% in a singlet-exciton-fission-based solar cell[1] , MARC BALDO, MIT, Department of Electrical Engineering and Computer Science — Singlet exciton fission can be used to split a molecular excited state in two. In solar cells, it promises to double the photocurrent from high energy photons, thereby breaking the single junction efficiency limit. We demonstrate organic solar cells that exploit singlet exciton fission in pentacene to generate more than one electron per incident photon in the visible spectrum. Using a fullerene acceptor, a poly(3-hexylthiophene) exciton confinement layer, and a conventional optical trapping scheme, the peak external quantum efficiency is (109+/-1)% at $\lambda = 670$ nm for a 15-nm-thick pentacene film. The corresponding internal quantum efficiency is (160+/-10)%. Independent confirmation of the high internal efficiency is obtained by analysis of the magnetic field effect on photocurrent, which determines that the triplet yield approaches 200% for pentacene films thicker than 5 nm. To our knowledge, this is the first solar cell to generate quantum efficiencies above 100% in the visible spectrum. Alternative multiple exciton generation approaches have been demonstrated previously in the ultraviolet, where there is relatively little sunlight. Singlet exciton fission differs from these other mechanisms because spin conservation disallows the usual dominant loss process: a thermal relaxation of the high-energy exciton into a single low-energy exciton. Consequently, pentacene is efficient in the visible spectrum at $\lambda = 670$ nm because only the collapse of the singlet exciton into *two* triplets is spin-allowed.

9:48AM M33.00008 An Electric Field Stimulated Spin Crossover Transition in a Molecular Adsorbate , XIN ZHANG, Department of Physics and Astronomy, University of Nebraska-Lincoln, Lincoln, NE, US., TATIANA PALAMARCIUC, PATRICK ROSA, JEAN-FRANÇOIS LÉTARD, CNRS, ICMCB, Groupe des Sciences Moléculaires, Université de Bordeaux, Pessac, France, EDUARDO V. LOZADA, FERNAND TORRES, L.G. ROSA, Dept. of Physics and Electronics, University of Puerto Rico - Humacao, Humacao, PR, US, BERNARD DOUDIN, Institut de Physique Applique de Physique et Chimie des Matériaux de Strasbourg, 3 Université Louis Pasteur Strasbourg, Strasbourg, France, PETER A. DOWBEN, Department of Physics and Astronomy, University of Nebraska-Lincoln, Lincoln, NE, US. — We have investigated the occupied and unoccupied electronic structure of ultra thin films of the spin crossover [Fe(H_2B(pz)$_2$)$_2$(bipy)] complex (with H_2B(pz)$_2$ = bis(hydrido)bis(1H-pyrazol-1-yl)borate and bipy = 2,2'-bipyridine) by ultraviolet photoelectron spectroscopy (UPS), inverse photoemission (IPES) and X-ray absorption spectroscopy (XAS). A bandgap of 2-3 eV is deduced from combined UPS and IPES measurements of the films on Au substrates. The shift of the unoccupied density of states seen in IPES is consistent with the thermally induced spin crossover transition for molecules deposited on the organic ferroelectric copolymer polyvinylidene fluoride with trifluoroethylene (PVDF-TrFE). Perhaps more significant is the fact that the spin crossover transition, and certainly the unoccupied electronic structure, is influenced by the ferroelectric polarization direction of PVDF-TrFE substrates at temperatures in the vicinity of the thermally driven spin crossover transition.

10:00AM M33.00009 Exploration of Excitonic States in Dilute Magnetic Organic Semiconductors[1] , LANE MANNING, NAVEEN RAWAT, CODY LAMARCHE, University of Vermont, LAUREN PALADINO, University of South Florida, ISHVIENE COUR, RANDALL HEADRICK, MADALINA FURIS, University of Vermont — The electronic and excitonic properties of mixed dilute metal/metal-free phthalocyanine crystalline thin films are explored. The immediate focus is on molecular systems containing Cobalt and Copper phthalocyanines in ratios to the metal-free phthalocyanines ranging from 1:1 to 1:10. The molecular thin films samples are deposited using a novel hollow pen-writing technique[2] that produce millimeter sized grains with long range macroscopic order. Electronic and excitonic states are investigated using temperature dependent absorption/transmission and photoluminescence spectroscopy. All optical characterization indicates a very uniform mixing of the species is achieved in films without loss of long range order previously observed in individual species. At low temperatures, a novel high energy state is observed. Its intensity is directly related to the ratio of metal to metal-free Phthalocyanine. In addition, a unique linear dichroism mapping is performed on these thin film samples, giving insight into electronic states both close to and far from grain boundaries.

10:12AM M33.00010 Harvesting singlet fission for solar energy conversion: one versus two-electron transfer electron transfer from the quantum superposition state , WAI-LUN CHAN, Department of Physics and Astronomy, University of Kansas, JOHN TRITSCH, Texas Materials Institute, University of Texas, Austin, XIAOYANG ZHU, Department of Chemistry, Columbia University — Singlet fission (SF) is being explored to increase the efficiency of organic photovoltaics. A key question is how to effectively extract multiple electron-hole pairs from multiple excitons with the presence of other competing channels such as electron transfer from the singlet state. Recent experiments on the pentacene and tetracene show that a quantum superposition of the singlet (S_1) and multiexciton (ME) state is formed during SF. However, little is known about the kinetics of electron transfer from this quantum superposition. Here, we apply time-resolved photoemission spectroscopy to the tetracene/C_{60} interface to probe one and two electron transfer from S_1 and ME states, respectively. Because of the relatively slow (7 ps) SF in tetracene, both one- and two-electron transfer are allowed. We show evidence for the formation of two distinct charge transfer states due to electron transfer from photo-excited tetracene to the lowest unoccupied molecular orbital (LUMO) and the LUMO+1 levels in C_{60}. Kinetic analysis shows that 60% of the quantum superposition transfers one electron through the S_1 state to C_{60} while 40% undergoes two-electron transfer through the ME state.

10:24AM M33.00011 Charge Transfer and Triplet States in High Efficiency OPV Materials and Devices[1]

, VLADIMIR DYAKONOV, Experimental Physics VI, Julius-Maximilian-University of Wurzburg, 97074 Wurzburg, Germany — The advantage of using polymers and molecules in electronic devices, such as light-emitting diodes (LED), field-effect transistors (FET) and, more recently, solar cells (SC) is justified by the unique combination of high device performance and processing of the semiconductors used. Power conversion efficiency of nanostructured polymer SC is in the range of 10% on lab scale, making them ready for up-scaling. Efficient charge carrier generation and recombination in SC are strongly related to dissociation of the primary singlet excitons. The dissociation (or charge transfer) process should be very efficient in photovoltaics. The mechanisms governing charge carrier generation, recombination and transport in SC based on the so-called bulk-heterojunctions, i.e. blends of two or more semiconductors with different electron affinities, appear to be very complex, as they imply the presence of the intermediate excited states, neutral and charged ones [1-3]. Charge transfer states, or polaron pairs, are the intermediate states between free electrons/holes and strongly bound excitons. Interestingly, the mostly efficient OLEDs to date are based on the so-called triplet emitters, which utilize the triplet-triplet annihilation process. In SC, recent investigations indicated that on illumination of the device active layer, not only mobile charges but also triplet states were formed [4]. With respect to triplets, it is unclear how these excited states are generated, via inter-system crossing or via back transfer of the electron from acceptor to donor. Triplet formation may be considered as charge carrier loss channel; however, the fusion of two triplets may lead to a formation of singlet excitons instead. In such case, a generation of charges by utilizing of the so far unused photons will be possible. The fundamental understanding of the processes involving the charge transfer and triplet states and their relation to nanoscale morphology and/or energetics of blends is essential for the optimization of the performance of molecular photovoltaic devices. I will present the state of the art in this field and discuss the mechanisms of polaron pair generation and recombination in the novel low band gap polymer-fullerene blends as well as in high-efficiency SC.

Session M34 DPOLY: Thin Films of Block Copolymers and Hybrid Materials: Directed Assembly I

342 - Bradley Olsen, Massachusetts Institute of Technology

8:00AM M34.00001 Inverse Solution for Directed Self-Assembly of Thin Film Cylindrical Morphology Block Copolymers

, ADAM HANNON, KEVIN GOTRIK, ALFREDO ALEXANDER-KATZ, CAROLINE ROSS, MIT — Using topographical templates, the directed self-assembly of thin film cylinder forming block copolymers has allowed for the fabrication of complex patterns with the sub-20nm length scales necessary for nanolithography. However, the templates for these circuit-like patterns have been developed from empirical methods that require either experimental examination of many input templates or time-consuming simulations over a wide parameter space. To address this problem, we have developed an inverse self-assembly algorithm that allows for the prediction of the template necessary to obtain a desired target pattern which includes bends, junctions, and terminals. The model system has been optimized for comparison with a cylindrical PDMS-PS block copolymer (45.5 kg/mol molecular weight and PDMS volume fraction 33.5%) under equilibrium neutral solvent annealing conditions. Example target structures are shown with the resulting predicted template found from the algorithm and compared with traditional simulation methods using those templates.

8:12AM M34.00002 Directed Assembly of Block Copolymer Ordering on Rough and Patterned Flexible Substrates

, ARZU HAYIRLIOGLU, MANISH KULKARNI, ALAMGIR KARIM, The University of Akron — Directed self-assembly of block copolymer (BCP) thin film on flexible substrates has potential in fabrication of flexible electronic devices due to its nanometer scale pattern formation capability. We studied the BCP ordering properties of polystyrene-b-poly(methyl methacrylate) (PS-b-PMMA) films on a flexible substrate, where the PS-b-PMMA films are initially coated on a smooth poly(dimethylsiloxane) (PDMS) substrate, whose surface energy (SE) was tuned between (20-69) mJ/m2 by UV-ozone (UVO) exposure. This range of SE allows for controlled wettability and orientation of the BCP overlayer. Further, we replicated different patterned media and observed perpendicular lamellar BCP orientation and parallel cylindrical BCP orientation on patterned flexible PDMS in the wetting SE regime. Rough surface structures created by silica xerogels were replicated on PDMS. RMS roughness of the xerogels is tuned by controlling sol-gel catalyst concentration and aging time. Effect of the aspect ratio of the rough PDMS substrates on the orientation of BCP films was studied. Surface morphology of the BCP films was studied by optical microscopy and Atomic Force Microscope (AFM), while orientation of the film's interior was studied using Grazing-Incidence Small Angle X-ray Scattering (GISAXS)

8:24AM M34.00003 Consequences of Surface Neutralization in Thin Film Block Copolymers[1]

, SANGWON KIM, University of Minnesota, Twin Cities, PAUL NEALEY, University of Chicago, FRANK BATES[2], University of Minnesota, Twin Cities — Changes in boundary conditions have been found to induce novel physical phenomena in numerous systems. In this presentation, the consequences of surface neutralization to the structures of thin-film block copolymers were investigated using partially epoxidized poly(styrene-*b*-isoprene) (PS-PI) diblock copolymers. The thickness dependence of thin-film structures, prepared on non-preferential and preferential underlying brushes, were studied using scanning electron microscopy and atomic force microscopy. The PS-PI precursor, without epoxidation, exhibited parallel, layer-by-layer structures covered with one component, and the corresponding hole/island structures had step heights of one bulk lamellar periodicity (L_0), consistent with previous studies. On the other hand, the thin films of epoxidized PS-PI showed perpendicular ordering independent of the thickness above non-preferential brushes, indicative of surface neutralization at both interfaces. The parallel lamellae of epoxidized PS-PI above preferential brushes were characterized as hole/island structures of 0.5 L_0 step heights and the free surface wetting by both components of the diblock copolymers. The formation of the distinctive relief structures was attributed to the surface neutralization from the chemical modification.

8:36AM M34.00004 Block Copolymer Directed Assembly for Nanomaterials and Nanodevices

, SANG OUK KIM, Center for Nanomaterials and Chemical Reactions, Institute for Basic Science (IBS), Materials Science and Engineering, KAIST — Block copolymer nanopatterning is a promising technology that can complement the inherent limitations of conventional photolithography. The spontaneous and parallel assembly of block copolymers may generate densely packed, periodic 10-nm-scale nanodomains in a scalable way. Furthermore, laterally ordered, device-oriented nanostructures are attainable by the directed self-assembly principles employing prepatterned substrates. In this presentation, the overview of my research achievements associated to block copolymer nanopatterning will be presented. My research group demonstrated the world-first successful integration of block copolymer nanopatterning with 193 nm ArF lithography. We also developed soft-graphoepitaxy, which generates highly aligned nanoscale metal and semiconductor nanostructures without any trace of structure-directing topographic pattern. Soft-graphoepitaxy could be further developed to ultralarge-area nanopatterning, where micrometer scale photoresist pattern can be completely transformed into large-area block copolymer nanopattern. My research group also developed various pattern transfer methods for block copolymer nanopatterning. Mussel-inspired block copolymer nanopatterning exploiting universal natural adhesive of mussel polydopamine enables the nanopatterning of low surface energy materials, such as gold, Teflon and graphene. Our recent transferrable and flexible nanopatterning employing chemically modified graphene films as pattern substrates makes it possible to apply block copolymer nanopatterning onto arbitrary nonplanar and flexible geometries and generates ideal three-dimensional assembly of carbon nanotubes and graphene.

9:12AM M34.00005 Self-annihilation of defects in block-copolymer thin films induced by corrugated substrates[1]

, GEORGES HADZIIOANNOU, GUILLAUME FLEURY, Universite de Bordeaux France, KARIM AISSOU, MIT, JONAH SAVER, LOMA Universite de Bordeaux, GILES PECASTAINGS, CYRIL BROCHON, Universite de Bordeaux France, CHRISTOPHE NAVARRO, ARKEMA, STEPHANE GRAUBY, JEAN-MICHEL RAMPNOUX, STEFANE DILHAIRE, LOMA Universite de Bordeaux, LCPO UNIVERSITE DE BORDEAUX TEAM, LOMA UNIVERSITE DE BORDEAUX TEAM, ARKEMA TEAM — Ultradense perfectly ordered structures with nanometric periodicity are of crucial importance for applications such as microelectronics, data storage media or meta-materials. Herein we demonstrate the use of a polymeric guiding pattern to control the self-assembly of block copolymers into highly-ordered 2D arrays. For this, a sinusoidal surface-relief grating was interferometrically inscribed onto an azobenzene containing copolymer sub-layer. A poly(styrene-*b*-ethylene oxide), PS-*b*-PEO, film was cast on top, resulting in cylinders with a 6-fold coordination. When film thickness reaches a critical value where the PS-*b*-PEO free-surface is smooth and no hint of the underlying sinusoidal pattern is apparent, a defect-free 2D-array of PS-*b*-PEO cylinders is observed over a large surface. Our results show that the surface deformation induced by the topological pattern controls the diffusion of defects and consequently their annihilation.

9:24AM M34.00006 Directed Self-assembly of High-Molecular-Weight Block Copolymer Films

, DU YEOL RYU, EUNHYE KIM, HYUNGJU AHN, SUNGMIN PARK, JUNE HUH, Yonsei University, JOONA BANG, Korea University, BYEONGDU LEE, Argonne National Lab., DEPARTMENT OF CHEMICAL & BIOMOLECULAR ENGINEERING, YONSEI UNIVERSITY COLLABORATION, DEPARTMENT OF MATERIALS SCIENCE AND ENGINEERING, YONSEI UNIVERSITY COLLABORATION, DEPARTMENT OF CHEMICAL AND BIOLOGICAL ENGINEERING, KOREA UNIVERSITY COLLABORATION, X-RAY SCIENCES DIVISION, ADVANCED PHOTON SOURCE, ARGONNE NATIONAL LAB. COLLABORATION — The solvent-vapor annealing of block copolymer (BCP) films facilitates the mobility of highly entangled polymer chains, or the path-way barriers to the formation of well-ordered structures. In this study, the microdomain orientation of BCP films has been studied by in-situ grazing incidence small angle x-ray scattering (GISAXS), atomic force microscopy (AFM), and scanning electron microscopy (SEM). We demonstrate the rapid evolution of a perpendicularly oriented lamellar morphology in high-molecular-weight (up to 1,000,000 g/mol) block copolymer films, to achieve topographically patterned BCP substrates.

9:36AM M34.00007 Directed Assembly of block copolymers on topologically complex surfaces: A self-consistent field theoretic study

, XIANGGUI YE, BAMIN KHOMAMI, Department of Chemical and Biomolecular Engineering, University of Tennessee Knoxville — The self-assembly of a lamella-forming diblock copolymer guided by topological complexity, namely, substrates composed of trenches with different heights and widths via self-consistent field theoretic simulations has been studied. In general, when the substrate is neutral to both blocks of the copolymer, the perpendicular lamella morphology is obtained. However, natural substrate usually has a preferred affinity to one of the blocks, and parallel lamella morphology is often obtained. Tuning the substrate roughness has proven useful in creating the perpendicular lamellar morphology. To this end, it has been shown that the perpendicular lamellae vertical to the trench direction is preferred when the trench size is relatively large. However, the orientation of the highly sought after perpendicular lamellar morphology can be changed by manipulation of the trench size, i.e., when the trench size is comparable to the natural periodic spacing of diblock copolymer, the perpendicular lamellae parallel to the trench direction is the preferred morphology. Overall this study clearly demonstrates the impact of this class of simulations in rational design of morphologies in thin multi-component polymeric films with application to technologies such as ultra-high-density magnetic recording media, metal nanostructures for metamaterials and plasmonic circuits, and sensors.

9:48AM M34.00008 Topcoat approaches for directed-assembly of copolymer films with blocks exhibiting differences in surface energy

, HYO SEON SUH, The University of Chicago, JEONG IN LEE, University of Wisconsin-Madison, ABELARDO RAMIREZ-HERNANDEZ, The University of Chicago, YASUHIKO TADA, HIROSHI YOSHIDA, Hitachi Ltd., LEI WAN, RICARDO RUIZ, HGST a Western Digital company, JUAN DE PABLO, PAUL NEALEY, The University of Chicago — Fabricating patterns with feature dimensions smaller than 10 nm scale using block copolymer lithography requires the use of materials with large Flory-Huggins interaction parameters. Because such block copolymers (BCPs) typically show the large differences in surface energy between the blocks, one block (with lower surface energy) tends to segregate to the free surface of films and precludes the assembly of the desired through-film perpendicularly oriented structures. Here we describe a generalizable strategy to overcome this limitation. By coating the BCP film with an additional layer, a topcoat, thermodynamically favorable boundary conditions at the top surface of the film can be engineered for directed self-assembly. The allowable properties of the topcoats depend on the interfacial energies of the layer with the blocks of the copolymer, and the block-block interfacial energy. The strategy is demonstrated experimentally by directing the assembly of polystyrene-block-poly-2-vinylpyridine (PS-*b*-P2VP) films on chemically nanopatterned substrates with different topcoat materials.

10:00AM M34.00009 Bad-solvent Induced Tunable Nanoscale Roughness in Polymer, Block Co-polymer and Carbon Thin Films

, MANISH KULKARNI, The University of Akron, CHANDRASHEKHAR SHARMA, Indian Institute of Technology, Hyderabad, ALAMGIR KARIM, The University of Akron — Nanoscale surface roughness of a material plays significant role in various applications such as adhesion, micro-/nano-electromechanical systems and antireflective coatings. We demonstrate here a novel and simple method for tuning nanoscale surface roughness of polymer coatings using a modified flow coater assembly. A dual-blade flow coating assembly was used to coat films of Poly(styrene) (PS), poly(methylmethacrylate) (PMMA) and PS-b-PMMA block co-polymer (BCP) dissolved in toluene on silicon substrates with a secondary blade flow coating a bad-solvent (water, ethanol) on top of the polymer film after a controlled delay. The bad-solvent and good–solvent miscibility and evaporation dynamics dictates the surface roughness/porosity in the polymer-liquid-air-interface. Combination of miscible ethanol-toluene solvents led to PS-chain formation of iterated function system (IFS) like fractal patterns with a root-mean-square (RMS) roughness $\sim$ 250 nm. However, PS films with much smaller roughness ($<$ 20nm) were obtained for immiscible water and toluene solvents. The rough polymer coatings were also pyrolysed under optimized conditions to obtain carbon films with similar morphologies. Surface morphology and chemistry of the polymer and carbonized films were studied using AFM and XPS.

10:12AM M34.00010 Orientation of Microdomains in Cylinder-Forming PS-PHMA Thin Films

, RALEIGH DAVIS, RICHARD REGISTER, Princeton University, PAUL CHAIKIN, New York University — There is much interest in the study of self-assembled block copolymer thin films for uses in nanofabrication. For many applications control of the microdomain order is required. One method to achieve long-range orientational order in thin films is through the use of shear, which has been shown to orient block copolymer microdomains in the direction of the applied shear. A particular interest is shear-alignment of cylinder-forming poly(styrene)-poly(hexylmethacrylate) (PS-PHMA) thin films, which are effective masks for nanofabrication via reactive-ion etching. The present work examines the effects of changing PS block volume fraction, within the cylinder-forming region of the phase diagram, to both modulate the range of film thicknesses over which in-plane vs. out-of-plane cylinders are observed as well as improve the quality of in-plane alignment post-shear. Increasing the volume fraction of PS, away from the cylinder-sphere boundary, increased the range of film thicknesses over which the cylinders orient in-plane. The effects of the substrate wetting condition on cylinder orientation were also examined through grafting of PS and PHMA brushes to the substrate before deposition of the PS-PHMA film.

10:24AM M34.00011 Tunable-Morphology Block Copolymer Thin Films with Controlled Solvent Vapor Annealing for Lithographic Applications

, BRIAN STAHL, NATHANIEL LYND, EDWARD KRAMER, CRAIG HAWKER, University of California, Santa Barbara — Solvent annealing is an alternative to thermal annealing for improving long-range order and reducing defect density in block copolymer thin films. However, the fundamentals of block-copolymer self-assembly under solvent annealing conditions have yet to be studied in detail. We have developed a specialized hardware platform to perform solvent annealing experiments with active and precise control over solvent vapor saturation which allows us to quantitatively understand the structure-processing relationship during different stages of solvent annealing. Using polystyrene-b-polyethylene oxide/water/toluene as a model system and AFM, TEM and GISAXS characterization, we have found that a decrease in water vapor saturation during the post-annealing quenching step induces a change in domain spacing and reduction in long-range order. We have also found that by changing the water vapor saturation during steady-state annealing we are able to tune the domain spacing over a wide range and that this spacing remains after quenching. This controlled approach to solvent annealing affords considerable control over the morphology of annealed block copolymer thin films and a deeper understanding of the fundamentals of the process, making this technique more relevant to industrial applications.

10:36AM M34.00012 Ultrathin block copolymer films under shear[1]

, MARCO PINNA, ROBERTA DESSI, ANDREI ZVELINDOVSKY, University of Central Lancashire — Ultrathin block copolymer films of 1-2 microdomains thick were investigated by means of a large scale coarse grained computer simulation, Cell Dynamics Simulation. Our simulation method allowed to computationally reach the size scale of experimental samples and to explain some recent experiments on sheared lamellae and cylindrical block copolymer morphologies. A detailed dynamical phase diagram, which covered parallel and perpendicular lamellae and cylinders, as well as perforated lamellae, was constructed. The crucial role of defects in orientation phase transitions and structure ordering and non-trivial defects dynamics was found. Our results provide detailed insights into how to use shear to control and manipulate block copolymer structure in thin films.

10:48AM M34.00013 Continuity and Network Morphologies of Lamellar Nanostructures Self-assembled in Block Copolymer Thin Films: Comparison of Processing by Thermal and Solvent Annealing

, IAN CAMPBELL, CHUNLIN HE, MARK STOYKOVICH, University of Colorado — Self-assembled block copolymers in thin films have advantages for nanolithography including tunable and scalable feature sizes below 50 nm, parallel patterning over large areas, inexpensive material costs, and attractive processability. One process for inducing order in block copolymer thin films is solvent annealing, in which a film is swollen with solvent and domain ordering is induced as the solvent evaporates from the film. Solvent annealing is advantageous compared to thermal processing because it occurs rapidly and enables the use of polymer constituents that may be thermally unstable. Here the continuity of lamellar networks formed in thin films of poly(styrene-block-methyl methacrylate) with volume fractions of PMMA ranging from 0.45 to 0.55 will be shown to be favored in the block with a higher volume fraction. Network characteristics such as branch point density and end point density correlate with continuity, but at lower densities in solvent annealed than thermally annealed thin films of identical composition. Further comparison between thermal and solvent annealed morphologies sheds light on the mechanism through which ordering is achieved in solvent annealing and allows for additional control over the nanoscale features formed by block copolymers in thin films.

Session M35 DMP: HTSC: Mainly X-ray Probes and Related Theory

343 - Michael Sentef, Stanford University

8:00AM M35.00001 ABSTRACT WITHDRAWN –

8:12AM M35.00002 Surface-enhanced charge-density-wave instability in underdoped Bi2201

, J.A. ROSEN, R. COMIN, G. LEVY, G. SAWATZKY, A. DAMASCELLI, Quantum Matter Institute, UBC, Vancouver, Canada, G. BLAKE, T.T.M. PALSTRA, University of Groningen, The Netherlands, B. KEIMER, MPI Stuttgart, Germany, L. PETACCIA, Elettra, Trieste, Italy, Y. YOSHIDA, H. EISAKI, AIST, Tsukuba, Japan — Neutron and x-ray scattering experiments have provided mounting evidence for spin and charge ordering phenomena in underdoped cuprates, ranging from stripe correlations in Nd-LSCO to the recently discovered charge-density-waves in YBCO. Here we show that these electron-lattice instabilities also exhibit a previously unrecognized bulk-surface dichotomy. Surface-sensitive electronic and structural probes uncover a temperature-dependent evolution of the CuO_2 plane band dispersion and apparent Fermi pockets in underdoped Bi2201, which is associated with a strong temperature dependence of the incommensurate superstructure periodicity below 130 K. In stark contrast, the structural modulation revealed by bulk-sensitive probes is temperature independent. These findings point to a surface-enhanced incipient charge-density-wave instability, driven by Fermi surface nesting. This discovery is of critical importance in the interpretation of single-particle spectroscopy data and establishes the surface of cuprates as a rich playground for the study of electronically soft phases.

8:24AM M35.00003 Distinct Charge Orders in the Planes and Chains of Ortho-III-Ordered YBa2Cu3O6 identified by Resonant elas- tic x-ray scattering

, D.G. HAWTHORN, A.J. ACHKAR, University of Waterloo, R. SUTARTO, University of British Columbia, X. MAO, University of Waterloo, F. HE, Canadian Light Source, A. FRANO, S. BLANCO-CANOSA, M. LE TACON, Max Planck Institute for Solid State Research, G. GHIRINGHELLI, L. BRAICOVICH, M. MINOLA, Politecnico di Milano, M. MORETTI SALA, European Synchrotron Radiation Facility, C. MAZZOLI, Politecnico di Milano, RUIXING LIANG, D.A. BONN, W.N. HARDY, University of British Columbia, B. KEIMER, Max Planck Institute for Solid State Research, G.A. SAWATZKY, University of British Columbia — Recently, charge density wave order with Q = [0.3 0 L] and [0 0.3 L] was detected for the first time in underdoped YBCO using resonant soft x-ray scattering at the Cu L_3 absorption edge. Here, we explore the energy and polarization dependence of the resonant scattering intensity in detwinned $YBa_2Cu_3O_{6.75}$ with ortho-III oxygen ordering in the chain layer. We show that the ortho-III order results in a commensurate peak at H = 0.33 whose energy and polarization dependence agrees with expectations for oxygen ordering in the chains. The [0.3 0 L] and [0 0.3 L] peaks, which result from a modulation of Cu $3d_{x^2-y^2}$ states in the CuO_2 planes, are shown to be distinct and seemingly unrelated to the structure of the chain layer. Moreover, the energy dependence of the [0.3 0 L] and [0 0.3 L] scattering intensity is found to result from a spatial modulation of the energies of the Cu $2p$ to $3d_{x^2-y^2}$ transition, similar to stripe-ordered 214 cuprates.

8:36AM M35.00004 Microscopic theory of resonant soft x-ray scattering , DAVID BENJAMIN, DMITRY ABANIN, Harvard University Physics Department, PETER ABBAMONTE, University of Illinois Department of Physics, EUGENE DEMLER, Harvard University Physics Department — We have developed a microscopic theory of resonant soft x-ray scattering (RSXS) that accounts for the delocalized character of valence electrons as well as excitonic and orthogonality catastrophe effects due to the core hole. We have derived a convenient and intuitive exact formula for RSXS intensities. Applying our formalism to the underdoped cuprates, we find that dynamic nesting in the band structure provides the most natural explanation for the two peaks observed in RSXS spectra. Our results give evidence for the existence of reasonably well-defined quasiparticles as far as 1.5 eV above the Fermi level in underdoped cuprates, and establish RSXS as a bulk-sensitive probe of electron quasiparticles.

8:48AM M35.00005 Determinant Quantum Monte Carlo Study of the Enhancement of d-wave Pairing by Charge Inhomogeneity , RUBEM MONDAINI, Instituto de Fisica, Universidade Federal do Rio de Janeiro Cx.P. 68.528, 21941-972 Rio de Janeiro RJ, Brazil, TAO YING, Department of Physics, Harbin Institute of Technology, Harbin 150001, China, THEREZA PAIVA, Instituto de Fisica, Universidade Federal do Rio de Janeiro Cx.P. 68.528, 21941-972 Rio de Janeiro RJ, Brazil, RICHARD T. SCALETTAR, Physics Department, University of California, Davis, California 95616, USA — Striped phases, in which spin, charge, and pairing correlations vary inhomogeneously in the CuO_2 planes, are a known experimental feature of cuprate superconductors, and are also found in a variety of numerical treatments of the two dimensional Hubbard Hamiltonian. In this paper we use determinant Quantum Monte Carlo to show that if a stripe density pattern is imposed on the model, the d-wave pairing vertex is significantly enhanced. We attribute this enhancement to an increase in antiferromagnetic order which is caused by the appearance of more nearly half-filled regions when the doped holes are confined to the stripes. We also observe an enhanced d-wave pair correlation inside stripes reaching its maximum value when the π-phase shift in the magnetic order takes place.

9:00AM M35.00006 Energetics of superconductivity in the two dimensional Hubbard model , EMANUEL GULL, University of Michigan, ANDREW J. MILLIS, Columbia University — The energetics of the interplay between superconductivity and the pseudogap in high temperature superconductivity is examined using the eight-site dynamical cluster approximation to the two dimensional Hubbard model. Two regimes of superconductivity are found: a weak coupling/large doping regime in which the onset of superconductivity causes a reduction in potential energy and an increase in kinetic energy, and a strong coupling regime in which superconductivity is associated with an increase in potential energy and decrease in kinetic energy. The crossover between the two regimes is found to coincide with the boundary of the normal state pseudogap, providing further evidence of the unconventional nature of superconductivity in the pseudogap regime. However the absence, in the strongly correlated but non-superconducting state, of discernibly nonlinear response to an applied pairing field, suggests that resonating valence bond physics is not the origin of the kinetic-energy driven superconductivity.

9:12AM M35.00007 Superconconductivity and antiferromagnetism for the one-band Hubbard model of the cuprates including inter-plane hopping[1] , SIMON VERRET, Universite de Sherbrooke, Quebec, Canada, CHUCK-HOU YEE, KITP, UCSB, DAVID SENECHAL, Universite de Sherbrooke, Quebec, Canada, A.-M.S. TREMBLAY, Universite de Sherbrooke, Quebec, Canada and CIFAR, Canada — While the overall features of the zero-temperature phase diagram of the cuprates are well described by the two-dimensional Hubbard model, the quest for a quantitative theory must include three-dimensional effects to account for differences between materials. To this end, using first-principles calculations [1,2], we obtain realistic parameters for the one-band Hubbard model that include hopping between planes. We then solve the resulting Hubbard Hamiltonian using the Variational Cluster Approximation [3] and Cellular-Dynamical Mean-Field Theory with an exact diagonalization impurity solver [4,5]. For single-layer materials, the effect of the inter-plane hopping is not sufficient to explain all the differences between the experimental phase diagrams for the various materials. We suggest other avenues of investigation. [1] Weber et al., Europhysics Lett. 100 37001 (2012) [2] Souza et al, Physical Review B 65 035109 (2001) [3] Sénéchal et al, Phys. Rev. 9:24AM M35.00008 Spectral properties near the Mott transition in the two-dimensional Hubbard model , MASANORI KOHNO, WPI Center for Materials Nanoarchitectonics, National Institute for Materials Science, Japan — Single-particle excitations near the Mott transition in the two-dimensional (2D) Hubbard model are investigated by using cluster perturbation theory. The Mott transition is characterized by the loss of the spectral weight from the dispersing mode that leads continuously to the spin-wave excitation of the Mott insulator [1,2]. The origins of the dominant modes of the 2D Hubbard model near the Mott transition can be traced back to those of the one-dimensional Hubbard model. Various anomalous spectral features observed in cuprate high-temperature superconductors, such as the pseudogap, Fermi arc, flat band, doping-induced states, hole pockets, and spinon-like and holon-like branches, as well as giant kink and waterfall in the dispersion relation, are explained in a unified manner as properties near the Mott transition in a 2D system [1].

[1] M. Kohno, Phys. Rev. Lett. 108, 076401 (2012).
[2] M. Kohno, Phys. Rev. Lett. 105, 106402 (2010).

9:36AM M35.00009 A RIXS study on Spin and Charge Excitations in Electron-Doped Cuprates, NCCO , WEI-SHENG LEE, SLAC National Accelerator Lab., JAMES J. LEE, Department of Physics, Stanford University, WOJCIECH TABIS, MARTIN GREVEN, The School of Physics and Astronomy, University of Minnesota, THOMAS. P. DEVEREAUX, SIMES, SLAC National Accelerator Lab. & Stanford University, THORSTEN SCHMIT, Swiss Light Source, Paul Scherre Inst., Z.X. SHEN, SIMES, SLAC National Accelerator Lab. & Stanford University — The phase diagram of the high-Tc cuprates is known to exhibit intriguing asymmetric doping evolution between the hole and electron-doping. ARPES and inelastic neutron scattering experiments have been extensively applied to study cuprates on both sides of the phase diagram, revealing a distinct Fermi surface evolution between the hole- and electron-doped cuprates, and the properties of low energy spin excitations. In this presentation, I will report high energy spin excitations and charge excitations of electron-deoped cuprates, Nd2-xCexCuO4, measured via resonant inelastic x-ray scattering (RIXS) at the Cu L-edge. The doping evolution of these excitations and their differences with those of the hole-doped cuprates will be discussed.

9:48AM M35.00010 Inelastic X-ray scattering measurement of electronic order in Bi2212 , CRAIG BONNOIT, DILLONG GARDNER, Massachusetts Institute of Technology, AYMAN SAID, Advanced Photon Source, Argonne National Laboratory, GENDA GU, JOHN TRANQUADA, Brookhaven National Laboratory, YOUNG LEE, Massachusetts Institute of Technology — We present inelastic x-ray scattering measurements on superconducting Bi2212, showing evidence for a phonon anomaly associated with an underlying electronic density-wave state. We observe an broadening of the longitudinal acoustic phonon at a wavevector comparable to the antinodal nesting wavevector, near (1/4,1/4,0) in orthorhombic notation. An observed asymmetry between phonon creation and annihilation processes indicates breaking of time reversal and inversion symmetry as temperature is lowered. These measurements are consistent with prior work on single layer Bi2201, indicating universality of these features in the family of Bi-based high-Tc materials.

10:00AM M35.00011 Temperature and doping dependence of x-ray absorption spectral weight in $YBa_2Cu_3O_y$[1] , JIUNN-YUAN LIN, Institute of Physics, National Chiao Tung University, Hsinchu 30043, Taiwan, CHUNG-YU MOU, 2Department of Physics, National Tsing Hua University, Hsinchu 30043, Taiwan, J.M. CHEN, National Synchrotron Radiation Research Center (NSRRC), Hsinchu 300, Taiwan — The comprehensive study of the temperature dependent x-ray absorption spectroscopy (XAS) could be attributed to a dynamical spectral weight α in $YBa_2Cu_3O_y$ (YBCO). Large spectral weight changes with the temperature for both the Upper Hubbard band and the Zhang-Rice band due to dynamics of holes are experimentally found in the underdoped regime. These spectral weight changes become larger when the doping level p goes deeper into the underdoped regime, but quickly vanishes as p goes to the undoped limit. Our results clearly indicate that the pseudogap is related to the double occupancy and originates from bands in higher energies.

10:12AM M35.00012 Doping Evolution of Oxygen K-edge X-ray Absorption Spectra in Cuprate Superconductors[1] , CHENG-CHIEN CHEN, Advanced Photon Source, Argonne National Laboratory, MICHAEL SENTEF, Stanford Institute for Materials and Energy Sciences, SLAC National Accelerator Laboratory, YVONNE KUNG, Department of Physics, Stanford University, CHUNJING JIA, Department of Applied Physics, Stanford University, RONNY THOMALE, Institute of Theoretical Physics, EPFL, BRIAN MORITZ, Stanford Institute for Materials and Energy Sciences, SLAC National Accelerator Laboratory, ARNO KAMPF, Center for Electronic Correlations and Magnetism, University of Augsburg, THOMAS DEVEREAUX, Stanford Institute for Materials and Energy Sciences, SLAC National Accelerator Laboratory — We study oxygen K-edge x-ray absorption spectroscopy (XAS) and investigate the validity of the Zhang-Rice Singlet (ZRS) picture in overdosed cuprate superconductors. Using large-scale exact diagonalization of the three-orbital Hubbard model, we observe the effect of strong correlations manifesting in a dynamical spectral weight transfer from the upper Hubbard band to the ZRS band. The quantitative agreement between theory and experiment highlights an additional spectral weight reshuffling due to core-hole interaction. Our results confirm the important correlated nature of the cuprates and elucidate the changing orbital character of the low-energy quasi-particles, but also demonstrate the continued relevance of the ZRS even in the overdosed region.

10:24AM M35.00013 Temperature and doping dependence of spectral features in determinant quantum Monte Carlo studies of the three-orbital Hubbard model of cuprate superconductors , Y.F. KUNG, E.A. NOWADNICK, SIMES, SLAC and Stanford University, S. JOHNSTON, University of British Columbia, C.-C. CHEN, APS, Argonne National Laboratory, B. MORITZ, Northern Illinois University and University of North Dakota, T.P. DEVEREAUX, SIMES, SLAC and Stanford University — Studying temperature and doping trends in strongly correlated materials is integral to understanding how their properties emerge and develop, and possibly can be tuned. To this end, determinant quantum Monte Carlo simulations are used to investigate spectral features in the three-orbital Hubbard model as applied to the cuprate superconductors. Spectral functions relevant to photoemission measurements are calculated and various spectral features, such as the indirect charge-transfer gap and Zhang-Rice singlet band, are shown to vary with doping and temperature. These orbitally resolved calculations help shed light on the applicability of the Zhang-Rice singlet picture at high hole doping levels. The density of states is also compared and contrasted with exact diagonalization studies as well as recent x-ray absorption spectroscopy measurements.

10:36AM M35.00014 Covalent magnetic form factor and neutron scattering in cuprates[1] , IGOR ZALIZNYAK, ZHIJUN XU, GENDA GU, Brookhaven National Laboratory, ANDREI SAVICI, GARRETT GRANROTH, MATTHEW STONE, NSSD, Oak Ridge National Laboratory — We investigate the effect of covalent hybridization on magnetic excitations measured by the inelastic neutron scattering (INS) in the 1D cuprate Sr_2CuO_3 and the 2D La_2CuO_4. It has been previously shown that strong hybridization of Cu 3d states with O p states leads to the dramatic modification of the measured INS intensity, which is strongly suppressed, by factor 2.5-3, compared to the ionic spin model [1]. The result was obtained by comparing the measured intensity in a chain cuprate Sr_2CuO_3 with the dynamical spin structure factor predicted by the exact theory [2] of the model spin-1/2 Heisenberg Hamiltonian, which is typically used for cuprates. In the present follow-up study we extend these measurements so as to probe directly the wave vector dependence of the magnetic form factor, which is the Fourier transform of the magnetic electron's density, both in Sr_2CuO_3, and in the LSCO parent material, the two-dimensional La_2CuO_4. Our results yield a model-independent measurement of the magnetic form factor and provide an explanation for the suppressed magnetic intensity in La_2CuO_4 and other cuprates.

10:48AM M35.00015 Angle and frequency dependence of the self-energy induced by boson fluctuation spectrum , SEUNG HWAN HONG, HAN-YONG CHOI, SungKyunKwan University — We study the effects of the electron-boson coupling on the angle and frequency dependence of the self-energy. The spin susceptibility spectrum of the LSCO in superconducting state measured by the inelastic neutron scattering experiments has commensurate and incommensurate peaks. The energy scale of the self-energy induced by the commensurate peak is independent on the angle because of a small correlation length. On the other hand, that induced by the incommensurate peak depends on the angle because it has a large correlation length. The Eliashberg calculation using the measure spin fluctuation spectrum yields that the energy scale of the self-energy is larger along the anti-nodal direction than along the nodal direction. This result, however, is not consistent with the self-energy extracted from the ARPES analysis. Then we also considered the self-energy induced by Varma's loop current fluctuations. The results will be presented in comparison with the ARPES experiments.

Wednesday, March 20, 2013 8:00AM - 11:00AM –

Session M36 DCMP: Superconductivity: Josephson and Nanoscale Phenomena 344 - John Clarke, University of California, Berkeley

8:00AM M36.00001 Frequency-dependent admittance of a short superconducting weak link , FILIP KOS, SIMON NIGG, LEONID GLAZMAN, Department of Physics, Yale University — We consider the electromagnetic response of a nanowire connecting two bulk superconductors. Andreev states appearing at a finite phase bias substantially affect the finite-frequency admittance of such wire junction. We evaluate the complex admittance analytically at arbitrary frequency and arbitrary, possibly non-equilibrium, occupation of Andreev levels. Special care is given to the limits of a single-channel contact and a disordered metallic weak link. We also evaluate the quasi-static fluctuations of admittance induced by fluctuations of the occupation factors of Andreev levels. In view of possible qubit applications, we compare properties of a weak link with those of a tunnel Josephson junction of the same normal conductance. Compared to the latter, weak link has smaller low-frequency dissipation. However, because of the deeper Andreev levels, quasi-static fluctuations of the complex admittance in a weak link are exponentially larger than in a tunnel junction. These fluctuations limit the applicability of nanowire junctions in superconducting qubits.

8:12AM M36.00002 Nonlocal transport in superconducting oxide nanostructures[1] , JOSHUA VEAZEY, GUANGLEI CHENG, SHICHENG LU, MICHELLE TOMCZYK, PATRICK IRVIN, MENGCHEN HUANG, University of Pittsburgh, CHUNG WUNG BARK, SANGWOO RYU, CHANG-BEOM EOM, University of Wisconsin-Madison, JEREMY LEVY, University of Pittsburgh — We report nonlocal transport signatures in the superconducting state of nanostructures formed[2] at the $LaAlO_3/SrTiO_3$ interface using conductive AFM lithography. Nonlocal resistances (nonlocal voltage divided by current) are as large as 200 Ω when 2-10 μm separate the current-carrying segments from the voltage-sensing leads. The nonlocal resistance reverses sign at the local critical current of the superconducting state. Features observed in the nonlocal *V-I* curves evolve with back gate voltage and magnetic field, and are correlated with the local four-terminal *V-I* curves. We discuss how nonlocal and local transport effects in $LaAlO_3/SrTiO_3$ nanostructures may result from the electronic phase separation and superconducting inhomogeneity reported by others in planar structures[3].

8:24AM M36.00003 Superconductivity in Centimeter Length Indium-Gallium Nanowires[1] , WEIWEI ZHAO, JESSE BISCHOF, MEENAKSHI SINGH, THOMAS FITZGIBBONS, XIN LIU, CHAOXING LIU, The Pennsylvania State University, LIN WANG, HPSync, Carnegie Institution of Washington, ZHONGHOU CAI, SI CHEN, Advanced Photon Source, Argonne National Laboratory, JOHN HAYES, PIER SAZIO, Optoelectronics Research Centre, University of Southampton, United Kingdom, JOHN BADDING, MOSES CHAN, The Pennsylvania State University — In-doped Ga nanowires 150 nm in diameter and 6mm in length have been formed in silica nanocapillaries. X-ray fluorescence and diffraction measurements performed at the Advanced Photon Source have been used to characterize their chemical composition and crystal structure. Investigation of the low temperature transport properties of these wires reveals a two stage superconducting transition. Magnetoresistance measurements are suggestive of vortex trapping in the wire. The X-ray fluorescence measurements suggest phase separation in the capillaries into Ga nanodroplets and In-Ga eutectic wires. A model to explain the vortex trapping consistent with this observation is being developed.

8:36AM M36.00004 Investigating long-range proximity effect in ferromagnetic Ni and Ni-Fe nanowires[1] , MEENAKSHI SINGH, JAMES KALLY, WEIWEI ZHAO, MOSES CHAN, Pennsylvania State University — Singlet superconductors and ferromagnets entail incompatible spin orders severely limiting the range of the superconducting proximity effect in a ferromagnet ($\sim$ 1 nm). Contrary to this expectation, a very long-range proximity effect (LRPE, $\sim$ 600 nm) was found in crystalline ferromagnetic nanowires [Wang et al., Nat. Phys. 6, 389 (2010)]. Several mechanisms have been suggested to explain the LRPE, the most intriguing of which is the possibility of triplet superconductivity in the ferromagnet. We have conducted experiments to probe the mechanism of the LRPE. The LRPE persists in granular Ni nanowires, ruling out ballistic transport as a possible mechanism. Surface superconductivity in the oxide layer on the ferromagnetic nanowire is also ruled out based on critical current measurements. On changing the nature of the contacting electrodes, the range of the proximity effect is found to diminish significantly. This indicates that the nature of the interface between the superconductor and the ferromagnet is important as expected for triplet superconductivity. Tunneling measurements probing the superconducting gap in the ferromagnetic nanowire are underway.

[1]This work is supported by the National Science Foundation (DMR 0820404).

8:48AM M36.00005 Critical current oscillations in superconducting Al strips[1] , TYLER MORGAN-WALL, BENJAMIN LEITH, NIKOLAUS HARTMAN, ATIKUR RAHMAN, NINA MARKOVIC, Johns Hopkins University — We have studied current-voltage characteristics as a function of temperature and magnetic field in superconducting aluminum strips with varying lengths and cross sections. We find that the critical current oscillates as a function of magnetic field and suggest that the effect depends on the relative energies of vortex configurations in the strips in different transport regimes.

9:00AM M36.00006 Ultralow Noise Microwave Amplifier Based on the Superconducting Low-inductance Undulatory Galvanometer , SHAOJIANG ZHU, DAVID HOVER, GUILHEM RIBEILL, ROBERT MCDERMOTT, University of Wisconsin, Madison — We have developed an ultralow noise microwave linear amplifier based on the Superconducting Low-inductance Undulatory Galvanometer (SLUG). The compact SLUG element is straightforward to model at microwave frequencies, allowing separate optimization of the SLUG element and the resonant input matching network. SLUG amplifiers incorporating high-Jc junctions have shown gains of order 15 dB in the frequency range from 3-10 GHz with instantaneous bandwidth up to several hundred MHz. Large-volume normal metal cooling fins have been integrated into the SLUG element to promote thermalization of hot electrons in the resistive shunts at millikelvin temperatures, and the amplifiers have achieved added system noise of one photon in the GHz frequency range. We discuss application of the SLUG amplifier to single shot dispersive readout of the transmon qubit.

9:12AM M36.00007 Flux noise in SQUIDs: Effects of deposited surface films[1] , S.R. O'KELLEY, S.M. ANTON, J.S. BIRENBAUM, JOHN CLARKE, UC Berkeley, G.C. HILTON, H.-M. CHO, K.D. IRWIN, NIST Boulder, C.D. NUGROHO, A.F. DOVE, G.A. OLSON, Z.R. YOSCOVITS, V. ORLYANCHIK, D.J. VAN HARLINGEN, J.N. ECKSTEIN, University of Illinois at Urbana-Champaign — Magnetic flux noise in SQUIDs and superconducting qubits with a spectral density $S_\Phi(f)$ scaling as $1/(f/1Hz)^\alpha$ is understood to arise from the random reversal of spins localized at the surface of the superconducting film. We present experimental results showing the effects on $S_\Phi(f)$ of Au, SiNx, NbN, and Al2O3 films deposited on the upper surface of Nb and NbN dc SQUID loops. For each measurement, we fabricated six identical SQUIDs on a single chip and then capped the surface of either half or all the SQUID loops. Certain capping layers, such as Au, had no discernible effect on $S_\Phi(f)$ with regard to the magnitude, slope α, and temperature dependence. On the other hand, some capping layers significantly reduced $S_\Phi(1Hz)$—by a factor of about two in the case of SiNx. Furthermore, some layers significantly affected the value of α and the temperature dependence of both $S_\phi(1Hz)$ and α. These results further establish the importance of the role of the surface of the SQUID loop on its flux noise. We discuss implications for microscopic models of flux noise in light of these measurements.

9:24AM M36.00008 Geometry and temperature dependence of low-frequency flux noise in dc SQUIDs[1] , S.M. ANTON, J.S. BIRENBAUM, S.R. O'KELLEY, UC Berkeley, D.S. GOLUBEV, G.C. HILTON, H.-M. CHO, K.D. IRWIN, NIST, Boulder, V. BOLKHOVSKY, D.A. BRAJE, G. FITCH, M. NEELEY, R.C. JOHNSON, W.D. OLIVER, MIT Lincoln Laboratory, F.C. WELLSTOOD, Univ of Maryland, JOHN CLARKE, UC Berkeley — Measurements on dc SQUIDs reveal a flux noise spectral density $S_\Phi(f) = A^2/(f/1\ Hz)^\alpha$. An analytic model assuming non-interacting spins localized at the surface of the SQUID loop predicts that the mean square noise scales as R/W—the radius and width of the loop, respectively. However, there are no established theories for the scaling of α with geometry or the dependences of A and α on temperature T. To test the predicted geometric scaling of this model experimentally, we measured flux noise in ten SQUIDs with systematically varying geometries. We find that, at fixed T, A^2 scales approximately as R. From the measured values of A and α, we estimate the mean square flux noise, which does not scale with R. As T is lowered, α increases significantly and in such a way that the spectra "pivot" about an approximately fixed frequency. This phenomenon implies that the mean square noise is temperature-dependent, an effect not predicted by the analytic model. We discuss our attempts to reconcile these discrepancies by considering the locking together of spins to form clusters.

9:36AM M36.00009 Niobium Nitride Thin Films and Multilayers for Superconducting Radio Frequency Cavities[1] , WILLIAM ROACH, The College of William and Mary, Department of Applied Science, DOUGLAS BERINGER, ZHAOZHU LI, The College of William and Mary, Department of Physics, CESAR CLAVERO, Lawrence Berkeley National Laboratory, ROSA LUKASZEW, The College of William and Mary, Department of Physics — Niobium nitride in thin film form has been considered for a number of applications including multi-layered coatings onto superconducting radio frequency cavities which have been proposed to overcome the fundamental accelerating gradient limit of ∼50 MV/m in niobium based accelerators [1]. In order to fulfill the latter application, the selected superconductor's thermodynamic critical field, H_C, must be larger than that of niobium and separated from the Nb surface by an insulating layer in order to shield the Nb cavity from field penetration and thus allow higher field gradients. Thus, for the successful implementation of such multilayered stack it is important to consider not just the materials inherent properties but also how these properties may be affected in thin film geometry and also by the specific deposition techniques used. Here, we show the results of our correlated study of structure and superconducting properties in niobium nitride thin films and discuss the shielding exhibited in NbN/MgO/Nb multilayer samples beyond the lower critical field of Nb for the first time.

9:48AM M36.00010 Induced superconducting FFLO states in patterned island systems and in topological insulators , SMITHA VISHVESHWARA, QINGLEI MENG, TAYLOR HUGHES, NADYA MASON, University of Illinois at Urbana-Champaign — We explore the possibility of inducing the elusive Fulde-Ferrell-Larkin-Ovchinnikov (FFLO) superconducting phase in 2D metal films by means of proximity coupling to patterned superconducting islands. We show that as a function of externally applied magnetic field, such a system not only renders the phase stable for a large region of parameter space but can also be tuned through different spatial ordering wavevectors associated with the FFLO order. We generalize these results to the surface states of 3D topological insulators and metallic surface states with Rashba coupling. We find that these FFLO states can be mapped into BCS states in which a uniform superconductor gap occurs in momentum space and can potentially be accessed in physical systems with relative ease.

10:00AM M36.00011 Evidence for synchronized Andreev reflections in NSN devices[1] , MARTIN P. STEHNO, DALE J. VAN HARLINGEN, University of Illinois at Urbana-Champaign — In mesoscopic NSN devices, in which a short superconducting region separates two metallic electrodes, the Andreev reflection process may delocalize and couple electron- and hole-states on opposite sides of the superconductor. In addition to such nonlocal (or crossed) Andreev reflections, quasiparticles may also tunnel directly between the electrodes. We have studied nonlocal transport and current correlations in Cu/Al/Cu structures. We observe that the current correlations are symmetric in applied bias and show local minima when the applied voltages at the two contacts are equal in magnitude. This behavior matches theoretical predictions for devices with intermediate interface transparency in which the nonlocal exchange of quasiparticles triggers additional synchronized Andreev reflection events at the two interfaces.

10:12AM M36.00012 Josephson current and density of states in proximity circuits with s+-superconductors , STANISLAV APOSTOLOV, ALEX LEVCHENKO, Michigan State University — We study the emergent proximity effect in mesoscopic circuits which involve conventional superconductor and unconventional pnictide superconductor separated by a diffusive normal or ferromagnetic wire. The focus is placed on revealing signatures of the proposed s^{+-} state of pnictides from the proximity-induced density of states and Josephson current. We find analytically a universal result for the density of states which exhibits both a Thouless gap at low energies, and peculiar features near the superconducting gap edges at higher energies. The latter may be used to discriminate between s^{+-} and s^{++} symmetry scenarios in scanning tunneling spectroscopy experiments. We also calculate Josephson current-phase relationships for different junction configurations, which are found to display robust $0-\pi$ transitions for a wide range of parameters.

10:24AM M36.00013 Results of Switching Measurements in MgB_2 Josephson Heterojunctions: Search for Multiple Tunneling Channels and Leggett-Mode Signatures , STEVE CARABELLO, JOSEPH LAMBERT, Drexel University, DANIEL CUNNANE, Temple University, WENQING DAI, Penn State University, KE CHEN, Temple University, QI LI, Penn State University, X. X. XI, Temple University, ROBERTO RAMOS, Indiana Wesleyan University — Josephson tunnel junctions made of multi-gap and single-gap superconducting electrodes provide a useful system for understanding multiple gap superconductivity. Peaks in the differential conductance curve have been used to characterize the energy gaps of such multi-gap materials [e.g. Chen, K. et al., Nat. Commun. 3:619 (2012)]. Superconducting-to-normal switching data can also provide useful insights. While ramping the current from zero to the critical current, the washboard potential is tilted, thereby adjusting the resonant frequency of the potential well, and altering the energy level spacing. By exciting the junction with microwaves, resonant modes may be explored. We report results of conductance and switching experiments on MgB_2/I/Pb and MgB_2/I/Sn junctions, with and without microwaves, in a helium dilution refrigerator with a base temperature 20mK. These results exhibit tunneling modes and resonances not observed in single-gap/single-gap junctions, including a peak in the escape rate that may be consistent with coupling to the Leggett mode.

10:36AM M36.00014 Evidence for Multi-photon transitions between energy levels in a large Current-Biased Magnesium Diboride Josephson Heterojunction , ROBERTO RAMOS, Indiana Wesleyan University, STEVEN CARABELLO, JOSEPH LAMBERT, Drexel University, DANIEL CUNNANE, Temple University, WENQING DAI, The Penn State University, KE CHEN, Temple University, QI LI, The Penn State University, XIAOXING XI, Temple University — When photons are strongly coupled to a quantum system, multiphoton transitions can be observed between two energy levels when the quantum energy of the exciting radiation, multiplied by an integer, matches the level spacing. This phenomenon can be observed in Josephson junction qubits exposed to weak microwave radiation at very low temperatures. At microwave resonance, the transition probability of a junction from superconducting to normal state is enhanced and these are used to map multiphoton transitions. We report observation of single- and multi-photon transitions between ground and first excited states in current-biased MgB2 thin film junctions by applying RF with frequencies between 0.5 and 3 Ghz. These large (up to 0.2mm x 0.3 mm) junctions consist of an MgB2 electrode insulated by native oxide from a lead (Pb) or tin (Sn) counter-electrode, and have areas at least 600 times bigger than Nb junctions previously shown to exhibit multiphoton transitions. The data is consistent with theoretical models of junctions behaving in the quantum limit and show anharmonicity of the junction potential when biased near the critical current.

10:48AM M36.00015 In-gap States of Josephson Junction with Two-gap Superconductiors , JU KIM, LADAN BAHRAINIRAD, University of North Dakota — We investigate the transport property of SIS junctions with two-gap superconductors. The effects of two superconducting condensates on critical current density is estimated by studying the microscopic structure of Josephson current density in a dual-mode tunnel junction with a narrow quasi-classical tunnel barrier. Following the suggestion by Golubov and coworkers [1], we use two Bloch functions to describe the condensates in the two-band superconductors. In this junction, the in-gap states which include the interband interference effect appear at the interfaces due to the discontinuity of the superconducting phase. Also, similar to a Josephson junction [2] involving one-gap and two-gap superconductors, novel broken time-reversal symmetry states are found. We estimate the effects of interband interference and broken time-reversal symmetry on the in-gap bound states and critical Josephson current density.

Session M37 DMP DCOMP: Focus Session: Fe-based Superconductors: Novel Selenides 345/346

- Xian-Hui Chen, University of Science and Technology of China

8:00AM M37.00001 The nodal crisis in Iron based superconductivity[1] , PIERS COLEMAN, T. TZEN ONG, Center for Materials Theory, Physics and Astronomy, Rutgers University — The recent observation of fully gapped high temperature superconductivity in an iron chalcogenide without a hole Fermi surface[1], combined with the observations that rule out a node-less d-wave state [2] constitute a "nodal crisis" in iron based superconductivity, for we do not understand how the underlying singlet state avoids the strong Coulomb interactions on the iron site without some kind of node within the superconducting condensate. In this work, we re-analyze the allowed symmetries of the superconducting condensate in the iron superconductors, taking into account both orbital symmetries between the zx and zy orbitals and the presence of two equivalent Fe sites per unit cell. We argue that the additional orbital degrees of freedom provide for a much richer class of pairing symmetries than normally considered. A particularly interesting possibility, is a p-wave, spin singlet, orbital triplet state that is a fully gapped iron analog of the B-phase of superfluid He-3. We will discuss this interesting possibility.

8:12AM M37.00002 ABSTRACT WITHDRAWN –

8:24AM M37.00003 Electronic Structure and Superconductivity in Bilayer FeSe\SrTiO$_3$ Films , XU LIU, National Lab for Superconductivity, Beijing National Laboratory for Condensed Matter Physics, Institute of Physics, CAS, Beijing 100190, China, WENHAO ZHANG, State Key Lab of Low-Dimensional Quantum Physics, Department of Physics, Tsinghua University, Beijing 100084, China, JUNFENG HE, LIN ZHAO, DEFA LIU, SHAOLONG HE, National Lab for Superconductivity, Beijing National Laboratory for Condensed Matter Physics, Institute of Physics, CAS, Beijing 100190, China, CHUANGTIAN CHEN, ZUYAN XU, Technical Institute of Physics and Chemistry, Chinese Academy of Sciences, Beijing 100190, China, XUCUN MA, Beijing National Laboratory for Condensed Matter Physics, Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China, QIKUN XUE, State Key Lab of Low-Dimensional Quantum Physics, Department of Physics, Tsinghua University, Beijing 100084, China, XINGJIANG ZHOU, National Lab for Superconductivity, Beijing National Laboratory for Condensed Matter Physics, Institute of Physics, CAS, Beijing 100190, China — We have carried out high resolution angle-resolved photoemission (ARPES) measurements on bilayer FeSe films grown on the $SrTiO_3$(001) substrate by the MBE method. Detailed doping evolution of the electronic structure has been investigated through an annealing process. Similar to the single-layer FeSe film, two phases are observed during the annealing process which coexist and compete. On the other hand, the bilayer FeSe film exhibits obviously different behaviors from that of the single layer FeSe film. Details of the experiment and their implications will be discussed.

8:36AM M37.00004 Spin fluctuations in alkali-metal iron selenide superconductors probed by inelastic neutron scattering , DMYTRO INOSOV, Max Planck Institute for Solid State Research, Stuttgart, Germany — We employ inelastic neutron scattering (INS) on iron-based superconductors to study the spectrum of low-energy magnetic excitations. According to the most commonly accepted theory of the superconducting state, spin fluctuations could act as the bosonic "glue" that mediates Cooper pairing in Fe-based compounds, thus playing the role similar to that of phonons in the conventional BCS theory. The knowledge of the spin-fluctuation spectrum is therefore important for understanding the mechanisms that stabilize high transition temperatures in Fe-based superconductors. Our most recent results include observations of magnetic resonant modes and normal-state paramagnon excitations in alkali-metal iron selenide superconductors $Rb_xFe_2Se_2$ and $K_xFe_2Se_2$. These excitations were found at a wave vector that differs from the ones characterizing magnetic resonant modes in other iron-based superconductors, but appears to be universal for all alkali-metal iron selenide compounds independently of the alkali-metal element or the crystal-growth procedure. Using time-of-flight neutron spectroscopy, we also estimated the absolute spectral weight of the magnetic resonant mode, which exceeds that in the iron arsenides.

9:12AM M37.00005 Evidence of Chemical Phase Separation in $K_{0.65}Fe_{1.74}Se_2$[1] , SVEN LANDSGESELL, DANIEL ABOU-RAS, Helmholtz-Zentrum Berlin, THOMAS WOLF, Karlsruher Institut für Technologie, KAREL PROKES, Helmholtz-Zentrum Berlin — $K_xFe_{2-y}Se_2$ has been widely investigated and many samples show a co–existence of superconductivity and antiferromagnetic properties. Recently the it was shown that this system shows a clear phase separation, however the nature of the two phases remained unclear. In the present work we report on a chemical phase separation in crystalline superconducting $K_{0.65}Fe_{1.74}Se_2$, investigated by means of magnetization experiments, scanning electron microscopy, electron backscatter diffraction, and energy–dispersive X–ray spectrometry. It is shown that the crystal consists of platelets oriented in <100> with an approximated volume fraction of about 30% in the surrounding <001> oriented matrix. The platelets (the matrix) are depleted in K (Fe) and enriched in Fe (K). Chemical phase separation is demonstrated by a stable, antiferromagnetic $K_{0.8}Fe_{1.6}Se_2$ matrix, and $K_xFe_ySe_2$ platelets inducing superconductivity. This time driven chemical spinoidal phase separation may therefore be responsible for several alternative properties measured in $K_xFe_{2-y}Se_2$ samples as superconductivity and antiferromagnetism.

[1]DFG SPP 1458

9:24AM M37.00006 Intrinsic crystal phase separation and detailed structural characterization in $Cs_xFe_{2-y}Se_2$ superconductor via high resolution diffraction , MIHAI STURZA, DUCK YOUNG CHUNG, HELMUT CLAUS, Argonne National Laboratory, MERCOURI KANATZIDIS, Argonne National Laboratory and Northwestern University, MATERIALS SCIENCE DIVISION-ARGONNE NATIONAL LABORATORY TEAM, DEPARTMENT OF CHEMISTRY- NORTHWESTERN UNIVERSITY COLLABORATION — The discovery of high critical temperature superconductivity in complex metal cuprate pnictide and chalcogenide compounds is a major breakthrough in materials synthesis and in developing new concepts, compounds and technologies. The mechanisms of charge carrier density control are important as small changes in composition produce metal-insulator transitions and generate superconductivity at temperatures of up to 37K in chalcogenides. Reported materials are based on a square FeSe layer built from edge-sharing of $FeSe_4$ tetrahedra. Insertion of alkali metal cations between FeSe layers affords superconductivity in this system. We have grown Cs-intercalated FeSe samples that show superconductivity with different Tc between 10K and 28K by changing the iron and cesium concentration in the nominal composition $Cs_xFe_{2-y}Se_2$ ($0.7 < x < 1.1$, $0 < y < 0.7$). These are two phase systems and only one phase is SC. The relationship between structural and superconducting properties will be discussed based on high-resolution X-ray diffraction and single-crystal X-ray measurements combined with magnetometry, heat capacity, and transport measurements.

9:36AM M37.00007 Phase separation and superconductivity in $K_{1-x}Fe_{2-y}Se_2$ single crystals under different thermal treatments , HAI-HU WEN, XIAXIN DING, JIAN TAO, HUAN YANG, Physics Department, Nanjing University — Single crystals with the starting composition of $K_{0.8}Fe_2Se_2$ have been thermally treated in three different ways: slow furnace cooling (SFC) from 1020 °C, retreated for 2 hours at 250 °C (S250) and 350 °C (S350:) and followed by quenching. The DC magnetization measurements on them exhibit very different behavior: the SFC samples show a tiny diamagnetic signal, while the sample S350 shows a quite large Meissner shielding volume with the S250 in the middle. The resistive measurements on the sample S350 show zero resistance below 31 K with a sharp transition; while those from the sample SFC or S250 show much larger residual resistance together with a much wider transition. By using the SEM, we have successfully identified that, in SFC, the superconducting areas have relatively larger sizes (about one micrometer) and are widely separated; the superconducting area change into many thin but well connected networks in the sample S350, which construct a 3D spider-web. This explains both the magnetic shielding and the resistive transitions in the three samples. In addition, the superconducting area has a composition of about $K_{0.64}Fe_{1.8}Se_2$. We suggest that the thermodynamically stable phase for the superconducting state has probably one vacancy in every 10 Fe-sites.

9:48AM M37.00008 Nodeless superconducting gap in $K_xFe_{2-y}Se_2$ and its evolution with doping probed from angle-resolved photoemission , MIN XU, YAN ZHANG, FEI CHEN, QINGQIN GE, Department of Physics, Fudan University, China, YI YU, AIFENG WANG, CHANGJIN ZHANG, XIANHUI CHEN, Hefei National Laboratory for Physical Science at Microscale and Department of Physics, University of Science and Technology of China, DONGLAI FENG, Department of Physics, Fudan University, China — The nodeless superconducting gap has been observed on the large Fermi pockets around the zone corner in $K_xFe_{2-y}Se_2$, whether its pairing symmetry is s wave or nodeless d wave is still under intense debate. Here we report an isotropic superconducting gap distribution on the small electron Fermi pocket around the Z point in $K_xFe_{2-y}Se_2$, which favors the s-wave pairing symmetry [1-3]. At the same time, we will present some of the recent data on the evolution of the band structure and superconducting gap of iron chalcogenides $K_xFe_{2-y}Se_2$ as a function of electron and hole doping.

10:00AM M37.00009 Terahertz spectroscopy on $Rb_{1-x}Fe_{2-y}Se_2$, ZHE WANG, JONAS FISHER, MICHAEL SCHMIDT, VLADIMIR TSURKAN, ALOIS LOIDL, JOACHIM DEISENHOFER, Experimental Physics V, EKM, Institute of Physics, University of Augsburg, Germany — Single crystals of superconducting and non-superconducting $Rb_{1-x}Fe_{2-y}Se_2$ [1] have been investigated by terahertz time-domain transmission spectroscopy as a function of temperature. In the superconducting samples, we observe the signatures of the superconducting transition [2] and an isosbestic point in the temperature dependence of optical conductivity in the vicinity of 100 K, which could be related to the reported phase separation in these compounds. In the non-superconducting samples, the optical conductivity exhibits features which can be interpreted in terms of spin wave excitations in agreement with neutron experiments [3].

10:12AM M37.00010 ABSTRACT WITHDRAWN –

10:24AM M37.00011 High T_C superconductivity in single-layer FeSe films on $SrTiO_3$[1] , ZHANG WENHAO, WANG QINGYAN, LI FANGSEN, ZHANG JINSONG, GUO MINGHUA, Department of Physics, Tsinghua University, LIU DEFA, HE SHAOLONG, The Institute of Physics, CAS, SUN YI, School of Physics, Peking University, HE KE, The Institute of Physics, CAS, CHEN XI, Department of Physics, Tsinghua University, WANG LILI, The Institute of Physics, CAS, WANG JIAN, School of Physics, Peking University, WANG YAYU, Department of Physics, Tsinghua University, ZHOU XINGJIANG, MA XUCUN, The Institute of Physics, CAS, XUE QI-KUN, Department of Physics, Tsinghua University — The latest scanning tunneling spectroscopy and angle resolved photoemission spectroscopy of single-unit-cell FeSe films on $SrTiO_3$ show signatures of high temperature superconductivity with $T_C > 55$ K, the maximum value that has been stagnant since the discovery of the iron-based superconductors in 2008. Here we report a detailed transport study of the single-unit-cell FeSe film. Electrical transport measurements reveal a transition temperature of ~ 50 K. The robust superconductivity is further confirmed by measuring Meissner effect. We show that the characteristics of the transition are consistent with a two-dimensional superconductor undergoing a Berezinskii-Kosterlitz-Thouless transition.

10:36AM M37.00012 Effective doping and suppression of Fermi surface reconstruction via Fe vacancy disorder in $K_xFe_{2-y}Se_2$[1] , TOM BERLIJN, PETER J. HIRSCHFELD, University of Florida, WEI KU, Brookhaven National Laboratory — We investigate[1] the effect of disordered vacancies on the normal-state electronic structure of the newly discovered alkali-intercalated iron selenide superconductors. To this end we use a recently developed Wannier function based method[2] to calculate from first principles the configuration-averaged spectral function $\langle A(k,\omega)\rangle$ of $K_{0.8}Fe_{1.6}Se_2$ with disordered Fe and K vacancies. We find that the disorder can suppress the expected Fermi surface reconstruction without completely destroying the Fermi surface. More interestingly, the disorder effect raises the chemical potential significantly, giving enlarged electron pockets similar to highly doped KFe_2Se_2, without adding carriers to the system. [1] T. Berlijn, P. J. Hirschfeld, and W. Ku, Phys. Rev. Lett. 109, 147003 (2012) [2] T. Berlijn, D. Volja and W. Ku, Phys. Rev. Lett. 106, 077005 (2011)

10:48AM M37.00013 Orbital-Selective Mott Phase in Multiorbital Models for Alkaline Iron Selenides , QIMIAO SI, RONG YU, Department of Physics and Astronomy, Rice University — The degree of electron correlations is crucial for understanding the properties of both the normal and superconducting states of the iron-based superconductors. The superconductivity near an antiferromagnetic insulating phase in the newly discovered alkaline iron selenide superconductors suggests stronger electron correlations in these materials than in iron pnictides. To investigate the correlation effects in the alkaline iron selenides, we study the metal-to-Mott-insulator transition in multiorbital models for this system using a slave-spin mean-field method [1]. We show that when the Hund's coupling is beyond a threshold, this transition is via an intermediate orbital-selective Mott phase, in which the 3d xy orbital is Mott localized while the other 3d orbitals remains itinerant. We find that this phase is still stabilized over a range of carrier dopings, and has unique experimental signatures [2,3]. Our results lead to an overall phase diagram for the alkaline iron selenides, in which the orbital-selective Mott phase provides a natural link between the alkaline iron selenide superconductor and its parent Mott-insulating compound. [1] R. Yu and Q. Si, arXiv:1208.5547. [2] M. Yi et al., arXiv:1208.5192. [3] P. Gao et al., arXiv:1209.1340.

11:00AM M37.00014 Modeling local interface and impurity effects in phase separated iron chalcogenide superconductor $K_xFe_{2-y}Se_2$, S. MUKHERJEE, M.N. GASTIASORO, University of Copenhagen, P.J. HIRSCHFELD, University of Florida, B.M. ANDERSEN, University of Copenhagen — Superconductivity in iron chalcogenide superconductor $KxFe_{2-y}Se_2$ exists near a phase separated block antiferromagnetic state (BAFM) with magnetic moments of $3.3\mu_B$/Fe. The nature of the superconducting state compared to other pnictide superconductors is unclear because the Fermi surface contains electron pockets only. This raises the fundamental question whether the superconducting phase is described by s- or d-wave gap symmetry. We study the magnetic state, the superconducting state as well as their interface in phase separated $K_xFe_{2-y}Se_2$ using a real space extended Hubbard model. The model includes the effects of all five Fe d-orbitals and the superconducting pairing interaction is generated within the spin-fluctuation exchange mechanism. We propose the existence of signatures in the local density of states near the interface and impurities that could discriminate between the d-wave and s-wave superconducting gap symmetries. Further, we show how the interface between the superconductor and BAFM leads to novel features in the various mean fields, including e.g. a strong interface-enhanced orbital-ordering.

Session M38 GERA: Energy Storage and Conversion 347 - Joseph Poon, University of Virginia

8:00AM M38.00001 Adsorbed Methane Film Properties in Nanoporous Carbon Monoliths[1] , YUCHOONG SOO, NAGARAJU CHADA, MATTHEW BECKNER, JIMMY ROMANOS, JACOB BURRESS, PETER PFEIFER, Physics Dept. U. of Missouri — Carbon briquetting can increase methane storage capacity by reducing the useless void volume resulting in a better packing density. It is a robust and efficient space-filling form for an adsorbed natural gas vehicle storage tank. To optimize methane storage capacity, we studied three fabrication process parameters: carbon-to-binder ratio, compaction temperature, and pyrolysis temperature. We found that carbon-to-binder ratio and pyrolysis temperature both have large influences on monolith uptakes. We have been able to optimize these parameters for high methane storage. All monolith uptakes (up to 260 bar) were measured by a custom-built, volumetric, reservoir-type instrument. The saturated film density and the film thickness was determined using linear extrapolation on the high pressure excess adsorption isotherms. The saturated film density was also determined using the monolayer Ono-Kondo model. Film densities ranged from ca. 0.32 g/cm^3 - 0.37 g/cm^3.The Ono-Kondo model also determines the binding energy of methane. Binding energies were also determined from isosteric heats calculated from the Clausius-Clapeyron equation and compared with the Ono-Kondo model method. Binding energies from Ono-Kondo were ca. 7.8 kJ/mol - 10 kJ/mol.

8:12AM M38.00002 Finite-Temperature Dihydrogen Adsorption/Desorption Thermodynamics on Metallo-Porphyrin Incorporated Graphene: Enthalpy versus Vibration , EUI-SUP LEE, SUNG-JAE WOO, Graduate School of Nanoscience and Technology (WCU), KAIST, Daejeon 305-701, MINA YOON, Oak Ridge National Laboratory, Oak Ridge, TN 37831, U.S.A., YONG-HYUN KIM, Graduate School of Nanoscience and Technology (WCU), KAIST, Daejeon 305-701 — Gas adsorption is closely related to a variety of important physicochemical processes and technologies. Especially, hydrogen storage has been attracting much interest due to high energy density and the environmetally-friendly nature. Although a lot of theoretical studies have been carried out, the thermal vibration effect on hydrogen-sorbent interaction is relatively laking. Here we report the thermodynamics of H_2 molecules adsorbed onto metallo-porphyrin-incoporated graphenes based on first-principles density-functional theory calculations. We found that the slow vibrations induced by weak binding tend to make the system more stable under finite temperature while the fast vibrations induced by strong binding disturb the adsorption. This tendency is expected to be universally found in various gas-sorbent systems.

8:24AM M38.00003 Hydrogen Storage Investigation on Nanotube, Graphene and Organometallic Complexes , HONG ZHANG, Sichuan University, China — New materials and methods for storing hydrogen at high gravimetric and volumetric densities are required because of the widely use of hydrogen for clean fuel. With exceptionally high surface areas, porous materials based on carbon have recently emerged as some of the most promising candidate materials. Here I reviewed our former work on hydrogen storage based on several kinds of organometallic Complexes. Maximum capacities of the hydrogen storage in organometallic compounds consisting of Co and Ni atoms bound to C_mH_m ring were found 3.48 wt % and 3.49 wt %, respectively; for the structures having a transition metal (TM) Co and Ni inserted in C_mH_m ring, the maximum number of H_2 molecule bound to the inserted-type CoC_mH_m and NiC_mH_m complexes is three, and the largest hydrogen storage density is 5.13 wt % and 3.49 wt % for CoC_4H_4 and NiC_4H_4, Meanwhile, the ionic ($C_4H_4^+$ and $C_5H_5^+$) improves the capability of hydrogen storage and makes all H_2 adsorbed to the charged compounds in molecular form. With the CH_3 ligand bound to the compounds, the adsorption energy of H_2 decreases to an ideal range, and stability of the compounds are improved. At last, the hydrogen adsorption properties on the complex structures $TiRH_7Si_8O_{12}$ are investigated, and the kinetic stability when H_2 was added to organometallic compounds is also discussed by analyzing HOMO-LUMO gaps. Here we also mentioned our results of hydrogen storage based on nanotubes and graphene.

8:36AM M38.00004 First-principles calculations of mass transport in magnesium borohydride

, CHAO YU, VIDVUDS OZOLINS, Department of Materials Science and Engineering, UCLA — $Mg(BH_4)_2$ is a hydrogen storage material which can decompose to release hydrogen in the following reaction: $Mg(BH_4)_{2(solid)} \rightarrow \frac{1}{6}MgB_{12}H_{12(solid)} + \frac{5}{6}MgH_{2(solid)} + \frac{13}{6}H_{2(gas)} \rightarrow MgH_{2(solid)} + 2B_{(solid)} + 4H_{2(gas)}$. However, experiments show that hydrogen release only occurs at temperatures above 300 °C, which severely limits applications in mobile storage. Using density-functional theory calculations, we systematically study bulk diffusion of defects in the reactant $Mg(BH_4)_2$ and products $MgB_{12}H_{12}$ and MgH_2 during the first step of the solid-state dehydrogenation reaction. The defect concentrations and concentration gradients are calculated for a variety of defects, including charged vacancies and interstitials. We find that neutral $[BH_3]$ vacancies have the highest bulk concentration and concentration gradient in $Mg(BH_4)_2$. The diffusion mechanism of $[BH_3]$ vacancy in $Mg(BH_4)_2$ is studied using the nudged elastic band method. Our results shows that the calculated diffusion barrier for $[BH_3]$ vacancies is $\approx .2$ eV, suggesting that slow mass transport limits the kinetics of hydrogen desorption.

8:48AM M38.00005 Effect of transition-metal additives on dehydrogenation kinetics of MgH_2[1]

, ANINDYA ROY, ANDERSON JANOTTI, CHRIS G. VAN DE WALLE, University of California Santa Barbara — Using first-principles calculations based on hybrid density functional theory we study the (de)hydrogenation process in MgH_2, an important solid-state hydrogen storage material. This reaction proceeds through diffusion processes, mediated by native point defects such as vacancies and interstitials. Reducing the formation energy of relevant defects increases their concentrations, resulting in higher diffusion rates and an enhancement in kinetics. We investigate the formation energies of native point defects in MgH_2 and determine the position of the Fermi level in the band gap using the charge neutrality condition. The presence of transition-metal (TM) impurities (Ti, Fe, Co and Ni) causes the Fermi level to shift according to the position of the TM acceptor/donor levels in the band gap. This shift can bring down the formation energy of native defects. Our calculations predict that all of the TM additives, in either interstitial or substitutional configurations, may cause such a shift in the Fermi level and thus increase the concentration of the hydrogen vacancies that govern hydrogen diffusion. Our proposed mechanism explains the experimentally observed enhancement in the rate of dehydrogenation of MgH_2 upon addition of TM impurities.

9:00AM M38.00006 Low-Energy Polymeric Phases of Alanates[1]

, HUAN TRAN, MAXIMILIAN AMSLER, Universität Basel, Switzerland, MIGUEL MARQUES, SILVANA BOTTI, Université de Lyon, France, ALEXANDER WILLAND, STEFAN GOEDECKER, Universität Basel, Switzerland — Low-energy structures of alanates are currently known to be described by patterns of isolated, nearly ideal tetrahedral $[AlH_4]$ anions and metal cations. We discover that the novel polymeric motif recently proposed for $LiAlH_4$ plays a dominant role in a series of alanates, including $LiAlH_4$, $NaAlH_4$, $KAlH_4$, $Mg(AlH_4)_2$, $Ca(AlH_4)_2$ and $Sr(AlH_4)_2$. In particular, most of the low-energy structures discovered for the whole series are characterized by networks of corner-sharing $[AlH_6]$ octahedra, forming wires and/or planes throughout the materials. Finally, for $Mg(AlH_4)_2$ and $Sr(AlH_4)_2$, we identify two polymeric phases to be lowest in energy at low temperatures.

9:12AM M38.00007 Stability of transition metals on the Mg-terminated MgB_2 (0001) surface and their effects on hydrogen dissociation

, YONGLI WANG, CHRIS WOLVERTON, Northwestern University — The re-hydrogenation of MgB_2 is a critical step in the reversibility of several key hydrogen storage reactions. Two main activated processes affect the kinetics of hydrogen absorption by MgB_2: the dissociation of the H_2 molecule and the diffusion of atomic H into the bulk. In order to have fast absorption kinetics both activated processes need to have a low barrier. Using first-principles calculations, we investigate the dissociation of H_2 on the Mg-terminated MgB_2 (0001) surfaces. We investigate both ideal surfaces as well as surfaces with vacancies, and transition-metal-dopants (TM=Sc∼Zn,Y∼Cd,Au,Pt). Our calculations show that the late TMs more favorably substitute for the Mg atoms in the outermost layer of the Mg-terminated surface, rather than for those in the sub-layers. We find the dissociation barrier for H_2 on the clean Mg-terminated MgB_2 (0001) surface is 0.46eV. The TM dopants have only a small effect on dissociation barrier when they are incorporated into the sub-layers. However, when doped in the outermost layer, we find examples of dopants that significantly decrease the activation barrier for the dissociation of H_2. We also investigate the diffusivity of H in MgB_2 and find strong anisotropy in the diffusion pathways.

9:24AM M38.00008 Adsorbed Hydrogen Film Densities and Thicknesses Determined from Low-Temperature Hydrogen Sorption Experiments[1]

, JACOB BURRESS, ELMAR DOHNKE, MATTHEW BECKNER, Physics Dept. U. of Missouri, MARK LEE, Chemistry Dept. U. of Missouri, CARLOS WEXLER, PETER PFEIFER, Physics Dept. U. of Missouri — Hydrogen storage through physisorption has shown tremendous promise. Advancement of our understanding about hydrogen behavior in confined pores can lead to a development of new storage materials. For example, isosteric heat is used to determine the quality of a sorbent. Yet, Clausius-Clapeyron isosteric heat calculations are typically performed on excess adsorption, which leads to unphysical results. Absolute adsorption should be used for these calculations. To determine absolute adsorption from excess adsorption, the volume of the adsorbed film is needed. We have built a Sievert type instrument capable of temperatures from 10 K to 300 K and pressures up to 200 bar. Using this instrument to measure low temperature ($<$ 77 K) and high pressure ($>$ 100 bar) isotherms, experimental film density and volume have been determined from the linear decrease in excess H_2 as a function of bulk gas density. Additionally, some materials have shown H_2 uptakes higher than what their surface area predicts. One hypothesis is N_2, the standard gas to determine surface areas, is sterically forbidden to go into pores that H_2 can. Sub-critical H_2 isotherms have been measured to determine surface area available to the H_2 and comparisons are made to N_2 surface area.

9:36AM M38.00009 Thermodynamics, kinetics, and catalytic effect of dehydrogenation from MgH2 stepped surfaces and nanocluster: a DFT study

, JASON REICH, Department of Chemistry, University of Illinois at Urbana Champaign, LINLIN WANG, Ames Laboratory, U.S. Department of Energy, DUANE JOHNSON, Ames Laboratory, U.S. Department of Energy; Department of Materials Science & Engineering, Iowa State University — We detail the results of a Density Functional Theory (DFT) based study of hydrogen desorption, including thermodynamics and kinetics with(out) catalytic dopants, on stepped (110) rutile and nanocluster MgH_2. We investigate competing configurations (optimal surface and nanoparticle configurations) using simulated annealing with additional converged results at 0 K, necessary for finding the low-energy, doped MgH_2 nanostructures. Thermodynamics of hydrogen desorption from unique dopant sites will be shown, as well as activation energies using the Nudged Elastic Band algorithm. To compare to experiment, both stepped structures and nanoclusters are required to understanding and predict the effects of ball milling. We demonstrate how these model systems relate to the intermediary sized structures typically seen in ball milling experiments.

9:48AM M38.00010 Measurements of Increased Enthalpies of Adsorption for Boron-Doped Activated Carbons[1] , ANDREW GILLESPIE, MATTHEW BECKNER, NAGARAJU CHADA, JOSEPH SCHAEPERKOETTER, Physics Dept. U. of Missouri, ANUPAM SINGH, MARK LEE, Chemistry Dept. U. of Missouri, CARLOS WEXLER, JACOB BURRESS, PETER PFEIFER, Physics Dept. U. of Missouri — Boron-doping of activated carbons has been shown to increase the enthalpies of adsorption for hydrogen as compared to their respective undoped precursors (>10kJ/mol compared to ca. 5kJ/mol). This has brought significant interest to boron-doped carbons for their potential to improve hydrogen storage. Boron-doped activated carbons have been produced using a process involving the deposition of decaborane ($B_{10}H_{14}$) and high-temperature annealing resulting in boron contents up to 15%. In this talk, we will present a systematic study of the effect that boron content has on the samples' structure, hydrogen sorption, and surface chemistry. Measurements have shown a significant increase in the areal hydrogen excess adsorption and binding energy. Experimental enthalpies of adsorption will be presented for comparison to theoretical predictions. Additionally, samples have been characterized by thermal gravimetric analysis, gas chromatography-mass spectroscopy, Fourier transform infrared spectroscopy, and X-ray photoelectron spectroscopy. TGA and GC-MS results investigated the decomposition of the decaborane in the carbon. Boron-carbon bonds are shown in the FTIR and XPS spectra, indicating that boron has been incorporated into the carbon matrix.

10:00AM M38.00011 Bulk Diffusion via a "kick-out" method for Lithium in the decomposition reaction LiAlH4/Li3AlH6 , BILJANA ROLIH, VIDVUDS OZOLINS, UCLA, OZOLINS TEAM — In the pursuit to find a practical system for hydrogen storage, complex metal hydrides have long been considered as viable candidates due to their high hydrogen content. However, some of the challenges faced with these types of systems are poor thermodynamics or kinetics. The underlying mechanisms, and their limiting processes, for the decomposition of these materials need to be understood. From experimental work on the decomposition of hydrogen storage materials, it has been suggested that bulk diffusion of metal species is the bottleneck for hydrogen release. In this work is the dehydrogenation we investigated the system $LiAlH_4 \longrightarrow LiAlH_6$ with favorable hydrogen release (5.3 wt %), at moderate temperatures. Using first-principles density functional theory we found the defects facilitating mass transport by calculating individual formation energies, highest concentrations, and activation barriers for defect mobility. The mass transport of Lithium is found to be mediated by a "kick-out" mechanism. The results are used to further our understanding of the fundamental mechanism of mass transport and evaluate the possibility of kinetics as the limiting process in this reaction.

10:12AM M38.00012 Gold Nanoparticle Enhancement for Polymer Electrolyte Membrane (PEM) Fuel Cell[1] , CHENG PAN, SISI QIN, MIRIAM RAFAILOVICH, Materials Science and Engineering, Stony Brook University — PEM fuel cell is one of the most promising future alternative energy sources. However, its relatively low power output has prevented it from many practical applications. Marvrikakis et al have predicted that gold nanoparticles that are platelet shaped andhave direct contact to the substrate to be the perfect catalysts. In our experiment, hydrophobic, thiol-functionalized gold nanoparticles were synthesized through two-phase method developed by Brust et al. When particle solution is spread at the air water interface, EXAFS spectroscopy indicate that some of the gold atoms are removed, as the water displaces the hydrophobic thiol chains from the particle surface, resulting in platelet shaped particles. Furthermore, after these nanoparticles are spread on the surface of water in a Langmuir-Blodgett trough where surface pressure can be applied to compress them, they form LB film consisting of one or more monolayers. This LB film can then be deposited onto a solid surface, such as the Nafion membrane where the particle surface can make direct contact with electrodes and take effect. We also find that there is an optimal surface pressure for forming gold nanoparticles monolayer to achieve the highest enhancement of output power.

[1]Funded by NSF-MRSEC-DMR-0606387

10:24AM M38.00013 Density Functional Theory Study of Oxygen Reduction Reaction Mechanism on $Pt_3Ti(111)$ Surface , SHYAM KATTEL, Department of Mechanical Engineering and Materials Science, University of Pittsburgh, ZHIYAO DUAN, GUOFENG WANG, University of Pittsburgh — Density functional theory (DFT) calculations are performed to explain the ORR mechanism on Pt segregated $Pt_3Ti(111)$ surface. The possible ORR mechanism is elucidated by calculating the activation energies of all ORR elementary reaction steps. Our preliminary results predict that the ORR proceeds via a H_2O_2 dissociation mechanism with coverage dependent kinetics. At high coverage, the rate determining step (RDS) is protonation of adsorbed O_2 to form OOH. The energy barrier for this process is 0.20 eV which is lower than the energy barrier for RDS on pure Pt(111) surface. These findings suggest that modified PtTi(111) surface has better ORR activity in comparison to pure Pt(111) surface. Furthermore, we have studied the corrosion behavior of $Pt_3Ti(111)$ surface by evaluating the electrochemical potential shift for clean and oxygenated surface. The computations predict enhanced stability of $Pt_3Ti(111)$ surface against surface Pt dissolution in comparison to Pt dissolution from pure Pt(111) surface.

10:36AM M38.00014 Neutron Scattering Studies of Destabilized Lithium Borohydride , NINA VERDAL, NIST Center for Neutron Research; University of Maryland, TERRENCE UDOVIC, NIST Center for Neutron Research, JOHN RUSH, NIST Center for Neutron Research; University of Maryland, ALEXANDER SKRIPOV, Institute of Metal Physics, Ural Division of the Russian Academy of Sciences — One of the most promising materials for hydrogen storage is lithium borohydride, $LiBH_4$, due to its high hydrogen mass fraction. However, applications require destabilization of the material in order to reduce the temperature and pressure required for hydrogen cycling. One possible avenue for destabilization has been via the use of mixed crystals, for example, LiI and $LiBH_4$, in which the relatively large iodide anion expands the crystal lattice of bulk $LiBH_4$. Here we present neutron scattering results comparing BH_4^- anion reorientational dynamics for bulk $LiBH_4$ and the destabilized LiI-$LiBH_4$ system. Quasielastic neutron scattering spectroscopy shows that at temperatures below room temperature, the reorientational dynamics for hexagonal LiI-$LiBH_4$ is very similar to that of the high-temperature (380 K and above) hexagonal phase of $LiBH_4$ instead of its low-temperature orthorhombic phase, which exhibits different dynamics. This is consistent with the behavior found using NMR spectroscopy.

10:48AM M38.00015 Predicting hydrogen and methane adsorption in carbon nanopores for energy storage[1] , YUNGOK IHM, University of Tennessee, JAMES MORRIS, VALENTINO COOPER, Oak Ridge National Lab, MORRIS LAB, U. TENNESSEE COLLABORATION, ADVANCED MATERIAL GROUP, ORNL COLLABORATION — There are increasing demands for alternate fuels for transportation, which requires safe, high energy density, lightweight storage materials. Experimental measurements and theoretical predictions show relatively low hydrogen storage capacities in various porous materials, limiting hydrogen as a viable alternative for automobiles. In this work, we use a continuum model based on van der Waals density functional (vdW-DF) calculations to elucidate the role that long-range interactions play in the hydrogen adsorption properties of model slit nanopores in carbon. The proper treatment of long-range interactions gives an optimal pore size for hydrogen storage of 8-9 Å (larger than previously predicted). Remarkably, we find a peak hydrogen density close to that of liquid H_2 at ambient temperatures, in agreement with recent experimental results on pore-size dependent adsorption in nanoporous carbon. We then show that such nanopores would be better suited to storing methane, possibly providing an alternative to fill the gap between the capacity required by DOE goals and that attainable with current hydrogen storage technology.

Session M39 DFD: Drops, Bubbles, and Interfacial Fluid Mechanics I 348 - Sidney R. Nagel, University of Chicago

8:00AM M39.00001 Condensed droplet jumping: Capillary to inertial energy transfer , RYAN ENRIGHT, Bell Labs Ireland, Alcatel-Lucent, NENAD MILJKOVIC, Massachusetts Institute of Technology, MICHAEL MORRIS, CRANN, University College Cork, EVELYN WANG, Massachusetts Institute of Technology — When condensed droplets coalesce on a superhydrophobic nanostructured surface, the resulting droplet can jump from the surface due to the release of excess surface energy. This behavior has been shown to follow a simple inertial-capillary scaling. However, questions remain regarding the nature of the energy conversion process linking the excess surface energy of the system before coalescence and the kinetic energy of the jumping droplet. Furthermore, the primary energy dissipation mechanisms limiting this jumping behavior remain relatively unexplored. In this work, we present new experimental data from a two-camera setup capturing the trajectory of jumping droplets on nanostructured surfaces with a characteristic surface roughness length scale on the order of 10 nm. Coupled with a model developed to capture the main details of the bridging flow during coalescence, our findings suggest that: 1. the excess surface energy available for jumping is a fraction of that suggested by simple scaling due to incomplete energy transfer, 2. internal viscous dissipation is not a limiting factor on the jumping process at droplet sizes on the order of 10 μm and 3. jumping performance is strongly affected by forces associated with the external flow and fields around the droplet. This work suggests bounds on the heat transfer performance of superhydrophobic condensation surfaces.

8:12AM M39.00002 How does an air film evolve into a bubble during drop impact? , JI SAN LEE, BYUNG MOOK WEON, JUNG HO JE, Pohang University of Science and Technology, KAMEL FEZZAA, Argonne National Laboratory — When a liquid drop impacts on a solid substrate, a tiny air film is generally entrapped between the drop and the substrate and eventually evolves into a bubble by surface energy minimization. We investigated how air evolves into a bubble during drop impact using ultrafast x-ray phase-contrast imaging that enables us to track the detailed morphological changes of air with high temporal and spatial resolutions. We found that the evolution takes place through complicated three stages: inertial retraction of the air film, contraction of the top air surface into a toroidal bubble, and pinch-off of a daughter droplet inside the bubble. The collapse and the pinch-off can be explained by energy convergence that is associated with Ohnesorge number (Oh) regarding capillary waves and viscous damping. We measured a critical Oh number, Oh* $\sim 0.026 \pm 0.003$, above which the generation of the daughter droplet is suppressed. Interestingly we found that the bubble is detached favorably from wettable surfaces, which suggests a feasible way to eliminate bubbles for many applications by controlling surface wettability. The threshold angle for bubble detachment was measured as $\sim 40 \pm 5^\circ$ for water, which agrees with a geometrical estimation.

8:24AM M39.00003 Swirls and splashes: air vortices created by drop impact , IRMGARD BISCHOFBERGER, KELLY W. MAUSER, ANDRZEJ LATKA, SIDNEY R. NAGEL, University of Chicago — A drop impacting a solid surface with sufficient velocity will splash and emit many small droplets. While liquid and substrate properties are clearly important for determining the splashing threshold, it has been shown that removing the ambient air suppresses splashing completely [1]. However, the mechanism underlying how the surrounding gas affects splashing remains unknown. As has been recently shown, there is no air beneath the liquid that could cause the splash [2] – thus where does the air matter? We use modified Schlieren optics combined with high-speed video imaging to visualize the air vortices created by the rapid spreading of the drop after it hit the substrate. In the first moments after impact, these vortices remain bound to the spreading drop, creating a low-pressure zone that travels with the advancing lamella. At a later time, after the occurrence of the splash, the vortices detach from the drop. We discuss possible connections between the forces generated by the vortices on the liquid lamella and the initiation of a splash. [1] L. Xu, W. W. Zhang and S. R. Nagel, Phys. Rev. Lett. 94, 184505 (2005) [2] M. M. Driscoll and S. R. Nagel, Phys. Rev. Lett. 107, 154502 (2011)

8:36AM M39.00004 Stability of electrically charged toroidal droplets in a viscous liquid. , ALEXANDROS FRAGKOPOULOS, EKAPOP PAIRAM, ALBERTO FERNANDEZ-NIEVES, Georgia Institute of Technology — Droplets and bubbles are spherical due to surface tension. As a result, making non spherical droplets and understanding their evolution is a challenge. Nevertheless, we were able to develop a method to generate toroidal droplets in a viscous liquid and study their stability. Recently, we have extended this method to generate charged toroidal droplets suspended in an electrically insulating and highly viscous liquid, and have studied the evolution of these droplets subject to constant charge or constant voltage constraints. In this talk I will be presenting the initial results on the stability of charged toroidal droplets.

8:48AM M39.00005 Clapping wet hands: dynamics of a fluid curtain , BRIAN CHANG, Virginia Tech, BRICE SLAMA, Ecole Polytechnique, France, RANDALL GOODNIGHT, SEAN GART, SUNGHWAN JUNG, Virginia Tech — Droplets splash around when a fluid volume is quickly compressed. This has been observed during common activities such as kids clapping with wet hands. The underlying mechanism involves a resting fluid volume being compressed vertically between two objects. This compression causes the fluid volume to be ejected radially, thereby generating fluid ligaments and droplets at a high speed. In this study, we designed and performed experiments to observe the process of ligament and drop formation while a fluid is squeezed. A thicker rim at the outer edge forms and moves after the squeezing, and then becomes unstable and breaks into smaller drops. We compared experimental measurements with theoretical models over three different stages; early squeezing, intermediate ejection, and later break-up of the fluid. We found that drop spacing set by the initial capillary instability does not change in the course of rim expansion; consequently final ejected droplets are very sparse compared to the size of the rim.

9:00AM M39.00006 Electric Charging Effects on Condensed Droplet Jumping , NENAD MILJKOVIC, DANIEL J. PRESTON, MIT, RYAN ENRIGHT, Bell Labs Ireland, RONG YANG, KAREN K. GLEASON, EVELYN N. WANG, MIT — When condensed droplets coalesce on a superhydrophobic surface, the resulting droplet can jump due to the conversion of surface energy into kinetic energy. This frequent out-of-plane droplet jumping has the potential to enhance condensation heat transfer. Furthermore, for more than a century, researchers have shown that droplet-surface interactions can be dominated by electrostatic charge buildup. In this work, we studied droplet jumping dynamics on nanostructured copper oxide and carbon nanotube surfaces coated with tri-chloro silane and PFDA hydrophobic coatings, respectively. Through analysis of droplet trajectories and terminal velocities under various electric fields (0 – 50 V/cm), we show that condensation on these surfaces having both conducting and insulating substrates results in a buildup of positive surface charge (H^+) due to dissociated water ion adsorption on the superhydrophobic coating. Consequently, an accumulation of the opposite charge (OH^-) occurs on the condensing droplet interface, which creates an attractive force between the jumping droplet and the condensing surface. Using this knowledge, we demonstrate a novel condensation mechanism whereby an external electric field is used to oppose the droplet-surface attraction, further enhancing the coalescing droplet jumping frequency and overall surface heat transfer.

9:12AM M39.00007 Dynamics of a Disturbed Sessile Drop Measured by Atomic Force Microscopy[1] , PATRICIA MCGUIGGAN, SAMUEL ROSENTHAL, ANDREA PROSPERETTI, Johns Hopkins University — A new method for studying the dynamics of a sessile drop by atomic force microscopy (AFM) is demonstrated. A hydrophobic microsphere (radius, r $\sim$ 20 - 30 μm) attached to an AFM cantilever is brought into contact with a sessile water drop. Immediately after the initial rise of the meniscus, the microsphere oscillates about a fixed average position while partially immersed in the liquid. The small ($<$ 100 nm) oscillations of the interface are readily measured with AFM. The oscillations correspond to the resonance oscillation of the entire droplet. Although the microsphere volume is 6 orders of magnitude smaller than the drop, it excites the normal resonance modes of the liquid interface. Resonance oscillation frequencies were measured for drop volumes between 5 and 200 μL. The results for the two lowest normal modes are quantitatively consistent with continuum calculations for the natural frequency of hemispherical drops with no adjustable parameters. The method may enable sensitive measurements of volume, surface tension, and viscosity of small drops.

9:24AM M39.00008 How leaves survive falling raindrops , SEAN GART, KATIE NORRIS, DANIEL CHIQUE, SUNGHWAN JUNG, Virginia Tech — Plant surfaces found in nature often exhibit hydrophobic or hydrophilic wetting properties; a particular example is the surface of leaves. Most leaves are compliant enough to survive while being impacted by rain droplets. Here, we investigate this leaf-drop system exhibiting a unique system of coupled elasticity and drop dynamics. By replacing the leaf with a thin piezoelectric cantilever beam, we further measure and harvest this drop kinetic energy as a workable model for an energy-harvester from rain drops.

9:36AM M39.00009 The Vibrating Vapor Layer Beneath a Leidenfrost Drop , THOMAS CASWELL, JUSTIN BURTON, SIDNEY NAGEL, University of Chicago — The levitation of a liquid drop above a hot surface is known as the Leidenfrost effect. Due to strong evaporation, a vapor layer forms beneath the drop that both levitates and thermally insulates the liquid, resulting in extremely long drop life times. The geometry of this vapor layer has been characterized using high-speed laser-light interference imaging [1], which showed spatial oscillations of the interface. Here we report the evolution of these oscillations using an algorithm we developed for identifying the interference fringes. From these fringes we extract the relative height profile of the vapor layer. We track the time evolution of the spatial-fluctuations and measure the absolute change in the average height of the drop over a time scale of seconds. Large, transient, azimuthal deformations to the bottom of the drop are correlated with the rapid escape of vapor and a change in height above the surface. We also observe and characterize a range of metastable star-like oscillations in the shape. [1] Burton et al., PRL 109, 074301 (2012).

9:48AM M39.00010 Coalescence of Two Drops Surrounded by an Outer Fluid , JOSEPH PAULSEN, RÉMI CARMIGNIANI, ANERUDH KANNAN, JUSTIN BURTON, SIDNEY NAGEL, University of Chicago — When two liquid drops make contact, a liquid bridge forms and then rapidly expands due to surface-tension forces that are divergent at the point where the drops first touch. This nonlinear process has received a lot of recent attention, especially for two liquid drops coalescing in vacuum or air. However, little is known about how the surrounding fluid influences the singularity when the two drops are surrounded by an external fluid with significant density or dynamic viscosity. We use a combination of high-speed imaging and an ultrafast electrical method to study coalescence in this regime. We find that even if the outer fluid is over 10 times more viscous than the fluid within the drops, the coalescence speed need not be affected, even near the singularity. In order to understand the nature of the flows in the surrounding fluid, we also study the limiting case of air bubbles coalescing inside a very viscous external liquid.

10:00AM M39.00011 Measurement of Bubble Size Distribution Based on Acoustic Propagation in Bubbly Medium[1] , XIONGJUN WU, CHAO-TSUNG HSIAO, JIN-KEUN CHOI, GEORGES CHAHINE, Dynaflow Inc. — Acoustic properties are strongly affected by bubble size distribution in a bubbly medium. Measurement of the acoustic transmission becomes increasingly difficulty as the void fraction of the bubbly medium increases due to strong attenuation, while acoustic reflection can be measured more easily with increasing void fraction. The ABS Acoustic Bubble Spectrometer®©, an instrument for bubble size measurement that is under development tries to take full advantage of the properties of acoustic propagation in bubbly media to extract bubble size distribution. Properties of both acoustic transmission and reflection in the bubbly medium from a range of short single-frequency bursts of acoustic waves at different frequencies are measured in an effort to deduce the bubble size distribution. With the combination of both acoustic transmission and reflection, assisted with validations from photography, the ABS Acoustic Bubble Spectrometer®© has the potential to measure bubble size distributions in a wider void fraction range.

10:12AM M39.00012 Experimental and Numerical Investigation of Pressure Wave Attenuation due to Bubbly Layers[1] , ARVIND JAYAPRAKASH, TIFFANY FOURMEAU, CHAO-TSUNG HSIAO, GEORGES CHAHINE, Dynaflow Inc., DYNAFLOW INC. TEAM — In this work, the effects of dispersed microbubbles on a steep pressure wave and its attenuation are investigated both numerically and experimentally. Numerical simulations were carried out using a compressible Euler equation solver, where the liquid-gas mixture was modeled using direct numerical simulations involving discrete deforming bubbles. To reduce computational costs a 1D configuration is used and the bubbles are assumed distributed in layers and the initial pressure profile is selected similar to that of a one-dimensional shock tube problem. Experimentally, the pressure pulse was generated using a submerged spark electric discharge, which generates a large vapor bubble, while the microbubbles in the bubbly layer are generated using electrolysis. High speed movies were recorded in tandem with high fidelity pressure measurements. The dependence of pressure wave attenuation on the bubble radii, the void fraction, and the bubbly layer thickness were parametrically studied. It has been found that the pressure wave attenuation can be seen as due to waves reflecting and dispersing in the inter-bubble regions, with the energy absorbed by bubble volume oscillations and re-radiation. Layer thickness and small bubble sizes were also seen as having a strong effect on the attenuation with enhanced attenuation as the bubble size is reduced for the same void fraction.

10:24AM M39.00013 Bubble Augmented Propulsor Mixture Flow Simulation near Choked Flow Condition[1] , JIN-KEUN CHOI, CHAO-TSUNG HSIAO, GEORGES CHAHINE, Dynaflow, Inc. — The concept of waterjet thrust augmentation through bubble injection has been the subject of many patents and publications over the past several decades, and computational and experimental evidences of the augmentation of the jet thrust through bubble growth in the jet stream have been reported. Through our experimental studies, we have demonstrated net thrust augmentation as high as 70%for air volume fractions as high as 50%. However, in order to enable practical designs, an adequately validated modeling tool is required. In our previous numerical studies, we developed and validated a numerical code to simulate and predict the performance of a two-phase flow water jet propulsion system for low void fractions. In the present work, we extend the numerical method to handle higher void fractions to enable simulations for the high thrust augmentation conditions. At high void fractions, the speed of sound in the bubbly mixture decreases substantially and could be as low as 20 m/s, and the mixture velocity can approach the speed of sound in the medium. In this numerical study, we extend our numerical model, which is based on the two-way coupling between the mixture flow field and Lagrangian tracking of a large number of bubbles, to accommodate compressible flow regimes. Numerical methods used and the validation studies for various flow conditions in the bubble augmented propulsor will be presented.

10:36AM M39.00014 Dynamics of a Cylindrical Bubble between Two Parallel Plates for Biomedical Applications , SOWMITRA SINGH, JIN-KEUN CHOI, GEORGES CHAHINE, Dynaflow, Inc. — Microbubbles have been shown to produce directional and targeted membrane poration of individual cells in microfluidic systems, which could be of use in ultrasound-mediated drug and gene delivery. To study and understand the mechanisms at play in such interactions, a full three- dimensional Boundary Element Method (BEM) has been developed to describe complex bubble deformations, jet formation, and bubble splitting. The present work aims at providing analytical validation for the three-dimensional BEM code, 3DynaFS©, when the dynamics of a bubble between two parallel plates is studied. The analytical equations of a cylindrical (2-D) bubble between two flat plates were derived without accounting for any shape deformation. Comparisons between the analytical model and the numerical model were carried out in scenarios where the shape of an expanding/collapsing bubble between two parallel plates is nearly cylindrical (large maximum equivalent bubble radius to plate gap ratio). Interestingly, both the analytical and the numerical methods predict a strong dependence of the bubble period on the plate size.

10:48AM M39.00015 Universality Results for Multi-phase Hele-Shaw Flows[1] , PRABIR DARIPA, Texas A&M University, College Station, Texas — Saffman-Taylor instability is a well known viscosity driven instability of an interface separating two immiscible fluids. We study linear stability of displacement processes in a Hele-Shaw cell involving an arbitrary number of immiscible fluid phases. This is a problem involving many interfaces. Universal stability results have been obtained for this multi-phase immiscible flow in the sense that the results hold for arbitrary number of interfaces. These stability results have been applied to design displacement processes that are considerably less unstable than the pure Saffman-Taylor case. In particular, we derive universal formula which gives specific values of the viscosities of the fluid layers corresponding to smallest unstable band. Other similar universal results will also be presented. The talk is based on the following paper.

Session M40 DCMP: Surfaces, Interfaces, and Thin Film Reactions: Kinetics & Dynamics 349

- Brad Conrad, Appalachian State University

8:00AM M40.00001 Effects of Plasmon Excitation on Photocatalytic Activity of Ag/TiO_2 and Au/TiO_2 nanocomposites[1] , DINKO CHAKAROV, RAJA SELLAPPAN, Chalmers University of Technology, NISFD TEAM — Model composite photocatalysts consisting of undoped TiO_2 films and optically active Ag or Au nanoparticles (NP) were prepared and examined in order to address the role of plasmon excitation in their performance. The particles were either in direct contact or isolated by thin SiO_2 layer from TiO_2. We found, as measured for the reactions of methanol and ethylene oxidation in two different photoreactors, that composites show always enhanced (up to x100) activity compared to pure TiO_2. Interfacial charge transfer between TiO_2 and NPs plays major role for the enhancement. Plasmonic near-, far-field and thermal effects are present but do not dominate.

8:12AM M40.00002 In-situ coherent x-ray scattering from Ag (001) and Ag (111) surfaces in vacuum and gas-phase environments[1] , ROBERT KARL, JR., Rochester Institute of Technology, ANDI BARBOUR, Argonne National Laboratory, VLADIMIR KOMANICKY, Safarik University, CHENHUI ZHU, Rochester Institute of Technology, DANIEL HENNESSY, University of Cincinnati Blue Ash, HOYDOO YOU, Argonne National Laboratory, MICHAEL S. PIERCE, Rochester Institute of Technology — We have been able to obtain X-ray photon correlation spectroscopy (XPCS) quality data from the Ag (001) and Ag (111) surfaces at two different locations along the specular scattering rod. We observe dynamic behavior related to temperature and gas-phase composition. We will present the methods of the XPCS analysis routines, as they have been adapted to this specific system, and the preliminary results for the dynamics, such as step edge motion, island growth, and surface phase transitions, of the Ag surface features in these different conditions. These dynamics are also q dependent and vary from slow at low q, to faster dynamics at positions near the Ag (001) anti-Bragg scattering position where the experimental sensitivity is sufficient to detect changes at a monolayer level. This indicates that the dynamics involved are occurring right at the surface and do not involve multiple layers. These results will then be compared to our recent similar measurements on the Au (001) surface [1].

8:24AM M40.00003 Inhibition of Hydrogen Absorption in Pd by the Formation of a Pd-Ru Surface Alloy[1] , A.L. CABRERA, P. FERRARI, S. ROJAS, DONOVAN E. DIAZ-DROGUETT, E. RAMOS-MOORE, Pontificia Universidad Catolica de Chile, Departamento de Fisica, LABORATORIO CIENCIA DE MATERIALES TEAM — Hydrogen absorption by palladium has been studied for decades due to the significant importance in a number of applications like production and storage of hydrogen and hydrogen sensors. Alloying Pd with just a 4% of Ru drastically reduces the absorption properties of the Pd. The fcc crystal structure is preserved but the lattice constant is reduced slightly. In order to understand this phenomenon, we used three samples: a Pd foil, a Pd-Ru(4%) alloy foil, and a Pd foil with a Pd-Ru surface alloy. The surface alloy was made evaporating 8 nm of Ru using an e-beam evaporation technique on top of Pd, followed with a heating the sample up to 700 °C in a high vacuum system. We studied the changes in absorption properties of these samples using Thermal Program Desorption (TPD), resistance changes and grazing incidence X-ray Diffraction (GID).

8:36AM M40.00004 Pd/Ru surface alloys – Creating a "noble" surface from reactive elements , XIANGSHI YIN, MUSTAFA M. ÖZER, HANNO H. WEITERING, The University of Tennessee, Knoxville, TN & Oak Ridge National Laboratory, Oak Ridge, TN, PAUL C. SNIJDERS, Oak Ridge National Laboratory, Oak Ridge, TN — We have studied the growth and reactivity of ruthenium thin films on palladium (111) substrates. To obtain smooth and well-ordered film surfaces, the films were annealed to 600 °C. The surface structure, morphology, and chemical composition were investigated with LEED, STM, and AES. The experiments showed that annealed Ru film surfaces contain large concentrations of Pd. The reactivity of this alloy surface towards oxygen was then studied in oxygen gas adsorption experiments at room temperature, and compared to the oxidative properties of bulk Ru and bulk Pd. The surface alloy of the film turns out to be quite inert to oxygen adsorption at room temperature. STM experiments of oxygen adsorption at 112 K reveal that oxygen does adsorb at low temperature but it readily desorbs above 200 K. This surprise finding of a "noble" Pd/Ru surface alloy provides an interesting contrast to the surfaces of bulk ruthenium and palladium, which oxidize easily at room temperature. Research supported by the U.S. Department of Energy, Basic Energy Sciences, Materials Sciences and Engineering Division

8:48AM M40.00005 Solid-State Diffusional Mixing in Cu Core/Ni Shell Nanoparticles , KARL UNRUH, BRIAN KELLY, JOHN KLODNICKI, University of Delaware, GERALD POIRIER, Princeton University — Cu core/Ni shell nanoparticles have been prepared in a polyol process using ethylene glycol as the solvent /reducing agent solution and Cu and Ni acetates as the metal sources. The more positive reduction potential of Cu(II) relative to Ni(II) lead to the formation of Cu core/Ni shell nanoparticles. The structural evolution of these core/shell diffusion couples was studied by high temperature x-ray diffraction measurements. Between room temperature and 350 °C, the evolution in the diffraction pattern was only due to lattice expansion. At higher temperatures, the elemental Cu and Ni diffraction peaks began to merge until, at a temperature of 600 °C only a single set of diffraction peaks remained, indicating the formation of a single homogeneous Cu-Ni alloy. These diffraction patterns have been decomposed into a set of 11 individual subpeaks corresponding to 9 intermediate Cu-Ni compositions in addition to subpeaks corresponding to pure Cu and Ni. The angular positions of each subpeak were fixed to the values appropriate for their composition and the best fit peak areas determined. These data were then used to reconstruct the radial composition profiles of the diffusion couples as a function of the reaction temperature and time.

9:00AM M40.00006 Investigation of Fe/CuO Interface by X-ray Photoelectron Spectroscopy[1] , A. CHOURASIA, R.L. MILLER, H. DONG, J.L. EDMONDSON, Texas A&M University-Commerce — The Fe/CuO interfaces have been investigated by x-ray photoelectron spectroscopy. Thin films of iron were deposited on copper oxide substrates at room temperature. The spectral data show considerable reactivity at the interfaces. The spectral data have been compared with those of the oxidized iron and confirms the formation of the iron oxide at the interface. The interface is found to consist of a mixture of iron oxide and elemental copper. Presence of unreacted iron near the interface has been observed for thicknesses equal to or greater than 0.9 nm of the iron overlayer. The interface was also prepared by depositing 2.0 nm of iron on the copper oxide substrate under two different conditions. In one, the substrate temperature was kept constant during the deposition of the iron overlayer. In the other, post deposition annealing of the sample was performed. The iron overlayer was observed to be completely oxidized at the sample temperature of 450 °C and the oxidation is independent of the processing conditions. The amount of elemental iron and iron oxide in the samples has been estimated by modeling the spectrum using the spectra of elemental iron and pure iron oxide. The investigation provides a new method of preparing sub-nano-oxide films of iron.

9:12AM M40.00007 Coherent X-ray Scattering Experiments of Pt (001) Surface Dynamics near Roughening Transition , HOYDOO YOU, Argonne National Laboratory, MICHAEL PIERCE, Rochester Institute of Technology, ANDI BARBOUR, VLADIMIR KOMANICKY, DANIEL HENNESSY, Argonne National Laboratory — We will present the results of a series of coherent x-ray scattering temperature dependent experiments from Pt (001) in high vacuum. The resulting speckled diffraction patterns are analyzed with x-ray photon correlation spectroscopy. We find that the hexagonally reconstructed Pt (001) surface exhibits orientational dynamics below 1640 K and a critical behavior as T increases to $T_{\rm R} = 1834$ K, near the roughening transition as proposed by Abernathy, et al. [Phys. Rev. Lett. **69**, 941 (1992)]. The inverse autocorrelation time constant τ^{-1} of the surface diverges as T approaches T_R. The average integrated intensity remains constant below $T_{\rm R}$ but drops suddenly over a narrow temperature range, indicating abrupt lifting of the hexagonal reconstruction with the roughening transition. This behavior is compared to that of Au (001), for which τ^{-1} approaches a finite value as the reconstruction lifts gradually over a wide temperature range.

9:24AM M40.00008 A DFT Study of the Interaction of Monometallic Pd_n/Pt_n (n=1, 9) Clusters with γ-$Al_2O_3(100)$ Surfaces , NALIN FERNANDO, New Mexico State University, Las Cruces, TYNE JOHNS, University of New Mexico, Albuquerque, YUE QI, CHANG KIM, General Motors Global R&D, Warren, MI, ABHAYA DATYE, University of New Mexico, Albuquerque, BORIS KIEFER, New Mexico State University, Las Cruces, NEW MEXICO STATE UNIVERSITY, LAS CRUCES COLLABORATION, UNIVERSITY OF NEW MEXICO, ALBUQUERQUE COLLABORATION, GENERAL MOTORS GLOBAL R&D, WARREN, MI COLLABORATION — The reduction of carbon monoxide and hydrocarbon emissions in advanced low temperature combustion engines has become more difficult for the advanced combustion systems in transportation sector. Exploration of effect of interface formation on the electronic properties of the existing platinum group materials may provide insight for the new material development that rivals platinum. In order to address the effects of the interface on the electronic properties of small Pd_n and Pt_n clusters (n=1-9) with a γ-$Al_2O_3(100)$ support we have performed density-functional-theory (DFT) computations. The preliminary results suggest that the most favorable Pd_9 binding geometry is characterized by four Pd atoms binding to both Al and O surface atoms. The average Pd-O bond length across the interface is ~ 2.2 Å, corroborating the formation of bonds. The preliminary analysis of the electronic density of states shows that the main electronic modifications occur at the Fermi energy, leading to an overall metallic behavior. We will discuss cluster size effects on the character of bonding across the interface, its stability, and electronic structure.

9:36AM M40.00009 Dynamics of tungsten and cobalt carbonyls on silica surfaces , KALIAPPAN MUTHUKUMAR, ROSER VALENTI, HARALD O. JESCHKE, Institut für Theoretische Physik, Goethe-Unversität Frankfurt, Max-von-Laue-Str. 1, 60438 Frankfurt, Germany — Metal carbonyl species adsorbed on a substrate are the starting point for the electron beam induced deposition of metallic nanostructures. We employ first principles molecular dynamics simulations to investigate the dynamics of tungsten hexa- and pentacarbonyl as well as cobalt octacarbonyl precursor molecules on fully and partially hydroxylated silica substrates. We find that physisorbed carbonyls are quite mobile on a silica surface saturated with hydroxy groups, moving around half an Angstrom per picosecond. In contrast, chemisorbed ions like $[W(CO)_5]^-$ or $[Co(CO)_4]^-$ are more stable at room temperature. We determine the vibrational spectra which can provide signatures for experimentally distinguishing the form in which precursors cover a substrate.

9:48AM M40.00010 Effects of biaxial strain on diffusivity of low index tungsten surfaces , ZHENGZHENG CHEN, NASR GHONIEM, Mechanical & Aerospace Engineering Department, University of California Los Angeles — Detailed knowledge of diffusion behaviors is necessary toward fully understanding of damage of tungsten serving as reactor pressure vessels. Using first-principles calculations, we observed different diffusion scenarios on W(001) and W(110) surfaces with external biaxial strains. Hopping is the major diffusion mechanism on the W(110) surface under all kinds of loadings in the present work. On the other hand, the main mechanism on the W(001) surface transfers between the adatom hopping and the formation and movement of surface crowdions depending on biaxial strains. Our results also indicate high mobile and strong anisotropy of surface crowdions on both surfaces. The microscopic explanation is presented by analyzing the charge density. We have built up the diagram of diffusion on the W(001) surface. This diagram presents that not only the diffusion mechanism, but also the diffusion direction can be modulated by patterns of biaxial strains. These results are important to the future dynamical modeling and simulations. We have further performed kinetic Monte Carlo simulations and observed (1) the modulation of diffusion of single adatom on W(001) surface by strains and (2) the aggregation of multiple adatoms on W(110) surface.

10:00AM M40.00011 Determination of shift in electrodic reaction rates due to the presence of stress[1] , SWARNAVO SARKAR, Cornell University, USA, WILKINS AQUINO, Duke University, USA — An extension of Butler-Volmer formulation is proposed to determine the stress-induced changes in electrodic reaction rates. Gibbs-Duhem equation is used to determine the stress-dependent chemical potential and the corresponding change in the reaction rate. The scope of possible amplification or reduction in the reaction rates due to tensile and compressive stress fields is explored numerically. Though quantitative experimental validation remains to be pursued, behavioral agreement of the extended Butler-Volmer model with some observations made in the field of corrosive dissolution is established. Our numerical results also indicate that in addition to altering the speed of a reaction, a stress field can modify the shape of an anodic dissolution front. The effect of stress-generated surface patterns is also considered. It is well-established that a stress field can create surface patterns due to surface wrinkling or surface diffusion. We determine the possible significance of such patterns on the reaction rate, and identify the factors that may enhance their contribution to electrodic reaction rates.

10:12AM M40.00012 The model that takes the Marangoni effect into account for drying process of polymer solution coated on a flat substrate , HIROYUKI KAGAMI, Department of Preschool Education, Nagoya College — We have proposed and modified a model of drying process of polymer solution coated on a flat substrate for flat polymer film fabrication supposing resist coating process in photolithography process. And we have clarified dependence of distribution of polymer molecules on a flat substrate on various parameters based on analysis of many numerical simulations of the model. Then we applied the model to thickness control of a thin film after drying through thermal management. Above model consists of two elements. One is vaporization at the gas-liquid interface. The other is the diffusion inside the liquid film on a substrate. The diffusion is divided into two kinds of diffusion, that is, diffusion of solvent with solutes due to gradient of the number density of particles per space and diffusion of diffusion of concentration of solution. Because it is assumed that coated solution film on a flat substrate is very thin and therefore both Rayleigh number and Marangoni number are small enough, it is thought that Bénard convection or Marangoni convection does not occur and therefore it is sufficient to consider only above-mentioned two kinds of diffusion inside the liquid film. However it is thought that there is some sort of Marangoni effect regardless Marangoni convection does not occur. Therefore, in this study we add the Marangoni effect to the existing model. Then we evaluate effects of the Marangoni effect in the drying process through numerical simulation of the modified model.

10:24AM M40.00013 Mesoscopic Aligned and Cu-Coordinated Surface Linear Polymerization at Low Temperature[1] , QING LI, Oak Ridge National Lab, JONATHAN R. OWENS, Rensselaer Polytechnic Institute, CHENGBO HAN, North Carolina State University, MIGUEL FUENTES-CABRERA, BOBBY G. SUMPTER, Oak Ridge National Lab, WENCHANG LU, JERRY BERNHOLC, North Carolina State University, PETRO MAKSYMOVYCH, Oak Ridge National Lab, VINCENT MEUNIER, Rensselaer Polytechnic Institute, MINGHU PAN, Oak Ridge National Lab — The on-surface synthesis of covalent organic aggregates and networks has received considerable attention. However, most of the polymerization reactions require high temperatures to overcome the activation barrier. We demonstrate a surface-coordinated linear polymerization, which occurred at 100 K and forms long chain that are well-organized into a "circuit-board" pattern on Cu(100) surface. This highly strained 1D conjugated polymer alters greatly the electronic structure compared to unperturbed polymer and it was investigated by electronic and vibrational spectroscopies, as well as *ab initio* calculations. More importantly, the processes of polymerization and depolymerization can be controlled locally at the nanoscale by a using a charged metal tip. This work thus demonstrates the feasibility of accessing and controlling chain-growth polymerization at low temperature that may lead to the bottom-up construction of sophisticated architectures for molecular nano-devices.

[1]Research was conducted at the Center for Nanophase Materials Sciences and sponsored by the Division of Scientific User Facilities, US DOE

10:36AM M40.00014 Surface reactivity/stability and hydration of calcium silicate phases , ENGIN DURGUN, Massachusetts Institute of Tecnology and UNAM-Institute of Materials Science and Nanotechnology, Bilkent University, CAN ATACA, HAMLIN M. JENNINGS, JEFFREY C. GROSSMAN, Massachusetts Institute of Technology — Recent studies on synthetic calcium silicate structures revealed important mechanisms to tune the reactivity of various cement phases. Interaction of water with dicalcium silicate (C2S-belite) and tricalcium silicate (C3S-alite), dominant phases in Portland Cement, are the most important and anticipated reactions. In this work, using first-principles calculations, a fundamental understanding of how water pressure affects the reactivity of C3S and C2S phases is provided. In order to understand the hydration of different phases, as a first step the surface energetics of all lower index orientations are calculated and the stability/reactivity of the surfaces are determined. Taking into account the most and least energetic surfaces of the C3S phase, detailed analyses are carried out in order to understand the induction period in hydration. Surface transformation from highly reactive C3S to low reactive C2S revealed that upon increasing the water pressure, the surface with C2S character becomes energetically more favorable. Reduction of the surface energy is more intense in the case of proton exchange of surface Ca atoms. Our calculations suggest that these processes are the most probable mechanisms underlying the rapid decrease in reactivity in alite hydration.

Wednesday, March 20, 2013 8:00AM - 10:36AM –

Session M41 DAMOP: Theory of Quantum Gases in Low Dimensions 350 - Juraj Radic, University of Maryland

8:00AM M41.00001 Adiabatic evolution of the Fulde-Ferrell-Larkin-Ovchinnikov state of imbalanced fermionic-atom superfluids in an optical lattice of coupled tubes[1] , C.J. BOLECH, KUEI SUN, University of Cincinnati — We study two-species imbalanced fermionic superfluids in an array of one-dimensional tubes that are coupled via particle tunneling between nearest neighbors. Incorporating the interplay of Cooper pairing, spin imbalance (or magnetization), and single-particle tunneling, we obtain imbalance profiles accompanied with oscillatory pairing reminiscent of a Fulde-Ferrell-Larkin-Ovchinnikov (FFLO) state, and show that the magnetization of the system can undergo an incompressible-compressible transition by the tuning of the magnetic field as well as tunneling strength [Phys. Rev. A **85**, 051607 (2012)]. The system's phase diagram is well described by an effective extended Bose-Hubbard model. In addition, we discuss another viable process of pair tunneling that strongly affects the evolution of the FFLO profiles. With this new element, one can build a model describing the development of signatures characteristic of the incipience of the dimensional crossover and in partial agreement with preliminary experimental data.

[1]This work was supported by the ARO Award No. W911NF-07-1-0464

8:12AM M41.00002 Asymptotic Limit of Momentum Distribution Functions in the Sudden Expansion of a Spin-imbalanced Fermi Gas in One Dimension , FABIAN HEIDRICH-MEISNER, LMU Munich, Germany, CARLOS BOLECH, University of Cinncinati, USA, STEPHAN LANGER, University of Pittsburgh, USA, IAN MCCULLOCH, University of Brisbane, Australia, GIULIANO ORSO, University Paris Diderot, France, MARCOS RIGOL, Penn State University, USA — We study the sudden expansion of a spin-imbalanced Fermi gas in an optical lattice after quenching the trapping potential to zero [1], described by the attractive Hubbard model. Using time-dependent density matrix renormalization group simulations we demonstrate that the momentum distribution functions (MDFs) of majority and minority fermions become stationary after surprisingly short expansion times. We explain this via a quantum distillation mechanism [2] that results in a spatial separation of excess fermions and pairs, causing Fulde-Ferrell-Larkin-Ovchinnikov correlations to disappear rapidly. We further argue that the asymptotic form of the MDFs is determined by the integrals of motion of this integrable quantum system, namely the rapidities from the Bethe ansatz solution. We discuss the relevance of our results for the observation of Fulde-Ferrell-Larkin-Ovchinnikov correlations in 1D systems, related to recent experiments from Rice University [3].

8:24AM M41.00003 Superfluidity of Bosons in Kagome Lattices with Frustration , XIAO-QI SUN, ZHU CHEN, YI-ZHUANG YOU, HUI ZHAI, Institute for Advanced Study, Tsinghua University, Beijing, 100084, China — We consider spinless bosons in a Kagome lattice with nearest-neighbor hopping and on-site interaction, and the sign of hopping is inverted by insetting a π flux in each triangle of Kagome lattice so that the lowest single particle band is perfectly flat. We show that in the high density limit, despite of the infinite degeneracy of the single particle ground states, interaction will select out the Bloch state at the K point of Brillouin zone for boson condensation at the lowest temperature. As temperature increases, the single boson superfluid order can be easily destroyed, while an exotic triple-boson paired superfluid order will remain. We establish that this trion superfluid exists in a broad temperature regime until the temperature is increased to the same order of hopping and then the system turns into normal phases. Finally we show that time of flight measurement of momentum distribution and its noise correlation can be used to distinguish these three phases.

8:36AM M41.00004 The Higgs amplitude mode in superfluids of Dirac fermions , SHUNJI TSUCHIYA, Department of Physics, Faculty of Science, Tokyo University of Science, RAMACHANDRAN GANESH, Institute for Theoretical Solid State Physics, IFW Dresden, TETSURO NIKUNI, Department of Physics, Faculty of Science, Tokyo University of Science — Motivated by recent developments of cold atom experiments in optical lattices, we study collective modes of atomic Dirac fermions on the two-dimensional honeycomb lattice. The attractive fermion Hubbard model on the honeycomb lattice was found to exhibit the quantum phase transition at half-filling between a semimetal with massless Dirac fermion excitations and a simple s-wave superfluid phase.[1] We calculate collective modes in superfluid phase as well as in normal phase in the vicinity of the quantum critical point within the generalized random phase approximation. We find evidence for a $undamped$ gapful Higgs amplitude mode below the two-particle continuum, together with a gapless Anderson-Bogoliubov (AB) mode in superfluid phase. As approaching the quantum critical point from the superfluid side, the energy gap of the Higgs mode decreases and eventually the Higgs mode and AB mode become degenerate at the quantum critical point. In the normal phase, we find that these collective modes split into Cooperon and exciton excitations that are particle-particle and particle-hole bound states, respectively. We discuss possibilities of observing these collective modes in optical lattice experiments.

8:48AM M41.00005 Quantum phase-manipulation of a two-leg ladder in mixed dimensional Fermonic cold atoms , WEN-MIN HUANG, KYLE IRWIN, SHAN-WEN TSAI, Department of Physics and Astronomy, University of California, Riverside, CA 92521, USA — The recent realization of mixed dimensional cold atoms has attracted intense attentions from both experimentalists and theoreticians. Exotic phases arise due to correlation effects, and the systems can be engineered with quantum phase-tunable parameters. We investigate a two-species Fermi gas: one is confined in a two-leg ladder with on-site interactions, and the other is free in a two dimensional square lattice. By integrating out the two-dimensional gas, a long-range mediated interaction in the ladder is generated due to the on-site interspecies interactions. Using the renormalization group method, we show that the mediated interactions enhance the instability of charge density waves, and can be controlled by the filling in the two-dimensional gas. Parameterizing the phase diagrams with different quantities, we discuss the possible quantum phase-manipulation of a two-leg ladder in mixed dimensional Fermionic cold atoms.

9:00AM M41.00006 Quantum phases of cold fermions in mixed dimensions: 2D layer embedded in 3D gas , KYLE IRWIN, CHEN-YEN LAI, WEN-MIN HUANG, SHAN-WEN TSAI, University of California, Riverside — Recently two-species cold atoms in mixed dimensions have been realized experimentally, triggering lots of studies to explore new exotic phases in these systems. Inspired by this, we study the phase diagram of a mixed Fermi system, in which one species is confined in a two-dimensional square or triangular lattice with a correlation effect, and the other is free to move in three-dimensional space. By integrating out the free three-dimensional fermions, a long-range mediated interaction is generated in the two-dimensional lattice due to the interspecies interaction. We employ a functional renormalization group method to discover the possible phases, which may shed light to new exotic quantum phases created in ultracold atoms systems.

9:12AM M41.00007 Exact Self-Consistent Condensates in (Imbalanced) quasi-1D Superfluid Fermi Gases , GIACOMO MARMORINI, Condensed Matter Theory Lab, RIKEN, RYOSUKE YOSHII, YITP Kyoto, SHUNJI TSUCHIYA, Tokyo U. of Science, MUNETO NITTA, Keio U. — Borrowing some techniques from high-energy physics, and in particular from the study of Nambu-Jona-Lasinio model in 1+1 dimensions [1,2], we present an analytic method to approach Eilenberger equation and the associated Bogoliubov-de Gennes equation for quasi-1D fermionic gases. The problem of finding self-consistent inhomogeneous condensates is reduced to solving a certain class of nonlinear Schrödinger equations, whose most general solitonic solution is indeed available. Previously known solutions can be retrieved by taking appropriate limits in the parameters. The applicability of the method extends to ring geometry and to population imbalanced Fermi gases [3,4]. In particular we show exactly that fermionic zero-modes are robust against imbalance. References:

9:24AM M41.00008 Tuning the Kosterlitz-Thouless transition to zero temperature in anisotropic boson systems , JHIH-SHIH YOU, HAO LEE, SHIANG FANG, Physics Division, National Center for Theoretical Sciences, Hsinchu, Taiwan, MIGUEL A. CAZALILLA, Graphene Research Centre National University of Singapore, 6 Science Drive 2, Singapore 117546, DAW-WEI WANG, Physics Division, National Center for Theoretical Sciences, Hsinchu, Taiwan — We study the two-dimensional Bose-Hubbard model with anisotropic hopping. Focusing on the effects of anisotropy on superfluid properties such as the helicity modulus and the normal-to-superfluid [Berezinskii-Kosterlitz-Thouless (BKT)] transition temperature, two different approaches are compared: large-scale quantumMonte Carlo simulations and the self-consistent harmonic approximation (SCHA). For the latter, two different formulations are considered, one applying near the isotropic limit and the other applying in the extremely anisotropic limit. Thus we find that the SCHA provides a reasonable description of superfluid properties of this system provided the appropriate type of formulation is employed. The accuracy of the SCHA in the extremely anisotropic limit, where the BKT transition temperature is tuned to zero (i.e., at a quantum critical point) and therefore quantum fluctuations play a dominant role, is particularly striking.

9:36AM M41.00009 ABSTRACT WITHDRAWN –

9:48AM M41.00010 Variational Matrix Product Ansatz for Interacting 1D Gases[1] , SANGWOO CHUNG, KUEI SUN, C.J. BOLECH, University of Cincinnati — Shortly after the advent of the density matrix renormalization group (DMRG) method, Ostlund and Rommer [PRL 75, 3537-3540 (1995)] have demonstrated that ground states of one-dimensional lattice systems obtained with the DMRG procedure can be written in terms of products of matrices and, remarkably, that those ground states can be obtained from variational methods without making any reference to DMRG. Since then, a lot of activity ensued and recently there was some additional success in going beyond lattice models and obtaining the ground state properties of interacting bosons in the continuum. We extend those findings and discuss systems of both interacting Bosons and Fermions in one-dimension.

10:00AM M41.00011 Revealing the breakdown of spin-charge separation in spin-imbalanced fermions in one dimension using quench dynamics[1] , PAATA KAKASHVILI, Department of Physics and Astronomy, Rutgers University, MICHAEL SEKANIA, Center for Electronic Correlations and Magnetism, Institute of Physics, University of Augsburg — Recently, spin-imbalanced fermions in one dimension have attracted considerable attention both theoretically and experimentally. This system was successfully simulated using ultracold atoms in optical lattices. The phase diagram was measured and found to be in agreement with exact analytical calculations. It was also established theoretically that the spin-charge separation, an important property of Luttinger liquids, is absent. Low-energy bosonic excitations do not carry spin and charge separately due to the interaction between spin and charge degrees of freedom. Based on our numerical (time-dependent density matrix renormalization group method (t-DMRG)) and analytical calculations (Bethe Ansatz, Bosonization) on the Hubbard model, we propose quench experiments which not only reveal the breakdown of spin-charge separation but also make it possible to study the so called "string" bound states in this system.

10:12AM M41.00012 Exploration of the Exact Bose-Fermi Mixture Phase Diagram via Quantum Monte Carlo , KYUNG DUK YOON, Salisbury School, Salisbury, CT — Following unprecedented success studying Bose and Fermi gases in optical lattices, atomic physicists are becoming increasingly interested in Bose-Fermi mixtures. It has been suggested that mixtures possess a complex phase diagram, containing a number of intriguing phases, including two-particle superfluids, supersolids, and density waves. Nevertheless, much of this phase diagram remains unknown because of algorithmic limitations. In this work, we explore the exact phase diagram of Bose-Fermi mixtures at finite temperatures in the hopes of uncovering Bose-Fermi density waves using a novel Auxiliary Field Quantum Monte Carlo (AFQMC) technique. Our AFQMC method expresses the Bose-Fermi partition function as a determinant that can be sampled to obtain accurate results throughout the phase diagram. Based upon this determinant, we calculate several correlation functions to look for signatures of mixture density waves. For certain system sizes and in certain parameter regimes, we compare and contrast with Exact Diagonalization and Mean Field Theory. Here, we begin this study by focusing on one-dimensional systems; future work will be extended to multidimensional systems were AFQMC is expected to be the only method capable of studying them.

10:24AM M41.00013 Finite-size scaling of the chemical potential of bosonic quantum fluids , C.M. HERDMAN, ADRIAN DEL MAESTRO, University of Vermont — We study the finite-size scaling of the chemical potential of interacting bosonic quantum fluids using large-scale quantum Monte Carlo calculations. We consider realistic interactions for helium as well as short range repulsive interactions for bosons in one, two and three dimensions at finite temperatures. In one dimension, we compare our results to the scaling predicted by Luttinger liquid theory allowing for the identification of a parametric regime of validity for quantum linear hydrodynamics. In higher dimensions, grand canonical simulations of helium allow for the accurate computation of experimentally relevant quantities such as the chemical potential along the liquid-solid transition line at low temperatures.

Session M42 DCP: Focus Session: Physics of Glasses and Viscous Liquids III Hilton Baltimore Holiday Ballroom 3 - Patrick Charbonneau, Duke University

8:00AM M42.00001 High-dimensional surprises neat the glass and the jamming transitions , PATRICK CHARBONNEAU, Duke University — The glass problem is notoriously hard and controversial. Even at the mean-field level, there is little agreement about how a fluid turns sluggish while exhibiting but unremarkable structural changes. It is clear, however, that the process involves self-caging, which provides an order parameter for the transition. It is also broadly assumed that this cage should have a Gaussian shape in the mean-field limit. Here we show that this ansatz does not hold, and explore its consequences. Non-Gaussian caging, for instance, persists all the way to the jamming limit of infinitely compressed hard spheres, which affects mechanical stability. We thus obtain new scaling relations, and establish clear mileposts for the emergence of a mean-field theory of jamming.

8:36AM M42.00002 Microscopic theories of the structure and glassy dynamics of ultra-dense hard sphere fluids , RYAN JADRICH, KENNETH SCHWEIZER, University of Illinois at Urbana-Champaign — We construct a new thermodynamically self-consistent integral equation theory (IET) for the equilibrium metastable fluid structure of monodisperse hard spheres that incorporates key features of the jamming transition. A two Yukawa generalized mean spherical IET closure for the direct correlation function tail is employed to model the distinctive short and long range contributions for highly compressed fluids. The exact behavior of the contact value of the radial distribution function (RDF) and isothermal compressibility are enforced, as well as an approximate theory for the RDF contact derivative. Comparison of the theoretical results for the real and Fourier space structure with nonequilibrium jammed simulations reveals many similarities, but also differences as expected. The new structural theory is used as input into the nonlinear Langevin equation (NLE) theory of activated single particle dynamics to study the alpha relaxation time, and good agreement with recent experiments and simulations is found. We demonstrate it is crucial to accurately describe the very high wave vector Fourier space to reliably extract the dynamical predictions of NLE theory, and structural precursors of jamming play an important role in determining entropic barriers.

8:48AM M42.00003 Beyond the mode-coupling theory: a perturbative diagrammatic approach[1] , GRZEGORZ SZAMEL, ELIJAH FLENNER, Department of Chemistry, Colorado State University — We analyze corrections to the mode-coupling theory of the glass transition, focusing on the self-consistent equation for the non-ergodicity parameter. We use a diagrammatic formulation of the dynamics of interacting Brownian particles[2]. Our approach builds upon an earlier identification of a divergent contribution to a four-point correlation function[3]. We find that diagrams similar to those generating the divergence of the four-point function lead to divergent corrections to the mode-coupling theory's prediction for the long time limit of the irreducible memory function. We propose and investigate a new equation for the non-ergodicity parameter that self-consistently includes the diagrams leading to the divergent corrections.

9:00AM M42.00004 Shapes of dynamically heterogeneous regions in glassy fluids with attractive and repulsive interactions as revealed through anisotropic four-point correlation functions , ELIJAH FLENNER, GRZEGORZ SZAMEL, Chemistry Department, Colorado State University — We investigate the size and anisotropy of dynamically heterogeneous regions in glassy fluids with attractive and repulsive interactions. To this end we simulate a binary Lennard-Jones mixture and its Weeks-Chandler-Andersen truncation. We use a four-point correlation function $G_4(\vec{k},\vec{r};t)$, which depends on the angle between $\vec{k}$ and $\vec{r}$, and its associated structure factor $S_4(\vec{k},\vec{q};t)$, which depends on the angle θ between $\vec{k}$ and $\vec{q}$, to characterize the size and anisotropy of the dynamically correlated regions. In particular, $G_4(\vec{k},\vec{r};t)$ allows us to explore dynamic heterogeneities at shorter distances. In contrast, to investigate dynamic heterogeneities at longer distances we analyze the small q behavior of $S_4(\vec{k},\vec{q};t)$ and obtain an anisotropic dynamic correlation length $\xi(\theta)$. We explore the dependence of dynamic heterogeneities at shorter and longer distances on the presence of attractive interactions.

9:12AM M42.00005 Reversible and Irreversible Behavior of Glass-forming Materials from the Standpoint of Hierarchical Dynamical Facilitation , AARON KEYS, Lawrence Berkeley National Laboratory — Using molecular simulation and coarse-grained lattice models, we study the dynamics of glass-forming liquids above and below the glass transition temperature. In the supercooled regime, we study the structure, statistics, and dynamics of excitations responsible for structural relaxation for several atomistic models of glass-formers. Excitations (or soft spots) are detected in terms of persistent particle displacements. At supercooled conditions, we find that excitations are associated with correlated particle motions that are sparse and localized, and the statistics and dynamics of these excitations are facilitated and hierarchical. Excitations at one point in space facilitate the birth and death of excitations at neighboring locations, and space-time excitation structures are microcosms of heterogeneous dynamics at larger scales. Excitation-energy scales grow logarithmically with the characteristic size of the excitation, giving structural-relaxation times that can be predicted quantitatively from dynamics at short time scales. We demonstrate that these same physical principles govern the dynamics of glass-forming systems driven out-of-equilibrium by time-dependent protocols. For a system cooled and re-heated through the glass transition, non-equilibrium response functions, such as heat capacities, are notably asymmetric in time, and the response to melting a glass depends markedly on the cooling protocol by which the glass was formed. We introduce a quantitative description of this behavior based on the East model, with parameters determined from reversible transport data, that agrees well with irreversible differential scanning calorimetry. We find that the observed hysteresis and asymmetric response is a signature of an underlying dynamical transition between equilibrium melts with no trivial spatial correlations and non-equilibrium glasses with correlation lengths that are both large and dependent upon the rate at which the glass is prepared. The correlation length corresponds to the size of amorphous domains bounded by excitations that remain frozen on the observation time scale, thus forming stripes when viewed in space and time. We elucidate properties of the striped phase and show that glasses of this type, traditionally prepared through cooling, can be considered a finite-size realization of the inactive phase formed by the s-ensemble in the space-time thermodynamic limit.

9:48AM M42.00006 Dynamical Heterogeneity in Higher Dimensions: Kinetically Constrained Models , YOUNJOON JUNG, SOREE KIM, Seoul National University — We use kinetically constrained models to investigate the dimensional dependence of dynamic heterogeneity in supercooled liquid systems. Higher dimensional generalizations of one dimensional East model and its variation with an embedded probe particle are used as a representative fragile liquid system. We first investigate how the breakdown of the Stokes-Einstein relation changes with the system dimensionality from $d = 1$ up to $d = 10$. The fractional scaling behavior $D \propto \tau^{-\xi}$ are observed, where D and ξ are the diffusion constant of the probe and the relaxation time of the liquid, respectively. The scaling exponent, ξ, decreases as the dimensionality increases. The decoupling between persistence and exchange times are also characterized as the dimensionality changes. Time and length scales of the dynamic heterogeneity are analyzed by calculating persistence functions and the dynamic susceptibility. Comparisons are made with respect to recent atomistic MD simulation results.

10:00AM M42.00007 Dynamics in a meta-basin and its relation to β relaxation in glass-forming liquids , CHANDAN DASGUPTA, PRANABJYOTI BHUYAN, Indian Institute of Science, Bangalore, India — A clear interpretation of the short-time β relaxation of glass-forming liquids in terms of dynamics in the potential energy landscape is not yet available. We have studied the relation between dynamics in a meta-basin of the potential energy landscape and β relaxation in a well-known glass-forming liquid - the Kob-Andersen binary mixture. Meta-basins are determined from the series of inherent structures obtained by minimizing the potential energy, starting from configurations obtained from a constant-temperature molecular dynamics (MD) simulation. The eigenvalues and eigenvectors of the Hessian matrices of the inherent structures in a meta-basin are then used to calculate various dynamical quantities in the harmonic approximation. We find that the results of the harmonic calculation begin to deviate from those obtained from MD simulations at time scales substantially shorter than the β relaxation time corresponding to the plateau in the mean-square displacement versus time plot. The agreement between the results of our analysis of the dynamics in a meta-basin and those of MD simulations is found to extend to longer times when anharmonic effects are included in the analysis. A detailed comparison between these two set of results will be presented.

10:12AM M42.00008 Universal Microstructure of Jammed Packings in Higher Dimensions , ERIC CORWIN, Department of Physics and Material Science Institute, University of Oregon, Eugene, Oregon 97403, PATRICK CHARBONNEAU, Department of Chemistry and Department of Physics, Duke University, Durham, North Carolina 27708, FRANCESCO ZAMPONI, LPT, École Normale Supérieure, UMR 8549 CNRS, 24 Rue Lhomond, 75005 France — Jammed packings' mechanical properties depend sensitively on their detailed local structure. We simulate the structure of jammed packings of frictionless spheres over a range of spatial dimensions d=3-10 using a variety of preparation protocols for both hard and soft spheres. We provide a complete characterization of the pair correlation close to contact and of the force distribution. We find that even as the density for jamming depends strongly on the packing protocol there nevertheless exist universal scaling relationships that hold true for all jammed packings. These relationships connect the behavior of particles participating in the mechanical structure of the packing and particles that bear no force but are almost in contact.

10:24AM M42.00009 Ginzburg criterion for the glass transition , FRANCESCO ZAMPONI, CNRS, Paris — I will discuss the onset of slow relaxation in glassy systems by constructing a static replica field theory approach to the problem. At the mean field level, criticality in the four point correlation functions arises because of the presence of soft modes and I will present an effective replica field theory for these critical fluctuations. At the Gaussian level many physical quantities are obtained: the correlation length, the exponent parameter that controls the Mode-Coupling dynamical exponents for the two-point correlation functions, and the prefactor of the critical part of the four point correlation functions. A one-loop computation allows to identify the region in which the mean field Gaussian approximation is valid. The result is a Ginzburg criterion for the glass transition, which confirms that the upper critical dimension for the glass transition is d=8. Finally, I will present numerical results for hard spheres in dimension d ranging from 3 to 9 that support the analytical results.

Session M43 DCP DBIO: Focus Session: Protein Misfolding and Aggregation II Hilton Baltimore Holiday Ballroom 2 - Joan Shea, UCSB

8:00AM M43.00001 In-Vivo Like Studies of the hIAPP Amyloid Precursors Using Dielectric Relaxation Spectroscopy[1] , YUSUKE HIRAI, REEM MAHOMMED ASSIRI, DONAL BARRY, Worcester Polytechnic Institute, FLORIN DESPA, University of California Davis, IZABELA STROE, Worcester Polytechnic Institute — Recent studies show that the amyloid formation in Type II diabetic disease involves aggregation of monomers of the human islet amyloid polypeptide (hIAPP) into oligomers, protofibrils, and fibrils. Here we present data showing that Dielectric Relaxation Spectroscopy is a very sensitive technique to detect the hIAPP precursors. We measured the dielectric response of amyloidogenic hIAPP and non-amyloidogenic rIAPP as a function of frequency (10^{-3} Hz to 10^{7} Hz), temperature (193K to 283K), and incubation time (0-120 h). To mimic in-vivo like conditions, the proteins were measured in bovine serum albumin. Our results show that the dielectric signal of amyloidogenic hIAPP shifts towards the dielectric signal of the background, as predicted by theoretical calculations. No similar shift is observed for the non-amyloidogenic rIAPP. In addition, the dielectric signal of both the hIAPP and the rIAPP shows two relaxation processes over the measured temperature range. We used two Havrilik-Negami functions plus conductivity to fit the two relaxation processes we determined the relaxation time for both processes and calculated the corresponding activation energies.

8:12AM M43.00002 Structure and Thermodynamic Stability of Islet Amyloid Polypeptide Monomers and Small Aggregates , CHI-CHENG CHIU, University of Chicago, SADANAND SINGH, University of Wisconsin-Madison, JUAN DE PABLO, University of Chicago — Human islet amyloid polypeptide (hIAPP, also known as human amylin) is associated with the development of type II diabetes. It is known to form amyloid fibrils that are found in pancreatic islets. Pramlintide, a synthetic analog of hIAPP with three proline substitutions, is not amyloidogenic and has been applied in amylin replacement treatments. In this work, we use molecular simulations with advanced sampling techniques to examine the effect of these proline substitutions on hIAPP monomer conformations. We find that all three proline substitutions are required to attenuate the formation of β-sheets encountered in amylin. Furthermore, we investigate the formation of hIAPP dimers and trimers, and investigate how that process is affected by the presence of various additives. Our simulations show that hIAPP can form a β-sheet at the N-terminus and the C-terminus independently, in agreement with experimental observations. Our results provide valuable insights into the mechanism of hIAPP early aggregation and the design of fibril formation inhibitors.

8:24AM M43.00003 Control the aggregation of model amyloid insulin protein under ac-electric fields , ZHONGLI ZHENG, BENXIN JING, Y. ELAINE ZHU, University of Notre Dame — In vitro experiments have been widely used to characterize the misfolding/unfolding pathway characteristic of amylodogenic proteins. Conversion from natively folded amyloidogenic proteins to oligomers via nucleation is the accepted path to fibril formation upon heating over a certain lag time period. In an alternative engineering approach to manipulate and control protein aggregation, we have investigated the aggregation kinetics of insulin, a well-established amyloid model protein, under applied ac-electric fields of varied ac-frequency and voltage at room temperature. Using fluorescence correlation spectroscopy and fluorescence imaging, we have observed that the insulin aggregation can occur at much shortened lag time under applied ac-electric fields, when a critical ac-voltage is exceeded. The strong dependence of lag time on ac-frequency over a narrow range of 500 Hz-5 kHz indicates the effect of ac-electroosmosis on the diffusion controlled process of insulin nucleation. Yet, no difference of conformational structure is detected with insulin under applied ac-fields, suggesting the equivalence of ac-polarization to the conventional thermal activation process for insulin aggregation.

8:36AM M43.00004 A physical chemical approach to understanding cellular dysfunction in type II diabetes , ANDREW MIRANKER, Yale University — The conversion of soluble protein into b-sheet rich amyloid fibers is the hallmark of a number of serious diseases. Precursors for many of these systems (e.g. Ab from Alzheimer's disease) reside in close association with a biological membranes. Membrane bilayers are reported to accelerate the rate of amyloid assembly. Furthermore, membrane permeabilization by amyloidogenic peptides can lead to toxicity. Given the b-sheet rich nature of mature amyloid, it is seemingly paradoxical that many precursors are either intrinsically b-helical, or transiently adopt an a-helical state upon association with membrane. We have investigated these phenomena in islet amyloid polypeptide (IAPP). IAPP is a 37-residue peptide hormone which forms amyloid fibers in individuals with type II diabetes. We report here the discovery of an oligomeric species that arises through stochastic nucleation on membranes, and results in disruption of the lipid bilayer. These species are stable, result in all-or-none leakage, and represent a definable protein/lipid phase that equilibrates over time. To characterize the reaction pathway of assembly, we apply an experimental design that includes ensemble and single particle evaluations *in vitro* and correlate these with quantitative measures of cellular toxicity.

9:12AM M43.00005 Amyloid Aggregation and Membrane Disruption by Amyloid Proteins , AYYALUSAMY RAMAMOORTHY, University of Michigan — Amyloidogenesis has been the focus of intense basic and clinical research, as an increasing number of amyloidogenic proteins have been linked to common and incurable degenerative diseases including Alzheimer's, type II diabetes, and Parkinson's. Recent studies suggest that the cell toxicity is mainly due to intermediates generated during the assembly process of amyloid fibers, which have been proposed to attack cells in a variety of ways. Disruption of cell membranes is believed to be one of the key components of amyloid toxicity. However, the mechanism by which this occurs is not fully understood. Our research in this area is focused on the investigation of the early events in the aggregation and membrane disruption of amyloid proteins, Islet amyloid polypeptide protein (IAPP, also known as amylin) and amyloid-beta peptide, on the molecular level. Structural insights into the mechanisms of membrane disruption by these amyloid proteins and the role of membrane components on the membrane disruption will be presented.

9:48AM M43.00006 New technology for 2D IR spectroscopy and its application to protein aggregation and drug binding , MARTIN ZANNI, University of Wisconsin-Madison — We are using 2D IR spectroscopy to study the aggregation and drug inhibition of proteins involved in common human diseases. It is extremely difficult to obtain precise structural information about drug inhibition of amyloid fibrillization, because it is very difficult to apply NMR spectroscopy and x-ray crystallography to these systems. As a result, there are very few molecular level details known about even the simplest inhibitors. We have studied a peptide inhibitor whose sequence was used to design an FDA approved drug, partially because this peptide has never before been observed to aggregate on its own. According to the sequence, we would expect that the C-terminal is responsible for inhibition, but in fact we found that the N-terminal was instead. In fact, we also observed that the complex formed between the inhibitor and amylin caused the inhibitor itself to form amyloid fibers. These surprising results were not previously observed, in part because the prior methods used to study inhibition was not sensitive to the specific structural fold of the fibers.

10:24AM M43.00007 Early-Stage Aggregation of Islet Amyloid Polypeptide on Membrane Surfaces Probed by Label-Free Chiral Sum Frequency Generation Spectroscopy , ZHUGUANG WANG, LI FU, ELSA YAN, Yale University — The aggregation of human islet amyloid polypeptide (hIAPP) into fibrils is associated with type II diabetes. It can be catalyzed by interactions with membranes. Recent studies have shown that cytotoxicity arises from the intermediates of aggregation instead of mature fibrils. However, the pathogenic mechanism is still unknown and it remains challenging to probe structures of the intermediates on membrane surfaces due to a lack of biophysical methods that are sensitive to both protein secondary structures and interfaces. Here, we used label-free chiral sum frequency generation spectroscopy (cSFG) to probe the intermediates. Recently, we have discovered cSFG provides highly specific peptide vibrational signatures that can distinguish protein secondary structures at interfaces. Using cSFG, we observed in situ and in real time the aggregation of hIAPP from disordered structures to α-helices and then β-sheets on membrane surfaces. We also obtained the orientation of the β-sheet aggregates inserted into the membranes. We further studied the S20G mutant, which is linked to the early onset of type II diabetes among Asian populations. We compared the mutant with the wild-type hIAPP to evaluate the effect of S20G in the early-stage aggregation on membrane surfaces.

10:36AM M43.00008 Achiral and Chiral Sum Frequency Generation Spectroscopy of Peptides , JOSHUA CARR, LU WANG[1], JAMES SKINNER, University of Wisconsin at Madison — In vibrational sum-frequency generation (SFG) spectroscopy, a resonant IR and a non-resonant visible laser pulse are applied to a sample, and a signal is detected at the sum frequency of the pulses. This signal is sensitive to the local environments of interfacial chromophores. For the *psp* polarization combination (*p*-polarized SF, *s*-polarized visible, *p*-polarized IR), the signal is selectively sensitive to chiral structures. Recently, it was found that peptide secondary structures could be distinguished by the presence of absence of *psp* signals for the amide I and NH stretch modes. This finding has been exploited to track the aggregation of human islet amyloid polypeptide at a water/air interface. To facilitate the interpretation of these experiments in terms of detailed structures, we present here a mixed quantum/classical method for the computation of both achiral and chiral SFG spectra for the peptide amide I mode, based on classical molecular dynamics simulations. We then apply this method to model systems, and comment as to the importance of both intrinsic chirality (the presence of atomic chiral centers) and structural chirality (the presence of chiral secondary structure) to the strength of the *psp* signal.

Session M44 DBIO: Focus Session: Translocation through Nanopores I

Hilton Baltimore Holiday Ballroom 1 - Aniket Battacharya, University of Central Florida

8:00AM M44.00001 Stiff Filamentous Virus Translocations through Solid-State Nanopores , ANGUS MCMULLEN, DEREK STEIN, JAY TANG, Brown University — We present experimental results of filamentous virus translocations through a solid-state nanopore. A nanopore can easily detect fd virus due to its linear shape and high linear charge density. With a width of 6.6 nm, a monodisperse length of 880 nm, and a long persistence length of 2.2 μm, fd is a model stiff polymer for testing theories of translocation dynamics. The distribution of measured ionic current blockade amplitudes indicates that fd virus does not fold during translocation. The mean fd translocation time was linearly proportional to the applied voltage in the range 75 mV to 500 mV. The dispersion in translocation times was much greater for fd virus than expected from Brownian motion or the conformation-dependent fluid drag. Possible explanations for the observed dispersion will be discussed in light of its dependence on voltage and the salt concentration. This work was supported by NSF Grant CBET0846505 and the Brown University IMNI.

8:12AM M44.00002 Biomolecular translocation through nanopores: from an anonymous polymer to realistic DNA , MARIA FYTA, Institute for Computational Physics, University of Stuttgart, SIMONE MELCHIONNA, IPCF - National Research Council, Rome, Italy, SAURO SUCCI, IAC - National Research Council, Rome Italy, EFTHIMIOS KAXIRAS, Physics Department, Harvard University, Cambridge, MA — We have developed an efficient multiscale approach to treat biomolecular motion in a fluid solvent. This scheme has been applied to the problem of polymer translocation through a nanopore, an intensively studied subject due to its variety of applications with ultra-fast DNA sequencing being one of them. Our first results involve an anonymous polymer translocating in pure water. We habe obtained important insight into the statistics and dynamics of the process. The translocation time exponent compares well with the experimental values, while we were able to monitor multiconformational translocation, the signatures of which are also relevant to the experimental counterparts. As a next step, we have made our modelling more realistic by including electrokinetic effects, i.e. ions, as well as a realistic quantum-mechanically derived potential for double stranded DNA. We are now able to look more deeply into what happens in the pore. The ionic conductance and DNA blockade can be qualitatively and quantitatively observed and connected to the experiments. Finally, we also investigate the effect of pore geometry in the DNA translocation process.

8:24AM M44.00003 Effect of charge patterns along nanopores on the translocation kinetics of flexible polyelectrolytes

, HARSH KATKAR, MURUGAPPAN MUTHUKUMAR, University of Massachusetts — One of the major challenges in DNA sequencing with nanopore-based electrophoresis is to slow down the DNA translocation. In the present study, we investigate the effectiveness of charge patterns along the pore on translocation dynamics. We perform a coarse-grained, three-dimensional Langevin dynamics simulation of a uniformly charged flexible polyelectrolyte translocating under uniform external electric field through a patterned solid-state nanopore. We maintain the total charge along the pore to be constant, while varying its distribution by placing alternate charged and uncharged sections of different lengths along the pore length. We observe a translocation success ratio close to 100 percent due to the presence of an attractive section near the cis end of the pore in all studied patterns. Further, we observe a nonmonotonic dependence of the translocation time with the period of the pattern. The optimum period corresponding to the longest translocation time is independent of lengths of polyelectrolyte and pore within the range studied. Calculations of mean first passage time based on free energy are able to predict the optimum period of the pattern qualitatively.

8:36AM M44.00004 Nanopore Translocation Dynamics of star polymers[1]

, RONG WANG, ZHU LIU, Nanjing University, Department of Polymer Science and Engineering, State Key Laboratoryof Coordination Chemistry — The translocation of polymers through a narrow channel or a nanopore has a significant impact on numerous biological systems and industrial process, examples including rapid DNA sequencing, controlling drug delivery, and designing nanopore sequencing device.We consider the dynamics of flow-induced translocation of star polymers through a nanopore in three dimensions by dissipative particle dynamics approach, focusing on the dependence of the translocation time on the polymer chain length. The scaling of the average translocation time τ *vs.* the total length N_{tot} of the star polymer with three arms, $\tau \sim N_{\mathsf{tot}}^{1.09\pm0.04}$, is obtained in our simulation. We establish that the overall translocation time, with the translocation probability P_i^{trans} and the translocation time τ_i under different translocation paths. We demonstrate that the translocation time τ of star polymers through the nanopore increases with the increase of the total arm numbers, while τ decreases with increasing number the forward arms that are initially squeezed into the nanopore. Our findings may provide a valuable guidance for experimental studies on the conformational and dynamics behaviors of star polymer translocation for further applications.

8:48AM M44.00005 ABSTRACT WITHDRAWN –

9:00AM M44.00006 A Fluid Channel Coincident With Graphene Tunneling Leads for DNA sequencing[1]

, LUKE SOMERS, Rutgers University, MANUEL SCHOTTDORF, Universität Würzburg, CHRIS FARINA, Rutgers University, MENI WANUNU, Northeastern University, EVA ANDREI, Rutgers University — One of the strategies towards controlled DNA sequencing by electrical readout of individual bases has been to direct single-stranded DNA through a tunnel junction. For this method to be viable, the DNA must be severely constrained to minimize geometric factors. We present a method for creating fluid channels the size of tunnel junctions, with tunneling leads across them. The fluid channel is formed by Atomic Layer Deposition around a gold wire thinned by feedback-controlled electromigration. The channel itself is used as a mask to assist in defining the tunneling leads out of graphene by electroburning. The principal reasons for selecting graphene are its proven tunnelling sensing ability, stability, and exceeding thinness.

9:12AM M44.00007 Dynamics of polymer translocation through a nanopore under an applied external field[1]

, KAIFU LUO, Department of Polymer Science and Engineering, University of Science and Technology of China — Polymer translocation is of considerable importance to many biological processes and is envisaged to be useful for rapid DNA sequencing. Using analytical techniques and Langevin dynamics simulations, we have investigated the following problems. (1) For polymer translocation into a long narrow channel driven by longitudinal flow,[2] we find that the translocation time shows a linear scaling behavior with the chain length. (2) For polymer translocation through nanochannels with different lengths,[3] we observe a minimum of translocation time as a function of the channel length. (3) We have examined polymer translocation into confined systems, such as a slit,[4] a fluidic channel,[5] nanocontainers with different shapes,[6] which shows different translocation dynamics compared with the translocation into an unconfined environment.

9:48AM M44.00008 Polymer Translocation Through a Nanopore from a Crosslinked Gel to Free Solution

, DAVID SEAN, HENDRICK W. DE HAAN, GARY W. SLATER, University of Ottawa — We present results from a computer simulation study of DNA translocation through a nanopore in a membrane that separates a gel region from free solution. The gel is modeled by a square lattice of fixed poles such that the pore size is set by the lattice spacing. Starting with the DNA on the gel side, we examine how the gel pore size affects the dynamics of translocation. We find that due to entropic and frictional forces, the mean translocation time is affected by gel pore size. Since the spatial restrictions imposed by the gel limit the dynamics to one-dimensional motion on the cis side, variations in the width of the distribution of translocations times are also observed.

10:00AM M44.00009 Statistical Inference of DNA Translocation using Parallel Expectation Maximization

, KEVIN EMMETT, JACOB ROSENSTEIN, DAVID PFAU, AKIVA BAMBERGER, KEN SHEPARD, CHRIS WIGGINS, Columbia University — DNA translocation through a nanopore is an attractive candidate for a next-generation DNA sequencing platform, however the stochastic motion of the molecules within the pore, allowing both forward and backward movement, prevents easy inference of the true sequence from observed data. We model diffusion of an input DNA sequence through a nanopore as a biased random walk with noise, and describe an algorithm for efficient statistical reconstruction of the input sequence, given data consisting of a set of time series traces. The data is modeled as a Hidden Markov Model, and parallel expectation maximization is used to learn the most probable input sequence generating the observed traces. Bounds on inference accuracy are analyzed as a function of model parameters, including forward bias, error rate, and the number of traces. The number of traces is shown to have the strongest influence on algorithm performance, allowing for high inference accuracy even in extremely noisy environments. Incorrectly identified state transitions account for the majority of inference errors, and we introduce entropy-based metaheuristics for identifying and eliminating these errors. Inference is robust, fast, and scales to input sequences on the order of several kilobases.

10:12AM M44.00010 Thermophoretic Regulation of Molecular Flux through a Nanopore[1] , MAXIM BELKIN, ALEKSEI AKSIMENTIEV, University of Illinois at Urbana-Champaign — Transport of ions, nucleic acids and other molecular species through pores in thin membranes is a process of fundamental importance to the biological function of a cell and practical applications in the field of molecular separation, filtering, and, recently, DNA sequencing. Various approaches to control the transport have been examined, including the effects of the geometry, charge and chemical functionalization of the nanopore surface. Thermophoresis in liquids, i.e. movement of molecules along a temperature gradient, was discovered more than a century ago and has already been employed in various applications, typically involving macroscopic systems. In this work, we explore the use of thermal gradients for regulation of nanoscale fluxes. Specifically, we use all-atom molecular dynamics simulations to examine the effect of thermal gradients on transport of ions, small organic solutes and long DNA molecules through solid-state nanopores. In our typical simulation, multiple thermostats are applied to different parts of the same simulation system, allowing steady-state temperature gradients to be established and the effective forces associated with the thermal gradients to be determined. The results of our simulations suggest that nanopore fluxes of molecular species can be regulated by means of thermal gradients. We expect our results to find applications in molecular separation and filtering technologies, nanofluidic electronics and nanopore sequencing of DNA.

10:24AM M44.00011 The effects of diffusion on an exonuclease/nanopore-based DNA sequencing engine , JOSEPH E. REINER, Physics Department, Virginia Commonwealth University, Richmond, VA 23284, ARVIND BALIJEPALLI, JOSEPH W.F. ROBERTSON, Physical Measurement Laboratory, NIST, Gaithersburg, MD 20899, BRYON S. DROWN, DANIEL L. BURDEN, Department of Chemistry, Wheaton College, Wheaton, IL 60187, JOHN J. KASIANOWICZ, Physical Measurement Laboratory, NIST, Gaithersburg, MD 20899 — The electronic detection and characterization of individual polynucleotides driven through a single protein nanopore holds promise for rapid and low-cost DNA sequencing. A variation on reading DNA in a ticker tape fashion was recently proposed. The pore would electrically detect single nucleotides that are cleaved sequentially by an exonuclease enzyme in close proximity to one pore entrance. We will present the results of an analytical and computational study of this scheme. The analysis examines the effects of diffusive motion on the capture probability for each nucleotide. The capture probability increases with the applied transmembrane potential, but this is offset by the reduction in the residence time of each nucleotide in the pore. The theoretical results demonstrate that these two effects limit the capability of a cleavage-based nanopore sequencing engine. We will discuss these constraints and speculate on how the system could be improved.

10:36AM M44.00012 DNA translocation through graphene nanopores , SLAVEN GARAJ, National University of Singapore; Harvard University, SONG LIU, Harvard University; Peking University, JENE A. GOLOVCHENK, DANIEL BRANTON, National University of Singapore — Nanopores are versatile platform for studying structure and behaviour of individual biopolymers. In a nanopore device, an individual DNA molecule in aqueous solution is electrophoretically threaded through the nano-scale pore in a linear fashion. Resulting modulation of the ionic current through the nanopore is characteristic of the geometrical and chemical properties of the translocating molecule. It has been shown that a new class of nanopore fabricated in free-standing single-layer graphene membrane – graphene nanopores – have excellent predisposition to achieve sub-nanometre resolution in discerning features along the length of individual DNA molecules [1]. In this talk, we will demonstrate very high sensitivity of the graphene nanopore current on small variation of the diameter of translocating molecule, and we will examine the dynamics of the DNA molecule within the graphene nanopore. The implications of those results on prospects of physical DNA sequencing will be discussed.

10:48AM M44.00013 Ionosphere perturbation of single DNA molecules in a.c. electric fields , ZUBAIR AZAD, ROBERT RIEHN, North Carolina State University — The collapse of DNA molecules under an a.c. electric field was recently established, but is little understood. We applied alternating electric fields (0 - 200 kV/cm) to fluorescently labeled λ-DNA confined in quasi 1-d nanochannels. DNA was dissolved in a buffer that contained anionic tracer dyes of varying mobilities. Under a.c. electric fields we obseved a depletion of the anionic fluorophores in the region occupied by the DNA, and enrichment in the regions directly flanking it. The critical field strength to induce expulsion of the fluorophores was above 60 kV/cm. We believe that double-sided isotachophoresis can model the ion distributions in our experiment. Furthermore, we will comment on the dynamics of fluorescent co-ions in the solution perturbed by the DNA by observing their dynamics.

Session M45 DBIO: Focus Session: Physics of the Cytoskeleton I Hilton Baltimore Holiday Ballroom 4 - Ajay Gopinathan, UC Merced

8:00AM M45.00001 Filament turnover kinetics determine the mechanical relaxation of entangled F-actin solutions , PATRICK M. MCCALL, Department of Physics and the James Franck Institute, University of Chicago, DAVID R. KOVAR, Department of Molecular Genetics and Cell Biology & Department of Biochemistry and Molecular Biology, University of Chicago, MARGARET L. GARDEL, Department of Physics, the James Franck Institute, & the Institute for Biophysical Dynamics, University of Chicago — The actin cytoskeleton of eukaryotic cells displays rich mechanical behaviors, which enable cells to efficiently transmit forces required for shape maintenance and tissue stability while also facilitating large shape changes required for morphogenic processes at longer time scales. The molecular processes that control mechanical relaxations of the actin cytoskeleton are poorly understood. Actin filament assembly kinetics are controlled in vivo by an assortment of regulatory proteins, which lead to a complete dissolution and re-formation of filaments on the timescale of seconds. How such "turnover" of filaments influences the mechanical properties of the actin cytoskeleton is less clear. To address this, we developed a system using purified actin regulatory proteins, including the severing protein ADF/cofilin and the formin nucleation/elongation factor mDia1, to tune filament turnover kinetics and measured the frequency-dependent shear modulus of entangled actin solutions via particle-tracking microrheology. We observe a tunable reduction in the terminal relaxation time when filament turnover is enhanced through severing, despite a constant mean filament length.

8:12AM M45.00002 Measuring actin dynamics during phagocytosis using photo-switchable fluorescence , DANIEL T. KOVARI, JENNIFER E. CURTIS, Georgia Institute of Technology — Phagocytosis has traditionally been investigated in terms of the relevant biochemical signaling pathways. However, a growing number of studies investigating the physical aspects of phagocytosis have demonstrated that several distinct forces are exerted throughout particle ingestion. We use variations on FRAP (Fluorescence Recovery After Photobleaching) in combination with photo-switchable fluorescent protein to investigate actin dynamics as a phagocyte attempts to engulf its prey. The goal of our actin studies are to determine the recruitment and polymerization rate of actin in the forming phagosome and whether an organized *contractile actin ring* is present and responsible for phagosome closure, as proposed in the literature. These experiments are ongoing and contribute to our long term effort of developing a physics based model of phagocytosis.

8:24AM M45.00003 Model of Yeast Actin Cable Distribution and Dynamics , HAOSU TANG, DIMITRIOS VAVYLONIS, Lehigh University — The growth of fission yeast relies on the polymerization of actin filaments at the cell tips. These filaments are nucleated by formin proteins that localize at tip cortical sites. These actin filaments bundle to form actin cables that span the cell and guide the movement of vesicles toward the cell tips. Since fluorescence microscopy shows the structure and dynamics of actin cables, we are able to compare the results of the theoretical models of actin cables to experiment, thus enabling quantitative tests of the mechanisms of actin polymerization in cells. We used computer simulations to study the spatial and dynamical properties of actin cables. We simulated individual actin filaments as three-dimensional semiflexible polymer, composed of beads connected with springs. Formin polymerization was simulated as filament growth out of cortical sites located at cell tips. Actin filament severing by cofilin was simulated as filament turnover. We added attractive interactions between beads to simulate filament bundling by actin cross-linkers such as fimbrin. Comparison of the results of the model to prior experiments suggests that filament severing, nucleation and crosslinking are sufficient to describe the many features of actin cables. We found bundled and unbundled phases as cross-linking strength was varied and propose experiments to test the model predictions.

8:36AM M45.00004 Myosin II Dynamics during Embryo Morphogenesis , KAREN KASZA, Sloan-Kettering Institute — During embryonic morphogenesis, the myosin II motor protein generates forces that help to shape tissues, organs, and the overall body form. In one dramatic example in the *Drosophila melanogaster* embryo, the epithelial tissue that will give rise to the body of the adult animal elongates more than two-fold along the head-to-tail axis in less than an hour. This elongation is accomplished primarily through directional rearrangements of cells within the plane of the tissue. Just prior to elongation, polarized assemblies of myosin II accumulate perpendicular to the elongation axis. The contractile forces generated by myosin activity orient cell movements along a common axis, promoting local cell rearrangements that contribute to global tissue elongation. The molecular and mechanical mechanisms by which myosin drives this massive change in embryo shape are poorly understood. To investigate these mechanisms, we generated a collection of transgenic flies expressing variants of myosin II with altered motor function and regulation. We found that variants that are predicted to have increased myosin activity cause defects in tissue elongation. Using biophysical approaches, we found that these myosin variants also have decreased turnover dynamics within cells. To explore the mechanisms by which molecular-level myosin dynamics are translated into tissue-level elongation, we are using time-lapse confocal imaging to observe cell movements in embryos with altered myosin activity. We are utilizing computational approaches to quantify the dynamics and directionality of myosin localization and cell rearrangements. These studies will help elucidate how myosin-generated forces control cell movements within tissues. *This work is in collaboration with J. Zallen at the Sloan-Kettering Institute.*

9:12AM M45.00005 Model of Capping Protein and Arp2/3 Complex Turnover in the Lamellipodium Based on Single Molecule Statistics , LAURA MCMILLEN, Lehigh University, MATTHEW SMITH, UCL London/Max Planck Institure-CBG Dresden, DIMITRIOS VAVYLONIS, Lehigh University — Capping protein (CP) and Arp2/3 protein complex regulate actin polymerization near the leading edge of motile cells. Actin and regulatory proteins assemble near the leading edge of the cell, undergo retrograde flow, and dissociate into the cytoplasm as single subunits (monomers) or as part of multiple actin subunits (oligomers.) To better understand this cycle, we modeled the kinetics of actin CP and Arp2/3 complex near the leading edge using data from prior experiments [Miyoshi et al. JCB, 2006, 175:948]. We used the measured dissociation rates of Arp2/3 complex and CP in a Monte Carlo simulation that includes particles in association with filamentous and diffuse actin in the cytoplasm. A slowly diffusing cytoplasmic pool may account for a big fraction of CP, with diffusion coefficients as slow as 0.5 $\mu m^2/s$ [Smith et al. Biophys. J., 2011,101:1799]. Such slow diffusion coefficients are consistent with prior experiments by Kapustina et al. [Cytoskeleton, 2010, 67:525]. We also show that the single molecule data are consistent with experiments by Lai et al. [EMBO J., 2008, 28:986]. We discuss the implication of disassembly with actin oligomers and suggest experiments to distinguish among mechanisms that influence long range transport.

9:24AM M45.00006 Effect of surface topography on actin dynamics and receptor clustering in B cells , CHRISTINA KETCHUM[1], XIAOYU SUN[2], WENXIA SONG[3], JOHN FOURKAS[4], ARPITA UPADHYAYA[5], University of Maryland - College Park — B cells are activated upon binding of the B cell receptor (BCR) with antigen on the surface of antigen presenting cells (APC). Activated B cells deform and spread on the surface of APCs which may comprise of complex membrane topologies. In order to model the diverse range of topographies that B cells may encounter, substrates fabricated with vertical ridges separated by gaps ranging from hundreds of nm to microns were coated with activating antigen to enable B cell spreading. Simultaneous imaging of actin and BCR shows that the organization of both depends profoundly on the ridge spacing. On smaller ridge spacing ($<$2 microns), actin forms long filopodial structures that explore the substrate parallel to ridges while the BCR clusters accumulate linearly along the direction of the ridges with limited ability to escape these channels. Cells on larger ridge spacing ($>$2 microns) exhibit central actin patches and peripheral actin waves and form semi-stable polymerization zones at ridges, while BCR distribution is more homogeneous. Our results indicate that surface topography may be a critical determinant of cytoskeletal dynamics and the spatiotemporal organization of signaling clusters.

9:36AM M45.00007 Biomimetic active emulsions capture cell dynamics and direct bio-inspired materials , ALLEN EHRLICHER, ESTHER AMSTAD, JANA SEGMEHL, Harvard University, FUMIHIKO NAKAMURA, THOMAS STOSSEL, Harvard Medical School, MARTIN POLLAK, Beth Israel Deaconess Medical Center, DAVID WEITZ, Harvard University — The main biopolymers which make up the cellular cytoskeleton and provide cells with their shape are well understood, yet, how they organize into structures and set given cellular behavior remains unclear. We have reconstituted minimal networks of actin, a ubiquitous biopolymer, along with an associated motor protein myosin II to create biomimetic networks which replicate cell structure and actively contract when selectively provided with ATP. We emulsify these networks in 10-100 micron drops, provide a system to investigate strain-mediated protein interactions and network behavior in confined cell-similar volumes. These networks allow us to study strain-mediated protein-specific interactions in an actin network at a precision impossible in vivo. Using this system, we have identified strain-dependent behavior in actin cross linking proteins; mechanotransduction of signaling proteins in Filamin A, and unique catch-bond behavior in Alpha-actinin. This understanding of biopolymer self-organization to set cell mechanics, will help clarify how biology both generates and reacts to force; moreover this system provides a highly controlled platform for studying non-equilibrium materials, and creating microscopic building block for a entirely new class of active materials.

9:48AM M45.00008 Eukaryotic and Prokaryotic Cytoskeletons: Structure and Mechanics , AJAY GOPINATHAN, University of California, Merced — The eukaryotic cytoskeleton is an assembly of filamentous proteins and a host of associated proteins that collectively serve functional needs ranging from spatial organization and transport to the production and transmission of forces. These systems can exhibit a wide variety of non-equilibrium, self-assembled phases depending on context and function. While much recent progress has been made in understanding the self-organization, rheology and nonlinear mechanical properties of such active systems, in this talk, we will concentrate on some emerging aspects of cytoskeletal physics that are promising. One such aspect is the influence of cytoskeletal network topology and its dynamics on both active and passive intracellular transport. Another aspect we will highlight is the interplay between chirality of filaments, their elasticity and their interactions with the membrane that can lead to novel conformational states with functional implications. Finally we will consider homologs of cytoskeletal proteins in bacteria, which are involved in templating cell growth, segregating genetic material and force production, which we will discuss with particular reference to contractile forces during cell division. These prokaryotic structures function in remarkably similar yet fascinatingly different ways from their eukaryotic counterparts and can enrich our understanding of cytoskeletal functioning as a whole.

10:24AM M45.00009 Cell shape can mediate the spatial organization of the bacterial cytoskeleton , SIYUAN WANG, Harvard University, NED WINGREEN, Princeton University — The bacterial cytoskeleton guides the synthesis of cell wall and thus regulates cell shape. Since spatial patterning of the bacterial cytoskeleton is critical to the proper control of cell shape, it is important to ask how the cytoskeleton spatially self-organizes in the first place. In this work, we develop a quantitative model to account for the various spatial patterns adopted by bacterial cytoskeletal proteins, especially the orientation and length of cytoskeletal filaments such as FtsZ and MreB in rod-shaped cells. We show that the combined mechanical energy of membrane bending, membrane pinning, and filament bending of a membrane-attached cytoskeletal filament can be sufficient to prescribe orientation, e.g. circumferential for FtsZ or helical for MreB, with the accuracy of orientation increasing with the length of the cytoskeletal filament. Moreover, the mechanical energy can compete with the chemical energy of cytoskeletal polymerization to regulate filament length. Notably, we predict a conformational transition with increasing polymer length from smoothly curved to end-bent polymers. Finally, the mechanical energy also results in a mutual attraction among polymers on the same membrane, which could facilitate tight polymer spacing or bundling. The predictions of the model can be verified through genetic, microscopic, and microfluidic approaches.

10:36AM M45.00010 Elastic behavior of vimentin intermediate filament networks , HUAYIN WU, ELIZA MORRIS, DAVID WEITZ, Harvard University — A cell's response to mechanical stress is closely linked to the structure and elasticity of its cytoskeleton, which is comprised primarily of actin, microtubule, and intermediate filament (IF) networks. Vimentin is an IF found in mesenchymal cells that plays a role in anchoring organelles and contributes to overall cellular elasticity. Previous research has shown that vimentin networks behave like softly crosslinked gels in the presence of divalent cations. The linear elastic modulus, a measure of stiffness and resistance to elastic deformation, of the network is related to the degree of crosslinking, which is itself controlled by the cation concentration. Increasing the concentration of the divalent cations further results in the formation of bundles within the network, but this bundling behavior is not well understood. Here we investigate the response of in vitro reconstituted vimentin networks to applied shear in the presence of various divalent species to better understand their individual contributions to the network's elastic behavior.

10:48AM M45.00011 Biopolymer Networks: Simulations of Rigid Rods Connected by Wormlike Chains , KNUT M. HEIDEMANN, Department for Numerical and Applied Mathematics, Georg August University Goettingen, MEENAKSHI M. PRABHUNE, FLORIAN REHFELDT, Third Institute of Physics - Biophysics, Georg August University Goettingen, MAX WARDETZKY, Department for Numerical and Applied Mathematics, Georg August University Goettingen, CHRISTOPH F. SCHMIDT, Third Institute of Physics - Biophysics, Georg August University Goettingen, SFB 755 NANOSCALE PHOTONIC IMAGING: HIGH-RESOLUTION STRESS-FIELD MAPPING IN FIBER NETWORKS AND CELLS COLLABORATION — The cytoskeleton of cells is a composite network of filaments ranging from stiff rod-like microtubules to semiflexible actin filaments that together play a crucial role in cell structure and mechanics. The collective dynamics of these cytoskeletal filaments with different mechanical properties are yet to be understood completely. To model such a strongly heterogeneous composite, we simulate networks of *rigid* rods connected by *flexible* linkers (wormlike chains). We extract elastic moduli by quasistatic deformations at varying filament densities and analyze the crossover between cross-link dominated and rod dominated regimes. In particular, we are interested in the asymptotic stress dependence of the *differential modulus*. The simulations are accompanied by rheological experiments on networks of *microtubules* (MTs) cross-linked by double-stranded *DNA* of variable length (cf. talk Meenakshi Prabhune).

Wednesday, March 20, 2013 8:00AM - 11:00AM –

Session M46 GIMS: Novel Instrumentation and Measurements for Biomedical Research Hilton Baltimore Holiday Ballroom 5 - Larry Nagahara, National Cancer Institute

8:00AM M46.00001 Investigation of cell morphology for disease diagnostics via high content screening , SHYAM KHATAU, Johns Hopkins University — Ninety percent of all cancer-related deaths are caused by metastatic disease, i.e. the spreading of a subset of cells from a primary tumor in an organ to distal sites in other organs. Understanding this progression from localized to metastatic disease is essential for further developing effective therapeutic and treatment strategies. However, despite research efforts, no distinct genetic, epigenetic, or proteomic signature of cancer metastasis has been identified so far. Metastasis is a physical event: through invasion and migration through the dense, tortuous stromal matrix, intravasation, shear forces of blood flow, successful re-attachment to blood vessel walls, migration, the colonization of a distal site, and, finally, reactivation following dormancy, metastatic cells may share precise physical properties. Cell morphology is the most direct physical property that can be measured. In this work, we develop a high throughput cell phenotyping process and investigate the morphological signature of primary tumor cells and liver metastatic pancreatic cancer cells.

8:36AM M46.00002 Multiplexing nano-electroporation for simultaneous transfection of multiple cells , M. HOWDYSHELL, G. VIEIRA, D. GALLEGO-PEREZ, X. ZHAO, L. J. LEE, R. SOORYAKUMAR, The Ohio State University — Transfection of biomolecules into cells via electrophoresis across nanochannels, or nano-electroporation, is a recently developed technique shown to deliver precisely controlled dosages with low cell mortality rates. Such advantages are due to the nanochannels used for transfection, which distinguish this technique from bulk and micro-electroporation. Recent demonstrations of nano-electroporation rely on optical tweezers for cell localization, which restrict throughput to sequential electroporation of one cell at a time. In the current work, we overcome this drawback by advancing a multiplexed approach that integrates the nano-channel device with an array of magnetic traps remotely controlled by external magnetic fields. This setup enables multiple magnetically labeled cells to be manipulated in parallel, allowing for simultaneous electroporation of many cells with precisely controlled dosages. After transfection, the cells can be moved downstream for further analysis. Such a magnetically-actuated, remotely-controlled approach for loading of cells and subsequent removal of transfected cells has the potential to transform the current device into an automated platform for simultaneous dosage-controlled biomolecule delivery to large numbers of individual cells.

8:48AM M46.00003 Nanopore Mass Spectrometry[1] , JOSEPH BUSH, MIRNA MIHOVILOVIC, WILLIAM MAULBETSCH, LAYNE FRENCHETTE, WOOYOUNG MOON, COLE PRUITT, Brown University Physics Department, CARTHENE BAZEMORE-WALKER, PETER WEBER, Brown University Chemistry Department, DEREK STEIN, Brown University Physics Department — We report on the design, construction, and characterization of a nanopore-based ion source for mass spectrometry. Our goal is to field-extract ions directly from solution into the high vacuum to enable unit collection efficiency and temporal resolution of sequential ion emissions for DNA sequencing. The ion source features a capillary whose tip, measuring tens to hundreds of nanometers in inner diameter, is situated in the vacuum $\sim$ 1.5 cm away from an extractor electrode. The capillary was filled with conductive solution and voltage-biased relative to the extractor. Applied voltages of hundreds of volts extracted tens to hundreds of nA of current from the tip. A mass analysis of the extracted ions showed primarily singly charged clusters comprising the cation or anion solvated by several solvent molecules. Our interpretation of these results, based on the works of Taylor and of de la Mora, is that the applied electric stresses distort the fluid meniscus into a Taylor cone, where electric fields reach $\sim$ 1V/nm and induce significant ion evaporation. Accordingly, the abundances of extracted ionic clusters resemble a Boltzmann distribution.

9:00AM M46.00004 Coupled External Cavity Photonic Crystal Enhanced Fluorescence[1] , ANUSHA POKHRIYAL, Department of Physics, University of Illinois at Urbana-Champaign, MENG LU, CHUN GE, BRIAN CUNNINGHAM, Department of Electrical and Computer Engineering, University of Illinois at Urbana-Champaign, NANO SENSORS GROUP TEAM — In this work we report a fundamentally new approach to enhance fluorescence in which surface adsorbed fluorophore-tagged biomolecules are excited on a photonic crystal surface that functions as a narrow bandwidth and tunable mirror of an external cavity laser. This scheme leads to ∼10x increase in the electromagnetic enhancement factor compared to ordinary photonic crystal enhanced fluorescence. In our experiments, the cavity automatically tunes its lasing wavelength to the resonance wavelength of the photonic crystal, ensuring optimal on-resonance coupling even in the presence of variable device parameters and variations in the density of surface-adsorbed capture molecules. We achieve $\sim 10^5$x improvement in the limit of detection of a fluorophore-tagged protein compared to its detection on an unpatterned glass substrate. The enhanced fluorescence signal and easy optical alignment make cavity-coupled photonic crystals a viable approach for further reducing detection limits of optically-excited light emitters that are used in biological assays.

9:12AM M46.00005 Confocal absorption microscopy of biomolecules and single cells from the visible to the ultraviolet spectral range , FATHOLAH SALEHI, SANGHOON PARK, Department of Physics and College of Optics, University of Central Florida, Orlando, MICHAEL E. SIGMAN, Department of Chemistry and College of Optics, University of Central Florida, Orlando, ALFONS SCHULTE, Department of Physics and College of Optics, University of Central Florida, Orlando — We present a versatile approach for absorption spectroscopy on the micron scale that combines a broadband white light source with a confocal microscope and a multichannel detector. The attenuation of the propagating light provides a mechanism for contrast that allows spectrally resolved measurements of biomolecules in minuscule quantities and of single live cells. UV absorption spectra of aromatic amino acids, proteins, and single stranded DNA oligomers (100 bases) in solution are measured with less than 10^7 molecules in the probe volume. We discuss applications to spectroscopically identify heterogeneities at the single cell level and to the label-free detection of nucleic acids.

9:24AM M46.00006 Reflectance spectrometry of placental vessels in cases of twin-twin transfusion syndrome: experiments and modeling , COLLIN LINES, OLEG KIM, University of Notre Dame, JOHN MCMURDY, None, FRANCOIS LUKS, Division of Pediatric Surgery and Maternal-Fetal Medicine, Alpert Medical School of Brown University, MARK ALBER, GREG CRAWFORD, University of Notre Dame — A stochastic photon transport model in multilayer skin tissue combined with reflectance spectroscopy measurements is used to study placental vessels in cases of twin-twin transfusion syndrome (TTTS). TTTS occurs in about 12% of monozygotic (identical) twin pregnancies wherein flow within placental vessels linking the twins together becomes unbalanced, leading to dual mortality. Endoscopic laser ablation can halt the syndrome by occluding the anastomoses connecting the two fetuses. The objective of this study is to develop a technique to determine hemoglobin (Hb) content through spectral analysis of diffuse reflectance spectra of placental vessels to aid in identification of the anastomoses. Previous work by researchers at Brown University has shown that the reflectance spectra of the donor twin and recipient twin are considerably different in the wavelengths for Hb absorbance. This presentation will give preliminary results for a Monte Carlo model adapted to fit the physiology of the placenta that can be used to quantitative determine the Hb levels. The reflectance spectra of the vessels are simulated for different values of Hb as well oxygenation and water concentration with the vessel and placental mass. The preliminary results will be shown to be in good approximation with the prior experimental data. The combination of modeling with spectroscopic measurement will provide a new tool for detailed prenatal study.

9:36AM M46.00007 Microwave Spectrometry for the Assessment of the Structural Integrity and Restenosis Degree of Coronary Stents , GIANLUCA ARAUZ-GAROFALO, VICTOR LOPEZ-DOMINGUEZ, ANTONI GARCIA-SANTIAGO, JAVIER TEJADA, Grup de Magnetisme, Departament de Fisica Fonamental, Facultat de Fisica, Universitat de Barcelona, JOAN M. O'CALLAGHAN, Department Signal Theory and Communications, Universitat Politecnica de Catalunya, ORIOL RODRIGUEZ-LEOR, ANTONI BAYES-GENIS, Servei de Cardiologia, Hospital Universitari Germans Trias i Pujol, GMAG TEAM, HUGTP TEAM, UPC TEAM — Cardiovascular disease is the main cause of death worldwide. Coronary stents are one of the most important improvements to reduce deaths from cardiovascular disorders. Stents are prosthetic tube-shaped devices which are used to rehabilitate obstructed arteries. Despite their obvious advantages, reocclusion occurs in some cases arising from restenosis or structural distortions, so stented patients require chronic monitoring (involving invasive or ionizing procedures). We study microwave scattering spectra (between 2.0 - 18.0 GHz) of metallic stents in open air, showing that they behave like dipole antennas in terms of microwave scattering. They exhibit characteristic resonant frequencies in their microwave absorbance spectra that are univocally related to their length and diameter. This fact allows one to detect stent fractures or collapses. We also investigate the "dielectric shift" in the frequency of the resonances mentioned above due to the presence of different fluids along the stent lumen. This shift could give us information about the restenosis degree of implanted stents.

9:48AM M46.00008 Higher Resolution and Faster MRI of ^{31}Phosphorus in Bone , MERIDETH FREY, SEAN BARRETT, Yale University, Physics Dept., ZACHARY SETHNA, Princeton University, Physics Dept., KARL INSOGNA, JOSHUA VANHOUTEN, Yale University, School of Medicine, Dept. of Internal Medicine — Probing the internal composition of bone on the sub-100 μm length scale is important to study normal features and to look for signs of disease. However, few useful non-destructive techniques are available to evaluate changes in the bone mineral chemical structure and functional micro-architecture on the interior of bones. MRI would be an excellent candidate, but bone is a particularly challenging tissue to study given the relatively low water density, wider linewidths of its solid components leading to low spatial resolution, and the long imaging time compared to conventional ^{1}H MRI. Our lab has recently made advances in obtaining high spatial resolution (sub-400 μm)^3 three-dimensional ^{31}Phosphorus MRI of bone through use of the quadratic echo line-narrowing sequence (1). In this talk, we describe our current results using proton decoupling to push this technique even further towards the factor of 1000 increase in spatial resolution imposed by fundamental limits. We also discuss our work to speed up imaging through novel, faster reconstruction algorithms that can reconstruct the desired image from very sparse data sets. (1) M. Frey, et al. *PNAS* **109**: 5190 (2012).

10:00AM M46.00009 Accelerated Acquisition of 2D NMR Spectra using Iterative Projections , SEAN BARRETT, Yale University, Physics Dept., ZACHARY SETHNA, Princeton University, Physics Dept., MERIDETH FREY, Yale University, Physics Dept., PATRICK LORIA, Yale University, Chemistry, Dept. — Typically, in 2D NMR (or 2D MRI), only one "row" of the time-dependent (or k-dependent) signal is sampled N times per $\sim T_1$ (spin-lattice relaxation time). Thus, filling a 2D Cartesian grid of $M \times N$ data points requires M additional experiments, for a total spectral acquisition time $T_{\mathrm{acq}} \approx M \times T_1$. Measuring fewer "rows" than required for Fourier reconstruction decreases T_{acq}, but this results in a low-quality spectrum (unless more complicated, computationally slower reconstruction techniques are used). Here, we show that a new approach to this problem, using iterative projections, can work on actual 2D NMR data. This approach is built upon the Fast Fourier Transform, so it can handle large data sets (2D, 3D, 4D). Moreover, this approach is expected to work even better in higher dimensions, yielding greater speed ups. Finally, we will discuss how the accelerated acquisition may also improve signal-to-noise and frequency resolution.

10:12AM M46.00010 Fast Spectral Reconstruction of Noisy, Sparse Time Domain Data through Iterative Projections , ZACHARY SETHNA, Princeton University, Physics Dept., MERIDETH FREY, SEAN BARRETT, Yale University, Physics Dept., SUVRAJIT SENGUPTA, KURT ZILM, Yale University, Chemistry Dept. — We discuss here an approach for reconstructing spectra from sparse time domain data, by way of iterated projections, and more specifically by alternating projections or by use of the difference map algorithm developed by Veit Elser. This is done in a purely deterministic way, by reformulating any a priori knowledge or constraints into projections, and then iterating. This method is extremely flexible, can be applied to a variety of different signals, and is robust enough to handle real data (with noise and artifacts). In this talk we explain the motivation behind this approach, the formulation of the specific projections, and various methods for handling noise. We will demonstrate the approach using 2D NMR spectra and will compare and contrast this approach with existing methods, such as Maximum Entropy reconstruction.

10:24AM M46.00011 Tether-free endoscopic biopsy with self-assembled micro-surgical tools[1] , EVIN GULTEPE, EUN JI SHIN, FLORIN SELARU, ANTHONY KALLOO, DAVID GRACIAS, The Johns Hopkins University — Feynman's futuristic vision of "swallowing the surgeon" or a truly non-invasive surgery relies on the invention and utilization of tetherless, stimuli-responsive and miniaturized surgical tools. We propose a step in this direction by the use of sub-millimeter scale, untethered, self-assembled endoscopic tools by designing and deploying microgrippers (μ-grippers) for effective mucosal sampling from large surface-area organs and for tissue retrieval from hard to reach places in the body. Due to their small size, tether-free actuation, parallel fabrication and deployment, μ-grippers can be dispersed in large numbers (hundreds or thousands) to collect tissue samples and allow statistical sampling of large mucosal areas. Monte Carlo simulations showed that using large number of biopsy tools increases the sampling coverage for screening procedures and hence the chance of detecting the malignant lesions. To establish the feasibility of using μ-grippers for sampling large organs we used with ex-vivo colon and in-vivo esophagus models. Our results showed that it is possible to retrieve high quality tissue samples which are suitable for either conventional cytologic or genetic analyses by using μ-grippers.

10:36AM M46.00012 Towards Truly Quiet MRI: animal MRI magnetic field gradients as a test platform for acoustic noise reduction , WILLIAM EDELSTEIN, ABDEL-MONEM EL-SHARKAWY, Johns Hopkins School of Medicine — Clinical MRI acoustic noise, often substantially exceeding 100 dB, causes patient anxiety and discomfort and interferes with functional MRI (fMRI) and interventional MRI. MRI acoustic noise reduction is a long-standing and difficult technical challenge. The noise is basically caused by large Lorentz forces on gradient windings—surrounding the patient bore—situated in strong magnetic fields (1.5 T, 3 T or higher). Pulsed currents of 300 A or more are switched through the gradient windings in sub-milliseconds. Experimenting with hardware noise reduction on clinical scanners is difficult and expensive because of the large scale and weight of clinical scanner components (gradient windings $\sim$ 1000 kg) that require special handling equipment in large engineering test facilities. Our approach is to produce a Truly Quiet (<70 dB) small-scale animal imager. Results serve as a test platform for acoustic noise reduction measures that can be implemented in clinical scanners. We have so far decreased noise in an animal scale imager from 108 dB to 71 dB, a 37 dB reduction. Our noise reduction measures include: a gradient container that can be evacuated; inflatable antivibration mounts to prevent transmission of vibrations from gradient winding to gradient container; vibration damping of wires going from gradient to the outside world via the gradient container; and a copper passive shield to prevent the generation of eddy currents in the metal cryostat inner bore, which in turn can vibrate and produce noise.

10:48AM M46.00013 Extracellular recording of *Hirudo medicinalis* neurons using high density, nanocoax neurointerface array[1] , JEFFREY R. NAUGHTON, MARGARET H. AASEN, MICHAEL J. BURNS, THOMAS C. CHILES, MICHAEL J. NAUGHTON, Boston College — We describe the development of a nanocoax-based neuroelectronic array with submicron pixelation with potential for recording and stimulation with high spatial and temporal resolution. Our device is composed of an array of nanoscale open-ended coaxial electrodes addressed in either a group or individual configuration. As a neuroelectronic interface, our device is characterized by noninvasive real-time coupling to the ganglion sac located along the main nerve cord of the *Hirudo medicinalis*. This allows for extracellular recording of interneural synaptic activity, while also showing the capability of actuating precisely-localized stimulation (faradaic regime). We report on initial results from measurements of electrical signals associated with induced and spontaneous synapse firing in pre- and post-synaptic somata.

Session M47 DBIO: Invited Session: Imaging and Manipulating Multicellular Systems and Molecular Clusters Hilton Baltimore Holiday Ballroom 6 - Raghuveer Parthasarath, University of Oregon

8:00AM M47.00001 Imaging proteins, cells, and tissues dynamics during embryogenesis with two-photon light sheet microscopy , THAI TRUONG, California Institute of Technology — Light sheet microscopy has gained widespread recognition in recent years due to its distinct advantages for the 3-dimensional imaging of living biological samples. Light sheet microscopy, also known as selective plane illumination microscopy, uses a planar sheet of light to illuminate a sample, generating fluorescence over an optical section of the sample that is collected by a wide-field microscope camera oriented orthogonal to the light sheet. The orthogonal geometry between the illumination and detection pathways enables massive parallelization in both illumination and detection. Furthermore, it allows light illumination to be confined to essentially only the optical section that is being interrogated, minimizing undesired interaction of light with the biological sample. Because of these features, light sheet microscopy significantly outperforms standard imaging modalities in imaging speed, photodamage, and signal to noise in many imaging applications. We recently applied two-photon excitation to light sheet microscopy to improve its penetration depth, allowing long-term imaging of cells deep inside of live embryos. We present a comparison of two-photon light sheet microscopy with other conventional imaging modalities in live imaging of embryos to demonstrate its ability to simultaneously achieve high penetration depth, high acquisition speed, and low photodamage. We also present a selection of applications where two-photon light sheet microscopy is utilized to study the spatio-temporal organization and control of proteins, cells, and tissues during embryogenesis.

8:36AM M47.00002 Voltage imaging in vivo with a new class of rhodopsin-based indicators , ADAM DOUGLASS, University of Utah, Dept. of Neurobiology and Anatomy; Harvard University, Dept. of Molecular and Cellular Biology — Reliable, optical detection of single action potentials in an intact brain is one of the longest-standing challenges in neuroscience. We have recently shown that a number of microbial rhodopsins exhibit intrinsic fluorescence that is sensitive to transmembrane potential. One class of indicator, derived from Archaerhodopsin-3 (Arch), responds to voltage transients with a speed and sensitivity that enable near-perfect identification of single action potentials in cultured neurons [Nat Methods. (2011). 9:90-5]. We have extended the use of these indicators to an in vivo context through the application of advanced imaging techniques to the larval zebrafish. Using planar-illumination, spinning-disk confocal, and epifluorescence imaging modalities, we have successfully recorded electrical activity in a variety of fish structures, including the brain and heart, in a completely noninvasive manner. Transgenic lines expressing Arch variants in defined cells enable comprehensive measurements to be made from specific target populations. In parallel, we have also extended the capabilities of our indicators by improving their multiphoton excitability and overall brightness. Microbial rhodopsin-based voltage indicators now enable optical interrogation of complex neural circuits, and electrophysiology in systems for which electrode-based techniques are challenging.

9:12AM M47.00003 Spatially and temporally coordinated processes of cells at molecular to cellular scales , JOACHIM SPATZ, Max Planck Institute for Intelligent Systems & University of Heidelberg — Our approach to engineer cellular environments is based on self-organizing spatial positioning of single signaling molecules attached to synthetic extracellular matrices, which offers the highest spatial resolution with respect to the position of single signaling molecules. This approach allows tuning tissue with respect to its most relevant properties, i.e., viscoelasticity, peptide composition, nanotopography and spatial nanopatterning of signaling molecule. Such materials are defined as "nano-digital materials" since they enable the counting of individual signaling molecules, separated by a biologically inert background. Within these materials, the regulation of cellular responses is based on a biologically inert background which does not initiate any cell activation, which is then patterned with specific signaling molecules such as peptide ligands in well defined nanoscopic geometries. This approach is very powerful, since it enables the testing of cellular responses to individual, specific signaling molecules and their spatial ordering. We found that integrin cluster have a functional packing density which is defined by an integrin-integrin spacing of approximately 68 nanometers. We have also developed methods which allows the light initiated activation of adhesion processes by switching the chemical composition of the extracellular matrix. This enabled us to identify the frequency of leader cell formation in collective cell migration as a matter of initial cell cluster pattern size and geometry. Moreover, "nano-digital supports" such as those described herein are clearly capable of involvement in such dynamic cellular processes as protein ordering at the cell's periphery which in turn leads to programming cell responses.

9:48AM M47.00004 From flexibility to cooperativity: multiscale modeling of cadherin-mediated cell adhesion , YINGHAO WU, Albert Einstein College of Medicine — Cadherins constitute a large family of Ca2+-dependent adhesion molecules in the Inter-cellular junctions that play a pivotal role in the assembly of cells into specific three-dimensional tissues. Although the molecular mechanisms underlying cadherin-mediated cell adhesion are still not fully understood, it seems likely that both cis dimers that are formed by binding of extracellular domains of two cadherins on the same cell surface, and trans-dimers formed between cadherins on opposing cell surfaces, are critical to trigger the junction formation. Here we present a new multiscale computational strategy to model the process of junction formation based on the knowledge of cadherin molecular structures and its 3D binding affinities. The cell interfacial region is defined by a simplified system where each of two interacting membrane surfaces is represented as a two-dimensional lattice with each cadherin molecule treated as a randomly diffusing unit. The binding energy for a pair of interacting cadherins in this two-dimensional discrete system is obtained from 3D binding affinities through a renormalization process derived from statistical thermodynamics. The properties of individual cadherins used in the lattice model are based on molecular level simulations. Our results show that within the range of experimentally-measured binding affinities, cadherins condense into junctions driven by the coupling of cis and trans interactions. The key factor appears to be a loss of molecular flexibility during trans dimerization that increases the magnitude of lateral cis interactions. We have also developed stochastic dynamics to study the adhesion of multiple cells. Each cell in the system is described as a mechanical entity and adhesive properties between two cells are derived from the lattice model. The cellular simulations are used to study the specific problems of tissue morphogenesis and tumor metastasis. The consequent question and upcoming challenge is to understand the functional roles of cell adhesion in intracellular signal transduction.

10:24AM M47.00005 Adhesion and receptor clustering stabilizes lateral heterogeneity in cell plasma membranes , SARAH VEATCH, University of Michigan — The thermodynamic properties of plasma membrane lipids play a vital role in many functions that initiate at the mammalian cell surface. Some functions are thought to occur, at least in part, because plasma membrane lipids have a tendency to separate into two distinct liquid phases, called liquid-ordered and liquid-disordered. We find that isolated cell plasma membranes are poised near a miscibility critical point separating these two liquid phases, and postulate that critical composition fluctuations provide the physical basis of functional membrane heterogeneity in intact cells. In this talk I will describe several possible mechanisms through which dynamic fluctuations can be stabilized in super-critical membranes, and will present some preliminary evidence suggesting that these structures can be visualized in intact cells using quantitative super-resolution fluorescence localization imaging.

Wednesday, March 20, 2013 8:00AM - 9:30AM –

Session M48 APS: Tutorial for Authors and Referees Key Ballroom 9-10 -

8:00AM M48.00001 Tutorial for Authors and Referees —Editors from Physical Review Letters and Physical Review will provide information and tips for our less experienced referees and authors. This session is aimed at anyone looking to submit to or review for any of the APS journals, as well as anyone who would like to learn more about the authoring and refereeing processes. Topics for discussion will include advice on how to write good manuscripts, similarities and differences in writing referee reports for PRL and PR, and other ways in which authors, referees, and editors can work together productively. Following a short presentation from the editors, there will be a m oderated discussion. A light breakfast of bagels, pastries, coffee and tea will be served.

Wednesday, March 20, 2013 11:15AM - 2:15PM –

Session N1 GQI DCMP: Invited Session: Quantum Computing With Diamond Ballroom I - Mohammad Hafezi, University of Maryland

11:15AM N1.00001 Entanglement and entanglement storage in dipolar coupled diamond defects , JOERG WRACHTRUP, University of Stuttgart — The generation of robust entangled states is one of the key steps in quantum science. Although diamond defects are highly versatile quantum bits mutual entanglement has not been demonstrated so far. The talk will describe the engineering of strongly coupled defect centers as well as their characteristic features. Entanglement generation as well as different means of tomography will be outlined. Correlated photon emission form coupled defect center pairs is analyzed. Robust storage of electron spin entanglement into nuclear spins resulting in entanglement storage lifetime of ms is demonstrated and roads towards efficient generation of strongly coupled defect arrays will be discussed.

11:51AM N1.00002 Mobile quantum sensing with spins in optically trapped nanodiamonds[1] , DAVID D. AWSCHALOM[2], Center for Spintronics and Quantum Computation, University of California, Santa Barbara, California 93106 — The nitrogen-vacancy (NV) color center in diamond has emerged as a powerful, optically addressable, spin-based probe of electromagnetic fields and temperature. For nanoscale sensing applications, the NV center's atom-like nature enables the close-range interactions necessary for both high spatial resolution and the detection of fields generated by proximal nuclei, electrons, or molecules. Using a custom-designed optical tweezers apparatus, we demonstrate three-dimensional position control of nanodiamonds in solution with simultaneous optical measurement of electron spin resonance (ESR)[3]. Despite the motion and random orientation of NV centers suspended in the optical trap, we observe distinct peaks in the ESR spectra from the ground-state spin transitions. Accounting for the random dynamics of the trapped nanodiamonds, we model the ESR spectra observed in an applied magnetic field and estimate the dc magnetic sensitivity based on the ESR line shapes to be $\sim$50 $\mu\mathrm{T}/\sqrt{Hz}$. We utilize the optically trapped nanodiamonds to characterize the magnetic field generated by current-carrying wires and ferromagnetic structures in microfluidic circuits. These measurements provide a pathway to spin-based sensing in fluidic environments and biophysical systems that are inaccessible to existing scanning probe techniques, such as the interiors of living cells.

[2]In collaboration with Viva R. Horowitz, Benjamín J. Alemán, Paolo Andrich, David J. Christle, and Andrew N. Cleland.

[3]V.R. Horowitz, B.J. Alemán, D.J. Christle, A.N. Cleland, and D.D. Awschalom, *Proc. Natl. Acad. Sci. USA*, **109**, 13493 (2012).

12:27PM N1.00003 Quantum optical networks with diamond nanophotonics , NATHALIE DE LEON, Harvard University Department of Physics — Scalable quantum optical networks require identical single photons from multiple quantum bits and high collection efficiency of these single photons. Nitrogen vacancy (NV) centers in diamond are a promising candidate for quantum information processing because they have quantum mechanical degrees of freedom that can be addressed optically and, as solid-state structures, can potentially be easily integrated into nanophotonic networks. In particular, they have a zero-phonon line (ZPL), which acts as an atom-like cycling transition that can be used for coherent optical manipulation. However, the ZPL only accounts for 3-5% of the total emission, and it is difficult to generate a high density of NV centers with stable ZPL. I will present progress toward gaining both spectral and spatial control over NV emission by coupling NV centers to nanophotonic devices. In particular, we have fabricated high quality factor (Q), small mode volume (V) photonic crystal cavities directly out of diamond, and have deterministically placed them around stable NV centers to enhance the spontaneous emission at the cavity resonance by a factor of 50-100. This emission is guided efficiently into a single optical mode, enabling integration with other photonic elements, as well as networks of cavities, each with their own optically addressable qubit. These nanophotonic elements in diamond will provide a building block for a variety of applications in quantum information processing, such as entanglement of distant NV centers and single photon transistors.

1:03PM N1.00004 Single-shot readout of multiple nuclear spin qubits in diamond under ambient conditions , VINCENT JACQUES, Laboratoire de Photonique Quantique et Moléculaire, Ecole Normale Supérieure de Cachan and CNRS UMR 8537, 94235 Cachan, France — Nuclear spins are attractive candidates for solid-state quantum information storage and processing owing to their extremely long coherence time. However, since this appealing property results from a high level of isolation from the environment, it remains a challenging task to polarize, manipulate and readout with high fidelity individual nuclear spins. A promising approach to overcome this limitation consists in utilizing an ancillary single electronic spin to detect and control remote nuclear spins coupled by hyperfine interaction. In this talk, I will show how the electronic spin of a single Nitrogen-Vacancy (NV) defect in diamond can be used as a robust platform to observe the real-time evolution of surrounding single nuclear spins under ambient conditions. Using a diamond sample with a natural abundance of ^{13}C isotopes, we first demonstrate high fidelity initialization and single-shot readout of an individual ^{13}C nuclear spin. By including the intrinsic ^{14}N nuclear spin of the NV defect in the quantum register, we then report the simultaneous observation of quantum jumps linked to both nuclear spin species, providing an efficient initialization of the two qubits. These results open up new avenues for diamond-based quantum information processing (QIP) including active feedback in quantum error correction protocols and tests of quantum correlations with solid-state single spins at room temperature.

1:39PM N1.00005 Quantum entanglement between diamond spin qubits separated by 3 meters , RONALD HANSON, Kavli Institute of Nanoscience, Delft University of Technology — Entanglement of spatially separated objects is one of the most intriguing phenomena that can occur in physics. This can lead "spooky action at a distance" where measurement of one object instantaneously affects the state of the other object. Besides being of fundamental interest, entanglement is also a valuable resource in quantum information technology enabling secure quantum communication networks and distributed quantum computing. Here we present our most recent results towards the realization of scalable quantum networks with solid-state qubits. We have entangled two spin qubits in diamond, each associated with a nitrogen vacancy center in diamond [1]. The two diamonds reside in separate setups three meters apart from each other. With no direct interaction between the two spins to mediate the entanglement, we make use of a scheme based on quantum measurements: we perform a joint measurement on photons emitted by the NV centers that are entangled with the electron spins. The detection of the photons projects the spins into an entangled state. We verify the generated entanglement by single-shot readout of the spin qubits in different bases and correlating the results. These results open the door to a range of exciting opportunities. For instance, the remote entanglement can be extended to nuclear spins near the NV center. Our recent experiments demonstrate robust methods for initializing, controlling and entangling nuclear spins by using the electron spin as an ancilla [2,3]. Entanglement of remote quantum registers will enable deterministic quantum teleportation, distributed quantum computing tasks and the implementation of an elementary quantum repeater.

Session N2 DCMP: Invited Session: Electron Matter in FE-Based Superconductors Ballroom II - Zhi-Xun Shen, Stanford University

11:15AM N2.00001 Pairing mechanism and gap symmetry in Fe-based superconductors with only electron or only hole pockets , ANDREY CHUBUKOV, University of Wisconsin — The pairing in moderately doped Fe-pnictides and Fe-chalcogenides is generally understood as being due to magnetically enhanced interaction between hole and electron pockets. Recently, however, superconductivity has been observed in AFe_2Se_2 (A = K, Rb, Cs), which contain only electron pockets, and in KFe_2As_2, which contains only hole pockets. In the talk, I review different (and sometimes conflicting) scenarios for the pairing in these systems and propose my own. I argue that the pairing condensate in systems with only electron pockets necessary contains not only a conventional intra-pocket component, but also inter-pocket component, made of two fermions belonging to different electron pockets. I analyze the interplay between intra-pocket and inter-pocket pairing depending on the ellipticity of electron pockets and the strength of their hybridization and show that with increasing hybridization the system undergoes a transition from a d-wave state to an s^{+-} state, in which the gap changes sign between hybridized pockets. This s^{+-} state has the full gap and at the same time supports spin resonance, in agreement with the data. Near the boundary between d and s^{+-} states the system develops s+id state which breaks time-reversal symmetry. For systems with only hole pockets, I argue for s^{+-} state in which the gap changes sign between hole pockets. I show that this state is qualitatively different from s^{+-} state when both hole and electron pockets are present. I further show that the transition from one s-wave state to the other involves highly unusual s+is state which again breaks time reversal symmetry.

11:51AM N2.00002 Atomic-scale Visualization of Electronic Nematicity and Cooper Pairing in Iron-based Superconductors[1] , MILAN P. ALLAN, Cornell University, ETH Zürich — The mechanism of high-temperature superconductivity in the relatively novel iron-based high-T_c superconductors is unresolved, both in terms of how the phases evolve with doping, and in terms of the actual Cooper pairing process. To explore these issues, we used spectroscopic-imaging scanning tunneling microscopy to study the electronic structure of $CaFe_2As_2$ in the antiferromagnetic-orthorhombic 'parent' state from which the superconductivity emerges. We discovered and visualized the now widely studied electronic 'nematicity' of this phase, whose suppression is associated with the emergence of superconductivity (*Science* 327, 181, 2010). As subsequent transport experiments discovered a related anisotropic conductance which increases with dopant concentration, the interplay between the electronic structure surrounding each dopant atom, quasiparticle scattering therefrom, and the transport nematicity has become a pivotal focus of research. We find that substituting Co for Fe atoms in underdoped $Ca(Fe_{1-x}Co_x)_2As_2$ generates a dense population of identical and strongly anisotropic impurity states that are distributed randomly but aligned with the antiferromagnetic a-axis. We also demonstrate, by imaging their surrounding interference patterns, that these impurity states scatter quasiparticles and thus influence transport in a highly anisotropic manner (M.P. Allan et al., 2013). Next, we studied the momentum dependence of the energy gaps of iron-based superconductivity, now focusing on LiFeAs. If strong electron-electron interactions mediate the Cooper pairing, then momentum-space anisotropic superconducting energy gaps $\Delta_i(k)$ were predicted by multiple techniques to appear on the different electronic bands i. We introduced intraband Bogoliubov quasiparticle scattering interference (QPI) techniques for the determination of anisotropic energy gaps to test these hypotheses and discovered the anisotropy, magnitude, and relative orientations of the energy gaps on multiple bands (*Science* 336, 563 (2012)). Finally, the electron-electron interactions generating Cooper pairing are often conjectured to involve bosonic spin fluctuations generated by interband scattering of electrons. We explore the STM signatures of both the interband scattering and the electron-boson coupling self-energy in LiFeAs, and detect the signatures of the electron-boson coupling (M.P. Allan et al., in preparation).

[1]In collaboration with A.W. Rost, T.-M. Chuang, F. Massee, M.S. Golden, Y. Xie, M.H. Fisher, E.-A. Kim, K. Lee, Ni Ni, S.L. Bud'ko, P.C. Canfield, Q. Wang, D.S. Dessau, K. Kihou, C.H. Lee, A. Iyo, H. Eisaki, D.J. Scalapino, A.P. Mackenzie and J.C. Davis

12:27PM N2.00003 Spin dynamics in electron and hole-doped iron pnictide superconductors , PENGCHENG DAI, University of Tennessee — No abstract available.

1:03PM N2.00004 ARPES studies of the superconducting gap symmetry of Fe-based superconductors , PIERRE RICHARD, Institute of Physics, Chinese Academy of Sciences — The superconducting gap is the fundamental parameter that characterizes the superconducting state, and its symmetry is a direct consequence of the mechanism responsible for Cooper pairing. Here I discuss about angle-resolved photoemission spectroscopy measurements of the superconducting gap in the Fe-based high-temperature superconductors. I show that the superconducting gap is Fermi surface dependent and nodeless with small anisotropy, or more precisely, a function of momentum. I show that while this observation is inconsistent with weak coupling approaches for superconductivity in these materials, it is well supported by strong coupling models and global superconducting gaps. I also stress the importance of scattering and the lifetime of quasiparticles in evaluation the superconducting gap by angle-resolved photoemission spectroscopy and other experimental techniques.

1:39PM N2.00005 Effects of disordered substitutions and vacancies in Fe based superconductors from first principles[1] , TOM BERLIJN, University of Florida — Most Fe pnictide and selenide superconductors are created by chemical substitution which inevitably introduces disorder. The relationship between nominal chemical valence, doping, and quasiparticle spectral weight appears to be quite complex. Using a recently developed Wannier function based first principles method for disordered systems [1], we compute the configuration-averaged spectral function $\langle A(k,\omega)\rangle$ of Fe based superconductors containing disordered substitutions and vacancies. In the transition metal doped $Ba(Fe_{1-x}M_x)_2As_2$ with M=Co/Zn we find[2] a loss of coherent carrier spectral weight. For the case of disordered Fe and K vacancies in $K_{0.8}Fe_{1.6}Se_2$ we find a disorder induced effective doping to give rise to enlarged electron pockets without adding electrons to the system. For the case of Ru substitutions in $Ba(Fe_{1-x}Ru_x)_2As_2$ we find[4] a cancelation between on- and off-site disorder to give rise to a surprising protection of the Fermi surface.

Wednesday, March 20, 2013 11:15AM - 2:15PM –

Session N3 DMP: Invited Session: Physics For Everyone Ballroom III - Laura H. Greene, University of Illinois at Urbana-Champaign

11:15AM N3.00001 New ways to engage the public with quantum physics[1] , JULIEN BOBROFF[2], Laboratoire de Physique des Solides, Universite Paris Sud & CNRS, 91405 Orsay Cedex, France — We are a few french condensed matter physicists involved in developping new routes to engage the public with our research field. We have worked with designers, graphists, artists, teachers and the public to produce original tools for outreach. In this talk, we will present some of them :

- demonstration tools such as a superconducting circus or a levitating Eiffel Tower
- futuristic videos (what life would be if room temperature superconductivity was achieved?)
- graphic animations to make quantum physic simple and appealing
- websites about quantum physics or superconductivity (www.quantummadesimple.com or www.superconductivity.eu)
- folding activities for kids to understand orbitals and superconductivity

We will also discuss the engagement of condensed matter physicists in outreach activities. Many of us find it hard to get involved : "not enough time", "my field is to complex to be popularized", "not good for my career", "science museums do it better"... We will give some insight of how we could overcome this reluctance among our colleagues and get many french researchers involved in engaging the public over the past two years. All our activities and productions can be found in English at the website: www.vulgarisation.fr

[1]We acknowledge support from ICAM-I2CAM, RTRA Triangle de la Physique, Science à l'Ecole, LABEX PALM, Société Française de Physique, Université Paris Sud and CNRS.

11:51AM N3.00002 The Physics of NASCAR: Why Going Fast is Harder than You Might Think , DIANDRA LESLIE-PELECKY, West Virginia University — NASCAR is unique among major sports in that science, math and engineering are integral to winning. You can't win races without getting the physics right. That constraint provides a novel way to reach the seventy-five million NASCAR fans who desperately want to understand why their driver is (or isnt winning). Unlike outreach to those already interested in science, using popular culture to reach out requires taking advantage of unexpected events and non-traditional means. Does a loose piece of metal really justify a $100,000 fine? (NPR didn't think so...) From the science of designing a 900-horsepower, 200 mph aerodynamic bullet to the knowledge and experience required to drive that car, physics is the ultimate arbiter of speed. Moving from simple introductory physics that approximates a race car as a point particle to computational fluid dynamics, you'll learn why driving fast isnt as easy as you might think.

12:27PM N3.00003 How the "Blues" reveals the intimacy of music and physics , J. MURRAY GIBSON, Northeastern University, College of Science — Little do most people know when they hear blues piano – and you'll hear some live in this talk – that physics permeates the style, as it does all of music. Why should you care? By deconstructing blues piano the intimacy of physics, mathematics and music will be revealed in its glory.[1] The exercise says something about how the brains of the music composer and of the listener must be intimately linked to the physical principles of acoustics. And it provides a great vehicle to explain physical phenomena to non-scientists – everything from quantum mechanics to protein structure.

[1]Gibson, J. M. "The birth of the blues: how physics underlies music," Reports on Progress in Physics **72**, 076001, (2009).

1:03PM N3.00004 How Plastics Work , LOUIS BLOOMFIELD, Department of Physics, University of Virginia, Charlottesville, VA 22904 — We encounter plastics every day, but despite their widespread use, amazing range of properties, and basic scientific underpinnings, most physicists—like most people—know relatively little about plastics. In contrast to hard crystalline and amorphous solids (e.g., metals, salts, ceramics, and glasses), we take plastics for granted, select them carelessly, and examine them more closely only on a need-to-know basis. By ignoring plastics until we need them, however, we risk not knowing what we don't know and using the wrong ones. To repurpose a familiar advertisement, "there's a plastic for that." This talk will review some of the basic physics and science of plastics. It will examine the roles of temperature, order, intermolecular forces, entanglements, and linkages in plastics, and how those issues affect the properties of a given plastic. We'll stop along the way to recognize a few of the more familiar plastics, natural and synthetic, and explain some of their mechanical, chemical, and optical properties. The talk will conclude by explaining the remarkable properties of a plastic that has been largely misunderstood since its discovery 70 years ago: Silly Putty.

1:39PM N3.00005 Looking at Art in the IR and UV[1] , CHARLES FALCO, University of Arizona — Starting with the very earliest cave paintings art has been created to be viewed by the unaided eye and, until very recently, it wasn't even possible to see it at wavelengths outside the visible spectrum. However, it is now possible to view paintings, sculptures, manuscripts, and other cultural artifacts at wavelengths from the x-ray, through the ultraviolet (UV), to well into the infrared (IR). Further, thanks to recent advances in technology, this is becoming possible with hand-held instruments that can be used in locations that were previously inaccessible to anything but laboratory-scale image capture equipment. But, what can be learned from such "non-visible" images? In this talk I will briefly describe the characteristics of high resolution UV and IR imaging systems I developed for this purpose by modifying high resolution digital cameras. The sensitivity of the IR camera makes it possible to obtain images of art "in situ" with standard museum lighting, resolving features finer than 0.35 mm on a 1.0x0.67 m painting. I also have used both it and the UV camera in remote locations with battery-powered illumination sources. I will illustrate their capabilities with images of various examples of Western, Asian, and Islamic art in museums on three continents, describing how these images have revealed important new information about the working practices of artists as famous as Jan van Eyck. I also will describe what will be possible for this type of work with new capabilities that could be developed within the next few years.

Wednesday, March 20, 2013 11:15AM - 2:15PM –

Session N4 GPC: Invited Session: Climate as a Complex Dynamical System Ballroom IV - John Wettlaufer, Yale University

11:15AM N4.00001 Changes in Polar Sea Ice and How They Illustrate the Complex Picture of Global Climate Change , CLAIRE PARKINSON, NASA Goddard Space Flight Center — Sea ice spreads over vast areas of the polar oceans, typically covering 17-28 million km2 globally. It is a critical element of the Arctic and Antarctic climate systems, with two of its most important roles being the reflection of solar radiation back to space and the hindering of exchanges of heat, mass, and momentum between the ocean and the atmosphere. Prior to the development of satellite technology, it was not feasible to obtain large-scale data records of the vast expanse of global sea ice. However, with satellites, and especially with multichannel passive-microwave satellite data available since late 1978, we can now monitor both Arctic and Antarctic sea ice coverages on a daily basis, irrespective of sunlight or darkness and under cloudy as well as cloud-free conditions. This has made sea ice one of the best observed climate variables since the late 1970s. The resulting satellite record has revealed many details of the seasonal cycle of the ice cover in both polar regions, considerable inter-annual variability, and long-term trends that show a decrease in the Arctic sea ice and an increase in the Antarctic sea ice since late 1978. The decreases in the Arctic sea ice extents, which have averaged approximately 51,000 km2 per year on a yearly-average basis, were predicted and are tied closely to the warming of the Arctic over the same time period. The increases in the Antarctic sea ice extents, which have averaged approximately 17,000 km2 per year, have come with stark spatial contrasts that suggest the likely impact of changes in atmospheric and/or oceanic circulations. Sea ice decreases in the vicinity of the Antarctic Peninsula, where warming has occurred, have been more than compensated for by increases in the ice cover elsewhere around the continent, especially in the Ross Sea. The patterns are suggestive of increased cyclonic flow centered over the Amundsen Sea, although more research is needed before the changes will be fully understood.

11:51AM N4.00002 The Solar Climate Link: How Large? How Come? How important? , NIR SHAVIV, Hebrew University of Jerusalem — Solar variations appear to have a significant effect on climate. I will begin by reviewing the evidence pointing to a large solar/climate link and present measurements quantifying it. I will then discuss the atmospheric effects of cosmic rays, which offer the most consistent mechanism linking between solar variations and climate change. I will end by placing the link in context of other climate questions, such as the value of the climate sensitivity and implications to the understanding of 20th and 21st century climate change.

12:27PM N4.00003 The Atmospheric Chemistry of Climate Change , SASHA MADRONICH, National Center for Atmospheric Research — The chemical composition of the atmosphere regulates the balance between incoming solar short-wave and outgoing terrestrial long-wave radiation, directly *via* absorption and scattering and indirectly *via* modification of clouds. Photo-oxidation reactions remove many chemicals emitted by natural sources, and on geological time scales have prevented runaway growth of infrared-active gases such as methane; however, the same reactions have byproducts (esp. ozone and suspended particles) that affect air quality as well as the radiative forcing of climate. Anthropogenic emissions are now modifying the natural chemical and radiative balances of the atmosphere, but the detailed mechanisms and net effects are still not fully understood. Given the non-linear and coupled nature of the atmospheric chemical system, it is important to realize that future regulations aimed at improving air quality could also influence climate-relevant properties of the atmosphere (and *vice versa*), in ways that may or may not be intended or even beneficial. Careful analyses will be required to distinguish between win-win strategies to address both climate and air quality, and those strategies that penalize one environmental issue to the benefit of the other.

1:03PM N4.00004 Testing climate models using instrumental and geologic observations , PETER HUYBERS, Harvard University, Department of Earth and Planetary Sciences — No abstract available.

1:39PM N4.00005 Climate modeling from first principles: Feasibility and prospects , WILLIAM (BILL) COLLINS, Climate Science Department, UC Berkeley — No abstract available.

Wednesday, March 20, 2013 11:15AM - 2:03PM –

Session N5 DMP DCOMP: Focus Session: Computational Discovery and Design of New Materials: Electronic properties of 1D and 2D materials 301 - Wei Ku, Brookhaven National Laboratory

11:15AM N5.00001 The Virial Theorem in Graphene and other Dirac Materials , JAMES STOKES, Boston College, BNL, HARI DAHAL, PRB, ALEXANDER BALATSKY, LANL, NORDITA, KEVIN BEDELL, Boston College — The virial theorem is applied to graphene and other Dirac Materials for systems close to the Dirac points where the dispersion relation is linear. From this, we find the exact form for the total energy given by $E = \mathcal{B}/r_s$ where $r_s a_0$ is the mean radius of the d-dimensional sphere containing one particle, with a_0 the Bohr radius, and $\mathcal{B}$ is a constant independent of r_s. This result implies that, given a linear dispersion and a Coulombic interaction, there is no Wigner crystalization and that calculating $\mathcal{B}$ or measuring at any value of r_s determines the energy and compressibility for all r_s. In addition to the total energy we calculate the exact forms of the chemical potential, pressure and inverse compressibility in arbitrary dimension.

11:27AM N5.00002 Create Dirac Cones in Your Favorite Materials[1] , CHIA-HUI LIN, WEI KU, Brookhaven National Laboratory / Stony Brook University — We propose a theoretical recipe to create Dirac cones into anyone's favorite materials. The method allows to tailor anisotropy and quantity of cones in any effective one-band two-dimensional lattice. The validity of our theory is demonstrated with two examples on the square lattice, an "unlikely" candidate hosting Dirac cones, and show that a graphene-like low-energy electronic structure can be realized. The proposed recipe can be applied in real materials via introduction of vacancy, substitution or intercalation, and also extended to photonic crystal, molecular array, and cold atoms systems.

[1]Work supported by DOE DE-AC02-98CH10886.

11:39AM N5.00003 Stability of Weyl metals under imuurity scattering[1] , ZHOUSHEN HUANG, Department of physics, University of California, San Diego, TANMOY DAS, ALEXANDER V. BALATSKY, Theoretical Division, Los Alamos National Laboratory, DANIEL P. AROVAS, Department of physics, University of California at San Diego — We investigate the effects of bulk impurities on the electronic spectrum of Weyl semimetals, a recently identified class of Dirac-type materials. Using a T-matrix approach, we study resonant scattering due to a localized impurity in tight binding versions of the continuum models recently discussed by Burkov, Hook, and Balents, describing perturbed four-component Dirac fermions in the vicinity of a critical point. The impurity potential is described by a strength g as well as a matrix structure Λ. Unlike the case in d-wave superconductors, where a zero energy resonance can always be induced by varying the impurity scalar and/or magnetic impurity strength, we find that for certain types of impurity (Λ), the Weyl node is protected, and that a scalar impurity will induce an intragap resonance over a wide range of scattering stength. A general framework is developed to address this question, as well as to determine the dependence of resonance energy on the impurity strength.

[1]This work is supported in part by the NSF through grant DMR-1007028. Work at LANL was supported by US DoE.

11:51AM N5.00004 A semi-classical analysis of Dirac fermions in 2+1 dimensions , MOITRI MAITI, Univerisität Kaiserslautern, Germany, R. SHANKAR, The Institute of Mathematical Sciences, Chennai, India — We investigate the semiclassical dynamics of massless Dirac fermions in 2+1 dimensions in the presence of external electromagnetic fields. By generalizing the α matrices by two generators of the $SU(2)$ group in the $(2S+1)$ dimensional representation and doing a certain scaling, we formulate a $S \to \infty$ limit where the orbital and the spinor degrees become classical. We solve for the classical trajectories for a free particle on a cylinder and a particle in a constant magnetic field. We compare the semiclassical spectrum, obtained by Bohr-Sommerfeld quantization with the exact quantum spectrum for low values of S. For the free particle, the semiclassical spectrum is exact. For the particle in a constant magnetic field, the semiclassical spectrum reproduces all the qualitative features of the exact quantum spectrum at all S. The quantitative fit for $S = 1/2$ is reasonably good.

12:03PM N5.00005 An *Ab Initio Study of the* Interaction between *3d* Transition Metal Atoms and Silicon Carbide Nanotubes[1] , KAPIL ADHIKARI, ASOK RAY, University of Texas at Arlington — Interaction of *3d*-transition metal atoms with armchair silicon carbide nanotubes (SiCNTs) of chiralities (3,3), (5,5), (7,7), and (9,9) is studied in detail using hybrid density functional PBE0 and an all electron basis set 6-31G**. The results show that the interaction energy between transition metal and SiCNTs depends not only on the number of *d*-electrons but also on the curvature of the nanotubes. Interaction between SiCNTs and transition metals increases with increase in curvature of the nanotubes. To explore the curvature effect in detail, both internal and external adsorption sites were chosen for the functionalization. With the exception for the SiCNTs functionalized by Ni and Zn, all 3d-transition metal-functionalized nanotubes were found to have magnetic ground states. The quenching of magnetism is strongly dependent on the curvature of the nanotubes. Mulliken charge analysis has been performed to study the amount and direction of charge transfer between transition metals and the SiCNTs. SiCNTs doped with transition metals have significantly lower band gaps, in general, than those of bare nanotubes. Transition metal atoms Ni and Zn have the least effect on the band gaps of the SiCNTs.

[1]Work partially supported by the Welch Foundation, Houston, Texas (Grant No. Y-1525).

12:15PM N5.00006 Interaction of a single Li atom with SiGe(6,6) nanotubes[1] , PRABATH WANAGURU, ASOK K. RAY, University of Texas at Arlington — A study of the interaction between four types of SiGe(6,6) nanotubes[2] and a Li atom was performed using the cluster approximation. Full geometry and spin optimizations were performed without any symmetry constraints using the hybrid functional B3LYP, an all electron 6-311G**//3-21G* basis set and the GAUSSIAN 09 suite of software. All possible internal and external adsorption sites were considered and it was found that some tubes were deformed as a result of the adsorption process. Among the nanotubes which retained the tubular shape, most preferred site for the external adsorption was quasi on top of Ge site with the highest adsorption energy being 1.639eV. Also, the band gaps of the systems decreased from the values of pristine SiGe nanotube values, the range being 0.880 to 0.958eV. For inside adsorption, most preferred site was the hollow site. Adsorption energies ranged from 1.606 to 1.657eV and band gaps, from 0.777 to 0.807eV. We will present, In detail, adsorption energies, band gaps, density of states, and the bonding nature of Li to the nanotubes.

[1]Work partially supported by the Welch Foundation, Houston, Texas (Grant No. Y-1525).

12:27PM N5.00007 On the possibility of population inversion in strained silicon nanowires: an atomistic study , DARYOUSH SHIRI, Institute for Qauntum Computing (IQC), University of Waterloo, AMIT VERMA, Texas A&M University-Kingsville, ANANT ANANTRAM, University of Washington — Density functional theory and Ensemble Monte Carlo studies show the possibility of population inversion in strained silicon nanowires. At room temperature and electric field of 15 KV/cm, a strain induced indirect subband can hold 10 times more electron population compared to the direct subband. The most dominant mechanism which depletes the indirect subband is scattering by longitudinal optical (LO) phonons. At T=300K the inter-sub band scattering is almost symmetric with the rate of 10^{11} s^{-1}. On the other hand the processes of thermalization to the bottom of the indirect subband (via acoustic phonon emission) and the 2nd order radiative recombination are very slow (10^{-9} sec and 10 sec, respectively). At T=77K the LO-phonon absorption rate (indirect to direct subband scattering) drops to 10^{8} s^{-1}. This induced asymmetry in scattering leads to the enhanced population difference between indirect and direct subbands even at higher electric fields. The spontaneous emission time is 10^{-7}sec and a few seconds for direct and indirect bandgap nanowires, respectively. This study suggests the usability of strained silicon nanowires in nano-lasers.

12:39PM N5.00008 Vortices in One Dimension: A Soliton Analysis of Gapped Carbon Nanotubes , MARK SWEENEY, JOEL EAVES, Department of Chemistry and Biochemistry, University of Colorado, Boulder — We study the optical properties of carbon nanotubes using the bosonization technique. The action has a general sine-Gordon form and the fundamental excitations are solitons and antisolitons. The bound soliton-antisoliton of the system is an exciton. Using a mean-field analysis we find bright and dark excitonic energies that are in good agreement with experimental values. Further, the large energy differences between the exitonic spectra and the single particle spectra agrees with perturbative treatments: Bethe-Salpeter excitonic energies compared to Hatree-Fock single particle energies.

12:51PM N5.00009 Berry phase dependent quantum trajectories of electron-hole pairs in semiconductors under intense terahertz fields[1] , FAN YANG, REN-BAO LIU, Department of Physics, The Chinese University of Hong Kong, Shatin, N.T., Hong Kong, China — Quantum evolution of particles under strong fields can be approximated by the quantum trajectories that satisfy the stationary phase condition in the Dirac-Feynmann path integrals. The quantum trajectories are the key concept to understand strong-field optics phenomena, such as high-order harmonic generation (HHG), above-threshold ionization (ATI), and high-order terahertz siedeband generation (HSG) [1]. The HSG in semiconductors may have a wealth of physics due to the possible nontrivial "vacuum" states of band materials. We find that in a spin-orbit-coupled semiconductor, the cyclic quantum trajectories of an electron-hole pair under a strong terahertz field accumulates nontrivial Berry phases. We study the monolayer MoS_2 as a model system and find that the Berry phases are given by the Faraday rotation angles of the pulse emission from the material under short-pulse excitation. This result demonstrates an interesting Berry phase dependent effect in the extremely nonlinear optics of semiconductors.

1:03PM N5.00010 Transport properties of semi-Dirac , PIERRE ADROGUER, Laboratoire de physique, ENS de Lyon — Recent theoretical works show the existence of a new type of dispersion relation in both VO_2/TiO_2 nanostructures[1] and in stressed graphene [2], where the electrons confined in a plane show a non-relativistic behavior along one direction, and relativistic in the other. This semi-Dirac dispersion $E = \sqrt{(v_F p_x)^2 + (p_y^2/2m)^2}$ can be observed in graphene when the Dirac cones of different valleys touch each other because of stress. When stress is increased, a gap is opened, and the graphene turns from a semi-metal to an insulator. We propose to adress this topological phase transition through transport measurements.

1:15PM N5.00011 Heat transport and correlations in anharmonic oscillator chains, a molecular dynamics study , MAXIME GILL-COMEAU, LAURENT J. LEWIS, Département de physique, Université de Montréal — It is well known that the anharmonic oscillator chain displays anomalous heat conduction, the most striking feature of which being a thermal conductivity diverging with length as $\kappa \propto L^{\alpha}$ where $\alpha = 2/5$ or $1/3$. By comparing MD simulations results with an analysis based on the use of the Peierls-Boltzmann equation, we shed light on the mechanisms behind this striking phenomenon in 1D and pseudo-1D systems. The possibility of persistent cross-mode correlations and its consequences were also investigated.

1:27PM N5.00012 Extended Electronic States above Diskoid Nanostructures , ARTEM BASKIN, PETR KRAL, University of Illinois at Chicago, HOSSEIN SADEGHPOUR, Institute for Atomic, Molecular and Optical Physics, Harvard-Smithsonian Center for Astrophysics — We demonstrate that charged graphene nanostructures, which can be modeled as charged metallic nanodisks, can support spatially extended electronic states with binding energies of 50-200 meV. In the case of high angular momenta these states can be highly separated from the disk surfaces, in analogy to image states above carbon nanotubes observed experimentally. We present the single-electron and approximate multi-electron wavefunctions.

1:39PM N5.00013 Low-energy local density of states of the 1D Hubbard model , SEBASTIAN EGGERT, STEFAN SOEFFING, University of Kaiserslautern, IMKE SCHNEIDER, Technical University of Dresden — We examine the local density of states (DOS) at low energies numerically and analytically for the Hubbard model in one dimension. The eigenstates represent separate spin and charge excitations with a remarkably rich structure of the local DOS in space and energy. The results predict signatures of strongly correlated excitations in the tunneling probability along finite quantum wires, such as carbon nanotubes, atomic chains or semiconductor wires in scanning tunneling spectroscopy (STS) experiments. However, the detailed signatures can only be partly explained by standard Luttinger liquid theory. In particular, we find that the effective boundary exponent can be negative in finite wires, which leads to an increase of the local DOS near the edges in contrast to the established behavior in the thermodynamic limit.

1:51PM N5.00014 Energy Partitioning of Tunneling Currents into Luttinger Liquids , TORSTEN KARZIG, GIL REFAEL, California Institute of Technology, LEONID I. GLAZMAN, Yale University, FELIX VON OPPEN, Freie Universität Berlin, Dahlem Center for Complex Quantum Systems — Tunneling of electrons of definite chirality into a quantum wire creates counterpropagating excitations, carrying both charge and energy. We find that the partitioning of energy is qualitatively different from that of charge. The partition ratio of energy depends on the excess energy of the tunneling electrons (controlled by the applied bias) and on the interaction strength within the wire (characterized by the Luttinger-liquid parameter K), while the partitioning of charge is fully determined by K. Moreover, unlike for charge currents, the partitioning of energy current should manifest itself in dc experiments on wires contacted by conventional (Fermi-liquid) leads.

Wednesday, March 20, 2013 11:15AM - 2:15PM –

Session N6 DMP: Focus Session: Graphene - Electronic Properties, Gap Formation 302 - Nancy Sandler, Ohio University

11:15AM N6.00001 Interaction-induced gapped state in charge neutral bilayer graphene , JAIRO VELASCO JR., University of California Berkeley — Bilayer graphene (BLG) at the charge neutrality point (CNP) possess instability to electronic interactions, and is expected to host a ground state with spontaneously broken symmetries. Within this regime, I will discuss our transport spectroscopy measurements using high quality suspended BLG samples. We observe an insulating state at CNP with a gap ~ 2 meV, which can be closed by finite doping or a perpendicular electric field of either polarity. For magnetic field B $>$ 1T, the gap increases linearly with B. Our work contributes towards understanding the rich interaction-driven physics in BLG. Finally, latest progress on transport spectroscopy measurements of Landau level gaps in these high quality samples will also be discussed.

11:51AM N6.00002 Electron-electron interactions in non-equilibrium bilayer graphene[1] , WEI-ZHE LIU, ICQD, Hefei National Laboratory for Physical Sciences at the Microscale, University of Science and Technology of China, Hefei 230026, Anhui, China, ALLAN MACDONALD, Department of Physics, The University of Texas at Austin, Austin TX 78712, DIMITRIE CULCER, ICQD, Hefei National Laboratory for Physical Sciences at the Microscale, University of Science and Technology of China, Hefei 230026, Anhui, China — The charge conductivity of doped bilayer graphene can be understood as a net steady-state pseudospin polarization. Due to the chirality inherent in the Hamiltonian, electron-electron interactions renormalize this polarization even at zero temperature, when the phase space for electron-electron scattering vanishes. Nevertheless, at usual transport densities the electron-electron interaction contribution displays only a weak density dependence and has a negligible effect on the conductivity. This smallness is due to the large value of the interlayer tunneling parameter. Interestingly, the effect of interactions in transport vanishes as the carrier number density tends to zero, in contrast to single-layer graphene and topological insulators. The vanishing is attributed to the fact that the pseudospin winds twice around the Fermi surface. Our study relies on the quantum Liouville equation in the first Born approximation with respect to the scattering potential, with electron-electron interactions taken into account self-consistently in the Hartree-Fock approximation, and screening in the random phase approximation.

[1]This work is supported by the National Natural Science Foundation of China under grant number 91021019.

12:03PM N6.00003 Ab initio quasiparticle bandstructure of ABA and ABC-stacked graphene trilayers , MARCOS MENEZES, RODRIGO CAPAZ, Instituto de Física, Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil, STEVEN LOUIE, Department of Physics, University of California at Berkeley, Berkeley, California, USA — We obtain the quasiparticle band structure of ABA and ABC-stacked graphene trilayers through ab initio density functional theory (DFT) and many-body quasiparticle calculations within the GW approximation. To interpret our results, we fit the DFT and GW π bands to a low energy tight-binding model, which is found to reproduce very well the observed features near the K point. The values of the extracted hopping parameters are reported and compared with available theoretical and experimental data. For both stackings, the quasiparticle corrections lead to a renormalization of the Fermi velocity, an effect also observed in previous calculations on monolayer graphene. They also increase the separation between the higher energy bands, which is proportional to the nearest neighbor interlayer hopping parameter γ_1. Both features are brought to closer agreement with experiment through the quasiparticle corrections. Finally, other effects, such as trigonal warping, electron-hole assymetry and energy gaps are discussed in terms of the associated parameters. This work was supported by the Brazilian funding agencies: CAPES, CNPq, FAPERJ and INCT-Nanomateriais de Carbono. It was also supported by NSF grant No. DMR10-1006184 and U.S. DOE under Contract No. DE-AC02-05CH11231.

12:15PM N6.00004 Magneto-Coulomb Drag in Double Layer Graphene[1] , WANG-KONG TSE, A. H. MACDONALD, University of Texas at Austin — We report on our theoretical investigations on the Coulomb drag in double-layer graphene in strong magnetic fields. Using diagrammatic perturbation theory, we obtain explicit analytical expressions for the nonlinear susceptibility and the drag conductivity. At low temperatures T, the drag conductivity behaves as $\exp(-\Delta/T)/T$, where Δ is the inter-Landau level transition energy nearest to the Fermi level. For full filling at the zeroth Landau level, we find a non-vanishing drag that arises from the intrinsic contribution of filled Landau levels below the Dirac point.

12:27PM N6.00005 Structural, electronic, and mechanical properties of superlattices of interlayer-bonded domains in twisted bilayer graphene , ANDRE MUNIZ, Federal University of Rio Grande do Sul, DIMITRIOS MAROUDAS, University of Massachusetts Amherst — We present a comprehensive computational analysis of the atomic and electronic structure and mechanical properties of a novel class of carbon nanostructures, formed due to interlayer covalent sp^3 C-C bonding in twisted bilayer graphene as a result of controlled chemical functionalization (hydrogenation or fluorination). Depending on the twist angle and local stacking of layers, these nanostructures are superlattices of diamond-like nanocrystals or caged fullerene-like configurations embedded within the bilayer. According to density functional theory calculations, the electronic behavior of these sp^2/sp^3 hybrid configurations ranges from semi-metallic, characterized by linear dispersion around the K point in the first Brillouin zone, to semi-conducting/insulating with electronic band gaps ranging from a few meV to $\sim$4 eV; this electronic character depends on the symmetry and periodicity of the superlattices and on the type of chemisorbed species. We have also studied the mechanical response of these superlattices to tensile and shear strain based on molecular dynamics simulations; their interlayer shear modulus increases strongly and their Young's modulus and tensile strength and strain decrease moderately compared to those of pristine bilayer graphene.

12:39PM N6.00006 Ising Phase in AA Stacked Bilayer Graphene[1] , HERBERT FERTIG, Indiana University, LUIS BREY, Instituto de Ciencia de Materiales de Madrid,(CSIC) — AA stacked bilayer graphene bears a close resemblance to biased, double layer graphene (in which a strong barrier separates the two layers), with layer bonding and anti-bonding states of the AA system playing the roles of layer states in the double layer system. The latter has a U(1) symmetry which can break, to form a condensed exciton groundstate. The AA system however has only Ising symmetry. In this presentation we analyze the possibility that electron-electron interactions break this to open a gap in the energy spectrum. We find that, in the mean field approximation, the ground state has a charge density wave character, with the charge modulation of each layer out of phase. We calculate the gap and the mean field critical temperature as a function of the strength of the Coulomb interaction, taking screening into account self-consistently with the calculation of the gap. We also analyze the transition between ordered and thermally disordered phases based on a continuum model, and find that the transition is controlled by an effective U(1) stiffness. We argue that in the limit of zero layer separation, for which the full U(1) symmetry of the Hamiltonian is restored, the Ising transition continuously goes into a Kosterlitz-Thouless transition.

12:51PM N6.00007 Electronic Properties of Curved Graphene-Ring Structures[1] , DAIARA FARIA, ANDREA LATGE, Universidade Federal Fluminense, SERGIO ULLOA, NANCY SANDLER, Ohio University — We have undertaken a theoretical investigation of electronic properties of a curved graphene ring in the Dirac approximation making use of elasticity theory. This study is motivated by experimental reports that indicate the existence of gauge-fields in graphene when it is under tension and also by the recent possibility of controlling deformations in its surface in a variety of shapes on different substrates [1]. We discuss how an Aharonov-Bohm field can be used to design new responses obtained by adding real magnetic fluxes and pseudomagnetic fields. We show that the persistent current tends to be inhomogeneous in the same way that the Fermi velocity has a spatial-dependent character[2]. We also discuss the role of strain in the position of the Dirac points that have been the source of recent controversies. [1] T. Georgiou et al., Appl. Phys. Lett. 99, 093103 (2011). 1:03PM N6.00008 Morphology and electronic transport study of suspended graphene , WENZHONG BAO, University of Maryland at College Park — This presentation will first describe our recent electrical transport studies of suspended bilayer and trilayer graphene devices at low temperature: Bilayer graphene at the charge neutrality point is unstable to electronic interactions, and expected to host a ground state with spontaneously broken symmetries, whereas in trilayer graphene stacking order provides another important degree of freedom for tuning its electronic properties. For instance, at the Dirac point, Bernal-stacked TLG remains metallic but r-TLG becomes insulating with an intrinsic interaction-driven gap around 6 meV. Our results underscore the rich interaction-induced phenomena in both bilayer and trilayer graphene with different stacking orders, and its potential towards electronic applications. Next we will discuss the manipulation of the morphology of suspended graphene via electrostatic and thermal control: We observe significant deflections of single-, bi-, and trilayer graphene sheets in response to electrostatic force. At low temperature, wide graphene sheets ripple and butterfly features form at its two free edges. These observations have important applications for understanding electrical, mechanical, and thermal properties as well as strain engineering in suspended graphene devices.

1:39PM N6.00009 Field-induced Energy Gaps in Bilayer Graphene under Shear[1] , SEON-MYEONG CHOI, YOUNG-WOO SON, Korea Institute for Advanced Study, Seoul, Korea — Using the first-principles calculations method, we study the effects of shear on field-induced insulating states of bilayer graphene (BLG). It is shown that the low energy bands near the charge neutral point of BLG change significantly upon application of shear. We also find that the energy gap of BLG under transverse electric field sensitively depend on both direction and amount of shear. Generally, the field-induced energy gap decreases as the sliding increases under shear. For BLG with the specific direction of shear, the shear can quench the energy gap to zero completely even in the presence of electric field thus realizing insulator-to-metal transition just by sliding. We discuss origins of these interesting phenomena and suggest some experimental methods to detect the transition.

1:51PM N6.00010 Kekule-induced band-gap opening in graphene in contact with ZrO2 , JUNG SUK GOH, HYOUNG JOON CHOI, Department of physics and IPAP, Yonsei University, Seoul 120-749, Korea — We have studied pressure-dependent atomic and electronic structure of graphene in contact with (111) surface of zirconium dioxide (ZrO2) using first-principles calculations. The atomic structures are optimized by relaxation, and we found that the lowest-energy configuration shows a band gap at the Dirac point at ambient pressure and the band gap increases as pressure increases. Our analysis shows that the band-gap opening is due to overlap of wavefunctions, change in potential energy, and in-plane distortion of graphene lattice. This in-plane distortion of graphene is found to be the Kekule distortion, which generates intervalley coupling. As pressure increases, the Kekule distortion in graphene increases and the band gap at the Dirac point is proportional to the size of the distortion. This work was supported by the NRF of Korea (Grant No. 2011-0018306) and KISTI Supercomputing Center (Project No. KSC-2012-C2-14).

2:03PM N6.00011 Quantum phase transitions to Kondo states in bilayer graphene[1] , DIEGO MASTROGIUSEPPE, Ohio University and Freie Universitat, ARTURO WONG, KEVIN INGERSENT, University of Florida, NANCY SANDLER, SERGIO ULLOA, Ohio University and Freie Universitat — We study a magnetic impurity intercalated in Bernal-stacked bilayer graphene described by a multiband Anderson Hamiltonian. Through a properly generalized Schrieffer-Wolff transformation, it reduces to a single-channel Kondo model with a strongly energy-dependent exchange coupling. The form of this effective Kondo Hamiltonian suggests the possibility of driving the system through quantum phase transitions via tuning of the chemical potential through doping or electrical means. The microscopic coupling of the impurity to the graphene layers determines symmetries and details of the various phases. We use the numerical renormalization group to accurately access the many-body physics of this system. Our calculations reveal zero-temperature transitions under variation of the band filling and/or the energy of the impurity level between a local-moment phase and a pair of singlet strong-coupling phases. The latter have conventional Kondo, pseudogap Kondo, and local-singlet regimes that can be distinguished through their thermodynamic and spectral properties, as well as their different rates of variation of the Kondo temperature with the chemical potential.

Session N7 DMP: Focus Session: Graphene Devices VIII 303 - Frank Koppens, ICFO Barcelona

11:15AM N7.00001 Mechanical resonators based on nanotubes and graphene , ADRIAN BACHTOLD, ICFO, Barcelona, Spain — Carbon nanotubes and graphene offer unique scientific and technological opportunities as nanoelectromechanical systems (NEMS). Namely, they have allowed the fabrication of mechanical resonators that can be operable at ultra-high frequencies and that can be employed as ultra-sensitive sensors of mass and charge. In addition, nanotubes and graphene have exceptional electron transport properties, including ballistic conduction over long distances. Coupling the mechanical motion to electron transport in these remarkable materials is thus highly appealing. Here, I will review some of our recent results on nanotube and graphene NEMSs, including the control of the mechanical oscillation using Coulomb blockade and mass sensing at the proton mass level.

11:51AM N7.00002 Graphene on silicon nitride resonators for optomechanics , ROBERTO DE ALBA, Department of Physics, Cornell University, VIVEK ADIGA, School of Applied & Engineering Physics, Cornell University, ISAAC STORCH, Department of Physics, Cornell University, PATRICK YU, Department of Engineering, University of North Texas, ROB ILIC, Cornell Nanoscale Science and Technology Facility, ROBERT BARTON, Department of Physics, Cornell University, SUNWOO LEE, JAMES HONE, Department of Mechanical Engineering, Columbia University, PAUL MCEUEN, Department of Physics, Cornell University, HAROLD CRAIGHEAD, School of Applied & Engineering Physics, Cornell University, JEEVAK PARPIA, Department of Physics, Cornell University — Recently, much work on nanoelectromechanical resonators has focused on high Q systems and on coherent back action used to suppress or enhance device motion. Here we attempt to merge these concepts by studying graphene on silicon nitride bilayer membranes. The high Q's of these hetero-structures, along with the conductivity of graphene, result in both electrostatic and optical tunability of mechanical resonance. By coupling these devices with a movable, highly reflective mirror to form a Fabry-Perot cavity, we are able to modulate resonator frequency and damping through cavity detuning. We thus present evidence of photothermal back action in these devices due to energy absorption from an impinging laser beam. We utilize both optical and electrical read-out schemes to detect device motion, enabling us to compare electrical and optical nonlinearities as a function of cavity detuning and capacitive drive.

12:03PM N7.00003 Self-sustained graphene mechanical oscillators , CHANGYAO CHEN, SUNWOO LEE, VIKRAM DESHPANDE, PHILIP KIM, JAMES HONE, Columbia University — Graphene poses excellent electrical and mechanical properties, therefore it is the most promising candidate for NanoElectroMechanical Systems. Recent developments of its CVD synthesis and fabrications makes the large scale integration for Radio Frequency (RF) applications possible. In this talk, I will present the structure and characteristics of self-sustained graphene mechanical oscillators, discuss the frequency tuning, and their phase noise performance, as well as low temperature behaviors. The demonstrated voltage controlled oscillators made from graphene pave the pathway for next generation on-chip integration of RF NEMS front-end.

12:15PM N7.00004 Adiabatic Electron Pumping through Graphene-based Nanoelectromechanical Resonators , CAIO LEWENKOPF, Universidade Federal Fluminense, ALEXANDER CROY, Chalmers University of Technology — We theoretically investigate the adiabatic electronic transport through graphene-based nanoelectromechanical resonators. The device is modeled by an effective long-wavelength Hamiltonian (given by the Dirac equation) for the electrons and using the continuum elastic theory for the mechanical motion. One obtains the equations of motion describing the system dynamics employing a non-equilibrium Green's function theory. Due to the mutual coupling between the electronic and mechanical degrees of freedom, both sets of equations have to be solved self-consistently. We present analytical and numerical results of the pumped charge and the mechanical response for a typical resonator setup. We also discuss the role of non-adiabatic corrections and the resulting damping of the mechanical motion.

12:27PM N7.00005 Fabrication and Detection of Graphene Nano-Mechanical Oscillators , SHONALI DHINGRA, JEN-FENG HSU, BRIAN D'URSO, Department of Physics and Astronomy, University of Pittsburgh — Graphene's exceptionally high crystal and electronic quality, combined with being only one-atom thick, make it quite a sought-after material for nano-mechanics, sensing and electronics. We fabricate and characterize Nano-Mechanical Oscillators (NMO) from large-domain single-layer graphene grown with Chemical Vapor Deposition (CVD) on $\sim$2mm thick copper discs. The graphene is transferred from copper using Poly (methyl methacrylate) (PMMA), onto indigenous substrates customized for enhanced graphene adhesion and assistance in its optical detection. It is patterned into devices of different geometrical shapes, such as doubly clamped beams, circular drums and rectangular drums, using deep-UV lithography of PMMA, either before or after transfer. The phase and frequency response of the resonant motion of the NMO is monitored, which is electrically actuated and optically detected using interferometric techniques. These oscillators would be used as building blocks for hybrid quantum systems which couple classical oscillators with a quantum spin system.

12:39PM N7.00006 Transfer-Free, Wafer-Scale Manufacturing of Graphene-Based Electromechanical Resonant Devices , MICHAEL CULLINAN, JASON GORMAN, National Institute of Standards and Technology — Nanoelectromechanical (NEMS) resonators offer the potential to extend the limits of force and mass detection due to their small size, high natural frequencies and high Q-factors. Graphene-based NEMS resonators are particularly promising due to their high elastic modulus and atomic thickness. However, widespread use of graphene in such systems is limited by the way in which graphene-based devices are typically fabricated. Most graphene-based NEMS devices are fabricated in a "one-off" manner using slow, limited scale methods such as mechanical exfoliation, electron beam lithography, or transfer from copper foils which can't be incorporated into standard micro/nanofabrication lines. This talk will present a method that can be used to manufacture graphene-based NEMS devices at the wafer scale using conventional microfabrication techniques. In this method graphene is grown directly on thin film copper using chemical vapor deposition. The copper film is then patterned and etched to produce graphene-based NEMS resonators. This talk will also address some of the challenges in fabricating a large number of graphene devices at the wafer scale including achieving high uniformity across the wafer, increasing device-to-device repeatability, and producing high device yields.

12:51PM N7.00007 Manipulating Graphene , ALEXANDER RUYACK, Materials Science and Engineering, Cornell University, MELINA BLEES, SAMANTHA ROBERTS, CHRIS MARTIN, ARTHUR BARNARD, Laboratory of Atomic and Solid State Physics, Cornell University, PAUL L. MCEUEN, Laboratory of Atomic and Solid State Physics, Kavli Institute at Cornell for Nanoscale Science, Cornell University — Graphene is both strong and flexible, making it a promising material for nanoscale hinges and other three-dimensional structures. Using sacrificial layers and surfactants, we are able to demonstrate control over the adhesion of monolayer graphene to a substrate. By patterning gold on the surface of the graphene, we created arrays of rigid pads bridged by graphene strips that can be decoupled from the surface in an aqueous environment. The pads allow us to manipulate the graphene both on and off the surface using lasers or micromanipulators. Our methods yield fundamental material data on graphene such as the macroscopic bending stiffness, and demonstrate the feasibility of a graphene hinge. We are currently exploring the use of magnetic control as a method for applying forces to stretch and fold graphene. We have already created micron-sized permanent magnets made of iron and successfully released them from the substrate, and are now integrating them into graphene devices.

1:03PM N7.00008 Graphene Membrane Mechanics , QIN ZHOU, A. ZETTL, Department of Physics, University of California at Berkeley; Materials Sciences Division, Lawrence Berkeley National Laboratory — Graphene has extremely low mass density and high mechanical strength, useful qualities for mechanically vibrating systems. Here we report on construction and testing of graphene-based vibrating drumheads. We explore frequency response and damping characteristics, and energy transduction.

1:15PM N7.00009 Measuring graphene's bending stiffness , MELINA BLEES, ARTHUR BARNARD, SAMANTHA ROBERTS, JOSHUA W. KEVEK, Laboratory of Atomic and Solid State Physics, Cornell University, ALEXANDER RUYACK, Cornell University, JENNA WARDINI, Oregon State University, PEIJIE ONG, Cornell University, ALIAKSANDR ZARETSKI, Florida International University, SIPING WANG, Cornell University, PAUL L. MCEUEN, Laboratory of Atomic and Solid State Physics, Kavli Institute at Cornell for Nanoscale Science, Cornell University — Graphene's unusual combination of in-plane strength and out-of-plane flexibility makes it promising for mechanical applications. A key value is the bending stiffness, which microscopic theories and measurements of phonon modes in graphite put at κ_0 =1.2 eV.[1] However, theories of the effects of thermal fluctuations in 2D membranes predict that the bending stiffness at longer length scales could be orders of magnitude higher.[2,3] This macroscopic value has not been measured. Here we present the first direct measurement of monolayer graphene's bending stiffness, made by mechanically lifting graphene off a surface in a liquid and observing both motion induced by thermal fluctuations and the deflection caused by gravity's effect on added weights. These experiments reveal a value κ_{eff} =12 keV at room temperature — four orders of magnitude higher than κ_0. These results closely match theoretical predictions of the effects of thermally-induced fluctuations which effectively thicken the membrane, dramatically increasing its bending stiffness at macroscopic length scales. [1] A. Fasolino et al., Nat. Mater. (2007) [2] D. R. Nelson and L. Peliti, J Physique (1987) [3] F. L. Braghin and N. Hasselmann, Phys Rev B (2010)

1:27PM N7.00010 Nonlinear Mechanics of Polycrystalline Two-Dimensional Materials such as Graphene , RYAN COOPER, ADAM HURST, ALEXANDRA HAMMERBERG, GWAN-HYOUNG LEE, CHRISTOPHER MARIANETTI, Columbia University, XIAODING WEI, Northwestern University, CHANGGU LEE, Sungkyunkwan University, BRYAN CRAWFORD, Nanomechanics, Inc. , JAMES HONE, JEFFREY KYSAR, Columbia University, COLUMBIA UNIVERSITY TEAM — Two-dimensional films such as graphene can potentially exist as pristine crystals. These crystals present a unique opportunity to design unique experiments that uncover intrinsic material properties. Recent experimental studies have shown graphene is the strongest material ever measured. An Agilent G200 nanoindenter and Park Systems atomic force microscope are used in this study to make measurements of the mechanical response of graphene and other two-dimensional materials. Chemical vapor deposition is employed to manufacture graphene. The mechanical properties of the chemical vapor deposited graphene is compared to that of pristine graphene. Experiments investigate the elastic response up to the point of fracture. These suspended sheets are probed using atomic force microscopy and nanoindentation. The experimental work is modeled using first-principles density functional theory and finite element analysis. Previous work has shown that density functional theory and finite element analysis accurately predicts the breaking force of graphene and molybdenum disulfide. This work also explores the probability of fracture using a generalized form of the Weibull modulus in finite element analysis.

1:39PM N7.00011 Electron transport measurement in locally strained graphene , HIKARI TOMORI, AKINOBU KANDA, University of Tsukuba and TIMS, YOUITI OOTUKA, University of Tsukuba, HIROMASA KARUBE, AKINOBU KANDA, University of Tsukuba and TIMS, DIVISION OF PHYSICS, FACULTY OF PURE AND APPLIED SCIENCES, UNIVERSITY OF TSUKUBA TEAM, SUKUBA RESEARCH CENTER FOR INTERDISCIPLINARY MATERIALS SCIENCE (TIMS) TEAM — Strain engineering is a promising method for controlling electron transport in graphene; Spatial variation of gauge fields produced by non-uniform strain in graphene causes electron scattering, leading to modulation of the electronic state such as band gap formation. We have succeeded in introducing local strain to graphene, by inserting designed dielectric nanostructures between the graphene sheet and its substrate. [1] The transport measurement of strained graphene has revealed that improvement of the mean free path is crucial for clear demonstration of effect of lattice strain on electron transport.

1:51PM N7.00012 Lubricating graphene with nanometer-thick perfluoropolyethers[1] , LEI LI, ANDREW KOZBIAL, STEVEN IASELLA, ALEXANDER TAYLOR, Department of Chemical and Petroleum Engineering, University of Pittsburgh, ZHITING LI, HAITAO LIU, Department of Chemistry, University of Pittsburgh — Due to its excellent optical, electrical and mechanical properties, graphene has found many important applications. Since graphene is atomic thick, the wear resistance is critical to the reliability of graphene-containing devices. In this study, both monolayer and multilayer graphene were coated with nanometer-thick perfluoropolyethers (PFPEs) and the effect of the nanolubricants on the wear and friction was investigated. The coefficient of friction (COF) was measured with a commercial nanotribometer and the wear was characterized with optically microscopy, AFM and Raman microscopy. Coated with PFPEs, monolayer graphene on silicon showed significantly decreased COF. However, the wear resistance was only slightly improved. For multilayer graphene on nickel substrate coated with PFPEs, COF also decreased significantly. Meanwhile, the wear resistance was improved substantially. The results were discussed based on the graphene-substrate adhesion and the thickenss of the graphene. The learning here potentially will lead to the methodology to improve the reliability of graphene-containing devices.

[1]We thank TTRF for financial support.

2:03PM N7.00013 Temperature and size dependent friction of gold nanoislands on graphene[1] , BEN D. DAWSON, MICHAEL S. LODGE, ZACHARY WILLIAMS, MASA ISHIGAMI, Department of Physics and Nanoscience Technology Center, University of Central Florida, Orlando, FL 32816 — Nanoscale motors and machines require the ability to tune frictional properties at the nanoscale. Yet a fundamental understanding of frictional processes of nanoislands still remains unknown. We have performed a quartz crystal microbalance study to investigate the role of temperature and island size on frictional energy dissipation for gold nanoislands on graphene. Significant frictional dissipation is observed even at room temperature, consistent with activated friction on the graphene surface. We will discuss these results and compare them to previously predicted models for thermally activated and size dependent friction.

Wednesday, March 20, 2013 11:15AM - 2:15PM –

Session N8 DMP: Transport and Optical Phenomena in Carbon Nanotubes 307 - Dan Prober, Yale University

11:15AM N8.00001 Terahertz Detection as a Probe of Luttinger-Liquid Behavior in an Individual Single-Walled Carbon Nanotube , JOEL D. CHUDOW, CHRIS B. MCKITTERICK, DANIEL E. PROBER, Depts. of Applied Physics and Physics, Yale University, DANIEL F. SANTAVICCA, Dept. of Physics, University of North Florida, PHILIP KIM, Dept. of Physics, Columbia University — Carbon nanotubes (CNTs) serve as an experimental system for verification of physical models of one-dimensional (1-D) conduction, in particular the Luttinger-liquid theory. We describe measurements of terahertz (THz) absorption in individual single-walled carbon nanotubes and distinguish between two response mechanisms: bolometric detection due to heating a CNT with a temperature-dependent resistance and the response due to non-thermal electrical contact nonlinearities. The effect of the contact nonlinearity is not significantly decreased at THz frequencies, allowing for analysis of the parallel contact capacitance to an individual CNT.[1] We study high-frequency charge excitations in a CNT as a probe of the strength of the electron-electron interactions due to the lack of screening in this 1-D system. This is achieved by exciting terahertz standing wave resonances along the length of a CNT, observed using the nonlinear detection mechanism. We exploit this experimental technique to test predictions of the Luttinger-liquid model. \\[4pt] [1] J.D. Chudow, D.F. Santavicca, C.B. McKitterick, D.E. Prober and P. Kim, *Appl. Phys. Lett.* **100**, 163503 (2012).

11:27AM N8.00002 Determination of absorption cross-section in suspended single-walled carbon nanotubes , XIAOPING HONG, KAIHUI LIU, SANGKOOK CHOI, STEVEN LOUIE, FENG WANG, University of California, Berkeley, FENG WANG GROUP TEAM — Quantitative determination of optical absorption cross-section at single tube level was performed for over 50 suspended single-walled carbon nanotubes (SWCNTs). The structures of the nanotubes are independently identified by electron diffraction, which allows a chirality-dependent study of the nanotube absorption cross-section. We will discuss the absorption strength as well as the linewidth of the optical resonances in both semiconducting and metallic nanotubes of different diameters.

11:39AM N8.00003 Triplet-triplet exciton interactions and delayed fluorescence in single-wall carbon nanotubes , TOBIAS HERTEL, FLORIAN SPATH, Julius-Maximilans University of Wurzburg, DOMINIK STICH, Suddeutsches Kunststoffzentrum Wurzburg, HANNES KRAUS, ANDREAS SPERLICH, VLADIMIR DYAKONOV, Julius-Maximilans University of Wurzburg — We present pump-probe-, time-correlated single photon counting and spin-sensitive photoluminescence studies of semiconducting single-wall carbon nanotubes (SWNTs) which unambiguously identify triplet-triplet annihilation as the mechanism underlying a long-lived delayed fluorescence (DF) signal. DF decays with a $t^{-0.9}$ power-law, characteristic of diffusion-limited annihilation reactions in 1-dimensional systems. The experiments allow to determine triplet diffusion constants in SWNTs to be on the order of $1\,\mathrm{cm}^2\mathrm{s}^{-1}$ and the triplet lifetime which is found to be $60 \pm 30\,\mu\mathrm{s}$. The experiments indicate that the rate of diffusion-limited photo-reactions, here exemplified by triplet-triplet annihilation, can be reduced by one-dimensional confinement. A comparison of optical transients in aqueous and organic solvent environments also indicates how polaron pair dynamics can be influenced by the environment.

11:51AM N8.00004 Nonequilibrium Tunneling Spectroscopy of Carbon Nanotubes[1] , NICHOLAS BRONN, NADYA MASON, University of Illinois at Urbana-Champaign, Department of Physics and Materials Research Laboratory — We have used nonequilibrium tunneling spectroscopy to elucidate the nature of electron-electron interactions in carbon nanotubes. Due to their reduced dimensionality, carbon nanotubes are thought to be described by Luttinger liquid theory, where electron-electron interactions play a considerable role. Superconducting tunnel probes are used to measure the electron energy distribution functions, whose shape can be related to electronic energy relaxation and scattering. We measure the dependence of the electron distribution function on nonequilibrium bias, position along the nanotube, and temperature.

12:03PM N8.00005 Ultrafast Spectral Diffusion of the First Subband Exciton in Single-Wall Carbon Nanotubes , DANIEL SCHILLING, TOBIAS HERTEL, Julius-Maximilans University of Wurzburg — The width of optical transitions in semiconductors is determined by homogeneous and inhomogeneous contributions. Here, we report on the determination of homogeneous linewidths for the first exciton subband transition and the dynamics of spectral diffusion in single-wall carbon nanotubes (SWNTs) using one- and two-dimensional time resolved spectral hole burning spectroscopy. Our investigation of highly purified semiconducting (6,5)-SWNTs suggests that room temperature homogeneous linewidths are on the order of 4 meV and are rapidly broadened by an ultrafast sub-ps spectral diffusion process. These findings are supported by our off-resonant excitation experiments where we observe sub-ps population transfer reflecting the thermal distribution of energy levels around the first subband exciton transition. The results of temperature-dependent spectral hole burning experiments between 17 K and 293 K suggest that homogeneous linewidths are due to exciton interaction with low energy optical phonons, most likely of the radial breathing mode type. In contrast, we find that inhomogeneous broadening is determined by an electronic degree of freedom such as ultrafast intra-tube exciton diffusion which is characteristic and unique for excitons in these one-dimensional semiconductors.

12:15PM N8.00006 Free Carrier Dynamics in Photoexcited Semiconducting Carbon Nanotube / C_{60} Planar Heterojunctions , DOMINICK BINDL, MENG-YIN WU, University of Wisconsin - Madison, ANDREW FERGUSON, NIKOS KOPIDAKIS, JEFFREY BLACKBURN, National Renewable Energy Laboratory, MICHAEL ARNOLD, University of Wisconsin - Madison — Semiconducting single walled carbon nanotubes (s-SWCNTs) have remarkable photophysical properties and are appealing for use as principal absorbers in photovoltaics. We have previously demonstrated the collection of photocurrent from thin s-SWCNT films with efficiencies approaching 100% at C_{60} interfaces. Exploiting this interface in high efficiency photovoltaics requires collecting free carriers from optically dense s-SWCNT/C_{60} films with negligible recombination losses, and therefore, an understanding of free carrier recombination kinetics and mechanisms. Time resolved microwave conductivity (TRMC) is a technique which monitors free carrier generation and decay transients in response to a spectrally tunable pump. Here, we report TRMC studies of free carrier dynamics in s-SWCNT thin films and in heterojunctions with C_{60}. We have found that free carrier generation yields increase by nearly an order of magnitude and lifetimes increase up to 850ns following introduction of a C_{60} interface, with free carrier lifetimes and generation yields strongly dependent on excited s-SWCNT diameter. We discuss yields, kinetics, and provide insight into relevant charge transfer and recombination mechanisms.

12:27PM N8.00007 p-n junction photodetectors based on macroscopic single-walled carbon nanotube films , XIAOWEI HE, Applied physics, Rice University, SÉBASTIEN NANOT, Physics Department, Rice University, ROBERT H. HAUGE, Chemistry Department, Rice University, JUNICHIRO KONO, Physics Department, Rice University — Single-Wall carbon nanotubes (SWCNTs) are promising in use of solar technology and photodetection. There have been many reports about photovoltaic effect in nanoelectronic devices based on individual SWCNTs, but they are limited by miniscule absorption. There has been a growing trend for merging SWNTs into mico- and macroscopic devices to provide more practical applications. Here we report p-n junction photodetectors based on macroscopic SWCNTs film. Factors affecting the PV amplitude and response time have been studied, including substrates, doping level. The maximal responsivity $\sim$ 1 V/W was observed with samples on Teflon tapes, while a fast response time $\sim$ 80 μs was observed with samples on AlN substrates. Hence an optimal combination of photoresponse time and amplitude can be found by choosing proper substrates. We found that the PV amplitude increases nonlinearly with increasing n-doping concentration, indicating the existence of an optimal doping concentration. Finally, we checked photoresponse in a wide wavelength range (360 to 900 nm), and PV was observed throughout, indicating that the device could potential be used as a broadband photodetector.

12:39PM N8.00008 Energies of higher optical transitions in semiconductor carbon nanotubes , SERGUEI GOUPALOV, Jackson State University — We show that short-range electron interactions in semiconductor carbon nanotubes promote inter-subband coupling. This coupling is revealed in a significant alteration of energies of E_{33} and E_{44} optical transitions with respect to the predictions of the non-interacting model. The influence of the short-range electron interactions is traced analytically and numerically, by switching it off entirely or partly while calculating optical absorption spectra.

12:51PM N8.00009 Effect of Disorder on AC Response of Metallic Carbon Nanotubes , DAISUKE HIRAI, The University of Tokyo, TAKAHIRO YAMAMOTO, Tokyo University of Science, SATOSHI WATANABE, The University of Tokyo — Metallic carbon nanotubes (M-CNTs) have long coherent lengths. In fact, the Anderson localization has been observed in M-CNTs with defects at room temperature [1]. In considering the AC response, not only the understanding of DC conductance behavior but also that of phase-difference between electric current and bias voltage are important. At present, however, the influence of disorder on the AC response remains unclear. In this study, we calculated the AC response of M-CNTs with disorder based on the nonequilibrium Green's function method combined with nearest-neighbor π-orbital tight-binding approximation and wide-band-limit approximation. In our simulation, disorder potential is described as $V = \Sigma_i V_i$, $|V_i| \leq W$, where V_i and W are localized potential at ith carbon atom and strength of disorder, respectively. We found that the DC conductance decreases with the CNT length, while the behaviors of phase-difference are drastically different by the disorder strength: for a small disorder the phase-difference always behaves inductive, while for a large disorder the phase-difference transits from inductive response to capacitive one with increase of the CNT length. Moreover, we clarified that inductive-capacitive transition universally occurs at the same value of DC conductance. [1] C. Gomez-Navarro et al., Nature 4, 534 (2005).

1:03PM N8.00010 An explicit formula for optical oscillator strength of excitons in semiconducting single-walled carbon nanotubes: family behavior , SANGKOOK CHOI, UC Berkeley and Lawrence Berkeley National Lab, JACK DESLIPPE, Lawrence Berkeley National Lab, RODRIGO B. CAPAZ, Universidade Federal do Rio de Janeiro, Brazil, STEVEN G. LOUIE, UC Berkeley and Lawrence Berkeley National Lab — The sensitive structural dependence of the optical properties of single-walled carbon nanotubes (SWCNTs), which are dominated by excitons and tunable by changing diameter and chirality, makes them excellent candidates for optical devices. Because of strong many-electron interaction effects, the detailed dependence of the optical oscillator strength of excitons on nanotube diameter d, chiral angle θ, and electronic subband index P (the so called family behavior) however has been unclear. Based on results from an extended Hubbard Hamiltonian with parameters derived from *ab initio* GW-BSE calculations, we have obtained an explicit formula for the family behavior of the oscillator strengths of excitons in semiconducting SWCNTs, incorporating environmental screening. The formula explains well recent measurements, and is expected to be useful in the understanding and design of possible SWCNT optical and optoelectronic devices. This work was supported by NSF grant No. DMR10-1006184 and U.S. DOE under Contract No. DE-AC02-05CH11231. Computational resources have been provided by NERSC and Teragrid.

1:15PM N8.00011 Theory of coherent phonons in carbon nanotubes and graphene nanoribbons[1] , G.D. SANDERS, C.J. STANTON, University of Florida, A.R.T. NUGRAHA, R. SAITO, Tohoku University — We have performed theoretical studies on generating and detecting coherent radial breathing mode (RBM) phonons in single-walled carbon nanotubes and coherent radial breathing like mode (RBLM) phonons in graphene nanoribbons. A microscopic theory incorporating electronic states, phonon modes, optical matrix elements, and electron-phonon interaction matrix elements allows us to calculate the coherent phonon spectrum. The coherent phonon amplitudes satisfy a driven oscillator equation with a driving term that depends on photoexcited carrier density. We study the coherent phonon spectrum for nanotubes of different chirality and for armchair and zigzag graphene nanoribbons. We compare our results with a simpler, effective mass theory where we find reasonable agreement with the main features of our computed coherent phonon spectrum.

1:27PM N8.00012 Nonlinear motion of cantilevered SWNT and Its Meaning to Phonon Dynamics[1] , HEEYUEN KOH, JAMES CANNON, SHOHEI CHIASHI, JUNICHIRO SHIOMI, SHIGEO MARUYAMA, The University of Tokyo — Based on the finding that the lowest frequency mode of cantilevered SWNT is described by the continuum beam theory in frequency domain, we considered its effect of the symmetric structure for the coupling of orthogonal transverse modes to explain the nonlinear motion of free thermal vibration. This nonlinear motion calculated by our molecular dynamics simulation, once regarded as noise, is observed to have the periodic order with duffing and beating, which is dependent on aspect ratio and temperature. It could be dictated by the governing equation from the Green Lagrangian strain tensor. The nonlinear beam equation from strain tensor described the motion well for various models which has different aspect ratio in molecular dynamics simulation. Since this motion is nothing but the interaction between 2nd mode of radial, tangential mode and 1st longitudinal mode, it was found that Green Lagrangian strain tensor is capable to deal such coupling. The free thermal motion of suspended SWNT is also considered without temperature gradient. The Q factor measured by this theoretical analysis will be discussed.

1:39PM N8.00013 Heat Pulse Propagation in Carbon Nanotube Peapods , MOHAMED OSMAN, Washington State University - Tricities — Earlier studies of heat pulse propagation in single and double wall nanotubes at very low temperatures have shown that the heat pulse generated wave packets that moved at the speed of sound corresponding to LA and TW phonon modes, second sound waves and diffusive components [1,2]. The energy content of LA mode wave packets in SWNT was significantly smaller than the TW mode. The energy of the leading LA mode wavepacket in DWNT had a significant increase in the energy content compared to SWNT LA mode. Additionally, an increase simple strain within the LA mode was higher in DWNT compared to SWNT was also reported in [1]. This has motivated us to examine heat pulse propagation in carbon nanopeapods and the coupling between the (10,10) SWNT nanotube and the C60 fullerenes enclosed. The major coupling frequency between the C60 and the (10,10) occurs at 4.88 THz which correspond to the radial breathing mode frequency. We will discuss these results and report on the major phonon modes involved in heat pulse propagation in the (10,10) SWNT-C60 nanopeapod.

1:51PM N8.00014 Microstructural characterization of nanoporous carbon fiber as determined by neutron scattering , LILIN HE, YURI MELNICHENKO, Oak Ridge National Laboratory, SOFIANE BAUKHALFA, GLEB YUSHIN, Georgia Institute of Technology — We have applied small angle neutron scattering (SANS) technique to investigate the microstructure of nanoporous carbon fiber. The scattering curves were fitted to various models, which allowed us to estimate the structural parameters (i.e. total radii of gyration of pores as well as cross sectional radius of gyration, physical radius and lengths of cylindrical pores) in the studied samples. Chord length analysis was performed to estimate the average sizes of pores and solid matrix. The information obtained from SANS data is in general agreement with independent measurements of surface area using gas sorption carried out in this study. SANS data obtained from carbons saturated with contrast matching liquid (D_2O) indicate that the scattering with power law decay of I(Q) in the low Q domain originates from outer surface of carbon fibers. Lower than anticipated decrease in scattering intensity in the high Q domain suggests that a certain amount of nanopores are not accessible to D_2O molecules. The investigation of the isotope effect on the pore filling suggests that the H_2O is more penetrated than D_2O, which is attributed to the stronger bond network among deuterium atoms than that in hydrogen atoms.

2:03PM N8.00015 Optical Characterization of Natural Nontoxic Nanomaterials , DEVULAPALLI RAO, CHANDRA YELLESWARAPU, University of Massachusetts Boston — Synthetic nanomaterials – carbon nanotubes, semiconductor nanoparticles, nanowires and nanorods, metal clusters in polymer films – are extensively studied for potential photonic applications. Naturally occurring halloysite nanotubes offer additional advantages of high tensile strength, nontoxcity and biocompatibility. Halloysite is receiving lot of attention for application as low cost nanoscale container for encapsulation of biologically active molecules, drugs, and anticorrosion agents. We studied the optical properties of halloysite nanotube samples of length ∼1000 nm with 50 nm external diameter and 15 nm internal diameter. The hollysite sample was provided by Prof. Yuri Lvov, Institute for Micromanufacturing, Louisiana Tech. The sample suspended in water at a concentration 2.5 mg/ml exhibits a broad optical absorption band in the visible region with a peak ∼600 nm. Z-scan studies are carried out, with 3 nsec laser pulses of frequency doubled Nd:YAG laser, using 1 mm glass cell containing the sample suspended in acetone at a concentration 0.66 mg/ml. Open aperture z-scan measurements indicate two-photon absorption. Closed aperture z-scan measurements exhibit a positive nonlinear refractive index. Results of photoacoustic z-scan currently in progress will also be presented.

Wednesday, March 20, 2013 11:15AM - 2:15PM –

Session N9 DCOMP: Invited Session: Computational Spectroscopy 308 - Giulia Galli, University of California, Davis

11:15AM N9.00001 Recent developments in time-dependent density-functional theory within and beyond linear response , E.K.U. GROSS, Max Planck Institute of Microstructure Physics, Halle, Germany — Time-dependent density functional theory (TDDFT) is a popular and rather successful method in the description of photo-absorption spectra of atoms and molecules in the linear response regime. In extended solids, however, a satisfactory description of excitonic effects has become possible only recently with the advent of advanced approximations for the exchange-correlation kernel f_{xc}. One of these advanced approximations is the so-called bootstrap kernel [S. Sharma et al, PRL **107**, 186401 (2011)]. We shall explore the performance of this kernel in the long-wavelength limit and for finite values of q, looking at electron-loss as well as photo-absorption spectra. We find, in particular, that excitonic effects in LiF and Ar are enhanced for values of q away from the Γ-point [S. Sharma et al, New J Phys **14**, 053052 (2012)]. Then we present two recent developments in TDDFT beyond the linear-response regime: (i) By using a geometrical partitioning, we calculate the angle and energy resolved photo-electron spectra of finite systems including multi-photon effects [De Giovannini, et al, A. Rubio, PRA **86**, 062515 (2012)]. (ii) Finally we show how the dynamics of many-electron systems can be controlled with lasers by marrying TDDFT with optimal control theory [A. Castro et al, PRL **109**, 153603 (2012)].

11:51AM N9.00002 Computational spectroscopy using many-body perturbation theory: Large scale calculations without virtual orbitals[1] , DARIO ROCCA, University of California, Davis (USA) and Université de Lorraine*, Nancy (France) — An accurate description of electronic excitations is essential to model and understand the properties of several materials of fundamental and technological interest. First principles, many-body techniques based on Green's functions are promising approaches that can provide an accurate description of excited state properties; however their applicability has long been hindered by their numerical complexity. In this talk we will summarize some recent methodological developments based on many-body perturbation theory for the efficient calculation of optical absorption spectra [1], photoemission spectra [2], and multiple exciton generation rates [3]. Several applications to realistic materials will be presented, with emphasis on materials for solar energy applications; these include silicon nanowires and bulk tungsten oxide, that are promising photoelectrode materials in water splitting solar cells, molecules used in organic photovoltaics, and semiconductor nanoparticles with potential use in third generation photovoltaic cells based on multiple exciton generation. Work done in collaboration with Y. Ping, T. A. Pham, M. Voros, D. Lu, H.-V. Nguyen, S. Wippermann, A. Gali, G. T. Zimanyi, and G. Galli.

12:27PM N9.00003 Many-electron interactions and first-principles studies of spectral functions: spin multiplets and plasmon satellites in photoemission spectra[1] , JOHANNES LISCHNER, UC Berkeley — The photoemission spectrum of an interacting system is often simply thought to be qualitatively similar to the corresponding non-interacting system: interactions only cause a shift and a broadening of the quasiparticle peak and result in a transfer of spectral weight into an incoherent background. We discuss two cases where this simple quasiparticle picture of photoemission fails and interactions result in a more drastic, qualitative difference from the non-interacting system. For electronic systems with unfilled shells, the coupling of angular momenta results in a multiplet structure in the photoemission spectrum. We describe how accurate calculations of multiplet splittings are possible within the GW approximation and present results for several magnetic molecules and defects, such as the negatively charged nitrogen-vacancy defect (NV^-) center in diamond. We also discuss plasmon satellite structures in photoemission spectra. We show for bulk silicon and doped graphene that the *ab initio*GW approximation overestimates the quasiparticle-satellite separation significantly and falsely predicts a plasmaron excitation. By including significant vertex corrections via the *ab initio*GW+cumulant approximation, we improve the description of plasmon satellites and find good agreement with experimental photoemission spectra.

Work was done in collaboration with Jack Deslippe, Manish Jain, Derek Vigil-Fowler and Steven G. Louie.

1:03PM N9.00004 Theory for Time-Domain Photon Spectroscopy , THOMAS DEVEREAUX, SLAC National Accelerator Lab and Stanford University — In this talk I will present some recent work concerning the development of theories for time-domain photon spectroscopies, with a focus on studying non-equilibrium pump-probe dynamics. Studies of several model systems will be presented, including non-equilibrium dynamics across of metal-insulator transition in correlated systems, strong electron-phonon interactions, and spectral properties in a charge density wave state. The similarities and differences between equilibrium dynamics will be highlighted [1].

1:39PM N9.00005 Computational Spectroscopy for Nanoscale Photovoltaics , MARCO BERNARDI, Massachusetts Institute of Technology — Nanoscale photovoltaic (PV) systems employ nanomaterial interfaces to dissociate bound excitons formed upon sunlight absorption. This mechanism results in a correlated electron, hole, and exciton interface dynamics whose accurate determination is challenging both theoretically and experimentally. In this talk, I will discuss approaches available to compute and combine relevant spectroscopic quantities to predict efficient nanoscale PV systems. Further, I will present our recent work on two novel families of nanoscale PV devices based on: 1) Nanocarbon materials, achieving 1.3% efficiency, tunable infra-red optical absorption, and superior photostability compared to organic solar cells 2) Two-dimensional monolayer semiconductors such as Graphene-BN and MoS_2, capable of absorbing a significant fraction of sunlight within just $\approx$ 10nm, and showing tunable absorption, band offsets, and power conversion efficiency (PCE).

In closing, I will discuss the errors and necessary accuracy in predicting PCE from first-principles calculations, and propose a suitable figure of merit to quantify absorption solar-matchedness to be used in large-scale searches of nanoscale PV materials.

Wednesday, March 20, 2013 11:15AM - 2:15PM –

Session N10 DCMP GMAG: Invited Session: Smart Magnetic Particles: On-Chip Transport, Assembly and Biomedical Applications 309 - Valentyn Novosad, Argonne National Laboratory

11:15AM N10.00001 High-speed transport and magneto-mechanical resonant sensing of superparamagnetic microbeads using magnetic domain walls[1] , ELIZABETH RAPOPORT, Massachusetts Institute of Technology — Surface-functionalized superparamagnetic (SPM) microbeads are of great interest in biomedical research and diagnostic device engineering for tagging, manipulating, and detecting chemical and biological species in a fluid environment [1-5]. Recent work has shown that magnetic domain walls (DWs) can be used to shuttle individual SPM microbeads and magnetically tagged entities across the surface of a chip [1-5]. This talk will describe the dynamics of SPM microbead transport by nanotrack-guided DWs, and show how these coupled dynamics can be exploited for on-chip digital biosensing applications. Using curvilinear magnetic nanotracks, we demonstrate rapid transport of SPM microbeads at speeds approaching 1000 μm/s [3], and present a mechanism for selective transport at a junction that allows for the design of complex bead routing networks. We further demonstrate that a SPM bead trapped by a DW exhibits a distinct magneto-mechanical resonance that depends on its hydrodynamic characteristics in the host fluid [4, 5], and that this resonance can be used for robust size-based discrimination of commercial microbead populations. By embedding a spin-valve sensor within a DW transport conduit, we show that the resonance can be detected electrically and on-the-fly [5]. Thus, we demonstrate a complete set of essential bead handling functions, including capture, transport, identification, and release, required for an integrated lab-on-a-chip platform.

11:51AM N10.00002 Binary Colloidal Superlattices Assembled by Magnetic Fields[1] , BENJAMIN YELLEN, Duke University — Colloidal particle superlattices represent a fascinating class of complex materials which in many cases have corollary structures at the atomic scale. These complex systems thus not only help elucidate the principles of materials assembly in nature, but further provide design criteria for fabrication of novel materials at the macroscopic scale. Methods for assembling colloidal particle superlattices include controlled drying, ionic interactions, and dipolar interactions. However, a general pathway for producing a wider variety of colloidal crystals remains a fundamental challenge. Here we demonstrate a versatile colloidal assembly system in which the design rules can be tuned to yield over 20 different pre-programmed lattice structures, including kagome, honeycomb, square tiles, as well as a variety of chain and ring configurations. We tune the crystal type by controlling the relative concentrations and interaction strengths between spherical superparamagnetic and diamagnetic particles. An external magnetic field causes like particles to repel and unlike particles to attract. The combination of our experimental observations with potential energy calculations of various lattice structures suggest that the lowest energy lattice configuration is determined by two parameters, namely the dipole moment and relative concentration of each particle type.

12:27PM N10.00003 Magnetic microstructures for regulating Brownian motion[1] , RATNASINGHAM SOORYAKUMAR, The Ohio State University — Nature has proven that it is possible to engineer complex nanoscale machines in the presence of thermal fluctuations. These biological complexes, which harness random thermal energy to provide functionality, yield a framework to develop related artificial, i.e., nonbiological, phenomena and devices. A major challenge to achieving positional control of fluid-borne submicron sized objects is regulating their Brownian fluctuations. In this talk a magnetic-field-based trap that regulates the thermal fluctuations of superparamagnetic beads in suspension will be presented. Local domain-wall fields originating from patterned magnetic wires, whose strength and profile are tuned by weak external fields, enable bead trajectories within the trap to be managed and easily varied between strong confinements and delocalized spatial excursions. Moreover, the frequency spectrum of the trapped bead responds to fields as a power-law function with a tunable, non-integer exponent. When extended to a cluster of particles, the trapping landscape preferentially stabilizes them into formations of 5-fold symmetry, while their Brownian fluctuations result in frequent transitions between different cluster configurations. The quantitative understanding of the Brownian dynamics together with the ability to tune the extent of the fluctuations enables the wire-based platform to serve as a model system to investigate the competition between random and deterministic forces.

1:03PM N10.00004 Smart Magnetic Materials for Controlling Cell Fate[1] , ELINA VITOL, Materials Science Division, Argonne National Laboratory — Toxicity of cancer chemotherapy, often resulting in failure of even healthy organs, represents one of the most vivid and still unavoidable outcomes of traditional medical approaches to treating a disease. The lack of specificity remains a fundamental obstacle in performing targeted treatment which should ideally affect only the particular cells in a human body. Nanotechnology has recently enabled the possibility to create materials comparable in sizes with cells and subcellular structures opening the opportunities for affecting intracellular processes on the level unattainable by macroscopic techniques. [1-2] Magnetic nanomaterials are especially promising for applications in life sciences due to their bi-functional behavior. On the one hand side, they are inherently stimuli-responsive and their properties can be controlled and modulated remotely. On the other hand, these materials themselves can be used for applying controlled stimulus to a cell thus changing its function and even inducing cell death [3]. For biological applications, such multifaceted functionality opens the unique opportunity to modulate cell behavior by interfacing it with magnetic material. Historically, chemically synthesized superparamagnetic iron oxide particles have been widely studied for biological applications such as magnetic separation, targeting, MRI contrast enhancement and magnetically induced heating [1,4]. At the same time, there is a growing interest to magnetic materials created by physical fabrication methods which allow for realization of very complex structures in terms of geometry and composition [5]. In this talk, both types of materials will be discussed. Thus, thermo-responsive magnetic micelles were used as nanocontainers for magnetically guided drug delivery and release triggered by heating in the RF frequency a.c. magnetic field. The microfabricated biofunctionalized microdisks targeted to the cancer cells were employed for mechanical stimulation of cell membrane due to oscillation of the disks in the low frequency (10-20 Hz) a.c. magnetic field, resulting in redistribution of free intracellular calcium and subsequent triggering of apoptosis - programmed cell suicide [3,5]. The details of mechanisms by which the cell responds to the stimulus applied by magnetic particles will be discussed.

1:39PM N10.00005 Biomedical Applications of Magnetic Nanoparticles: Delivering Genes and Remote Control of Cells , JON DOBSON, University of Florida — The use of magnetic micro- and nanoparticles for biomedical applications was first proposed in the 1920s as a way to measure the rehological properties of the cell's cytoplasm. Since that time, magnetic micro- and nanoparticle synthesis, coating and bio-functionalization have advanced significantly, as have the applications for these particles. Magnetic micro- and nanoparticles are now used in a variety of biomedical techniques such as targeted drug delivery, MRI contrast enhancement, gene transfection, immno-assay and cell sorting. More recently, magnetic micro- and nanoparticles have been used to investigate and manipulate cellular processes both *in vitro* and *in vivo*. This talk will focus on magnetic nanoparticle targeting to and actuation of cell surface receptors to control cell signaling cascades to control cell behavior. This technology has applications in disease therapy, cell engineering and regenerative medicine. The use of magnetic nanoparticles and oscillating magnet arrays for enhanced gene delivery will also be discussed.

Wednesday, March 20, 2013 11:15AM - 2:15PM –

Session N11 FEd: Invited Session: Landmark Reports in Education 310 - Daniel Crowe, Loudon County Publc Schools Academy of Science

11:15AM N11.00001 Linking National and International Educational Assessments: NAEP and TIMSS , TASLIMA RAHMAN, U.S. Department of Education — In an increasingly global economy, comparisons of student achievement in the United States to student achievement in other countries are of interest to the nation. The National Center for Education Statistics (NCES) reports on mathematics and science achievement of 4^{th}- and 8^{th}-grade students for the all U.S. states and 60 countries. However, the reports are based on two separate assessments. Results for the U.S. states are based on the National Assessment of Educational Progress (NAEP) and results for the other countries are based on the Trends in International Mathematics and Science Study (TIMSS). Further, unlike NAEP, TIMSS does not have an on-going state component. Thus, U.S. states cannot compare performance of their students with those of the students in other countries. To enable such comparisons, NCES launched a NAEP-TIMSS Linking study where the goal is to project TIMSS mathematics and science scores for the students in the 50 states that participated in NAEP. This linking study targeted eighth-grade students. NAEP assessments of mathematics and science were conducted in winter 2011 (January-March) and TIMSS assessments of mathematics and science were conducted in spring 2011 (April-June). Three approaches— statistical moderation, calibration, and projection—are applied in linking the two scales. In this presentation, discussion will focus on the study design and approaches applied. In addition, results will be shared if released to the public by the NCES before March 2013. Otherwise results of earlier linking study conducted by the American Institutes for Research in 2007 using the statistical moderation technique will be shared.

11:51AM N11.00002 Linking NAEP to TIMSS Using Statistical Moderation , GARY PHILLIPS, American Institutes for Research — No abstract available.

12:27PM N11.00003 The NRC Study of Undergraduate Physics Education: The role, status and outlook for physics education research , PAULA HERON, University of Washington — The Board on Physics and Astronomy of the National Academies formed the "Committee on Undergraduate Physics Education, Research and Implementation" in 2011 and charged it with producing a report that "identifies the goals and challenges facing undergraduate physics education and identifies how best practices for undergraduate physics education can be implemented on a widespread and sustained basis." (Further information on the committee and its charge can be found at: http://sites.nationalacademies.org/BPA/BPA_059078.) The report is expected to be released in early 2013. This talk will address the committee's process, some of the findings, and their implications for physics education. The role of physics education research in driving innovation will be emphasized.

1:03PM N11.00004 A Future for Undergraduate Physics Education? , DONALD LANGENBERG, Retired — About two years ago, the Board on Physics and Astronomy of the National Research Council created a Committee on Undergraduate Physics Education (UPE), with support from the National Science Foundation. The Committee was given the task to identify "the goals and challenges facing undergraduate physics education," and "how best practices for undergraduate physics education can be implemented on a widespread and sustained basis." The Committee was also asked to "assess the status of physics education research (PER)" and to "discuss how PER can assist in accomplishing the goal of improving undergraduate physics education best practices and education policy." This presentation will report the Committee's findings and recommendations, the latter aimed at audiences ranging from individual physics faculty to departmental and university-wide leadership, and professional societies and funding agencies. The Committee's challenge was daunting. We are experiencing revolutionary changes in higher education, driven by new education technologies and demands for broader and deeper STEM education for more students in more fields. Only a relatively small fraction of undergraduates take physics courses. Nevertheless, half a million undergraduates enroll in at least one physics course in every academic year. PER has become a productive research field with the potential for major contributions to the improvement of undergraduate STEM education generally. Yet, in many—probably most–institutions UPE remains persistently traditional. We all have much to do!

1:39PM N11.00005 Disciplined Based Educational Research – What is it? What has it done? Where is it going? , KENNETH HELLER, School of Physics & Astronomy, University of Minnesota — The National Research Council of the National Academies of Science has just released its study of Disciplined Based Educational Research (DBER) funded by the National Science Foundation. This two year study attempted to define the emerging field of DBER and investigated its state in the fields of Astronomy, Biology, Chemistry, Engineering, Geosciences, and Physics. This talk will give a brief review of the report, discuss the recommendations, implications for future research, and impact of DBER in improving science and engineering instruction at the undergraduate level.

Wednesday, March 20, 2013 11:15AM - 2:15PM –

Session N12 DMP GERA FIAP: Focus Session: Thermoelectrics Materials Waste Heat 314 - Brian Sales, ORNL

11:15AM N12.00001 On the thermodynamics of waste heat recovery from internal combustion engine exhaust gas[1] , G.P. MEISNER, GM Global R and D — The ideal internal combustion (IC) engine (Otto Cycle) efficiency $\eta_{\rm IC}$ = 1-$(1/r)^{(\gamma-1)}$ is only a function of engine compression ratio r=$V_{\rm max}/V_{\rm min}$ and exhaust gas specific heat ratio $\gamma = c_P/c_V$. Typically r= 8, γ = 1.4, and $\eta_{\rm IC}$ = 56%. Unlike the Carnot Cycle where $\eta_{\rm Carnot}$ = 1-(T_C/T_H) for a heat engine operating between hot and cold heat reservoirs at T_H and T_C, respectively, $\eta_{\rm IC}$ is not a function of the exhaust gas temperature. Instead, the exhaust gas temperature depends only on the intake gas temperature (ambient), r, γ, c_V, and the combustion energy. The ejected exhaust gas heat is thermally decoupled from the IC engine and conveyed via the exhaust system (manifold, pipe, muffler, etc.) to ambient, and the exhaust system is simply a heat engine that does no useful work. The maximum fraction of fuel energy that can be extracted from the exhaust gas stream as useful work is (1-$\eta_{\rm IC}$) $\times$ $\eta_{\rm Carnot}$ = 32% for T_H = 850 K (exhaust) and T_C = 370 K (coolant). This waste heat can be recovered using a heat engine such as a thermoelectric generator (TEG) with $\eta_{\rm TEG} > 0$ in the exhaust system. A combined IC engine and TEG system can generate net useful work from the exhaust gas waste heat with efficiency $\eta_{\rm WH}$ = (1-$\eta_{\rm IC}$) $\times$ $\eta_{\rm Carnot}$ $\times$ $\eta_{\rm TEG}$, and this will increase the overall fuel efficiency of the total system. Recent improvements in TEGs yield $\eta_{\rm TEG}$ values approaching 15% giving a potential total waste heat conversion efficiency of $\eta_{\rm WH}$ = 4.6%, which translates into a fuel economy improvement approaching 5%.

11:27AM N12.00002 Synthesis of High Performance Thermoelectric Materials Directly from Natural Mineral , XU LU, Department of Physics & Astronomy Michigan State University, DONALD MORELLI, Department of Chemical Engineering & Materials Science Michigan State University, YI XIA, FEI ZHOU, VIDVUDS OZOLINS, Department of Materials Science & Engineering University of California, Los Angeles, HANG CHI, XIAOYUAN ZHOU, CTIRAD UHER, Department of Physics University of Michigan — We report high performance TE materials synthesized directly from natural mineral. Lattice dynamics and electronic band structure calculations suggest that the compound tetrahedrite ($Cu_{12-x}M_xSb_4S_{13}$), where M is transition metal such as Zn or Fe, will have low lattice thermal conductivity and good electronic transport properties. We have experimentally investigated the relationship between ZT and x content of different transition metals in synthetic tetrahedrites. We have found that the maximum of ZT value is not sensitive to the value of x but is related to valence band hole filling fraction; high ZT can be maintained over a large range of x. The compositions studied span the range of those of natural mineral tetrahedrite. To demonstrate that the natural mineral itself can be used as a source material, we synthesized samples by mixing natural mineral with synthetic $Cu_{12}Sb_4S_{13}$ by balling milling and hot pressing. The resulting samples were single phase with hole filling fraction in the optimum range and displayed maximum ZT values of unity at 723K. This new synthesis method can directly use natural mineral to produce TE materials in large quantities with little effort.

11:39AM N12.00003 First-Principles Studies of Earth-Abundant Tetrahedrite Thermoelectrics , YI XIA, FEI ZHOU, VIDVUDS OZOLINS, UCLA — Recent experiments have shown inexpensive and naturally occuring tetrahedrite-based materials that exhibit a thermoelectric figure of merit near unity. These compounds are typically of the form $Cu_{12-x}M_xSb_4S_{13}$, where M is a transition metal, such as Zn or Fe, for a wide range of x. Using density-functional theory calculations, the ternary phase diagram and various defect formation energies are calculated. Furthermore, the electronic structure, phonon spectrum and thermoelectric properties are investigated. We observe metallic behavior and strong lattice anharmonicity of stoichiometric $Cu_{12}Sb_4S_{13}$. In addition, doping with transitional metals Zn or Fe increases both resistivity and anharmonicity. The theoretical calculations are in good agreement with experimental measurements.

11:51AM N12.00004 Configuring pnicogen rings in skutterudites for low phonon conductivity[1]

, CTIRAD UHER, University of Michigan — During the past dozen or so years, skutterudites have attracted much interest as prospective thermoelectric materials for power-generation applications in the temperature range 500K - 850K. Primary interest was focused on filled forms of skutterudites where loosely-bonded filler species resonantly scatter normal phonon modes of the structure thus reducing the lattice thermal conductivity. Using this approach with multiple fillers and incorporating various forms of nanoinclusions, impressive figures of merit ZT = 1.5-1.7 have been reported with n-type filled skutterudites. Since the dominant heat-carrying modes in skutterudites are associated with vibrations of the pnicogen rings, disruptions of the ring structure by substitutional alloying should be a similarly effective approach of lowering the lattice thermal conductivity. In this talk I discuss our recent work exploring alloying configurations of pnicogen rings that yield particularly low values of the thermal conductivity. We found that compensated double-substitution (replacing two Sb atoms with one atom each from the column IV and column VI elements) is a very effective approach. Our ab initio calculations, in combination with a cluster expansion, have allowed us to identify stable alloy configurations on the Sb rings. Subsequent molecular and lattice dynamics simulations on low energy configurations established the range of atomic displacement parameters and values of the thermal conductivity. Theoretical results turned out to be in good agreement with our experimental thermal conductivity values. Combining both approaches of compensated double-substitution and filling of structural cages should be an effective way of further improving the thermoelectric figure of merit of skutterudites.

12:27PM N12.00005 Vibrational dynamics of filled skutterudites $M_{1-x}Fe_4Sb_{12}$ (M = Ca, Sr, Ba, and Yb)

, ANDREAS LEITHE-JASPER, MPI for Chemical Physics of Solids, Dresden, MICHAEL MAREK KOZA, HANNU MUTKA, Institut Laue Langevin, Grenoble, France, WALTER SCHNELLE, HELGE ROSNER, YURI GRIN, MPI for Chemical Physics of Solids, Dresden — First-principles density-functional theory and lattice-dynamics calculations were performed to study the vibrational dynamics and related observables of the ternary compounds $M_{1-x}Fe_4Sb_{12}$ (A = Ca, Sr, Ba, Yb). The calculation results are supported by experimental data, which were obtained from neutron inelastic scattering, neutron-diffraction, and heat-capacity measurements. Within the calculation approach based on the theory of harmonic solids all observables are linked to the phonon density of states $Z(\omega)$. The good agreement with experimental data shows that the vibrational dynamics of the ternary skutterudite structures can be described by a set of normal modes. Features in the experimentally obtained density of states $G(\omega)$ reflecting the variation in properties (mass, ionic radius) of the cations Ca, Sr, Ba, and Yb are reproduced by the calculations.

12:39PM N12.00006 Cr and Ru substituted defect manganese silicides $MnSi_\delta$ ($\delta \sim$ 1.72-1.74) as low thermal conductivity thermoelectrics*

, VIJAYABARATHI PONNAMBALAM, DONALD T. MORELLI, Dept. of Chemical Engineering & Materials Science, Michigan State University — Defect manganese silicides $MnSi_\delta$ ($\delta \sim$ 1.72-1.74) belong to a large family of compounds known as Nowotny chimney-ladder (NCL) phases and are closely related to an orthorhombic NCL compound $TiSi_2$. One interesting feature is the low lattice thermal conductivity ($\kappa_L \sim$ 2.5 W/m K) which may be due to several reasons: Since δ doesn't exceed 1.75 in $MnSi_\delta$, a considerable concentration of random vacancies exists on the Si-sublattice and can give rise to a low thermal conductivity. In addition, as synthesized $MnSi_\delta$ is a mixture of many phases including Mn_4Si_7, $Mn_{11}Si_{19}$, $Mn_{15}Si_{26}$ and $Mn_{27}Si_{47}$ and in all these phases, while a-lattice parameter is closely matched, the c-lattice parameter substantially varies with δ. Such a closely matched a-lattice parameter can cause lattice strain and potentially reduce κ_L. Ru_2Si_3 forms solid solutions and Cr can be substituted as much as 20% in $MnSi_\delta$. These substitutions can favorably modify the lattice strain and reduce the thermal conductivity further. Hence manganese silicides substituted with small amounts of Cr and Ru have been synthesized. Thermoelectric properties including resistivity, Seebeck and Hall coefficients and thermal conductivity will be studied and presented. *This work was supported as part of the Center for Revolutionary Materials for Solid State Energy Conversion, an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences under Award Number DE-SC0001054.

12:51PM N12.00007 P-type electronic and thermal transport properties of $Mg_2Sn_{1-x}Si_x$[1]

, SUNPHIL KIM, Department of Mechanical and Aerospace Engineering, The Ohio State University, Columbus, OH, BARTLOMIEJ WIENDLOCHA, Faculty of Physics and Applied Computer Science, AGH University of Science and Technology, 30-059 Krakow, Poland, JOSEPH P. HEREMANS, Department of Mechanical and Aerospace Engineering, Department of Physics, The Ohio State University, Columbus, OH — P-type Mg_2Sn doped with various acceptors[(1)(2)] has been studied as a potential thermoelectric material. Because of its narrow band gap and high lattice thermal conductivity, the zT values of the binary compound are limited: zT_{max} reported is 0.3[(3)]. In this work, we synthesize and characterize p-type-doped $Mg_2Sn_{1-x}Si_x$ with various acceptors. Silicon is added in order to widen the band gap and scatter the phonons. The conduction band degeneracy that yields excellent zT in n-type material in the $Mg_2Sn_{1-x}Si_x$ alloy system unfortunately does not apply to p-type material. Thermomagnetic and galvanomagnetic properties (electrical resistivity, Seebeck, Hall, and Nernst coefficients) are measured, along with thermal conductivity and band gap measurements. Finally, zT values are reported. (1) H. Y. Chen et al. Journal of Electronic Materials, Vol. 38, No. 7, 2009 (2) S. Choi et al. Journal of Electronic Materials, Vol. 41, No. 6, 2012 (3) H. Y. Chen et al. Phys. Status Solidi A 207, No. 11, 2523-2531 (2010)

1:03PM N12.00008 Electronic and thermoelectric properties of CoSbS and FeSbS[1]

, DAVID PARKER, Oak Ridge National Laboratory, ANDREW F. MAY, HSIN WANG, MICHAEL A. MCGUIRE, BRIAN C. SALES, DAVID J. SINGH, ORNL — We present a combined theoretical and experimental study of the potential thermoelectric performance of three transition metal antimonide sulfides, CoSbS, FeSbS and NiSbS. From theory we find that NiSbS is metallic and hence of little interest regarding thermoelectric performance. CoSbS and FeSbS are both semiconductors with rather heavy valence and conduction bands, whose thermopower can exceed 200 μV/K at temperatures of 900 K and carrier concentrations of 10^{21}cm^{-3}, which is similar to the n-type high performance thermoelectric filled skutterudites. The experimental results on several non-optimized n-type CoSbS samples confirm its semiconducting nature and indicate a potential for good high temperature thermoelectric performance, finding a ZT for two of the samples of 0.35 at 773 K. Substantially higher ZT values may be possible if the lattice thermal conductivity can be reduced by alloying and the effects of extrinsic scattering, which appear to be substantial in the experimental results, are reduced.

1:15PM N12.00009 Doping studies of alkali-metal rocksalt based I-V-VI_2 compounds with intrinsically minimal thermal conductivity

, MICHELE NIELSEN, Department of Mechanical Engineering, The Ohio State University, VIDVUDS OZOLINS, Department of Materials Science, UCLA, JOSEPH HEREMANS, Department of Mechanical Engineering, Department of Physics, Ohio State University — Past research has shown that rocksalt-based I-V-VI compounds have intrinsically low thermal conductivity as a result of the lone-pair electrons on the group V element. Theoretical calculations have revealed the presence marginally stable acoustic phonons which have extremely large Grüneisen parameters. These result in a strong anharmonicity in heat-carrying acoustic phonon branches of select I-V-VI_2 compounds. Here, we extend this work to the electronic properties of the materials, which all have similar valence band structures. As a result of these two material properties, we are able to explore if the excellent zT observed in $AgSbTe_2$ extends to materials with cheaper starting elements and better high-temperature stability. Here we introduce new doping studies in I-V-VI_2 compounds where the group I element is an alkali-metal atom.

1:27PM N12.00010 Role of Chemical Doping in Enhancement of Thermoelectric Properties of $Ca_3Co_4O_9$, JIANMING BAI, Oak Ridge National Laboratory, TAO WU, TREVOR A. TYSON, HAIYAN CHEN, New Jersey Institute of Technology, KAUMUDI PANDYA, Brookhaven National Laboratory, CHERNO JAYE, DANIEL FISCHER, National Institute of Standards and Technology — Single-phase $[Ca_2CoO_3][CoO_2]_{1.61}$ ($Ca_3Co_4O_9$) materials doped by transition metals were prepared by solid state reaction followed by annealing under oxygen. The temperature dependent thermoelectric properties, including resistivity (ρ), Seebeck coefficient (S) and thermal conductivity (κ), were measured. In order to understand the origin of the changes in ZT with doping, local (XAS) and long range (XRD) structural measurements as a function of doping were conducted. The electronic properties were probed by x-ray spectroscopic methods. Identification of the locations of the dopant sites and the impact on ZT will be discussed. This work is supported by DOE Grant DE-FG02-07ER46402. The Physical Properties Measurements System was acquired under NSF MRI Grant DMR-0923032 (ARRA award).

1:39PM N12.00011 Thermoelectric Performance of Hole-Doped Cu_2O[1] , XIN CHEN, DAVID PARKER, MAO-HUA DU, DAVID J. SINGH, Oak Ridge National Laboratory — We present an analysis of the thermopower and related properties of hole-doped Cu_2O using first-principles calculations and Boltzmann transport theory. Our results show that hole-doped Cu_2O has a high thermopower of above 200 μV/K with doping levels as high as 5.5×10^{20} cm^{-3} at 500 K, mainly attributed to the heavy valence bands of Cu_2O. The current theory suggests that hole-doped Cu_2O could be a good thermoelectric material. Future experiments are thus suggested to explore its thermoelectric potential for practical use in cooling and power generation applications.

1:51PM N12.00012 The Seebeck Coefficient in Oxygen Enriched La_2NiO_4 , PAUL BACH, VICTOR LEBORAN, FRANCISCO RIVADULLA, University of Santiago de Compostela — Oxide-based devices show promise for themoelectric applications due to their chemical stability and straightforward fabrication. The $La_2NiO_{4+\delta}$ system has been predicted to show an increased thermopower coupled with an increased electrical conductivity around $\delta = 0.05$ [Pardo et al. PRB 86, 165114 (2012)] that could lead to a large thermoelectric figure of merit (ZT). We investigate the suitability of lanthanum nickelate as a candidate material for high-ZT devices through a systematic study of oxygenated thin films grown by pulsed laser deposition. We report the electrical conductivity, Seebeck coefficient, and structural morphology of La_2NiO_4 grown in a range of oxidizing atmospheres and discuss their implications for controlled engineering of thermoelectric properties. We have explored the possibility of gate-tuning these systems in order to fabricate single-oxide based devices. This work was supported by the Ministerio de Ciencia e Innovación (Spain), grant MAT2010-16157, and the European Research Council, grant ERC-2010-StG 259082 2D THERMS.

2:03PM N12.00013 Spin-entropy origin and scaling behaviour of thermopower in LaBaCoO system[1] , DEWEI ZHANG, National Laboratory of Solid State Microstructures and Department of Physics, Nanjing University, HUAIHONG GUO, TENG YANG, Institute Of Metal Research, Chinese Academy of Sciences, ZHIHE WANG, National Laboratory of Solid State Microstructures and Department of Physics, Nanjing University, ZHIDONG ZHANG, Institute Of Metal Research, Chinese Academy of Sciences, YOUWEI DU, National Laboratory of Solid State Microstructures and Department of Physics, Nanjing University — We report a detailed investigation of thermopower and magnetic properties for $La_{1-x}Ba_xCoO_3$. A large negative magnetothempower is found to scale with both magnetic field and temperature, indicating that a spin entropy contribution to thermompower. We have formulated a new and general expression to describe the thermopower from spin entropy with spin-interaction considered. Our formula can fit the scaling behavior quite well and provides a satisfactory description to the observed data. The magnetic results further consolidate our claim. This investigation suggests that spin entropy plays a substantial role in the enhanced thermopower in this cobaltite system.

Session N13 DMP: Focus Session: Topological Materials - Topological Superconductivity 315

- Peter Armitage, Johns Hopkins University

11:15AM N13.00001 Zero bias conductance peak anomaly in topological insulator - superconductor junctions , WENQING DAI, ANTHONY RICHARDELLA, Department of Physics, Pennsylvania State University, University Park, PA 16802, USA, JOSEPH BROM, JOAN REDWING, Materials Science and Engineering, Pennsylvania State University, University Park, PA 16802, USA, NITIN SAMARTH, C.X. LIU, QI LI, Department of Physics, Pennsylvania State University, University Park, PA 16802, USA — We have fabricated planar junctions between topological insulator Bi_2Se_3 and superconducting Pb with MgO barrier and studied the conductance spectra of the junctions under different temperatures and magnetic fields. Two types of Bi_2Se_3 thin films, grown by hybrid physical-chemical vapor deposition (HPCVD) and molecular beam epitaxy (MBE), were used. A few nanometers thick MgO layer made by RF sputtering was used as the barrier. We observed a zero bias conductance peak (ZBCP) anomaly in the spectra. The peak width ranges from 1 mV to 17 mV in different samples. The ZBCP height decreases with increasing temperature and disappears when the temperature is above the T_c of Pb. The ZBCP is also suppressed by both perpendicular and parallel magnetic fields and vanishes above the critical field of Pb. We will discuss the possible origins of the ZBCP in the junctions.

11:27AM N13.00002 Superconducting-Tip STM on Cobaltates as a Platform for Exploring Topological Superconductivity[1] , ALEX W. CONTRYMAN, FRANCIS NIESTEMSKI, YULIN CHEN, Stanford University, THORSTEN HESJEDAL, Oxford University, CAROLINA PARRA, SUK BUM CHUNG, HAI-JUN ZHANG, Z.X. SHEN, SHOU-CHENG ZHANG, HARI C. MANOHARAN, Stanford University — In recent years, Na_xCoO_2 has attracted much attention for its unconventional superconductivity and antiferromagnetic phases. More recently it has been proposed that inducing superconductivity into the stoichiometric compound through the proximity effect could lead to topological superconductivity where Majorana physics might be accessed. We first explore this surface state with standard scanning tunneling spectroscopy and tuning fork-based atomic force microscopy, and then investigate the proximity effect scenario by introducing a superconducting tip to probe the superconductor-vacuum-topological junction.

[1]Supported by DOE, Office of Basic Energy Sciences, Division of Materials Sciences and Engineering under contract DE-AC02-76SF00515. Alex W. Contryman is supported by a Dr. Robert N. Noyce Stanford Graduate Fellowship.

11:39AM N13.00003 Dynamics of Josephson vortex interacting with Majorana bound modes in Long Josephson Junctions , YEN LEE LOH, JU H. KIM, University of North Dakota — We investigate the effects of Majorana bound modes on Josephson vortex (i.e., fluxon) dynamics by examining a long Josephson junction deposited on a topological insulator. Majorana bound states are represented as two counterpropagating edge modes along either superconducting side, which couples to the local Josephson phase difference. A fluxon (a 2π phase configuration) interacts with Majorana bound states via the Jackiw-Rebbi mechanism [1] as pointed out by Grosfeld and Stern [2]. We find the effective equation of motion for the fluxon by integrating out the Majorana modes. This motion can be described by the double sine-Gordon equation. As a consequence, there may be fractional Shapiro steps in the I-V characteristics. In addition, the fluxon may have internal modes. We study the criteria for these effects to occur and to be detectable.

11:51AM N13.00004 Edge superconducting correlation in attractive-U-Kane-Mele Hubbard model[1] , JIE YUAN, JINHUA GAO[2], Department of Physics, and Center of Theoretical and Computational Physics, University of Hong Kong, Hong Kong, China, WEIQIANG CHEN[3], Department of Physics, and Center of Theoretical and Computational Physics,University of Hong Kong, Hong Kong, China, FEI YE, Department of Physics, South University of Science and Technology of China, Shenzhen, Guangdong 518055, China, YI ZHOU, Department of Physics, Zhejiang University, Hangzhou 310058, China, FUCHUN ZHANG[4], Department of Physics, and Center of Theoretical and Computational Physics, University of Hong Kong, Hong Kong, China — The two-dimensional Kane-Mele model with attractive Hubbard interaction U is studied by using a self-consistent mean-field theory. At $U = 0$, the ground state is a topological insulator. At U larger than a critical value U_c, the ground state is a bulk superconductor. At $0 < U < U_c$, the bulk remains insulating while the edge state shows superconducting correlation. The effective model for the edge superconducting state is discussed.

12:03PM N13.00005 Strong and weak 2D topological superconductors with spin-orbit coupling , HONG YAO, Institute for Advanced Study, Tsinghua University, Beijing, FAN YANG, School of Physics, Beijing Institute of Technology, Beijing — We study pairing symmetries of superconducting states in a centrosymmetric system with quasi-one dimensional bands and spin-orbit coupling. When the spin-orbit coupling is weak, we mainly find even-parity pairing which is topologically trivial. When the spin-orbit coupling is (moderately) strong, the paring is dominantly p-wave, which is an odd-parity pairing. Depending on the interaction parameters, we find two different odd-parity pairing states. One has p+ip pairing with nonzero strong topological invariants, which breaks time reversal symmetry and possesses gapless chiral Majorana modes. The other has p+ip pairing for spin-up electrons but p-ip pairing for spin-down electrons, which preserves time reversal symmetry and hosts nontrivial weak Z_2 topological invariants. In the weak topological superconductors, there are gapless modes associated with lattice dislocations. Possible applications to the recent discovered BiS-based superconductors will be discussed.

12:15PM N13.00006 Majorana bound states and non-local spin correlations in a quantum wire on a topological superconductor , SHO NAKOSAI, Dept. Appl. Phys., Univ. of Tokyo, JAN BUDICH, Dept. Phys., Stockholm Univ., YUKIO TANAKA, Dept. Appl. Phys., Nagoya Univ., BJOERN TRAUZETTEL, Inst. Theor. Phys. and Astrophys., Univ. of Wuerzburg, NAOTO NAGAOSA, Dept. Appl. Phys., Univ. of Tokyo, CERG, RIKEN, CMRG, RIKEN — We theoretically study the proximity effect of the one-dimensional quantum wire of usual metal without the spin-orbit interaction on the substrate of unconventional superconductor. Three cases are considered for the substrate, i.e., (i) chiral superconductor in class D with broken time reversal symmetry, and class DIII superconductor (ii) with and (iii) without the nontrivial Z_2 number. The Cooper pairs are induced into the wire, resulting effective one dimensional superconducting system. We found the degenerate zero energy Majorana bound states at both ends of the wire for all the cases, unlike single Majorana state in spin-orbit coupled system with s-wave superconductor, which might have been experimentally observed. The degenerate Majorana bound states are unstable against the spin-orbit interaction in case (i) while are protected by time reversal symmetry in cases (ii) and (iii). These degenerate Majorana bound states constitute the spin 1/2 degrees of freedom at each end of the wire. It is also shown that the non-locally correlated two spins at the two ends of the wire can be controlled by the gating potential on the wire.

12:27PM N13.00007 Josephson supercurrent through a topological insulator surface state , ALEXANDER BRINKMAN, University of Twente — The long-sought yet elusive Majorana fermion is predicted to arise from a combination of a superconductor and a topological insulator. We present direct evidence for a Josephson supercurrent in superconductor (Nb) - topological insulator (Bi_2Te_3) - superconductor e-beam fabricated junctions by the observation of clear Shapiro steps under microwave irradiation, and a critical current modulation by magnetic field. The dependence of the critical current on temperature and electrode spacing shows that the junctions are in the ballistic limit on a length scale of 100 nm. Shubnikov-de Haas oscillations in magnetic fields up to 30 T reveal a topologically non-trivial two-dimensional surface state. We argue that the ballistic Josephson current is hosted by this surface state despite the fact that the normal state transport is dominated by diffusive bulk conductivity. Nanostructured SQUIDs containing topological Josephson junctions are realized experimentally. Clear critical current modulation of both the junctions and the SQUID with applied magnetic fields have been observed. We show that the SQUIDs have a periodicity in the voltage-flux characteristic of Φ_0 consistent with numerical expectations. We propose several strategies towards realizing a doubled periodicity, belonging to the presence of Majorana fermions.

1:03PM N13.00008 Microscopic theory for a ferromagnetic nanowire/superconductor heterostructure: Transport, fluctuations, and topological superconductivity[1] , VICTOR GALITSKI, SO TAKEI, The University of Maryland College Park, THE CONDENSED MATTER THEORY CENTER AND THE JOINT QUANTUM INSTITUTE TEAM — Motivated by the recent experiment of Wang et al. [Nat. Phys. **6**, 389 (2010)], who observed a highly unusual transport behavior of ferromagnetic cobalt nanowires proximity-coupled to superconducting electrodes, we study the proximity effect and temperature-dependent transport in such a mesoscopic hybrid structure. It is assumed that the asymmetry in the tunneling barrier gives rise to the Rashba spin-orbit coupling in the barrier that enables induced p-wave superconductivity in the ferromagnet to exist. We first develop a microscopic theory of Andreev scattering at the spin-orbit-coupled interface, derive a set of self-consistent boundary conditions, and find an expression for the p-wave minigap in terms of the microscopic parameters of the contact. Second, we study the temperature dependence of the resistance near the superconducting transition, and we find that it should generally feature a fluctuation-induced peak. The upturn in resistance is related to the suppression of the single-particle density of states due to the formation of fluctuating pairs, whose tunneling is suppressed. In conclusion, we discuss this and related setups involving ferromagnetic nanowires in the context of one-dimensional topological superconductors.

[1]Funding support: DOE-BES (DESC0001911).

1:15PM N13.00009 Odd-frequency superconducting pairing in topological insulators , ANNICA BLACK-SCHAFFER, Uppsala University, ALEXANDER BALATSKY, NORDITA — We discuss the appearance of odd-frequency spin-triplet s-wave superconductivity, first proposed by Berezinskii [J. Exp. Theor. Phys. 20 287 (1974)], on the surface of a topological insulator proximity coupled to a conventional spin-singlet s-wave superconductor. Using both analytical and numerical methods, we show that this disorder robust odd-frequency state is present whenever there is an in-surface gradient in the proximity induced gap. Such a gradient exists in both superconductor-normal state junctions as well as when an in-surface supercurrent is present. The time-independent order parameter for the odd-frequency superconductor is proportional to the in-surface gap gradient. The induced odd-frequency component does not produce any low-energy states.

1:27PM N13.00010 Detection of one-dimensional helical mode in topological insulator nanowire interferometer , SEUNG SAE HONG, YI ZHANG, JUDY CHA, XIAO-LIANG QI, YI CUI, Stanford University — In topological insulators (TIs), the spin-momentum locking together with time reversal symmetry (TRS) protects surface electrons from localization, which is the defining signature of TIs and the key property to realize exotic physics and applications. In quasi-one-dimensional (1D) TI nanowires, the surface electrons form 1D quantum modes of different topological natures, allowing us to observe topological protection via quantum interference modulated by magnetic flux[1,2]. We report low-temperature transport of bismuth selenide (Bi2Se3)-Se core-shell nanowire devices in parallel magnetic fields. Magneto-oscillations of different physical origins are studied systematically in ballistic regime and diffusive regime. Especially at strongly disordered limit, we observe a topologically-protected helical 1D mode at half magnetic flux quantum (h/2e). The quantum interference under TRS breaking magnetic field will be discussed as well.

1:39PM N13.00011 ABSTRACT WITHDRAWN –

1:51PM N13.00012 Superconducting Proximity Effect in Topological Insulators , ANDREW BESTWICK, MELIS TEKANT, JAMES WILLIAMS, DAVID GOLDHABER-GORDON, Stanford University, KEHUI WU, YONGQIN LI, Institute of Physics Chinese Academy of Sciences, JAMES ANALYTIS, University of California, Berkeley, ANDREW BLEICH, IAN FISHER, Stanford University — Superconductor-topological insulator interfaces are prime candidates in the search for Majorana fermions in the solid state. We report on recent transport measurements of proximity-induced superconductivity through topological insulators with varying chemical compositions and growth methods. We will discuss the Josephson effect, tunneling spectroscopy, and measurement of normal-state conduction channels as means to detect Majorana states.

2:03PM N13.00013 Transport study on tunnel junction structures based on In2Se3/Bi2Se3 heterostructures , NIKESH KOIRALA, MATTHEW BRAHLEK, Department of Physics, Rutgers University, NAMRATA BANSAL, Department of Electrical Engineering, Rutgers University, SEONGSHIK OH, Department of Physics, Rutgers University — Bi2Se3 is a 3D Topological Insulator (TI) candidate material with structural similarity to In2Se3, which is a band insulator with large band gap. This compatibility leads to possibility of epitaxial growth of In2Se3/Bi2Se3 heterostructure, which has various application potential. For example, by depositing Superconducting or Ferromagnetic materials on top of this heterostructure, tunnel junctions can be fabricated. We have studied device structures made up of such tunnel junctions. In2Se3 was grown on top of Bi2Se3 using molecular beam epitaxy on Al2O3(0001) substrates. Superconductor (Nb) or Ferromagnet (CoFe, Gd) was then sputtered on top of In2Se3 and photolithography was used to make the tunnel junctions. Transport measurement data obtained from such structures will be presented.

Wednesday, March 20, 2013 11:15AM - 2:15PM –

Session N14 DMP FIAP GMAG: Focus Session: Spin-dependent Tunneling and High Magnetoresistance Devices 316 - See-Hun Yang, IBM Almaden Research Center

11:15AM N14.00001 Optimizing Co concentration in $Co_xFe_{1-x}/MgO/Co_xFe_{1-x}$ magnetic tunnel junctions to maximize tunneling magnetoresistance[1] , JONATHAN TRINASTIC, YAN WANG, HAI-PING CHENG, Department of Physics and Quantum Theory Project, University of Florida, Gainesville, FL 32611 — $Fe_{1-x}Co_x$ /MgO magnetic tunnel junctions (MTJs) are of great experimental interest due to large differences in conductance between parallel and anti-parallel spin alignment in the electrodes that lead to high tunneling magnetoresistance (TMR). However, the optimal Co concentration in the electrodes that maximizes TMR is still under investigation (Bonell et al 2012,*PRL*,108,176602). Using first-principles calculations, we compare the conductance and TMR of $Fe_{1-x}Co_x$/MgO junctions using 1) disordered electrodes modeled with the virtual crystal approximation (VCA), and 2) ordered $Fe_{0.75}Co_{0.25}$ and $Fe_{0.50}Co_{0.50}$ electrodes. For disordered electrodes, we find that the optimal Co concentration varies between 20 and 30 percent and TMR decreases with MgO barrier thickness. For ordered electrodes, pure Co electrodes exhibit the highest TMR for a thin MgO barrier; however, $Fe_{0.75}Co_{0.25}$ electrodes demonstrate the highest TMR for a thicker MgO barrier, replicating recent experimental results. In all cases, a decrease in anti-parallel transmission drives the TMR increase.

11:27AM N14.00002 Large Magnetoresistance of MnBi/Bi/MnBi Spin Valve , NABIL AL-AQTASH, University of Nebraska at Omaha , KHALDOUN TARAWNEH, Princess Sumaya University for Technology, Amman, Jordan, RENAT SABIRIANOV , University of Nebraska at Omaha — Recently, a large transport spin polarization was demonstrated in MnBi films by Andreev reflection experiments [1]. Furthermore, a large magnetoresistance (MR) of 70% was observed in MnBi junctions at room temperature [2]. Because of this, a spin-valve MnBi/Bi/MnBi device is promising to have large MR that can be controlled by the varying the thickness of Bi spacer. Thin films of Bi show a semimetal-semiconductor transition at reduced thicknesses. Bismuth itself shows a substantial MR and a large mean free path of electron. In this system both the electrodes and the spacer have a hexagonal unit cell. A transport magetoresistance of MnBi/Bi(6 layers)/MnBi film was calculated using density functional theory coupled with nonequilibrium Green's function method as implemented in SIESTA code. The calculations display a high transport spin polarization of MnBi. A transmission MR of the spin valve around 77% is calculated, consistent with the previous experimental observation of a large magnetoresistance in MnBi contacts. Thus, MnBi is promising candidate for high MR devices with tunable spacer properties. [1] P. Kharel, P. Thapa, P. Lukashev, R. F. Sabirianov, E. Y. Tsymbal, D. J. Sellmyer, and B. Nadgorny, Phys. Rev. B 83, 024415 (2011) [2] E. Clifford, M. Venkatesan and J. M. D. Coey, J. Mag. Magn. Mater. 272-276, 1614(2004).

11:39AM N14.00003 Self-Organized Defects of Half-Metallic Nanowires in MgO-Based Magnetic Tunnel Junctions , MASAYOSHI SEIKE, TETSUYA FUKUSHIMA, KAZUNORI SATO, HIROSHI KATAYAMA-YOSHIDA, Grad. School of Eng. Sci., Osaka Univ. — The purpose of this study is to examine the possibility of self-organization of defects and defect-induced properties in MgO-based magnetic tunnel junctions (MTJs). Using the Heyd-Scuseria-Ernzerhof (HSE06) hybrid functional, first-principles calculations were performed to estimate the electronic structures and total energies of MgO with various defects. From our thorough evaluation of the calculated results and previously reported experimental data, we propose that self-organized half-metallic nanowires of magnesium vacancies can be formed in MgO-based MTJs. This self-organization may provide the foundation for a comprehensive understanding of the conductivity, tunnel barriers and quantum oscillations of MgO-based MTJs. Further experimental verification is needed before firm conclusions can be drawn.

11:51AM N14.00004 Mechanisms of perpendicular magnetic anisotropy and interlayer exchange coupling in MgO-based tunnel junctions[1] , MAIRBEK CHSHIEV, SPINTEC, CEA/CNRS/UJF-Grenoble 1, INAC, 38054 Grenoble, France — Magnetic tunnel junctions (MTJ) comprising ferromagnetic (FM) electrodes with MgO spacer have been an object of high interest for spintronics due to Bloch states symmetry spin filtering leading to high tunnel magnetoresistance (TMR) [1] and due to observation of antiferromagnetic (AF) coupling between FM electrodes across MgO spacer [2]. This attention have been strongly reinforced in a view of a huge interest in MTJs with perpendicularly magnetized magnetic layers (p-MTJs) originating from large values of interfacial perpendicular magnetic anisotropy (PMA) first observed at Pt|Co|MOx interfaces (M=Ta, Mg, Al, Ru...) [3,4] and later reported for Co|MgO [4,5] and CoFeB|MgO p-MTJs [6]. In this talk we will elucidate mechanisms responsible for the PMA from first-principles [7] and report the effect of interfacial oxidation conditions on the PMA in Fe(Co)|MgO p-MTJs. In particular, we found very large PMA values for MTJs with pure interfaces in agreement with recent experiments [4,6]. Furthermore, it will be demonstrated that oxidation conditions strongly affect the PMA which strongly correlates with TMR in agreement with experiments [7,8]. Finally, we will discuss the origin of AF coupling in Co|MgO p-MTJs which oscillates as a function of FM layer thickness in agreement with theories of interlayer exchange coupling in MTJ [5].

12:27PM N14.00005 Point-contact study of soft magnetic CoSiBFeNb amorphous alloys[1] , HEIDI SEINIGE, CHENG WANG, University of Texas at Austin, USA, VALERII TSOI, Institute of Solid State Physics, Chernogolovka, Russia, MAXIM TSOI, University of Texas at Austin, USA — We study magnetotransport in nanoscale point contacts to soft magnetic CoSiBFeNb ribbons. Such ultrasoft amorphous alloys attracted considerable attention previously because they exhibit Giant Magnetoimpedance (GMI) effect - large variations in the electrical impedance as a function of an external magnetic field [see, for instance, M.-H. Phan, H.-X. Peng, Prog. Mater. Sci. 53, 323 (2008) and references therein]. GMI is attributed to the field-induced variations in alloy permeability and has been established through ac measurements on bulk samples which revealed a strong dependence on ac frequency and amplitude but did not show any variations in dc resistance at all. In our experiments, we use nanocontacts to probe magnetotransport in amorphous CoSiBFeNb at the nanoscale. We use point contacts to inject both ac and dc currents into the alloy ribbons prepared by a melt-spinning technique. Measurements with ac currents revealed GMIs similar to those in macroscopic samples. Interestingly, we also observe a dc magnetoresistance which may be attributed to magnetic domain reorientations in a small contact region. Effects of high dc densities on the magnetoresistance are discussed in terms of spin-transfer torque (STT) effect. We thank A. Serebryakov for providing ribbon samples.

12:39PM N14.00006 Measurement of the transport spin polarization of Ag/Fe_3O_4 bilayers using point-contact Andreev reflection[1] , MICHAEL OSOFSKY, Naval Research Laboratory, PRIYANGA JAYATHILAKA, CASEY W. MILLER, Department of Physics, University of South Florida — The development of point-contact Andreev reflection (PCAR) has provided a relatively simple method for determining the spin polarization of various ferromagnetic materials. This technique utilizes point contact tunneling from a superconducting tip into a ferromagnet (FM) as a probe of the spin-polarization of the FM. Quantitative information can be extracted from the conductance data through a modified Blonder, Tinkham, Klapwijk (BTK) model of supercurrent conversion at a superconductor-metal interface (Andreev reflection) which includes the spin-polarization of the normal metal. The 100% spin polarized oxide, Fe_3O_4, which is insulating at low temperature, is of great interest for spintronics applications. In order to use PCAR to measure the spin polarization of this system, it is necessary to provide a conducting layer. In this talk we will describe the results of PCAR measurements of Ag/Fe_3O_4 bilayers as a function of Ag thickness.

12:51PM N14.00007 3D Effect in Determination of Spin Polarization using Andreev Reflection Spectroscopy , JESSICA GIFFORD, CHARLES SNIDER, JONNY MARTINEZ, TINGYONG CHEN, Arizona State University — Andreev Reflection Spectroscopy (ARS) has been utilized to measure spin polarization of magnetic materials, as well as the superconducting gap of superconductors. These values are extracted by a modified Blonder-Tinkham-Klapwijk (BTK) model or the more recent Chen-Tesanovic-Chien (CTC) model. Both consider the F/S interface as one dimensional (1D). However, a tip may have a point angle with three dimensional (3D) effects. We present both theoretical and experimental studies of the 3D effects in the determination of spin polarization. We have found that for an ideal interface without interfacial scattering (Z), the 3D ARS spectra are the same as 1D spectra. But for non-ideal interfaces the 3D effect can drastically change the conductance spectra depending on the point angle of the tip. The 3D spectra can be well described by the 1D model with a different interfacial scattering factor and a slightly different inelastic scattering factor. The spin polarization and superconducting gap is the same as the1D model, demonstrating that 1D ARS model can be utilized to determine spin polarization as long as Z is not of any concern. Finally, we apply the both the 1D and the 3D models to a set of ARS data and show that the extracted spin polarization value is the same for both models.

1:03PM N14.00008 Graphene-based magnetic tunnel junctions , ENRIQUE COBAS, Naval Research Laboratory — Graphene's in-plane transport has been widely researched and has yielded extraordinary carrier mobilities of 10^5 cm^2/Vs and spin diffusion lengths of exceeding 100μm. These properties bode well for graphene in future electronics and spintronics technologies. Its out-of-plane transport has been far less studied, although its parent material, graphite, shows a large conductance anisotropy. Recent calculations [1,2] show graphene's interaction with close-packed ferromagnetic metal surfaces should produce highly spin-polarized transport out-of-plane, an enabling breakthrough for spintronics technology. In this work, we fabricate and measure FM/graphene/FM magnetic tunnel junctions using CVD-grown single-layer graphene. The resulting juctions show non-linear current-voltage characteristics and a very weak temperature dependence consistent with charge tunneling transport. Furthermore, we study spin transport across the junction as a function of bias voltage and temperature. The tunneling magnetoresistance (TMR) peaks at two percent for single-layer graphene junctions and exhibits the expected bias asymmetry and a temperature dependence that fits well with established spin-polarized tunneling models. [3] Results of mutli-layer graphene tunnel junctions will also be discussed.

1:39PM N14.00009 Magnetic Tunnel Junctions with a Graphene Tunnel Barrier , WAN LI, DANIEL RALPH, Cornell University — We have fabricated ferromagnet/graphene/ferromagnet (FM/Gr/FM) junctions in which current flows vertically so that the graphene acts as a single-atom-thick barrier. In contrast to previous work, we utilize a fabrication process that avoids oxidation of the magnetic electrodes. We measure typical resistance-area products significantly lower than previously reported. We will present an analysis of whether this difference is due to the absence of a magnetic oxide or to defects in the graphene. We will also discuss the magnetoresistance of these devices, and how both the resistance and the magnetoresistance depend on the quality of the graphene.

1:51PM N14.00010 Magnetoresistance and negative differential resistance in Ni/Graphene/Ni vertical heterostructures driven by finite bias voltage: A first-principles study[1] , KAMAL K. SAHA, University of Delaware, USA, ANDERS BLOM, QuantumWise A/S, Denmark, KRISTIAN S. THYGESEN, Technical University of Denmark, BRANISLAV K. NIKOLIC, University of Delaware, USA — Using the nonequilibrium Green function formalism combined with density functional theory, we study finite-bias quantum transport in Ni/Gr$_n$/Ni vertical heterostructures where n graphene layers are sandwiched between two semi-infinite Ni(111) electrodes. We find that recently predicted pessimistic magnetoresistance of 100% for $n \geq 5$ junctions at zero bias voltage $V_b \to 0$, persists up to $V_b \simeq 0.4$ V, which makes such devices promising for spin-torque-based device applications. In addition, for parallel orientations of the Ni magnetizations, the $n = 5$ junction exhibits a pronounced negative differential resistance as the bias voltage is increased from $V_b = 0$ V to $V_b \simeq 0.5$ V. We confirm that both of these nonequilibrium transport effects hold for different types of bonding of Gr on the Ni(111) surface while maintaining Bernal stacking between individual Gr layers.

2:03PM N14.00011 Large spin accumulation due to spin-charge coupling across a break-junction[1] , SHUHAN CHEN, HAN ZOU, SIU-TAT CHUI, YI JI, Dept. of Physics, Univ. of Delaware — We investigate large spin signals in break-junction nonlocal spin valves (NLSV). The break-junction is a nanometer-sized vacuum tunneling gap between the spin detector and the nonmagnetic channel, formed by electro-static discharge. The spin signals can be either inverted or non-inverted and the magnitudes are much larger than those of standard NLSV. Spin signals with high percentage values (10% - 0%) have been observed. When the frequency of the a.c. modulation is varied, the absolute magnitudes of signals remain the same although the percentage values change. These observations affirm the nonlocal nature of the measurements and rule out local magnetoresistive effects. Owing to the spin-charge coupling across the break-junction, the spin accumulation in a ferromagnet splits into two terms. One term decays on the charge screening length (0.1 nm) and the other decays on the spin diffusion length (10 nm nm). The magnitude of the former is proportional to the resistance of the junction. Therefore a highly resistive break-junction leads to a large spin accumulation and thereby a large spin signal. The signs of the spin signal are determined by the relationship between spin-dependent conductivities, diffusion constants, and density of states of the ferromagnet.

Session N15 GMAG DMP: Focus Session: Frustration in 1D and Spinels 317 - Craig Fennie, Cornell University

11:15AM N15.00001 Block versus Stripy Antiferromagnetism in the Fe-Based Spin-Ladder Materials (Ba,K)Fe_2Se_3[1] , WEI-GUO YIN, LIMIN WANG, WEI KU, Brookhaven National Laboratory — We present a theoretical study of the novel magnetism in the insulating two-leg spin-ladder material $Ba_{1-x}K_xFe_2Se_3$, which exhibits a spontaneous formation of block and stripy antiferromagnetic spin orders in the Ba and K end members, respectively, and spin glass behavior in between. The bare spin susceptibility calculated with the first-principles electronic structure is found to remain qualitatively unchanged upon hole doping (substitution of K for Ba), ruling out the simple scenario of Fermi surface nesting. We show that these doping-dependent spin orders can be explained by use of a model of coexisting itinerant and localized electronic states on the Fe atoms, which are coupled by Hund's rule coupling. Our results reveal a strong spin frustration coming from the competing antiferromagnetic superexchange and ferromagnetic double-exchange interactions in this system, and unify its magnetism with that of the iron-based superconductors [1,2]. 11:27AM N15.00002 Optical Reflection Study of Low-Dimensional Quantum Magnets[1] , JUDY CHERIAN, National High Magnetic Field Laboratory; Dept. of Physics, Florida State University, TAKAHISA TOKUMOTO, National High Magnetic Field Laboratory, HAIDONG ZHOU, National High Magnetic Field Laboratory; Dept. of Physics, University of Tennessee, STEPHEN MCGILL, National High Magnetic Field Laboratory — We performed a linear optical reflection analysis of a low-dimensional, frustrated quantum magnet. Strongly-correlated low-dimensional systems are important for understanding spin-excitations, which form an important class of low-energy phenomena. Of particular interest are how these spin excitations arise and are then tuned by the environment (e.g. temperature, applied magnetic field). The temperature dependence of the reflection spectra from 215 K down to 4 K was measured. Magnetic field dependence of the reflection spectra from 0 T to 35 T was also measured. We will discuss the behavior of the reflection edge with temperature and magnetic field and its correlation with spin excitations.

[1]This work is supported by the NHMFL through an UCGP grant

11:39AM N15.00003 Non-Fermi liquid d-wave metal phase of strongly interacting electrons on the two-leg ladder , RYAN V. MISHMASH, UCSB, HONG-CHEN JIANG, KITP, MATTHEW S. BLOCK, UK, Lexington, JAMES R. GARRISON, UCSB, D. N. SHENG, CSU, Northridge, OLEXEI I. MOTRUNICH, Caltech, MATTHEW P. A. FISHER, UCSB — Developing a theoretical framework for conducting electronic fluids qualitatively distinct from those described by Landau's Fermi liquid theory is of central importance to many outstanding problems in condensed matter physics. Perhaps the most important such pursuit is a microscopic characterization of the cuprates, where the so-called "strange metal" behavior above T_c near optimal doping is inconsistent with being a traditional Landau Fermi liquid. Indeed, a microscopic theory of such a strange metal quantum phase could possibly shed new light on the interesting low-temperature behavior in the pseudogap and on the d-wave superconductor itself. Here, we present a theory for a specific example of a strange metal, which we term the "d-wave metal." Using variational wave functions, gauge theoretic arguments, and ultimately large-scale DMRG calculations, we establish compelling evidence that this remarkable quantum phase is the ground state of a reasonable microscopic Hamiltonian: the venerable t-J model supplemented with a frustrated electron ring-exchange term, which we study extensively here on the two-leg ladder. These findings constitute one of the first explicit examples of a non-Fermi liquid metal existing as the ground state of a realistic model.

11:51AM N15.00004 Moving toward two dimensions in a t-J-K model with frustrating ring exchange: the quest to stabilize a non-Fermi liquid d-wave metal phase , JAMES R. GARRISON, UCSB, HONG-CHEN JIANG, KITP, RYAN V. MISHMASH, UCSB, BRYAN K. CLARK, Station Q, OLEXEI I. MOTRUNICH, Caltech, MATTHEW P. A. FISHER, UCSB — Recent work (arXiv:1207.6608) has established compelling evidence, on the two-leg ladder, for the existence of a non-Fermi liquid strange metal phase as the ground state of a realistic model Hamiltonian—the t-J model supplemented with a frustrating ring-exchange term. Here we present our findings, guided by VMC and DMRG calculations, as we move toward two dimensions in an attempt to fully characterize the phase diagram and to stabilize this "d-wave metal" phase beyond the two-leg ladder. Ultimately, we are motivated by a desire to understand the strange metal phase in the cuprates, and to determine whether the superconductor and pseudo-gap regimes can potentially be understood as instabilities of the d-wave metal phase resulting from this (or a similar) model Hamiltonian.

12:03PM N15.00005 Nontrivial ferrimagnetism on the low-dimensional quantum spin systems with frustration , TOKURO SHIMOKAWA, Kobe University, HIROKI NAKANO, University of Hyogo, TORU SAKAI, Japan Atomic Energy Agency, SPring-8 — In low-dimensional quantum spin systems with frustration, nontrivial magnetisms often occur due to strong quantum fluctuation. Ferrimagnetism in non-frustrated systems is well-known to occur from the mechanism based on the Marshall-Lieb-Mattis theorem. This type of ferrimagnetism is called "Lieb-Mattis (LM) type." Recently, the occurrence of nontrivial ferrimagnetism has been reported in some one-dimensional Heisenberg spin systems with frustration, in which the continuous change of spontaneous magnetization and the incommensurate modulation in local magnetization are observed. This type is called "non-Lieb-Mattis (NLM) type." In this study, we tackle a problem whether the NLM ferrimagnetism occurs or not in higher dimensional systems. We investigate the S=1/2 Heisenberg models on the spatially anisotropic two-dimensional (2D) kagome lattice and on the quasi-one-dimensional (Q1D) kagome strip lattices by the numerical diagonalization and density matrix renormalization group methods. The Q1D models share the same structure in their inner part with the spatially anisotropic 2D kagome lattice; we examine two cases with respect to strip width. We will discuss the relationship between the ground-state properties of the Q1D lattices and those of the 2D lattice.

12:15PM N15.00006 Theory of the NMR $1/T_1$ relaxation rate in a quantum spin nematic , ANDREW SMERALD, NIC SHANNON, Okinawa Institute of Science and Technology — Recently, it has been proposed that the material $LiCuVO_4$ may realise quantum spin-nematic order when a magnetic field close to saturation is applied [1,2]. Potentially, a bond-centred, 2-sublattice antiferroquadrupole spin-nematic state is stable at low temperature. However, the experimental evidence for this state remains inconclusive. Building on previous work [3], we develop a detailed theory of the NMR $1/T_1$ relaxation rate in spin-nematic states, and apply this to the specific case of $LiCuVO_4$. We show that $1/T_1$ in the proposed spin-nematic state has qualitatively different features to conventionally ordered magnets, and propose this as an unambiguous test of spin-nematic order.

12:27PM N15.00007 Double Magnetic Field-induced Phase Transitions in the Spin-1/2 Alternating Chain System $AgVOAsO_4$, FRANZISKA WEICKERT, Los Alamos Natl. Lab., Los Alamos, NM 87545, ALEXANDER A. TSIRLIN, MONIKA GAMZA, MPI for Chemical Physics of Solids, 01087 Dresden, Germany, ALBIN DEMUER, GHMFL, CNRS, 38042 Grenoble, France, ALEXANDER STEPPKE, MPI for Chemical Physics of Solids, 01087 Dresden, Germany, RAMESH NATH, Ames Laboratory, Ames, IA 50011, HELGE ROSNER, MPI for Chemical Physics of Solids, 01087 Dresden, Germany — The new spin-1/2 compound AgVOAsO4 shows one-dimensional magnetic behavior and a spin gap of about 14 K. The crystal structure of AgVOAsO4 is rather complex with alternating spin chains aligned along the [110] and [1$\bar{1}$0] direction. The experimental magnetic susceptibility yields values of 40 K and 26 K for J1 and J1′, respectively. The magnetization curve taken at 1.5 K cannot be fully described by only two coupling constants, which points to sizable inter chain coupling. Furthermore, the magnetization shows the closing of the spin gap at Hc1 =10.5 T and a saturation at Hc2=48.5 T. In the talk, we report the magnetic field - temperature (H-T) phase diagram of AgVOAsO4 measured by specific heat and magnetization experiments. The specific heat taken in high DC fields up to 28 T reveals a distinct double anomaly around 4 K and 2 K. Magnetization experiments follow this double structure down to mk temperatures and reveal a variety of anomalies close to the critical field Hc1 in AgVOAsO4.

12:39PM N15.00008 Order and excitations near quantum criticality in quasi-1D S=1/2 easy-plane antiferromagnet Cs2CoCl4 , GHEORGHE PASCUT, Rutgers, The State University of New Jersey, US, RADU COLDEA, University of Oxford, UK, FRANZ DEMMEL, ISIS Facility, UK, ZBIGNIEW TYLCZYNSKI, Adam Mickiewicz University, Institute of Physics, Poland — We explore the magnetic order and spin dynamics in the quasi-one-dimensional spin-1/2 easy-plane anisotropy antiferromagnet Cs2CoCl4 in a magnetic field applied close to the easy-plane which drives a transition from spontaneous long-range magnetic order to a gapped quantum paramagnet. The commensurate antiferromagnetic order observed at low fields is stable over a wide field range but is replaced by an incommensurate magnetic order (spin density wave) just below the transition to paramagnetic. The main result is the observation of the new incommensurate magnetic phase which was not seen experimentally prior to this work and was also not predicted theoretically. Deep in the paramagnetic phase the excitations are sharp, gapped magnons with minima at the incommensurate wavevectors of the magnetic order below BC = 2.36(2) T and the dispersion relations give values for the intra- and inter-chain couplings. In addition to one magnon excitations at high energies we also observe weak magnetic continuum scattering, which becomes stronger upon approaching the critical field from above and is attributed to multi-magnon transverse field scattering processes.

12:51PM N15.00009 Phase diagram of frustrated ladder and 2D antiferromagnets[1] , ALEXANDROS METAVITSIADIS, DANIEL SELLMANN, SEBASTIAN EGGERT, University of Kaiserslautern — We investigate the low energy properties of the frustrated two leg diagonal ladder exhibiting both intra- and inter-chain frustration. The renormalization group is used to obtain the phase diagram while varying the microscopic lattice parameters. We particularly emphasize the role of the in-chain marginal operators, which is tuned by the in-chain frustration and can promote a dimer phase in the system. Finally, the physics of the quasi one dimensional diagonal ladder is incorporated into a two dimensional square lattice since the former is used as the primary structure to build up the square lattice. Within the validity of our method, the classical phases—a Néel antiferromagnet and a collinear antiferromagnet—are predicted. The results are compared to numerical DMRG calculations.

[1]Supported by the DFG via the SFB/TR49

1:03PM N15.00010 Quantum criticality and fractional charge excitations in itinerant ice-rule systems , MASAFUMI UDAGAWA, HIROAKI ISHIZUKA, YUKITOSHI MOTOME, Dept. of Applied Physics, Univ. of Tokyo — "Ice rule" is a configurational constraint on Ising-type variables defined on tetrahedron-based lattices, such as a pyrochlore lattice, so that two out of the four sites on a tetrahedron are in the opposite state to the other two. This concept plays an important role in many systems, such as water ice I_h, magnetite Fe_3O_4, and spin ice materials $Ho(Dy)_2Ti_2O_7$. Under the ice-rule constraint, the ground state is disordered and retains macroscopic degeneracy. Nevertheless, the ice-rule configuration is not completely random but has a peculiar spatial structure with quasi-long-range correlation. It is interesting to ask how itinerant electrons change their properties by coupling to this anomalous spatial structure. To answer this problem, we adopt an extended Falicov-Kimball model as a minimal model, in which itinerant electrons interact with localized charge degrees of freedom under the ice rule. We exactly solve this model on a loop-less variant of the tetrahedron-based lattices, a tetrahedron Husimi cactus and clarify the ground-state phase diagram. The exact solution reveals a quantum critical point separating two insulating phases, where a novel non-Fermi-liquid behavior emerges. We also discuss the nature of fractional excitations breaking the ice-rule manifold.

1:15PM N15.00011 Doped Mott insulators in (111) bilayers of perovskite transition-metal oxides with the strong spin-orbit coupling[1] , SATOSHI OKAMOTO, Oak Ridge National Laboratory — We study the electronic properties of Mott insulators realized in bilayers of perovskite transition-metal oxides grown along the [111] crystallographic axis. The low-energy effective Hamiltonians for such Mott insulators are derived in the presence of the strong spin-orbit coupling. These models are characterized by the antiferromagnetic Kitaev interaction and the antiferromagnetic or ferromagnetic Heisenberg interaction depending on the d orbital occupancy. From exact diagonalization analyses on finite clusters, Kitaev spin liquid phases are shown to be confined in narrow parameter regimes. Slave-boson mean-field analyses indicate the possibility of non-trivial superconducting states induced by carrier doping into the Mott-insulating parent systems. We also discuss the possible experimental realization of these systems in $4d$ and $5d$ transition-metal oxides.

1:27PM N15.00012 ^{27}Al-NMR Study of the Spinel Compound $CoAl_2O_4$[1] , BEAS ROY, ABHISHEK PANDEY, DAVID C. JOHNSTON, YUJI FURUKAWA, Ames Laboratory & Dept. Phys. Astro., Iowa State Univ., Ames IA — $CoAl_2O_4$, a geometrically frustrated magnet, is believed to be located in the vicinity of a quantum melting point of the AFM ordered state. In $CoAl_2O_4$, magnetic frustration originates from $Co^{2+}(S = 3/2)$ spins on the tetrahedral A-site via non-magnetic Al ions occupying the octahedral B-site. To study the magnetic properties of $CoAl_2O_4$ from a microscopic point of view, we have carried out ^{27}Al-NMR measurements using a well-characterized powder sample of $CoAl_2O_4$. The temperature dependence of the magnetic susceptibility χ shows a broad peak around 15 K and does not show any difference in zero-field-cooled and field-cooled measurements. ^{27}Al-NMR spectra at 9.3 MHz (H = 0.84 T) show seven peaks characterized by quadrupolar splitting with ν_Q = 0.55 MHz at temperatures above 10 K. Below 10 K, the spectrum broadens suddenly. We also observe a peak of $1/T_1$ of ^{27}Al at 10 K. These NMR results clearly indicate magnetic ordering at 10 K, although χ does not exhibit any signature of long-range magnetic ordering.

1:39PM N15.00013 What controls the sign of exchange-induced phonon splitting in ACr_2O_4 spinels? , ALEKSANDER WYSOCKI, TURAN BIROL, CRAIG J. FENNIE, School of Applied and Engineering Physics, Cornell University — The interplay of spin and lattice degrees of freedom can lead to a variety of fundamentally and technologically interesting phenomena. In ACr_2O_4 spinels, it has been well established that antiferromagnetic order alone can lower the symmetry of a crystal resulting in a splitting of degenerate phonon frequencies without any structural distortion. A simple model based on nearest neighbor exchange striction has been proposed and confirmed by a novel first-principles approach. Recently however it has been suggested that magnetically induced phonon splitting is universally controlled by the nondominant exchange interaction. In this talk we present our recent first principles study of magnetically induced phonon anisotropy in ACr_2O_4 (A=Mg, Zn, Cd, Hg) spinels. We demonstrate that the different spin ordering patterns observed in the different spinel compounds can lead to an opposite sign of phonon splitting. This naturally explains the difference in sign experimentally observed for $ZnCr_2O_4$ compared with $CdCr_2O_4$, which have very different magnetic ground states. Additionally, we show that the *ab initio* values for the phonon frequencies can be very well fitted to the previously proposed spin-phonon coupling model including only the nearest neighbor exchange interaction.

1:51PM N15.00014 Competing Jahn-Teller and spin Jahn-Teller ordering in $A\mathrm{Cr_2O_4}$ spinels[1] , MOUREEN KEMEI, Materials Department and Materials Research Laboratory University of California, Santa Barbara, California 93106, USA, STEPHANIE MOFFITT, Materials Science and Engineering Department Northwestern University, Evanston, Illinois 60208, USA, MATTHEW SUCHOMEL, X-Ray Science Division Argonne National Laboratory, Argonne, Illinois 60439, USA, DANIEL SHOEMAKER, Material Science Division Argonne National Laboratory, Argonne, Illinois 60439, USA, RAM SESHADRI, Materials Department and Materials Research Laboratory University of California, Santa Barbara, California 93106, USA — Magnetic ordering is strongly linked to structural distortions in the frustrated antiferromagnets $ZnCr_2O_4$ and $MgCr_2O_4$. These systems undergo spin Jahn-Teller distortions at the onset of magnetic order. The addition of magnetic A site cations in ACr_2O_4 spinels can relieve frustration. High-resolution variable-temperature synchrotron powder X-ray diffraction, detailed magnetic studies, and heat capacity measurements show that dilute amounts of Jahn-Teller active Cu^{2+} or Co^{2+} on the A sites of these spinels have different effects on structure but similar effects on magnetism. Partial replacement of A by Cu^{2+} generates Jahn-Teller distortions at temperatures above the endmember Neel temperatures, yet spin interactions remain frustrated to ~ 12 K. This contrasts with Co^{2+} substitution which also maintains frustration, but results in a suppression of spin Jahn-Teller ordering in $ZnCr_2O_4$. We report decoupled Jahn-Teller and spin Jahn-Teller ordering in the canonical frustrated systems $ZnCr_2O_4$ and $MgCr_2O_4$ that is tunable by varying the identity of the magnetic A site substituent.

2:03PM N15.00015 Volume Sensitivity and Effect of Fluctuations on the Frustrated Magnetism in $\mathrm{YMn_2}$, BRIAN P. NEAL, WARREN E. PICKETT, UC Davis — Cubic Laves phase (C15) YMn_2 with its highly frustrated pyrochlore type sublattice of Mn sites, is one of a small but growing class of ordered magnets that lie close to a quantum critical point at stoichiometry. Its ground state displays long-spiral helical magnetic order that is highly sensitive to volume, disappearing due the substitution of 3% Sc for the larger Y atom (chemical pressure), or by application of just 0.4 GPa pressure. The large change of volume (5%) upon ordering ($T_N = 100$ K) argues for itinerant magnetism, and in recent years there have been developments in modeling magnetic fluctuations in itinerant magnets near the ordering point. We extend earlier results of Terao and Yamada on the first principles based energetics versus volume, and quantify the sensitivity of the magnetic state to pressure. The effects of fluctuations within an itinerant picture will be discussed.

Session N16 GMAG DMP: Focus Session: Molecules on Surfaces

318 - Sebastian Loth, Center for Free-Electron Laser Science, Hamburg

11:15AM N16.00001 Kondo-like Resonances in the high spin MnPc. Atomic and Molecular Theoretical Approach , MARIA SORIANO, Autonomous University of Madrid. Madrid. Spain, DAVID JACOB, Max Planck Institute of Microstructure Physics. Halle (Saale). Germany, JUAN JOSE PALACIOS, Autonomous University of Madrid. Madrid. Spain — In recent years, Kondo−like resonances have been measured by different experimental groups in the 3\2 high spin Manganese Phthalocyanine (MnPc) on different kinds of surfaces [1,3]. With the aim to understand these resonances we have performed Dynamical Mean Field Theory calculations based on models extracted from Density Functional Theory calculations and Green's function formalism [4,5]. Two types of models are considered: one based on atomic d orbitals and one based on frontier molecular orbitals which contain the spin of the molecule.

11:27AM N16.00002 DFT+U studies of atomic scale magnetism: A curious case study for future spintronic devices[1] , SHRUBA GANGOPADHYAY, IBM Almaden Research Center, HOSSEIN HASHEMI, University of Michigan, BARBARA JONES[2], IBM Almaden Research Center — Atomic scale magnetism attracts interest due to both its possible application to nanoscale spintroic devices, and due to its inherent interest as a source of basic quantum mechanical interactions. We work together with the local Scanning Tunneling Microscopy (STM) team to match our calculations to experiment, and in the process learn much which can't be measured with the STM. In particular we use DFT+U to calculate the properties of magnetic atoms on nanolayers of insulator on top of a metal such as silver. In this talk we report the results of detailed calculations of singles and dimers of Mn on MgO/Ag. As time permits we may include our calculations of other magnetic adatoms for comparison. We find that the local interactions are very different for the three stable binding sites on this surface, both for charge and spin densities. Using on onsite Hubbard U parameter which we determine from first principles, we are able to study the variability of the magnetic moment between the binding sites, as well as determine the lowest energy binding site. The magnetic adatoms affect the surrounding interface layer in unexpected ways. We are able to obtain interesting insights which help us understand how magnetism propagates along surfaces as well as between interfaces.

11:39AM N16.00003 High magnetic anisotropy of magnetic atoms on thin MgO films on Ag(001) , SUSANNE BAUMANN, ILEANA G. RAU, CHRISTOPHER P. LUTZ, ANDREAS J. HEINRICH, IBM Almaden Research Center — High quality thin films of magnesium oxide on silver (MgO/Ag(001)) are obtained by magnesium evaporation in an oxygen atmosphere. MgO is often used as insulating layer in magnetic tunnel junctions. Therefore, the interplay of magnetic atoms with MgO is of interest e.g. to the hard drive industry. We characterize the thin films by a combination of scanning tunneling microscopy (STM) and atomic force microscopy (AFM). In particular, we determine the thickness of the deposited layers by a combined use of the two tools. We find that single transition metal atoms, such as Iron and Cobalt, deposited on the thin oxide film show inelastic tunneling steps at higher voltages compared to other insulating layers. The inelastic tunneling spectroscopy (IETS) is used to detect the discrete spin excitations of these atoms. The measured IETS steps indicate high magnetic anisotropies.

11:51AM N16.00004 Magnetic excitations of molecular spins on a superconductor , KATHARINA J. FRANKE, Freie Universitaet Berlin — Single magnetic molecules on a superconducting substrate present a model system to study the influence of a local magnetic moment on the superconducting state at the atomic scale. The magnetic moment of the adsorbate interacts with the Cooper pairs by exchange coupling and tends to break them apart [1]. Signatures of this interaction are localized states in the superconducting gap, which can be probed by tunneling spectroscopy [2,3]. On the other hand, the quasi-free electrons in the substrate screen the localized spin via the Kondo effect. The delicate balance between these phenomena determines the resulting ground state of the system. Using scanning tunneling spectroscopy, we show that the interaction of paramagnetic molecules with a superconducting lead surface is very sensitive to the details of the atomic scale surrounding [4]. Depending on the interaction strength, the magnetic moment is able to perturb the Cooper pairs, or the superconducting state is unaffected.

12:27PM N16.00005 Probing superexchange coupling in atomically fabricated d-metal complexes , BENJAMIN BRYANT, ANNA SPINELLI, MARJOLEIN GERRITS, SANDER OTTE, Kavli Institute of Nanoscience, Delft University of Technology — Magnetic coupling between transition metal atoms that are linked through ligand p-orbitals relies on the virtual exchange of electrons between neighboring sites. The characteristics of the resulting superexchange coupling rely on a complex interplay between electron hopping and Coulomb interaction. In this talk I will review recent experiments on individual superexchange coupled d-metal atoms placed inside a covalent surface network. By using low temperature scanning tunneling microscopy, Fe atoms may be positioned in a Cu_2N lattice with atomic precision, and their quantum-magnetic properties probed. Our experiments reveal novel insights into the resulting p-orbital mediated magnetic coupling, that are of importance in the fields of molecular magnetism and strongly correlated transition metal oxides.

12:39PM N16.00006 Exploring the magnetic properties of metallophthalocyanines on a thin insulator , BEN WARNER, London Center for Nanotechnology; Department of Physics & Astronomy, UCL, FADI EL HALLAK, London Center for Nanotechnology, GABRIEL AEPPLI, London Center for Nanotechnology; Department of Physics & Astronomy, UCL, MATS PERSSON, Department of Chemistry/Surface Science Research Centre, The University of Liverpool, CYRUS F. HIRJIBEHEDIN, London Center for Nanotechnology; Department of Physics & Astronomy, UCL; Department of Chemistry UCL — The scaling of electrical components to the atomic-scale limit has led to a great deal of interest in molecular electronics. Further proposals outline the use of magnetic molecules in new applications in information technology and spintronics. Since the electronic and magnetic properties of a molecule can be modified by interactions with the surfaces on which they are deposited, understanding these changes is of significant importance. Here we present studies of metal-doped pthalocyanine (MPc) molecules deposited on the thin insulator copper nitride (Cu_2N). FePc molecules have been shown to display a large magnetic anisotropy on copper oxide, which is also a thin insulator [1]. Using STM imaging and theoretical calculations we investigate how the interaction of the surface with the molecule varies and how this can affect the charge transport through the molecules. Through the application of a magnetic field and both elastic and inelastic spectroscopy, we gain access to the magnetic states of the molecule. In addition, by imaging the molecules at different bias voltages, we are able to probe the different molecular orbitals and explore how they are modified by interactions with the surface.

12:51PM N16.00007 Spin-resolved measurements of single molecular magnets on graphene , JENS BREDE, REGIS DECKER, JOERG SCHWOEBEL, MACIEJ BAZARNIK, ROLAND WIESENDANGER, Institute of Applied Physics, University of Hamburg — The use of magnetic molecules opens a gateway to a flexible design of novel spintronic devices to store, manipulate, and read spin information at the nanoscale. Crucial is the precise knowledge of molecular properties at the interface towards an electrode. Progress in this field relies on resolving and understanding the physics at the relevant interfaces. In particular the role of individual molecular constituents and the impact of the atomic environment on molecular properties determine device relevant parameters, such as conductance and spin polarization. Recently, the incorporation of a graphene sheet to electronically decouple molecules from a ferromagnetic surface has been addressed by surface averaging high-resolution electron energy loss spectroscopy. Here, we applied spin-polarized scanning tunneling microscopy to resolve the physics of the molecule-graphene-ferromagnet interface. The analysis focuses on different phthalocyanine molecules adsorbed on cobalt-intercalated graphene on Ir(111). The phthalocyanine constitutes of an organic macrocyclic ligand and can be functionalized with various metal ions in order to modify, e.g. the molecular spin state. We will discuss the spin-dependent transport from magnetic surfaces through such molecules. In particular, the spin polarization of molecular frontier orbitals is resolved with sub-molecular spatial resolution and the variations in the lifetimes of different orbitals are discussed.

1:03PM N16.00008 A first-principles study of a single-molecule magnet Mn12 adsorbed on Bi(111)[1] , KYUNGWHA PARK, Department of Physics, Virginia Tech, Blacksburg, VA 24061, USA, JUN-ZHONG WANG, School of Physical Science and Technology, Southwest Univ., Chongqing 400715, China — Recently, elemental Bi and Bi-based alloys have attracted a lot of attention due to unique quantum properties of their surface states induced by strong spin-orbit coupling. A single-molecule magnet Mn12 is known to be a prototype molecular magnet with significant magnetic anisotropy caused by spin-orbit coupling. Despite a great effort to fabricate monolayers of single-molecule magnets on various substrates, there are few studies of single-molecule magnets on strongly spin-orbit coupled substrates. Here we present our theoretical study of electronic and magnetic properties of single-molecule magnets Mn12 adsorbed on a strongly spin-orbit coupled semi-metallic Bi surface without any linker molecules. This work was motivated by a recent low-temperature scanning tunneling microscopy (STM) experiment where individual single-molecule magnets Mn12 were grafted on Bi. We apply density-functional theory (DFT) including on-site Coulomb repulsion U and self-consistent spin-orbit coupling, to two adsorption geometries of Mn12 on Bi. We compare our calculated electronic and magnetic properties of the Mn12 molecule on Bi with those of an isolated Mn12.

1:15PM N16.00009 STM Studies of Mn_{12}-Ph , K. REAVES, Texas A&M University Materials Science & Engineering,Texas A&M University Department of Physics & Astronomy, WPI-AIMR Tohoku University, K. KIM, K. IWAYA, T. HITOSUGI, WPI-AIMR, Tohoku University, H. ZHAO, K.R. DUNBAR, Texas A&M University Department of Chemistry, H.G. KATZGRABER, Texas A&M University Department of Physics and Astronomy, ETH Zurich Theoretische Physik, W. TEIZER, Texas A&M University Materials Science & Engineering,Texas A&M University Department of Physics & Astronomy, WPI-AIMR Tohoku University — Mn_{12}-Ph displays tunneling of quantized magnetization below 3K. In other Mn_{12} ligand variants this magnetic behavior can alter the electronic behavior of the molecule making them good candidates for a molecular logic gate or q-bit. $Mn_{12}O_{12}(C_6H_5COO)_{16}$ (referred to as Mn_{12}-Ph) has a Mn_{12} core with 16 Phenyl ligands and is deposited via spray injection onto surfaces of highly oriented pyrolytic graphite (HOPG) and other surfaces. We report Mn_{12}-Ph in isolation, resembling single molecules with metallic core atoms and organic outer ligands. The local tunneling current observed within the molecular structure shows a strong bias voltage dependence, which is distinct from that of the surface. Further, evidence of internal inhomogeneity in the local density of states has been observed with high spatial resolution, and this inhomogeneity appears to be due to localized metallic behavior. These results facilitate magneto-metric studies of single molecule magnets in isolation. As compared to bulk crystal studies, our experiments allow the specific investigation of atomic sites in individual molecules.

1:27PM N16.00010 Magnetic Relaxation in Iron Chains of Phthalocyanine Thin Films[1] , THOMAS GREDIG, DANIEL JAVIER, MATHEW WERBER, MATTHEW BYRNE, California State University Long Beach — Self-assembled iron chains are formed in metallo-organic thin films based on the small iron phthalocyanine molecule. The chains are grown parallel to the substrate and the mean chain length is controlled via deposition parameters from 30 – 300 nm. The strong intra-chain coupling with weak inter-chain coupling leads to ferromagnetic behavior below the critical temperature. After application of a magnetic saturation field, the remanent magnetic moment is not stable when measured over time scales of 10^4 s. The magnetic relaxation can be fit to a stretched exponential function, which yields the mean relaxation time and a stretch exponent. The temperature-dependent peak of the relaxation time occurs at lower temperatures for shorter iron chains that also have smaller coercivities. This means that by templating iron phthalocyanine thin films both magneto-crystalline anisotropy and inter-grain interactions can be selected.

1:39PM N16.00011 Binding Structures of Diatomic Molecules to Co-Porphyrins on Au(111) Studied by Scanning Tunneling Microscopy , SOON-HYEONG LEE, Department of Physics, Korea University, YUN HEE CHANG, Graduate School of Nanoscience and Technology (WCU), KAIST, HOWON KIM, WON JUN JANG, Department of Physics, Korea University, YONG-HYUN KIM, Graduate School of Nanoscience and Technology (WCU), KAIST, SE-JONG KAHNG, Department of Physics, Korea University, DEPARTMENT OF PHYSICS, KOREA UNIVERSITY COLLABORATION, GRADUATE SCHOOL OF NANOSCIENCE AND TECHNOLOGY (WCU), KAIST COLLABORATION — Axial bindings of diatomic molecules to metalloporphyrins involve in the dynamic processes of biological functions such as respiration, neurotransmission, and photosynthesis. The binding reactions are also useful in sensor applications and to control molecular spins in metalloporphyrins for spintronic applications. Here, we present the binding structures of diatomic molecules to surface-supported Co-porphyrins studied using scanning tunneling microscopy. Upon gas exposure, three-lobed structures of Co-porphyrins transformed to bright ring shapes on Au(111), whereas H2-porphyrins of dark rings remained intact. The bright rings are explained by the structures of reaction complexes where a diatomic ligand, tilted away from the axis normal to the porphyrin plane, is under precession. Our results are consistent with previous bulk experiments using X-ray diffraction and nuclear magnetic resonance spectroscopy.

1:51PM N16.00012 ABSTRACT WITHDRAWN –

2:03PM N16.00013 Molecule-induced Spin Rotation of Photoelectrons from FePc on Fe(110)[1] , ANDREAS SANDIN, J.E. (JACK) ROWE, DANIEL DOUGHERTY, North Carolina State University, ELIO VESCOVO, National Synchrotron Light Source, Brookhaven National Labs — We have studied sub-monolayers to multi-layers of iron phthalocyanine (FePc) adsorbed on $\sim$ 10-20 monolayer epitaxial films on Fe(110) on W(110). We find that the spin-resolved photoemission changes rapidly as a function of coverage and the initial (majority spin axis along [110] rotates by $\sim$ 30 degrees for sub-monolayer coverage and then becomes unpolarized at $\sim$ 1 monolayer (ML). The coverage is determined by work function measurements which show that the initial work function of clean Fe(110) of 5.0 eV decreases monotonically to a value of $\sim$ 3.8 eV at a coverage that we assign as $\sim$ 1 monolayer of FePc. These values were determined from the measurements of the photoelectron spectrum using the low-energy vacuum-level cutoff of a biased sample. Our spin-resolved data for clean Fe(110) show highly spin-polarized photoelectrons from the Fermi energy to values about 3.5 eV below the Fermi energy for an applied B-field along [110] both for majority-spin and minority-spin electrons. The polarization is about 60% at -3.2 eV below E-Fermi. For 0.13 ML adsorbed FePc the spin polarization is somewhat reduced and is rotated from [110] towards [100] in the plane of the sample. We interpret this rotation as due to a strong coupling of the orbital moment of FePc with the conduction electrons of the Fe substrate.

Session N17 DMP GMAG: Focus Session: Manganite Dynamics and Structure 319 - Dmitry Reznik, University of Colorado

11:15AM N17.00001 Magnetic structure and dynamics of Rh-doped Sr_2IrO_4 probed by resonant x-ray scattering , J.P. CLANCY, H. GRETARSSON, University of Toronto, JUNGHO KIM, M.H. UPTON, Argonne National Laboratory, G. CAO, University of Kentucky, YOUNG-JUNE KIM, University of Toronto — The physics of 5d iridates has recently attracted considerable attention due to the potential for novel electronic and magnetic ground states driven by strong spin-orbit coupling (SOC). One material which has attracted particular interest is the layered perovskite Sr_2IrO_4, which has been proposed as the first experimental realization of a spin-orbital Mott insulator with a $j_{eff} = 1/2$ ground state [1,2]. It has been shown that by substituting Ir^{4+} ($5d^5$) ions for Rh^{4+} ($4d^5$), the strength of the SOC in this system can be tuned through a series of electronic phase transitions [3]. We have performed resonant magnetic x-ray scattering (RMXS) and resonant inelastic x-ray scattering (RIXS) measurements to determine the effect of Rh-doping on the magnetic structure and excitation spectrum of $Sr_2Ir_{1-x}Rh_xO_4$. We find that increasing Rh concentration results in (i) suppression of the magnetic transition temperature, (ii) a doping-induced change in magnetic structure, (iii) alteration of the magnon dispersion relation, and (iv) significant reduction of magnon lifetimes. [1] B.J. Kim et al, PRL 101, 076402 (2008). [2] B.J. Kim et al, Science 323, 1329 (2009). [3] T.F. Qi et al, PRB 86, 125105 (2012).

11:27AM N17.00002 Strain control of spin and orbital transitions in La_2NiO_4 , CHOONG H. KIM, CRAIG J. FENNIE, School of Applied and Engineering Physics, Cornell University — We have studied the electronic and magnetic structure of the layered nickelates, La_2NiO_4 within density functional theory. We show that biaxial strain induces a high spin to low spin transition, which coincides with a significant change in the $x^2 - y$ and $3z^2 - r^2$ orbital occupancy. We discuss the role of the on-site Coulomb interaction, the crystal field, and prospects for the strain control of the spin and orbital state.

11:39AM N17.00003 Magnetic and Orbital Orders Coupled to Negative Thermal Expansion in Mott Insulators, $Ca_2Ru_{1-x}M_xO_4$ (M = 3d transition metal ion)[1] , T.F. QI, O.B. KORNETA, L. LI, Center for Advanced Materials, University of Kentucky, JIANGPING HU, Department of Physics, Purdue University, S. PARKIN, G. CAO, Center for Advanced Materials, University of Kentucky — Ca_2RuO_4 is a structurally-driven Mott insulator with a metal-insulator transition at T_{MI} = 357K, followed by a well-separated antiferromagnetic order at T_N = 110 K. Slightly substituting Ru with a 3d transition metal ion M effectively shifts T_{MI} and induces exotic magnetic behavior below T_N. Moreover, M doping for Ru produces negative thermal expansion in $Ca_2Ru_{1-x}M_xO_4$ (M = Cr, Mn, Fe or Cu); the lattice volume expands on cooling with a total volume expansion ratio, $\Delta V/V$, reaching as high as 1%. The onset of the negative thermal expansion closely tracks T_{MI} and T_N, sharply contrasting classic negative thermal expansion that shows no relevance to electronic properties. In addition, the observed negative thermal expansion occurs near room temperature and extends over a wide temperature interval [1, 2]. These findings underscores new physics driven by a complex interplay between orbital, spin and lattice degrees of freedom.

11:51AM N17.00004 THz magneto-electric excitations in the chiral compound Ba3NbFe3Si2O14 , SOPHIE DE BRION, LAURA CHAIX[1], FLORENCE LEVY-BERTRAND, VIRGINIE SIMONET, RAFIK BALLOU, BENJAMIN CANALS, PASCAL LEJAY, Institut Néel, CNRS and Université Joseph Fourier, JEAN-BLAISE BRUBACH, GAEL CREFF, FABRICE WILLAERT, PASCALE ROY, Synchrotron SOLEIL, ANDRES CANO, ESRF — The langasite $Ba_3NbFe_3Si_2O_{14}$ displays a chiral structure and orders magnetically with a Neel temperature T_N=27K. We have determined its terahertz (THz) spectrum by means of synchrotron-radiation measurements. Three different types of excitation are present. The first one, at 13cm^{-1}, disappears at T_N and is assigned to magnons. The others, at 23cm^{-1} and 29cm^{-1}, persist up to four times T_N. According to their selection rules, they are interpreted as rotational modes of the lattice whose magneto-electric activity reveals a structural transition into a polar helical state.

12:03PM N17.00005 Orbital physics in RIXS , KRZYSZTOF WOHLFELD, SLAC and Stanford University, PASQUALE MARRA, IFW Dresden, MARKUS GRUENINGER, University of Cologne, THORSTEN SCHMITT, Paul Scherre Institute, JEROEN VAN DEN BRINK, IFW Dresden — In contrast to magnetism, phenomena associated with the orbital degrees of freedom in transition metal oxides had always been considered to be very difficult to observe. However, recently resonant inelastic x-ray scattering (RIXS) has established itself as a perfect probe of the orbital excitations [1] and orbital order [2] in transition metal oxides. Here we give a brief overview of these recent theoretical and experimental advances which have inter alia led to the observation of the separation of the spin and orbital degree of freedom of an electron [1, 3].

12:15PM N17.00006 Magnetism and Magnetic Order in La_2CuRuO_6 , MATTHEW SMYLIE, XU LUO, ULRICH WELP, WAI-KWONG KWOK, Materials Science Division, Argonne National Laboratory, HOWARD BLACKSTEAD, BRENDAN BENAPFL, Dept. of Physics, University of Notre Dame, PAUL MCGINN, Dept. of Chemical Engineering, University of Notre Dame — Long-range magnetic order has been observed in the insulating double perovskite compound La_2CuRuO_6. This monoclinic compound shows a rock salt like ordering of the B sites in the double perovskite $A_2BB'O_6$ lattice. We show that elevated processing temperatures improve the magnetic properties of the material, possibly by reducing the number of antisite defects between the Cu and Ru ions. In polycrystalline samples, microwave resonance and dc SQUID susceptibility measurements indicate a ferrimagnetic or antiferromagnetic ground state at low temperatures (T < 19 K). Specific heat measurements also show a transition consistent with the magnetization data.

12:27PM N17.00007 Hourglass dispersion in overdoped single-layered manganites , MARKUS BRADEN[1], II. Physikalisches Institut, University of Cologne — Two non-metallic single-layered manganites with a doping level well above half doping, $Nd_{0.33}Sr_{1.67}MnO_4$ and $Pr_{0.33}Ca_{1.67}MnO_4$, exhibit an incommensurate ordering of magnetic, charge and orbital degrees of freedom. Inelastic neutron scattering experiments reveal an hourglass-like excitation spectrum very similar to that seen in various cuprates superconductors, but only for sufficiently short correlation lengths. We find the characteristic features of the hourglass dispersion as the enhanced intensity at the merging of the incommensurate branches, the rotation of intensity maxima at higher energy, and suppression of the outwards-dispersing branches at low energies. The correlation length of the magnetic ordering and the large ratio of intra- to inter-stripe couplings can be identified as the decisive parameters causing the hourglass shape of the spectrum.

1:03PM N17.00008 Magnetic excitations in a 5d-based double perovskite Ba_2FeReO_6[1] , ARUN PARAMEKANTI, K. PLUMB, A. COOK, P. CLANCY, A. KOLENSIKOV, YOUNG-JUNE KIM, University of Toronto, B.-C. JEON, T.-W. NOH, Seoul National University — There is great interest in double perovskite materials, from a fundamental viewpoint of studying correlated electron magnetism as well as spintronics applications. We report theoretical calculations and experimental powder inelastic neutron scattering data on magnetic excitations in the 5d-based double perovskite Ba_2FeReO_6. We find evidence of multiple spin wave branches consistent with local moment magnetism on Fe sublattice coexisting with highly correlated and spin-orbit coupled local moments on Re.

[1]We acknowledge funding from NSERC, CIfAR, and CRC.

1:15PM N17.00009 Effects of Doping and Coulomb Correlations on Tc and Competing Phases in Half-metallic Double Perovskites[1] , DANIEL KESTNER, ONUR ERTEN, OINAM NGANBA MEETEI, MOHIT RANDERIA, NANDINI TRIVEDI, The Ohio State University — Double perovskites such as Sr_2FeMoO_6 (SFMO) are rare examples of materials with half-metallic ground states and a ferrimagnetic T_c much greater than room temperature. We have shown that the electronic and magnetic properties of SFMO are well described by a generalized double exchange model [1] for itinerant electrons from Mo coupled to localized Fe spins. However, the simplest model proves inadequate when SFMO is electron-doped by La-substitution on the Sr sites. Ignoring Coulomb correlations for the itinerant electrons, the ferromagnetism of Fe spins becomes progressively weaker with electron doping, and eventually the model is unstable to a metallic antiferromagnetic ground state. This is in contradiction with experiments [2], which find a ferromagnetic T_c increasing with carrier concentration and no evidence for an antiferromagnetic state up to $SrLaFeMoO_6$. In this talk we will show that the Hubbard U on the Mo-site is responsible for the observed doping trends. We will show that correlations stabilize the ferromagnetism, with the observed $T_c(n)$ behavior, and that the antiferromagnetic metal is not a competitive state for reasonable values of n.

1:27PM N17.00010 Predictions for Spin Resolved Spectral Function and Optical Conductivity in Half-metallic Double Perovskites[1] , JULIA JANCZAK, OINAM NGANBA MEETEI, MOHIT RANDERIA, NANDINI TRIVEDI, The Ohio State University — We present the effects of thermal fluctuations and anti-site (AS) disorder on the spin resolved spectral function $A(k,\omega)$ and optical conductivity $\sigma(\omega)$ for half-metallic double perovskite Sr_2FeMoO_6, which holds great promise in spintronics applications. While both $T \neq 0$ and AS destroy the half metallic state, they produce distinct effects. Increasing T produces smooth broadening in the energy distribution curves of $A(k,\omega)$ while AS produces localized states at specific energies with broad momentum distribution curves for spin up. Our results can be tested directly in spin resolved ARPES experiments. We also calculate $\sigma(\omega)$ by evaluating the Kubo formula in the exact eigenstate basis. We show for $T \neq 0$ the height of the secondary peak in $\sigma(\omega)$, also seen in experiments, tracks the polarization P of conduction electrons, whereas for disordered samples at $T = 0$, the weight of the secondary peak indicates the amount of AS. From the spin resolved conductivity, we show that small ($< 10\%$) amounts of AS prevalent in real samples has little impact on the spin polarization of the DC current. The features of the optical spectrum provide a relatively simple experimental probe of the polarization and amount of disorder.

1:39PM N17.00011 Mapping chemical/structural order in double perovskite Sr2-xGdxMnTiO6 by atomic resolution electron microscopy[1] , INMACULADA ALVAREZ, NEVEN BISKUP[2], MARIA LOPEZ, U. Complutense Madrid, Spain, MAR GARCIA-HERNANDEZ, ICMM, CSIC, Spain, LUISA VEIGA, U. Complutense Madrid, Spain, MARIA VARELA[3], Oak Ridge National Laboratory, UCM COLLABORATION, ORNL COLLABORATION, CSIC COLLABORATION — We report on visualizing the chemical and structural order of double perovskite Sr2-xGdxMnTiO6. The antisite disorder of Mn and Ti is detected even at atomic scale at all x, resulting in Mn-rich and Ti-rich regions. For x ?0.75, the majority of manganese ions are in Mn3+ state and are centered in Jahn-Teller distorted MnO6octahedra. The Fourier transformation of atomic resolution images along the [110] zone axis reveals a superstructure that corresponds to the tilting of oxygen octahedra and that doubles the unit cell along [001]c. This superstructure is spatially inhomogeneous and coincides with the regions where B-site ion (Mn/Ti) is displaced along the [110] direction. We discuss these findings in the frame of possible local ferroelectricity and in the light of strong electroresistance observed in Sr1.25Gd0.75MnTiO6.

1:51PM N17.00012 Structural transition in an unusual $5d$-electron ferromagnetic insulator[1] , ZAHIRUL ISLAM, R.K. DAS, J.P.C. RUFF, Advanced Photon Source, Argonne National Laboratory, H. LEE, Department of Applied Physics, Stanford University, D.S. ROBINSON, Advanced Photon Source, Argonne National Laboratory, I.R. FISHER, Department of Applied Physics, Stanford University — Double-perovskite barium sodium osmate (Ba_2NaOsO_6) is a ferromagnetic (FM) insulator ($T_c \sim 6.8$ K, ordered moment $\sim$0.2 μ_B per formula unit) with $< 110 >$ easy axis. We present precision x-ray diffraction studies on single crystals to understand structural symmetry in this rare FM compound. At room temperature there is a subtle splitting of crystal Bragg peaks indicating the global symmetry to be weakly tetragonal. At or slightly above T_c, the material becomes orthorhombic. These changes are crucial in lifting the degeneracy of d-state manifold and are likely associated with orbital ordering.

[1]Work performed at the Advanced Photon Source was supported by the DOE, under Contract No. DE-AC02-06CH11357.

2:03PM N17.00013 Magnetic properties and electronic structure of $Cr_2(Te_{1-x}W_x)O_6$[1] , X. KE, D. DO, Department of Physics and Astronomy, Michigan State University, H. ZHOU, Department of Physics and Astronomy, Univeristy of Tennessee, C.R. DELA CRUZ, Quantum Condensed Matter Division, Oak Ridge National Laboratory, S.D. MAHANTI, M. ZHU, Department of Physics and Astronomy, Michigan State University — We report magnetic properties of $Cr_2(Te_{1-x}W_x)O_6$ system combining neutron powder diffraction measurements and first principles electronic structure calculations. Both the end members possess an ordered inverse-trirutile structure, in which there are bilayers of Cr-O separated by a W(Te)-O layer, yet Cr_2TeO_6 and Cr_2WO_6 display distinct magnetic structures and antiferromagnetic transition temperatures: $T_N \sim 92$ K for Cr_2TeO_6 with antiferromagnetic spin alignment within bilayers, while $T_N \sim 45$ K for Cr_2WO_6 with spins aligned ferromagnetically within the bilayer. Spins belonging to neighboring bilayers are antiferromagnetically coupled for both the compounds. For the mixed system $Cr_2(Te_{1-x}W_x)O_6$, both T_N and sublattice magnetization (M_s) reach a minimum ($T_N \sim 0$ K) for $x \sim 0.6$, suggesting the existence of a quantum critical point. Electronic structure calculations using *ab initio* density functional theory correctly give the ground state spin configurations for the end compounds (x=0,1). We suggest that unoccupied W 5d states play a key role in intra-bilayer ferromagnetic ordering seen in the x=1 system.

Session N18 GMAG DMP FIAP: Focus Session: Spin-Dependent Phenomena in Semiconductors - Spin Orbit and Mesoscopic 320 - Jean Heremans, Virginia Polytechnic Institute and State University

11:15AM N18.00001 Gate-control of spin polarization waves[1]

, LUYI YANG, J.D. KORALEK, J. ORENSTEIN, UC Berkeley and LBNL, D.R. TIBBETTS, J.L. RENO, M.P. LILLY, SNL — We report on control of the persistent spin helix (PSH) in semiconductor quantum wells with tunable spin-orbit (SO) coupling via external gates. The PSH is a collective spin excitation of two-dimensional electron systems that emerges as a new conserved quantity of the SU(2) symmetry. It occurs when the strengths of Rashba and linear Dresselhaus SO coupling are equal. Previously, this effect was demonstrated by a set of samples with different doping asymmetry and well width [1]. Now we fabricate samples with both front and back gates aiming to control Rashba SO coupling continuously and increase the lifetime-enhancement by reducing the symmetry-breaking cubic Dresselhaus term.

11:27AM N18.00002 Chiral Spin Waves in Fermi Liquids with Spin-Orbit Coupling

, ALI ASHRAFI, DMITRII MASLOV, University of Florida — We predict the existence of chiral spin waves–collective modes in a two-dimensional Fermi liquid with the Rashba or Dresselhaus spin-orbit coupling. Starting from the phenomenological Landau theory, we show that the long-wavelength dynamics of magnetization is governed by the Klein-Gordon equations. The standing-wave solutions of these equations describe "particles" with effective masses, whose magnitudes and *signs* depend on the strength of the electron-electron interaction. The spectrum of the spin-chiral modes for arbitrary wavelengths is determined from the Dyson equation for the interaction vertex. We propose to observe spin-chiral modes via microwave absorption of standing waves confined by an in-plane profile of the spin-orbit splitting.

11:39AM N18.00003 Magnetic control of spin-orbit fields: a first principles study of Fe/GaAs junctions[1]

, JAROSLAV FABIAN, MARTIN GMITRA, ALEX MATOS-ABIAGUE, Institute for Thoeretical Physics, University of Regensburg, Germany, CLAUDIA DRAXL, Institute for Physics, Humboldt University Berlin, Germany — The possibility to control the spin-orbit fields in semiconductor heterostructures by electric fields has been used to influence the spin dynamics of itinerant electrons. We show that the spin-orbit fields can also be controlled by magnetic fields. On the example of Fe/GaAs junctions we illustrate how the electronic band structure of ferromagnet/semiconductor interfaces, here calculated from first principles for a slab geometry using the FLEUR code, can be mapped to effective spin-orbit field Hamiltonians whose parameters are extracted directly from the band structure, without requiring a priori knowledge of the functional form of the spin-orbit fields, as has been the standard up to now. We show that the spin patterns resulting from the spin-orbit fields change qualitatively as the magnetization orientation of the junction changes in the plane of the interface. The magnetic control of spin-orbit fields is important for transport and optical magnetoanisotropies of ferromagnet/non-magnetic conductor junctions.

11:51AM N18.00004 Stern-Gerlach effect and spin separation in InGaAs nanstructures[1]

, MAKOTO KOHDA, Tohoku University — The demonstration of quantized spin splitting by Stern and Gerlach in 1922 is one of the most important experiments in modern physics. We utilized an effective non-uniform magnetic field which originates from Rashba spin orbit interaction (SOI) and demonstrated an experimental manifestation of electronic Stern-Gerlach spin separation in InGaAs based quantum point contacts (QPCs) [1]. Lateral potential confinement in a trench-type QPC creates a spatial modulation of Rashba SOI inducing a spin dependent force Clear conductance plateaus are observed in steps of $2e^2/h$when the strength of Rashba SOI becomes small. However, when the Rashba SOI is enhanced by applying the top gate, a half-integer plateau additionally appears at $0.5(2e^2/h)$, indicating the spin polarized current. We found that the spin polarization of the conduction electrons in this plateau is as high as 70%. Our new approach for generating spin polarization in semiconductor nanostructures provides a way to seamlessly integrate electrical spin generation, manipulation, and detection in a single semiconductor device without the need for either external magnetic fields or magnetic materials.

12:27PM N18.00005 Spin blocking effect in symmetric double quantum well due to Rashba spin-orbit coupling[1]

, SATOFUMI SOUMA, MATSUTO OGAWA, Department of Electrical and Electronic Engineering, Kobe University, YOSHIAKI SEKINE, NTT Basic Research Laboratories, NTT Corporation, ATSUSHI SAWADA, TAKAAKI KOGA, Division of Electronics for Informatics, Graduate School of Information Science and Technology, Hokkaido University — We report a theoretical study of the spin-dependent electronic current flowing laterally through the $In_{0.53}Ga_{0.47}As/In_{0.52}Al_{0.48}As$ double quantum well (DQW) structure, where the values of the Rashba spin-orbit parameter α_R are opposite in sign but equal in magnitude between the constituent quantum wells [1]. By tuning the channel length of DQW and the magnitude of the externally applied in-plane magnetic field, one can block the transmission of one spin (e.g., spin-up) component, enabling us to obtain a spin-polarized current. Our experimental progress toward realizing the proposed device is also reported [2]. [1] T. Matsuura, S. Faniel, N. Monta, and T. Koga, Physica E **42**, 2707 (2010). [2] T. Koga, T. Matsuura, S. Faniel, S. Souma, S. Mineshige, Y. Sekine, and H. Sugiyama, IEICE Trans. Electron. **E95-C**, 770 (2012).

12:39PM N18.00006 Spin-orbit edge states in semiconductor two-dimensional systems

, L.L. XU, SHAOLA REN, J.J. HEREMANS, DJORDJE MINIC, Virginia Tech, C.K. GASPE, S. VIJEYARAGUNATHAN, T.D. MISHIMA, M.B. SANTOS, University of Oklahoma — The electromagnetic duality between the Aharonov-Casher and the Aharonov-Bohm topological phases can lead to magnetoelectronic edge effects in two-dimensional systems. Based on this duality, we propose and experimentally explore a quantized Hall effect in which magnetization transport may be quantized analogously to charge transport. When the magnetic moment is fully projected, the edge effect is a magnetization dual to the integer quantum Hall effect. An analogy also exists between this dual and the bosonic quantum Hall effect currently under investigation. In experiments we search for edge states induced by the equivalent vector potential from Rashba-type spin-orbit interaction. We use mesoscopic side-gated channel structures on InGaAs/InAlAs heterostructures where backscattering between edge states can experimentally form evidence for edge states. The side-gate voltage varies the effective gauge field and resistance as function of side-gate voltage is measured across the mesoscopic structures at either low applied magnetic field or at fixed magnetic filling factors to obtain states of defined spin (DOE DE-FG02-08ER46532, NSF DMR-0520550).

1:15PM N18.00009 Antilocalization, quantum coherence and spin coherence in quasi-one-dimensional GaAs/AlGaAs hole wires[1] , SHAOLA REN, J.J. HEREMANS, Virginia Tech, M. SHAYEGAN, Princeton University — Antilocalization is measured in quasi-1D (Q1D) lithographic wires fabricated on a GaAs/AlGaAs 2D hole system. Shubnikov-de Haas oscillations show substantial spin-orbit interaction in the asymmetric quantum well. A set of 10 Q1D wires of length 20 μm and conducting width 300 nm were fabricated. Mobility and density are preserved in the wires, which show predominantly specular boundary scattering, indicating high quality hole wires. Antilocalization is present in both the wires and the unpatterned system, confirming the existence of spin-orbit interaction. The spin and phase coherence times are measured as functions of temperature by fitting the magnetoconductance to antilocalization theory. Q1D antilocalization theory, as used on InSb and InAs wires, does not fit the hole wires well, likely due to a combination of ballistic transport and strong spin-orbit interaction not fully accounted for theoretically. For both wires and unpatterned system the measurements still indicate the spin coherence times and the phase coherence times with the expected temperature dependence. The measurements allow a comparison of the spin coherence times, and of their lengthening under dimensional confinement, with observations on other spin-orbit coupled 2D systems.

1:27PM N18.00010 The influence of the spin-orbit effect on the 0.7-anomaly: a functional renormalization group approach , OLGA GOULKO, FLORIAN BAUER, JAN HEYDER, JAN VON DELFT, Ludwig-Maximilians Universitaet Munich — In addition to plateaus at integer values of $G_0 = 2e^2/h$, the linear conductance of a quantum point contact shows an anomalous shoulder at around $0.7G_0$ – the so-called 0.7-anomaly. Although the dependence of the 0.7-anomaly on parameters such as the temperature, the magnetic field, the bias voltage etc. has been widely studied, little is known about the influence of spin-orbit effects. We present a microscopic theory for the 0.7-anomaly, based on a one-dimensional tight binding model with a local on-site interaction, a smooth potential barrier and a homogeneous magnetic Zeeman field. In addition, we introduce Rashba and Dresselhaus terms into the Hamiltonian to capture the effect of spin-orbit coupling. We use a functional renormalization group approach to calculate the influence of interactions on the conductance at zero temperature. In this talk we present our theoretical predictions for the shape of the conductance curve, which depends strongly on the angle of the magnetic field if spin-orbit coupling is present. We also provide a detailed microscopic explanation of how the interplay of the magnetic field, the interaction and the spin-orbit coupling influences the conductance.

1:39PM N18.00011 Microscopic Origin of the 0.7-Anomaly in Quantum Point Contacts , J. VON DELFT, F. BAUER, J. HEYDER, Arnold Sommerfeld Center, Ludwig-Maximilians-Universität München, E. SCHUBERT, D. BOROWSKI, D. TAUBERT, Center for NanoScience, Ludwig-Maximilians-Universität München, B. BRUOGNOLO, Arnold Sommerfeld Center, Ludwig-Maximilians-Universität München, D. SCHUH, Institut für Angewandte Physik, Universität Regensburg, W. WEGSCHEIDER, Laboratory of Solid State Physics, ETH Zürich, S. LUDWIG, Center for NanoScience, Ludwig-Maximilians-Universität München — Despite the simple structure of quantum point contacts, their conductance properties exhibit anomalous features, collectively known as the "0.7-anomaly", whose origin is still subject to controversial discussions. We offer a detailed microscopic explanation for the 0.7-anomaly and the zero-bias peak that typically accompanies it: the common origin of both is a smeared van Hove singularity in the local density of states at the bottom of the lowest one-dimensional subband of the point contact, which causes an anomalous enhancement in the Hartree potential barrier, magnetic spin susceptibility and inelastic scattering rate. We present theoretical calculations and experimental results that show good qualitative agreement for the dependence of the conductance on gate voltage, magnetic field, temperature, bias voltage (including the zero-bias peak) and interaction strength. For low field and temperature we predict and observe Fermi-liquid behavior analogous to that known for the Kondo effect in quantum dots. At high energies, however, the analogy between 0.7-anomaly and Kondo effect ceases to be applicable.

1:51PM N18.00012 Tunable All Electric Spin Polarizer Using A Quantum Point Contact With Two Pairs of In-Plane Side Gates[1] , NIKHIL BHANDARI, JAMES CHARLES, MAITREYA DUTTA, School of Electronics and Computing Systems, University of Cincinnati, Cincinnati, Ohio, PARTHA DAS, Physics of Nanodevices, Zernike Institute for Advanced Materials, University of Groningen, Groningen, The Netherlands,, MARC CAHAY, School of Electronics and Computing Systems, University of Cincinnati, Cincinnati, Ohio, RICHARD NEWROCK, Physics Department, University of Cincinnati, Cincinnati, Ohio, STEVEN HERBERT, Department of Physics, Xavier University, Cincinnati, Ohio — We report the first experimental investigation of a device consisting of a quantum point contact (QPC) with four gates – two in-plane side gates in series. The first set of gates (nearest the source contact) is asymmetrically biased to create spin polarization in the channel of the QPC. A symmetric bias is then applied on the second set of side gates (nearest the drain) and varied to tune the location of a conductance anomaly near 0.5 ($x2e^2/h$). The experimental results compare well with simulations of the four-gate QPC devices using a Non-Equilibrium Green's Function formalism. The device is shown to be a tunable all-electric spin polarizer. The range of common-mode bias on the first set of gates over which maximum spin polarization can be achieved is much broader for the four-gate structure compared with the case of a QPC with a single pair of in-plane side gates.

2:03PM N18.00013 ABSTRACT WITHDRAWN –

Wednesday, March 20, 2013 11:15AM - 2:15PM –

Session N19 GQI: Open Quantum Systems and Decoherence 321 - Daniel Lidar, University of Southern California

11:15AM N19.00001 Complementarity of information and the emergence of the classical world , MICHAEL ZWOLAK, Oregon State University, WOJCIECH ZUREK, Los Alamos National Laboratory — We prove an anti-symmetry property relating accessible information about a system through some auxiliary system F and the quantum discord with respect to a complementary system F'. In Quantum Darwinism, where fragments of the environment relay information to observers – this relation allows us to understand some fundamental properties regarding correlations between a quantum system and its environment. First, it relies on a natural separation of accessible information and quantum information about a system. Under decoherence, this separation shows that accessible information is maximized for the quasi-classical pointer observable. Other observables are accessible only via correlations with the pointer observable. Second, It shows that objective information becomes accessible to many observers only when quantum information is relegated to correlations with the global environment, and, therefore, locally inaccessible. The resulting complementarity explains why, in a quantum Universe, we perceive objective classical reality, and supports Bohr's intuition that quantum phenomena acquire classical reality only when communicated.

11:27AM N19.00002 Quantum Decoherence with Bath Size: Dynamics, Randomness, and Connectivity[1]

, MARK NOVOTNY, Mississippi State U., FENGPING JIN, KRISTEL MICHIELSEN, Jülich Supercomputing Centre, Germany, SEIJI MIYASHITA, U. Tokyo, Japan, HANS DE RAEDT, U. Groningen, Netherlands — The decoherence of a quantum system S coupled to a quantum environment E is considered, where $S+E$ is a closed quantum system. For typical states X of the Hilbert space, i.e. for states chosen randomly from the Hilbert space unit hypersphere, we derive a scaling relation for the sum of the off-diagonal elements of the reduced density matrix ρ_S of S. This sum is a measure of the decoherence of S, and decreases as $D_E^{-\frac{1}{2}}$ as the dimension of the environment Hilbert space D_E increases. We present long-time calculations of the time dependent Schrödinger equation (TDSE) of spin $\frac{1}{2}$ particles comprising $S+E$ in order to test this scaling. The Hamiltonian has uniform or random Heisenberg couplings of a spin chain for $S+E$. Factors that affect the approach to the predicted scaling relation for the Heisenberg $d=1$ ring include how quickly and successfully the dynamics drives an initial configuration to an X state, and this depends on the randomness of the coupling strengths in the Hamiltonian and the addition of other connections either within E or between S and E.

[1]NSF DMR-1206233

11:39AM N19.00003 Open Quantum Walks: Microscopic Derivation and Generalised Master Equation[1]

, FRANCESCO PETRUCCIONE, ILYA SINAYSKIY, University of KwaZulu-Natal and National Institute for Theoretical Physics, QUANTUM RESEARCH GROUP TEAM — Recently, a formalism for discrete time open quantum walks was introduced [S. Attal et al., J. Stat. Phys., 147 (2012) 832; S. Attal, F. Petruccione, I. Sinayskiy, Phys. Lett. A, 376 (2012) 1545]. This formalism is exclusively based on the non-unitary dynamics induced by the environment. This approach rests upon the implementation of appropriate completely positive maps. Open quantum walks include the classical random walk and through a realization procedure a connection to the Hadamard quantum walk is established. Open quantum walks allow for an unravelling in terms of quantum trajectories. It was shown [I. Sinayskiy and F. Petruccione, QIP 11 (2012) 1301] that open quantum walks can perform universal quantum computation and can be used for quantum state engineering. Here, we present the microscopic derivation of open quantum walks. A walk on a graph is considered and transitions between vertices are mediated by the interaction of the walker with a shared bosonic environment. The reduced dynamics of the walker is shown to be described in terms of a generalised Markovian master equation. The time discretization of the master equation gives raise to an open quantum walk. Based on the class of microscopic models considered here possible physical implementations are discussed.

11:51AM N19.00004 Efficient simulation of stochastically-driven quantum systems

, MOHAN SAROVAR, MATTHEW GRACE, Sandia National Laboratories, Livermore CA, USA — The simulation of noisy quantum systems is critical for accurate modeling of many experiments, including those implementing quantum information tasks. The expansion of a stochastic equation for the coupled evolution of a quantum system and an Ornstein-Uhlenbeck process into a hierarchy of coupled differential equations is a useful technique that simplifies the simulation of stochastically-driven quantum systems. We expand the applicability of this technique by completely characterizing the class of diffusive Markov processes for which a useful hierarchy of equations can be derived. The expansion of this technique enables the examination of quantum systems driven by non-Gaussian stochastic processes with bounded range. We present an application of this extended technique by simulating Stark-tuned Forster resonance transfer in Rydberg atoms with non-perturbative position fluctuations.

The work was supported by the Sandia National Laboratories Directed Research and Development Program. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

12:03PM N19.00005 Realizing a lattice-based quantum simulator using circuit quantum electrodynamics

, DEVIN UNDERWOOD, WILL SHANKS, Princeton University, ANDY LI, Northwestern University, JAMES RAFTERY, DARIUS SADRI, Princeton University, JENS KOCH, Northwestern University, ANDREW HOUCK, Princeton University — Recent experimental progress in circuit quantum electrodynamics (CQED) has triggered extensive theoretical research on using these systems to implement a CQED lattice-based quantum simulator for non-equilibrium physics. CQED systems are inherently open due to unavoidable photon loss and the ease of replenishing photons through driving. The focus of this research is to experimentally realize proposals focused on building lattice-based simulators, where each lattice site contains a single CQED element. Results will be presented on a kagome lattice of 49 niobium coplanar waveguide resonators, each coupled a single aluminum transmon qubit

12:15PM N19.00006 Decoherence and Thermalisation dynamics in many-body systems[1]

, DEREK LEE, Imperial College London, UK, SAM GENWAY, University of Nottingham, UK, ANDREW HO, Royal Holloway University of London, UK — An isolated quantum system prepared in a pure state will evolve coherently in time. However, local observables of the system can appear thermalised in the sense that the reduced density matrix of a small part of the system approaches the form expected from a thermal Gibbs distribution. This eigenstate thermalisation hypothesis has been demonstrated numerically. We explore the dynamics of how the system approaches this thermalised state. Our previous numerical work on the Hubbard model [Phys. Rev. Lett. 105, 260402 (2010)] has found two dynamical regimes with exponential and Gaussian decay towards the thermal state respectively. We discuss how this can be understood analytically in a generic theory. We will explore the impact of symmetry laws on the dynamics.

12:27PM N19.00007 Wigner distribution functions for complex dynamical systems: a path integral approach

, DRIES SELS, WIM MAGNUS, FONS BROSENS, University of Antwerp — Starting from Feynman's Lagrangian description of quantum mechanics, we propose a method to construct explicitly the propagator for the Wigner distribution function of a single system. For general quadratic Lagrangians, only the classical phase space trajectory is found to contribute to the propagator. Inspired by Feynman's and Vernon's influence functional theory we extend the method to calculate the propagator for the reduced Wigner function of a system of interest coupled to an external system. Explicit expressions are obtained when the external system consists of a set of independent harmonic oscillators.

12:39PM N19.00008 Chain representations of Open Quantum Systems and Lieb-Robinson like bounds for the dynamics[1] , MISCHA WOODS, Imperial College — This talk is concerned with the mapping of the Hamiltonian of open quantum systems onto chain representations, which forms the basis for a rigorous theory of the interaction of a system with its environment. This mapping progresses as an interaction which gives rise to a sequence of residual spectral densities of the system. The rigorous mathematical properties of this mapping have been unknown so far. Here we develop the theory of secondary measures to derive an analytic, expression for the sequence solely in terms of the initial measure and its associated orthogonal polynomials of the first and second kind. These mappings can be thought of as taking a highly nonlocal Hamiltonian to a local Hamiltonian. In the latter, a Lieb-Robinson like bound for the dynamics of the open quantum system makes sense. We develop analytical bounds on the error to observables of the system as a function of time when the semi-infinite chain in truncated at some finite length. The fact that this is possible shows that there is a finite "Speed of sound" in these chain representations. This has many implications of the simulatability of open quantum systems of this type and demonstrates that a truncated chain can faithfully reproduce the dynamics at shorter times. These results make a significant and mathematically rigorous contribution to the understanding of the theory of open quantum systems; and pave the way towards the efficient simulation of these systems, which within the standard methods, is often an intractable problem.

12:51PM N19.00009 Understanding the role of counter-rotating terms of Rabi Model under dissipation , RESUL ERYIGIT, FERDI ALTINTAS, Department of Physics, Abant Izzet Baysal University, Bolu, Turkey. — Rabi Hamiltonian is one of the most complete quantum mechanical models that describe the interaction of a qubit with a quantized field which became more relevant with the recent developments in the circuit QED technologies that made possible to obtain strong coupling in the field-qubit interactions. In the dissipative regime, the standart Lindblandian quantum optical master equation with Rabi Hamiltonian leads to unphysical effects such as an increase of total excitation number in the qubit-field system with increasing cavity decay rate. Recently, a new Liouville superoperator describing the loses of the system have been derived [F.Beaudoin, J.M.Gambetta, A.Blais, Phys. Rev. A 84, 043832 (2011)] at the ultrastrong coupling regime. In this study, by using the new dissipators for cavity loses, we have investigated the role of counter-rotating terms on the dynamics of entanglement and quantum discord at ultrastrong coupling regime and provided a comprehensible picture for the role of counter-rotating terms on quantum correlations. Contrary to the standart dissipators case, the steady-state of the system is found to contain non-zero entanglement.

1:03PM N19.00010 Classical memoryless noise-induced maximally discordant mixed separable steady states , ARZU KURT, FERDI ALTINTAS, RESUL ERYIGIT, Department of Physics, Abant Izzet Baysal University, Bolu, Turkey. — Noise is, generally, detrimental to quantum correlations. For some initial states, it has been shown that back-action of the environment or the memory in environment-system interactions can create and/or sustain some of the quantum correlations in the system. In the present study, we have investigated the dynamics of quantum discord and entanglement for two qubits subject to independent global transverse and/or longitudinal memoryless noisy classical fields and have shown that a classical memoryless noise can lead to maximally discordant mixed separable states. Moreover, two independent noises in the system are found to enhance both the steady state randomness and quantum discord in the absence of entanglement for some initial states.

1:15PM N19.00011 Decoherence effects of a charge detector on a nearby quantum dot[1] , DAVID RUIZ-TIJERINA, Ohio University, EDSON VERNEK, Universidade Federal de Uberlandia, GEORGE MARTINS, Oakland University, SERGIO ULLOA, Ohio University and Freie Universitat — We study the effects of a charge detector, implemented by a quantum point-contact (QPC), on the Kondo state of an adjacent spin-1/2 quantum dot (QD). The Coulomb interaction between electrons traversing the QPC and those within the QD contribute to charge fluctuations and decoherence of the Kondo state in the QD, which can be detected through conductance measurements. Modeling the QPC as two current leads coupled through a localized level near resonance with the Fermi level of the leads, one can explore different transport regimes of the detector: Coulomb blockade, ballistic resonant-transport, and a Kondo screening state (associated with the "0.7 anomaly"). Transitions between different states are achieved by tuning the capacitive coupling u, or the local gates in the QPC. The transitions are studied using Varma–Yafet variational techniques, providing interesting insights into the different regimes. We employ numerical renormalization-group calculations to accurately evaluate the spectral densities and conductance behavior of the coupled QPC–QD system. We report the dependence of the Kondo temperatures of both subsystems on the capacitive coupling strength u, and describe the phases' signatures in the local spectral densities and the conductance profile of the QPC.

1:27PM N19.00012 Full Counting Statistics of Photons Emitted by a Double Quantum Dot[1] , CANRAN XU, MAXIM VAVILOV, University of Wisconsin — We analyze the full counting statistics of photons emitted by a double quantum dot (DQD) to a high-quality microwave resonator due to the dipole coupling. We show that at the frequency matching condition $\omega_0 = \Delta E/\hbar$ for the energy splitting ΔE of the DQD and the resonator frequency ω_0, photon statistics exhibits both a sub-Poissonian distribution and anti-bunching. In the ideal case, when the system decoherence stems only from photo-detection process, the photon noise is reduced to nearly one-half of the noise for the Poisson distribution. The photon distribution remains sub-Poissonian even at moderate decoherence in the DQD, but eventually become super-Poissonian in the regime of strong decoherence of the DQD.

1:51PM N19.00014 Dephasing by a Zero Temperature Detector and the Friedel Sum Rule , BERND ROSENOW, University of Leipzig, YUVAL GEFEN, Weizmann Institute of Science — Detecting the passage of an interfering particle through one of the interferometer's arms, known as "which path" measurement, gives rise to interference visibility degradation (dephasing). Here we consider a detector at *equilibrium* [1]. At finite temperature dephasing is caused by thermal fluctuations of the detector. More interestingly, in the zero temperature limit, equilibrium quantum fluctuations of the detector give rise to dephasing of the out-of-equilibrium interferometer. This dephasing is a manifestation of an orthogonality catastrophe which differs qualitatively from Anderson's. Its magnitude is directly related to the Friedel sum rule.

2:03PM N19.00015 Quantum dynamics of a spin chain in the presence of engineered collective noise , CHRISTOPHER ZEITLER, LAUREL E. ANDERSON, LORENZA VIOLA, CHANDRASEKHAR RAMANATHAN, Dartmouth College — We experimentally and theoretically investigate the effect of engineered collective noise on the quantum dynamics of a spin chain evolving under the double-quantum Hamiltonian. This Hamiltonian is related by a similarity transformation to the isotropic XX Hamiltonian, and is experimentally accessible in solid-state NMR using coherent averaging techniques. In the absence of noise, a localized magnetic moment is observed to move down the chain at a constant velocity. We show that this transport is disrupted by the presence of collective z-noise, and that the magnetic moment becomes localized at the initial site as the strength of the noise increases. The relevance to quantum information transport in spin chains is also discussed.

Session N20 DMP: Focus Session: Mesoscopics - Tunneling 322 - Gabriel Ramirez, University of California, San Diego

11:15AM N20.00001 Scanning gate spectroscopy of a quantum Hall island near a quantum point contact , BENOIT HACKENS, FREDERICO MARTINS, SEBASTIEN FANIEL, VINCENT BAYOT, IMCN/NAPS, Universite catholique de Louvain, Belgium, BERND ROSENOW, Institute for Theoretical Physics, Leipzig University, Germany, LUDOVIC DESPLANQUE, XAVIER WALLART, IEMN, UMR CNRS 8520, UST Lille, BP 60069, F-59652 Villeneuve d'Ascq, France, MARCO PALA, IMEP-LAHC, Grenoble INP, Minatec, BP 257, F-38016 Grenoble, France, HERMANN SELLIER, SERGE HUANT, Institut Néel, CNRS & Université Joseph Fourier, BP 166, F-38042 Grenoble, France — We report on low temperature (100 mK) scanning gate experiments performed at high magnetic field (around 10 T) on a mesoscopic device patterned in an InGaAs/InAlAs heterostructure. Magnetotransport measurements yield signatures of ultra-small Quantum Hall Islands (QHI) formed by closed quantum Hall edge states and connected to propagating edge channels through tunnel barriers. Scanning gate microscopy and scanning gate spectroscopy are used to locate and probe a single QHI near a quantum point contact. The presence of Coulomb diamonds in the local spectroscopy confirms that Coulomb blockade governs transport across the QHI. Varying the microscope tip bias as well as current bias across the device, we uncover the QHI discrete energy spectrum arising from electronic confinement and we extract estimates of the gradient of the confining potential and of the edge state velocity.

11:27AM N20.00002 Noise Intensity-Intensity Correlations and the Fourth Cumulant of Current Fluctuations , JEAN-CHARLES FORGUES, FATOU BINTOU SANE, CHRISTIAN LUPIEN, BERTRAND REULET, Université de Sherbrooke — We report measurements of the correlation between intensities of noise at different frequencies on a tunnel junction under ac excitation. We show that such correlations exist only for certain relations between the excitation frequency and the two detection frequencies, which are similar to three-wave and four-wave mixing in optics, depending on the dc bias of the sample. We demonstrate that the correlation we measure is proportional to the fourth cumulant of current fluctuations.

11:39AM N20.00003 Optical Spectra of Au Nanoparticle Arrays in Grating Templates on a Silver Mirror , EDGAR PALACIOS, AIQING CHEN, RYAN MILLER, EUGENE DEPRINCE III, STEPHEN GRAY, ELENA SHEVCHENKO, ULRICH WELP, VITALII VLASKO-VLASOV, Argonne National Laboratory — Reflection spectra of close packed spherical gold nanoparticle assemblies in grating templates on a silver film covered with a thin dielectric spacer are studied in a wide range of incidence angles. Wide spectral minina corresponding to the plasmonic eigen-modes of the nanoparticle arrays are observed and compared with spectra of empty gratings. These minima correspond to extended optical bands of the arrays formed due to the strong interactions between localized plasmons modes of nanoparticles, silver film surface plasmons and grating resonances. From the angular variations of the spectra we obtain the dispersion of plasmonic excitations which yield a strong amplificatin of the light intensity in our system. Raman signal enhancement for Benzenethiol molecules in the gaps between nanoparticles is estimated as $3x10^{10}$. The intense light amplification in a wide spectral range and the large number of regular hot spots makes our structures an advanced platform for optical sensing, solid state lighting, and solar harvesting technologies.

11:51AM N20.00004 Quantum Mesoscopic Physics of Electrons and Photons[1] , ERIC AKKERMANS, Physics Dept. Technion Israel Institute of Technology — We first review basic notions of coherent quantum transport at the mesoscopic scale for both electronic and photonic systems. We then show that successful descriptions developed for coherent electronic transport (e.g. weak localization and UCF) and thermodynamics (persistent currents), noise and full counting statistics can be extended and applied to the study of Quantum Electrodynamics of quantum conductors and of quantum optics based on photons emitted by such conductors. In this context, we discuss the two following specific problems : (1) Ramsey fringes and time domain interference for particle creation form a quantum vacuum with a specific application to dynamical Coulomb blockade. In that setup, the current noise of a coherent conductor is biased by two successive voltage pulses. An interference pattern between photon assisted processes is observed which is explained by the contribution of several processes to the probability to emit photons after each pulse. Recent experiments in this context will be discussed. (2) Quantum emitter coupled to a fractal environment. A new and unexpected type of oscillatory structures for the probability of spontaneous emission has been obtained which results from the fractal nature of the quantum vacuum. When applied to the case of a tunnel junction as a quantum emitter of photons, the same oscillatory structure arises for the conductance of the tunnel junction.

12:27PM N20.00005 Squeezing in Photo-assisted Electron Quantum Shot Noise , GABRIEL GASSE, BERTRAND REULET, CHRISTIAN LUPIEN, University of Sherbrooke — The current/voltage fluctuations generated by a conductor are another point of view of a randomly fluctuating electromagnetic field, i.e. "white" light. We demonstrate experimentally that this light is naturally squeezed, i.e. that the noise on one quadrature can go below the vacuum fluctuations, for a tunnel junction at very low temperature irradiated by a microwave. A classical current in a conductor generates a coherent state of light. We show that a quantum current can emit non-classical light.

12:39PM N20.00006 Electron tunneling in chaotic quantum ring[1] , BRANISLAV VLAHOVIC, IGOR FILIKHIN, SERGEI MATINYAN, North Carolina Central University — Single electron confinement states of two dimensional InAs/GaAs quantum ring (QR) are considered under the effective approach [1]. The symmetry of the QR shape is violated as it is in well-known Bohigas annular billiard [2]. For weak violation of the symmetry, the energy spectrum may be represented by a set of quasi-doublets. We study the correlation between electron localizations and quasi-doublet splitting for complete spectrum. The bands with different "radial" quantum numbers are well determined within our calculations. The inter-band tunneling is considered in relation to the chaotic properties of the QR. We propose an alternative interpretation of the experimental data [3] to that made in Ref. [3], where the "first experimental evidence for chaos-assisted tunneling" in a microwave annular billiard was reported. We show that this effect can be explained by inter-band tunneling that occurs due to the anti-crossing of the levels having different "radial" quantum numbers. [1] I. Filikhin, V. M. Suslov and B. 12:51PM N20.00007 Emergence of the collective-response of granular solid - liquid mixtures to wave- pulse excitations , HASSON M. TAVOSSI, Valdosta State University, Department of Physics — The phenomenon of emergence of new properties observed in the collection of solid particles in liquid, due to pulse-wave excitations, can be found in many macroscopic systems. In this paper the uniform mixtures of solid spherical grains in water were subjected to high intensity, 60-Volts amplitude, pulsed -Ultrasonic waves of 45 kHz peak frequency. The observed response of the mixture was imbedded in the modified transmitted pulse, and could be extracted and compared to that of a reference pulse. Analysis of the results, in the frequency and time domains, includes; Fast Fourier Transform, amplitude and phase changes, and frequency dependent attenuation. The experimental findings and numerical results show that, the response of the mixture can be made independent of the scale, up to relatively small scale. The findings also show that, several collective- response to elastic wave propagation in the crystalline solids at the atomic scale, such as; cut-off frequency, tunneling effect, and absorption and conduction bands, can also have analogous ones in intermediary, and equivalences in these relatively simple mixtures.

1:03PM N20.00008 Theory of Solvent-Mediated Environmental Effects on Transport in Molecular Junctions , MICHELE KOTIUGA, Department of Physics, UC Berkeley & Molecular Foundry, LBNL, PIERRE DARANCET, Molecular Foundry, LBNL & Department of Applied Physics and Applied Mathematics, Columbia, LATHA VENKATARAMAN, Department of Applied Physics and Applied Mathematics, Columbia, JEFFREY NEATON, Molecular Foundry, LBNL — Single-molecule junctions, formed with well-defined and robust metal-molecule contacts, can provide an ideal model system to study mechanisms of charge transport at the molecular scale. However, the presence of solvent is often unavoidable, and recent experiments have shown that the junction conductance can be altered by a factor of two depending on the solvent present. Here, we use a first-principles scattering-state approach, based on self-energy corrected density functional theory (DFT), to explore how solvent and coverage impacts the transmission and conductance of bipyridine-Au molecular junctions. We find the conductance can shift by more than a factor of 5 by varying the bipyridine coverage, which is an effect associated with work function shifts that can be understood with a 2D polarizable dipole model fit with DFT values. A generalization of this electrostatic model to include solvent molecules allows us to estimate the work function shift for a mixed molecular coverage based both on the experimental parameters and system thermodynamics. By combining the results of our transmission calculations and the electrostatic model, we can accurately describe the conductance shifts observed experimentally. We acknowledge DOE for support, and NERSC for computational resources.

1:15PM N20.00009 Correlating Molecular Energy Level Alignment with the Conductance of Single Molecular Junctions , TAEKYEONG KIM, JONATHAN R. WIDAWSKY, Columbia University, PIERRE DARANCET, MICHELE KOTIUGA, JEFFREY B. NEATON, Lawrence Berkeley National Laboratory, LATHA VENKATARAMAN, Columbia University — There has been increased interest in understanding electronic and thermoelectric transport in single molecule junctions and metal/organic interfaces. While the ionization potential and electron affinity of molecules can be calculated for molecules in the gas-phase, additional physical effects, such as charge transfer and rearrangement, hybridization, and electrode polarization are expected to alter these electronic energies for molecular junctions. Therefore, it is hard to determine energy level alignments in molecular junctions. Here, we determine the relationship between electronic energy level alignment at a metal-molecule-metal interface and single-molecule junction conductance properties for 4,4'-bipyridine via direct and simultaneous measurement of electrical and thermoelectric currents using a scanning tunneling microscope-based break-junction technique. We measure directly, the position of the lowest unoccupied molecular orbital (LUMO) relative to the Au Fermi level assuming a Lorentzian resonance lineshape. Furthermore, we correlate the energy level alignment and coupling strength between two conductance states through repeated junction elongation and compression. We find that these values are in excellent agreement with our self-energy corrected density functional theory calculations. These results thus provide the first evidence for correlation between energy level alignment and single molecule transport.

1:27PM N20.00010 Transition from Coulomb Diamonds to Checherboard-like Spectroscopies in a Mesoscopic Quantum Hall Interferometer , S. FANIEL, F. MARTINS, V. BAYOT, B. HACKENS, NAPS/IMCN, Universite catholique de Louvain, Belgium, L. DESPLANQUE, X. WALLART, IEMN, Villeneuve d'Ascq, France, B. ROSENOW, Institute for Theoretical Physics, Leipzig University, Germany, S. MELINTE, ELEN/ICTM, Universite catholique de Louvain, Belgium — We report low temperature ($\sim$ 100 mK) magnetotransport, scanning gate microscopy and scanning gate spectroscopy measurements in an $In_{0.7}Ga_{0.3}As/In_{0.52}Al_{0.48}As$ quantum point contact (QPC). The magnetoresistance of the QPC shows oscillations in the vicinity of integer quantum Hall states. We attribute these magnetoresistance oscillations to the formation of an electron interferometer around a small, disorder-induced quantum Hall island located within the constriction. The magnetic field B tunes the edge states configuration in the QPC, leading to different signatures in the transport measurements. Interestingly, near the Landau level filling factor $\nu = 3$, the spectroscopy measurements performed on the quantum Hall interferometer, as a function of B or scanning gate tip voltage, exhibit a smooth transition from Coulomb diamonds to a checkerboard pattern.

1:39PM N20.00011 Fluctuations of g factors of discrete levels in ferromagnetic nanoparticles[1] , DRAGOMIR DAVIDOVIC, WENCHAO JIANG, FELIPE TIJIWA BIRK[2], PATRICK GARTLAND, School of Physics, Georgia Institute of Technology — It has been known that the interplay between electron-electron interactions and spin-orbit scattering can cause a wide distribution of g factors in tunneling spectra of metallic nanoparticles, including g-factors much larger than 2 if electron-electron interactions are strong. Here, we present our studies of single Co nanoparticles in Al/Al_2O_3/(Co nanoparticles)/Al_2O_3/Al tunnel junctions using electron tunneling spectroscopy at mK-temperatures. The g factor of discrete energy levels exhibits significant difference between minority-spin and majority-spin levels. We have clearly observed large g factors ($\approx$ 6) in one sample at magnetic field greater than 4T, suggesting $\Delta S = 3/2$ in the tunneling transition, S is the magnitude of the spin. We will present the latest results on tunneling junctions containing Ni, Permalloy or Gd nanoparticles, which have weaker magnetic anisotropy fluctuations.

1:51PM N20.00012 Band edge noise spectroscopy , FARKHAD ALIEV, JUAN PEDRO CASCALES, Universidad Autonoma de Madrid, FREDERIC BONELL, STEPHANE ANDRIEU, Universite Poincare Nancy — Although metal/insulator interfaces are expected to play a major role in charge, spin and phonon flow, little is known about the real underlying band structure. The reason is the difficulty in directly obtaining this information from interfaces by the use of a non-invasive physical tool. Here we introduce and demonstrate the feasibility of a conceptually new method that enables us to gather information on the interface electron bands. The low frequency and low temperature noise measurements as a function of applied bias voltage clearly reveal the appearance of the electron band edges at the Fermi level. By analyzing the bias dependence of the normalized 1/f noise (Hooge factor) in Fe1-xVx/MgO/Fe (with 0< x< 0.16) epitaxial magnetic tunnel junctions with diminished misfit dislocations, we observe strong anomalies in the 1/f noise at specific voltages where the band edges of the ferromagnetic electrodes which form the tunnel junction are expected to cross the Fermi level. These effects, understood within a simple model of 1/f noise due to localized states near the band edges, open up new perspectives for a reliable "in situ" characterization of electron bands in normal metal or spintronic devices.

Wednesday, March 20, 2013 11:15AM - 2:15PM –

Session N21 DMP: Focus Session: BiFeO3 and Domain Wall Conductance 323 - Alexei Belik, NIMS Japan

11:15AM N21.00001 Current at domain walls, roughly speaking: nanoscales studies of disorder roughening and conduction

, PATRYCJA PARUCH, MaNEP-DPMC, University of Geneva — Domain walls in (multi)ferroic materials are the thin elastic interfaces separating regions with different orientations of magnetisation, electric polarisation, or spontaneous strain. Understanding their behaviour, and controlling domain size and stability, is key for their integration into applications, while fundamentally, domain walls provide an excellent model system in which the rich physics of disordered elastic interfaces can be accesses. In addition, domain walls can present novel properties, quite different from those of their parent materials, making them potentially useful as active components in future nano-devices. Here, we present our atomic force microscopy studies of ferroelectric domain walls in epitaxial $Pb(Zr_{0.2}Ti_{0.8})O_3$ and $BiFeO_3$ thin films, in which we use piezorespose force microscopy to show unusual domain wall roughening behaviour, with very localised disorder regions in the sample leading to a complex, multi-affine scaling of the domain wall shape [1]. We also show the effects of temperature, environmental conditions, and defects on switching dynamics and domain wall roughness [2]. We combine these observations with parallel conductive-tip atomic force microscopy current measurements, which also show highly localised variations in conduction, and highlight the key role played by oxygen vacancies in the observed domain wall conduction [3].

11:51AM N21.00002 Nanoscale spatial control of domain wall conductivity in $BiFeO_3$ thin films

, BRIAN SMITH, University of Twente, RAMA VASUDEVAN, University of New South Wales, BOUWE KUIPER, ANDRE TEN ELSHOF, University of Twente, ART BADDORF, PETER MAKSYMOVICH, SERGEI KALININ, Oak Ridge National Laboratory, MARK HUJBEN, GUUS RIJNDERS, GERTJAN KOSTER, University of Twente — Use of ferroelectric domain walls for applications is an attractive prospect. Domain walls can have properties not found in bulk allowing added functionality. The 1D nature of a ferroelectric domain wall could be exploited to create devices with dimensions on the order of a single unit cell. Intensive research on domain wall conductivity in $BiFeO_3$ is ongoing since the first report in 2009 [1]. Here we report on the spatial control of domain wall conductivity in an epitaxial grown $BiFeO_3$ film 25nm thick on self-assembled $SrRuO_3$ nanowires using an ordered mixed terminated $DyScO_3$ substrate as a growth template [2]. The $SrRuO_3$ nanowires (5nm high, 100nm wide separated by 200nm) run across the substrate and are contacted at the sample edge creating alternating insulating/conducting surfaces. Using PFM/cAFM the domains, switching and domain wall conductivity is explored. Domain wall conductivity is only present in over the nanowires. In addition to providing spatial control of the conductivity this result provides evidence that the conduction is confined to a single domain wall throughout the thickness of the film and is not the results of network of interconnected domains.

12:03PM N21.00003 Domain walls in a perovskite oxide with two primary structural order parameters: first-principles study of $BiFeO_3$

, OSWALDO DIÉGUEZ, ICMAB-CSIC and Rutgers University, PABLO AGUADO-PUENTE, JAVIER JUNQUERA, Universidad de Cantabria, JORGE ÍÑIGUEZ, ICMAB-CSIC — We present a first-principles study of ferroelectric domain walls (FE-DWs) in multiferroic $BiFeO_3$ (BFO), a material in which the FE order parameter coexists with anti-ferrodistortive (AFD) modes involving rotations of the O_6 octahedra. We find that the energetics of the DWs are dominated by the capability of the domains to match their O_6 octahedra rotation patterns at the plane of the wall, so that the distortion of the oxygen groups is minimized. Our results thus indicate that, in essence, it is the discontinuity in the AFD order parameter, and not the change in the electric polarization, what decides which crystallographic planes are most likely to *host* BFO's FE-DWs. Such a result clearly suggests that the O_6 rotational patterns play a primary role in the FE phase of this compound, in contrast with the usual (implicit) assumption that they are subordinated to the FE order parameter. Interestingly, we find that the structure of BFO at the most stable DWs resembles the atomic arrangements that are characteristic of low-lying (meta)stable phases of the material. Our work thus contributes to shape a coherent picture of the structural variants that BFO can present and the way in which they are related.

12:15PM N21.00004 Ferroelectric Tunnel Junctions Based on Pseudotetragonal $BiFeO_3$[1]

, FLAVIO Y. BRUNO, S. BOYN, V. GARCIA, S. FUSIL, H. YAMADA, C. CARRETERO, C. DERANLOT, E. JACQUET, K. BOUZEHOUANE, Unité Mixte de Physique CNRS/Thales, 91767 Palaiseau, France, S. XAVIER, Thales Research and Technology, 91767 Palaiseau, France, J. GROLLIER, M. BIBES, A. BARTHELEMY, Unité Mixte de Physique CNRS/Thales, 91767 Palaiseau, France — The concept of a ferroelectric tunnel junction (FTJ) was formulated in the early 70s by Esaki et al. It took more than 30 years to realize this idea experimentally in a reliable and reproducible manner[1]. FTJs have shown to be versatile devices and the possibility to use them as memories [2] and memristors [3] have been recently demonstrated on $BaTiO_3$ based junctions. With the aim of expanding its functionalities we have realized FTJ with multiferroic pseudotetragonal $BiFeO_3$ (T-BFO) tunnel barriers. In order to fabricate junctions we deposited fully epitaxial bilayers consisting of a $LaNiO_3$ or doped $CaMnO_3$ bottom electrodes and the T-BFO tunnel barriers. On top of this bilayers, Co/Au electrodes as small as 200 nm in diameter were defined by e-beam lithography and lift-off. We have measured ON/OFF ratios as large as 10000 on these junctions, much larger than that observed in FTJs with $BaTiO_3$ tunnel barriers. We will show that the resistance of the FTJ in its high, low and intermediate states is related with the polarization state of the barrier as observed by PFM. [1]Nature 460,81(2009). [2]Nat. Nanotech. 7, 101 (2011). [3] Nature Mat. 11, 860 (2012).

12:27PM N21.00005 THz spectroscopy of spin waves in multiferroic $BiFeO_3$ in high magnetic fields[1]

, URMAS NAGEL, T. RÕÕM, Nat.-I Inst. of Chem. Phys. & Biophys., Tallinn, Estonia, H. ENGELKAMP, HFML, Radboud University Nijmegen, The Netherlands, D. TALBAYEV, Tulane Univ., New Orleans, USA, H.T. YI, S.-W. CHEONG, Rutgers Univ., New Jersey, USA — $BiFeO_3$ is both antiferromagnetic and ferroelectric with high Nèel and Curie temperatures, about 640 K and 110 K, respectively. In low magnetic field Fe^{3+} spins order cycloidally, inducing an additional electric polarization, which interacts with the feeroelctric polarization of the lattice and produces a magneto-electric term in the total energy. We have measured the magnetic field dependence of infrared active magnon modes in an untwinned $BiFeO_3$ single crystal at 4K. The magnon modes soften close to the critical field of about 18.8T along the [001] cubic axis, where the cycloid is destroyed and the low field magnon modes disappear. A new strong mode with linear magmetic field dependence appears above 19T and persists at least up to 31T. The dramatic change of the THz spectrum at 19T allows us to assign all the low field modes as excitations of the cycloid.

12:39PM N21.00006 Strain dependence of transition temperatures, structural symmetry, and phase coexistence of BiFeO3 within the tetragonal-like structure , WOLTER SIEMONS, CHRISTIANNE BEEKMAN, GREGORY MACDOUGALL, ADAM ACZEL, MICHAEL BIEGALSKI, Oak Ridge National Laboratory, JEREL ZARESTKY, Iowa State University, SHUHUA LIANG, ELBIO DAGOTTO, University of Tennessee, STEVE NAGLER, HANS CHRISTEN, Oak Ridge National Laboratory — We have investigated the influence of strain-imposed in-plane lattice symmetry on the structural and magnetic properties of tetragonal-like $BiFeO_3$. We find that an increase in the in-plane distortion results in an increase of the Néel temperature from 313 K to 324 K for films grown on $YAlO_3$ and $LaAlO_3$ respectively. The change in magnetic ordering temperature is reproduced in 3D Heisenberg Monte-Carlo simulations. The structural transition temperatures, from M_C to M_A monoclinic around 100 °C and to a true tetragonal phase at higher temperature, are also found to depend on strain. Some of the strain is relieved through the creation of an additional polymorph, which causes stripe patterns in the surface morphology. We present how the abundance and shape of these patterns changes with the amount and symmetry of strain. These results show strain cannot be treated as a single scalar number or simply as a direct consequence of the lattice mismatch between the film material and the substrate. Research supported by the U.S. Department of Energy (DOE), Basic Energy Sciences (BES), Materials Sciences and Engineering Division, and performed in part at ORNL's Spallation Neutron Source and Center for Nanophase Materials Sciences (sponsored by DOE-BES).

12:51PM N21.00007 Local conductivity in supertetragonal and rhombohedral-like $BiFeO_3$ films , SAEEDEH FAROKHIPOOR, University of Groningen, CHRISTIANNE BEEKMAN, WOLTER SIEMONS, HANS M. CHRISTEN, Oak Ridge National Laboratory, BEATRIZ NOHEDA, University of Groningen — Materials in which structural polymorphs coexist are of great interest in the design of magnetoelectric devices and piezoactuators at the nanoscale. In $BiFeO_3$, coexisting polymorphs are stabilized in thin film form by strain resulting from film/substrate lattice mismatch and/or thermal expansion differences. In films on $LaAlO_3$ substrates, these polymorphic phases give rise to stripe patterns; they are formed by the coexistence of the highly-strained (T') phase with an intermediary polymorph (S') in samples devoid of the rhombohedral-like relaxed (R') structure. Here, we investigate the local properties of the stripe patterns by piezoresponse force microscopy and conductive atomic force microscopy. This makes it possible to investigate the local conductivity both of specific domains and of different domain walls, and to compare the results to those obtained for R'-$BiFeO_3$ films (on $SrTiO_3$ substrates). We show that patterns of locally varying polarization and conductivity can be reversibly written and erased at length scales determined by the phase stability of the strain-induced structural polymorphs, and illustrate similarities and differences between R' and T' $BiFeO_3$.

1:03PM N21.00008 Temperature dependent dielectric and ferroelectric studies of BiFeO3 thin film[1] , ANAND P.S. GAUR, None, SUJIT K. BARIK, RAM S. KATIYAR, Dr. — Although $BiFeO_3$ (BFO) has received a lot of interest due to its good multiferroic properties at room temperature, high leakage current limit its usage for practical applications. Recently, it is found that these properties in thin films can be different due to strain effect induced by substrate, preparation conditions and electrode effects, etc. In this context, we have studied the temperature dependence of polarization and dielectric properties of BFO thin film by varying the bottom electrode thickness and using different electrodes. The strain dependent ferroelectric switching behaviors have also been investigated with a traditional ferroelectric tester and switching spectroscopy piezoresponse force microscopy (SS-PFM), respectively. We used pulsed laser deposition to fabricate thin films of BFO using Si (100) substrate and $SrTiO_3$ (STO) as buffer layer with different bottom electrodes such as $SrRuO_3$ (SRO), $LaNiO_3$ (LNO) and Pt/Si. The thickness of STO layer is kept fixed around 70 nm and the thicknesses of BFO and electrode layer were varied from 70 nm to 200nm. The layers were grown under optimized conditions and polycrystalline nature is found from room temperature XRD. A large enhancement of polarization is found while using LNO electrode and also with reducing the thickness of BFO layer. The remnant polarization and cohesivity also shows large increase with increaisng temperature, although leakage current increases significantly.

1:15PM N21.00009 Temperature dependence of acoustic and low-energy optic phonons in the multiferroic BiFeO3 studied by inelastic neutron scattering , GUANGYONG XU, ZHIJUN XU, JOHN SHNEELOCK, Brookhaven National Laboratory, PETER GEHRING, CHRIS STOCK, NIST Center for Neutron Research, MASAAKI MATSUDA, Oak Ridge National Laboratory, GENDA GU, Brookhaven National Laboratory, T. ITO, Natl Inst Adv Ind Sci & Technol, Tsukuba, Ibaraki 3058562, Japan, JINSHENG WEN, R.J. BIRGENEAU, UC Berkeley, STEPHEN SHAPIRO, Brookhaven National Laboratory — We report inelastic neutron scattering measurements on the acoustic and low-energy phonons in the multiferroic material $BiFeO_3$. The phonon dispersion in the (200) and (111) zones have been mapped out for temperatures between 300K to 750K. The temperature dependence of the dispersion and phonon intensities will be discussed. Possible connections between the the antiferromagnetic phase transition at 640K and anomalies in the phonon modes are observed.

1:27PM N21.00010 Phase coexistence, phase transitions, and piezoelectric switching in highly-strained $BiFeO_3$[1] , HANS M. CHRISTEN, C. BEEKMAN, W. SIEMONS, M. CHI, J.Y. HOWE, M.D. BIEGALSKI, N. BALKE, P. MAKSYMOVYCH, T.Z. WARD, Oak Ridge National Laboratory, A.K. FARRAR, J.B. ROMERO, D. TENNE, Boise State University — Highly strained (T') BiFeO3 films are investigated as function of temperature by x-ray diffraction in combination with atomic-force, piezo-response force, and transmission electron microscopies. In these films on $LaAlO_3$ substrates, the coexistence of the T' majority phase (c/a $\sim$ 1.25) with an intermediary S' polymorph (c/a $\sim$ 1.09) leads to the formation of stripe patterns in samples where the bulk-like, nearly rhombohedral R' polymorph is absent. While T' films at 300K are monoclinic, our results reveal a true tetragonal high-temperature phase (at T$\geq$700K) for which Raman spectroscopy demonstrates a polar nature. However, piezoelectric switching of the T' phase is possible only in the presence of the S' polymorph. This polymorph, and the stripe patterns that result from its coexistence with the T' form appear after growth upon cooling below $\sim$570K. This shows that the S' polymorph is formed by additional stress resulting from the differences in thermal expansion between film and substrate. These results point to new approaches for tuning functional properties in materials exhibiting strain-induced polymorphic phase transitions.

1:39PM N21.00011 ABSTRACT WITHDRAWN –

1:51PM N21.00012 Symmetry of Epitaxial $BiFeO_3$ Films in the Ultrathin Regime[1] , YONGSOO YANG, University of Michigan, CHRISTIAN SCHLEPÜTZ, Argonne National Laboratory, CAROLINA ADAMO, DARRELL SCHLOM, Cornell University, ROY CLARKE, University of Michigan — $BiFeO_3$ (BFO) films grown on $SrTiO_3$ (STO) with a $SrRuO_3$ buffer layer exhibit a monoclinic structure at thicknesses greater than 40 nm, but higher structural symmetry can be observed for thinner films [Phys. Rev. B 81, 144115 (2010)]. We report a structural phase transition from monoclinic to tetragonal in ultra-thin BFO films grown directly on (100)-oriented STO. X-ray diffraction measurements of 3-dimensional reciprocal space maps reveal half-integer order peaks due to oxygen octahedral tilting. When the film thickness is decreased below 20 unit cells, the integer-order Bragg peak splitting associated with the presence of multiple domains of the monoclinic phase disappears. Instead, a single peak that is commensurate with the STO substrate lattice appears. The diffraction pattern has four-fold symmetry, ruling out the presence of a single monoclinic domain in favor of a tetragonal film structure. The evolution of the oxygen octahedra tilt pattern inferred from the intensities of half-order peaks suggests that this transition originates from the corner-connectivity of oxygen atoms at the interface between BFO and STO, and also strongly supports this monoclinic to tetragonal transition.

2:03PM N21.00013 First-Principles Calculation of the Bulk Photovoltaic Effect in Bismuth Ferrite , STEVE YOUNG, FAN ZHENG, ANDREW RAPPE, Makineni Theoretical Laboratories, Department of Chemistry, University of Pennsylvania — Bismuth ferrite is a multiferroic material with a large bulk polarization and a band gap in the visible spectrum. Significant anomalous photovoltaic effects have been observed in the material; however, the origins of this effect are unclear. While some investigations indicate that observed photovoltages and photocurrents are due to the bulk photovoltaic effect, in striped polydomain samples there is no evidence of this, and the observed response is attributed to a domain-wall-driven mechanism. We have computed the bulk photovoltaic response from first principles using shift current theory and compared it to the available experimental data, finding good agreement. By accounting for the geometry of the polydomain samples, we are able to explain the lack of observed bulk photovoltaic response. Furthermore, we show that these two mechanisms act antagonistically, suggesting that enhanced efficiency may be found in materials where these two effects interact cooperatively.

Session N22 DCMP: Artificially Structured Materials: Growth, Structure, and Related Phenomena 324 - Connie Li, Naval Research Laboratory

11:15AM N22.00001 First-principle Investigation of the Stability and Vibrational Spectrum of MoSx Nanostructures Grown on Cu(111)[1] , TALAT S. RAHMAN, MARAL AMINPOUR, DUY LE, MARISOL ALCÁNTARA ORTIGOZA, University of Central Florida, Department of Physics, Orlando FL 32816-2385, USA — Recent experiments have successfully synthetized MoS_X nanostructures in a controlled manner by evaporating Mo adatoms on the copper sulfide monolayer that forms on Cu(111) upon sulfur preloading [1,2]. STM observations and total-energy calculations based on density functional theory, including van-der-Waals interactions, have proposed several structures for MoS_X/Cu(111). In this study, we investigate the plausibility of those structures and provide elements for further experimental substantiation or refutation. In particular, we perform density-functional-theory calculations (including ab intio van-der-Waals interactions) of vibrational spectrum of the proposed structures to (1) attest their dynamical stability; (2) compare their thermodynamic stability as obtained from the total free energy; and (3) provide the vibrational frequencies that uniquely fingerprint the proposed structures.

11:27AM N22.00002 Vibrational and thermodynamic properties of transition-metal nanoclusters[1] , VALERI G. GRIGORYAN, MICHAEL SPRINGBORG, Physical and Theoretical Chemistry, University of Saarland, Germany — The knowledge of the vibrational spectrum of a cluster, which is the fingerprint of its structure, is necessary for the development of thermodynamics of clusters (melting, heat capacity, solid-solid structural transitions) and for the understanding of experimental vibrational spectra. In summary, the full vibrational spectrum of Ni_N and Cu_N nanoclusters with N from 2 to 150 atoms has been determined using the analytical expression of the embedded-atom method (EAM) for the *force-constant tensor* for the first time. In the determination of the spectra we have employed the global-minimum structures obtained in our previous unbiased EAM studies (see e.g. Physical Review B, 2004; 2006). Furthermore, using those spectra and the superposition approximation, the thermodynamic properties of the clusters have been calculated quantum mechanically, including their heat capacity and solid-solid transition temperatures for several structural changes in the Ni and Cu clusters. Both the vibrational spectrum and the thermodynamic functions show strong cluster-size effects. We emphasized that our approach is general. It is based only on the (common) EAM form of the total energy and applicable to many other many-body potentials.

11:39AM N22.00003 Material Improvements of ZnCdSe/ZnCdMgSe Heterostructures for Quantum Cascade Laser Applications with Incorporation of Growth Interruptions During MBE Growth , THOR GARCIA, The Graduate Center of CUNY, New York, NY 10016, JOEL DE JESUS, The Graduate Center of CUNY,New York, NY 10016, ARVIND RAVIKUMAR, Princeton University, Princeton, NJ 08544, SONGWOUNG HONG, The City College of New York, New York, NY 10031, CLAIRE GMACHL, Princeton University, Princeton, NJ 08544, AIDONG SHEN, The City College of New York, New York, NY 10031, MARIA TAMARGO, The City College of New York, NY, NY 10031 — We report on the growth of ZnCdSe/ZnCdMgSe/InP Quantum Cascade (QC) structures with improved electrical and material properties. Material quality has been previously addressed by limiting the lattice mismatch to within 0.2% of InP. However, the yields of high quality material have remained low and lasing has not been observed. To address the low growth yields we have investigated possible mechanisms for degradation of the material. Growth interruptions during the MBE growth were added to the active core of the QC laser structure. High resolution XRD and PL were used to evaluate the material quality. Fabricated devices with growth interruptions show a dramatic improvement in the electroluminescence spectral properties.

11:51AM N22.00004 New crystal structures in hexagonal $CuInS_2$ nanocrystals , XIAO SHEN, EMIL A. HERNÁNDEZ-PAGAN, Vanderbilt University, WU ZHOU, Vanderbilt University and Oak Ridge National Lab, YEVGENIY S. PUZYREV, Vanderbilt University, JUAN C. IDROBO, Oak Ridge National Lab, JANET E. MACDONALD, Vanderbilt University, STEPHEN J. PENNYCOOK, Oak Ridge National Lab, SOKRATES T. PANTELIDES, Vanderbilt University and Oak Ridge National Lab — $CuInS_2$ is one of the best candidate materials for solar energy harvesting. Its nanocrystals with a hexagonal lattice structure that is different from the bulk chalcopyrite phase have been synthesized by many groups. The structure of these $CuInS_2$ nanocrystals has been previously identified as the wurtzite structure in which the copper and indium atoms randomly occupy the cation sites. Using first-principles total energy and electronic structure calculations based on density functional theory, UV-vis absorption spectroscopy, X-ray diffraction, and atomic resolution Z-contrast images obtained in an aberration-corrected scanning transmission electron microscope, we show that $CuInS_2$ nanocrystals do not form random wurtzite structure. Instead, the $CuInS_2$ nanocrystals consist of several wurtzite- related crystal structures with ordered cation sublattices, some of which are reported for the first time here. This work is supported by the NSF TN-SCORE (JEM), by NSF (WZ), by ORNL's Shared Research Equipment User Program (JCI) sponsored by DOE BES, by DOE BES Materials Sciences and Engineering Division (SJP, STP), and used resources of the National Energy Research Scientific Computing Center, supported by the DOE Office of Science under Contract No. DE-AC02-05CH11231.

12:03PM N22.00005 Measuring the Elastic Modulus of the Grain Boundary Component of Nanocrystalline Copper , GUO-JIE GAO, YUNJIANG WANG, SHIGENOBU OGATA, Osaka University — In the past twenty years, it has been widely accepted that the Young's modulus of the grain boundary (GB) part of nanocrystalline metals is about 70% of that of the crystalline core component. However, this belief is an assumption based on numerical studies of specific grain boundary like $\Sigma 5$ twist boundary where atoms interact with one another via simplified Lennard-Jones potential at $0K$ or experimental studies assuming the GB behaves like amorphous alloys. A thorough investigation driven from completely realistic atomic simulation at finite temperature is still lacking. We reexamine this assumption by measuring the Young's modulus of pure copper (Cu) with grain size ranging from 3 to 25 nm at $300K$ using molecular dynamics (MD) uniaxial tensile tests. We implement a novel Voronoi protocol to build nanocrystalline structures of fully dense pure Cu with well-controlled grain size distribution and Mishin embedded atom model (EAM) potential. We find the following key results concerning the stiffness for nanocrystalline metals at finite temperature: 1) The GB is more thermally sensitive and therefore elastically much softer than the crystalline interior. 2) The Young's modulus of the GB is about 20% or less of that of the grain interior.

12:15PM N22.00006 Structural and compositional characterization of "covetics" a new class of materials containing high C concentration[1] , R.A. ISAACS, University of Maryland College Park, A. HERZING, National Institute of Standards and Technology, D.R. FORREST, A.N. MANSOUR, Naval Surface Warfare Center, M.C. LEMIEUX, Chemical Engineering Department, Stanford University, J. SHUGART, Third Millennium Metals, LLC, L. SALAMANCA-RIBA, University of Maryland College Park — "Covetics" are a new class of materials formed by the incorporation of high concentrations ($> 6wt\%$) of nanoscale carbon in a metal matrix. The carbon incorporates into the crystal structure of the host metal and remains dispersed after subsequent melting and re-solidification. The carbon is highly stable in these materials despite the absence of a predicted solid solution at such concentrations in the binary phase diagrams. Covetics have been shown to exhibit enhanced electrical, mechanical and thermal properties when compared with non-covetic metals. We have performed energy dispersive X-ray spectroscopy (EDS), X-ray photoelectron spectroscopy (XPS), X-ray absorption spectroscopy (XAS), SEM, TEM, STEM/electron energy loss spectroscopy (EELS), AFM, and Raman spectroscopy to investigate the structure of Al, Cu, and Ag covetics. Both bulk samples and thin films are investigated. Carbon was detected in the form of nanoparticles 5 nm - 200 nm in diameter with an interconnecting carbon matrix. The carbon is detectable by EDS and XPS, but not by analytical methods such as LECO and GDMS. Raman indicates a similar signal to that of CNTs in covetics. A detailed investigation of the morphology of the nanocarbon and the structure of several covetics will be presented.

[1]Supported in part by NSF MRSEC DMR 0520471.

12:27PM N22.00007 Computational Investigations of a Possible New Class of Materials: A Superatom Ionic Solid , KARL SOHLBERG, VIOLETA NASTO, Drexel University — A "superatom" is a cluster of atoms that shows high stability. High stability can arise from the geometric arrangement of the atoms in the cluster. For example, when atoms are close packed, clusters containing an integer number of closed shells of atoms, (i.e. 13, 55, 137... atoms) exhibit enhanced stability and are termed "magic clusters." High stability can also arise from the electronic structure. High symmetry metal clusters that have exactly 8, 20, 40..., valence electrons show enhanced stability. Superatoms can act chemically like a single atom of a different element. We have used electronic structure calculations to test the idea that a new class of materials may be formed based on the periodic arrangement of superatom ions, instead of the typical atomic or polyatomic ions of a conventional ionic solid. A solid is formed based on crystalline packing of anionic ($Al@Cu_{54}^-$) and cationic ($Ce@C_{60}^+$), nearly spherical superatom species that show exceptional stability. According to radius-ratio rules, these ions will favor a CsCl crystal structure with a body-centered (bcc) type of unit cell. Calculations on this material suggest that it is stable, semiconducting and less dense than common metal oxides, but that the metal anion clusters deform within the material.

12:39PM N22.00008 Electronically Guided Self Assembly within Quantum Corrals[1] , RONGXING CAO, BINGFENG MIAO, ZHANGFENG ZHONG, LIANG SUN, BIAO YOU, WEI ZHANG, DI WU, AN HU, Department of Physics, Nanjing University, SAMUEL BADER, Center for Nanoscale Materials, Argonne National Laboratory, HAIFENG DING, Department of Physics, Nanjing University, LOW DIMENSIONAL MAGNETISM TEAM, CENTER FOR NANOSCALE MATERIALS COLLABORATION — A grand challenge of nanoscience is to master the control of structure and properties in order to go beyond present day functionality. The creation of nanostructures via atom manipulation by means of a scanning probe represents one of the great achievements of the nano era. Here we build on this achievement to self-assemble nanostructures within quantum corrals. We constructed circular and triangular Fe quantum corrals on Ag(111) substrate via STM manipulation and studied the quantum confinement of electronic states and the diffusion of Gd atoms inside the corrals. Statistical results reveal the motion of the Gd atoms forming several individual orbits that are closely related to the local density of states. We experimentally demonstrate that different self-organized Gd atomic structures are formed within 30-nm circular and triangular Fe quantum corrals with a step-by-step guiding process. The findings demonstrate that quantum confinement can be used to engineer atomic structures and atom diffusion. And 30-nm resolution can be reached by means of advanced lithography. Adding quantum engineering to augment it opens new possibilities for local functionality design down to the atomic scale.

[1]Work at Nanjing is supported by the State Key Program for Basic Research of China (Grant No. 2010CB923401), NSFC (Grants Nos. 10974087, 10834001, and 11023002) and PAPD.

12:51PM N22.00009 Simultaneous hypersonic and optical mirrors in nanometric porous silicon multilayers , JESUS MANZANARES-MARTINEZ, Departamento de Investigacion en Fisica, Universidad de Sonora, Apartado Postal 5-088, Hermosillo, Sonora 83180, Mexico, PAOLA CASTRO-GARAY, DAMIAN MOCTEZUMA-ENRIQUEZ, YOHAN JASDID RODRIGUEZ-VIVEROS, Departamento de Fisica, Universidad de Sonora, Blvd. Luis Encinas y Rosales, Hermosillo, Sonora 83180, Mexico. — We study by theoretical simulations the non-perpendicular propagation of electromagnetic and elastic waves in Porous Silicon Multilayers (PSM). Our work is inspired by recent experimental results where the angular variation of the optical and hypersonic stop bands has been explored in PSM. [L. C. Parsons and G. T. Andrews, J. Appl. Phys. 111, 123521 (2012)] We proceed in three steps. First, we found the conditions to obtain a simultaneous photonic-phononic mirror at normal incidence. Second, we determined the angular variation of the mirrors computing the projected band structure. Finally, we found the conditions to obtain an omnidirectional mirror for hypersonic waves. However, we have found that for the optical case the mirror is limited to an angular cone.

1:03PM N22.00010 Dynamic Structural Disorder in Supported Nanoparticles[1] , F.D. VILA, J.J. REHR, Dept. of Physics, U. of Washington, Seattle, WA 98195, S.D. KELLY, S.R. BARE, UOP LLC, Des Plaines, IL 60016 — Supported Pt based nanoclusters are of wide interest in nano-scale physics and have many industrial applications, yet an understanding of their structure is far from complete. Experimental probes such as x-ray absorption spectroscopy (XAS) only yield globally averaged properties, e.g., mean bond distances and mean-square radial disorder (MSRD), which can give a misleading characterization of such complex systems. To obtain a more detailed picture we have carried out finite temperature DFT/MD simulations[2] of Pt and PtSn nanoclusters up to 600 K (*operando* conditions). These show that the nano-scale structure and charge distribution are inhomogeneous and dynamically fluctuating over several time-scales, ranging from fast (200-400 fs) bond vibrations to slow fluxional bond breaking (>10 ps). In particular the anomalous behavior of the MSRD is not static, but rather due to "dynamic structural disorder" (DSD) driven by stochastic motion of the center of mass over 1-4 ps time-scales. In addition the nanoclusters exhibit a semi-melted, Sn-rich surface. These findings show that, and how an improved XAS interpretation of supported nano-scale structure must take into account DSD and other structural inhomogeneities.

1:15PM N22.00011 The Orientation Control of Iodine Molecules inside nano-scale channels , DINGDI WANG, JUANMEI HU, WENHAO GUO, SHENGWANG DU, Z.K. TANG, Hong Kong University of Science and Technology — We demonstrate a technique to control the spatial orientation of iodine molecules inside nano-scale channels of an $AlPO_4$-11 zeolite crystal. The orientation of iodine molecules can be precisely controlled by the water molecule density inside the channels due to the interaction between iodine and water molecules. Without the presence of water molecules, all the embedded iodine molecules are directed along the direction of nano channels. As increasing the number of water molecules, the iodine molecules gradually "stand up" insde nano channels. The experimental results obtained from polarized Raman spectroscopy agree well with the theoretical analysis using molecular dynamics simulation. This technique may be used for engineering molecular orientation in nano-structured devices.

1:27PM N22.00012 Epitaxial growth of YSi_2 nanowires the on Si(110) surface , SABAN HUS, HANNO WEITERING, The University of Tennessee — High-aspect-ratio YSi_2 nanowires have been grown epitaxially on the Si (110) surface. In contrast to epitaxial growth on the Si (100) surface, YSi_2 nanowires on Si (110) grow in a single orientation and show a clear preference of nucleating at terrace edges, thus providing a promising method for fabricating regular nanowire arrays with controlled wire separation. The thinnest YSi_2 nanowires have a cross section of $\sim$ 0.5 x 2.8 nm^2 with wire lengths of up to a few hundred nm, while thicker nanowires can grow up to several μm long. Scanning tunneling spectroscopy measurements on individual nanowires indicate that the nanowires have metallic properties while the surface between the nanowires has a band gap of $\sim$ 1eV. These nanowires thus represent an ideal platform for studies of quasi one-dimensional electrical transport. Such studies are currently underway in our laboratory.

1:39PM N22.00013 Absence of Dirac Electrons in Silicene on Ag (111) Surfaces , ZHI-XIN GUO, SHINNOSUKE FURUYA, JUN-ICHI IWATA, ATSUSHI OSHIYAMA, Department of Applied Physics, The University of Tokyo, Tokyo 113-8656, Japan — We report first-principles calculations that clarify stability and electronic structures of silicene on Ag(111) surfaces. We find that several stable structures exist for silicene /Ag(111), exhibiting a variety of surface morphology. We also find that Dirac electrons are absent near Fermi energy in all the stable structures due to buckling of the Si monolayer and mixing between Si and Ag orbitals. We propose that either BN substrate or hydrogen processing of Si surface is a good candidate to preserve Dirac electrons in silicene.

1:51PM N22.00014 Engineering of the Static Interface Dipole in Metal/Organic Nanohybrid Materials[1] , AXEL ENDERS, DONNA KUNKEL, JUSTIN NITZ, PETER DOWBEN, University of Nebraska - Lincoln, LUCIE ROUTABOUL, BERNARD DOUDIN, PIERRE BRAUNSTEIN, Université de Strasbourg, Strasbourg, France, SCOTT SIMPSON, EVA ZUREK, Dept. of Chemistry, SUNY Buffalo — We studied small molecules with large intrinsic electrical dipole as model system for molecular films adsorption on surfaces for altering the interface dipole screening. More specifically, we investigated the self-assembly and electronic interface properties of zwitterionic molecules of type C6H2(...NHR)2(...O)2 (R = H, ...), adsorbed on Cu(111), Ag(111), Au(111) surfaces with scanning tunneling microscopy in UHV. These molecules carry positive and negative charges on opposite parts of the molecule, resulting in a large electric dipole of typically 10 Debye. We find that the dipole of the surface-supported molecule is decreased with respect to free species and of order of 1 - 2 Debye, depending on the substrate material. The molecules self-assemble into 2D structures upon adsorption, where the substrate-dependent strength of the dipolar interactions between the adsorbed molecules dictates the network architecture. DFT calculations were performed to analyze adsorption geometry, charge transfer and dipole moment. We will show that zwitterionic molecules provide a unique opportunity to engineer the interface dipole in metal/organic hybrid structures, which ultimately controls the charge injection barrier in devices.

2:03PM N22.00015 Self-Organized Growth of Single Crystalline Copper Nanobead Strings by Electrodeposition , CONG MENG, RUWEN PENG, MU WANG, Nanjing University — Here we report a self-organized growth of single-crystalline strings of nano sized copper beads electrodeposited from an ultrathin layer of CuSO4 electrolyte solution without adding any additives. Spontaneous oscillation of voltage/current has been observed when potentiostatic/galvanostatic mode is applied. Scanning electron microscopy indicates that the filaments developed from the cathode are made of smooth copper beads a few hundreds of nanometers in size connected by thin single-crystalline rods. The periodicity along the string may vary from 500nm to one micron, and the spatial periodicity is strict up to hundreds of microns. To pinpoint the growth mechanism, we intentionally terminate the growth at different stage of the spontaneous oscillation of the voltage across the electrodes, and established the relation of the microscopic deposit morphology and the voltage oscillations. A growth mechanism is proposed based on the experimental observations. Structural and luminescent properties of the copper strings have been investigated, and the possible applications of such a unique structure have been discussed.

Wednesday, March 20, 2013 11:15AM - 2:15PM –

Session N23 FIAP: Fractional Quantum Hall Theory I 325 - B. Andrei Bernevig, Princeton University

11:15AM N23.00001 When is a "wavefunction" not a wavefunction?: a quantum-geometric reinterpretation of the Laughlin state[1] , F.D.M. HALDANE, Princeton University — The Laughlin state is the fundamental model for the description of fractional quantum Hall (FQH) fluids and was presented as a "lowest Landau-level (LLL) Schrödinger wavefunction", i.e., of the form $f(z_1,\ldots,z_N)\exp-\sum_i z_i^* z_i/2$, where $z_i = (x_i + iy_i)/\sqrt{2}\ell_B$, and $|z_i - z_0|^2$ = constant is the shape of a Landau orbit. Its characterization as a LLL wavefunction was generally accepted without question, and leads to "explanations" of its success in terms of judicious placement of its zeroes. However, the Laughlin state also occurs in the n=2 LL, and now has been found in Chern-insulator lattice systems. Numerical studies confirm that (without direct reference to which LL is partially-occupied) its success can be explained solely in terms of the short-range repulsion between the non-commuting guiding centers of Landau orbits. These (as a "quantum geometry") do not by themselves have a Schrödinger (as opposed to Heisenberg) description. A reexamination shows that the variable "z" describes the shape of an emergent geometry of the FQH fluid derived from the Coulomb interaction, not the Landau-orbit shape, and that the holomorphic function is a coherent state representation of a Heisenberg state, not a Schrödinger wavefunction.

[1]Supported by DOE DE-SC0002140.

11:27AM N23.00002 The correct theory of the quantum Hall effect fractions , KESHAV SHRIVASTAVA, University of Hyderabad — The effective charge,e*=(1/2)ge, obtained by introducing the symmetric g values, g=(2J+1)/(2L+1) with J given by L and S with both signs for S, and the Bohr magneton, used in the cyclotron frequency leads to factors of the type (1/2)g(n+1/2) in the eigen values which give the correct description of the modified Landau levels. The resistivity after introducing the flux quantization is modified by the effective charge which gives the plateaux. The helicity of every electron is defined by the sign of p.s where p is the linear momentum and s is the spin. Hence the +s particles move in the direction opposite to those of -s. The principal fractions, two-particle states and resonances explain most of the data. The remaining data is explained by the formation of electron clusters with spin different from 1/2. In this way all of the 101 or more fractions of the experimental data are correctly derived from the theory. The theory does not depend seriously on the dimensionality so it explains the graphite as well as the graphene.

11:39AM N23.00003 Nematic order and a new field theory of the quantum Hall effect , JOSEPH MACIEJKO, BENJAMIN HSU, YEJE PARK, Princeton University, STEVE KIVELSON, Stanford University, SHIVAJI SONDHI, Princeton University — Motivated by recent experimental and theoretical studies of anisotropic versions of the fractional quantum Hall (FQH) effect, we construct an effective field theory for a continuous quantum phase transition between an isotropic FQH state and a nematic FQH state. The theory parallels earlier work on FQH ferromagnets. The $SO(3)$ order parameter $\mathbf{n}$ of the ferromagnet is replaced by the Landau-de Gennes nematic tensor order parameter Q_{ab} which can be mapped to a $SO(2,1)$ Lorentz vector. We construct an analog of the CP^1 representation of a ferromagnet in terms of complex $SU(1,1)$ spinors. We identify these vector and spinor order parameters with the unimodular metric and zweibein fields appearing in Haldane's recent geometrical description of the FQH effect, where the metric field g_{ab} is given by the matrix exponential of the nematic order parameter Q_{ab}. Our theory predicts that if the gap of the Girvin-MacDonald-Platzman collective mode can be made to collapse at zero momentum in a FQH system, an instability to a FQH nematic state should occur.

11:51AM N23.00004 Elementary formula for the Hall conductivity of interacting systems , TITUS NEUPERT, Paul Scherrer Insitute, LUIZ SANTOS, Perimeter Institute, CLAUDIO CHAMON, Boston Univeristy, CHRISTOPHER MUDRY, Paul Scherrer Insitute — We proof a formula for the Hall conductivity of interacting electrons under the assumption that the ground state manifold has finite degeneracy and discrete translation symmetry is neither explicitly nor spontaneously broken. Via an algebraic regularization, our derivation makes use of the noncommutative relations obeyed by the components of the position and density operators in topological band structures. We discuss the implications of our result in the context of fractional Chern insulators.

12:03PM N23.00005 Fractional Quantum Hall Effect from Phenomenological Bosonization[1] , VLADIMIR ZYUZIN, University of Maryland — In this work we propose a model of the fractional quantum Hall effect within conventional one-dimensional bosonization. It is shown that in this formalism the resulting bosonized fermion operator corresponding to momenta of Landau gauge wave function is effectively two-dimensional. At special filling factors the bulk gets gapped, and the theory is described by a sine-Gordon model. The edges are shown to be gapless, chiral, and carrying a fractional charge. The hierarchy of obtained fractional charges is consistent with existing experiments and theories. It is also possible to draw a connection to composite fermion description and to the Laughlin many-body wave function.

12:15PM N23.00006 Axial anomaly of Lifshitz fermions with arbitrary anisotropic scaling z in $2n$ spacetime dimensions , XUEDA WEN, Physics Department, UIUC — We calculate the axial anomaly of a Lifshitz fermion with arbitrary anisotropy scaling exponent z which is coupled to gauge fields in $2n$ spacetime dimensions. We find that the result is identical to the relativistic case. The conclusion is verified with both path integral methods and spectral methods in $2n$ spacetime dimensions. Our work is a generalization of I. Bakas' work (arXiv:1110.1332) which focuses on (3+1) dimensions. In addition, we discuss the application of our conclusion to transport processes in quantum Hall systems as well as Weyl semi-metals.

12:27PM N23.00007 Metallic phase of the quantum Hall effect in four-dimensional space[1] , JONATHAN EDGE, Leiden University, JAKUB TWORZYDLO, University of Warsaw, CARLO BEENAKKER, Leiden University — We study the phase diagram of the quantum Hall effect in four-dimensional (4D) space. Unlike in 2D, in 4D there exists a metallic as well as an insulating phase, depending on the disorder strength. The critical exponent $\nu \approx 1.2$ of the diverging localization length at the quantum Hall insulator-to-metal transition differs from the semiclassical value $\nu = 1$ of 4D Anderson transitions in the presence of time-reversal symmetry. Our numerical analysis is based on a mapping of the 4D Hamiltonian onto a 1D dynamical system, providing a route towards the experimental realization of the 4D quantum Hall effect.

12:39PM N23.00008 Correlations in incompressible quantum liquid states: constructions of electronic trial wavefunctions , JOHN QUINN, University of Tennessee, Knoxville — Numerical studies indicate that incompressible quantum Hall states occur when the relation between the single particle angular momentum l and the number N of electrons in the partially filled Landau level is $2l = \nu^{-1}N - c_\nu$. Here, ν is the filling factor and c_ν is a "finite size shift." The values of c_ν found numerically depend on correlations, and for $\nu = p/q \leq 1/2$ are given by $c_\nu = q + 1 - p$. This finite size shift points the way to constructing electronic trial wavefunctions. A trial wavefunction can always be written $\Psi = FC$, where $F = \prod_{i<j} z_{ij}$ and $C(z_{ij})$ is a symmetric correlation function caused by interactions. For the Moore-Read state, $C_{MR}(z_{ij})$ is a product of F and the antisymmetric Pfaffian. C_{MR} is not the only possible correlation function for this state. Another choice is the quadratic function $C_Q = S\left\{\prod_{i<j\in g_A}\prod_{k<l\in g_B}(z_{ij}z_{kl})^2\right\}$, where S is a symmetrizing operator, and g_A and g_B each contain $N/2$ particles resulting from a partition of N into two sets. For the Jain states (e.g. $\nu = 2/5$), different partitioning of N particles into sets of unequal size gives appropriate correlation functions.

12:51PM N23.00009 Exactly solvable $U(1)\times U(1)$ boson models for integer and fractional quantum Hall insulators in two dimensions , OLEXEI MOTRUNICH, SCOTT GERAEDTS, California Institute of Technology — We present a solvable boson model with $U(1) \times U(1)$ symmetry in (2+1) dimensions that realizes insulating phases with a quantized Hall conductivity σ_{xy}. The model is short-ranged, with no topological terms, and can be realized by a local Hamiltonian. For one set of parameters, the model has a non-fractionalized phase with $\sigma_{xy} = 2n$ in appropriate units, with n an integer. In this case, the physical origin is dynamical binding between n bosons of one species and a vortex of the other species and condensation of such composites. Other choices for the parameters of the model yield a phase with $\sigma_{xy} = 2\frac{c}{d}$, where c and d are mutually prime integers. In this phase, c bosons dynamically bind to d vortices and such objects condense. The are two species of excitations that are bosonic by themselves but carry fractional charge $1/d$ and have mutual statistics $2\pi\frac{b}{d}$, where b is an integer such that $ad - bc = 1$, and a is also an integer. The model can be studied using sign-free Monte Carlo. We have performed simulations which include a boundary between a quantum Hall insulator and a trivial insulator, and found gapless edge states on the boundary.

1:03PM N23.00010 Matrix Product States and Fractional Quantum Hall , B. ANDREI BERNEVIG, Princeton University, BENOIT ESTIENNE, Paris Jussieu, NICOLAS REGNAULT, Princeton University/ Ecole normale superieure paris, ZLATKO PAPIC, Princeton University — We present an exact matrix product state expansion (MPS) for a large series of Jack polynomial wavefunctions which serve as Fractional Quantum Hall ground-states of pseudopotential Hamiltonians. Using the basis of descendants in Virasoro and W algebras we build MPS descriptions of the (k,2) Jacks which include the Moore-Read state and the Gaffnian state, as well as MPS representation of the Z_3 Read-Rezayi state. We then give a general method for computing MPS representations for other non-abelian states and their quasiholes.

1:15PM N23.00011 Benchmarking MPS for fractional quantum Hall states , NICOLAS REGNAULT, Ecole Normale Superieure-CNRS / Princeton University, BENOIT ESTIENNE, LPTHE, UPMC Universite Paris 06, ZLATKO PAPIC, B. ANDREI BERNEVIG, Princeton University — We discuss the numerical apsects of the Matrix Product State (MPS) representation for a large series of Fractional Quantum Hall states. We benchmark the MPS for several model states such as the Read-Rezayi series using both overlap, energies, densities and pair correlation functions. We discuss how accurate this description is depending on the geometry (sphere, disk or cylinder). As an application, we use the MPS to compute the size of the quasiholes for the Read-Rezayi series.

1:27PM N23.00012 Exact Matrix Product States for Quantum Hall Wave Functions , ROGER MONG, California Institute of Technology, MICHAEL ZALETEL, University of California, Berkeley — We show that the model wave functions used to describe the fractional quantum Hall effect have exact representations as matrix product states (MPS). These MPS can be implemented numerically in the orbital basis of both finite and infinite cylinders, which provides an efficient way of calculating arbitrary observables. We extend this approach to the charged excitations and numerically compute their Berry phases. Finally, we present an algorithm for numerically computing the real-space entanglement spectrum starting from an arbitrary orbital basis MPS, which allows us to study the scaling properties of the real-space entanglement spectra on infinite cylinders. The real-space entanglement spectrum obeys a scaling form dictated by the edge conformal field theory, allowing us to accurately extract the two entanglement velocities of the Moore-Read state.

1:39PM N23.00013 Long-wavelength corrections to Hall conductivity in fractional quantum Hall fluids[1] , BO YANG, F.D.M. HALDANE, Princeton University — Recent work by Hoyos and Son, then Bradlyn et al., has investigated the relation between the long-wavelength ($O(q^2)$) corrections to the Hall conductivity $\sigma_H(\mathbf{q})$ and the Hall viscosity of quantum Hall states. These works assume the presence of Galilean and rotational invariance. However, these are not generic symmetries of electrons in condensed matter. We identify translation and (2D) inversion symmetry as the only generic symmetries of an "ideal" quantum Hall liquid, as these are needed to guarantee the absence of any dissipationless ground state current density; then $\sigma_H(\mathbf{q}) = \sigma_H(-\mathbf{q})$ characterizes the dissipation less current that flows in response to a spatially-non-uniform electric field. We consider the general problem for fractional quantum Hall (FQH) states without Galilean or rotational invariance, when the guiding-center contribution to the Hall viscosity becomes a non-trivial tensor property related to an emergent geometry of the FQH state, (Bo Yang et,al (PRB 85,165318).

1:51PM N23.00014 Fractional topological superconductors with fractionalized Majorana fermions , ABOLHASSAN VAEZI, Cornell Univeristy — In Ref[1], I introduced a two dimensional fractional topological superconductor (FTSC) as a strongly correlated topological state which can be achieved by inducing superconductivity into an Abelian fractional quantum Hall (FQH) state, through the proximity effect. When the proximity coupling is weak, the FTSC has the same topological order as its parent state, and thus Abelian. However, upon increasing the proximity coupling, the bulk gap of such an Abelian FTSC closes and reopens resulting in a new topological order: a non-Abelian FTSC. I show that the conformal field theory (CFT) that describes the edge state of non-Abelian FTSC is $U(1)/Z_2$ orbifold theory and use this to write down the ground-state wave-function. Further, I predict FTSC based on Laughlin state at $\nu = 1/m$ filling to host vortices with fractionalized Majorana zero modes. These zero modes are non-Abelian quasi-particles which is evident in their quantum dimension of $d_m = \sqrt{2m}$. Using the multi-quasi-particle wave-function based on the edge CFT, I derive the braid matrix for the zero modes. Finally, the potential applications of the non-Abelian FTSCs in the topological quantum computation will be illustrated. [1] A. Vaezi, ArXiv:1204.6245 (2012)

2:03PM N23.00015 Momentum polarization: an entanglement measure of topological spin[1] , XIAOLIANG QI, Stanford University — Topologically ordered states are states of matter which are distinct from trivial states by topological properties such as ground state degeneracy and quasi-particles carrying fractional quantum numbers and fractional statistics. The topological spin is an important property of a topological quasi-particle, which is the Berry phase obtained in the adiabatic self-rotation of the quasi-particle by 2π. In this paper we propose a new approach to compute the topological spin in candidate systems of two-dimensional topologically ordered states. We identify the topological spin with a new quantity, the momentum polarization defined on the cylinder geometry. We show that the momentum polarization is determined by the quantum entanglement between the two halves of the cylinder, and can be computed from the reduced density matrix. As an example we present numerical results for the honeycomb lattice Kitaev model, which correctly reproduces the expected spin $e^{i\frac{2\pi}{16}}$ of the Ising non-Abelian anyon (σ particle). Our result provides a new efficient approach to characterize and identify topological states of matter from finite size numerics.

11:15AM N24.00001 Large-scale Bethe-Salpeter equation calculations of core-level x-ray spectra[1] , J. J. REHR, J. VINSON[2], K. GILMORE, U. Washington — Recently an approach has been developed for Bethe-Salpeter equation (BSE) calculations of core-level x-ray spectra, which is implemented in the OCEAN package [3] which combines plane-wave, pseudopotential DFT electronic structure, PAW transition elements, GW self-energy corrections, and the NIST BSE solver. The method yields both dipole limited and finite momentum transfer spectra. Here we discuss several recent advances which yield a unified treatment of both extended states and atomic multiplet effects. In particular our approach now includes spin-dependent potentials and hole-dependent lifetimes, and gives an improved treatment of $L_{2,3}$ edges, where contributions to spectral weight come from a mix of two distinct core holes. We have also extended the code interface to include pseudopotential wave functions from ABINIT, QUANTUMESPRESSO, or an interpolation based scheme, thus enabling large-scale calculations with unit cells in excess of 2000 Å^3. Applications to water and ice structures are briefly discussed.

11:27AM N24.00002 Calculation of charge-transfer satellites in x-ray absorption spectroscopy of transition metal oxides[1] , E. KLEVAK, University of Washington, J.J. KAS, U. Washington, J.J. REHR, University of Washington — Charge-transfer (CT) satellites in x-ray absorption spectroscopy (XAS) require treatments of correlation effects beyond the quasi-particle approximation. Here we present an approach for including CT effects in XAS that follows the model of Lee *et al.*[2] The approach is based on a three level system coupled to an itinerant state, with parameters obtained from either ab inito calculations or x-ray photoemission spectroscopy. The model yields an approximation to CT satellites in XAS in terms of a convolution of the quasi-particle spectrum with an energy-dependent spectral function that accounts for both localized CT excitations and solid state effects. The approach illustrates the crossover from the sudden to adiabatic approximations. Calculations for transition metal oxides, e.g. NiO and CoO, give reasonable agreement with XAS experiment. Finally, an extension of the present approach to CT satellites in resonant inelastic x-ray spectroscopy is also discussed.

11:39AM N24.00003 Correlation matrix renormalization approximation for total energy calculations of correlated electron systems[1] , Y.X. YAO, C. LIU, J. LIU, Ames Laboratory and Iowa State University, W.C. LU, Jilin University and Qingdao University, C.Z. WANG, K.M. HO, Ames Laboratory and Iowa State University — The recently introduced correlation matrix renormalization approximation (CMRA) was further developed by adopting a completely factorizable form for the renormalization z-factors, which assumes the validity of the Wick's theorem with respect to Gutzwiller wave function. This approximation (CMR-II) shows better dissociation behavior than the original one (CMR-I) based on the straightforward generalization of the Gutzwiller approximation to two-body interactions. We further improved the performance of CMRA by redefining the z-factors as a function of f(z) in CMR-II, which we call CMR-III. We obtained an analytical expression of f(z) by enforcing the equality in energy functional between CMR-III and full configuration interaction for the benchmark minimal basis H2. We show that CMR-III yields quite good binding energies and dissociation behaviors for various hydrogen clusters with converged basis set. Finally, we apply CMR-III to hydrogen crystal phases and compare the results with quantum Monte Carlo.

11:51AM N24.00004 Disorder effects in solid state systems beyond a single-site prospective: theories and applications , ALBERTO MARMODORO, ARTHUR ERNST, Max-Planck-Institut für Mikrostrukturphysik, Halle — We review development and applications of improvement attempts upon the original Coherent Potential Approximation for the first-principles treatment of disordered systems. The single-site theory is examined in its basic aspects of analyticity and convergence, and compared with alternative methods for the study of solid state systems where a rigorous application of Bloch's theorem is no longer possible. The aspects of local environment effects, short-range ordering and off-diagonal disorder are considered in different extension proposals, in tight-binding and ab-initio illustrations based on multiple-scattering theory. In this context, results from application of a generalized version of the method are discussed evaluating some effects of disorder in solid state metallic solutions, molar doping materials for fuel cell technology, and magnetic compounds and excitations. Results from alternative methodologies such as supercell or special quasi-random structure approximations are also examined.

12:03PM N24.00005 First-principles studies of photoelectron spectroscopy of solvated hydronium and hydroxide in water , CHARLES SWARTZ, XIFAN WU, Temple University — Solvated hydronium ($H3O^+$) and hydroxide (OH^-) are important solutions of water defects. In a recent state-of-the-art photoelectron spectroscopy (PES) experiment, the binding energies of these water defects have been measured. Theoretically, we show that the photoelectron spectroscopy can be accurately computed based on GW quasi-particle theories, in which the molecular solvation structures are generated by ab initio molecular dynamics (AIMD). The resulting hydronium and hydroxide binding energies are 10 eV and 19 eV respectively, which are closely consistent with the recent PES experimental values of 9.2 eV and 20 eV. A close inspection reveals that the defect orbitals originate from the $1b_2$ ($1b_1$) state of $H3O^+$ (OH^-) molecules in the gas phase. These orbitals are further strongly distorted by the surrounding water molecules, in which the H3O+ and OH- defects states are clearly localized on the so-called Zundel and Eigen solvation structures respectively. Proton transfers are found to further broaden the PES spectrum, which is more prominent in $H3O^+$ than in OH^- solutions.

12:15PM N24.00006 Bethe-Salpeter equation calculations of resonant inelastic x-ray scattering at the nitrogen K edge , JOHN VINSON, TERRENCE JACH, NIST, Gaithersburg, MD, TIM ELAM, Applied Physics Laboratory, U. Washington, JONATHON DENLINGER, Advanced Light Source, LBL — We present theoretical calculations of resonant inelastic x-ray scattering (RIXS) at the nitrogen K edge of several materials along with direct comparison to experimental results. Our approach is based on a Bethe-Salpeter equation formalism, and our calculations are carried out using an extension of the OCEAN package,[1] including both intermediate and final-state excitonic effects. By building upon a DFT basis we include ground-state effects without system-dependent fitting parameters. We are able to account for the general trends and features seen in experiment. A more *ad hoc* account of other contributions to the measured spectra, primarily phonon coupling, is attempted, but this highlights some current shortcomings limiting fully *ab initio* calculations of the near-edge x-ray spectra of extended systems.

[1]J. Vinson, E. L. Shirley, J. J. Rehr, and J. J. Kas, Phys. Rev. B **83**, 115106 (2011)

12:27PM N24.00007 Generalized optimization of Wannier functions , EMANUEL LAZAR, HYOWON PARK, CHRIS MARIANETTI, ANDY MILLIS, Columbia University — Marzari and Vanderbilt introduced and developed a technique for defining and computing "maximally localized" Wannier functions to represent localized orbitals in periodic materials [1]. Since then, this method has been heavily used in computational condensed matter physics calculations. The Marzari-Vanderbilt procedure localizes all orbitals in a given energy window. In this talk we present some ongoing work in generalized minimization strategies which can apply different constraints to different subspaces of the manifold (for example, localizing some orbitals more than others). Applications to model systems and more realistic low-dimensional materials are presented.

[1] Marzari et al. Rev. Mod. Phys. 84, 1419 (2012).

12:39PM N24.00008 Improving the Accuracy of Diffusion Monte Carlo: Insights from Calculations of High Pressure Solid-Solid Phase Transitions , L. SHULENBURGER, T. R. MATTSSON, Sandia National Laboratories — A challenging application for any electronic structure method is the calculation of solid-solid phase transitions under pressure. Due to stringent requirements on accuracy imposed by the sensitivity of such transitions on small changes in free energy these calculations are exquisitely sensitive to any systematic errors in the calculations. In this talk we will review the present sources of methodological uncertainties in the diffusion quantum Monte Carlo (DMC) technique and study their effects on the calculation of solid-solid phase transitions. Particular attention will be paid to finite size effects and errors arising from the use of pseudopotentials.
Sandia National Laboratories is a multiprogram laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under Contract No. DE-AC04-94AL85000.

12:51PM N24.00009 Assessing the connection between charge density and local fields , ERIC SHIRLEY, NIST — The dielectric screening of a potential disturbance depends on the electronic charge density. Local-field effects, such as those which generate non-zero off-diagonal matrix elements of the dielectric matrix, are related to Fourier components of the charge density. This talk will review the degree to which one can predict such off-diagonal effects based on the charge density alone. This shall be done within an independent-particle approximation and using model dielectric functions so that the results can be compared. We shall sample a range of metals, semiconductors and insulators.

1:03PM N24.00010 Anomalous Anharmonic Phonons in PbTe Reproduced from First-Principles Calculations , YUE CHEN, CHRIS MARIANETTI, Columbia University in the City of New York — PbTe is of great interest due to its thermoelectric properties. Inelastic neutron scattering experiments reveal a signature of strong anharmonicity as evidenced in an anomalous temperature dependence of the phonon spectra. Novel approaches based on first-principles calculations have been developed for computing anharmonic phonons at elevated temperatures in recent years, though these techniques do not include lifetime effects and hence cannot address the anomalies observed in experiment. Here we perform first-principles molecular dynamics which includes the anharmonic terms at lowest order. The temperature dependent phonon spectra is computed and compared to experimental measurements, yielding insight on the origin of the observed anomalies.

1:15PM N24.00011 Endohedral fullerene as acceptor: A DFT study on charge transfer states of $Sc_3N@C_{80}$-porphyrin complex[1] , FATAMEH AMERIKHEIRABADI, LUIS BASURTO, RAJENDRA ZOPE, TUNNA BARUAH, University of Texas at El Paso — C_{60} fullerene and its derivatives are the most popular acceptors which are used in molecular/polymeric complexes used in organic photovoltaics. Endohedral fullerenes are shown to produce long lived charge separated states. The $Sc_3N@C_{80}$, the third most abundant fullerene after C_{60} and C_{70}, has a larger cage with a radius of 4.1 Ang. We have carried out a DFT study on the electronic structure of ground and charge transfer states of a model $Sc_3N@C_{80}$-Zn tetraphenyl porphyrin cofacial complex. The C_{80} cage used in our calculations has icosahedral symmetry. We find that the lowest charge transfer state with a hole on the porphyrin and an electron on the $Sc_3N@C_{80}$ is at 2.1 eV above the ground state. The calculations show that different orientations of the Sc_3N unit to the porphyrin plane do not significantly alter the electronic structure. The electronic structure of the complex and its components along with the exciton binding energies will be presented.

1:39PM N24.00013 Melting of ice simulated by a multicanonical method combined with a first-principles calculation , YOSHIHIDE YOSHIMOTO, Department of Applied Mathematics and Physics, Graduate School of Engineering, Tottori University — Water is a ubiquitous material and is both scientifically and technologically important. For the simulation of water, the most common PBE semi-local exchange correlation (XC) functional has an issue: it gives over-structured liquid compared to the experimental one for a given temperature. On the other hand, the PBE0 hybrid XC functional was claimed to be better for the description of water recently [1,2]. In this study, the melting of ice, one of its most fundamental property, was simulated by a multicanonical method combined with a first-principles calculation [3,4]. Both the PBE XC functional and the PBE0 hybrid XC functional were adopted for the simulation. With accelerated computation of the hybrid functional by GPGPU, it was found that the PBE0 XC hybrid functional gave an improved melting temperature compared to that by PBE [5].

1:51PM N24.00014 DCA^+: Incorporating self-consistently a continuous momentum self-energy in the Dynamical Cluster Approximation , PETER STAAR, ETH Zurich, THOMAS MAIER, Oak Ridge National Lab, THOMAS SCHULTHESS, ETH Zurich, COMPUTATIONAL MATERIAL SCIENCE COLLABORATION — The dynamical cluster approximation (DCA) is a systematic extension beyond the single site approximation of dynamical mean field theory (DMFT) to include spatially non-local correlations in quantum many-body simulations using a finite size embedded cluster. In the last decade, the DCA has been very useful in describing and analyzing phase transitions in models of correlated electron systems such as the single-band Hubbard model. In the standard DCA algorithm, the single-particle self-energy is approximated by a step function in momentum space, with constant values in regions about the cluster momenta. As a consequence, results often depend sensitively on the topology and morphology of the chosen cluster and the corresponding cluster momenta. Here, we present an extension to the standard DCA that incorporates a self-energy with smooth, continuous momentum dependence self-consistently in the DCA algorithm. In this new algorithm, the influence of the cluster-geometry is significantly reduced and the self-energy converges much more rapidly as a function of cluster-size. We demonstrate the improved convergence of this algorithm for results of the pseudo-gap temperature T^* and the superconducting temperature T_c versus cluster-size.

2:03PM N24.00015 Polaron Localization in Conjugated Polymers by Hybrid DFT Methods[1] , NAN SHAO[2], QIN WU[3], Brookhaven National Laboratory, THEOREY AND COMPUTATION GROUP TEAM — Reliable application of density functional theory (DFT) to study the electronic properties of polarons remains controversial. A proper description should exhibit both the formation of a charge-localized electronic state and saturation of the polaron size for increasing oligomer length. The aim of this work is to find a proper hybrid DFT method to study the chain length related electronic properties of charged conjugated polymer system. Using oligopyrrole cations as a test case, global hybrid functionals such as BHandHLYP can show charge localization, but a well-defined polaron size does not emerge when the length of the oligomer is increased; the saturation effect was not predicted correctly. By applying 100% long-range corrected hybrid functionals, LRC-PBE, the saturation of charge distribution has been achieved, implying that the LRC-PBE is a better way to describe the spatial extent of the electronic state of polypyrrole than the conventional hybrid functionals. The tuning of the range parameter and the study of other polymer polaron systems will be discussed.

11:51AM N25.00002 ABSTRACT WITHDRAWN –

12:27PM N25.00003 Temperature and rate sensitivity of melting in Cu , AMIT SAMANTA, Applied and Computational Mathematics, Princeton University, Princeton, NJ, USA, TANG-QING YU, Courant Institute of Mathematical Sciences, New York University, New York, USA, WEINAN E, Department of Mathematics and Program in Applied and Computational Mathematics, Princeton University, Princeton, NJ, USA — The nature of melting of a crystal is a long standing topic of interest in materials science. Using advanced simulation techniques such as finite temperature string method and temperature accelerated molecular dynamics, we trace the minimum free energy path (MFEP) for a transition from solid to liquid phase at different temperatures in copper. Analysis of the configurations along the MFEP reveals that the rate determining transition state and the ensuing melting mechanisms are a function of temperature of the system. Close to equilibrium melting temperatures, the saddle point is determined by the critical size of the liquid nucleus, however, at higher temperatures, we find that the saddle structure consists of defect clusters from which the liquid nucleus is formed.

12:39PM N25.00004 Efficient minimum mode finding in transition states calculations , WEIGUO GAO, JING LENG, CHENG SHANG, ZHI-PAN LIU, Fudan University — Transition states are fundamental to understanding the reaction dynamics qualitatively in chemical physics. To date various methods of first principle location of the transition states have been developed. In the absence of the knowledge of the final structure, the minimum-mode following method climbs up to a transition state without calculating the Hessian matrix. One weakness of this kind of approaches is that the number of rotations to determine the minimum mode is usually unpredictable. In this work, we propose a locally optimal search direction finding algorithm which is an extension of the traditional conjugate gradient method without additional calculations of the forces. We also show that the translation of forces improves the numerical stability. Experiments for the Baker test system show that the proposed algorithm is much faster than the original dimer conjugate gradient method.

12:51PM N25.00005 Extension of the string method for saddle points search , WEIQING REN, National University of Singapore and IHPC — The string method was designed for finding minimum energy paths between two minima of a potential (or free) energy. It evolves a continuous curve in the path space by steepest descent dynamics. In this talk, we discuss how the string method can be modified for saddle point search. Compared to the existing algorithms, the new method has the advantage that the computed saddle points are guaranteed to be directly connected to the minima. We will also discuss how the convergence can be accelerated using an inexact Newton method.

1:03PM N25.00006 On extreme value statistics of correlated random variables , MAXIME CLUSEL, Laboratoire Coulomb, CNRS Université Montpellier 2, JEAN-YVES FORTIN, Institut Jean Lamour, CNRS Nancy-Universite — The statistics of extreme values of a set on independent and identically distributed random variables is a well established mathematical theory that can be traced back to the late 1920s, with pioneering work by Fisher and Tippett. While efforts have been made to go beyond the uncorrelated case, little is known about the extremes of strongly correlated variables. Notable exceptions are the distribution of extreme eigenvalues of random matrices (Tracy and Widom 1994), the Airy law for one-dimensional random walks (Majumdar and Comtet 2005), and random variables with logarithmic interactions (Fyodorov and Bouchaud 2008). We propose to adapt the equivalence between extremes and sums (Bertin and Clusel 2006) to obtain asymptotic distributions of correlated random variables. We will show how this approach works in the logarithmic case, before extending it to power-law correlations and beyond. We will eventually illustrate these cases with a simple model, a one-dimensional gas of interacting particles.

1:15PM N25.00007 Study of the diffusion of points defects in crystalline silicon using the kinetic ART method , MICKAEL TROCHET, Universite de Montreal, PETER BROMMER, University of Warwick, LAURENT-KARIM BELAND, JEAN-FRANCOIS JOLY, NORMAND MOUSSEAU, Universite de Montreal — Because of the long-time scale involved, the activated diffusion of point defects is often studied in standard molecular dynamics at high temperatures only, making it more difficult to characterize complex diffusion mechanisms. Here, we turn to the study of point defect diffusion in crystalline silicon using kinetic ART (kART)[1-2], an off-lattice kinetic Monte Carlo method with on-the-fly catalog building based on the activation-relaxation technique (ART nouveau). By generating catalogs of diffusion mechanisms and fully incorporating elastic and off-lattice effects, kART is a unique tool for characterizing this problem. More precisely, using kART with the standard Stillinger-Weber potential we consider the evolution of crystalline cells with 1 to 4 vacancies and 1 to 4 interstitials at various temperatures and to provide a detailed picture of both the atomistic diffusion mechanisms and overall kinetics in addition to identifying special configurations such as a 2-interstitial super-diffuser.

1:27PM N25.00008 An iterative action minimizing method for computing optimal paths in stochastic dynamical systems , BRANDON LINDLEY, IRA SCHWARTZ, Naval Research Laboratory — We present a numerical method for computing optimal transition pathways and transition rates in systems of stochastic differential equations (SDEs). In particular, we compute the most probable transition path of stochastic equations by minimizing the effective action in a corresponding deterministic Hamiltonian system. The numerical method presented here involves using an iterative scheme for solving a two-point boundary value problem for the Hamiltonian system. We validate our method by applying it to both continuous stochastic systems, such as nonlinear oscillators governed by the Duffing equation, and finite discrete systems, such as epidemic problems, which are governed by a set of master equations. Furthermore, we demonstrate that this method is capable of dealing with stochastic systems of delay differential equations.

1:39PM N25.00009 The stability of vacancy-like defects in amorphous silicon , JEAN-FRANCOIS JOLY, NORMAND MOUSSEAU, Universite de Montreal — The contribution of vacancy-like defects to the relaxation of amorphous silicon (a-Si) has been a matter of debate for a long time. Due to their disordered nature, there is a large number local environments in which such a defect can exists. Previous numerical studies the vacancy in a-Si have been limited to small systems and very short timescales. Here we use kinectic ART (k-ART), an off-lattice kinetic Monte-Carlo simulation method with on-the-fly catalog building [1,2] to study the time evolution of 1000 different single vacancy configurations in a well-relaxed a-Si model. Our results show that most of the vacancies are annihlated quickly. In fact, while 16% of the 1000 isolated vacancies survive for more than 1 ns of simulated time, 0.043% remain after 1 ms and only 6 of them survive longer than 0.1 second. Diffusion of the full vacancy is only seen in 19% of the configurations and diffusion usually leads directly to the annihilation of the defect. The actual annihilation event, in which one of the defective atoms fills the vacancy, is usually similar in all the configurations but local bonding environment heavily influence its activation barrier and relaxation energy.

1:51PM N25.00010 Ga Surface Diffusion on GaAs(001) β 2(2 $\times$ 4): An ab initio Local Superbasin Kinetic Monte Carlo Study[1] , YANGZHENG LIN, KRISTEN FICHTHORN, Penn State University — We use first-principles density functional theory to characterize the diffusion of a Ga adatom on GaAs(01) β 2(2 $\times$ 4). Beginning with previously identified potential energy minima on this surface, we used the climbing-image nudged elastic band method to identify transition states and delineate diffusion pathways. These studies led to the discovery of eight new binding sites for Ga, which more than doubles the number that had been previously identified. The diffusion pathways for hopping between these minima involve energy barriers that vary significantly in magnitude, such that minima are spatially arranged in groups connected by low barriers and separated from each other by high barriers. Thus, the diffusion process is significantly more complex than was previously believed. To resolve the diffusion, we applied our recently developed local superbasin kinetic Monte Carlo method, which efficiently resolves the long-time dynamics of this complex process.

2:03PM N25.00011 Physical Point Consequences , ALFRED PHILLIPS JR., Source Institute — We have considered a physical point, and accordingly we have made a distinction between a physical derivative and a mathematical derivative. We trace how this consideration impacts spacetime, general relativity (the so-called cosmological constant problem), quantum mechanics, and their one hundred twenty orders-of-magnitude discrepancy in vacuum energy.

Wednesday, March 20, 2013 11:15AM - 2:15PM –

Session N26 GQI: Entanglement in Many-Body Systems 328 - Ari Mizel, LPS

11:15AM N26.00001 Noise of Quantum Channels can Generate Quantum Entanglement from Classical Correlation[1] , LASZLO GYONGYOSI, Budapest University of Technology and Economics, Hungarian Academy of Sciences, SANDOR IMRE, Budapest University of Technology and Economics — Transmission of quantum entanglement will play a crucial role in future networks and long-distance quantum communications. Quantum Key Distribution, the working mechanism of quantum repeaters and the various quantum communication protocols are all based on quantum entanglement. To share entanglement between distant points, high fidelity quantum channels are needed. In practice, these communication links are noisy, which makes it impossible or extremely difficult and expensive to distribute entanglement. In this work we first show that quantum entanglement can be generated by a fundamentally new idea, exploiting the most natural effect of the communication channels: the noise itself of the link. We prove that the noise transformation of communication links that are not able to transmit quantum entanglement can be used to generate entanglement from classically correlated, unentangled input. We call this new phenomenon the Correlation Conversion property (CC-property) of communication channels. Our results have serious implications and fundamental consequences for the future of quantum communications, and for the development of global-scale quantum communication networks.

11:27AM N26.00002 Measuring Entanglement Entropy of a Generic Many-Body System with a Quantum Switch[1] , DMITRY ABANIN, EUGENE DEMLER, Harvard University — Entanglement entropy has become an important theoretical concept in condensed matter physics because it provides a unique tool for characterizing quantum mechanical many-body phases and new kinds of quantum order. However, the experimental measurement of entanglement entropy in a many-body system is widely believed to be unfeasible, owing to the nonlocal character of this quantity. Here, we propose a general method to measure the entanglement entropy. The method is based on a quantum switch (a two-level system) coupled to a composite system consisting of several copies of the original many-body system. The state of the switch controls how different parts of the composite system connect to each other. We show that, by studying the dynamics of the quantum switch only, the Rényi entanglement entropy of the many-body system can be extracted. We propose a possible design of the quantum switch, which can be realized in cold atomic systems. Our work provides a route towards testing the scaling of entanglement in critical systems as well as a method for a direct experimental detection of topological order.

11:39AM N26.00003 Postion-momentum duality in the entanglement spectrum of free fermions , CHING HUA LEE, XIAO-LIANG QI, Stanford University — The entanglement spectrum (ES) provides a valuable way of studying the topological properties of a system, i.e. those of exotic phases where no usual topological order parameter exists. In this talk, I shall discuss a framework where the partitionings of various spaces, i.e. real, momentum and spin space are treated on equal footing. This relies on an equivalence of the eigenvalue spectra of certain combinations of projection operators. For instance, the ES remains invariant if we mathematically interchange the real-space projector with the occupied band projector. One can go a step further and conclude that exchanging the physical roles of real-space and momentum space projectors lead to two different systems with identical ES. Such reinterpretations allow one to extend well-known results involving real-space cuts in critical systems to those with simultaneous momentum-space cuts. The results for gapped systems are even more interesting, with the real-space ES of a generic band insulator shown to be identical to that of two different layers or spins in a specific fermi liquid state. This framework also allows one to view the Wannier polarization spectrum as the infinite temperature limit of the ES of a certain system originally defined at zero temperature.

11:51AM N26.00004 Characterizing disordered fermion systems using the momentum-space entanglement spectrum , IAN MONDRAGON-SHEM, MAYUKH KHAN, TAYLOR HUGHES, University of Illinois, Urbana-Champaign — We show that momentum-space entanglement can reveal the existence of robust extended states in disordered fermions systems. This approach represents a novel alternative to the more conventional position-space entanglement used in condensed matter settings. We illustrate this proposal by using explicit 1D models with spatially correlated disorder that exhibit phases which avoid complete Anderson localization. The momentum space entanglement spectrum clearly reveals the location of delocalized states in the energy spectrum and can be used as a signature of the phase transition between a delocalized and localized phase. We further discuss possible applications to 2D systems that exhibit topological properties which arise from the existence of robust bulk extended states in their energy spectrum.

12:03PM N26.00005 Geometric entanglement for the toric code, color code and quantum double models , TZU-CHIEH WEI, C.N. Yang Institute for Theoretical Physics, Stony Brook University, ROMÁN ORÚS, Max-Planck-Institut für Quantenoptik, OLIVER BUERSCHAPER, Perimeter Institute for Theoretical Physics, MAARTEN VAN DEN NEST, Max-Planck-Institut für Quantenoptik — We use the geometric entanglement to characterize ground states in the toric code, color code and quantum double models. We find that the entanglement in all these cases scales with the system size plus a constant term. Such a constant contribution has a topological origin, characterized previously by the entanglement entropy. In particular, the constant term in the color code is twice that in the toric code, a result consistent with a recent study that the color code is equivalent to two copies of the toric code.

12:15PM N26.00006 Log divergence in finite-size quantum Riemann metric , TIAGO SOUZA, MICHAEL KOLODUBETZ, ANATOLI POLKOVNIKOV, Boston University — We study the geometric tensor, an object that describes distances between quantum states within a ground state manifold. Traditionally, it has been studied for changes in external parameters, e.g., magnetic field, at fixed system size. Here, instead, we treat the system size as a tunable parameter, and hence analyze the distance between wave functions at different system sizes. For some simple fermion models, we find that the geometric tensor diverges logarithmically with system size in the thermodynamic limit, similar to the entanglement entropy in a CFT. We discuss similar calculations for the XY model, and comment on the relationship to RG.

12:27PM N26.00007 Entanglement Entropy of the composite fermion non-Fermi liquid state at $\nu = 1/2$, JUNPING SHAO, Binghamton University, EUN-AH KIM, Cornell University — There has been much interest in entanglement entropy as a measure to theoretically probe strongly correlated states that do not involve broken symmetries. In particular, one may hope entanglement entropy can offer quantitative characteristic of Non-Fermi liquids which are otherwise defined based on "what they are not part of." Swingle and Senthil [1] conjectured that the entanglement entropy of non-Fermi liquids will be at most of order $L^{d-1}\log L$ for a region of linear size L. However, to date, there is no explicit calculation of entanglement entropy for non-Fermi liquids (though there are calculations for spin-liquids with spinon fermi surface). Here we perform a Monte Carlo calculation of the entanglement entropy for the best established example of strongly correlated non-Fermi liquid: gapless state at $\nu = 1/2$. We use a composite fermion many body wavefunction in a toroidal geometry and use the swap operator to calculate the second Renyi entropy. We discuss the resulting scaling behavior in the context of the Swingle-Senthil conjecture.

[1] B. Swingle and T. Senthil, arXiv:1112.1069.

12:39PM N26.00008 Renyi Entropy of the Interacting Fermi Liquid , JEREMY MCMINIS, NORM TUBMAN, University of Illinois — Entanglement properties, including the Renyi α-entropies and scaling laws, are becoming increasingly important in condensed matter physics. In this work we use variational quantum Monte Carlo to compute the Renyi α-entropies, their scaling laws, and the relationship between different α-entropies for one of the most important phases in condensed matter, the interacting Fermi liquid. Contrary to recent theoretical predictions, we find that interactions increase the prefactor for the α-entropy scaling laws for all particle interaction strengths and forms.

12:51PM N26.00009 Multipartition of Spatially Entangled Systems with Sine Square Deformation , ISAO MARUYAMA, Osaka university — We propose a method to decouple quantum systems without disturbing the Fermi sea, extending the sine-square deformation (SSD)[1,2] toward more general cases. This multipartition operation opens a way to real-time manipulation for separating the gapless Fermi liquid system spatially into several decoupled systems without losing quantum entanglement among them. As a demonstration of entanglement preservation, by solving the time-dependent Scrödinger equation numerically, we show that our method works well in entanglement dynamics of non-interacting tight-binding models on a one dimensional zigzag chain and a two dimensional square lattice. [1] A. Gendiar, et. al., Prog. Theo. Phys. 122. 953 (2009) [2] IM, et.al., Phys. Rev. B. 84. 165132 (2011) and references therein

1:03PM N26.00010 Entanglement in fermionic superlattices[1] , RAIMUNDO DOS SANTOS, TIAGO MENDES-SANTOS, THEREZA PAIVA, Universidade Federal do Rio de Janeiro — We discuss how entanglement of strongly correlated fermions is influenced by a superlattice structure, by considering a one-dimensional Hubbard superlattice, made up of a repeated pattern of L_U repulsive sites followed by L_0 free sites. Lanczos diagonalization of lattices up to 24 sites are used to calculate the von Neumann entropy and the negativity. The breakdown of particle-hole symmetry broadens the maxima of the entropy in the underdoped region, while the entanglement in the overdoped region is crucially influenced by the nature of the magnetic state, with dips at densities corresponding to repulsive layer singlets and to $q = \pi$ (in units of inverse unit cell length, $L_U + L_0$) spin-density waves; at these special densities the system is either a Mott insulator or a 'compressible insulator'. We have also found that sites in the repulsive layer (for $L_U \geq 2$) are monogamically entangled with each other.

1:15PM N26.00011 Thermal Reduced Density Matrices in Fermion and Spin Ladder Systems , XIAO CHEN, EDUARDO FRADKIN, University of Illinois at Urbana-Champaign — A recent numerical study [1] found that the reduced density matrix of a spin 1/2 system on a two-leg ladder is the same as the spectrum of a spin 1/2 chain at a finite temperature determined by the spin gap of the ladder. We investigate this interesting result by considering two-leg ladders of free fermions and spin systems with a gapped ground state using several controlled approximations. We calculate the entanglement entropy for the cut made between the chains. In the fermionic system we find the explicit form of the reduced density matrix for one of the chains and determine the entanglement spectrum explicitly. In the case of the spin system, we consider both the strong coupling limit by using perturbation theory and weak coupling limit by using replica trick method. The calculation shows that, 1) the Von Neumann entropy equals to the thermal entropy of one chain, 2) the R'enyi entropy is equivalent to the free energy of one chain, and 3) the coupling constant (gap) plays the role of effective temperature. This result can be generalized to other coupled critical systems with a bulk gap. This work was supported in part by the NSF grant DMR-1064319 at the University of Illinois [1] D. Poilblanc, Phys. Rev. Lett. **105**, 077202 (2010)

1:27PM N26.00012 Entanglement measures and the quantum to classical mapping[1] , JESKO SIRKER, TU Kaiserslautern — A quantum model can be mapped to a classical model in one higher dimension. Here we introduce a finite-temperature correlation measure based on a reduced density matrix $\bar{\rho}_{\bar{A}}$ obtained by cutting the classical system along the imaginary time (inverse temperature) axis. We show that the von-Neumann entropy $\bar{S}_{\rm ent}$ of $\bar{\rho}_{\bar{A}}$ shares many properties with the mutual information, yet is based on a simpler geometry and is thus easier to calculate. For one-dimensional quantum systems in the thermodynamic limit we prove that $\bar{S}_{\rm ent}$ is non-extensive for all temperatures T. For the integrable transverse Ising and XXZ models we demonstrate that the entanglement spectra of $\bar{\rho}_{\bar{A}}$ in the limit $T \to 0$ are described by free-fermion Hamiltonians and reduce to those of the regular reduced density matrix ρ_A—obtained by a spatial instead of an imaginary-time cut—up to degeneracies.

1:39PM N26.00013 Entanglement Entropy and Spectra of the One-dimensional Kugel-Khomskii Model , REX LUNDGREN, VICTOR CHUA, GREGORY FIETE, University of Texas at Austin — We study the quantum entanglement of the spin and orbital degrees of freedom in the one-dimensional Kugel-Khomskii model, which includes both gapless and gapped phases, using analytical techniques and exact diagonalization with up to 16 sites. We compute the entanglement entropy, and the entanglement spectra using a variety of partitions or "cuts" of the Hilbert space, including two distinct real-space cuts and a momentum-space cut. Our results show the Kugel-Khomski model possesses a number of new features not previously encountered in studies of the entanglement spectra. Notably, we find robust gaps in the entanglement spectra for both gapped and gapless phases with the orbital partition, and show these are not connected to each other. We observe the counting of the low-lying entanglement eigenvalues shows that the "virtual edge" picture which equates the low-energy Hamiltonian of a virtual edge, here one gapless leg of a two-leg ladder, to the "low-energy" entanglement Hamiltonian breaks down for this model, even though the equivalence has been shown to hold for similar cut in a large class of closely related models.

1:51PM N26.00014 Understanding the entanglement entropy and spectra of 2D quantum systems through arrays of coupled 1D chains , ANDREW JAMES, ROBERT KONIK, Brookhaven National Laboratory — We study the entanglement entropy and spectra of a coupled array of N one dimensional quantum Ising chains in their continuum limit. Employing a DMRG algorithm specifically adapted to the study of coupled, continuum systems, we are able to study large arrays of chains (up to N=200) both in their gapped phase and in the approach to criticality. Away from criticality the entanglement entropy obeys an area law. Close to criticality the entanglement entropy continues to obey the area law but possesses an additive piece scaling as $c_{eff}\log(N)/6$ with $c_{eff} \approx 1$. We also study the entanglement spectra of the coupled chains. Away from criticality in the disordered phase the low lying portion of the entanglement spectra appears similar to that of a single gapped quantum Ising chain. As the critical point is approached the entanglement gap closes. A finite size scaling analysis shows that the entanglement gap and the energy gap vanish at the same value of interchain coupling.

2:03PM N26.00015 Entanglement spectrum and entangled modes of random XX spin chains , MOHAMMAD POURANVARI, KUN YANG, Florida State University — We study in this work the ground state entanglement properties of finite XX spin-1/2 chains in with random couplings, using Jordan-Wigner transformation. We divide system into two parts and study reduced density matrixes (RDMs) of its subsystems. Due to the free-fermion nature of the problem, the RDMs take the form of that of a free fermion thermal ensemble. Finding spectrum of the corresponding entanglement Hamiltonian and corresponding eigenvectors, and comparing them with real space renormalization group (RSRG) treatment, we establish the validity of the RSRG approach for entanglement in the limit of strong disorder, but also find its limitations when disorder is weak. In the latter case our work provides a way to visualize the effective spins that form long distance singlet pairs.

Session N27 Focus Session: Nano/Optomechanics II 329 - Michael Metcalfe, Booz Allen Hamilton

11:15AM N27.00001 On-chip cavity quantum phonodynamics: spin qubits and nano/optomechanics , CHARLES TAHAN, Laboratory for Physical Sciences — Sound can be just as quantum as light. But our toolbox for single quanta of sound, i.e. phonons, is currently insufficient. Here we propose a new component that enables a chip-based, solid-state analogue of cavity-QED utilizing acoustic phonons instead of photons. We show how long-lived and tunable acceptor impurity states in silicon nanomechanical cavities can play the role of a matter non-linearity for coherent phonons just as, for example, the Josephson qubit plays in circuit-QED. Both strong coupling (number of coherent Rabi oscillations of approximately 100) and strong dispersive coupling (0.1-2 MHz) can be reached in the 1-20 GHz frequency range, making the system compatible with existing high-Q, nanomechanical resonators. We give explicit experimental signatures and measurement protocols of the acceptor-cavity system via a phonon probe. This system enables the control of single phonons and phonon-phonon interactions, dispersive phonon readout of the acceptor qubit, and compatibility with other nano/optomechanical components such as phonon-photon translators. (This work in collaboration with Rusko Ruskov, LPS; work with Oney Soykal, LPS, will also be discussed.)

11:51AM N27.00002 Cavity optomechanics in the quantum regime , AMIR H. SAFAVI-NAEINI, SIMON GROEBLACHER, JEFF HILL, JASPER CHAN, OSKAR PAINTER, Caltech — We use coherent laser light to address the mechanical degrees of freedom of engineered nanostructures with record high efficiency. With sufficient cryogenic precooling, the effects of the quantum optical shot-noise coupled onto the mechanics, and its modification by the mechanical susceptibility can be probed. In this talk we present our recent experiments studying the quantum properties of such systems.

12:03PM N27.00003 Silicon Integrated Cavity Optomechanical Transducer , JIE ZOU, HOUXUN MIAO, THOMAS MICHELS, YUXIANG LIU, National Institute of Standards and Technology; University of Maryland, KARTIK SRINIVASAN, VLADIMIR AKSYUK, National Institute of Standards and Technology — Cavity optomechanics enables measurements of mechanical motion at the fundamental limits of precision imposed by quantum mechanics. However, the need to align and couple devices to off-chip optical components hinders development, miniaturization and broader application of ultrahigh sensitivity chip-scale optomechanical transducers. Here we demonstrate a fully integrated and optical fiber pigtailed optomechanical transducer with a high Q silicon micro-disk cavity near-field coupled to a nanoscale cantilever. We detect the motion of the cantilever by measuring the resonant frequency shift of the whispering gallery mode of the micro-disk. The sensitivity near the standard quantum limit can be reached with sub-uW optical power. Our on-chip approach combines compactness and stability with great design flexibility: the geometry of the micro-disk and cantilever can be tailored to optimize the mechanical/optical Q factors and tune the mechanical frequency over two orders of magnitudes. Electrical transduction in addition to optical transduction was also demonstrated and both can be used to effectively cool the cantilever. Moreover, cantilevers with sharp tips overhanging the chip edge were fabricated to potentially allow the mechanical cantilever to be coupled to a wide range of off-chip systems, such as spins, DNA, nanostructures and atoms on clean surfaces.

12:15PM N27.00004 Developement of an optomechanical device for microwave to telecom wavelength quantum state transfer[1] , J.M. FINK, A. PITANTI, C.U. LEI, J.T. HILL, A.H. SAFAVI-NAEINI, O. PAINTER, California Institute of Technology — A promising hardware platform for quantum computers is based on solid-state superconducting circuits which offer fast processing times and scalability. Circuit QED systems can however only operate in ultra-cold environments where thermal noise and resistive losses are negligible. We are working on an integrated optomechanical microwave-photonic device which has the potential to efficiently convert microwave excitations to telecom wavelength photons. Such a device would put within reach the realization of hybrid and long distance quantum communication networks. We have designed and fabricated slot mode photonic crystal cavities which share a mechanical mode with the capacitance of a lumped element microwave resonator. A continuously pumped state transfer protocol should enable efficient wavelength conversion even in the absence of strong optomechanical and electromechanical coupling [1] and has recently been demonstrated within the optical domain [2]. We will present our latest progress with the design, fabrication and characterization of our electro-optomechanical wavelength conversion device.

12:27PM N27.00005 Optomechanical effects of two-level states in electromechanical devices , JUNHO SUH, AARON WEINSTEIN, KEITH SCHWAB, Applied Physics, California Institute of Technology — It is now clearly established that the presence of two-level states can act as a power-dependent dielectric and lead to non-linear response of lithographic superconducting circuits. We observe these effects in a parametrically coupled, superconducting electro-mechanical system. In this case, the driven two-level states shift the microwave resonance frequency, and modulate the mechanical resonance through the optical spring effect. When pumping with two tones to realize a back-action evading measurement, these effects produce mechanical frequency modulation at twice the mechanical resonance, leading to a parametric instability for strong drives sufficient to produce a single quadrature measurement near the zero-point level. We also discuss schemes to avoid these effects in future devices.

12:39PM N27.00006 Diamond mechanical resonators for strain coupling to nitrogen-vacancy centers , PREETI OVARTCHAIYAPONG, LAETITIA PASCAL, KENNETH LEE, BRYAN MYERS, ANIA BLESZYNSKI JAYICH, University of California Santa Barbara — The nitrogen-vacancy (NV) center in diamond is promising for applications in quantum information and quantum assisted sensing. We have fabricated NV-containing single-crystal diamond mechanical resonators that exhibit high quality factors in excess of 300,000. These structures provide a highly controlled platform for investigating the effect of strain on the NV. The strain is calculated from the mode shape of a driven resonator and we correlate the strain to the measured energy level shift. Understanding the strain coupling is an important step toward NV center spin manipulation using local strain fields as an alternative to external magnetic and electric fields. Furthermore, such a mechanical-spin interface could enable mechanical control of spin states as well as provide a hybrid approach to a scalable quantum network.

12:51PM N27.00007 Two-mode back-action-evading measurements in cavity optomechanics , MATTHEW WOOLLEY, UNSW Canberra, AASHISH CLERK, McGill University — The field of cavity optomechanics aims to achieve the quantum measurement and control of macroscopic mechanical resonators via coupled, cavity-enhanced electromagnetic fields. Here, we study a system composed of two mechanical oscillators independently coupled to a common electromagnetic cavity mode. By driving the cavity at frequencies both above and below the cavity resonance frequency, with a detuning equal to the average of the two mechanical oscillator frequencies, it is possible to couple a quadrature of the cavity mode to a joint quadrature of the two mechanical modes. This allows a back-action-evading measurement of the joint quadrature of the mechanical oscillators to be performed. If the output of the coupled cavity is continuously monitored, in the regime where the effective joint oscillator frequency greatly exceeds the average damping rate of the mechanical oscillators, it is possible to conditionally generate an all-mechanical, entangled two-mode squeezed state. This conditional entanglement may be verified from the measurement record, and converted to unconditional squeezing via the application of feedback. The same system may be employed for force sensing beyond the standard quantum limit. The experimental prospects for such a system are considered.

1:03PM N27.00008 Prospects for coupling Surface Acoustic Waves to superconducting qubits , MARTIN GUSTAFSSON, Chalmers University of Technology — Recent years have seen great development in the quantum control of mechanical resonators. These usually consist of membranes, cantilevers or suspended beams, whose vibrational modes can be cooled to the quantum ground state. This presentation will focus on a different kind of micromechanical system, where the motion is not confined to a mode with fixed boundaries, but propagates along the surface of a microchip. These modes are known as Surface Acoustic Waves (SAWs), and superficially resemble ripples on water, moving with low loss along the surfaces of solids. On a piezoelectric substrate, electrode gratings known as Interdigital Transducers (IDTs) can be used to convert power between the electric and acoustic domains. Devices based on this effect are of profound technological importance as filters and analog signal processors in the RF domain. In the realm of quantum information processing, SAWs have primarily been used to transport carriers and excitons through piezoelectric semiconductors, in the electric potential wells propagating along with the mechanical wave. Our approach, however, is different in that we aim to explore the mechanical wave itself as a carrier of quantum information. We have previously shown that a single-electron transistor can be used as a local probe for SAWs, with encouraging sensitivity levels. Building on this, we now investigate the prospects for coupling a SAW beam directly to a superconducting qubit. By merging a circuit model for an IDT with a quasi-classical description of a transmon qubit, we estimate that the qubit can couple to an acoustic transmission line with approximately the same strength as to an electrical one. This type of coupling opens for acoustic analogs of recent experiments in microwave quantum optics, including the generation of non-classical acoustic states.

1:39PM N27.00009 Nanoscale Torsional Optomechanics[1] , PAUL H. KIM, CALLUM DOOLIN, BRADLEY D. HAUER, ALLISON J. R. MACDONALD, MARK R. FREEMAN, University of Alberta, PAUL E. BARCLAY, University of Calgary, JOHN P. DAVIS, University of Alberta — Torsional resonators, which can be designed to measure torques with high sensitivity, have been an effective tool to study magnetism, gravity, and various material and optical properties. Taking advantage of improved micro-fabrication techniques, these torque sensors are now pushing the limit in terms of size - scaling all the way down to the nanoscale regime - and therefore must be equipped with sensitive mechanical transduction schemes. Here we present a method for measuring torques as little as 4 $\times 10^{20} N$m, using optomechanics. Recently optomechanics has been revealed as a reliable method for mechanical transduction, with higher sensitivity than previously possible. This sensitivity of the optomechanical system comes from the evanescent coupling between a high quality factor optical resonator and the mechanical device, and is fully integratable on a chip using the silicon-on-insulator platform. We present our first generation torsional optomechanics, using a dimpled optical fiber system for measurement, with a calibrated sensitivity down to 7 fm/$\sqrt{\text{Hz}}$. This torsional optomechanical platform will now serve as a basis for further experiments to explore new physics and technology, in particular quantum resonators at low temperatures.

1:51PM N27.00010 Beating the standard quantum limit for force sensing with a coupled two-mode optomechanical system , XUNNONG XU, JACOB M. TAYLOR, Joint Quantum Institute, University of Maryland/National Institute of Standards and Technology, College Park, Maryland 20742, USA — The scheme of optomechanical sensing of weak forces with a coupled two-mode cavity is presented. We consider the mirror-in-the-middle setup and use the two coupled cavity modes originated from normal mode splitting as pump and probe to realize force detection. We find that this two-mode model can be reduced to an effective single-mode model, if we drive the pump mode strongly and detect the signal from the weak probe mode. The optimal force detection sensitivity at zero frequency (DC) is calculated and we show that we would be able to beat the standard quantum limit by detuning the cavity far away from resonance. Furthermore, we find that the laser input power requirement will depend linearly on the cavity detuning, if the cavity mode coupling is close to cavity detuning, which is a great advantage over conventional single-mode force sensing scheme where the laser power has a cubic dependence on the cavity detuning.

Session N28 GSNP: Continua, Networks, & Earthquakes 336 - Oscar Lopez-Pamies, University of Illinois at Urbana-Champaign

11:15AM N28.00001 Earthquakes in the Laboratory: Continuum-Granular Interactions , ROBERT ECKE, DREW GELLER, CARL WARD, SCOTT BACKHAUS, Los Alamos National Laboratory — Earthquakes in nature feature large tectonic plate motion at large scales of 10-100 km and local properties of the earth on the scale of the rupture width, of the order of meters. Fault gouge often fills the gap between the large slipping plates and may play an important role in the nature and dynamics of earthquake events. We have constructed a laboratory scale experiment that represents a similitude scale model of this general earthquake description. Two photo-elastic plates (50 cm x 25 cm x 1 cm) confine approximately 3000 bi-disperse nylon rods (diameters 0.12 and 0.16 cm, height 1 cm) in a gap of approximately 1 cm. The plates are held rigidly along their outer edges with one held fixed while the other edge is driven at constant speed over a range of about 5 cm. The local stresses exerted on the plates are measured using their photo-elastic response, the local relative motions of the plates, i.e., the local strains, are determined by the relative motion of small ball bearings attached to the top surface, and the configurations of the nylon rods are investigated using particle tracking tools. We find that this system has properties similar to real earthquakes and are exploring these "lab-quake" events with the quantitative tools we have developed.

11:27AM N28.00002 Extreme statistics of avalanches near the depinning transition , MICHAEL LEBLANC, Deparment of Physics, University of Illinois at Urbana-Champaign, LUIZA ANGHELUTA, Deparment of Physics, University of Illinois at Urbana-Champaign; Physics of Geological Processes, Deparment of Physics, University of Oslo, Norway, KARIN DAHMEN, NIGEL GOLDENFELD, Deparment of Physics, University of Illinois at Urbana-Champaign — Near the depinning transition, motion proceeds by avalanche fluctuations with power law distributed sizes and durations. We derive exact exponents and scaling functions for the statistics of maximum avalanche velocities in a mean field theory of the transition. We find a power law regime in the maximum velocity distribution with an exponent that agrees with the distribution of peak amplitudes observed in acoustic emission experiments of crystal plasticity. Our results should be applicable to the study of a number of systems considered to be in the mean field interface depinning universality class, ranging from magnets to earthquakes.

11:39AM N28.00003 Acoustic-Friction Networks and the Evolution of Shear Ruptures in Laboratory Earthquakes , H.O. GHAFFARI, R.P. YOUNG, Department of Civil Engineering and Lassonde Institute, University of Toronto — The evolution of shear rupture fronts in laboratory earthquakes are analysed with the corresponding functional networks, constructed over photo-elastic, real-time contacts and acoustic emission friction-patterns. We show that the mesoscopic and transport characteristics of networks follow the same trends for the same type of the shear ruptures in terms of rupture speed, while also comparing the results of four different friction experiments. The classified fronts–obtained from a saw-cut fault and natural faulted Westerly granite - regarding friction network parameters show a clear separation into two groups, indicating two different rupture fronts. With respect to the scaling of local ruptures' durations with the networks' parameters, we show that the gap is related to the possibility of a separation between slow and regular fronts. Based on our results, we develop a statistical based method to model the evolution of functional damage networks while we consider that any rupture flows in a critical plane with two main fixed points.

11:51AM N28.00004 Forecasting large earthquakes using small-quake correlations , BRADEN BRINKMAN, MICHAEL LEBLANC, University of Illinois at Urbana-Champaign, YEHUDA BEN-ZION, University of Southern California, J.T. UHL, Retired, KARIN DAHMEN, University of Illinois at Urbana-Champaign — It has long been speculated that periodic stress variations, such as the tides, may trigger earthquakes, and hence tide-earthquake correlations could be used as signals for predicting large earthquakes prior to failure. We developed a simple probabilistic model of earthquake triggering which we used to simulate series of earthquake events in a fault subjected to external periodic stresses of amplitudes and frequencies representative of tidal or seasonal stress variations. By analyzing correlations between small events and periodic stress cycles, we compute the probability that a large event will occur. We find that seasonal stresses are better predictors of impending large earthquakes. In addition, our results also apply to many other sheared frictional stick-slip systems which display small slips, such as rock interfaces or granular matter.

12:03PM N28.00005 Critical Scaling of Avalanche Dynamics in Sheared Amorphous Solids with Inertia[1] , K. MICHAEL SALERNO, Johns Hopkins University, CRAIG MALONEY, Carnegie Mellon University, MARK O. ROBBINS, Johns Hopkins University — We present results from molecular-dynamics simulations of model disordered solids under quasi-static, steady-state shear in two and three dimensions. Plastic deformation occurs through intermittent "avalanches" of local rearrangements. As in other slowly-driven systems from magnets to geologic faults, avalanches exhibit critical scaling behavior. Results for the avalanche statistics, duration and power spectrum are analyzed with finite-size scaling. The exponents describing the power law distribution of avalanches and the relation between their size and duration are independent of dimension, suggesting that mean field behavior extends to two dimensions. In contrast, the scaling exponents depend on the degree of inertia or damping, with distinct universality classes in the underdamped and overdamped limits [1]. The same universality classes are observed with Galilean-invariant and non-Galilean-invariant thermostats, but the crossover between these limits will be contrasted. The implications for different experimental systems will be discussed. [1] PRL 109, 105703 (2012).

12:15PM N28.00006 Phase-Field Crystal Models and Elastic Excitations[1] , VILI HEINONEN, CRISTIAN ACHIM, Department of Applied Physics, Aalto University, Finland, KEN ELDER, Department of Physics, Oakland University, MI, USA, TAPIO ALA-NISSILÄ, Department of Applied Physics, Aalto University, Finland — Phase Field Crystal (PFC) models and their amplitude expansions are a novel attempt to bridge the gap between atomistic and continuum models in materials modeling. The studied quantity is the atomic density field that varies in time and space. Not only do these new models allow longer length scales but also longer time scales: many interesting phenomena happen over diffusive time scales that are beyond the reach of classical molecular dynamics or Monte Carlo methods. As with Dynamic Density Field theory a local equilibrium in the system is assumed leading into diffusive dynamics. This implies that the time scale under study is lot slower than time scale of elastic excitations in the system. In other words, we are assuming that phonon modes die out instantaneously. However, it turns out that the system exhibits elastic excitations that have to be relaxed separately. We propose a physical constraint to the time evolution of the density field, which ensures elastic equilibrium at all times.

12:27PM N28.00007 Strain recovery in dual cross-linked polymer grafted nanoparticle networks , BALAJI IYER V S, VICTOR YASHIN, University of Pittsburgh, ISAAC SALIB, Intel, TOMASZ KOWALEWSKI, KRZYSTOF MATYJASZEWSKI, Carnegie Mellon University, ANNA BALAZS, University of Pittsburgh, ANNA BALAZS COLLABORATION, KRZYSTOF MATYJASZEWSKI COLLABORATION — Via computational modeling, we investigate the mechanism of strain-recovery in dual cross-linked polymer grafted nanoparticle networks. The individual nanoparticles are composed of a rigid core and a corona of grafted polymers that encompass reactive end groups. With the overlap of the coronas on adjacent particles, the reactive end groups form permanent or labile bonds, and thus form a "dual cross-linked" network. We consider the strain recovery of the material after it is allowed to relax from the application of the tensile force. We apply multiple cycles of tension and relaxation and determine how the stress-strain curves change in the course of these repetitive deformations. Notably, the existing labile bonds can break and new bonds can form in the course of deformation. Hence, a damaged material could be "rejuvenated" both in terms of the recovery of strain and the number of bonds, if the relaxation occurs over a sufficiently long time. We show that this rejuvenation depends on the fraction of permanent bonds, strength of labile bonds, and maximal strain.

12:39PM N28.00008 ABSTRACT WITHDRAWN –

12:51PM N28.00009 An analytical method for determining material parameters from inflation tests of thick nonlinear materials , THERESA K. TONGE, THAO D. NGUYEN, Johns Hopkins University — The inflation test is a widely used method for applying a biaxial stress state to polymers and biological tissues. The stress response is determined by assuming the inflated specimen can be modeled as a membrane. However, neglecting the effect of bending can generate large errors for thick specimens and in particular for those exhibiting highly nonlinear material behavior. We have developed a novel thin shell method to analytically determine material properties from the inflation test while accounting for bending. The method assumes a linear strain gradient from bending to calculate the in-plane stress resultants from the constitutive relations for the stress response. These stress resultants are fit to the experimentally determined stress resultants calculated from the applied pressure and measured local curvatures. We have applied the method to fit an anisotropic constitutive model to inflation tests of human skin tissue. We have used Finite Element Analysis to validate the method as well as the resulting material parameters for the constitutive model. This thin shell method is sufficiently general to be applied to determine material properties for other thick, nonlinear materials such as aortic valves or gastrointestinal tissues.

1:03PM N28.00010 Solvent-driven shape-memory effects for amorphous networks , RUI XIAO, THAO NGUYEN, Johns Hopkins University — The swelling-induced shape memory behavior in polymers has inspired interest for their implications for biomedical applications. For amorphous polymers, the behavior is caused by a large decrease in the glass transition temperature caused by the absorption of a small amount of solvent. In this work, we present a theoretical model of the effect of low solvent concentration on the glass transition behavior of the materials. Specifically, the presence of solvent increases the configurational entropy; thus altering the temperature-dependence of the molecular mobility. The model was implemented numerically for finite element simulation. The computational model also considers the effect of diffusion process to describe more accurately the time-dependent effects of solvent-induced shape recovery behavior. To validate the model, we performed isothermal uniaxial tension tests on both the dry and fully saturated materials. Shape recovery performance was investigated by observing the shape change of an initially deformed sample in an isothermal water bath by using digital image tracking. Comparison between experimental data and simulations shows good agreement.

1:15PM N28.00011 Distorted tetrahedral shapes of nematic vesicles[1] , THANH SON NGUYEN, JONATHAN SELINGER, Liquid Crystal Institute, Kent State University — In membranes with internal orientational or crystalline order, there is a geometric coupling between 2D internal order and 3D shape. Nonuniformity in internal order tends to induce curvature, and curvature provides an effective potential acting on internal order. For a closed vesicle with nematic liquid-crystalline order, there must be a total topological charge of $+2$, which normally occurs as four defects of $+1/2$ each. Previous research has suggested that these four defects form a regular tetrahedron, leading to a tetrahedral shape of the vesicle, which may be useful in colloidal crystals for photonic applications. Here, we develop an explicit model to calculate energies of defect structures in nematic vesicles. When the liquid-crystal interaction energy is a purely 2D intrinsic interaction, we find that the perfect tetrahedral shape is stable only up to a maximum interaction strength (Frank constant), where it changes to an elongated rectangular configuration. When the interaction energy is a 3D extrinsic and intrinsic interaction, the perfect tetrahedral shape is never stable; the vesicle is a distorted tetrahedron for small Frank constant and a highly elongated rectangle for larger Frank constant. These results show the difficulty in designing tetrahedral structures.

1:27PM N28.00012 Simple model for plastic deformation and slip avalanches in bulk metallic glasses[1] , KARIN DAHMEN, JAMES ANTONAGLIA, University of Illinois at Urbana Champaign, JUNWEI QIAO, Taiyuan University of Technology, Taiyuan, Peoples Republic of China, XIE XIE, PETER LIAW, The University of Tennessee, Knoxville, JONATHAN UHL, University of Illinois — Ductile bulk metallic glasses are known to deform under shear in an intermittent way with slip-avalanches detected as acoustic emission and serrations in the stress-strain curves. In many such materials, power laws govern the statistics of these avalanches. A basic micromechanical model for deformation of solids with only one tuning parameter is introduced. The model predicts the observed stress-strain curves, acoustic emissions, related power spectra, and power-law statistics of slip avalanches, including the dependence of the cutoff on experimental parameters with a continuous phase transition from brittle to ductile behavior. Material independent ("universal") predictions for the power-law exponents and scaling functions are extracted using the mean-field theory and renormalization group tools. The results agree with recent experimental observations on deformed bulk metallic glasses.

1:39PM N28.00013 Cavitation in Amorphous Solids , MICHAEL FALK, PENGFEI GUAN, Johns Hopkins University, SHUO LU, Beijing University of Aeronautics and Astronautics, MICHAEL SPECTOR, PAVAN VALAVALA, Johns Hopkins University — Molecular dynamics simulations of cavitation in a Zr50Cu50 metallic glass exhibit a waiting time dependent cavitation rate. On short time scales nucleation rates and critical cavity sizes are commensurate with a classical theory of nucleation that accounts for both the plastic dissipation during cavitation and the cavity size dependence of the surface energy. All but one parameter, the Tolman length, can be extracted directly from independent calculations or estimated from physical principles. On longer time scales aging in the form of shear relaxations results in a systematic decrease of cavitation rate. The high cavitation rates that arise due to the suppression of the surface energy in small cavities provide a possible explanation for the quasi-brittle fracture observed in metallic glasses. Analogous simulations of Fe80P20 reveal that segregation of P on the nanoscale leads to qualitatively different behavior that may be attributable to the idiosyncrasies of the interatomic potential.

1:51PM N28.00014 Cavitation in rubber: An elastic instability or a fracture phenomenon?[1] , OSCAR LOPEZ-PAMIES, University of Illinois at Urbana-Champaign — In this presentation, I will confront a recently developed theory of cavitation for soft solids to a variety of cavitation experiments with the objective of establishing whether the phenomenon of cavitation is an elastic instability (and hence depends only on the elastic properties of the rubber), or, on the other hand, a fracture process (and hence depends on the fracture properties of the rubber).

2:03PM N28.00015 Experimental realization of the zero temperature Random Field Ising Model : the condensation of ^{4}He in aerogels[1] , GEOFFROY AUBRY, LAURENT GUYON, MATHIEU MELICH, PANAYOTIS SPATHIS, Institut Néel, CNRS/UJF, Grenoble, FRA, FLORENCE DESPETIS, Laboratoire Charles Coulomb, CNRS/UM2, Montpellier, FRA, PIERRE-ETIENNE WOLF, Institut Néel, CNRS/UJF, Grenoble, FRA — Although widely studied, the effect of disorder on a first order phase transition is still highly debated. Numerical simulations of the $T = 0$ Random Field Ising Model show that magnetization evolves by avalanches, the average size of which diverges below a critical disorder (Sethna et al., PRL 70 3347 (1993)). Nevertheless, experimental evidence is scarce up to now (Berger et al., PRL 85, 4176 (2000)). In the case of the liquid gas transition in disordered porous media, the same theoretical concepts can be applied (Detcheverry et al., PRE 72 051506 (2005)). We have studied experimentally this phase transition using ^{4}He in silica aerogels. Optical and thermodynamical measurements show that the condensation is an out of equilibrium process. We clearly observe two filling regimes separated by a critical temperature T^* : below T^*, filling is discontinuous (macro avalanche) whereas above T^* it becomes continuous (micro avalanches). In addition, we have developed a speckle interferometry technique to detect single avalanches. We argue that our results support the disorder induced phase transition.

Session N29 GSNP: Granular Packing and Impacting 337 - Eric Corwin, University of Oregon

11:15AM N29.00001 A Dynamically Based Study of Percolation through Spaces between Polyhedral Grains , DONALD PRIOUR, Youngstown State University — Many porous materials in nature are made up of grains in the form of non-spherical crystallites. Depending on the density of the grains, such systems may admit the flow of fluid through the spaces between the grains on a macroscopic scale (percolation for sufficiently sparsely spaced grains) or prevent fluid flow (percolation is blocked if the grain concentration is high enough that voids between grains are not contiguous). To provide a more realistic treatment of percolation through granular media, we examine systems comprised of randomly placed angular impermeable inclusions (e.g. disks, tetrahedrons, cubes, and octahedrons), and we give a rigorous continuum treatment to the geometry of the grains and the spaces between them. To extrapolate to the bulk limit in the context of a finite-size scaling analysis, we examine multiple systems of different sizes, where disorder averaging mitigates statistical fluctuations unrelated to bulk properties. An order parameter based on root mean square (RMS) excursion of dynamical trajectories is calculated in the context of a large-scale Monte Carlo simulation and used to evaluate the critical concentration ρ_c of grains. In addition, critical exponents such as ν for the correlation length ξ are determined.

11:27AM N29.00002 Simulation of current-activated pressure-assisted densification[1] , DIETRICH WOLF, SEBASTIAN ANGST, GABI SCHIERNING, University of Duisburg-Essen — Cohesive particles usually form very porous agglomerates. They support loads up to a consolidation pressure, which increases with decreasing particle size. Compaction of nano-powders can therefore be very costly and time consuming. If the particles are electrically conducting, which is the case e.g. for novel nano-structured thermoelectric materials, the technique of current-activated pressure-assisted densification (CAPAD) turns out to have many advantages. Electrical power deposited locally as Joule heat lowers the consolidation pressure such that particles fill nearby pores. This process leads to fast, scalable densification without much coarsening. Simulations are presented which address the influence of correlations on density and conductivity [1]. They also take thermal conductivity and Peltier coefficient into account [2].

11:39AM N29.00003 Fully ordered to disordered granular sphere packings with random deposition , ARSHAD KUDROLLI, ANDREEA PANAITESCU, Department of Physics, Clark University, Worcester, MA 01610 — Granular packings are typically obtained by pouring grains into a container in a gravitational field as when sugar is poured into a jar, or grains into a silo. We deconstruct this method and study the impact on packing by simply varying the pour rate and energy of particles dropped randomly but spatially uniformly in a large container whose substrate can act as a template. We find that fully disordered packings are observed when large number of particles are added all at once but an ordered fcc crystal is observed when particles are added sequentially at random locations and allowed to come to rest before adding the next layer. By scanning the packings obtained by 3D X-ray tomography, we identify the positions of all the particles and the growth of order and defects. We present an analysis of the structures formed and compare and contrast it with packings obtained using other protocols including by cyclic shear [1]. [1]: "Nucleation and Crystal Growth in Sheared Granular Sphere Packings," Andreea Panaitescu, K. Anki Reddy, and Arshad Kudrolli, Phys. Rev. Lett. 108, 108001 (2012).

11:51AM N29.00004 Comparison between bridges and force-chains in granular packings[1] , LING ZHANG, SHUXIAO CAI, ZUNPENG HU, Department of Physics, Shanghai Jiao Tong University, Shanghai 200240, China, JIE ZHANG, Institute of Natural Sciences and Department of Physics, Shanghai Jiao Tong University, Shanghai 200240, China — In dense granular materials, there exist chain-like force networks from which we can obtain much information on the mechanical properties of packings. But it is extremely difficult to characterize these structures, especially in 3D packings. Mehta and her coauthors have proposed theoretically that bridge-like structures can form because of spatial inhomogeneity and large fluctuations, and they conjecture that these mesoscopic geometric structures play the role of force-chains (Mehta et. al. 2004, Pugnaloni et. al. 2001). Some statistical features of bridges have been observed in a recent paper by Mattew C. Jenkins et al (Jenkins et. al. 2011). Despite the success, the lack of independent force network information makes the justification of Mehta et al.'s theoretical conjecture inconclusive. In this study, we focus on the comparison of bridges and force-chains in two different granular packing using photo-elastic granular particles. We have found no clear evidence that there exists a one-to-one mapping between bridges and force-chains. Nonetheless, for systems of different force chain structures, it does seem to show some differences in the respective bridge structures. This seems to suggest that some connection may exist between bridges and force-chains.

12:03PM N29.00005 Novel spiral-like columnar packings of hard spheres from sequential deposition - a route to new architecture in the scientific world[1] , HO-KEI CHAN[2], Department of Physical and Theoretical Chemistry, School of Chemistry, University of Nottingham, United Kingdom — Recent work [Physical Review E 84, 050302(R) (2011)] shows that the densest columnar packings of identical hard spheres inside a cylinder can be constructed from a sequential deposition of such spheres onto a specially designed template at the cylinder base, if the cylinder-to-sphere diameter ratio D is within [1,2.7013]. In this talk, I will present some novel, non-densest spiral-like structures as discovered from the same deposition algorithm, and will elaborate on how we can manipulate a columnar structure by changing its underlying template.

12:15PM N29.00006 Cavity method for jammed disordered packings of hard particles at mean-field level , LIN BO, The City College of New York & The Graduate Center, CUNY, ROMAIN MARI, The City College of New York, CHAOMING SONG, Northeastern University, HERNAN MAKSE, The City College of New York, SOFT MATTER AND COMPLEX SYSTEMS LAB TEAM — We apply the cavity method at mean-field level to investigate the problem of random close packings of hard particles. We derive the Belief Propagation equations describing this force/torque balance problem to solve the force distribution and suggest an estimation of the coordination number of the jammed packing. We compare the numerical results with approximate analytical solutions and show the dependence of coordination numbers on particle shapes. The method can be applied to spherical frictionless and frictional particles as well as non-spherical particles to obtain the jamming properties and study the appearance of isostaticity.

12:27PM N29.00007 Detection of Multidimensional Structures in Granular Materials[1] , DANIELLE BASSETT, University of California Santa Barbara, KAREN DANIELS, ELI OWENS, North Carolina State University, MASON A. PORTER, University of Oxford, M. LISA MANNING, Syracuse University — Granular media display features across a range of spatial scales, from the particle scale to the force-chain scale and the bulk scale. In contrast to particulate and continuum models, network representations facilitate the simultaneous examination of microscopic, mesoscopic, and macroscopic features. We treat granular materials as spatially embedded networks in which the nodes (particles) are connected by weighted edges obtained from contact forces. Using community detection techniques, we identify local 2D geographic domains composed of particles that exert strong forces on one another. We subsequently develop and apply a novel spatial null model constrained by the contact network to extract chain-like structures reminiscent of force chains. We demonstrate that most of these chain-like structures are located close to the center of mass of the 2D geographic domains. However, a minority are located towards the edge of the 2D geographic domains, potentially forming points of instability in granular media. We explore the robustness of these detection techniques to algorithmic degeneracies, to simulation versus experimental data, and to varying pressure states.

12:39PM N29.00008 Compaction of frictional octahedra , N. NIRMAL THYAGU, MAX NEUDECKER, STEPHAN HERMINGHAUS, MATTHIAS SCHROETER, Max Planck Institute for Dynamics and Self-Organization, Goettingen, Germany — We perform experiments with frictional polypropylene octahedra to study the packing properties. Starting with the loose packing, compaction of octahedra is done by two types of forcing – a) tapping and b) shearing. The compaction gives rise to crystallization of octahedra due to heterogenous nucleation from the walls. We obtain the X-ray tomograms of the packing configurations as a function of packing fraction. From the contact geometries we obtain results for the packings such as - pair correlation function, distance to isostaticity, and spatial & angular correlation functions. We contrast these results with a similar study on the simplest platonic solid, the tetrahedron[1] and the sphere.

[1]Jammed frictional tetrahedra are hyperstatic, M. Neudecker, S. Ulrich, S. Herminghaus, M. Schröter. (arXiv:1202.6272v2)

12:51PM N29.00009 Revealing the structure of a granular medium through acoustic measurements[1] , RAMON PLANET LATORRE, SÉBASTIEN LHERMINIER, GILLES SIMON, LOIC VANEL, OSVANNY RAMOS, Laboratoire PMCN Université Claude Bernard Lyon 1 — An array of acoustic sensors records the sound that has travelled across a bi-dimensional granular medium, consisting of photoelastic discs, which are confined between two transparent plates and arranged into different crystalline or disordered structures. The system is compressed along one direction (either force-controlled or displacement-controlled) and can be sheared in the direction perpendicular to the applied force; while the acoustic signals are generated through a well-controlled and local mechanical excitation. The results show power-law regimes in the force vs. sound speed relation, with exponents that are sensitive to the structure of the packing. Small structural changes are also detectable which, in principle, can be used to predict large avalanches during the slow shearing of the system.

1:03PM N29.00010 The vanishing Janssen effect in a confined 2D granular system compressed by friction , YASIN KARIM, ERIC CORWIN, Materials Science Institute and Department of Physics, University of Oregon — As described by H.A. Janssen in 1895, the pressure in a granular packing saturates above a certain filling height, determined by the particle-particle and particle-wall interactions. This effect has been studied extensively for 2D and 3D confined granular packs compressed by gravity. However, many industrially relevant processes involve the horizontal transport of granular materials by conveyor belts. In such a case gravity becomes irrelevant and the system is driven by frictional forces. We study horizontal 2D confined granular packs on a conveyor belt as they are driven into a stationary barrier. We measure the relationship between pressure and filling height and, surprisingly, find no saturation of pressure. Instead, we observe a linear relationship between pressure and filling height irrespective of the particle-wall coefficient of friction demonstrating that the Janssen effect is not relevant for such systems. However, we can recover a Janssen-like saturation if we replace the straight confining walls with a sawtooth pattern on the scale of the particle size. This allows for a mechanical transfer of load onto the walls and can be interpreted in terms of an effective mechanical "friction."

1:15PM N29.00011 From Kepler to Ulam: searching for the optimal packing in the space of object shapes , ROMAIN MARI, Levich Institute, City College of New York, ADRIAN BAULE, Levich Institute, City College of New York, and School of Mathematical Sciences, Queen Mary University of London, LIN BO, Levich Institute and Physics Department, City College of New York, MAXIMILIEN DANISCH, Levich Institute, City College of New York, and Laboratoire d'Informatique de Paris 6, Université Pierre et Marie Curie, HERNAN MAKSE, Levich Institute and Physics Department, City College of New York — The quest for the best packing of particles has been guided by two notorious conjectures. Kepler stated that the optimal sphere packing is the face-centered-cubic lattice, while Ulam conjectured that all convex shapes pack better than spheres. While the former was proved by Hales, there is yet no theoretical framework to predict the density of non-spherical particles. Here, we present a formalism to describe packings of objects of arbitrary shape in random configurations by reducing the particle interactions to simple sets of points, and lines. The framework predicts the optimum packing fraction of a large class of shapes as an analytical continuation from the spherical point, thus paving the way for a proof of Ulam's conjecture. In particular, the formalism predicts that spherocylinders pack better than both spheres and dimers. Ellipsoids and tetrahedra can be studied, highlighting the universality 1of the framework to search for optimal packings.

1:27PM N29.00012 Forces on Intruders in Granular Media , IBAR DE LA CRUZ, WPI — We measure the forces acting on intruders moving in different directions in a granular medium consisting of mono-disperse spherical glass beads. We present the dependence of the drag force on the intruder's geometry and surface roughness, bead size, dragging speed and immersion depth. We present a model that considers not only the wedge dragged by the intruder but also the pile created as the intruder moves through the granular material to calculate the drag force. We compare our experimental and analytical results.

1:39PM N29.00013 Granular Dynamics during Impact[1] , KERSTIN NORDSTROM, University of Maryland, EMILY LIM, Duke University, MATT HARRINGTON, WOLFGANG LOSERT, University of Maryland — In this work, we study the impact of a projectile onto a bed of 3 mm grains immersed in an index-matched fluid. Using a laser sheet scanning technique, a high speed camera, and particle tracking, we can measure the trajectory of each grain throughout an impact event. We characterize the bulk and microscopic dynamics within the granular material as a function of initial sample preparation, specifically applying a uniaxial prestrain to the sample. We find that small changes in sample preparation lead to drastic departures from the universal depth scaling seen in previous studies of shallow granular impacts. By examining the nonaffine motion within the system, we propose the effect is due to different loading and buckling of force chains within the system.

1:51PM N29.00014 What is the granular response to a high-speed impact?[1] , ABRAM CLARK, Duke University, LOU KONDIC, New Jersey Institute of Technology, ROBERT BEHRINGER, Duke University — Although many studies of impact on a granular material exist, the connections between the local granular response, the microscopic processes which dissipate kinetic energy, and the intruder dynamics are unclear, largely due to experimental difficulties in obtaining very fast data at the grain scale. We use high-speed imaging (40 kHz) of an intruder striking a quasi-2D system of photoelastic disks, yielding both the intruder dynamics and the force response of individual grains. The frame rates are fast enough to resolve rich acoustic activity on the particle scale. For long time scales, the intruder dynamics are consistent with previously used empirical force laws. However, for short time scales, we observe very large fluctuations in the deceleration, which we connect to the intermittent acoustic activity beneath the intruder as it moves. We show that these intense, intermittent acoustic pulses, which travel much faster than the intruder along networks of grains, are the primary microscopic mechanism of energy loss. These pulses carry energy away into the medium, and they decay roughly exponentially with distance. We examine the statistics of these fluctuations in order to better understand their origin and behavior.

2:03PM N29.00015 The Jamming transition in photoelastic disks: local perturbations versus diverging responses , CORENTIN COULAIS, University of Leiden, Leiden, The Netherlands, ANTOINE SEGUIN, Paris Sud University, Paris, France, OLIVIER DAUCHOT, ESPCI, Paris, France, CEA SACLAY/SPEC/SPHYNX - FAST LAB, PARIS SUD UNIV. TEAM, ESPCI - CEA SACLAY/SPEC/SPHYNX COLLABORATION — We investigate the spatial response of the contact network to local perturbations in experiments on horizontal packings of bidisperse photo-elastic soft disks close to jamming. First, an intruder is pulled at constant force through the packing: while the overall contact number remains unchanged, the contact network geometry drastically changes and develops a strong asymmetry between the front and the back of the intruder. Second, an intruder is inflated inside the packing leading to a global increase of the contact number. While particle rearrangements become increasingly large as the unjamming transition is approached, there are only few contact changes in the packing. We discuss these results in the light of a recent work [1] on fluctuations where a similar link between dynamical heterogeneities and contact fluctuation has been reported.

Session N30 DCMP: Self-Assembly: Mostly Biopolymers, DNA and Nanoparticles 338 - Xiangyun Qiu, George Washington University

11:15AM N30.00001 Formation of Heterogeneous Toroidal-Spiral Particles – by Drop Sedimentation and Interaction[1] , YING LIU, LUDWIG NITSCHE, RICHARD GEMEINHART, VISHAL SHARMA, MAGDALENA SZYMUSIAK, HAO SHEN, University of Illinois at Chicago — We describe self-assembly of polymeric particles, whereby competitive kinetics of viscous sedimentation, diffusion, and cross-linking yield a controllable toroidal-spiral (TS) structure. Precursor polymeric droplets are splashed through the surface of a less dense, miscible solution, after which viscous forces entrain the surrounding bulk solution into the sedimenting polymer drop to form TS channels. The intricate structure forms because low interfacial tension between the two miscible solutions is dominated by viscous forces. The biocompatible polymer, poly(ethylene glycol) diacrylate (PEG-DA), is used to demonstrate the solidification of the TS shapes at various configurational stages by UV-triggered cross-linking. The dimensions of the channels are controlled by Weber number during impact on the surface, and Reynolds number and viscosity ratio during subsequent sedimentation. Within the critical separation distance, interaction of multiple drops generates similar structure with more flexibility. Furthermore, the understanding of multiple drop interaction is essential for mass production of TS particles by using parallel and sequential arrays of drops.

11:27AM N30.00002 ReaxFF Reactive Force Field Study of Oriented Attachment of TiO_2 Nanocrystals in Vacuum and Humid Environments , MURALIKRISHNA RAJU, Dept of Physics, The Pennsylvania State University, KRISTEN FICHTHORN, Dept of Chemical Engineering, Dept of Physics, The Pennsylvania State University, ADRI VAN DUIN, Dept of Mechanical and Nuclear Engineering, The Pennsylvania State University — We use a ReaxFF reactive force field to study the aggregation of various titanium dioxide (anatase) nanocrystals in vacuum and humid environments. The nanocrystals are in the 2-6nm size range, with shapes dictated by the Wulff construction. In vacuum, the nanocrystals tend to merge along their direction of approach, resulting in a polycrystal. By contrast, in the presence of water vapor, the nanocrystals tend to reorient themselves and aggregate via the oriented attachment mechanism to form a single or twinned crystal. We find that adsorbed water molecules and hydroxyl groups play multiple roles in oriented attachment. As the nanocrystals approach one another closely, adsorbed water molecules and surface hydroxyls prevent their immediate aggregation. These adsorbed species create a hydrogen bonding network, which aligns the nanoparticles in registry. Upon the eventual elimination of these species, the nanoparticles fuse into a single-crystal or twinned aggregate. We observe this aggregation mechanism for anatase(101), anatase(112), and anatase(001) surfaces, as is also seen experimentally. This indicates the important role that solvent plays in nanocrystal aggregation and how solvent can be a powerful tool for directing and controlling nanocrystal growth.

11:39AM N30.00003 Improving reaction rates by confinement within biocompatible polymers , CECILE MALARDIER-JUGROOT, XIA LI, MICHAEL N. GROVES, Department of Chemistry and Chemical Engineering, Royal Military College of Canada, MANISH JUGROOT, Department of Mechanical and Aerospace Engineering, Royal Military College of Canada — The most efficient catalysts have been developed and optimized by living systems. Indeed, in vivo enzyme-catalyzed reactions are several orders of magnitude more efficient than platinum based catalyzed reactions. However, the rate of reaction and equilibrium interactions are considerably reduced when the biological systems are studied in vitro. This phenomenon is largely attributed to the effect of confinement or macromolecular crowding present in the cell. This paper will present the comprehensive characterization of amphiphilic polymeric template with hydrophobic cores inducing 1D and 2D confinement on hydrophobic reactants diffusing within the templates. The paper will show that effect of confinement allows reactions to occur without external factors essential for these reactions to occur in the bulk. The products synthesized in a very controlled environment within amphiphilic polymeric nanotubes and nanosheets are monodispersed at the nanoscale ($\sim$ 2nm). The effect of confinement opens new possibilities for environmentally friendly synthesis of novel nanoscale materials.

11:51AM N30.00004 Unraveling the Mechanism of Nanotube Formation by Chiral Self-Assembly of Amphiphiles , DGANIT DANINO, Technion - Israel Institute of Technology and the Russell Berrie Nanotechnology Institute — The self-assembly of *nanotubes* from chiral amphiphiles and peptides is still poorly understood. Here, we present the first complete path to nanotubes by chiral self-assembly studied with C_{12}-β_{12}, a tailored molecule designed to have unique hybrid architecture. Using direct-imaging cryo-transmission electron microscopy (cryo-TEM) we show the time-evolution from micelles to closed nanotubes, passing through several types of 1-dimensional (1-D) intermediates such as elongated fibrils, twisted ribbons, and coiled helical ribbons. Scattering and diffraction techniques confirm that the fundamental unit is a monolayer lamella, with the hydrophobic tails in the gel state and beta-sheet arrangement. The lamellae are held together by a combination of hydrophobic interactions, and 2 sets of hydrogen bonding networks. Our data exclusively indicate that twisted ribbons are the precursors for coiled ribbons, and we show this transition is directly linked to the ribbon width. Furthermore, quantitative analysis shows that neither the "growing width" model nor the "closing pitch" model accurately describe the process of nanotube formation, and *both* ribbon width and pitch grow with maturation, maintaining a linear growth in their ratio. We also show that chirality is a key requirement for nanotube formation. 12:03PM N30.00005 Programmable Mesoscopic Architecture using Directionally-Functionalized Nanoparticles[1] , JONATHAN HALVERSON, ALEXEI TKACHENKO, Brookhaven National Laboratory — Nanoparticles that have been isotropically-functionalized with complementary DNA strands have been shown to self-assemble into a variety of crystalline morphologies. To produce a nanoparticle assembly with a finite size and arbitrary shape, the NPs must be endowed with directional interactions. Directionally-functionalized nanoparticles (dfNPs) can be constructed by grafting ssDNA at specific locations on the particles, and proof-of-principle experiments have successfully demonstrated the self-assembly of such particles. Using these building blocks we have previously demonstrated with numerical simulations that a variety of target mesoscopic structures, each with a programmed local morphology and complex overall shape, can be self-assembled in near perfect yield. Here we present a model to describe the kinetics of assembly of a structure composed on dfNPs. The capability to produce these structures can be utilized in a variety of applications where bottom-up construction of 3D nano-objects with well-defined composition and architecture is required (e.g., nanoplasmonics, nanomedicine, metamaterials).

12:15PM N30.00006 Biomimetic DNA emulsions: specific, thermo-reversible and adjustable binding from a liquid-like DNA layer , LEA-LAETITIA PONTANI, LANG FENG, Department of Physics, New York University, REMI DREYFUS, Complex Assemblies of Soft Matter, Centre National de la Recherche Scientifique-Rhodia-University of Pennsylvania, NADRIAN SEEMAN, Department of Chemistry, New York University, PAUL CHAIKIN, JASNA BRUJIC, Department of Physics, New York University — We develop micron-sized emulsions coated with specific DNA sequences and complementary sticky ends. The emulsions are stabilized with phospholipids on which the DNA strands are grafted through biotin-streptavidin interactions, which allows the DNA to diffuse freely on the surface. We produce two complementary emulsions: one is functionalized with S sticky ends and dyed with red streptavidin, the other displays the complementary S' sticky ends and green streptavidin. Mixing those emulsions reveals specific adhesion between them due to the short-range S-S' hybridization. As expected this interaction is thermo-reversible: the red-green adhesive droplets dissociate upon heating and reassemble after cooling. Here the fluid phospholipids layer also leads to diffusive adhesion patches, which allows the bound droplets to rearrange throughout the packing structure. We quantify the adhesion strength between two droplets and build a theoretical framework that captures the observed trends through parameters such as the size of the droplets, the DNA surface density, the various DNA constructs or the temperature. This colloidal-scale, specific, thermo-reversible biomimetic emulsion offers a new versatile and powerful tool for the development of complex self-assembled materials.

12:27PM N30.00007 Hybridization dynamics to DNA guided crystallization[1] , TING LI, Northwestern University, RASTKO SKNEPNEK, Syracuse University, MONICA OLVERA DE LA CRUZ, Northwestern University, NORTHWESTERN UNIVERSITY TEAM — DNA recognition inspires an elegant protocol to design versatile nanoparticle assemblies. Although great achievements in DNA programmed periodic structures have been obtained, it took over a decade to realize even the basic crystal structures like FCC and BCC in an experiment. We use molecular dynamics simulations to discuss the dynamic aspects of the assembly process and identify ingredients that are key to successfully assemble nanoparticle superlattices through DNA hybridizations. The scale-accurate coarse-grained model [1,2] faithfully captures the relevant dynamics of the DNA hybridization, and is able to recover the in situ formation of all to date experimentally reported binary superlattices (BCC, CsCl, AlB2, Cr3Si and Cs6C60 lattices). We used a multi-scale simulation approach to study the assembly mechanism in systems with up to 10^6 degrees of freedom and found that the assembly process is enthalpy-driven. Finally, we investigated the optimal strength of DNA linkers, hybridization dynamics, and percentage of hybridizations for different binary systems. Based on these results, we suggest a protocol for future nanomaterial designs with versatile DNA interactions. [1] Knorowski, C., et al. P.R.L. 2011,106,215501; [2] Li, T.I.N.G., et al. Nano Letters 2012,12,2509.

12:39PM N30.00008 When DNA Meets Depletion , KUN-TA WU, LANG FENG, PAUL CHAIKIN, Center for Soft Matter Research, Department of Physics, New York University, 4 Washington Place, New York, NY 10003, USA — Depletion is a widely used tool in colloidal particle system for universal attraction. Recently, the rapid development of DNA-coated particles also opens a door to colloidal architecture due to the specificity of DNA hybridization. In our study, we combine these two techniques, depletion and DNA hybridization, in colloidal system and find out that DNA-coated particles in depletion system aggregate faster and have the higher melting temperature than the ones without depletion. We studied quantitatively how the kinetics and thermodynamics of DNA-coated particles are changed with the concentration of depletion and DNA. We also find out that by using the depletion-and-DNA coupled system, particle can form crystals within hours rather than days due to the catalysis effect from depletion. Our study illustrates how DNA and depletion can be used in the same system to create more various and unique systems, which can not be achieved by neither DNA nor depletion along.

12:51PM N30.00009 Template-mediated catalysis of DNA tiles , CORINNA MAASS, XIAOJIN HE, RUOJIE SHA, YOEL OHAYON, NADRIAN SEEMAN, PAUL CHAIKIN, New York University — We present a novel mechanism for the selective creation of irreversible bonds between DNA nanotiles in the presence of a DNA template of complementary joined DNA tiles. The hybridisation transition of DNA sticky ends is highly concentration dependent. While immobilised on a template, adjacent DNA tiles are subject to a greatly increased local concentration (10^{12}), as compared to free tiles in solution. This reduces the entropy penalty for sticky end hybridisation and shifts the hybridisation transition to higher temperatures. We have developed a tile-template model consisting of two DNA tiles with sticky ends that will, at room temperature, only react when attached to template tiles and which can be bound irreversibly via an UV crosslinkable nucleobase substitute. The selectivity is high and the irreversible crosslinking is enhanced by a factor of roughly 100.

1:03PM N30.00010 DNA Photo Lithography with Cinnamate-based Photo-Bio-Nano-Glue , LANG FENG, MINFENG LI, JOY ROMULUS, RUOJIE SHA, JOHN ROYER, KUN-TA WU, QIN XU, NADRIAN SEEMAN, MARCUS WECK, PAUL CHAIKIN, New York University — We present a technique to make patterned functional surfaces, using a cinnamate photo cross-linker and photolithography. We have designed and modified a complementary set of single DNA strands to incorporate a pair of opposing cinnamate molecules. On exposure to 360nm UV, the cinnamate makes a highly specific covalent bond permanently linking only the complementary strands containing the cinnamates. We have studied this specific and efficient crosslinking with cinnamate-containing DNA in solution and on particles. UV addressability allows us to pattern surfaces functionally. The entire surface is coated with a DNA sequence A incorporating cinnamate. DNA strands A'B with one end containing a complementary cinnamated sequence A' attached to another sequence B, are then hybridized to the surface. UV photolithography is used to bind the A'B strand in a specific pattern. The system is heated and the unbound DNA is washed away. The pattern is then observed by thermo-reversibly hybridizing either fluorescently dyed B' strands complementary to B, or colloids coated with B' strands. Our techniques can be used to reversibly and/or permanently bind, via DNA linkers, an assortment of molecules, proteins and nanostructures. Potential applications range from advanced self-assembly, such as templated self-replication schemes recently reported [1], to designed physical and chemical patterns, to high-resolution multi-functional DNA surfaces for genetic detection or DNA computing. [1] Tong, W et al, Nature, 478, 225-228(2011)

1:15PM N30.00011 Controlling the temperature-dependent assembly of DNA-coated colloids with toehold exchange , WILLIAM ROGERS, JESSE COLLINS, Harvard SEAS, VINOTHAN MANOHARAN, Harvard SEAS and Physics — DNA is increasingly being used as a tool for directing the self-assembly of particle-based systems. The transient bridging of grafted, complementary DNA strands induces specific, attractive interactions that can direct nanoparticles or colloids to form clusters, ordered crystal lattices, or other interesting structures. In most cases, the DNA-induced binding strength is a monotonic and near exponential function of temperature, resulting in a single, narrow temperature window for equilibrium assembly that may frustrate efforts to make multicomponent or hierarchical structures. Here, we present and quantitatively demonstrate a new approach to controlling the temperature dependence of DNA-induced colloidal interactions using toehold exchange hybridization, a concept borrowed from dynamic DNA nanotechnology. These competitive hybridization pathways allow additional control over the thermodynamics of bridge formation and provide a simple way to engineer novel temperature dependences that need not be exponential or monotonic. This additional functionality will be useful in the rational design of new multicomponent, hierarchical, or reconfigurable self-assembling systems.

1:27PM N30.00012 Colloidal Clusters via Short, Specific, and Isotropic DNA Interactions , JESSE W. COLLINS, Harvard SEAS, VINOTHAN N. MANOHARAN, Harvard SEAS and Physics — Many of the material systems scientists have successfully described using statistical mechanics have a number of distinct chemical species that does not scale with the total number of particles. Do any different equilibrium phenomena emerge in systems of a much wider variety of chemical species? We investigate the case in which the number of chemical species is equal or very nearly equal the total number of particles. We coat microspheres with short and specific DNA strands, and observe small numbers of these spheres at a time self-assemble using various forms of microscopy, including holography for 3-D particle positions and fluorescence for species identification. We have learned some simple rules that modulate the energy landscape of these particles. The relative chirality of substructures, including pairs of trimers, varies for each local minima on the landscape of small clusters like the ones we observe. If the ground state structure is rigid, the higher energy local minima structures are generally soft. Although our experiments are limited to about 6 particles, ideas from graph theory and statistical mechanics suggest that much larger numbers of short-ranged, specific and chemically isotropic spheres can robustly assemble into rigid ground state clusters as well.

1:39PM N30.00013 Phases and Dynamics of Self-Assembled DNA Programmed Nanocubes[1] , CHRISTOPHER KNOROWSKI, Department of Physics and Astronomy and Ames Laboratory, Iowa State University, Ames, IA, ALEX TRAVESSET, Iowa State University Department of Physics and Astronomy and Ames Lab DOE — Systems of Nanoparticles grafted with complementary DNA strands have been shown to self-assemble into an array of superlattices. In this talk, we extend our previous model [1], which successfully predicted equilibrium phases and dynamics of assembly for spherical Nanoparticles [1,2] without fitting parameters, to the case of nanocubes. We show that the phase diagram consists of bcc and sc lattices, depending on DNA length. The bcc lattices are either rotator and orientational glass or cubatic. For temperatures above the DNA melting temperature, the system is equivalent to f-star polymer systems, and consist of bcc, also with rotator, orientational glass or cubatic orientational order as well as sc. We also provide a characterization of the dynamics, including the role of topological defects in crystal nucleation and growth.

1:51PM N30.00014 Assembly of tetrahedral gold nanoclusters from binary colloidal mixtures[1] , NICHOLAS B. SCHADE, Harvard University, DAZHI "PETER" SUN, Brookhaven National Laboratory, MIRANDA C. HOLMES-CERFON, ELIZABETH R. CHEN, EMILY W. GEHRELS, JONATHAN A. FAN, Harvard University, OLEG GANG, Brookhaven National Laboratory, VINOTHAN N. MANOHARAN, Harvard University — We experimentally investigate the structures that form when colloidal gold nanospheres cluster around smaller spheres. We use nanoparticles coated with complementary DNA sequences to assemble the clusters, and we observe them under electron microscopy. Previous experiments using polystyrene microspheres indicate that a 90% yield of tetrahedral clusters is possible near a critical diameter ratio; random sphere parking serves as a useful model for understanding this phenomenon. Here we examine how this approach can be scaled down by an order of magnitude in size, using gold building blocks. We study how this method can be used to assemble tetrahedral plasmonic resonators in order to create a bulk, isotropic, optical metamaterial.

[1]We acknowledge support from the DOE Office of Science Graduate Fellowship program.

2:03PM N30.00015 Field-directed assembly of colloidal ellipsoids[1] , PETER J. BELTRAMO, ERIC M. FURST, University of Delaware — Self-assembly of colloidal building blocks into ordered structures has become a rapidly evolving area of research due to the novel properties (thermal transport, photonic, electromagnetic) imparted by periodicity.[2] Assembly of anisotropic particles presents numerous challenges, namely kinetic arrest at high particle volume fractions due to glassy dynamics. This prevents the realization of theoretically predicted close-packed phases.[3] In this work, we use AC electric fields to align dilute polystyrene ellipsoidal particles in suspension and a drying front to concentrate the particles into orientationally ordered thin films. Results using several aspect ratio particles are presented. The dilute electrokinetic properties which enable this field-directed assembly are characterized by dielectric spectroscopy and electrophoretic mobility measurements. Light scattering is used to evaluate the frequency and field strength dependence of particle alignment. Finally, the nanomechanical and phononic properties of the films are evaluated by Brillouin light scattering.

Wednesday, March 20, 2013 11:15AM - 1:39PM –

Session N31 DPOLY: Membrane and Membrane Protein Interactions 339 - Yossef Elabd, Drexel University

11:15AM N31.00001 Investigating the Structural Properties of Integral Membrane Proteins with Pulsed EPR Spectroscopy , GARY LORIGAN, Miami University — Very limited structural and dynamic information on proteins embedded inside a membrane currently exist, because they are difficulty to crystalize. New biophysical/structural biology methods are needed to probe these systems in a lipid bilayer. The Lorigan lab is applying unique hybrid NMR and spin-label EPR spectroscopic techniques to study membrane proteins. Magnetic resonance spectroscopic data of ^{15}N-, ^{2}H-labeled and/or spin-labeled membrane proteins incorporated into vesicles and bicelles will be presented. State-of-the-art pulsed EPR techniques such as Electron Spin Echo Envelope Modulation (ESEEM) spectroscopy, and Double Electron-Electron Resonance (DEER) spectroscopy will be used. The ESEEM technique can determine short to medium range distances (out to about 8 Å) between a site-specific nitroxide spin label and a nearby NMR-active isotopic labeled residue for a variety of different peptides and proteins which ultimately can be used to determine the difference between an α-helical and β-sheet secondary structure. DEER can be used to measure distances between 2 spin labels out to about 70 Å. We have shown a huge improvement is sensitivity with DEER measurements at Q-band when compared to X-band.

11:51AM N31.00002 Tocopherol activity correlates with its location in a membrane: A new perspective on the anti-oxidant Vitamin E , DREW MARQUARDT, Department of Physics, Brock University, JUSTIN WILLIAMS, Department of Physics, Indiana University Purdue University Indianapolis, NORBERT KUCERKA, National Research Council, Canadian Neutron Beam Centre, JEFFREY ATKINSON, Department of Chemistry, Brock University, JOHN KATSARAS, Oak Ridge National Laboratory, Oak Ridge, STEPHEN WASSALL, Department of Physics, Indiana University Purdue University Indianapolis, THAD HARROUN, Department of Physics, Brock University — There are no proven health benefits to supplementing with Vitamin E, so why do we require it for healthy living? The whole notion that vitamin E is an in-vivo antioxidant is now being seriously questioned. Using neutron diffraction and supporting techniques, we have correlated vitamin E's location in model membranes with its antioxidant activity. experiments were conducted using phosphatidylcholine (PC) bilayers whose fatty acid chains varied in their degree of unsaturation. We observe vitamin E up-right in all lipids examined, with its overall height in the bilayer lipid dependant. Interestingly we observe vitamin E's hydroxyl in the headgroup region of the bilayer for both the fully saturated and poly unsaturated lipids. Vitamin E was most effective at intercepting water borne oxidants than radical initiated within the bilayer core. However for lipids where vitamin E resides slightly lower (glycerol backbone) we observe comparable antioxidant activity against both water borne and hydrocarbon borne oxidants. Thus showing lipid species can modulate the location of vitamin E's activity.

12:03PM N31.00003 Redistribution of Cholesterol in Model Lipid Membranes in Response to the Membrane-Active Peptide Alamethicin[1] , WILLIAM HELLER, SHUO QIAN, Oak Ridge National Laboratory — The cellular membrane is a heterogeneous, dynamic mixture of molecules and macromolecules that self-assemble into a tightly-regulated functional unit that provides a semipermeable barrier between the cell and its environment. Among the many compositional differences between mammalian and bacterial cell membranes that impact its physical properties, one key difference is cholesterol content, which is more prevalent in mammals. Cholesterol is an amphiphile that associates with membranes and serves to maintain its fluidity and permeability. Membrane-active peptides, such as the alpha-helical peptide alamethicin, interact with membranes in a concentration- and composition-dependent manner to form transmembrane pores that are responsible for the lytic action of the peptide. Through the use of small-angle neutron scattering and deuterium labeling, it was possible to observe a redistribution of the lipid and cholesterol in unilamellar vesicles in response to the presence of alamethicin at a peptide-to-lipid ratio of 1/200. The results demonstrate that the membrane remodeling powers of alamethicin reach beyond the membrane thinning effect to altering the localization of specific components in the bilayer, complementing the accepted two-state mechanism of pore formation.

12:15PM N31.00004 Relationship between peptide membrane curvature generation and bactericidal activities , NATHAN SCHMIDT, MICHELLE LEE, DAVID KUO, Bioengineering Dept, UCLA, ANDRE OUELLETTE, Pathology & Laboratory Medicine Dept, USC, GERARD WONG, Bioengineering Dept, UCLA — Many amphipathic peptides and amphipathic domains in proteins can restructure biological membranes. Two examples are host defense antimicrobial peptides (AMPs) which disrupt and destabilize the cell membranes of microbes, and apolipoproteins which help stabilize nanoscale lipid aggregates. We use complementary x-ray and bacterial cell assays to elucidate the molecular length scale membrane deformations generated by amphipathic peptides with different structural motifs and relate these deformations to their activities on bacteria. Small angle x-ray scattering is used to study the interactions of model membranes with prototypical AMPs and consensus peptides from the amphipathic domains in apolipoproteins. By characterizing the nanoscale curvature deformations induced by these two distinct classes of membrane restructuring peptides we will discuss the role of amino acid composition on curvature generation. Bactericidal assays are used to access the in vivo activities of different amphipathic peptide motifs in order to understand the relationships between cell viability and membrane curvature generation.

12:27PM N31.00005 Observing Stepwise Unzipping of Neuronal Snare Protein with Steered Molecular Dynamics , MUSTAFA TEKPINAR, Yuzuncu Yil University, WENJUN ZHENG, University at Buffalo — Soluble N-ethylmaleimide-sensitive factor Attachment Protein Receptors (SNARE) play a crucial role in membrane fusion. Neuronal SNAREs are made up of four helices: a snaptobrevin, a syntaxin 1, and two SNAP-25 helices. We applied constant velocity pulling forces to C terminal of snaptobrevin in SNARE complex to understand unzipping mechanism of neuronal SNAREs. We successfully observed unzipping of snaptobrevin from the other three helices in two steps: C terminal unzipping and N terminal unzipping. Our results have good agreement with recent optical tweezer experiments that observe this stepwise unzipping. Additionally, our simulations reveal that these two steps differ from each other. We believe that these different mechanisms can help us to understand SNARE mediated membrane fusion process better.

12:39PM N31.00006 Information processing in the plasma membrane , BENJAMIN MACHTA, Lewis Sigler Institute, Princeton University — The plasma membrane is a 2D liquid where information from the world is received and processed. Motivated by the recent discovery that these membranes seem to be tuned close to a 2D liquid-liquid critical point, we set out to understand the different channels through which membrane bound proteins can communicate with each other. Diffusing proteins can carry out reactions when they come in contact with each other. Near criticality, proteins can also exert long-ranged critical Casimir forces on one another by coupling to the local composition order parameter. By modulating the growth and breakdown of the rigid cytoskeleton, they can direct forces on even more distant regions. In addition, proteins can control the release and production of second messengers that diffuse either through the bulk, or in the plane of the membrane itself. By making simple models for these processes we bound functional measures for them as communication channels. These include information theoretic measures of bandwidth, as well as physical measures of energetic efficiency and speed. Our results will likely prove useful in understanding functional reasons underlying the clustering and collective behavior often seen in experiments.

12:51PM N31.00007 Yeast mitochondrial fission proteins induce antagonistic Gaussian membrane curvatures to regulate apoptosis , MICHELLE LEE, GHEE HWEE LAI, NATHAN SCHMIDT, WUJING XIAN, GERARD C. L. WONG, Dept. of Bioengineering, University of California at Los Angeles — Mitochondria form a dynamic and interconnected network, which disintegrates during apoptosis to generate numerous smaller mitochondrial fragments. This process is at present not well understood. Yeast mitochondrial fission machinery proteins, Dnm1 and Fis1, are believed to regulate programmed cell death in yeast. Yeast Dnm1 has been previously shown to promote mitochondrial fragmentation and degradation characteristic of apoptotic cells, while yeast Fis1 inhibits cell death by limiting the mitochondrial fission induced by Dnm1 [Fannjiang et al, *Genes & Dev.* 2004. 18: 2785-2797]. To better understand the mechanisms of these antagonistic fission proteins, we use synchrotron small angle x-ray scattering (SAXS) to investigate their interaction with model cell membranes. The relationship between each protein, Dnm1 and Fis1, and protein-induced changes in membrane curvature and topology is examined. Through the comparison of the membrane rearrangement and phase behavior induced by each protein, we will discuss their respective roles in the regulation of mitochondrial fission.

1:03PM N31.00008 On the modeling of endocytosis , TAO ZHANG, RASTKO SKNEPNEK, JENNIFER SCHWARZ, MARK BOWICK, Syracuse University — Endocytosis is the primary mechanism by which extracellular material enters the cell. During endocytosis, the cell membrane deforms to surround the extracellular material and draw it into the cell, followed by a pinch-off to produce an internal vesicle. Recent experiments on clathrin-mediated endocytosis all agree that the actin cytoskeleton plays a crucial role in the deformation of the cell membrane. The actin cytoskeleton is a crosslinked network of filaments exerting active forces. However, competing ideas remain as to precisely how the actin cytoskeleton organizes itself to help drive the deformation. To begin to resolve this controversy, we mathematically model clathrin-mediated endocytosis using variational methods and Monte Carlo simulations. In particular, we investigate how the deformation of the cell membrane depends on the organization of the actin cytoskeletal network, and its associated active forces, to rule out one or more of the competing ideas.

1:15PM N31.00009 Structural studies of lipid-protein interactions on cushioned bilayers , S.K. GHOSH, UC-San Diego, La Jolla, CA, M.K. MUKHOPADHYAY, SINP, Kolkata, India, Y. MA, I. LOPEZ, UC-San Diego, La Jolla, CA, S. BERA, L.B. LURIO, NIU, DeKalb, IL, A. CHAKRABARTI, SINP, Kolkata, India, J.E. KIM, UC-San Diego, La Jolla, CA, M.K. SANYAL, SINP, Kolkata, India, S.K. SINHA, UC-San Diego, La Jolla, CA — Biological membranes are heterogeneous and dynamical organizations of lipids and proteins, which perform functions fundamental to cell survival. Lipid-protein interactions control these functions by influencing folding and stability of integral or peripheral membrane proteins. Further, the incorporation or adsorption of these proteins into the membrane can in turn influence the lipid bilayer properties. In spite of some progress in understanding this process, a detailed structural analysis is lacking. Towards a better understanding of this interaction, we have performed an advanced interface sensitive scattering experiment using synchrotron x-rays. To accurately mimic the biological membranes with their natural thermal fluctuations and in-plane mobility of lipid molecules, polymer cushioned lipid bilayers have been used. This study shows that the adsorption of peripheral membrane protein*spectrin*depends on the lipid headgroups, exhibiting different types of binding to phosphatidylcholine (PC) and phosphatidylethanolamie (PE). Further, the interaction of *outer membrane protein A (OMP-A)*, an integral membrane protein is sensitive to the thermodynamic phase of the lipids. A detailed physical modeling of the lipid-protein interactions is under way.

1:27PM N31.00010 Critical cell wall hole size for lysis in Gram-positive bacteria , GABRIEL MITCHELL, KURT WIESENFELD, Georgia Institute of Technology, DANIEL NELSON, University of Maryland, JOSHUA WEITZ, Georgia Institute of Technology — Gram-positive bacteria transport molecules necessary for their survival through holes in their cell wall. The holes in cell walls need to be large enough to let critical nutrients pass through. However, the cell wall must also function to prevent the bacteria's membrane from protruding through a large hole into the environment and lysing the cell. As such, we hypothesize that there exists a range of cell wall hole sizes that allow for molecule transport but prevent membrane protrusion. Here we develop and analyze a biophysical theory of the response of a Gram-positive cell's membrane to the formation of a hole in the cell wall. We predict a critical hole size in the range 15-24nm beyond which lysis occurs. To test our theory, we measured hole sizes in *Streptococcus pyogenes* cells undergoing enzymatic lysis via transmission electron microscopy. The measured hole sizes are in strong agreement with our theoretical prediction. Together, the theory and experiments provide a means to quantify the mechanisms of death of Gram-positive cells via enzymatically mediated lysis and provides insight into the range of cell wall hole sizes compatible with bacterial homeostasis.

Session N32 FIP FHP: International Physics Programs and History of Physics 340 - Gloria Lubkin, Physics Today Editor

11:15AM N32.00001 Fulbright Opportunities in the Physical Sciences , KATRIN DEWINDT, IIE/Council for International Exchange of Scholars — The Fulbright Scholar Program is sponsored by the United States Department of State and is principally funded by taxpayer contributions. Bi-national in nature, it includes academic year opportunities for both American and foreign scholars. More than 800 grants in 125 countries are available each year. The Program supports research, teaching and lecturing opportunities in all academic disciplines, numerous professional fields and the arts. American academics and administrators have multiple opportunities to internationalize their campuses and their discipline points of view. Further, Fulbright not only sends American scholars abroad but also brings scholars to the United States and should be considered a strategic internationalization opportunity both for individuals and for campuses. During the 2013-14 competition cycle there were 33 awards available in physics and astronomy and 175 all discipline awards. The presentation will guide attendees in identifying appropriate opportunities through the Fulbright Scholar Program and will make suggestions as to how to be successful in a proposal. Special attention will be given to opportunities available for specialists in physics. The workshop will also cover non-Core Fulbright Scholar opportunities for physicists and university administrators, including a number of short-term, innovative programs that send an additional 400 scholars from the United States to universities and research institutes abroad to offer expertise on issues of global interest from cutting-edge research to policy, to technical expertise in curriculum development, institutional planning, program assessment, and institutional capacity building.

11:41AM N32.00002 Revisiting the Bohr Atom 100 Years Later , ERNST WALL, Institute for Basic Research, Palm Harbor, FL — We use a novel electron model wherein the electron is modeled as a point charge behaving as a trapped photon revolving in a Compton wavelength orbit at light speed. The revolving point charge gives rise to spiraling Compton wavelets around the electron, which give rise to de Broglie waves. When applied to the Bohr model, the orbital radius of the electron scales to the first Bohr orbit's radius via the fine structure constant. The orbiting electron's orbital velocity, Vb, scales to that of the electron's charge's internal velocity (the velocity of light, c) via the fine structure constant. The Compton wavelets, if they reflect off the nucleus, have a round trip time just long enough to allow the electron to move one of its diameters in distance in the first Bohr orbit. The ratio of the electron's rotational frequency, fe, to its rotational frequency in the Bohr orbit fb, is fe/fb $= 1/\alpha^2$, which is also the number of electron rotations in single orbit. If we scale the electron's rotational energy (h*fe) to that of the orbit using this, the orbital energy value (h*fb) would be 27.2114 eV. However, the virial theorem reduces it to 13.6057, the ground state energy of the first Bohr orbit. Ref: www.tachyonmodel.com.

12:07PM N32.00003 A transformational year in physics: 1932 , CHARLES W. CLARK, Joint Quantum Institute, JOSEPH READER, National Institute of Standards and Technology — On New Year's Day, 1932, the *Physical Review* announced Urey's discovery of deuterium by the observation of Balmer emission lines in atomic hydrogen that were at the wavelengths predicted by Bohr's theory for an isotope with a mass twice that of the proton. At the time it was thought that the deuterium nucleus contained two protons and one "nuclear electron" confined inside the nucleus by an unknown force. This view quickly changed when *Nature* published Chadwick's discovery of the neutron nine weeks later. In June, Heisenberg made the suggestion that the neutron and proton were alternative levels of a quantum two-state system: the isospin concept that guides nuclear theory to this day. In August, Anderson discovered particles with the mass of, and charge opposite to, that of the electron: the first discovery of antimatter. Meantime, Cockroft and Walton effected the first disintegration of nuclei by particles accelerated by high voltages, and Lawrence and Livingston showed that the cyclotron could make high energy particles without high voltages. Six Nobel Prizes are directly traceable to work done within that one year! We review these events and their consequences. This talk is based on an article published in *Physics Today*, March 2013.

12:33PM N32.00004 Discovery and development of x-ray diffraction , YEUNCHEOL JEONG, University of South Carolina, MING YIN, Benedict College, Columbia, SC, TIMIR DATTA, University of South Carolina — In 1912 Max Laue at University of Munich reasoned x-rays to be short wavelength electromagnetic waves and figured interference would occur when scattered off crystals. Arnold Sommerfeld, W. Wien, Ewald and others, raised objections to Laue's idea, but soon Walter Friedrich succeeded in recording x-ray interference patterns off copper sulfate crystals. But the Laue-Ewald's 3-dimensional formula predicted excess spots. Fewer spots were observed. William Lawrence Bragg then 22 year old studying at Cambridge University heard the Munich results from father William Henry Brag, physics professor at Univ of Leeds. Lawrence figured the spots are 2-d interference of x-ray wavelets reflecting off successive atomic planes and derived a simple eponymous equation, the Bragg equation d*sin(theta)= n*lamda. 1913 onward the Braggs dominated the crystallography. Max Laue was awarded the physics Nobel in 1914 and the Braggs shared the same in 1915. Starting with Rontgen's first ever prize in 1901, the importance of x-ray techniques is evident from the four out of a total 16 physics Nobels between 1901-1917. We will outline the historical back ground and importance of x-ray diffraction giving rise to techniques that even in 2013, remain work horses in laboratories all over the globe.

12:59PM N32.00005 Latest developments on documentary film "The State of the Unit: The Kilogram" , AMY YOUNG, University of Illinois at Urbana-Champaign, Illinois Wesleyan University — This presentation shows the recent developments in the documentary film project "The State of the Unit." The film, to be completed Fall 2013, looks at historical and current efforts to define precisely the unit of mass.

Wednesday, March 20, 2013 11:15AM - 2:15PM –

Session N33 DPOLY: Focus Session: Polymers for Energy Storage and Conversion 341 - Jodie Lutkenhaus, Texas AM University

11:15AM N33.00001 Power Factor Improvements in PEDOT:PSS Tellurium Nanowire Composites , SHANNON YEE, University of California, Berkeley, NELSON COATES, JEFFREY URBAN, Lawrence Berkeley National Laboratory, RACHEL SEGALMAN, University of California, Berkeley — The thermoelectric properties of a composite consisting of tellurium nanowires in a conducting polymer, poly(3,4-ethylenedioxythiophene) poly(styrenesulfonate) (PEDOT:PSS) matrix, is optimized by controlling the shape of the nanowire and doping of the polymeric matrix with polar solvents. The mechanism for an observed improvement in power factor is attributed to the unique conducting nature of PEDOT:PSS, which exhibits a transition from a hopping transport-dominated regime to a diffusive transport-dominated regime upon doping with polar solvents. Near this transition, the electrical conductivity of the composite is improved without significantly reducing the thermopower. Relying on this principle, the power factor optimization for this new thermoelectric material is experimentally carried out and found to exceed 100 μ W/m-K^2, which is nearly five orders of magnitude greater than pure PEDOT:PSS. This improvement in power factor suggests a new area of research into polymer based thermoelectric materials where transport interactions between the polymer and an inorganic component can be tuned.

11:27AM N33.00002 Charge Transport Properties of P3HT-PEO block copolymers that are Electrochemically Oxidized in the Solid-State , SHRAYESH PATEL, UC Berkeley, Dept. of Chemical and Biomolecular Engineering, ANNA JAVIER, Lawrence Berkeley National Lab, NITASH BALSARA, UC Berkeley, Dept. of Chemical and Biomolecular Engineering — We report on the relationship between morphology and electronic/ionic charge transport of Poly(3-hexylthiophene)-*b*-Poly(ethylene oxide) (P3HT-*b*-PEO) and lithium bis-(trifluoromethanesulfonyl) imide (LiTFSI) mixtures. Using ac impedance spectroscopy, we show that P3HT-*b*-PEO/LiTFSI mixtures can conduct electronic and ionic charges simultaneously. The electronic resistance of P3HT-*b*-PEO can be controlled through the electrochemical oxidation of P3HT with LiTFSI. We designed an all solid-state electrochemical cell with three terminals to measure the electronic conductivity of P3HT-*b*-PEO under applied potentials. The addition of a third terminal within the P3HT-*b*-PEO layer allows for the *in-situ* measurement of the electronic conductivity as a function of the P3HT electrochemical oxidation level. Our experimental setup is unique in that electrochemical oxidation occurs in the presence of solid-polymer electrolyte. Previous studies on the electrochemical oxidation of polythiophenes have been done in the presence of a liquid electrolyte. The results of the *in-situ* electronic conductivity measurements as a function of electrochemical doping level and block copolymer composition will be presented.

11:39AM N33.00003 Ion Transport in Amorphous Polymer Electrolytes , KATHERINE P. BARTEAU, NATHANIEL A. LYND, GLENN H. FREDRICKSON, CRAIG J. HAWKER, EDWARD J. KRAMER, University of California, Santa Barbara — Successful development of lithium polymer batteries has been limited by low ionic conductivities in the polymer electrolyte, especially at low temperatures. In order to generate strategies for improvement of ionic conductivity, we have developed highly-controlled syntheses for a number of well-defined poly(glycidyl ether)s, PGEs, to serve as low temperature polymer electrolytes. The properties of PGEs can be tuned through structure control and functionalization, making them model systems for understanding ion transport and elucidating structure-property relationships. In this work we will discuss the synthesis and characterization of a family of PGEs that exhibit systematic differences in glass transition temperature (Tg), viscosity, oxygen-content, dielectric constant, and ionic conductivity.

11:51AM N33.00004 Dynamics of a Novel Class of Polymers: Polymerized Sulfur[1] , KEVIN MASSER, JENNY KIM, VLADIMIR OLESHKO, National Institute of Standards and Technology, JARED GRIEBEL, WOO CHUNG, ADAM SIMMONS, JEFF PYUN, The University of Arizona, CHRISTOPHER SOLES, National Institute of Standards and Technology — In this study we investigate the dynamics of a new type of polymer, consisting mainly of sulfur. Room-temperature stable polymerized sulfur samples were prepared by crosslinking the well-known living sulfur polymers formed at elevated temperatures by the addition of a crosslinking agent. This reverse vulcanization process was used to create a series of samples with different amounts of crosslinking agent. These polymers show great promise for use in advanced batteries as cathode materials. Each system exhibits a glassy-state beta relaxation, with the intensity of this relaxation proportional to the crosslinking content. A dynamic glass transition is also observed for each system, and the glass transition temperature/segmental relaxation moves to higher temperatures with increased crosslink content as is typically observed in crosslinked systems. As is typical of polymers, ion motion in these systems is closely coupled to the backbone motion of the host polymer.

12:03PM N33.00005 Investigation of the capacity retention mechanisms in novel composite sulfur copolymer-base cathodes for high-energy density Li-S batteries[1] , VLADIMIR OLESHKO, JENNY KIM, KEVIN MASSER, STEVEN HUDSON, CHRISTOPHER SOLES, Material Measurement Laboratory, National Institute of Standards and Technology, 100 Bureau Drive, Gaithersburg, MD 20899, JARED GRIEBEL, WOO JIN CHUNG, ADAM SIMMONDS, JEFFREY PYUN, Department of Chemistry, University of Arizona, 1306 E University Blvd, Tucson, AZ 85721 — Utilization of the active cathode material in high-energy density Li-S batteries limited by the insulating nature of sulfur and losses in the form of insoluble polysulfides was improved by the use of 1,3-diisopropenylbenzene (DIB) copolymerized with molten sulfur. This approach termed, inverse vulcanization, transforms elemental sulfur into chemically stable processable copolymer forms with tunable thermomechanical properties. According to dielectric spectroscopy and dc conductivity measurements, composite sulfur-DIB copolymer cathodes exhibit a glassy-state beta relaxation related to short sulfur segments or to the DIB cross-linker. High-resolution AEM and FESEM studies down to the atomic scale reveal multiscale 3D-architectures created within the pristine and cycled composite cathodes with various contents of the electroactive copolymers. The morphology, structures, bonding and local compositional distributions of the constituents (sulfur, copolymers, aggregated conductive carbon nanoparticles) as well as extended pore structures and their transformations under cycling have been examined to provide insights into mechanisms of the enhanced capacity retention in the modified Li-S cells.

[1]NIST support under grant MML12-1053-N00

12:15PM N33.00006 TiO_2-SEO Block Copolymer Nanocomposites as Solid-State Electrolytes for Lithium Metal Batteries , INNA GUREVITCH, RAFFAELLA BUONSANTI, ALEXANDER TERAN, JORDI CABANA, NITASH BALSARA, None — Replacing the liquid electrolyte in lithium batteries by a solid has been a long-standing goal of the battery industry due to the promise of better safety and the potential to produce batteries with higher energy densities. Recently, symmetric polystyrene-block-poly(ethylene oxide) (SEO) copolymers/LiX salt mixtures with high ionic conductivity and high shear modulus were developed as solid electrolytes. For an enhancement in mechanical properties and its effect on the dendrite growth from lithium metal electrodes, we study the effect of adding TiO_2 nanoparticles to the SEO/LiX mixtures. We find that TiO_2/SEO/LiX nanocomposite electrolytes have stable performance against the lithium metal electrodes. There appears to be a correlation between the stability of the electrolytes, morphology, and mechanical properties.

12:27PM N33.00007 High Aspect Ratio Nanofillers for Solid Polymer Electrolytes[1] , LALITHA GANAPATIBHOTLA, JANNA MARANAS, The Pennsylvania State University — In this study, we explore high aspect ratio nanofillers as additives that enhance solid polymer electrolyte (SPE) conductivity at battery working temperatures.SPEs are the key to light-weight and energy-dense lithium ion batteries but suffer from low room temperature ion conductivities.Spherical ceramic fillers are known to improve SPE conductivity and mechanical properties.Our experiments on spherical Al2O3 particle filled SPEs indicate highest conductivity enhancement at eutectic composition and temperature.A new mechanism, via stabilization of alternating layers of PEO and highly conducting PEO6:LiClO4 tunnels at the filler surface, was suggested by us.More such structures would be stabilized at a filler surface with high aspect ratio.Consistent with this hypothesis, γ-Al2O3 nanowhiskers intensify the effect of γ-Al2O3 nanoparticles.Increase in conductivity at eutectic composition, and decrease at non-eutectic compositions is more than the nanoparticles.Diameters of the two fillers are similar, but the change in aspect ratio (1to100) improves conductivity by a factor of 5. The influence of morphology and PEO dynamics on conductivity enhancement will be presented.All measurements are performed at a series of Li compositions, temperatures and nanowhisker loadings.

12:39PM N33.00008 Atomistic Simulations Reveal a Surprising Variety of Morphologies in Precise Ionomers , MARK STEVENS, DAN BOLINTINEANU, AMALIE FRISCHKNECHT, Sandia National Labs — Ionomers are being investigated as potential solid electrolytes in battery applications, due to their unique electrical properties. However, the relationships between ionomer chemistry, morphology and ion transport are poorly understood, which has hindered the development of ionomer-based batteries. To this end, we report atomistic molecular dynamics (MD) simulations of a model ionomer (polyethylene-co-acrylic acid) neutralized with different ions at various neutralization levels. The structure factor computed from the simulations is in good agreement with experimental X-ray scattering data. The simulations provide new insight into the shape, size and composition of ionic aggregates. In particular, we observe a wide variety of aggregate morphologies, ranging from small spherical aggregates to string-like shapes and large percolated networks. The unexpected morphologies of these ionic aggregates imply the need for a new interpretation of scattering spectra for these materials. We quantify cation-anion and oxygen-hydrogen association, the two interactions primarily responsible for aggregate formation, and report detailed information pertaining to local structures around cations, which is difficult to obtain experimentally and may have important consequences for ion transport.

12:51PM N33.00009 Mechanism of Ion Diffusion in Coarse-Grained Ionomer Melts , LISA M. HALL, The Ohio State University, MARK J. STEVENS, AMALIE L. FRISCHKNECHT, Sandia National Laboratories — Ionomers (polymers with a small amount of charged groups) have been identified as possible single ion conducting battery electrolytes. A barrier their use in such applications is that the strong electrostatic interactions lead to ionic aggregation and can make ion diffusion very slow. In order to understand the physics underlying ionomer dynamics and especially how charge transport occurs, we perform molecular dynamics simulations. Our model has polymers with charged groups either in the backbone or pendant to it, explicit counterions, and long-range Coulomb interactions. Depending on placement, amount, and spacing of the ionic groups, various morphologies of ionic aggregates are formed. We find for all systems, ions can rearrange locally within the ionic aggregates on a relatively short timescale. Ions can move a longer distance when they rearrange collectively on a longer timescale, that is especially long for systems with discrete ionic aggregates. Because of this, a typical ion trajectory shows mostly small movements and rare large, sudden movements. However, these features are not due to 'hopping' as typically understood. Instead, nearby aggregates of ions join together, rearrange, and later break apart, during which time some ions are exchanged and appear to have 'hopped'.

1:03PM N33.00010 Coarse-Grained MD Simulation of String-like Aggregates in Single-Ion Conductors , KERAN LU, JANNA MARANAS, SCOTT MILNER, Penn State University — Single-ion conductors, or ionomers, have been investigated as a potential polymer electrolyte for advanced batteries. Ionic aggregates are prevalent in ionomers, and their sizes and shapes are not well characterized by experiment. Atomistic molecular dynamics simulations have been used to explore these aggregates, but may not be fully equilibrated because the aggregrates break and join infrequently. We report on an ion-only coarse-grained molecular dynamics simulation of a well-equilibrated ionomer system that reproduces structural features of the parent united atom simulation. Results for radius of gyration, shape anisotropy, and average ion coordination number from our simulation show that ionic aggregates are string-like, with random-walk configurations. An analogy to worm-like micelle equilibrium predicts an exponential length distribution for aggregates, in agreement with simulations. The implications of the size and structure of aggregates on conduction are discussed.

1:15PM N33.00011 Anion Conduction in PEO-Functionalized Polyphosphazene Ionomers , JOSHUA BARTELS, ANDREW HESS, HARRY ALLCOCK, RALPH COLBY, JAMES RUNT, Penn State University — A series of novel polyphosphazene ionomers with short chain poly(ethylene oxide) (PEO) moieties, bound ammonium cations, and free iodide anions were previously synthesized. Ion dynamics during anion conduction of the ionomers were studied by dielectric relaxation spectroscopy (DRS). These polyphosphazenes provide interesting conductive materials to study because of their low glass transition temperature, high segmental mobility, and high ion content. Analysis of DRS results provides static dielectric constant, conducting ion mobility, and conducting ion content for the materials. An increase in the length of the alkyl group extending from the polymer-bound ammonium cation increases conductivity and conducting ion concentration due to new steric interactions weakening ion-ion associations that restrict segmental mobility. By placing ether oxygens in the short alkyl group a large increase in conductivity and a decrease in the glass transition temperature is observed due to strong associations between the cation and ether oxygen lone pairs.

1:27PM N33.00012 Decoupling ion flux and mechanical strength in polymer battery membranes , DERRICK SMITH, SHAN CHENG, Drexel University, TIMOTHY BUNNING, Wright-Patterson Air Force Base, CHRISTOPHER LI, Drexel University — While much research has demonstrated repeatable characteristics of electrolyte membranes, the fundamentals behind the interactions during ionic diffusion in solid polymer electrolyte membranes for battery applications are not well understood, specifically the role of nanostructures, which hold the key to improving performance of energy storage devices such as fuel cells and Lithium ion batteries. The challenges in fabricating highly controlled model systems are largely responsible for the interdependent ambiguities between nanostructures and the corresponding ion transport behavior. In this work, Holographic Polymer Electrolyte Membrane (hPEM) volume gratings comprised of alternating layers of cross-linked polymer resin and ionic liquid were fabricated using holographic polymerization with an average d-spacing of 180 nm. These one-dimensional confinement structures were used to quantitatively study the anisotropic ionic conductivity properties, and correlate this behavior to nano-confinement and phase mixing. These membranes provide a platform in decoupling ion flux and bulk mechanical properties for future blend systems for battery applications. These volume gratings also offer an exciting route to fabricate multifunctional gratings for optic and sensing applications.

1:39PM N33.00013 Structure-Property Relationship of Perfluorinated Sulfonic Acid (PFSA) Membranes , AHMET KUSOGLU, ADAM WEBER, Lawrence Berkeley National Laboratory — Perfluorosulfonic-acid (PFSA) membrane is the most commonly used ionomer in electrochemical energy storage and conversion devices thanks to its remarkable proton conductivity, perm-selectivity, wide electrochemical window, and mechanical stability. Most of these properties are the result of the membrane's phase-separated nanostructure where ions and solvents transport through the hydrated domains while the surrounding hydrophobic PTFE backbone acts as a mechanical support. Thus, it is essential to understand the solvent- and humidity-induced morphological changes and their associated impact on the membrane's properties for optimizing the structure-property relationship desired by the electrochemical devices. In this talk, correlations among the mechanical (e.g., modulus), electrochemical (e.g., ionic conductivity) and nanostructural (e.g., domain spacing) properties during hydration is discussed. Moreover, the impact of thermal history, mechanical reinforcement, and side-chain length on the structure-property correlation is examined. Even though the properties vary for the membranes investigated, similar correlations are found between the degree of hydration, domain spacing, and ionic conductivity.

1:51PM N33.00014 Hard X-ray tomography as a non-destructive technique to study the growth of lithium dendrites in lithium polymer batteries[1] , KATHERINE HARRY, UC Berkeley, DANIEL HALLINAN, DILWORTH PARKINSON, ALASTAIR MACDOWELL, Lawrence Berkeley National Laboratory, NITASH BALSARA, UC Berkeley — Lithium metal electrodes have the highest energy density of any battery electrode technology and are, therefore, being considered for electric vehicles. However, lithium metal changes its shape under cycling, resulting in the growth of lithium metal dendrites through the electrolyte that eventually short-circuit the cell. While polystyrene-block-poly(ethylene oxide) copolymer electrolytes extend cell life by suppressing dendrite growth, dendrites eventually do grow. We show that hard X-ray microtomography is a non-destructive tool for studying the formation and growth of lithium dendrites at the interface between lithium metal and a block copolymer electrolyte.

2:03PM N33.00015 A New Mechanical Loading Configuration for Maximizing The Performance of Dielectric Elastomer Generators , SAMUEL SHIAN, JIANGSHUI HUANG, ZHIGANG SUO, DAVID CLARKE, Harvard University — Electrical energy can be generated from mechanical deformations using dielectric elastomers but currently achieved energy densities and conversion efficiencies are still small. In this presentation, we demonstrate that significant improvements, an energy density over 500 mJ/g and up to 10% in efficiency, can be produced using VHB elastomers by altering the mechanical loading geometry. A major limitation is viscous losses in the VHB elastomer indicating that higher efficiencies with other elastomers will be attainable. The basic concept of mechanical energy harvesting with a dielectric elastomer sheet is a straightforward electromechanical cycle leading to a voltage step-up: a sheet is stretched, electrical charge at low voltage is placed on either side using compliant electrodes, the stretch is released causing the sheet's initial thickness and area to be recovered increasing the charge potential which can then be harvested. Integral to maximizing the energy conversion is the amount of mechanical energy that can be stored elastically and the amount of capacitance change in the elastomer sheet during stretching. We show that these factors can be maximized by equi-biaxial loading. Details of our dielectric elastomer generator will be described as well as the procedures we use for quantifying its performance.

Wednesday, March 20, 2013 11:15AM - 2:15PM –

Session N35 DMP: Focus Session: Search for New Superconductors II 343 - Ivan Bozovic, Brookhaven National Laboratory

11:15AM N35.00001 Charge Density Wave Instability and Soft Phonon in APt$_3$P (A=Ca, Sr, and La)[1] , CHAO CAO, HUI CHEN, XIAOFENG XU, JIANHUI DAI, Hangzhou Normal University, HANGZHOU NORMAL UNIVERSITY CONDENSED MATTER PHYSICS GROUP TEAM — The electronic and phonon properties of the platinum pnictide superconductors APt$_3$P (A=Ca, Sr, and La) were studied using first-principles calculations. The spin-orbit coupling effect is significant in LaPt$_3$P but negligible in CaPt$_3$P and SrPt$_3$P. Moreover, SrPt$_3$P has been demonstrated to exhibit an unexpected weak charge-density-wave (CDW) instability which is neither simply related to the Fermi-surface nesting nor to the momentum-dependent electron-phonon coupling alone. The instability is absent in CaPt$_3$P and can be quickly suppressed by the external pressure, accompanied with decreases in the phonon softening and BCS T_c. Our results suggest SrPt$_3$P as a rare example where superconductivity is enhanced by the CDW fluctuations.

[1]Phys. Rev. B 86, 125116 (2012) (NSFC No. 11274006, 11274084, and 11104051, NSF of Zhejiang Province No. LR12A04003 and Z6110033)

11:27AM N35.00002 Charge density wave fluctuations and possible heavy fermion behavior without magnetism in ThCr$_2$Si$_2$-type KNi$_2$S$_2$ and KNi$_2$Se$_2$, JAMES NEILSON, Johns Hopkins University, ANNA LLOBET, Los Alamos National Laboratory, JIAJIA WEN, Johns Hopkins University, MATTHEW SUCHOMEL, Advanced Photon Source, Argonne National Laboratory, TYREL MCQUEEN, Johns Hopkins University — Materials with the ThCr$_2$Si$_2$-type structure host myriad examples of many-body physics, including high-temperature superconductivity and heavy fermion behavior. In these compounds, the emergence of the collective state frequently occurs near a magnetic instability, suggesting that magnetic fluctuations underlie the electronic phenomena. I will provide evidence for similar many-body physics in the structurally related, but non-magnetic compounds, KNi$_2$S$_2$ and KNi$_2$Se$_2$. From the analysis of synchrotron X-ray diffraction and neutron total scattering data, we observe spatially incoherent charge density wave fluctuations that disappear on cooling. Along with the implied and unusual increase in local symmetry, we find that there is negative thermal expansion and enhancement of the electronic band mass below $T \sim 15$ K, with superconductivity emerging below 1 K. These findings demonstrate that collective electronic phenomena occurs in ThCr$_2$Si$_2$-type materials without direct proximity to localized magnetism. Furthermore, these results highlight the importance in understanding charge fluctuations and their hybridization in driving the emergence of coherent or many-body electronic states, akin to localized magnetism associated with heavy fermion behavior.

11:39AM N35.00003 Charge-order fluctuations and electron-phonon coupling in organic superconductors , ALBERTO GIRLANDO, MATTEO MASINO, Univ. of Parma (Italy), NATALIA DRICHKO, Univ. J. Hopkins, Baltimore (U.S.A.), MARTIN DRESSEL, Univ. of Stuttgart (Germany) — Organic superconductors (SC), like other new classes of SC, are characterized by important electronic correlations. Spin or charge-order (CO) fluctuations have been invoked as mediators in the pairing mechanism, in place of, or in addition to, the conventional phonon mediated pairing. In the phase diagram of BEDT-TTF based 1/4-filled layered charge transfer salts, a CO metal-insulator transition is close to the metal-SC transition, with CO fluctuations in the proximity of the instabilities. We present the characterization of CO fluctuations obtained through optical spectroscopy of SC and non-SC BEDT-TTF salts, with an estimate of the average charge on the molecules and the velocity of charge "jump" from one molecule to the other. It turns out that the latter is not connected to the SC. A correlation seems instead to occur between SC and the average charge on the molecules. We shall also discuss other possible signatures of the charge fluctuations in the optical spectra, as well as the connection between CO fluctuations and intra- and inter-molecular electron-phonon coupling. The relevance of these ideas to the recently discovered class of doped acene superconductors will be shortly discussed.

11:51AM N35.00004 Ferroelectric Soft Phonons, Charge Density Wave Instability, and Strong Electron-Phonon Coupling in BiS$_2$-Layered Superconductors , TANER YILDIRIM, NIST, Gaithersburg, MD and UPENN, Philadelphia, PA — Very recently a new family of layered materials, containing BiS$_2$ planes was discovered to be superconducting at temperatures up to T$_c$=10 K, raising questions about the mechanism of superconductivity in these systems. Here, we present state-of-the-art first principles calculations that directly address this question and reveal several surprising findings [1]. The parent compound LaOBiS$_2$ possesses anharmonic ferroelectric soft phonons at the zone center with a rather large polarization of $\approx 10\mu C/cm^2$, which is comparable to the well-known ferroelectric BiFeO$_3$. Upon electron doping, new unstable phonon branches appear along the entire line $Q = (q, q, 0)$, causing Bi/S atoms to order in a one-dimensional charge density wave (CDW). We find that BiS$_2$ is a strong electron-phonon coupled superconductor in the vicinity of competing ferroelectric and CDW phases. Our results suggest new directions to tune the balance between these phases and increase T$_c$ in this new class of materials.

12:03PM N35.00005 Searching for High-T_c Superconductivity in Low-Z, Low-Ne Materials

, O-PAUL ISIKAKU-IRONKWE[1], The Center for Superconductivity Technologies, Michael Okpara University of Agriculture, Umudike, Nigeria, TIMOTHY HAUGAN, Mechanical Energy Conversion Branch, Propulksion Directorate, Wright-Patterson AFB, Ohio 45433-7251, ALEX ANIMALU, University of Nigeria, Nsukka, Anambra State, Nigeria — The discovery in 2001 of HTSC at 39K in MgB_2, a low-atomic number (Z) and low-valence electron count per atom (Ne) material, strongly suggested that similar materials may exist with comparable or even higher Tcs. Efforts to find MgB_2-like HTSC materials in binary and ternary systems have not been very successful. Using recently developed material specific formula for Tc, we have extended the computational and experimental search for potential low-Z, low-Ne HTSCs beyond the ternary structure into the 4 and 5-element systems. Exploring the family of low-Z, low-Ne materials represented by Z = 1.333p + 2 where p is an integer, we find in this broad spectrum, hundreds of potential HTSC materials. Here we present some of the combinatorial-computational datasets and preliminary experimental results using a novel non-DFT material-specific characterization dataset (MSCD) method. MSCD promises to accelerate the computational search for new materials, particularly superconductors. The computations and preliminary experimental results suggest that HTSC, comparable to the cuprates may exist in low-Z, low-Ne materials with 4 and 5-element systems.

12:15PM N35.00006 High-temperature surface superconductivity in rhombohedral graphite[1]

, TERO HEIKKILÄ, NIKOLAI KOPNIN, Low Temperature Laboratory, Aalto University, MARI IJÄS, ARI HARJU, Department of Applied Physics, Aalto University, GRIGORI VOLOVIK, Low Temperature Laboratory, Aalto University — We show that rhombohedral graphite may support surface superconductivity with an unusual relation between the BCS coupling constant and the order parameter. This feature results from the properties of the states localized on the graphite surfaces. In a description including only the nearest neighbour coupling of the graphene layers, the surface states are topologically protected and have a flat band dispersion. We show that including higher order couplings destroys this flat band character and leads to a particle-hole symmetry breaking quadratic dispersion with a large effective mass. Employing this dispersion, we then show its effect on superconductivity and find two regimes of parameters, depending on the relation between the strength of the coupling constant and the details of the quadratic dispersion. For low coupling strengths, superconductivity is localized on the surfaces, but the order parameter is exponentially suppressed as in a conventional BCS superconductor, whereas for large coupling strengths we obtain surface superconductivity with a linear relation between the order parameter and the coupling constant. Our results offer an explanation for the recent findings of graphite superconductivity with an unusually high trans

12:27PM N35.00007 Phase separation instabilities and pairing in layered BSCCO-like lattice geometries

, ARMEN KOCHARIAN, California State University, Los Angeles, KUN FANG, GAYANATH FERNANDO, Connecticut University, Storrs, ALEXANDER BALATSKY, Los Alamos National Laboratory, Los Alamos, KALUM PALANDAGE, Trinity College, Hartford — The electron spontaneous phase separations accompanied by local inhomogeneities are evaluated by monitoring the charge and spin pairing gaps in the ground state and corresponding crossovers at finite temperatures in various cluster geometries and wide range of inter-site interaction U. The effects of the next nearest neighbor hopping on electron instabilities at level crossings in the vicinity of quantum critical points are considered. The calculated energy gap at one hole away from half filling displays universal features consistent with the lattice structure symmetry in non-bipartite geometries. The charge and spin collective excitations in layered pyramidal structures driven by out-of-plane variation of lattice parameters yield intriguing insights into the coherent and incoherent pairings and gap modulations in Bi-like based cuprates, iron pnictides, and other transition metal oxides layered structures. The phase diagrams resemble a number of inhomogeneous, coherent and incoherent nanoscale phases seen in $Bi_2Sr_2CaCu_2O_{8+\delta}$. The found similarities and differences in the mechanisms of electron pairing, driven by attractive and repulsive electron interaction are analyzed. The phase separation instabilities in related intercalated layered geometries are discussed.

12:39PM N35.00008 Tuning the charge-transfer energy in hole-doped cuprates

, CHUCK-HOU YEE, Kavli Institute of Theoretical Physics, UCSB, GABRIEL KOTLIAR, Dept. of Physics & Astronomy, Rutgers University — Chemical substitution, combined with strain, allows the charge-transfer energy in hole-doped cuprates to be broadly tuned. We theoretically characterize the structural and electronic properties of the family of compounds $R_2CuO_2S_2$, constructed by sulfur replacement of the apical oxygens and rare earth substitutions in the parent cuprate La_2CuO_4. Additionally, the enthalpies of formation for possible synthesis pathways are determined.

12:51PM N35.00009 The effective half-filled band model is inappropriate for the dimerized 2D organic superconductors[1]

, NILADRI GOMES, University of Arizona, R. TORSTEN CLAY, Mississippi State University, SUMIT MAZUMDAR, University of Arizona — The antiferromagnetism in κ-$(ET)_2X$ can be understood within the effective $\frac{1}{2}$-filled band anisotropic triangular lattice Hubbard Hamiltonian for strong anisotropy. DMFT theories have claimed antiferromagnetic-to-superconductor transition within the same model, as the anistropy is reduced. In previous work we have shown the absence of superconductivity within the triangular lattice $\frac{1}{2}$-filled band Hubbard model for any Hubbard U and any anisotropy. Other DMFT approaches theories have claimed superconductivity within the so-called Hubbard-Heisenberg model, which incorporates an additional antiferromagnetic spin-exchange over and above that due to the Hubbard U. Very recent work has also claimed a valence-bond solid (VBS) phase within the Hubbard-Heisenberg model, which would seemingly explain the observed VBS phase in $EtMe_3P[Pd(dmit)_2]_2$. We report exact calculations that show that neither the VBS nor the superconducting phase occur within the Hubbard-Heisenberg model, showing clearly that the effective $\frac{1}{2}$-filled band model is unsuitable for describing the complete phase space of the κ-$(ET)_2X$. Our work raises serious doubts about the DMFT theories of superconductivity of metal intercalated C_{60} and picene.

1:03PM N35.00010 A possible paired-electron liquid in a $\frac{1}{4}$-filled band model of κ-$(ET)_2X$[1]

, R.T. CLAY, Mississippi State University, N. GOMES, S. MAZUMDAR, University of Arizona — A minimal model for the κ-(ET) conducting layers is a $\frac{1}{2}$-filled anisotropic triangular lattice Hubbard model, where a dimer of molecules is replaced with a single effective site. This effective model can explain occurrence of an antiferromagnetic (AFM) phase, but recent results do not find superconductivity in the model. We have shown that in a $\frac{1}{4}$-filled system on a dimerized square lattice, the AFM phase gives way to a Paired Electron Crystal singlet-paired state in the presence of lattice frustration. Here we present results of calculations on the actual $\frac{1}{4}$-filled κ lattice rather than the simplified square lattice. We find not only an AFM-to-singlet transition, but show that the singlet phase may be a Paired Electron Liquid state consisting of a superposition of nearest-neighbor singlets. We show that in the excitation spectrum the lowest singlet excited state occurs below the lowest triplet. This may indicate gapless singlet excitations and gapped spin excitations, which would explain the observed heat capacity versus thermoelectric behavior in κ-$(ET)_2$-$Cu_2(CN)_3$ and $EtMe_3Sb[Pd(dmit)_2]_2$. We further discuss superconducting pair correlation functions.

1:15PM N35.00011 Crystal structure, electronic properties, and superconductivity mechanism of La-Phenanthrene[1] , SHAHAB NAGHAVI, SISSA, CNR-IOM Democritos, MICHELE FABRIZIO, SISSA, ICTP, CNR-IOM Democritos, TAO QIN, SISSA, CNR-IOM Democritos, ERIO TOSATTI, SISSA, ICTP, CNR-IOM Democritos — Recently, polycyclic aromatic hydrocarbon (PAH) molecular solids: picene, coronene, dibenzopentacene, phenanthrene among them, have been reported to turn from insulating to metallic and superconducting upon intercalation of electron-donating atoms, such as K, Ba, La. Despite experimental uncertainties, understanding these novel light-element based superconductors is important since both electron phonon coupling and electron electron correlations seem important, as indicated by early theory work. Choosing La-Phenanthrene (La-PA) as our working case, we first search for the theoretical optimal crystal structure and electronic properties by first principles density functional calculations. We single out a stable insulating phase with $P1$ symmetry and, slightly higher in energy, a metastable metallic $P2_1$ phase–the same (higher) symmetry of pristine PA, also proposed for La-PA. A tight binding model representing the metallic La-PA electronic structure, its dominant electron phonon coupling with an intermolecular dimerizing mode, and an intramolecular Coulomb U is formulated and discussed. In that model it can be argued that BCS pairing may be essentially unhindered by the Coulomb repulsion. Being symmetry-based, the mechanism could apply to other PAH superconductors as well.

1:27PM N35.00012 Anisotropic Migdal-Eliashberg theory using Wannier functions[1] , ELENA ROXANA MARGINE, FELICIANO GIUSTINO, University of Oxford — We combine the fully anisotropic Migdal-Eliashberg theory with electron-phonon interpolation based on maximally-localized Wannier functions, in order to perform reliable and highly accurate calculations of the anisotropic temperature-dependent superconducting gap and critical temperature of conventional superconductors. Compared with the widely used McMillan approximation, our methodology yields a more comprehensive and detailed description of superconducting properties, and is especially relevant for the study of layered or low-dimensional systems as well as systems with complex Fermi surfaces. In order to validate our method, implemented within the EPW package [1,2], we perform calculations on two prototypical superconductors, Pb and MgB_2, and obtain good agreement with previous studies [3]. 1:39PM N35.00013 Search for chalcogenide based superconductors: Sulfur based solution growth[1] , UDHARA KALUARACHCHI, SERGEY BUD'KO, PAUL CANFIELD, Department of Physics, Iowa State University — As part of our effort to develop tools for searching for new chalcogenide based superconductors we are expanding the range of S-based binary melts that we can use for solution growth of single crystals. As a recent example, we have been able to grow single crystals of $Rh_{17}S_{15}$ and separate them for excess binary melt via high temperature decanting. In addition to refining the details of the Rh-S binary phase diagram, microscopic, thermodynamic and transport measurement on $Rh_{17}S_{15}$ crystals confirm their $T_c \sim 5.5$ K as well as their remarkably large $H_{c2}(T)$ behavior. The possible cause of the enhanced $H_{c2}(T)$ will be discussed. As time allows we will also review other S-based growths and compounds.
